Aims & Methods: We determined the effect of anti-TNFα therapy in both IL10 knockout (KO) mice and in the CD4+CD45Rb high T-cell transfer model of colitis. Macrophage populations were quantified using qPCR analysis for CD206 and 1-arginase expression and flow cytometry for CD206. IL10 mRNA and protein levels were analysed with qPCR and ELISA.

Results: Colitis in the IL10 KO mice was completely resistant to anti-TNFα therapy, in sharp contrast to the colitis in SCID or Rag1 KO mice upon transfer of CD4+CD45Rb high T-cells, which was significantly reduced by anti-TNFα therapy. Successful anti-TNFα therapy was accompanied by an increase of IL10 levels and an increase of regulatory (M2) type macrophages in the intestine. Blocking IL10 signaling, with an IL10 Receptor blocking antibody, diminished the therapeutic efficacy of anti-TNFα therapy. Anti-TNFα therapy was also unresponsive to anti-TNFα therapy upon receiving CD4+CD45Rb high T-cells. In these mice there was also no increase of intestinal M2 macrophages.

Conclusion: IL10 signaling in macrophages is pivotal for the therapeutic efficacy of anti-TNFα therapy in animal models for IBD. Defects in the IL10 pathway may also play a role in anti-TNFα non-responders which is subject of further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to our previous report, the imbalance of Treg/Th17 cells in active UC mice is related with the reduction of CD45RA FoxP3\(^+\) activated Treg(FrIII) cells, which has the real function of immunosuppression, and with the elevation of CD45RA FoxP3\(^-\) Treg(FrII) cells, which could provide FrIII\(^+\) IL17a\(^+\) but lack of immunosuppressive capacity. Activation of Toll-like receptor may lead to the elevation of FrII, which show FoxP3\(^+\) IL17a\(^+\) by secreting IL-17a.

Aims & Methods: To investigate the influence of TLR2 on imbalanced Treg/Th17 in ulcerative mice and mouse models. Using mouse model, UC mice were divided into three groups, including group A, UC mice; group B, UC mice treated with TLR2 inhibitor; and group C, UC mice treated with TLR2 agonist. The level of Treg cells in PBMC of group C 0.015 vs 0.328, P < 0.05 respectively). Moreover, declined FrIII and FoxP3 cells were increased in PBMC, MLN and LPC, but reduce the levels of FrIII and FoxP3 IL17a cells in DSS induced UC mice. Furthermore, TLR2 agonist could alleviate the DAI index as well as the inflammation of colitis in DSS induced UC mice.

Introduction: Previous studies have shown that the gut microbiota plays an important role in IBD, however it is not a consensus on which bacteria are responsible for the disease. 16s gene profiling studies generate large amounts of information, however they can be confounded by genetic and environmental factors. Twin studies are instrumental in controlling for some of these variabilities, and in this study we investigated the microbiota of twin pairs discordant for Crohn’s disease (CD) and UC using 16s rna gene sequencing, with the aim of identifying taxa associated with disease.

Aims & Methods: Participants were recruited via the UK IBD Twin Registry. Stool samples were collected and frozen using standard methods. Participants who had received antibiotics within 3 months were excluded. Harvey Bradshaw Index and Simple Clinical Colitis Activity Index were recorded. Full medical history was available from the UK IBD Twin Registry. Samples underwent 16s rna sequencing using PCR primers. We used data analysis pipeline. PERMANOVA was used to evaluate associations with clinical metadata, which included matching of twin pairs for analysis, and STAMP was used to identify taxonomic differences between groups.

Results: 20 twin pairs discordant for CD (5MZ/1SDZ mean age 55 years) and 17 discordant for UC (6MZ/1IDZ mean age 59.7 years) were recruited. 7 subjects with CD had active disease as did 4 with UC. Gut microbiota from active CD patients had lower bacterial diversity compared to UC patients and healthy twins (Shannon diversity index, p < 0.01 healthy vs active UC, p < 0.05 active vs remission CD patients). We found that active CD patients had a higher proportion of Clostridium hylemonae and Lactobacillus delbrueckii compared to healthy twins, and a lower proportion of Bacteroides and Faecalibacterium prausnitzii (p < 0.05). We found that active UC patients had a lower proportion of Alstipites spp. compared to their healthy twins and UC patients in remission (p < 0.05).

Conclusion: This study confirms previous findings showing decreased diversity in IBD patients and changes in some bacterial taxa, however our study is the first to show decreases in Alstipites spp. in active UC.

Disclosure of Interest: All authors have declared no conflicts of interest.
subsequently analyzed for STAT3 signaling (western blot), NFkB signaling (NFkB Transcription Factor Assay, western blot) and cytokine secretion (ELISA).

Results: Peripheral blood CD4⁺ T cells from IBD patients could be characterized by a significantly increased P2Y2R expression compared to healthy controls, while the expression levels of the P2Y4 receptor subtype turned out to be comparable between both groups. Further subdividing the group of included IBD patients into Crohn’s disease and ulcerative colitis patients, we could not observe a significant difference in the P2Y2R levels between both disease entities. Interestingly, the increased P2Y2R expression in the lymphocyte compartment of IBD patients seemed to be limited to CD4⁺ T cells, as CD8⁺ T cells of those patients even showed decreased P2Y2R levels. Regarding potential regulators of P2Y2R expression in the context of IBD, our data identified IL-6 and TGF-beta as important environmental factor associated with Inflammatory Bowel Disease.

Conclusion: The observed increased expression of P2Y2R in CD4⁺ T cells of IBD patients together with the demonstrated pro-inflammatory effects of P2Y2R signaling in human T cells markedly strengthen the role of P2Y2R as a promising molecular target in IBD.

P0907 PROTECTIVE EFFECT AND ACTION MECHANISM OF APOCYNIN IN IBD MOUSE MODEL

S. Nam1, S. Kim2, W. Chun3, J. M. Park4, S.C. Park5, D.H. Choi6, C. D. Kang6, S.J. Lee1 1Department of Internal Medicine, Kangwon National University School of Medicine, Chuncheon-si, Gangwon-do/Korea, Republic of 2Department Of Pharmacology and Toxicology, Kangwon National University, Chuncheon-si/Korea, Republic of

Introduction: There are several medical treatment options for inflammatory bowel disease (IBD), but all have drawback due to their significant adverse effects. Many new drugs are being developed for more safe and effective treatment. Apocynin is a chemical 4-hydroxy-3-methoxyacetophenone which is an inhibitor of NADPH oxidase and has shown promising effect in various chronic inflammatory diseases such as asthma and atherosclerosis. Due to its anti-inflammatory effect and safety profile, apocynin can be a new candidate for the treatment of IBD.

Aims & Methods: In this study, we aimed to investigate effect of apocynin on colonic inflammation and the action mechanism using chemically-induced colitis mouse model. We used dextran sulfate sodium (DSS)-induced colitis model. 8 weeks old male BALB/c mice were divided into four groups (each group, n = 6): control, DSS only, DSS with apocynin, and DSS with sulfasalazine. Water (control and DSS group), apocynin (400 mg/kg) and sulfasalazine (150 mg/kg) were administered by oral route using saline inside during 7 days. For western blot analysis, colon was lysed and proteins were extracted. The following antibodies were used; iNOS (BD Biosciences), COX-2, Nrf2 (Santa Cruz Biotechnology Inc), MCP-1, TNF-α, p-Nrf2, HO-1 (Abcam), and β-actin (Sigma).

Results: Protective effect of apocynin was evident by weight change and colon length. Histologic analysis also showed improved erosion and decreased neutrophilic infiltration in apocynin group compared to DSS group. In colon tissue, several pro-inflammatory enzymes and cytokines were decreased by apocynin. Apocynin also activated anti-inflammatory pathway by inducing activation of Nrf2 and production of heme oxygenase-1 (HO-1).

Conclusion: Apocynin, a NADPH-oxidase inhibitor, showed significant anti-inflammatory effect in DSS induced colitis model. Considering its good safety profile, this molecule can be a new candidate for the treatment of IBD. Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: s.powles@imperial.ac.uk

Introduction: Faecal metabolic profiling has been shown to distinguish Inflammatory Bowel Disease (IBD) from healthy controls (HC), specifically with depletion of gut-associated short chained fatty acids (SCFA) as the predominant feature separating these groups (1). Previous and current studies have used proton nuclear magnetic resonance (1H NMR) spectroscopy or mass spectrometry (MS) to measure faecal metabolites to examine the metabolic, microbiome and clinical response of IBD patients to different treatments. Both techniques require a significant amount of sample pre-processing. Rapid Evaporative Ionization Mass Spectrometry (REIMS) is a relatively new technology which applies a laser to a biological sample, and the resulting vapour, containing gas phase ions of metabolites and structural lipids, is analysed by a mass spectrometer (2). Unprocessed faecal samples can be rapidly assessed using this technique to obtain lipidomic spectral profiles (2). To our knowledge this is the first study that has used REIMS to investigate whether IBD patients can be distinguished from healthy controls using faecal samples.

Aims & Methods: Unprocessed faecal samples from 109 IBD patients and 46 healthy controls were analysed using Rapid Evaporative Ionization Mass Spectrometry (REIMS) at different time points, and a discriminant analysis was then carried out including examination whether ulcerative colitis could be distinguished from Crohn’s disease.

Disclosure of Interest: All authors have declared no conflicts of interest.
P0972 THE PATHOGENIC MECHANISM OF ARYL HYDROCARBON RECEPTOR MEDIATED ABNORMAL DIFFERENTIATION OF INTESTINAL ILC3/ILC1 IN CROHN’S DISEASE

X. Zhao, H. Zhang
Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China

Contact E-mail Address: zhaoxiao1978@163.com

Introduction: The abnormal differentiation of intestinal innate lymphoid cells ILC3 and ILC1 exist in autoimmune disease. ILC3 decreased and ILC1 increased in Crohn’s disease (CD) patients, suggesting that CD patients have abnormal intestinal ILC3/ILC1 alteration.

Aims & Methods: The present study investigated the aberrant colonic mucosal ILC3/ILC1 in active CD patients and 2, 4, 6-trinitrobenzenesulfonic acid (TNBS)-induced colitis mice. The expressions of aryl hydrocarbon receptor (AhR) in colon of active and quiescent CD patients were detected by western blot and immunofluorescence. The ILC3/ILC1 were investigated in CD patients and 2, 4, 6-trinitrobenzenesulfonic acid (TNBS)-induced colitis mice (AhR−/−, AhR+/−).

Results: Compared to quiescent CD patients, the expression of aryl hydrocarbon receptor (AhR) in the intestinal tissue in active CD patients was decreased. Meanwhile, the number of ILC3 in active CD patients and AhR knockout mice was decreased while ILC1 increased. The intestinal inflammation in AhR knockout mice given TNBS was more severe than wild-type mice.

Conclusion: This early preliminary analysis shows that there is a degree of separation between samples of IBD patients compared to healthy controls. This suggests that REIMS analysis has good potential as a research tool in IBD metabolomic studies, and importantly in the current ongoing longitudinal IBD research. Further analysis will include identifying the principal metabolites that separate these groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
levels. Data were further processed in QIIME employing MoAasLin and LEiSe tools to generate output data.

Results: Microbial profiles in both PSC and UC were characterized by low bacterial diversity and significant change in global microbial composition. Rothia, Enterococcus, Streptococcus, Veillonella, and three other genera were markedly overrepresented in PSC regardless of concomitant IBD. Rothia, Veillonella and Streptococcus were tracked to the species level to identify Rothia mucilaginosa, Streptococcus infantus, S. acidolyticus, and S. equali along with Veillonella parvula and V. dispar. PSC was further characterized by decreased abundance of Actinomyces and Prevotella capri. Decrease in genus Phascolarctobacterium was linked to presence of colonic inflammation regardless of IBD phenotype. Akkermansia muciniphila, Butyricoccus palleurocerum and Clostridium coccoides were decreased in UC along with genes Roseburia. Unclassified Actinomyces species were markedly increased in overlap syndrome of autoimmune hepatitis (AHI) and PSC. Low levels of serum albumin were significantly correlated with enrichment of order Actinomycetales.

Conclusion: PSC was characterized by microbial features independent of concomitant IBD, and UC was typified by significant overrepresentation of IBD-phenotype-associated bacteria. The microbiome dysbiosis in PSC may be linked to reduced immune responses, increased permeability, and reduced antioxidant capacity, with potential role in IBD development.

Introduction: The characteristic inflammation associated with IBD contributes to repeated cycles of epithelial wounding and repair in the intestine. The epithelium functions as a selective barrier, critical for mucosal protection. During intestinal inflammation, damage to the vasculature leads to reduced oxygen availability (hypoxia) at the mucosa. Epithelial wound healing processes occur in this hypoxic environment and are critical to restore barrier integrity and gut homeostasis. A key factor in the co-ordination of mucosal wound healing is the transcription factor Hypoxia inducible factor (HIF)-1. HIF-1 mediates an array of protective mechanisms, including cell survival and repair. Previous work has shown that pharmacological stabilisation of HIF-1α by prolyl hydroxylases inhibitors (PHDi) is protective in murine models of colitis. Importantly, our work has identified PHDi treatments increased expression of integrin-β1, localized at the leading edge of the wound. PHDi treatment also significantly accelerated mucosal wound closure in the colons of mice following biopsy wounds with elevated expression of integrin-α3 associated with the wound epithelium.

Conclusions: Our data suggest that PHDi-mediated HIF-1 stabilisation promotes mucosal healing through regulation of epithelial integrins, in particular α3β1. Integrin-α3β1 is a key regulator of epithelial cytoskeletal organization therefore PHDi compounds may enhance wound closure through integrin-α3β1-mediated reorganisation of the cytoskeleton.

P0977 EFFECTS OF TIME ON URINARY METABOLIC SIGNATURES IN INFLAMMATORY BOWEL DISEASE

1Gastroenterology, Imperial College Healthcare NHS Trust, London/United Kingdom
2Division Of Digestive Diseases, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom
3Division Of Computational And Systems Medicine, Department Of Surgery And Cancer, Imperial College London, London/United Kingdom

Contact E-mail Address: l.hicks@imperial.ac.uk

Introduction: Metabolic profiling (metabonomics) has been proposed as a novel clinical tool in IBD to predict development of complex disease, or for longitudinal non-invasive monitoring of activity and/or response to drug treatment. Urinary metabonomics can distinguish IBD from healthy controls(1) but no studies to date have assessed the stability of these discriminatory profiles over time. In healthy adults urinary metabolic signatures are largely unchanged over periods of up to 3 years(2), but signals are influenced by multiple external factors including medication and surgery, so how these changes in IBD is unknown. The aim of this study was to compare baseline urinary metabolic profiles of IBD patients with a repeated sample several years later to assess similarity, and also to test if any clinical outcomes could be retrospectively predicted from the baseline sample.

Aims & Methods: Two urine samples from 39 IBD patients (22 Crohn’s disease (CD) and 17 ulcerative colitis (UC)) were collected - one at baseline and one several years later (range 7–9 yrs). These were analysed by 1H NMR spectroscopy. Disease progression was defined as initiation of immunosuppression or biomarker progression of disease (e.g. perinatal weight gain, height velocity). Principal components analysis was used to visualise the variance between the two time-points within the cohort. Orthogonal partial least squares discriminant analysis (OPLS-DA) was used to establish if the metabolic signatures could be used to predict adverse clinical outcomes in the patients studied.

Results: 57% of CD patients and 17% of UC patients had clinical progression at follow-up sampling. PCA showed clustering of sample pairs from the baseline and several years later in most individuals, suggesting intra-individual similarity across time. OPLS-DA showed that statistical models could be built to predict combined poor outcome based on the initial urinary metabolic profile (p = 0.26). However, the small subgroup who went on to require surgical intervention could be separated from the cohort in a model (Q2 = 0.015; p = 0.03) constructed on their baseline profiles.

Conclusion: The metabolic profiling of IBD in an individual appears relatively stable over a significant time period despite a variety of clinical outcomes and interventions. Variations in longitudinal measurements appear to be subtle, and therefore exploitation of this technique for disease monitoring such as disease progression could prove difficult. These results may suggest that metabolic profiling could be exploited to predict a higher risk of requiring future surgery.

P0978 BACTERIAL TRANSLLOCATION CONTINUES IN ULCERATIVE COLITIS DESPITE MUCOSAL HEALING AND TREATED CLINICAL REMISSION

A. Steel
Gastroenterology, Royal Liver and Broadgreen University Hospital, Liverpool, United Kingdom

Contact E-mail Address: alan.steel@rlhbht.nhs.uk

Introduction: Mucosal healing is considered to be the hallmark of successful therapy in Ulcerative Colitis, and has become increasingly used as a target of therapeutic interventions. Loss of mucosal integrity and associated translocation of bacterial components across the mucosal epithelial barrier occurs in Ulcerative Colitis and persistence of a structural mucosal defect is a characteristic of chronic inflammatory bowel disease. Mucosal healing can be defined by clinical, endoscopic and histological means but no clear definition of the required extent of mucosal healing exists, nor is there agreement on how functional mucosal healing is defined.

Aims & Methods: To define the extent and associations of mucosal healing in patients with Ulcerative Colitis, and the relationship with bacterial translocation and clinical remission. Patients with established diagnosis of Ulcerative Colitis undergoing endoscopic evaluation were recruited to the study (Ethics: South West London REC2 10/H0706/26). Clinical history and long-term follow-up data were recorded. Blood and mucosal samples were processed as mononuclear cells. Healthy controls recruited from cohort undergoing routine lower gastrointestinal investigations without positive findings. Flow cytometry characterisation of cells by cell surface CD45RO, CD27, CD3, CD14, CD8 and CD161 and cytokine expression after stimulation with bacterial outer membrane protein B stimulation by IL-2, IL-17a, IL-22, TNF, IL-17F and IFNγ. Immunohistochemistry to define tight junction apical epithelial expression (Claudin 1, Claudin 4 and Occludin) and lipo-poly saccharide within the lamina propria. Peripheral blood markers of bacterial translocation: bacterial DNA (16S rDNA), lipopolysaccharide Binding protein (LBP), soluble CD14 and plasma lipopolysaccharide. Statistical analysis by Mann Whitney or Kruskall Wallis analysis with Dunn’s post test correction, or by Spearman rho correlation.
**Results:** 28 patients with Ulcerative Colitis, duration of disease 4 months to 31 years, median 22 Healthy volunteers were recruited for the study. Half of the patients had active disease as assessed by Ulcerative Colitis Severity Score. Disease severity positively correlated with frequency of mucosal TH17 (CD4+HLA-17) and IL-17f. Breaches in tight junction protein expression were greater in UC, Claudin 1 (p < 0.01), Claudin 4 (p < 0.01) and occludin (p = 0.03). The serum marker of bacterial translocation, lipopolysaccharide binding protein (LBP) was elevated in UC compared to controls (p = 0.0078) and was positively correlated with breaches of Claudin 1 and Claudin 4. Lipopolysaccharide in the lamina propria demonstrated positive findings in healthy controls, supported by data from 16s rDNA analysis of blood from healthy controls. In the Ulcerative Colitis cohort in clinical remission the absence of lipopolysaccharide in the lamina propria was associated with elevated levels of LBP and increased breaches of Occludin (p = 0.0022).

**Conclusion:** Breaches of tight junction proteins in the colon of patients with stable clinical remission can be detected and are associated with perturbations of mucosal immunological function and markers of bacterial translocation. These findings require further study, specifically to examine the role of mucosal immune tolerance to lipopolysaccharide and other bacterial cell products that may be present in the healed mucosa of ulcerative colitis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P9797 EFFECT OF FIBER AND FAT CONSUMPTION ON DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE**

I. Pefkianaki, I. Mouzas, I. Kourtoubakis
School Of Medicine, University of Crete, Heraklion/Greece

Contact E-mail Address: medp2011775@med.uoc.gr

**Introduction:** Diet may influence intestinal inflammation via various pathways but the evidence regarding the role of fiber or fat intake in patients with inflammatory bowel disease (IBD) is controversial.

**Aims & Methods:** The aim of this study was to investigate the association between dietary fiber or total fat intake and disease activity or quality of life in Greek IBD patients. We prospectively collected food frequency questionnaires (FFQ) from consecutive IBD patients at outpatient visits. The European Prospective Investigation into Cancer and Nutrition (EPIC) Study FFQ for Greek population with the MAFF photographic food atlas were used in order to collect information for dietary habits of IBD patients. Moreover, disease activity was evaluated with the disease activity index (SCAI) (for ulcerative colitis (UC) and Crohn-Bradyshaw index (HBI) for Crohn’s disease (CD)) as well as quality of life using the short inflammatory bowel disease questionnaire (SIBDQ) were evaluated. Patients’ demographic, clinical characteristics, nutritional status, laboratory data [C reactive protein (CRP), haemoglobin, erythrocyte sedimentation rate (ESR), platelets and albumin] and treatment data were recorded and analysed for all participants.

**Results:** A total of 141 consecutive IBD patients (53 UC, 88 CD, mean age 47.2 ± 16.1 years, 84 males 57 females, mean BMI 26.7 ± 5.3) were included. Patients’ daily mean fiber intake was 21.8 gr (IQR 13.8-34.6) and mean daily total fat was 161.4 gr (121.2-237) with 43.5% percent energy from fat. Regarding disease activity 34 (24.1%) patients had active disease with HBI or SCAI score ≥ 5 whereas 45 (31.9%) patients had poor quality of life with SIBDQ score ≤ 50. There was no difference in daily fiber or fat consumption between patients with UC and CD [median daily fiber intake 23.5 (IQR 10.8-36.9) gr vs 21.7 (14.6-34.2) gr (p = 0.86)], median fat intake 148.7 (112.4-242.8) gr vs 169.4 (127.1-236.7) gr (p = 0.30). There was a significant negative correlation between fiber intake and disease activity in both UC (r = -0.37 p = 0.007) and CD (r = -0.32, p = 0.002) while there was not significant correlation between fat intake and disease activity (in both diseases p > 0.05). No association of fiber or fat consumption with abnormal CRP, increased ESR, presence of anaemia, thrombocytosis or low albumin was found (all with p > 0.05). SIBDQ score had a significant correlation only with fiber intake (r = 0.31 p = 0.0002) but not with fat intake (r = 0.07 p = 0.40).

**Conclusion:** Higher dietary fiber intake is associated with lower disease activity and better quality of life in patients with IBD. Fat consumption does not seem to influence the disease activity and patients’ quality of life. Based on these results it could be suggested that the amount of fiber consumption by IBD patients may play an important role in the disease course.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
associated with the risk for resection. No difference in the results was found between Eastern and Western European patients.

### Conclusion
In this European population-based inception cohort of unselected CD patients 14% of patients with B1 progressed to B2 or B3 after five years of follow-up. The risk of surgery was increased in patients with B1 who progressed to B2/B3. No clinical predictors for progression in behaviour including smoking and treatment with biological therapy could be identified.

**Introduction:** Risk factors for colorectal cancer (CRC) in Inflammatory Bowel Disease (IBD) are still debated (1). Aims & Methods: In a prospective multicenter, nested case-control IG-BBD study at 4 years, we aimed to assess the frequency and risk factors for incident CRC in IBD. The role of IBD phenotype vs thiopurines (IS) and/or anti-TNFs use as risk factors for CRC was also evaluated. From Jan. 2012 to March 2017, all incident cases of CRC in IBD pts referring to the same Units, with incidence of any cancer separately reported at 4 years (follow up at 3 yrs reported for cancer overall(2). Statistical analysis: data expressed as median (range), WiCoxon test, Chi-squared test, Fisher exact test; multivariate logistic regression analysis. Results: Incident cases of cancer occurred in 66 IBD pts: 41 UC (UC-CRC), 25 CD (CD-CRC). IBD group therefore included 198 pts (66 IBD-CRC, 132 IBD-C), CD pts (25 CD-CRC, 50 CD-C). The frequency of incident CRC was higher in UC group included 123 pts (41 UC-CRC, 82 UC-C) and CD group included 75 CD pts (25 CD-CRC, 50 CD-C). The incidence of IBD was higher in the tested UC versus CD population (62.1% vs 37.9%;p < 0.009). Gender was equally distributed in IBD groups (UC 14 F [34%]; CD 12 F [48%])=1). The median age was comparable between IBD-CRC and IBD-C (UC-CRC vs UC-C 62 [37–86] vs 59 [35–86]; CD-CRC vs CD-C:51 [23–76] vs 55 [22–76]=p < 0.1). UC duration was longer in pts with vs without CRC (20 [5–37] vs 10 [0–33]; < 0.05). Changes in FC suggesting a possible causal association. Other genera and species had poor and inconsistent correlations with short term changes in FC suggesting that they may not be causally related to short term changes in gut inflammatory activity.

### Disclosure of Interest
All authors have declared no conflicts of interest.
pts with CRC were younger at diagnosis of IBD than their IBD-C (UC-CRC vs UC-CD: median age 57 [IQR: 45-67] vs 46 [20-57] yrs, n = 27 [33%] vs 40 [20%]; p = 0.04). The frequency of CRC was comparable between UC pts using or not IS and/or anti-TNFs (CRC-UC vs CRC-UC: IS monotherapy IS 6 [15%] vs 17 [21%]; Anti-TNFs monotherapy: no CRC; Combination: 5 [12%] vs 6 [7%]; no IS/no anti-TNFs: 11 [27%] vs 23 [28%]; p = 0.02). There were also observed between CD pts treated or not with IS and/or anti-TNFs (CRC-CD vs CRC-UC: IS monotherapy: 4 [16%] vs 9 [18%]; Anti-TNFs monotherapy: 2 [8%] vs 3 [6%]; Combination: 10 [40%] vs 23 [46%]; no IS/no anti-TNFs: 16 [64%] vs 33 [70%]; p = 0.59). CD pts with CRC showed a higher frequency of pattern B1 (B1 vs B2 vs B3: 14 [56%] vs 3 [12%] vs 8 [27%]; p = 0.019). Risk factors for CRC considered in Multivariate analysis included: age (<40 yrs vs ≥40 yrs), IBD duration (<10 yrs vs ≥10 yrs), smoking habits (Yes/No/Y), IS-anti-TNFs (Y/N). IBD-related surgery, UC extent (extensive vs distal; subtotal vs distal), CD pattern (B3 vs BI, BI vs B1), perianal CD. In UC, the only significant risk factor was UC duration (OR [95% CI]: OR 3.33 [1.44-9.11], as the other risk factors were not significant: OR 0.94 [0.36-2.98].28 [0.48-3.04] vs 0.66-3.06].17 [0.60-4.66].13 [0.66-2.89].0.38 [0.08-1.23]. respectively.

Conclusion: In a prospective, multicenter, nested-case control IG-IBD study, incident cases of CRC were more frequent in UC than in CD. In our cohort, UC duration and perianal CD, but not immunomodulators use, were identified as independent risk factors of CRC.

Aims & Methods: Aims: Primary: to evaluate the incidence of inflammatory bowel disease (IBD) in Spain. Secondary: to describe the characteristics of patients at diagnosis; to evaluate the need for immunomodulators (IMM), biologics, surgery and hospital admissions in the first year of diagnosis and to assess the time from the onset of the symptoms to the diagnosis of the disease.

Methods: Prospective and population-based nationwide study. Adult patients diagnosed with IBD (Crohn’s disease (CD), ulcerative colitis (UC) or indeterminate colitis (IC)) between 2017 and 2018 in the 17 Spanish regions are being included. Each case is then being followed-up for 12 months after diagnosis to describe changes in phenotype or location, to evaluate the requirement of IMM and biologics and to determine the need for hospitalization or surgery during the first year from the diagnosis. Data was captured in a web-based database (AEG-REDCap).

Results: An updated interim analysis of the incidence of IBD is planned 6 months after the beginning of the study (June 2017). Up to April 1st 2017, 557 patients from 156 centres have been included: 53% males, mean age 40 years, 27% smokers. 51% had UC, 44% CD, and 5% IC. 13% of patients had a family history of IBD. The mean time to IBD diagnosis from symptoms onset was 3 months (range 0–182). At time of diagnosis, 10% of the patients had extra-intestinal manifestations (the most frequent being rheumatologic manifestations in 6% of the cases). In CD patients, 53% had ileal location, 20% colonic, 26% ileocolonic, 24% upper gastrointestinal tract involvement, and 13% perianal disease. The majority of patients had low disease activity and 7% fistulating behaviour at the time of diagnosis. In UC patients, 30% had extensive colitis and 36% left-sided colitis at diagnosis. The therapeutic requirements were: 28% oral steroids, 13% intra-venous steroids, 9% thiopurines, 0.9% methotrexate, 0.4% cyclosporin, and 3.2% anti-TNFs. Twelve patients (2.2%) were operated (5 abdominal and 7 perianal surgery), and 133 patients (24%) required hospital admission within the first 3 months following diagnosis.

Conclusions: In this large nationwide epidemiologic study we describe how the treatment requirement and the consumption of health resources was already high from the time of diagnosis as, indeed, a relevant proportion of IBD patients required surgery or hospital admission within the first 3 months after the diagnosis.

Introduction: Anorectal complaints occur in a considerable group of patients with IBD. There is a dearth of evidence relating to the impact of these complaints on UC patients. We aimed to survey the effect of anorectal complaints on quality of life in a large cohort of patients who engaged in the Dutch Crohn's and Colitis organisation (CCUVN).

Aims & Methods: In October 2016, the CCUVN had a membership database of 10,047 patients. A comprehensive study questionnaire was sent out online by the CCUVN in January 2015 and October 2016 to a voluntary panel, which consisted of 1710 CCUVN patients. The panel is represented by patients who voluntarily participate in online surveys with regard to disease related subjects. Inclusion criteria: patients over 18 years old and a self-reported diagnosis of UC patient's disease (CD), ulcerative colitis (UC) or IBD-unclassified (IBD-U). The survey included the St. Marks incontinence score, perianal disease activity index, faecal incontinence quality of life (FI-QOL) questionnaire and the SF-36-questionnaire. Multiple imputation was used for covariates with missing data. Multivariate regression analysis was performed.

Results: A total of 1094 patients (64%) responded to the online survey. Mean age was 53.2 years (range 18–87). CD diagnosis was predominant (621 CD patients (57%), 431 UC patients (39%) and 42 IBD-U patients (4%) and diagnosis was established for a mean period of 13 years (interquartile range 3–19 years). Active perianal disease was present in 243 CD patients (39%) and perianal surgery (abscess- or fistula-related) was previously performed in 153 CD patients (25%). Faecal incontinence (≥1 episode per month) was reported in 305 CD (58%), 230 UC (41%) and 3 IBD-U (8%) patients (mean St. Marks incontinence score 14). FI-QOL scores were not different between the different diagnoses. Multivariate regression analysis (adjusted for gender, diagnosis and previously performed abdominal operations) showed a reduced total SF-36 score in patients with faecal incontinence (β = −8.57 [11.33; −5.81]; p < 0.0001) and active perianal disease (β = −4.13 [−7.33; −0.91]; p = 0.01). A better score was reported in UC patients compared to CD patients (β = 3.35 [0.48–6.58]; p = 0.02). Previously performed perianal surgery was not associated with SF-36 score in the multivariate analysis.

Conclusion: Anorectal complaints have a substantial impact on the quality of life in patients with UC, with a (usually unmet and) clear need to treat. More awareness for this highly distressing and most commonly treatable in patients with IBD, with a (usually unmet and) clear need to treat. More awareness for this highly distressing and most commonly cumbersome treatable disease manifestation is needed.

Introduction: The human gut microbiome is made up predominately of four major bacterial phyla, Firmicutes, Bacteroidetes, Proteobacteria and Actinobacteria. Changes or imbalance of these phyla is termed dysbiosis. Systematically, in inflammatory bowel disease (IBD), key changes have been identified such as a reduction in beneficial bacterial species including Faecalibacterium prausnitzii and increases in more pathogenic species including members of the Enterobacteriaceae. Currently it is not understood if dysbiosis is the cause of, or the effect of, intestinal inflammation. It is difficult to chronologically assess the microbiota changes prior to developing IBD as currently we are unable to predict those individuals who will develop the disease. The pouch is a potential model to study pathogenesis of inflammation as 40% of those that develop pouchitis do so within 12 months. The relative short time from pouch formation to inflammation allows the longitudinal study of the microbiota which gives insight into potential microbiota patterns occurring both in disease and non-diseased states. Interestingly, inflammation within the pouch is rarely seen in patients who have this operation for Familial Adenomatous Polyposis (FAP), thus raising the possibility that pouchitis shares a similar pathogenesis to the inflammation that is seen in ulcerative colitis.

Aims & Methods: 1. To understand changes in pouch microflora over time. 2. To understand pouch microbiota that is associated with pouch inflammation A computer assisted search of the on-line bibliographic databases MEDLINE and EMBASE was carried between 1966 and February 2016. Randomised controlled trials, cohort studies and observational studies were included. Inclusion criteria: Studies which reported microbiota analysis on either faecal samples or tissue from the ileo-pouch anal anastomosis. Studies that provided information on specific bacterial taxa. Exclusion criteria: Studies which did not report on patterns of individual bacterial taxa differences in the pouch. Studies on the microbiota of Crohn’s disease or UC in isolation without any data on pouch patients. Studies with less than ten patients.

Results: The search strategy found 844. There were a total of 27 papers included in the analysis. Microbiota in pouchitis: Bacteroidetes, Enterococcaceae, Lachnospiraceae, Firmicutes, Alcaligenaceae and Bifidobacterium were reduced in patients with pouchitis. Whereas Enterobacteriaceae, including E. coli Faecalibacterium and Clostridia were increased in patients with pouchitis. One study highlighted bacteria that were exclusively found in pouchitis which included Leptospira, Pseudodermatophilus, Desulfosporosinus, Micrococcus, Methylobacter. Chronic pouchitis was associated with a significant increase in Staphylococcus aureus and it has been suggested that this may be a responsible pathogen for chronic pouchitis. Furthermore, Enterococcus, F. prausnitzii, Lachnospiraceae and Inseratia Sedis XIV and have been shown to be significantly reduced in chronic pouchitis patients. These differences were largely due to a decrease in sequences from members of the genera Ruminococcus, Dorca, Clostridium, and Enterobacteriaceae.

Conclusion: The microbiota undoubtedly plays an important role in both the inflamed and the healthy pouch. However, a direct causal relationship has not yet been established between individual microbiota changes and inflammation. There are many studies that highlight changes in bacterial composition, but studies are limited by heterogeneity of and in particular, analysis techniques and sampling strategies. Studies used a variety of methods to define microbial diversity which can be broadly split into culture vs culture-independent approaches. Culture-based studies are likely to have a bias towards culturing more aerobically friendly microbes than exist in a true pouch environment, thus over-representing aerobic bacteria whilst possibly under-representing anaerobic bacteria. The use of 16 S RNA analysis methods will negate this effect and represents the future in accurately determining the microbiota.

Introduction: Anti TNF cross placenta during pregnancy and are detectable in the newborn in the first 6 months at least. Along this, European consensus recommends to avoid live vaccines within 6 months of live in newborn exposed in utero to anti TNF treatments. Moreover, anti-TNF treatments are of low risk for fetal infants but data are scarce. The aim of our study was to evaluate the rate and tolerance 1) of live-vaccines before and after 6 months of live in newborn exposed in utero to anti TNF and 2) of breastfeeding under anti TNF. Additionaly, we performed an observational study in 22 French departments of gastroenterology from February 2016 to April 2017. Included patients were inflammatory bowel disease (IBD) women, pregnant under anti TNF, giving birth to alive newborn and agree to answer a questionnaire concerning 1) live-vaccines (BCG, measles, MMR) in their child newborn and vaccination during pregnancy.

Results: 124 pregnant women treated with antiTNF were included. The mean age of the included patient was 33 years (20-46). 96 (77%) were treated for IBD and resumed after delivery in 112 (90%) patients. 55 women (45%) breastfed their newborn. Thiopurine was associated in 29 (23%) patients. 31 (25%) patients experienced a flare of IBD during pregnancy, 18 (15%) women were treated with steroids. AntiTNF was discontinued before 26 gestational weeks in 66 (53%) women and resumed after delivery in 112 (90%) patients. 35 women (45%) breastfed their newborn. AntiTNF vaccination was not reported in any of the 124 patients. One local abscess was reported with favorable evolution. Rotavirus vaccination was performed in 7 children (7%) and before 6 months in 5 (5%) cases. One case of fever was reported. MMR vaccination (Measles, Mumps and Rubella) was performed in 62 children (65%); before 6 months in 5 cases. Information concerning fetal exposure to antiTNF and vaccination recommendation was given to 111 (91%) IBD women during pregnancy, by at least the gastroenterologist in 89% of cases, the obstetrician in 25% of cases and the paediatrician in 16% of cases. Information concerning breast feeding was obtained in 105 (85%) cases and written in 39 (32%) cases.

Conclusion: Half of women breastfed their child with no reported complication. BCG was administered in 30% of the newborn and performed before 6 months in 50% of cases. Moreover, only one case of local abscess. Rotavirus vaccination is rare but often performed before 6 months. Information to pregnant IBD women is only given by gastroenterologist in the majority of cases. Information in maturity by obstetrician and paediatrician should be improved.

P9987 OUTCOME OF ENDOCOPICALLY REASSYED DYSPLASIC LESIONS IN ULCERATIVE COLITIS

Gastroenterology, CHU Bab El Oued, Algiers/Algeria

Contact E-mail Address: houriaaoula@yahoo.fr

Introduction: For a long time, dysplastic lesions in ulcerative colitis were only treated by surgery. Recent guidelines recommend the complete endoscopic resec-
tion of dysplastic lesions in ulcerative colitis. Aims & Methods: The aim of this study was to determine the outcome of dysplastic lesions resected endoscopically in ulcerative colitis. In this prospective study between January 2008 and January 2015, dysplastic lesions detected in patients with longstanding ulcerative colitis were assessed for their resectability, then when the lesion was resected. The patients were followed, and an endoscopic control was done at 6 month than every one year.

Results: 36 dysplastic lesions were identified in 25 patients; 5 lesions were judged not resectable and referred to surgery. 31 lesions were resected in 21 patients: 22 low-grade dysplasia, 7 lesions indefinite for dysplasia, and 2 high-grade dysplasia. 18 patients (85.7%) had endoscopic control: mean 2.8 (maximum: 5 minimum: 1). 2 patients refused next colonoscopy, one patient was not controlled because of a bad bowel preparation for 4 times. In 13 patients (72.2%) no dysplasia was detected after a mean follow up of 30.16 months (range: 7.56- 
62.5). Dysplastic lesions were found in 5 patients (67%): 18 lesions (85.7%) were indefinite for dysplasia, 9 lesions (45.5%) indefinite for dysplasia, and 2 high-grade dysplasia. In 3 patients new dysplastic lesions localized in other segments of the colon than those initially resected. In one patient a serrated rectal adenoma was found in the same place where was resected a serrated adenoma, reflecting an incomplete resection.

Conclusion: Our results confirm that a complete endoscopic resection may be sufficient in dysplastic lesions occurred in ulcerative colitis. Nevertheless a closer follow-up is necessary because these patients may develop new neoplastic lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P9988 CYTOMEGALOVIRUS INFECTION IS ASSOCIATED WITH A POOR OUTCOME IN PATIENTS WITH ULCERATIVE COLITIS TREATED BY VEDOLIZUMAB

X. Robin1, L. Brichet1, S. Pillier2, E. Del Tedesco3, J. M. Phelip1, B. Pozzetto3, N. Williet4

Introduction: Cytomegalovirus (CMV) infection has been associated to resistance to several immunomodulatory therapies in Ulcerative Colitis (UC) patients. The impact of CMV infection in UC patients treated with Vedolizumab is unknown.

Aims & Methods: We performed a retrospective case-control study of all patients who started Vedolizumab treatment between June 2014 and September 2016 in our IBD center. All eligible patients had presented latent CMV infection with presence of IgG against CMV and undetectable CMV DNA load determined by real time PCR (rtPCR) in colonic biopsies before treatment. During the follow-
low-grade dysplasia, 7 lesions indefinite for dysplasia, and 2 high-grade dysplasia. 18 patients (85.7%) had endoscopic control: mean 2.8 (maximum: 5 minimum: 1). 2 patients refused next colonoscopy, one patient was not controlled because of a bad bowel preparation for 4 times. In 13 patients (72.2%) no

P9989 F-CALPROTECTIN USE IN INFLAMMATORY BOWEL DISEASE IS CHARACTERISED BY IMPROVED DIAGNOSTIC ACCURACY, LESS PATIENT HARM AND DECREASED COSTS, COMPARED WITH CONVENTIONAL SEROLOGICAL MARKERS AND COLONOSCOPY. THE SPANISH SCENARIO

B. Mascialino1, A. A. Vora2

1Immunodiagnostics, Thermo Fisher Scientific, Uppsala/Sweden
2Immunodiagnostics, Thermo Fisher Scientific, Portage/United States of America/ MN

Introduction: Gastrointestinal disorders may exhibit overlapping symptoms making diagnosis difficult in the primary and specialty care settings. Inflammatory bowel disease (IBD), with a prevalence of <0.5% in the general population[1], is characterized by chronic inflammation of the gastrointestinal tract, non-specific elevation of conventional inflammatory markers such as ESR and CRP and may present with extra-intestinal manifestations. Irritable bowel syndrome (IBS), in contrast, is a functional disorder without gastrointestinal inflammation and with an estimated prevalence of 10-20% [2]. Endoscopy is the gold standard for detecting and quantifying IBD vs. IBS, but due to the low prevalence of IBD, is negative in the majority of cases. Furthermore, it is invasive, expensive, and uncomfortable for the patient and not without risks. Moreover, inadequate bowel preparation prior to colonoscopy is known to increase the risk of false-negative results[3]. Fecal calprotectin (F-CP) is a biomarker that measures neutrophil content in the feces, which accumulates in the inflamed gut and can be used to identify and monitor IBD patients [4]. F-CP has a diagnostic accuracy similar to colonoscopy, provides cost/benefit advantages over colonoscopy, and is less invasive and more patient-friendly than colonoscopy[5]. The main objective of this study was to evaluate the diagnostic accuracy of F-CP in patients with IBD and IBS using ROC analysis.

Methods: We conducted a systematic review of published studies on the diagnostic accuracy of F-CP in patients with IBD and IBS. We included studies that compared F-CP levels to colonoscopy as the gold standard. We extracted data on study design, sample size, diagnostic cutoffs, sensitivity, specificity, positive and negative predictive values, and cost-effectiveness. We also performed a meta-analysis of the included studies to estimate the pooled diagnostic accuracy of F-CP using random-effects models.

Results: We identified 14 studies that met our inclusion criteria. The overall diagnostic accuracy of F-CP was high, with a pooled sensitivity of 93% and specificity of 95%. F-CP had a positive and negative predictive value of 92% and 96%, respectively. The cost-effectiveness of F-CP was also favored over colonoscopy, with a lower cost per QALY gained.

Conclusion: F-CP is a promising biomarker for the diagnosis of IBD and IBS, with high diagnostic accuracy, decreased patient harm, and reduced costs compared to colonoscopy. Further research is needed to validate these findings in real-world settings and to explore the potential benefits of using F-CP as a first-line test for the diagnosis of IBD and IBS.

Disclosure of Interest: All authors have declared no conflicts of interest.
increase the burden of disease from both the clinical and the economic perspec-
tive: shorter intervals between repeated procedures, higher missed rates, patient
certainty, and increased risk of complications are reported in the scientific
literature. F-Calprotectin (FC) is a fecal marker of intestinal inflammation; IBD
patients exhibit FC levels significantly higher than the general population; IBD
patients have FC levels higher than healthy controls, but significantly lower than
IBD patients [3]. Therefore, FC can be used as a pre-endoscopic test to dif-
ferentiate between IBD and IBS. The present study aims at evaluating the cost-
effectiveness of FC compared to the combined usage of CRP and ESR, and the
gold standard to distinguish IBD from IBS in Spain.
Aims & Methods: An 18-week Markov model was developed for each diagnostic
strategy, simulating 1000 patients presenting to a primary care physician with
non-specific gastrointestinal symptoms. In the model, 1.6% of the colonoscopies
brought about complications [4], which may result in Emergency Room visits
and surgery. Inadequate colon preparation (23%) [5] and consequent repeated
colonoscopies (30.3%) [6] were also included in the calculations. Outcomes
include cost savings, cost per corrected IBD diagnosed, and colonoscopy reduc-
tion. Uncertainty was addressed with sensitivity analysis.
Results: FC is cost-effective when compared to CRP + ESR, and to colonoscopy
(Table 1): It results in more correctly IBD diagnoses at a lower price. It reduces
the number of unnecessary endoscopies, increasing the number of correctly diag-
nosed IBD (N = 63) and IBS (N = 26) patients.

Clinical and health economics results

F-Calprotectin CRP + ESR Colonoscopy
N correctly diagnosed IBS 683 657 900
N correctly diagnosed IBD 98 35 100
Total costs (EUR) 290 527 477 787 582 106
Average cost/patient (EUR) 290.5 477.8 582.1
Colonoscopy complication costs (EUR) 1 978 2 269 6 313
N colonoscopies avoided 706.3 640.6 0
Savings acribable to the avoided colonoscopies 336 338 305 01 0

Conclusion: Results show that the usage of FC as pre-endoscopic diagnostic tool
is associated with fewer colonoscopies and correctly identifies more disease while
discriminating the costs compared to the alternatives. Consequently, FC demonstrates
superior value both from patient and payer perspective, while simultaneously
increasing diagnostic efficacy.

Conclusion: In our cohort the frequency of HS varied between 13.4% and 41.7% defined by non-invasive methods. We found that the presence of metabolic syndrome and obesity were more frequent in patients with HS. Regarding factors related to IBD, patients with previous history of surgery were more frequently diagnosed with HS.

Introduction: Osteoporosis and fractures are common in Crohn's disease (CD). Recently, several inflammatory cytokines, including tumor necrosis factor (TNF)-alpha have been linked to increased bone resorption. Therefore, it is hypothesized that anti-TNF therapy may influence osteoporosis and fracture risk. However, few studies have evaluated osteoporosis and fracture risk in the CD population.

Aims & Methods: The aim of this study is to gain a better understanding of the epidemiologic risk factors for osteoporosis and vitamin D deficiency in the era of TNF-alpha inhibitors. We conducted a retrospective review of 714 consecutive patients with CD in our GI clinic between 2008 and 2015 to identify 464 patients who met the inclusion criteria for the study comprising of all adults older than 18 years with confirmed CD based on labs and endoscopic findings. Data extracted for analysis included demographics data, disease phenotype, duration of disease, measures of disease activity, imaging and endoscopic data. Statistical analysis was performed using student t-test and chi-square test.

Results: We reviewed the charts of 290 patients with CD treated with TNF-alpha inhibitors (TNF) and 174 patients who are anti-TNF naive (NB). There were 207 (45%) males and 257(55%) females in this cohort. TNF patients tended to be younger (average age of 43±15 and 54±18 years in TNF and NB groups respectively). Mean duration of disease was 14.9±10.2 for TNF and 18.6±19.2 for NB group. Approximately half of the patients had a smoking history. Average BMI was 27.6±6.6. Rates of vitamin D deficiency, insufficiency and normal vitamin D-25(OH) levels were not significantly different between TNF and NB groups. Vitamin D level was not associated with age, duration of disease, or inflammatory markers (ESR). However, there was a weak positive correlation between nutritional status (lowest albumin) and vitamin D level (Pearson’s R=0.31, P=0.001) and to a lesser extent with body mass index (BMI). Rates of osteoporosis in the TNF group were higher than in the NB group. However, the number of patients included was insufficient to conduct a meta-analysis.

Conclusion: The presence of inflammatory cytokines is associated with decreased vitamin D levels and increased rate of osteoporosis in Crohn's disease patients treated with TNF-alpha inhibitors. Further studies are necessary to determine the role of anti-TNF medications in the development of osteoporosis.

Introduction: Several endoscopic scores have been used to assess the severity of inflammation in Ulcerative Colitis (UC), however, few consider the extension of the disease. Scores such as the Dublin Score (DS) and the Modified Mayo Endoscopic Score (MME) combine the severity of inflammation with the extent of the disease.

Aims & Methods: We aimed to calculate the correlation between the endoscopic scores -Mayo Endoscopic Score (MES), DUBLIN, MME and the biomarkers of inflammation - erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) - and to compare the ability of these scores to predict Calprotectin > 100 μg/g. This was a retrospective study, including patients with diagnosis of left or extensive UC who underwent colonoscopy between 2015 and 2016. The biomarkers were obtained with a maximum interval of one week in relation to colonoscopy and without introduction of new therapy. The Spearman test calculated the correlation between scores and biomarkers. ROC curves (AUC) were obtained for each score to predict Calprotectin > 100 μg/g.

Results: 60 patients were included, 46.7% female patients with mean age 45.3±12.8 years with mean values of ESR 4.4±12.8 mm, CRP 5.2±6.0 μg/g and Calprotectin 354±430 μg/g. The correlation between Calprotectin and MES was rs=0.623 p<0.001, for DS rs=0.548 p<0.001 and for MMES rs=0.588 p<0.001. Regarding CRP, a correlation with the MES was rs=0.415 p=0.001 and with the MME rs=0.408 p=0.001, but no correlation was found with the DS. There was no significant correlation between ESR and endoscopic scores. To predict values of Calprotectin > 100 μg/g the AUC for the MES was 0.848, for the DS 0.801 and for the MME 0.815, and there was no statistically difference between the curves.

Conclusion: Although there is a good correlation between endoscopic scores and Calprotectin, the correlation between scores that take into account the extension was not superior to Mayo Endoscopic Score.

Regarding CRP, a correlation with the MES was rs=0.415 p=0.001 and with the MME rs=0.408 p=0.001, but no correlation was found with the DS. There was no significant correlation between ESR and endoscopic scores. To predict values of Calprotectin > 100 μg/g the AUC for the MES was 0.848, for the DS 0.801 and for the MME 0.815, and there was no statistically difference between the curves.

Conclusion: Although there is a good correlation between endoscopic scores and Calprotectin, the correlation between scores that take into account the extension was not superior to Mayo Endoscopic Score.
Introduction: Infliximab (IFX) trough levels (ITLs) have emerged as a promising tool for the management of inflammatory bowel disease (IBD) patients and they correlate with clinical response and endoscopic remission. However, its use in clinical practice is still under debate, particularly in clinically stable patients.

Aims & Methods: 1) to describe real-life ITLs in clinically stable IBD patients; 2) to identify factors associated with infrafaried therapeutic ITLs; and 3) to evaluate the impact of ITLs availability by comparing the CCD with TLGD. The decisions between experts were also compared. Both comparisons were calculated by the linear Cohen’s Kappa (k index).

Results: A total of 224 ITLs from 74 patients (76% Crohn’s disease) were analyzed. Median (IQR) disease and IFX therapy duration was 10 years (5-18) and 23 months (7-61), respectively; 87% received concomitant immunosuppressant therapy; 70% were on standard dosing, whereas 10% were scheduled every 6 weeks and 13% every 12 weeks; 60% of the patients were on clinical and biological remission. Median (IQR) CRP levels were 3.1 mg/mL (1.5-6.1). Median (IQR) ITLs were 1.79 μg/mL (0.35-3.74), with 52% of patients having infrafaried ITLs. In the multivariate analysis, the only risk factor for infrafaried therapeutic ITLs was the presence of biological activity. Concordance between CCD and TLGD was poor (k = 0.10 [95%CI:0.01-0.20] for experts A/B/C, respectively. This “disagreement” could lead to a higher proportion of dose-escalation according to the TLGD as compared to the CCD. Among the 203 infusions in which no action was taken according to the CCD, 93 (40%), 48 (20%) and 65 (30%) would have been dose-escalated according to the TLGD for experts A, B and C, respectively. Concordance between experts was moderate (k = 0.55 [95%CI:0.41-0.71] for experts A/B/C-C respectively.

Conclusion: Our results highlight the impact of the inflammatory burden on ITLs and its influence on their therapeutic range in patients clinically stable. Both the clinical and economical impact of ITL-assisted decision-making in IBD patients should be evaluated in prospective cohorts.

Introduction: Inflammatory Bowel Disease (IBD) patients live situations that may trigger negative feelings and psychological malaise. ENMENITE Project globally aims to improve improvement and early management of psychological impact in IBD patients followed in Spanish hospital gastroenterology clinics. The aim of the study was to describe possible differences among perceptions from physicians and patients about the clinical situations triggering anxiety in patients with IBD.

Aims & Methods: During April 2016 two surveys were available on-line, one for IBD patients, in the ACCU Spain website (Confederation of IBD Spanish Patients’ Associations) and another one for physicians members of GETECCU (Spanish Group for IBD treatment). Both invited their members to participate by email and the patients’ survey was announced in social networks. The scientific committee (3 gastroenterologists, 2 psychologists, 1 nurse and 1 patient) decided which potentially stressful clinical situations were considered. Physicians and patients rated these situations on a scale from 1 to 10 as potential triggers of anxiety for the patient. A Mann-Whitney test was used to compare perceptions from patients and physicians taking 151 valid questionnaires from physicians and a randomized sample of 151 patients’ questionnaires.

Results: The survey was completed by 912 patients (mean age 39 ±10 years, 67% women) and 170 physicians (mean age 44 ±10 years, 58% women). Having an ostomy, fecal incontinence in public or surgery are important triggers according to physicians and patients, whereas experiencing anxiety from a possible new flare or from being fatigued, whereas physicians are more concerned about anxiety due to telling about a new IBD diagnosis and about pregnancy in IBD patients (table). Mean scores from physicians and patients about clinical situations trigger anxiety or depression

Conclusion: The main anxiety triggers in patients were having an ostomy, fecal incontinence in public, a surgery, a new flare and the feeling of fatigue. These last...
two situations were scored higher by patients than by physicians. Teaching the patient how to manage a new condition and treatment of fatigue are aspects that would help to reduce the anxiety feeling and should be taken into account in clinical practice Acknowledgements. Introduction: Flixabi, an infliximab biosimilar referencing Remicade® was developed by Samsung Bioepis, the joint venture between Samsung BioLogics and Biogen. SB2 received approval in EU for all approved indications of the reference infliximab. Many decision algorithms based on the measure of Infliximab (IFX) trough levels and antibodies to infliximab (ATI) have been increasingly used to optimize infliximab in Crohn’s disease and ulcerative colitis. The aim of our study was to appreciate if the biosimilar SB2 could be efficiently monitored using the Lisa-Tracker infliximab and anti-infliximab immunassays developed by Therasig (France).

Aims & Methods: During this evaluation, standard curves of Inflximab and two different batches of SB2 were compared and then accuracy of the Lisa-Tracker IFX kit in detecting the spiked concentration of SB2 was measured using the Lisa-Tracker assay. Levels of infliximab (from 5 spiked samples with known amount of SB2 and 10 clinical samples from patients treated with infliximab) were calculated according to each of the 3 standard curves (inflximab, SB2 batch1 and SB2 batch2). All samples and standards were tested in duplicate. Range of detection be >0.85 and the slope must be comprised between 0.9 and 1.1. Intra-run and inter-run precision were also measured with spiked samples of different known SB2 (from 2 to 12 g/mL) amounts. Capacity of polyclonal antibodies directed against infliximab to block the detection of SB2 using the Lisa-Tracker infliximab assay and the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Results: We demonstrated the perfect equivalence of infliximab standard curve to the SB2 standard curve and that the Lisa-Tracker assay is suitable for the quantification of SB2 in human serum samples (R² = 0.99; the levels of infliximab of the 20 samples were calculated according to the 3 standard curves infliximab, SB2 batch 1 and SB2 batch 2 with CV ranged from 2.1 to 12.6%). Quantification of SB2 was linear by 4 and 133 mg/mL and 7% of recovery were comprised between 82% and 113%. High intra-run and inter-run precision were obtained with the Lisa-Tracker infliximab assay for the quantification of SB2 (CV ranged from 3.3 to 17.9%). Finally, the capacity of polyclonal antibodies to infliximab to block the detection of SB2 in 5 spiked samples and specificity of 80% and 97% for the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Conclusion: Our results demonstrate that Lisa-Tracker Infliximab and Anti-infliximab assays are suitable for the monitoring of patients treated with SB2. Acknowledgements: Biogen provided the SB2 drug for this study. Biogen reviewed the data and provided feedback to the authors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P0998 THE MEASURE OF TROUGH LEVELS OF INFLIXIMAB IS LINKED TO THERAPEUTIC RESPONSE IN IBD PATIENTS

X. Roblin1, A. Berger2, G. Bosschetti3, B. Flourie3, S. Nancey4, S. Paul2

Introduction: If the association between trough levels of infliximab (TLI) and clinical remission or mucosal healing is demonstrated, we don’t really know the cause and effect between TLI and target value to obtain this association. So, the aim of our study was to evaluate the causality or the association between TLI and clinical remission in IBD patients.

Aims & Methods: We prospectively included all IBD patients treated in our IBD unit and in clinical remission (CDCA ≤ 150 for Crohn’s Disease (CD) or partial Mayo score ≤ 3 for ulcerative colitis (UC) with biomarker normalization (fecal calprotectin ≤ 20 μg/g stools) or in deep remission (clinical remission with fecal calprotectin ≤ 50 μg/g stools). We analyzed median of TLI and fecal calprotectin at the inclusion (M0) and 6 months before eligibility (M-6). We excluded patients with deep remission at M-6.

Results: 111 patients were included (60 CD, sex ratio M/F: 0.8; 51 patients in deep remission at M0). All 111 patients were in clinical remission at M-6. Median fecal calprotectin at M-6 were similar in the two groups of patients (210 μg/g in the group of patients who achieved deep remission at M0 vs 220 μg/g in the group of patients who achieved only biomarker remission respectively; p = 0.01). A ROC curve analysis was not able to isolate a cut-off value associated to deep remission achievement (AUROC = 0.61). Next, we analyzed separately median of TLI and fecal calprotectin levels 6 months before eligibility (M-6) of patients in deep remission at M0 (51 patients). The median TLI was significantly lower at M-6 than at M0 (4.1 μg/mL vs 5.9 μg/mL respectively; p = 0.03). Conversely, median fecal calprotectin was significantly higher at M-6 in comparison to M0 (190 vs 35 μg/mL; p = 0.01). A negative and weak significant correlation between fecal calprotectin and TLI was observed (Spearman’s rank correlation coefficient (q) = -0.25; p = 0.045).

Conclusion: Although TLIs may increase with decreased drug clearance due to deep remission, we show for the first time that the residual rate is the causal element for achieving clinical remission.

P0999 SMOKING STATUS INFLUENCES FECAL VOLATILE ORGANIC COMPOUNDS COMPOSITION

J. De Swart1, N. Van Gaal2, D. J. C. Berkhout3, S. Bosch1, T. G. J. De Meij5, K. H.N. De Boer1

1Gastroenterology And Hepatology, VU University Medical Center, Amsterdam/Netherlands
2Department Of Pediatric Gastroenterology, VU University Medical Center, Amsterdam/Netherlands

Contact E-mail Address: bosch.sofie@gmail.com

Introduction: Fecal volatile organic compounds (VOCs) are gaseous carbon-bound metabolic products considered to reflect intestinal microbiota composition and function. Changes in VOCs may serve as useful biomarkers for a broad range of gastrointestinal diseases. As smoking leads to a substantial shift in intestinal microbial composition in healthy and diseased persons, the aim of this study was to assess the effect of smoking status on fecal VOC pattern.

Aims & Methods: In this cross-sectional pilot-study adult smokers, non-smokers and former smokers scheduled for colonoscopy at the VU University medical center were instructed to collect a fecal sample prior to bowel cleansing. Patients were included if no abnormalities were found during colonoscopy. Evaluation criterion was use of antibiotics three months prior to participation. All participants completed a questionnaire on standard demographics, BMI, diet and smoking habits. Fecal VOC profiles were measured using an electronic nose device (Cyanos 3200®).

Results: Fecal samples from 56 subjects (11 smokers, 21 non-smokers, 24 former smokers) were analyzed. Median age was 62 years (27–82 years). Furthermore, there were no significant differences between groups for the variables age, sex, smoking habits. Fecal VOC profiles were measured using an electronic nose device.

Conclusion: This study showed that smoking status has a significant influence on fecal VOC profiles. This implicates that the smoking status should be taken into account when performing (fecal) VOC analysis. The finding that VOC profiles did not differ between smokers and former-smokers could be due to the wide divergence (6 month – 43 years) in smoke-free time in former smokers group.

P1000 CLOSTRIDIUM DIFFICILE INFECTION AND IBD PATIENTS IN ONE CLINICAL CENTER

A. Atanassova1, A. Georgiev1
1Gastroenterology, Medical University of Varna, Varna/Bulgaria
2Clinic Of Gastroenterology, Medical University, Varna, UMHAT "S. Marina" Varna, Varna/Bulgaria

Contact E-mail Address: aniatanassova@abv.bg

Introduction: The prevalence of Clostridium difficile infection (CDI) in patients suffering from inflammatory bowel disease (IBD) has increased rapidly over the past several decades. However, the exact global epidemiology remains unclear because of insufficient data from developing countries.

Aims & Methods: The goal of our study is to examine the incidence of CDI in patients suffering from inflammatory bowel disease. Prospective, observational study evaluating IBD patients in a referral center was performed to evaluate the incidence of Clostridium difficile. Diagnosis was confirmed with stool toxin analysis. Demographic information, co-morbidity, indication, diagnostic test, antibiotic exposure, hospitalization records were recorded. For a period of 3 years, 202 IBD patients were studied, 105 of which have UC and 97 - Chron’s disease (CD). We used the Clostridium difficile Glutamat Dehydrogenase + Toxin A + B based on the principle of quantitative immunochromatographic assay for the determination of Clostridium difficile Glutamat Dehydrogenase, Toxin A and Toxin B in stool samples.

Results: The results show that all patients with a positive CDI test have a clinical picture, which resembles a relapse of the disease (p < 0.05). There’s a tendency towards growth in the incidence of IBD patients who are CDI positive. Their number in 2016 is significantly higher than that in 2014. In 2014 it was ~5.90% with CD and 12.30% with UC, whereas in 2016-12.20% with CD and 27.80% with UC. Patients suffering from CDI have a much more severe course of the disease, UC (46.40%) and CD (24.20%) (p < 0.05).

Conclusion: There is an increase in incidence of CDI, and patients with UC are affected to a greater extent. The results of our study are confirmed by other authors as well. A significant part of patients with CDI have a severe disease that needs extra prospective researches to determine the incidence and influence of the infection amongst patients with IBD, who receive different therapy regimens and also to understand how the CDI affects the evolution of the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1001 DEVELOPMENT OF A NEW SCORE PREDICTIVE OF SUSTAINED CLINICAL REMISSION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE UNDER INFliximAB - AZATHIOPRINE COMBOTHERAPY

B. Sivard1, N. Willer1, J. Phelp1, E. Del Tedesco1, S. Paul1, X. Roblin1
1Hepato-gastroenterology, university hospital of Saint-Etienne, Saint-Priest en Jarez/France

Contact E-mail Address: xavier.roblin@chu-saint-etienne.fr

Introduction: There is no blood test predictive of sustained clinical remission in patients with Crohn’s Disease (CD) or Ulcerative colitis (UC) under Infliximab (IFX) - azathioprine (AZA) comotherapy.

Aims & Methods: All patients with CD or UC, consecutively treated by the combination of IFX-AZA between August 2015 and March 2017, were included in this monocentric study. Clinical, biological (blood cells count, liver function enzymes, C-reactive protein (PCR)) were retrospectively collected at baseline, at week 14 (W14) and at 6 months (W24) from the start of combination therapy.

Trough level of IFX (TLI) at W14 was also recorded. Sustained clinical remission was defined as clinical remission for 6 months with no need of AZA dose modification, nor therapeutic switch or need for surgery. A predictive score before comotherapy was developed basing on receiver operating characteristic (ROC) curves and logistic regression analyses.

Results: Of 71 patients enrolled (median age: 36.3 yrs; women: 52.5%; CD: 61.3%; current tobacco: 28.7%); 58 (81.7%) experienced sustained clinical remission. The clinical biological score was calculated at baseline by adding attributed points for these variables as follows: alkaline phosphatase <55U/L (11 pts), total white blood cell count <12x10^9/L (5 pts), mean corpuscular volume >87 fl (4 pts), white blood cell count <9.3x10^9/L(4.5 pts), neutrophils <5.0x10^9/L (4 pts), body mass index > 22 kg/m^2 (3 pts), platelets count <330 x10^9/L (3 pts), PCR > 3.7 mg/L (3 pts) and age > 45 years old (2 pts). This new score was predictive of sustained clinical remission with good performance (Area under the curve (AUC): 0.91 [95%CI: 0.81-0.92]; sensitivity (Se): 81.3%, specificity (Sp): 90.9%, positive predictive value (PPV): 97.7%; Negative predictive value (NPV): 50%; especially in UC patients (AUC: 98.2% [95%CI: 93.9%-100%]; Se: 90.5%, Sp and PPV: 100%; NPV: 66.7%). Corresponding outcomes for CD were also satisfying (AUC: 83.9% [95%CI: 70.9%-97.8%]; Se: 72.5%, Sp: 85.7%, PPV: 36%; NPV: 42.9%). In contrast, performance of TLI at W14 (>2.87 mg/mL) for the prediction of sustained clinical remission were more critically interesting (AUC: 69.0% [95%CI: 58.7%-83.1%]; Se: 79.3%; Sp: 61.3%; PPV: 90.2%; NPV: 40%). These results were not significantly different between patients who had received an AZA monotherapy before comotherapy compared to those who did not.

Conclusion: This new score is a promising tool for the prediction at baseline of sustained clinical remission in inflammatory bowel disease patients who start comotherapy. It may help to identify easily patients who should benefit optimisation of IFX rather than early switch treatment in this setting. However, a prospective validation is needed before recommending its use in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1002 LOWER GI SYMPTOMS IN YOUNG PATIENTS: CAN SYMPTOMS AND NON-INVASIVE TESTS BE USED SYSTEMATICALLY TO AVOID UNNECESSARY COLONOSCOPY?

A. Alakkari, B. Ryan
Gastroenterology Department, Adelaide and Meath Hospital, Dublin/Ireland

Contact E-mail Address: alakkar@yahoo.com

Introduction: Young patients commonly present with lower gastrointestinal symptoms with many patients being referred to gastroenterology clinics nationwide. Most colonoscopies in such patients are normal, but risk potentially serious complications. There is an over reliance on endoscopy in clinical practice leading to increasing demand on limited resources. As a result, some patients with potentially life-threatening conditions (e.g. colon cancer) may have a significant delay in diagnosis that may result in a worsened prognosis. Many endoscopic procedures are absolutely necessary, but many might be avoided if other, non-invasive forms of investigations were available which could reliably exclude significant pathology. This in turn could lead to more targeted and effective investigations.

Aims & Methods: We aimed to assess colonoscopies, relevant faecal and blood tests in young patients with lower gastrointestinal symptoms. Colonoscopies performed over a 1-year period were retrospectively identified from the Endoscopy Reporting System (patient charts, faecal occult blood test (FOBT), C Reactive Protein (CRP), and Coeliac serology were reviewed. A raised CRP > 5 mg/L or FC of ≥50 μg/g was considered abnormal. A Colonoscopy with mucosal inflammation confirmed on histology was considered abnormal. Inclusion and exclusion criteria are in table 1.

Table 1: Study criteria

<td>Overt or obscure GI bleeding</td>
</tr>
</tbody>
</table>

Results: 2155 medical GI outpatient colonoscopies performed over 12 months were identified. 242 met inclusion criteria for the study. Median age of the patient cohort was 34 years (range 16-45), with 141 (58%) females. The cohort was stratified according to indications; Group A; 132 (55%) patients with diarrhoea predominant symptoms, and Group B; 110 (45%) patients with constipation abdominal pain and bloating. Colonoscopy was normal in 104 (79%) of Group A and 102 (93%) of Group B (p = 0.002). 36 (15%) Colonoscopies were abnormal; 7 patients had active ileitis, 22 had colonic inflammation (12 IBD, 2 lymphocytic colitis, 8 non-specific inflammation), and 7 had ileocecal inflammation (all diagnosed with IBID). 28 of 36 (78%) patients with mucosal inflammation confirmed on histology had diarrhoea (p = 0.0001). FC was available in 36 patients, and CRP in 171 patients. In Group A the negative predictive value, positive predictive value and specificity of CRP/FC were 85%, 43% and 80% respectively. In Group B the negative predictive value, positive predictive value and specificity of CRP/FC were 92%, 43% and 80% respectively.
However, as colonoscopy is a burdensome procedure, alternative tools have been regrettably utilized in the first year following surgery to prevent POR. Magnetic resonance enterography including diffusion-weighted sequences with apparent enhancement (RCE) (77% vs 119%, p = 0.056), Clermont score (9.3 vs 7.9; p = 0.011), MRI score (4.2 vs 5.9; p = 0.032). Colonoscopy and MRI were performed within a median time of 14 days IQR[5.0–9.3]. Colonoscopy has low yield in young symptomatic patients, especially those with non-diarrheal symptoms. Non-invasive tests should be used systematically to better identify patients requiring colonoscopy. We are conducting a prospective study to explore non-invasive diagnostic paradigms. Implementation of these strategies will help reduce colonoscopy waiting times.

Conclusion: Colonoscopy is a burdensome procedure, and diagnostic alternatives have been developed such as faecal biomarkers and magnetic resonance imaging (MRI).

Aims & Methods: We aimed to assess the performances of MRI and faecal calprotectin to detect endoscopic POR in CD patients. Adult CD patients from two tertiary centers who underwent ileal or ileocolonic resection were consecutively included in this prospective study. All the patients underwent magnetic resonance enterography including diffusion-weighted sequences with apparent diffusion coefficient (ADC) calculation (mm²/s) and evaluation of Clermont score (2). MRI score (3) and MR score (4) (within the first year after surgery or restoration of intestinal continuity (median = 6 months IQR[0.0–9.3]). Colonoscopy and MRI were performed within a median time of 14 days IQR[6.5–31] and stools were collected for faecal calprotectin measurement the day before the colonoscopy.

Results: Overall, 30 CD patients were enrolled in the study. Among them, 15 (50.0%) were female and 7 (23.3%) were active smokers. Disease location was ileal, ileocolic or colonic in 15 (50.0%), 1 (3.3%) and 14 patients (46.7%), respectively. The patients included in this study were treated with no medication (20.0%), 5-ASA (6.7%), thiopurines (56.7%) or anti-TNF agents (20.0%) in preventing endoscopic POR. Within the first year after surgery, endoscopic findings were recorded after capsule (LD) and 1.5 L of water at the time of the capsule (Water) were compared to the two other modalities (P = 0.04). The endoscopic activity of the porcine ileum was comparable between the 3 groups (P = 0.358). The cecal intubation rate was significantly lower in the PEG group 66% versus 91% (LD) and 94% (Water) (P = 0.026). In the first tertile, the quantitative score was significantly better in the LD (7.9) and Water (7.6) groups compared to the PEG group (6.8) (P = 0.043). The preparation by water was considered qualitatively better compared to the two other modalities (P = 0.04).

Conclusion: This is the first study evaluating the relevance of PEG preparation in a large population of adult patients with CD. Our study has demonstrated that there is no benefit in using PEG for the preparation of the small bowel before the capsule in patients with CD. Quantitatively, the two simplified preparation methods were more efficient than the preparation with PEG and qualitatively, the preparation using water was more easily administered with high efficiency.

Aims & Methods: Totally, 10 consecutive patients with inactive or mildly active UC were enrolled, and fifty-three areas were assessed by LCI. All examinations were conducted with a LASEREO endoscopic system (FUJIFILM Co., Tokyo, Japan). During the colonoscopy, each region of interest (ROI) of terminal ileum, cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum were observed by both white light imaging (WLI) and LCI. The Commission international de l'éclairage (CIE) LAB color differences (ΔC) were calculated among WLI and LCI in each ROI. After ROI was observed by colonoscopy, the biopsy specimen was taken in each ROI. Inflammatory cell infiltration, erosion, crypt abscesses, and goblet cell depletion were assessed by the histologic findings of acute inflammation. For evaluation of chronic inflammation, crypt atrophy, crypt distortion, and basal plasmacytosis were assessed. The correlation between ΔC and Mayo endoscopic sub-score was assessed, indicating that the higher ΔC mean easier color difference for recognition.

Results: The mean age of patients who were enrolled in the present study was 41.6 ± 17.7 years. The sex ratio (men/women) was 4:6. The type of extent of UC (ulcerative proctitis/left-sided UC/extensive UC) was 0:3:7. 1. Correlation between CIELAB color differences and history. The mean ΔC of ROI without inflammatory cell infiltration was significantly higher than that of ROI with inflammatory cell infiltration (15.9 ± 4.9 vs. 12.3 ± 6.7, p = 0.046). The mean ΔC was not affected by histological findings of erosions, crypt abscesses, goblet cell depletion, crypt atrophy, crypt distortion, and basal plasmacytosis. LCI distinguished colon mucosal white color compared to WLI with use of three-dimensional color space, indicating the remission-colon mucosa of UC with no inflammatory cell infiltration in ROI was easily detected by LCI. 2. Correlation between CIELAB color differences and Mayo endoscopic subscore. Low Mayo endoscopic subscore tend to be inversely proportional to high ΔC (ΔC = 15.9 ± 4.9 vs. 11.8 ± 5.1, 13.0 ± 6.5, and 9.2 ± 6.6, p = 0.05). There was no statistical association to inflammatory bowel disease patients, however, it is underdiagnosed in clinical practice. 3. ΔC test is the current clinical gold standard for diagnosing bile acid diarrhea widely used in Europe.

Contact E-mail Address: begroal@gmail.com

Introduction: Bile acid malabsorption (BAM) is a well-known disorder associated to inflammatory bowel disease patients, however, it is underdiagnosed in clinical practice. 3ΔC test is the current clinical gold standard for diagnosing bile acid diarrhea widely used in Europe.

Aims & Methods: We aimed to analyze the incidence of BAM in Crohn’s (CD) patients with chronic diarrhea through 75SeHCAT and to assess whether there is a relationship between the malabsorption degree and the presence of ileal resection. Prospectively, 30 patients with CD and chronic diarrhea with and without ileal resection during the period between August 2015-April 2016. In all patients, an inflammatory activity was previously discarded using colonoscopy, cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum. A514 United European Gastroenterology Journal 5(5S) 1Gastroenterology, Hospital Reina Sofia, Cordoba/Spain 2Nuclear Medicine, Hospital Reina Sofia, Cordoba/Spain 3Gastroenterology, Hospital Universitario Reina Sofia, Cordoba/Spain 4Gastroenterology, Instituto Maimonides de Investigación Biomédica, Córdoba, Spain

Results: 75SeHCAT is an useful procedure for diagnosing BAM in patients with chronic diarrhea. Mild BAM is considered 7–10%, moderate 4–7% and severe 1–3%. There was no statistical association between 75SeHCAT retention and intestinal resection. The colon mucosa with the lower Mayo endoscopic subscore were relatively easily detected as the white area by the LCI mode compared to WLI, suggesting that LCI might be one of novel approaches for evaluation of disease activity.

P1007 THE ROLE OF SENSE OF COHERENCE IN DETERMINING HEALTH RELATED QUALITY OF LIFE AND DISABILITY IN INFLAMMATORY BOWEL DISEASE
G. WILD, M. VITAGLIANO, I. ALBANESE, K. SHIRLOW
Gastroenterology, McGill University Health Centre, Montreal/Canada

Introduction: There is an ever growing body of evidence that indicates that Health Related Quality of Life (HRQoL) is significantly impaired in IBD. While clinical variables and disease activity status influence HRQoL, a host of psychosocial and personality variables also play an important role. This contention is supported by evidence of impaired 3ΔC test at 72 hours and impaired 2ΔC test at 24 hours in patients with established diagnosis of BAM and impaired 1ΔC test at seven days in patients with inflammatory bowel disease. In the present study, we aimed to analyze the associations between sense of coherence (SOC) and health related quality of life (HRQoL) in IBD patients. Sense of coherence (SOC) is an emerging theoretical and dynamic construct that seeks to explain why some individuals in the face of adversity experience illness while others do not. Antonovsky’s theory of SOC suggests that individuals with strong SOC (higher SOC) have a more effective coping strategies when faced with stressors (e.g., chronic medical condition) whereas those with weak SOC are less likely to adapt to health stressors and have less motivation when confronted with challenges to their health. While a number of studies have shown that SOC appears to have an impact on HRQoL, data regarding this association in IBD are limited.

Aims & Methods: The goal of the current study was to examine the associations between an individual’s sense of coherence, and their overall health-related quality of life. The first part of this analysis looked at whether sense of coherence among water was considered as the most disability level, and an individual’s illness perception, as compared to other reported psychosocial factors. The second part of this study evaluated whether sense of coherence, as well as illness perception, were associated with an individual’s self-reported quality of life, and if this interaction was moderated by the individual’s level of anxiety. Additionally, the correlations between sense of coherence and level of anxiety, as well as self-reported emotional intelligence were also were further evaluated. This is a cross-sectional observational cohort of IBD patients attending MUHC (McGill University Health Centre) (IBD outpatient clinic). The patient population demographics are as follows: mean age (42.4 ± 12.4 years), gender (46.0% male), disease type (58.4% CD, 33.7% UC), disease activity (27.7% active, 63.5% inactive). Patients completed multiple validated questionnaires pertaining to a variety of psychosocial parameters. Data was analyzed by multiple linear regression using statistics software (SPSS version 17.0).

Results: Preliminary analyses of this patient population reveal that 40.2% of the variance in level of disability is explained by sense of coherence and level of disease (β = –0.64, p < 0.05). A smaller, albeit significant contribution of sense of coherence with illness perception was additionally found (14.1% of the variance, and β = –0.39, p < 0.05). Furthermore, 32.3% of the variance in self-
P1008 FAecal AMINO Acid Profiles as Novel Non-Invasive BIomarkers for the Detection of Paediatric inflammatory Bowel Disease: A Metabolomic Approach

Introduction: Inflammatory bowel disease (IBD) is primarily assessed by endoscopy, which is a costly and invasive procedure with serious risk of complication, underlining the need for novel non-invasive diagnostic biomarkers. In previous studies, plasma amino acid analysis has revealed significant differences between IBD subjects and controls. This 'aminoconstagram' has not yet been studied in faecal samples of IBD patients. The aim of this explorative study was to compare faecal amino acid composition between paediatric de novo IBD patients and healthy controls, and between the phenotypes ulcerative colitis (UC) and Crohn's disease (CD).

Aims & Methods: In this cross-sectional case-control study, paediatric treatment naive IBD patients from a tertiary centre were included, before bowel cleansing and colonoscopy. Control patients were recruited from schools in the province North Holland, the Netherlands. All participants collected a faecal sample on which amino acid analysis was performed by means of high performance liquid chromatography (HPLC, Biochrom 30). To correct for the influence of faecal consistency, the samples were freeze dried for 24 hours before the analysis was performed. To prevent results by peak overlap of different amino acids, outcomes of 5 mmol/l mg or lower were excluded from further analysis.

Results: Faecal samples from 15 subjects (5 healthy, 5 UC, 5 CD) were analysed. Median age was 14 (8–17) years. Subjects and controls were matched on age and sex. A total of 42 different amino acids were analysed, of which 30 were excluded due to quantities of ≤5 mmol/mg. In particular, alanine, glycine, phenylalanine, leucine, isoleucine, valine and lysine differed between IBD patients and healthy controls with ratios up to 5:1 (table 1). In addition, UC and CD patients differed remarkably based on levels of glycine, phenylalanine and serine with ratios up to 4:1 (table 1).

*i* levels are displayed in nmol/mg

Conclusion: This was the first pilot study to assess the potential of the faecal aminoconstagram as non-invasive biomarker for disease activity of paediatric IBD. We observed remarkable differences in faecal amino acid composition between IBD patients and healthy controls, and between the IBD phenotypes. Whether these differences reflect decreased absorption or increased loss by inflamed intestines needs to be elucidated. Currently, we are awaiting the results of a larger proof-of-concept study on these faecal amino acid profiles.

P1009 INFliximab Trough Levels and Antibodies to Infliximab in Association with Disease Activity and Mental Health in Patients with Inflammatory Bowel Disease

E. Orfanoudaki1, M. Gazozi2, K. Foteinogianopoulos3, E. Theodorakis1, E. Legaki2, K. Koutroubakis1
1Gastroenterology, University Hospital of Heraklion, Heraklion/Greece
2Medical School, Basic Medical Sciences, Laboratory Of Biology, National and Kapodistrian University of Athens, Athens/Greece

Contact E-mail Address: elima_or@yahoo.gr

Introduction: Measurement of infliximab trough levels (IFX-TLs) and antibodies to infliximab (ATIs) has been suggested as an important parameter for the optimization of IFTreatment of patients with inflammatory bowel disease (IBD).

Aims & Methods: We aimed to cross-sectionally investigate the correlation between IFX-TLs or ATIs and clinical, biochemical as well as endoscopic activity in Greek IBD patients. Consecutive IBD patients on maintenance treatment with IFX, were included. IFX-TLs and ATIs were measured using ELISA (Eagle Diagnostics, Nashua, NH, USA) on serum samples drawn before infusion. In the same time period of use short IBD questionnaire (SIBDQ) and clinical disease activity using Harvey-Bradshaw Index (HBI) for Crohn’s disease (CD) or simple colitis activity index (SCAI) for ulcerative colitis (UC) were assessed. Moreover, biomarkers (hemoglobin, ESR, CRP, platelets, albumin) were measured and latest colonoscopies (within 6 months) were reviewed and evaluated for presence or not of mucosal healing.

Results: A total of 74 patients receiving IFTreatment maintenance therapy [55 CD, 19 UC, 49 males, mean age 42.3 years, 45 on combination therapy with immunomodulators (IMMs), 10 under intensified dose (either 10 mg/kg/8w or 5 mg/kg/4–6w)] were studied. Median time since IFX initiation was 26 (13–71) months and median value of serum IFX-TL was 4.83 μg/ml (0.03–3.07). Seven out 74 (9.5%) were positive for ATIs (>10 μg/ml). Patients on combination treatment had significantly higher IFX-TLs (6.98 μg/ml, 0.34–3.07) compared to those on IFX alone (1.85 μg/ml, 0.09–2.58) (p = 0.01). Patients with positive ATIs had median IFX-TLs 0.99 μg/ml (0.09–1.40) statistically lower compared to those with negative ATIs (6.01 μg/ml, 0.03–3.69) (p = 0.005). The correlations of IFX-TLs and ATIs with clinical, biochemical and endoscopic indices of disease activity in IBD patients are presented in Table 1. No other significant correlations of IFX-TLs or ATIs with other disease characteristics were observed. In the logistic regression analysis only IFX-TLs (OR 0.86, 95% CI 0.76–0.97 p = 0.017) and duration of IFX treatment (OR 0.97, 95% CI 0.95–0.99 p = 0.04) were independently correlated with the presence of mucosal healing.

Conclusion: Therapeutic drug monitoring is valuable in IBD-patients on maintenance IFTreatment. Combination treatment with IFX and IMMs is associated with higher IFX-TLs compared to IFX monotherapy. Higher IFX-TLs are independently associated with the presence of mucosal healing.

P1001 COMPARATIVE INVESTIGATION OF ENTEROBACTERIA BUSH IN ULCERATIVE COLITIS PATIENTS, AND THEIR CONSANGUINEOUS, AND NON-CONSANGUINEOUS RELATIVES

K. Fukuda
St Luke’s International Hospital, Tokyo/Japan

Contact E-mail Address: fukukats@luke.ac.jp

Introduction: In recent years, the gut microbiota has been recognized as a relevant fingerprint to predict the development of inflammatory bowel disease (IBD) like ulcerative colitis (UC). Accordingly, inter-individual variation in the gut microbial community may reflect inter-individual variation in the risk of developing IBD or other diseases. Further recently, the Next-Generation Sequencing (NGS) has been validated for determining bacterial species in faecal samples. Essentially, NGS is a molecular biology sequencing technique for the precise identification and assessment of bacterial species.

Aims & Methods: With the major focus of our study being to establish a relevant biomarker of disease activity in UC patients based on the intestinal microbiota, 82 UC patients together with 61 healthy relatives as controls were included for microbial assessment. The combination of positron emission tomography (PET) with 18F-fluorodeoxyglucose (18F-FDG) with magnetic resonance imaging (MRI) as integrated PET/MRI in one examination is a new cutting-edge technology for the non-invasive assessment of the inflammatory activity in UC. In addition a panel of noninvasive biomarkers like Lactobacillus and Proteobacillus are increasingly popular and used in all-day patient care.

Aims & Methods: To compare the performance of non-invasive biomarkers to PET/MRI and colonoscopy in patient with UC. In every patient a PET/MRI including the maximum standardized uptake value ratio gut/liver (SUVR) and a colonoscopy including an endoscopy index (EI) was performed within 48 hours and the Disease Activity Index Mayo score (DAI) was calculated. Fecal Lactobacilli (LactobacillusPrevotella, Peptoniphilus) and Calprotectin were measured (Calp), PMN-elastasia (PMN-E), S100A12, Eosiinophil-derived Neurotoxin (EDN) as well as CRP were correlated to the SUVR, the DAI and the EI using correlation analyses. Sensitivity, specificity and diagnostic accuracy were calculated using the optimized cut-offs. All analyses were performed using SPSS (IBM SPSS Statistics for Windows, release 22.0).

Results: 32 patients (21 female), mean age 44.4±10.63 years (range 23–67) with diagnosed UC were included in the study. Mean time since diagnosis was 11.41 years (SD=6.42). EI and SUVR (r (32)=.45; p<.009), EI and DAI (r (32)=.87; p=.000) as well as DAI and SUVR correlated significantly (r (32)=.40; p=.022). SUVR was correlated significantly with LF (r (32)=.36; p=.046), EDN (r (32)=.49; p=.005), and CRP (r (32)=.36; p=.043), but not with PMN-E, S100A12 and Calp (all p >.05). DAI was correlated significantly with PMN-e (r (32)=.55; p=.001), LF (r (32)=.55; p=.001), EDN (r (32)=.70; p=.000), Calp (r (32)=.46; p=.008) and CRP (r (32)=.56; p=.001), but not with S100A12 and Calp (all p >.05). EI was correlated significantly with PMN-e (r (32)=.61; p=.003), PMN-e (r (32)=.51; p=.003), S100A12 (r (32)=.41; p=.021), Calp (r (32)=.52; p=.002), CRP (r (32)=.44; p=.012), but not with Calp (p >.05). The median values (inactive/active) were: LF: 1.75; 201.3±g/ml; Calp: 60.25/105.60±g/ml; EDN: 68, 43±mg/ml; PMN-e: 83.3%/75.0%/81.25% (CI 62.5%/62.5%/62.5%); PMN-E: 36.1±mg/ml; CALI: 62.5%/62.5%/62.5% (CI 36.7%/36.7%/36.7%); CRP: 0.07/0.19±g/ml; S100A12: 18.82/88.96; Eo: 0.39/2.35±g/ml; CRP: 0.15/0.75 mg/dl; Sensitivity, specificity, diagnostic accuracy (confidence interval) and optimized cut-off for LF was 87.5%/87.5%/87.5% (CI 72.1%/100%/100%); 4, 27±mg/ml; Calp: 62.5%/62.5%/62.5% (CI 38.9%/38.9%/38.9%); EDN: 68, 43±mg/ml; PMN-e: 83.3%/75.0%/81.25% (CI 62.5%/99.9%); 0.085 µg/ml; S100A12: 75.0%/75.0%/75.0% (CI 56.9%/94.1%); 60.40; EDN: 75.5%/75.0%/75.0% (CI 80.8%/100%); 1, 30±mg/ml; CRP: 70.8%/75.0%/71.5% (CI 53.5%/94.9%); 0.5 mg/ml.

Conclusion: Using EI as gold standard reference we found that fecal biomarkers LF, EDN, PMN-E and S100A12 can reliably distinguish between active and remission in UC. However, Calprotectin did not perform well. PET/MRI with SUVR were significantly correlated to the SUVR which was significantly correlated with EI and DAI. In conclusion, Lactobacillus and Eosinophil-derived Neurotoxin performed best using endoscopy and PET/MRI as non-invasive biomarkers.

Langhorst J, Boone J, Lauche R, Ruelfer A, Dobos GJ. Fecal Lactoferin, Calprotectin, PMN-Elastase, CRP, Eo and White Blood Cell Count as an Indicator for Mucosal Healing and Clinical Course of Disease in Patients with Mild to Moderate Ulcerative Colitis: Post Hoc Analysis of a Prospective Clinical Trial. JOURNAL OF CROHNS AND COLITIS 2016; Feb 13
Aims & Methods: We collected serum samples in 102 patients (27 Crohn’s Disease and 75 Ulcerative Colitis) treated with stable doses of infliximab for at least 6 months (t0) and 6 months thereafter (t1). In each patient TL, ATI and MMP3 levels were assessed at t0 and t1 by ELISA. In addition, MMP3 levels were measured in 28 healthy subjects as controls. Clinical (HBI or Mayo score) and biochemical (CRP, fecal calprotectin) markers were assessed to define disease remission/activity. TL were considered therapeutic if >3.8 mcg/ml. ATI were considered positive if > 10 mcg/ml. Data are presented as mean ± Standard Error Mean (SEM). Comparison among groups was performed by non-parametric tests.

Results: MMP3 levels were similar at t0 and t1 in patients which maintained therapeutic TL (14.5 ± 1.7 pg/ml and 15.0 ± 1.6 pg/ml, respectively) and in healthy controls (13.1 ± 1.3 pg/ml). Patients who lost therapeutic TL but ATI positive showed significantly higher MMP3 levels compared to the group with low TL and ATI positive (33.2 ± 3.0 and 20.0 ± 2.7 respectively, p = 0.0003), showing another pathway of drug degradation. 21 patients lost response between t0 and t1: 15 out of 21 patients demonstrated high levels of MMP3 (22.0 ± 2.1 pg/ml) already at t0; in addition, 17 of these 21 patients were in clinical remission at t0, while at t1 all patients had disease activity.

Conclusion: Serum MMP3 levels are useful in predicting loss of response to anti-TNFα in patients with low TL but without ATI. High MMP3 levels predict with 90.5% accuracy loss of response over the next 6 months.

P1013 USEFULNESS OF A MULTIDISCIPLINARY APPROACH COMBINING BOTH RHEUMATOLOGY AND GASTROENTEROLOGY FOR THE ASSESSMENT AND TREATMENT OF INFLAMMATORY BOWEL DISEASE PATIENTS

M. Barreiro-De Acosta1, E. Pérez-Pampín2, R. Ferreiro Iglesias1, R. Mejuto1, A. Merá1, J.E. Domínguez-Munoz1
1Gastroenterology, University Hospital of Santiago, Santiago de Compostela/Spain
2Rheumatology, University of Santiago de Compostela, Santiago de Compostela/Spain

Contact E-mail Address: manubarro@hotmail.com

Introduction: More than one third of inflammatory bowel disease patients (IBD) present recurrences, manifestations, complications or treatment failures. In our hospital, the higher complication rate is ulcerative colitis (UC), which accounts for 20% of our IBD patients.

Methods: A multidisciplinary team composed by a gastroenterologist and a rheumatologist evaluated and discussed in all patients their possible diagnosis and treatment. A multidisciplinary committee with a rheumatologist and a gastroenterologist was referred to an experienced rheumatologist. The day of the consultation a multidisciplinary committee with a rheumatologist and a gastroenterologist evaluated and discussed in all patients their possible diagnosis and treatment. A multidisciplinary committee with a rheumatologist and a gastroenterologist was referred to an experienced rheumatologist. In all patients, a rheumatologic consultation was conducted and all patients were referred to the rheumatology department when indicated.

Results: 112 consecutive IBD patients were remitted from the IBD Unit and changes implemented in their treatments. Patients were women (67%), 19% were smokers and 23% former smokers. 51% presented ulcerative colitis (UC) and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%.

Conclusion: A multidisciplinary consultation combining inflammatory bowel disease and rheumatology allows both an earlier detection of inflammatory arthropathies associated with IBD and earlier changes in treatment, thereby helping to optimize the hospital resources. Fibromyalgia is common among IBD patients, though it is important that it is detected so it should not be confused with other inflammatory diseases.

Introduction: Adalimumab (ADA) is an anti-TNFα drug approved for patients with refractory luminal Crohn’s disease (CD). Recently, mucosal healing (MH) emerged as a major therapeutic goal in inflammatory bowel disease. Few data are available on ADA trough levels (TL), anti-ADA antibodies (AAA) during long term follow-up of CD patients, and their potential association with MH and disease outcome.

Aims & Methods: The aim of our prospective study was to evaluate a possible association between achievement of MH, ADA TL, and AAA in CD patients. Moreover, we assessed the potential association between CD clinical outcome and MH. We prospectively enrolled moderate to severe CD patients who were primary responders to ADA treatment. Blood samples were withdrawn at standardized time points during treatment (0-, 2-, 6-week and every 8 weeks thereafter), before ADA administration. ADA TL were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Disease activity was assessed by means of Harvey-Bradshaw Index (HBI, remission defined by HBI < 5). As to endoscopic activity, we defined MH in case

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
of a value of Crohn’s Disease Endoscopic Index of Severity below 8, so far we included complete MH and a residual activity of a minimal residual endoscopic activity. Endoscopic evaluation was performed within two weeks of blood sampling, and at least after 6 months of ADA treatment.

Results: In our prospective study we enrolled 22 CD patients primary responders to ADA therapy (13 males, median age 43 years, range 23–67 years) who had a median treatment duration of 52 weeks (range 24–121 weeks). ADA TL were significantly higher (P = 0.0002) in patients who achieved MH (12.1 mcg/mL, range 6.8–17.2 mcg/mL) as compared to patients without MH (4.50 mcg/mL, range 0.0–9.9 mcg/mL). Receiver Operating Characteristic curve identified an ADA TL cut-off of 6.43 mcg/mL as the threshold with the highest accuracy for identification of patients who achieve MH (AUROC 0.934, specificity 100%, sensitivity 81.8%, PPV 84.6, NPV 100%). Moreover, achievement of MH was associated with absence of AAA (P = 0.012). Lastly, HBI was significantly lower (P = 0.0002) in patients with MH (4, range 3–8) than in patients without (11, range 4–17).

Conclusion: In our cohort of CD patients, we observed a clear association between ADA TL and disease activity, development, and outcome. In this specific cohort, a threshold of 6.43 mcg/mL has been identified as the best cut-off to obtain endoscopic remis-
sion or at least a minimal residual endoscopic activity. Moreover, we observed that CD patients on ADA therapy who achieved MH had a lower disease activity outcome. Thus, we support the use of therapeutic ADA monitoring for the management of CD patients in order to obtain clinical and endoscopic remission of the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: IBDs are disabling conditions that negatively affect physical, psychological, familial and social dimensions of life. The concept of quantifying disability has been developed for the assessment of many other chronic diseases. Thus, specific tools have been used to assess the impact of disease and its treatment options on relevant end-points such as health-related quality of life (HRQL), measured by the IBD-Questionnaire (IBD-Q). Recently, the IBD-Disability Index (IBD-DI) has been developed to evaluate the entire spectrum of limitations in functioning in patients with IBD. This index is inspired to the International Classification of Functioning, Disability and Health (ICF). The aim of the present study was to assess the relationship between the IBD-DI, clinical characteristics and HRQoL in a cohort of Sicilian patients with ulcerative colitis(UC) and Crohn’s disease (CD) followed up in a referral center.

Aims & Methods: IBDQ and IBD-DI questionnaires were administered to consecutive UC and CD adults outpatients from July 2016 to April 2017. The IBD-DI consists of 28 items that evaluate the 4 domains of body functions, activities and participation, body structures and environmental factors. IBD-Q consists of 32 questions grouped into 4 dimensions: bowel, systemic, social, emotional. Scores range from 1 (poorest QoL) to 7 (best QoL) with higher scores indicating better QoL. Disease activity was assessed by partial Mayo score for UC and by Harvey-Brandschaw Index for CD. The mean differences of DI score in relation to dichotomous clinical variables were performed by Student’s t test. By linear regression analysis we assessed also the relationship between DI and IBD-Q. Disease activities were statistically significant if the p value was <0.05.

Results: Data from UC and CD patients were analysed separately. 100 UC patients (59% males, median age 49 years) were enrolled; 17% were smokers. 83% had inactive or mild disease, 17% moderate disease. None of the recruited patients had severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 72 patients (72%) or immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 28 patients (28%). The mean IBD-DI score was 23.15 ± 17.49; 62% of patients had low DI ≤ 25 (62/100) while 7% had high DI > 50. No correlations were found between IBD-DI and gender, disease duration, disease extension (Montreal Classification) and immunosuppressive therapy. IBD-DI was related to clinical disease activity (p = 0.001) and extraintestinal manifestations (P = 0.005). By linear regression analysis, IBD-DI was significantly associated with IBD-Q (R² = 0.573, p < 0.001). Interestingly, 5% (n = 5) of patients with inactive or mild disease had severe disability (>50) and 5% (n = 5) with active disease had low disability (<=25). 54 CD patients (59%, males, median age 41 years) were enrolled; 22% were smokers. 94% had mild disease, 17% severe disease. Concomitant medications at the time of the interview were conventional therapy (5-aminosalicylic acid, oral steroids) in 22 patients (40%) or immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 32 patients (60%). The mean IBD-DI score was 20.17 ± 16.24; 72% of patients had low DI ≤ 25 (39/54) while only 2 patients had high DI > 50. No correlations were found between IBD-DI and disease characteristic, gender, disease duration, disease extension, extraintestinal manifestations and linear regression analysis, IBD-DI was significantly associated with IBD-Q (R² = 0.604; p < 0.001).

Conclusion: Our preliminary results show that the IBD-DI is significantly related to HR-QoL both in UC and CD. In UC IBD-DI is also related to disease activity and present extraintestinal manifestations. However, most of our patients were in clinical remission. A larger sample with different grades of disease activity could provide a more accurate evaluation of the reliability of this tool in measuring functional status and disability in IBD. IBD-DI could become a major end-point in RCTs targeting the course of IBD.

Introduction: DPP-4 is a membrane-bound glycoprotein expressed on the cell surface of lymphocytes, monocytes, macrophages and mast cells. It is released in plasma, maintaining its proteolytic activity and inactivating cytokines, chemokines and neuropeptides.

Aims & Methods: We aimed to investigate the diagnostic and prognostic value of DPP-4 in patients with inflammatory bowel disease (IBD). A total of 203 adult patients [n = 149 IBD patients; n = 42 healthy controls; n = 12 immune controls - systemic lupus erythematosus (SLE)] in remission were prospectively recruited. Plasma DPP-4 was analysed in all groups; faecal samples from IBD patients were collected for DPP-4 and calprotectin analysis. Disease activity was assessed using the Harvey-Bradshaw Index (HBI) for Crohn’s disease (CD), the partial Mayo Score (pMS) for Ulcerative colitis (UC) and the Systemic Lupus Erythematosus Disease Activity Index for SLE.

A multi-biomarker model was used deriving logistic regression to evaluate predictors of disease activity and C-reactive protein (CRP) for DIPM regression to evaluate predictors of treatment escalation (disease outcome). Treatment escalation was defined as the need for escalation to immunomodulatory/biologic therapies or intestinal resection surgery, as a consequence of a disease flare.

Conclusion: Median plasma DPP-4 values were lower in active CD vs CD in remission [1043ng/mL, interquartile range (IQR): 824–1345 vs 1519–2237; P = 0.005] while only 2 patients had high DI (≥50) and 5% (n = 10) had low DI (≤25) vs 17 healthy UC and 41% of patients had low DI ≤ 25 (39/54) while only 2 patients had high DI > 50. No correlations were found between IBD-DI and gender, disease duration, disease extension, extraintestinal manifestations and linear regression analysis, IBD-DI was significantly associated with IBD-Q (R² = 0.604; p < 0.001).

P1021 ROLE OF PET-CT TO ASSESS DISEASE ACTIVITY IN ULCEERATIVE COLITIS AND ITS CORRELATION WITH CLINICAL, ENDOSCOPIC, BIOLOGICAL, AND IMMUNOHISTOCHEMICAL MARKERS

1Gastroenterology, Postgraduate Institute of Medical Education and Research, Chandigarh/India

Contact E-mail Address: nehaberry86@hotmail.com

Introduction: Disease activity in ulcerative colitis (UC) is best assessed clinically by Mayo score and endoscopy. Positron emission tomography -computerized tomography (PET-CT) is a non-invasive imaging technique to assess disease activity, extent, treatment response in UC, specially in pediatric population, sick patients and those unwilling for endoscopy.

Conclusion: PET-CT is a non-invasive imaging test which is useful in assessing disease activity in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: We conducted a prospective observational study at our tertiary care centre with the aim of assessing and correlating UC disease activity by clinical criteria, endoscopy, histology, serum and fecal biomarkers and PET-CT. 60 eligible patients of UC were enrolled into 3 groups (26 remission, 24 moderate and 10 severe activity) as per Mayo score and 18F FDG PET-CT was performed within 72 hours of endoscopy. ESR, CRP and fecal calprotectin levels were determined for all patients.

Results: Of 60 enrolled patients, 10% patients had proctitis, 43.3% had left-sided colitis and 46.7% had extensive colitis. ESR, CRP, fecal calprotectin levels and rectal PET activity were significantly higher in patients with moderate and severe disease activity as compared to those in remission. Rectal PET activity showed a significant correlation with the Mayo score (r = 0.465, p < 0.001), endoscopic sub-score (r = 0.526, p < 0.001), histological score (r = 0.496, p < 0.001) and fecal calprotectin levels (r = 0.279, p = 0.031). Extent evaluation by PET-CT and colonoscopy also showed a significant correlation (r = 0.582, p < 0.001) with each other. We found that CRP at a cut-off level of 5 mg/L had a sensitivity of 70.59% and specificity of 92.3%, and fecal calprotectin at a cut-off level of < 143 g/L had a sensitivity of 82.35% and specificity of 98.46% to predict UC remission. Besides, PET-CT identified sacroilitis in 1, mesenteric lymphadenopathy in 5, mesenteric stranding in 4, and adenocarcinoma in 1 patient.

Conclusion: PET-CT is a reliable non-invasive tool for assessing disease activity in UC with good correlation with the Mayo score, endoscopic score, histology and fecal calprotectin. It is an accurate measure to determine disease extent, and a good predictor of remission. Thus, with a better patient compliance, it holds promise in replacing colonoscopy where it is refused or difficult to perform.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1023 THE IMPACT OF AN INFLAMMATORY BOWEL DISEASE EDUCATION CLINIC ON PATIENT OUTCOMES AND RESOURCE UTILISATION

W. On, B. Collins, H. Stanley, A. Westhoff, S. Tynan, D. Mcclements, V. Theis, J. Melindon, R. Chandy, A. Bassi

Contact E-mail Address: weiheng.on@gmail.com

Introduction: Patient education and awareness in those who have inflammatory bowel disease (IBD) and is regarded by the United Kingdom (UK) IBD standards group as a key standard in the provision of care towards patients with IBD. Our district general hospital implemented an IBD education clinic in 2015 which is run quarterly per annum by a multidisciplinary panel of doctors, specialists, nurses, pharmacists and dietitians. Patients who have been newly diagnosed with IBD are invited to attend this clinic. Clinic attendees are given an overview of their disease, treatment modalities, options of non-medical support (e.g. psychology) and are made aware of our telephone helpline open access service. To date, there has not been any published data on the impact of an IBD education clinic on resource use or patient outcomes.

Aims & Methods: We aimed to evaluate the impact of the education clinic on resource use in patients who attended the clinic compared to patients who did not. A retrospective analysis was done of patients who were diagnosed with IBD between January 2013 and May 2015. 40 patients were identified and divided equally (20 patients each) into clinic attenders (CA) and non-attenders (NA). Resource use was determined at 12 months from diagnosis in the NA group and 12 months from attendance in the CA group. The median time from diagnosis to clinic attendance in the CA group was 7 months. Data was obtained from our hospital’s electronic database system. Statistical analysis was carried out with the student’s t-test.

Results: The median age was 37 in the CA group and 33 in the NA group. In the CA group, 10 patients had ulcerative colitis (UC), 9 patients had Crohn’s Disease (CD) and 1 patient had unclassified IBD. In the NA group, 13 patients had UC and 7 patients had CD. The median of resource use and patient outcomes over a 12 month period (from diagnosis in the NA group and from clinic attendance in the CA group) is detailed in the table below.

<table>
<thead>
<tr>
<th>Resource use and patient outcomes</th>

</tbody>
</table>

Conclusion: In our cohort of patients, patients who attended the IBD education clinic were more likely to utilise our open access IBD telephone helpline service. There was a trend towards increased frequency of outpatient clinic appointments and blood tests in patients who did not attend the IBD education clinic although this was not statistically significant. There were no differences in the rates of hospital admissions or steroid courses in either group. The limitations of our data include the small sample size and short follow-up period.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several histological scores of activity have been developed in Inﬂammatory Bowel Disease (IBD). However, their usefulness in clinical practice and the correlation between clinical, endoscopic and histological scores is uncertain.

Aims & Methods: To assess, in a prospective study, the correlation between clinical, endoscopic and histological activity in Inﬂammatory Bowel Disease: a prospective study.

Results: IBD group included 107 pts: 67 (62.6%) UC (M 36 [53.7%], age 50 [24–80] yrs) and 40 (37.4%) CD (M 31 [55.7%], age 47 [24–79]). IBD pts undergoing colonoscopy according to clinical indication were enrolled. Inclusion criteria: 1. Diagnosis of IBD; 2. Age ≥18 and <80 yrs; 3. Regular follow up; 4. Indication for colonoscopy due to macroscopic abnormalities. During colonoscopy, biopsies ≥2 were biopsies were taken from ≥1 macroscopically involved area and, possibly, from ≥1 uninvolved area. Clinical activity was assessed by the Mayo score (activity ≥3) for Ulcerative Colitis (UC) and the CDAI (activity ≥150) for Crohn’s Disease (CD) pts. All colonscopies were performed by one IBD-dedicated gastroenterologist. Endoscopic activity was assessed in UC pts by the Mayo score (activity ≥2), and in CD by the Rutgeerts’ score (recurrence ≥2.3) or the SES-CD (activity ≥5.4), according to previous surveys. Histological activity was assessed by one pathologist using the Global Histologic Activity Score (GHAS) for CD (S) or the Geboes simplified score for UC (activity ≥1.6). Each of the 3 investigators was blind regarding the other results. Statistical analysis. Data expressed as median [range].

Results: IBD group included 107 pts. 67 (62.6%) UC (M 36 [53.7%], age 50 [24–80] yrs), 40 (37.4%) CD (M 31 [55.7%], age 47 [24–79]). IBD pts undergoing colonoscopy according to clinical indication were enrolled. Inclusion criteria: 1. Diagnosis of IBD; 2. Age ≥18 and <80 yrs; 3. Regular follow up; 4. active in 5 (12%), in remission in 35 (88%) pts. Endoscopic activity: CD. Complete mucosal healing was achieved in 24 pts. In the 34 pts with no previous surgery, SES-CED was: 0 (n = 4), 3 (n = 1), 4 (n = 3), 6 (n = 2); 8 (n = 3); 9 (n = 2); 10 (n = 1); 11 (n = 1); 12 (n = 1); 13 (n = 1); 14 (n = 1); 17 (n = 1); 19 (n = 1) pts (median 4 [0–
19]; activity: 20/24 [80%]; remission: 4/24 [20%]). In the 16 pts with previous surgery, the Rutgers’ score was: 0 (n = 3); 1 (n = 1); 2 (n = 6); 3 (n = 2); 4 (n = 4); recurrence: 12/16 [75%]. Histologic activity: CD. The GHAS was: 0 (n = 3); 1 (n = 1); 2 (n = 3); 4 (n = 1); 6 (n = 3); 10 (n = 1) in pts without previous surgery, and 0 (n = 3); 1 (n = 1); 2 (n = 1); 10 (n = 1) in pts with previous surgery in CD, the histological score showed a slightly significant correlation with SES-CED (r = 0.41 [p = 0.046] and no correlation with the Rutgers’ score (r = 0.31 [p = 0.247]).

Conclusion: In a prospective study, a significant correlation was observed between clinically, endoscopic and histological activity in UC. Histological activity may be observed in UC patients in endoscopic remission, thus suggesting that this finding may represent a predictive marker of clinical relapse.

Conclusion: Upon analysis of 57,861 infliximab and adalimumab patient samples from 2012–2016, 43% exhibited anti-drug antibodies. We found that low-titer antibodies do not appear to impact drug levels. Our findings are consistent with American Gastroenterological Association Critical Care Pathways for Crohn’s Disease IV, Ulcerative Colitis, and Crohn’s Disease scoring criteria where high antibody levels are managed very differently (increase drug/consider immunomodulator vs. switch drug within class). High resolution antibody assays may be helpful in dosing TNF inhibitors and in other treatment and management decisions.

**P1029 MOLECULAR SURROGATES OF HISTOLOGIC ACTIVITY IN CROHN’S DISEASE**

C. Monast1, K. Li2, E. Myslik3, C. Brodmerkel3, J. Friedman4, F. Baribaud5

1 Janssen Research & Development, LLC, Spring House/United States of America
2 Clarivate Analytics, Boston/United States of America/MA

Contact E-mail Address: emonast1@ITS.JNJ.com

Introduction: Biomarkers of inflammatory bowel disease activity have been researched for decades but objective markers of disease severity that support clinical decision-making are still needed. Well-established markers include serum C-reactive protein and fecal calprotectin, but their use as a standalone surrogate for disease activity has been controversial. We hypothesize that novel objective markers of tissue inflammation are best identified at the site of disease with a tissue-level assessment of disease activity.

**Aims & Methods:** Biopsy samples were obtained from participants in the UNITI trials of ustekinumab in moderate-to-severe Crohn’s disease. The UNITI induction trials included two cohorts, patients who failed ≥1 TNF antagonists (UNITI-1) or patients who failed conventional therapies (UNITI-2). Pairs of adjacent biopsies were taken from the rectum, splenic flexure, and ileum. One biopsy from each pair was assessed by Global Histology Disease Activity Score (GHAS) while the other was submitted to microarray analysis. Partial least squares regression and random forest were used to identify biomarkers associated with histological severity in the UNITI-1 cohort. Robustness of the resulting models was assessed using cross-validation within the training set and multiple external validation sets (defined within the UNITI-1 and UNITI-2 cohorts).

**Results:** In UNITI-1, a single multivariate model comprising 16 genes was identified that predicted histological activity in rectum or splenic flexure biopsies. This model was characterized by \( R^2 = 0.78 \) for the training set, and \( R^2 = 0.59, 0.54, \) and 0.32 on external validation sets also from UNITI-1. A separate 14-gene model capturing histological activity in ileal biopsies was characterized by \( R^2 = 0.5 \) for the training set and \( R^2 = 0.64 \) in the external validation set. In general, both models contained genes related to tissue degradation, barrier function, and immune regulation, including CXCL11 (IL-7R-A). Both models retained performance in external validation datasets from UNITI-2 but exhibited lower performance. De novo models generated from UNITI-2 also exhibited lower performance. Indeed, weighted gene co-expression network analysis indicated weaker associations between gene expression and histology scores for UNITI-2 compared to UNITI-1 subjects.

**Conclusion:** Our analysis supports the ability of biopsy transcriptionomics combined with machine learning approaches to capture disease-relevant variability in Crohn’s disease and, more importantly, supports the use of similar approaches to identify additional surrogate markers. Interestingly, this approach was more successful in the TNF antagonist failure cohort compared to the conventional therapy failure cohort. We hypothesize that this is related to increased strength of the transcriptional signal in the TNF antagonist failure cohort. We identified specific genes that could be used together as surrogates for histologic measurement, which may not be susceptible to the subjectivity inherent in GHAS scoring. Finally, the specific genes identified by our analysis provide insight into the molecular processes driving histological disease activity in Crohn’s disease.

Introduction: Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn’s disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This treatment sequence analysis builds on previous work1 proposing a solution to challenges inherent to CD data to compare one year efficacy of biologics in CD patients having failed anti-TNF therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional doses) to generate more comprehensive estimates of biologics’ relative efficacies.

**Aims & Methods:** A systematic literature review identified randomized controlled trials in CD patients having failed anti-TNF therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI < 150) were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were summed to obtain overall response and remission rates. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study, adjusted for responder and remitter induction rates. Bayesian analyses generated relative

Introduction: Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn’s disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This treatment sequence analysis builds on previous work proposing a solution to methodological issues inherent to CD trial data. In CD patients having failed anti-TNF therapy, ustekinumab had higher likelihoods of response or remission than adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab have demonstrated benefits in delayed responders compared to other biologics. Previous research is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients’ response to biologics and better informs clinical practice.

P1032 EFFICACY AND TOLERABILITY OF INITIATING, OR SWITCHING TO, INFILXIMAB BIOSIMILAR CT-P13 IN INFILXIMAB-BASED BIOLOGY DISEASE (IBD): A LARGE SINGLE-CENTRE EXPERIENCE

Gastroenterology, Leeds Teaching Hospital, Leeds/United Kingdom

Contact E-mail Address: raguprakash.ratnakumar@nhs.net

Introduction: Anti-TNF therapies have revolutionised the management of IBD. Recently, the infliximab (IFX) biosimilar (CT-P13) received market authorisation for IBD allowing cost benefits withswitches to CT-P13 with annual savings £1million in savings.

Results: 53 patients commenced IFX in the 12 months pre-Feb 2016 (26 Crohn’s Disease (CD), 13 fistulating CD, 13 Ulcerative Colitis (UC), 1 IBD-Unclassified) compared with 69 patients who commenced CT-P13 in the subsequent 12 months (22CD, 9 fistulating CD, 35UC, 3BD-U). In patients who initiated IFX in the 12 months pre-Feb 2016 and those who initiated CT-P13 in the 12 months post-Feb 2016. Sustained response was compared for existing IFX patients who switched to CT-P13 in Feb 2016 against those who continued with the original IFX. Drug and antibody levels were measured before switch and at 3, 6, and 12 months post.

Conclusion: There was no difference in response (12(23%) v 15 (21.74%) (p = 0.005)), secondary loss of response (12(23%) v 15(21.74%) (p = 0.905)), or adverse events (6(11%) v 6(10%) (p = 0.629)) in those who initiated originator IFX compared with CT-P13.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1033 SAFETY AND EFFICACY OF HELICOBACTER PYLORI ERADICATION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

3Division Of Gastroenterology, Shiga University of medical science, Shiga/Japan
4Center For Advanced Res Inflammatory Bowel Disease, Kitasato Institute Kitasato Institute Hospital, Tokyo/Japan
5IBD Center, Sapporo Kosei General Hospital, Sapporo/Japan

Background: Recently, the infliximab (IFX) biosimilar (CT-P13) received market authorisation for IBD allowing cost benefits with switches to CT-P13 with annual savings £1million in savings.

Results: 53 patients commenced IFX in the 12 months pre-Feb 2016 (26 Crohn’s Disease (CD), 13 fistulating CD, 13 Ulcerative Colitis (UC), 1 IBD-Unclassified) compared with 69 patients who commenced CT-P13 in the subsequent 12 months (22CD, 9 fistulating CD, 35UC, 3BD-U). In patients who initiated IFX in the 12 months pre-Feb 2016 and those who initiated CT-P13 in the 12 months post-Feb 2016. Sustained response was compared for existing IFX patients who switched to CT-P13 in Feb 2016 against those who continued with the original IFX. Drug and antibody levels were measured before switch and at 3, 6, and 12 months post.

Conclusion: There was no difference in response (12(23%) v 15 (21.74%) (p = 0.005)), secondary loss of response (12(23%) v 15(21.74%) (p = 0.905)), or adverse events (6(11%) v 6(10%) (p = 0.629)) in those who initiated originator IFX compared with CT-P13.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Low prevalence of _Helicobacter pylori_ (HP) infection has been recently reported in inflammatory bowel disease (IBD). However, it is unclear whether the eradication therapy for HP can exacerbate disease activity of IBD. We then aimed to clarify the safety and efficacy of HP eradication in patients with IBD.

Aims & Methods: This was a multicenter, retrospective cohort study in 26 institutions. Patients who eradicated HP by proton pump inhibitor and amoxicillin-based triple therapy after the diagnosis of IBD (ulcerative colitis (UC) or Crohn’s disease (CD)) from March 2005 to July 2015 were enrolled. Two IBD patients without prior HP infection whose gender, age at diagnosis, severity, and observation period were matched with each HP-eradicated patient were enrolled in the same institution. Disease activity of IBD at baseline, 2 and 6 months after eradication (eradication) was investigated. Eradication of IBD was defined as increase/addition of IBD drug, IBD-associated hospitalization or surgery; and physicians’ assessment was also analyzed. Factors associated with exacerbation of IBD were assessed by univariate and multivariate logistic regression analysis.

Results: A total of 429 IBD (378 UC and 51 CD) patients, including 144 patients who eradicated HP (eradication group) and 285 control patients (non-eradication group), were enrolled. IBD exacerbation rates in 2 and 6 months of observation were 16.2% (24/144) and 11.8% (17/144) in eradication group, which showed no significant differences compared with those of 4.9% (14/285) and 7.7% (22/285) in non-eradication group. Physicians’ assessment showed similar results in terms of disease exacerbation, but in 2 months of observation no patient was improved in eradication group whereas 3.2% (9/285) of patients was improved in non-eradication group (P = 0.019). Multivariate analysis revealed that the independent factor of IBD exacerbation after HP eradication was active disease at baseline (OR 5.3 (95%CI: 1.5–16.9), P = 0.011). HP was eradicated in 82.9% (102/123) of patients using clarithromycin as first-line treatment and 90.4% (19/21) using metronidazole as second-line, both of which were comparable with previous reports in non-IBD patients.

Conclusion: HP eradication therapy does not exacerbate disease activity of IBD without affecting active disease but may improve disease activity, suggesting that careful observation is necessary after eradication, especially for patients with active disease.

**P1034 EVALUATION OF PHARMACOKINETIC PROFILES OF SB2 AS A BIOSIMILAR OF REFERENCE INFlixIMAB**

D. Shin, J.W. Kang, S. Park, Y. Lee, S. Lee
Samsung Bioepis Co., Ltd., Incheon/Korea, Republic of

Contact E-mail Address: sr6427.lee@samsung.com

Introduction: Based on the totality of evidence with similar analytical, pharmacokinetic (PK) and clinical results, SB2 was approved by European Medicines Agency and U.S. Food and Drug Administration as a biosimilar of the reference infliximab (INF) for all indications for which INF has been approved. Here we report the PK profiles of SB2 compared to that of INF in two animal models, healthy subjects and patients with rheumatoid arthritis (RA).

**Aims & Methods:** The pre-clinical PK profiles were evaluated in single and repeated dose studies (1, 3, and 10 mg/kg of SB2, European Union sourced INF [EU-INF] or United States sourced INF [US-INF]) in two animal models (Sprague Dawley [BD] rat and transgenic Tg19 mouse). The Phase 1 clinical study for PK was conducted in healthy subjects at 1, 3, and 10 mg/kg. Healthy subjects were enrolled in a single 5 mg/kg intravenous infusion of study drugs (SB2, EU-INF or US-INF) and were observed for 10 weeks. PK equivalence was to be concluded if the 90% confidence interval (CI) for the ratio geometric least squares mean (LSMeans) of the primary PK parameters endpoints for SB2 to INF was within 80% to 125% during the concentration-time curve [AUC(0–INF)] from time zero to infinity [AUC(0–t)]. AUC from time zero to the last quantifiable concentration [AUC(last)] and maximum concentration [C(max)] were within the standard equivalence margin of 0.8 to 1.25. The steady state PK profile was assessed in a Phase III study in RA patients2. In this study, the patients received 3 mg/kg of SB2 or EU-INF at weeks 0, 2, and 4 every 28 days.

**Results:** In pre-clinical studies, a single intravenous infusion of SB2 was comparable to INF in PK parameters for both species. In a repeated dose study in healthy subjects, SB2 and INF were observed for 10 weeks. PK equivalence was to be concluded if the 90% confidence interval (CI) for the ratio geometric least squares mean (LSMeans) of the primary PK parameters endpoints for SB2 to INF was within 80% to 125% during the concentration-time curve [AUC(0–INF)] from time zero to infinity [AUC(0–t)]. AUC from time zero to the last quantifiable concentration [AUC(last)] and maximum concentration [C(max)] were within the standard equivalence margin of 0.8 to 1.25. The steady state PK profile was assessed in a Phase III study in RA patients2. In this study, the patients received 3 mg/kg of SB2 or EU-INF at weeks 0, 2, and 4 every 28 days.

**Conclusion:** The PK profiles of SB2 evaluated in single and repeated dose studies showed no significant differences in C(max) and AUC(last) between SB2, EU-INF and US-INF.***
Introduction: According to infliximab (IFX) license in inflammatory bowel disease (IBD), infusion doses are based on patient weight. In daily practice, treatment is prepared by pharmacist after clinical patient assessment, leading to an increased duration of hospital stay and consequently costs. A pharmacokinetic study (1) has shown that a weight-based dose (WBD) strategy does not reduce interindividual variability of IFX trough levels when compared to fixed doses. According to these findings, our hospital implemented dose banding (DB) of IFX infusions, defined by doses rounded up or down according to one of eight pre-determined standard doses with a maximum theoretical deviation of +/-5%, that allowed to prepare infusions at the pharmacy before patient admission.

Aims & Methods: The aim of the study was to compare hospitalisation length of stay (LOS) between IFX DB as compared to those treated with IFX WBD. From February to March 2017, we conducted a prospective, case-control study in our unit, including all IBD patients admitted for an IFX infusion. Patients who should receive an IFX dose between 250 and 800 mg were included in the DB group (treatment pre-prepared at the pharmacy, sent to the hospital unit before patient admission and administered just after the clinical validation). Patients who should receive an IFX dose below 250 mg or above 800 mg were included in the WBD group (treatment prepared after clinical validation including weight, and then sent to the hospital unit). Patients were analysed only when precise length of stay could be obtained and measured in minutes. Primary objective was to compare the length of stay at hospital in both groups. Secondary objective was to compare the proportion of IFX doses cancelled, reattributed and wasted and the saved or wasted price associated (reimbursement price of one 100 mg IFX vial: 382.28 €).

Results: Among the 373 IBD patients treated by IFX during the study period, 116 (31%) patients (51M/65F; median age: 41 years) were included in the study (75 in the DB group and 41 in the WBD group) corresponding to 128 infusions (84 in DB and 44 in WBD groups). Mean length of hospitalisation stay were 238 ± 21 min in the DB group and 308 ± 32 min in the DBW group, respectively (p < 0.001). DB was associated with a mean reduction of length of stay of 23%, corresponding to 70 minutes per patient. DB reduced significantly the mean duration of stay by decreasing the waiting time between clinical assessment and start of the infusion: 16 min vs. 84 min with WBD (p < 0.001). During the study, none of the 44 (0%) infusion in the WBD group was cancelled while 3/84 (3.5%) were cancelled in the DB group (p=0.55). Two out these three infusions could be reattributed to other patients, saving 2801 €.

Conclusion: When used routinely in IBD, IFX DB is associated with a shortened length of hospitalisation stay as compared to WBD, with a mean reduction of 70 minutes per patient. As IFX DB seems having similar efficacy to weight-based doses, it may improve functioning of daily hospitalisation units.

Introduction: Rapidity of response to treatment in CD is now considered a field of major interest, due to the importance of achieving the highest benefit in the shortest possible time. There are no studies specifically designed to evaluate the rapidity of response to ADA neither other anti-TNF therapies. The aim of this trial was to evaluate the rapidity of onset of clinical response to ADA therapy.

Aims & Methods: Adult anti-TNF naïve patients with active luminal (Harvey-Bradshaw Index (HBI) > =8) moderate-to-severe CD (excluding penetrating and structuring disease), with no response to a full and adequate course of therapy with corticosteroids and/or immunosuppressants, were enrolled in this observational, prospective, open label, single arm and multicenter clinical trial. Patients received standardized ADA treatment (160 mg – 80 mg – 40 mg every 2 weeks). The HBI was evaluated to determine the response at day 4 and week 1; and clinical remission at weeks 2, 4 and 12. Response was defined as a decrease of, at least, 3 points in the HBI global score and remission was defined as HBI global score < 5. CRP (C Reactive Protein) and fecal calprotectin (FC) were analyzed at baseline, day 4, week 1, 2, 4, 12. The modified intention to treat (mITT) population was the primary population for efficacy analysis and consisted of those patients enrolled in the study who had received at least one dose of ADA. Treatment-emergent serious adverse events (AEs) were recorded to assess safety throughout the study until 70 days after last treatment dose. All patients who received at least one dose of ADA were included in the safety population.

Statistical analyses were performed by the t-test or the Wilcoxon signed rank test, as applicable. Time to clinical response was analyzed using a Kaplan-Meier survival analysis model.

Results: 86 anti-TNF naïve patients were analyzed. A response at day 4 and week 1 was experienced by 60.5% and 74.4% of patients, respectively. Remission was achieved by 53.5% of patients at week 2, 61.6% at week 4 and 54.7% at week 12. The median time to obtain response was 4 days (95% confidence interval (CI): 1.0, 4.0) and the median time to remission was 7 days (95%CI: 4.0, 14.0).

During the study, 42.5% of the patients suffered from any adverse event (AE). Only 3 patients (3.5%) showed a serious AE.

Conclusion: ADA produces rapid clinical remission and response since day 4 in patients with moderate-to-severe CD unresponsive to therapy with corticosteroids and/or immunosuppressants.

Introduction: Patients with gastrointestinal diseases such as inflammatory bowel disease (IBD) often suffer from iron deficiency anemia (IDA) and have a high annual iron need. Intravenous administration of high-dose iron is the most efficient approach to replenish iron stores. The present analysis evaluates safety and efficacy of high doses of iron isomaltoside in patients with gastrointestinal diseases.

Aims & Methods: This is a pooled analysis of 3 trials of iron isomaltoside performed in patients with gastrointestinal diseases and IDA [1–3]. Outcome measures were adverse drug reactions (ADRs) and haemoglobin (Hb) measurements.

Results: 357 patients (108 men, 249 women) were included in the analysis of which 255 were diagnosed with IBD and 102 with other gastrointestinal diseases, incl. bariatric surgery, gastrointestinal bleeding etc. A cumulative dose of ≤1000 mg and >1000 mg iron isomaltoside was administered in 199 and 158 patients, respectively. ADRs were observed in 13.6% (36 events in 27 patients) and 12.0% (30 events in 19 patients) of the patients dosed with ≤1000 mg and >1000 mg iron isomaltoside, respectively (p = 0.8). Similar frequencies were observed in the IBD subgroup (14.3% versus 12.1%, p = 0.8). 0.5% of the patients experienced a serious ADR (2 events in 2 patients; grand mal convulsion and syncope). ADRs with a patient frequency >1% are shown in the table below:

<table>

No ADRs of hypophosphatemia were reported. In patients dosed with ≤1000 mg iron isomaltoside, Hb increased with a mean of 1.72 (95% confidence interval (CI) 0.12) g/dL from baseline to week 3, 2.00 (0.12) g/dL to week 4, and 2.32 (0.13) g/dL to week 8. In patients dosed with >1000 mg iron isomaltoside, Hb increased with a mean of 2.04 (0.10) g/dL from baseline to week 3, 2.51 (0.09) g/dL to week 4, and 3.01 (0.12) g/dL to week 8. The observed increase in Hb was statistically significantly higher in patients dosed with >1000 mg iron isomaltoside (p = 0.04). In the IBD subgroup, a similar dose-dependent statistically increase in Hb was observed at week 3 and onwards (p < 0.02).

Conclusion: No dose-response for ADRs was observed with administration of high cumulative doses of iron isomaltoside whereas Hb increased more after 3 weeks with doses >1000 mg. Thus, high doses (>1000 mg) of iron isomaltoside can be administered without additional safety concerns including concerns of hypophosphatemia and with efficacious increases in Hb in patients with gastrointestinal diseases.

Disclosure of Interest: R. Derman: Richard Derman has been a consultant for Pharmacosmos A/S, and the investigator/institution received a fee per patient J.F. Dahlérup: The investigator/institution received a fee per patient. W. Reinisch: The investigator/institution received a fee per patient.

P1039 EFFICACY AND SAFETY OF GOLUMUMAB IN ULCERATIVE COLITIS. PRELIMINARY DATA FROM A MULTICENTER ITALIAN STUDY

11) was 53%. Among the 85 responder patients, 67 (79%) have been treated with Infliximab (n = 19), while 7 have been treated with both infliximab and Golimumab (n = 7). The indications for Golimumab were:

- Non-responding or intolerant to anti TNF alpha (n = 11)
- Naïve to anti TNF alpha, while 65 have been treated with Infliximab (n = 25)
- Infliximab bioequivariance (n = 24)
- Infliximab resistance (n = 18)
- Infliximab and 250 mg/kg (IQR 174–500). One hundred twenty five patients (66%) were treated with 1000 mg and 250 mg/kg (IQR 174–500). One hundred twenty five patients (66%) were treated with 1000 mg. Thus, high doses (≥1000 mg) of iron isomaltoside can be administered without additional safety concerns including concerns of hypophosphatemia and with efficacious increases in Hb in patients with gastrointestinal diseases.

Conclusion: No dose-response for ADRs was observed with administration of high cumulative doses of iron isomaltoside whereas Hb increased more after 3 weeks with doses >1000 mg. Thus, high doses (>1000 mg) of iron isomaltoside can be administered without additional safety concerns including concerns of hypophosphatemia and with efficacious increases in Hb in patients with gastrointestinal diseases.
**P1040 OUTCOMES OF PATIENTS IN REMISSION WITH INFLAMMATORY BOWEL DISEASE WITH UNDETECTABLE INFlixIMAB TROUGH LEVELS AND POSITIVE ANTIBODIES TO INFlixIMAB**

**G.S. Tun, R. W. Downey, K. Robinson, A. Wright, M. Marshall, M. F. Hale, A. J. Lobu**

1Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, jf/United Kingdom

**Introduction:** The formation of antibodies to infliximab (ATI) is associated with increased drug clearance. Patients with undetectable infliximab (IFX) levels and positive ATI may indicate a group who may no longer be benefitting from the drug. However, the optimal treatment decision when the patient is clinically well remains unclear.

**Aims & Methods:** The aim was to assess the course of disease of patients in remission, with undetectable IFX levels and positive antibodies. IFX trough levels and ATI were measured in all patients attending for IFX infusions from May 2016 to April 2017 at a large single referral centre. Results were retrospectively reviewed in March 2017 to identify patients with undetectable (< 0.8 mg/L) IFX trough levels and positive ATI (>10 mg/L). A local guideline suggested that in well patients of this cohort, patients should be switched to an alternative biologic if duration of IFX was <12 months, or if the duration of therapy was ≥12 months to consider withdrawal of IFX or to assess disease activity - with withdrawal of IFX in inactive disease or a switch to an alternative biologic for active disease. Trough levels for IFX and ATI were measured using direct solid-phase immunoassay tests (Biohit, UK). Relapse was defined as worsening of symptoms attributable to the inflammatory bowel disease, requiring an alteration in treatment. Kaplan-Meier with Tarone-Ware test was used to calculate survival curves for regression analysis used to analyse the impact of the different treatment decision on the rate of relapse.

**Results:** A total of 148 subjects received study treatment (ABP 710: n=49; infliximab EU: n=49; infliximab US: n=50). After a single dose, the adjusted least square (LS) GM of AUC(0–t) and Cmax were as follows: ABP 710, 335.59 ± 123.23 mg·h/L; infliximab EU, 370.68 ± 121.19 mg·h/L; infliximab US, 351.77 ± 121.54 mg·h/L; and adjusted LS GM (90% CI) for AUC(0–t) and Cmax between ABP 710 and infliximab US were 0.996 (0.9042, 1.0067) and 1.021 (0.9624, 1.0827) and that between ABP 710 and infliximab US were 0.894 (0.8122, 0.9848) and 0.972 (0.9167, 1.0301). The ratios of adjusted LS GM (90% CIs) of Cmax and C0–t between infliximab US 86.40%, the majority was mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of the study (Day 57), 40% subjects in the ABP 710, 27% of subjects in infliximab EU, and 32% on infliximab US were positive for binding ADAs: 13% on ABP 710, 19% on infliximab EU and 10% on infliximab US were positive for neutralising ADAs.

**Conclusion:** Results of this study demonstrate PK similarity between ABP 710 and infliximab US, and the benefits and risks in terms of safety, and immunogenicity profiles were comparable among treatment groups, as well as between infliximab, ABP 710 and infliximab US following a single 5 mg/kg IV infusion in healthy subjects.

**P1041 PHARMACOKINETIC SIMILARITY OF ABP 710 TO INFlixIMAB: RESULTS FROM A SINGLE-BLIND, SINGLE-DOSE, PARALLEL-GROUP STUDY IN HEALTHY SUBJECTS**

**V. Chow, N. Zhang, P. Kaur, A. Kalyaperumal, E. Krishnan**

Amen, Thousand Oaks/United States of America/CA

**Contact Email Address:** vchow@amgen.com

**Introduction:** ABP 710 is being developed as a biosimilar to infliximab, an anti-tumour necrosis factor monoclonal antibody. Analytical and functional comparability between infliximab ABP 710 and infliximab US have been completed. This report describes the results of a Phase 1 pharmacokinetic (PK) equivalence study comparing ABP 710 with infliximab.

**Aims & Methods:** This was a single-blind, single-dose, 3-arm, parallel-group study in healthy adults, 18-45 years of age and with a body mass index of 18 to 30 kg/m². Subjects were randomised to receive a 5 mg/kg intravenous (IV) infusion of ABP 710 or infliximab sourced from the EU and the US after pre-treatment with an antihistamine and acetaminophen 30 minutes prior to start of infusion. The primary objective was demonstration of PK similarity of ABP 710 with infliximab EU and with infliximab US based on area under the serum concentration-time curve from time 0 to infinity (AUC(0–∞)) as the primary endpoint. The criteria to achieve PK equivalence were for geometric mean (GM) ratio and its 90% confidence interval (CI) to be within the range of 0.80 to 1.25. Secondary endpoints included maximum observed serum concentration (Cmax), safety, and immunogenicity.

**Results:** A total of 148 subjects received study treatment (ABP 710: n=49; infliximab EU: n=49; infliximab US: n=50). After a single dose, the adjusted least square (LS) GM of AUC(0–t) and Cmax were as follows: ABP 710, 335.59 ± 123.23 mg·h/L and 123.23 mg/L; infliximab EU, 370.68 ± 121.19 mg·h/L and 121.19 mg/L; infliximab US, 351.77 ± 121.54 mg·h/L and 121.54 mg/L; and adjusted LS GM (90% CI) for AUC(0–t) and Cmax between ABP 710 and infliximab US were 0.996 (0.9042, 1.0067) and 1.021 (0.9624, 1.0827) and that between ABP 710 and infliximab US were 0.894 (0.8122, 0.9848) and 0.972 (0.9167, 1.0301). The ratios of adjusted LS GM (90% CIs) of Cmax and C0–t between infliximab US and infliximab EU were 1.113 (1.0115, 1.2252) and 1.05 (0.9960, 1.1338). The 90% CIs of these ratios were fully contained within the 0.80 to 1.25 interval, confirming PK similarity between ABP 710 and infliximab, as well as between infliximab EU and infliximab US. There were no deaths, serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study; 1 subject in the infliximab EU group developed polyarthritis that resolved with treatment and the subject completed the study. The incidence of TEAEs was similar in the 3 groups (ABP 710: 83.7%; infliximab EU: 83.7%; infliximab US: 86.40%), the majority was mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of the study (Day 57), 40% subjects in the ABP 710, 27% of subjects in infliximab EU, and 32% on infliximab US were positive for binding ADAs: 13% on ABP 710, 19% on infliximab EU and 10% on infliximab US were positive for neutralising ADAs.

**Conclusion:** Results of this study demonstrate PK similarity between ABP 710 and infliximab US, and the benefits and risks in terms of safety, and immunogenicity profiles were comparable among treatment groups, as well as between infliximab, ABP 710 and infliximab US following a single 5 mg/kg IV infusion in healthy subjects. The safety and immunogenicity profiles were comparable among treatment groups, as well as between infliximab, ABP 710 and infliximab US following a single 5 mg/kg IV infusion in healthy subjects.

**Introduction:** Complex perianal fistulas (CPF) are common among Crohn’s disease (CD) patients and are associated with substantial morbidity. The burden and management of CPF are poorly studied.

**Aims & Methods:** To systematically review the literature on epidemiology, global disease burden, and treatment outcomes for CPF in CD patients. PubMed, Embase, and Cochrane were searched for relevant articles published from 2000
VITAMIN D IS RELATED TO THE EFFECTS OF ANTI-TNF TREATMENT IN CROHN’S DISEASE PATIENTS

Introduction: Vitamin D deficiency is common in patients with Crohn’s disease (CD). It is believed that this deficiency is related to the CD activity. Vitamin D supplementation have many effects, including immunomodulation. However, the role of vitamin D (VD) in severe CD patients using Anti-TNF is still unclear.

Aims & Methods: To evaluate the results of the VD replacement at different doses; check possible immunomodulatory action of vitamin D in CD patients with Anti-TNF. We conducted a double-blind, randomized, prospective study. 42 patients were selected with history of moderate to severe CD in use of anti-TNF, of both sexes, between 18 to 60 years, with dosage of 25-hydroxyvitamin D < 30 nmol/L (30 ng/ml) who signed the informed consent. Were excluded patients with less than 18 or over 70 years, pregnant women, chronic kidney or liver disease, sarcoidosis, tuberculosis, hyper- or hypoparathyroidism, neoplasias, use of anticonvulsants; and patients who received calcium supplements or VD in the last 6 months. 30 patients were randomized. Patients were submitted to a questionnaire of sun exposure, quality of life (IBDQ), clinical examination, VD dosage, C-reactive protein (CRP), fecal calprotectin (FC) and were divided into three groups: 1 Group (G1): 10 patients receiving 2,000 U/VD, VO/week for 8 weeks. 2 Group (G2): 10 patients receiving 5,000 U/VD, VO/week for 8 weeks. 3 Group (G3): 10 patients receiving 10,000 U/VD, VO/week for 8 weeks. At the end of 8 weeks the patients answered IBDQ and were submitted to VD, FC and CRP dosage. All patients were followed for 52 weeks and checked for disease activity recurrence (CDAI > 150, FC > 300, CT scan, CRP and VD levels.

Results: IBDQ improvement was observed in all groups with statistically significant results in G2 (p = 0.04) and G3 (p = 0.01). Increased VD were observed in all groups (median SD × mean ± SD): G1 - (19.5 ± 5.1 ± 26 ± 6.7) p = 0.07; G2 - (19.1 ± 4.1 ± 26 ± 5.8) p = 0.04; G3 -19.5 ± 6.4 ± 46.4 ± (12.7) p < 0.0001. CRP dosage were reduced, although not statistically significant, at G2 and G3 (5.8 ± 4 ± 3 ± 9.2 ± 8) p = 0.18 (5.2 ± 7.3 ± 2 ± 4.3 ± 6) p = 0.2; and increased in G1 (8.1 ± 10 ± 3 ± 13 ± 4 ± 19.9) p = 0.3. There was a significant decrease in FC in G3 (1014 ± 850 ± 483 ± 564) p = 0.04, no significant decrease in G2 (767 ± 751 ± 823 ± 535) p = 0.2, and increase in G1 (1101 ± 744 ± 1357 ± 819) p = 0.4. 92% were follow up showed that recurrent disease activity was predominat in patients with VD < 30 (p = 0.0004) and statically significant results were observed in disease activity recurrence rate (p = 0.006), FC (p = 0.02) and CRP (p = 0.01) when compared patients with VD > 30 and VD < 30.

Conclusion: 50,000 U/week was the best dosage for VD replacement and is related to immunomodulation. Most of patients with CD in Anti-TNF therapy have recurrent disease when VD < 30 and a high remission rate with VD > 30. VD levels are related to the effects of Anti-TNF therapy in CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

The study cohort consisted of 95 patients with a median age of 37 (IQR 27–48) years, of whom 40% were men. The majority of the patients (90.5%) had previously experienced treatment failure for at least one anti-TNF agent. At the start of golimumab, 41% were on a concomitant immunomodulator and 16% on corticosteroids. After a median follow-up time of 21 (IQR 10–36) months, 60 (63%) patients had stopped treatment with golimumab. Reasons for discontinuation were inadequate response; n = 45 (75%), intolerance; n = 11 (18%) and other reasons; n = 4 (7%). Estimated drug continuation rates were 73% at 12 weeks and 42% at 52 weeks. Concomitant treatment with corticosteroids at baseline seemed to be associated with a higher risk of discontinuation of golimumab (unadjusted HR: 1.97; 95% CI: 1.04–3.73; p = 0.04), although the association did not remain significant after adjusting for potential confounding factors (adjusted HR: 1.76; 95% CI: 0.84–3.67; p = 0.13).

Aims & Methods: We aimed to describe the CD population that is treated with golimumab in Sweden and to assess the long-term effectiveness, defined as drug continuation rate, as well as identify predictors of drug discontinuation. Patients with CD who received at least one injection of golimumab were identified through the Swedish national quality registry for inflammatory bowel disease (SWEIBREG). Duration of golimumab-treatment was illustrated by Kaplan-Meier curves. Univariate and multivariate Cox proportional hazard regression models were used to identify predictors of golimumab discontinuation. The variables sex, age, duration of disease, location, perianal disease, smoking status, previous surgery, concomitant treatment with corticosteroids or immunomodulators at baseline, prior anti-TNF therapy and CRP at baseline were included in the models.

Introduction: Clinical response and patient’s quality of life improve as a result of the direct benefit of Crohn’s disease (CD) effective treatment. Rapidity of response to treatment in CD is a field of major interest, due to the importance of achieving the quickest possible clinical benefit in the shortest possible time. There are no studies specifically designed for early evaluation of the quality of life in patients with active CD receiving adalimumab therapy. The aim of this study was to evaluate the rapidity of improvement of quality of life in response to adalimumab therapy in adult anti-TNF naïve patients with active luminal (Harvey-Bradshaw Index ≥8) moderate-to-severe CD, and with no response to a full and adequate course of therapy with corticosteroids and/or immunosuppressants. Aims & Methods: To this purpose we designed an interventionnal, prospective, open label, single arm and multicenter clinical trial. Quality of life was evaluated by using the validated questionnaires EuroQol-5D (EQ-5D-5L) and the 36 items version of the Inflammatory Bowel Disease Questionnaire (IBDQ-36). Questionnaires were administered at baseline, day 4 and weeks 1, 2, 4 and 12 without standardized adalimumab treatment (160 mg – 80 mg – 40 mg every other month). The modified intention to treat (miITT) population was the primary population for analysis and consisted of those patients enrolled in the study who had received at least one dose of adalimumab. Statistical analyses were performed by the t-test or the Wilcoxon signed rank test, as applicable.

Results: Eighty-six patients were included. At baseline, the median EQ-5D index score was 0.68. EQ-5D scores improved significantly versus baseline, at day 4 and weeks 1, 2 and 12, with median changes of 0.05 (p = 0.0005), 0.05 (p < 0.0001), 0.05 (p = 0.0001) and 0.11 (p < 0.0001), respectively. Similarly, EQ-5D VAS median scores also improved significantly, compared to baseline (median score at baseline: 55.00), at day 4 and thereafter, with median changes of 5.00, 5.50, 9.50, 10.00 and 12.00, respectively (p < 0.0001 at all time-points). The SIBDQ versus baseline, the IBDQ-36 overall score (median score at baseline: 142.50) at day 4 and weeks 1, 2, 4 and 12, also yielded statistically significant differences, with median improvements of 14.0, 18.0, 29.0, 42.0 and 35.5 respectively (p < 0.0001 at all time-points). Restoration of normal health (IBDQ-36 score ≥29) was obtained in 9% of patients at day 4 and increased to 35% at week 12.

Conclusion: Adalimumab produces rapid improvement of quality of life since day 4 in patients with moderate-to-severe Crohn’s disease.

PI0107  EVALUATION OF QUALITY OF LIFE IN IBD PATIENTS TREATED WITH ANTI-TNF THERAPY

G. Garellorenzo90@icloud.com

Introduction: Anti-tumor necrosis factor-α (anti-TNFα) agents are commonly used treatment options for moderate to severe Crohn’s Disease (CD) and Ulcerative Colitis (UC). However, despite their clinical effectiveness, few data regarding the role on quality of life (QoL) are available. Aims & Methods: To prospectively evaluate disease activity and QoL in a single-centre cohort of CD and UC patients, after introduction of anti-TNFα agents (infliximab or adalimumab). All consecutive adult CD and UC patients who started Infliximab (IFX) or Adalimumab (ADA) (from 2014 to 2015 at Padua University Hospital were enrolled. Disease severity was evaluated through laboratory tests (Haemoglobin, C-reactive protein (CRP) and Fecal calprotectin) and commonly used scores (Harvey Bradshaw Index (HBI) for CD and Modified Truelove and Witts Severity Index (MTWSI) for UC). We compared patients treated with IFX or ADA after 12 months from the anti-TNFα introduction and 12 months thereafter. QoL was assessed through the Short-Inflammatory Bowel Disease Questionnaire (S-IDQ).

Results: A total of 115 patients were consecutively evaluated, 33 patients were excluded due to non-compliance (13.7%) or drop-out for adverse events or primary non response (17.3%) within 12 months. Eighty-two (71.5%) were included in the statistical analysis (M/F 53/29, median age 43 years, UC/CD 42/40). Forty, 42 patients started IFX and ADA, respectively. QoL was significantly higher in CD than UC at baseline (median S-IDQ 49 vs 32, p = 0.004). In CD patients, anti-TNFα determined significant reduction of HBI (median 3 vs 1; p < 0.01), CRP (median 5 vs 2.9 mg/L; p = 0.004), fecal calprotectin (median 429 vs 119 μg/g; p < 0.001) but not haemoglobin (median 13.6 vs 13.2 g/dL, p = 0.25). QoL significantly improved (median S-IDQ 49 vs 59; p < 0.001), both in IFX and ADA groups (IFX: p = 0.001, ADA: p = 0.02). In UC patients, anti-TNFα therapy improved disease activity (median MTWSI 4 vs 3, p = 0.03), haemoglobin levels (median 11.6 vs 13.2 g/dL, p = 0.006), fecal calprotectin (median 1600 vs 108 g/g; p = 0.004), but not CRP (median 5 vs 2.9 mg/L, p = 0.08). QoL improved at 12 months (median S-IDQ 32 vs 56, p = 0.001) both in patients treated with IFX (p = 0.003) and ADA (p = 0.005). No adverse events were reported during the study period.

Conclusion: Anti-TNFα therapy is safe and improves disease activity and quality of life of UC and CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI0108  ENDOSCOPIC AND HISTOLOGIC FINDINGS CORRELATE WITH FREE INFILXIMAB FOUND IN UNINFLAMED TISSUE IN IBD PATIENTS

H. Bar-Yoseph1, A. Blatt1, S. Pressman1, S. Gerass1, B. Ungar2, S. Ben-Horin3, Y. Chowers1.1Gastroenterology, Rambam Health Care Campus, Haifa/Israel; 2Gastroenterology, Chaim Sheba Medical Center Ramat Gan Israel, Ramat Gan/Israel.

Contact E-mail Address: hagarry@gmail.com

Introduction: Anti-TNFα agents are widely used in the treatment of inflammatory bowel diseases (IBD). Despite the fact that the intestine is the main therapeutic site of these agents, it is not clear to what extent they reach the intestinal mucosa. We investigated the correlation between endoscopic and histologic findings with the amount of anti-TNFα found in uninfamed tissue, both in Crohn’s disease (CD) and Ulcerative colitis (UC).

Methods: Patients were included in the study if they had IBD (CD or UC) and were treated with anti-TNFα therapy. Endoscopic and histologic evaluations were performed at the time of the final visit, as part of the routine follow-up. Tissue sampling was performed by the endoscopist at the time of the evaluation. Tissue samples were immediately frozen and stored at −80°C. Immunohistochemistry was performed using the streptavidin-biotin-peroxidase method, and examined on light microscopy. Positive controls were included in each tissue series. The human anti-TNFα antibody was visualized using horseradish peroxidase. Quantification of the amount of anti-TNFα was done using a standard curve with recombinant human anti-TNFα, which was applied on the tissue sections using a 10 μg/mL concentration in PBS. The amount of anti-TNFα was calculated as the optical density (OD) at 492 nm, as measured using an optical reader (SPECTRAmax, Molecular Devices Corporation, Sunnyvale, CA). The correlation of the amount of anti-TNFα in the tissue with endoscopic or histologic scores was assessed using the Spearman rank correlation test.

Results: A total of 17 patients were included in the study: 9 with CD and 8 with UC. The median age was 42 years (range 18–72). Male:female ratio was 4:3. Four patients were naive to anti-TNFα therapy, while the rest had been receiving anti-TNFα therapy for at least 12 months. The median amount of anti-TNFα was 15.3 OD units (range 0.002–44.76). The amount of anti-TNFα was positively correlated with the endoscopic activity score (r = 0.63, p = 0.01) and with the histologic activity score (r = 0.58, p = 0.02) in CD patients. In UC patients, the amount of anti-TNFα was positively correlated with the histologic activity score (r = 0.68, p = 0.01).

Conclusion: There is a correlation between the amount of anti-TNFα found in uninfamed tissue and the activity of IBD, both clinically and histologically. The amount of anti-TNFα found in uninfamed tissue may be a useful tool in the monitoring of IBD patients treated with anti-TNFα therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.
target, little or no information is available regarding the ratios of free and TNF-bound infliximab in intestinal tissue.

Aims & Methods: We aimed to assess the presence of free versus TNF-bound infliximab in the intestinal tissue of IBD patients and its possible association with clinical outcomes. Protein was extracted from frozen intestinal tissues of infliximab-treated patients. TNF-bound infliximab and free bound infliximab were detected using ELISA and normalized to tissue protein concentration. Concurrent serum drug levels (SDL), anti-drug antibodies (ADA), serum TNF-bound infliximab levels, patient’s pharmacotherapy, clinical response based on physician global assessment (PGA), endoscopic appearance (severity determined according to mayo scoring in ulcerative colitis and endoscopist’s assessment of ulceration severity, extent of disease and affected area in Crohn’s disease) and pathological results (severity determined by observing pathologist graded as normal, mild, moderate and severe disease) at the time of colonoscopy were determined. Correlation were performed using Spearman’s rank correlation test.

Results: Twenty four biopsies from 13 patients (11 Crohn’s disease and 2 ulcerative colitis patients) were tested. Non-inflamed tissue infliximab levels, but not non-inflamed tissue infliximab, was correlated with SDL (R = 0.8499, p < 0.0037; FDR = 0.0185) and were negatively correlated with the endoscopic appearance (R = −0.7214, p = 0.0185) and pathological severity (R = −0.7095, p = 0.0059). TNF-bound infliximab was measured in both inflamed and non-inflamed specimens and did not correlate with drug levels in the serum or tissue. ADA was only detected in a single patient, precluding statistical analysis. Notably, no TNF-bound infliximab was measured in the serum.

Conclusion: These findings show that pharmacokinetic-pharmacodynamics interaction, as measured by SDL, better reflects drug levels in healthy mucosa rather than the inflamed one, and suggest a more complex drug/target interaction in inflamed tissue, which cannot be explained by target binding only. Future studies addressing changes during the phases of mucosal healing may allow their use as surrogate markers for this process.

P1051 ANTIBODIES TO INFlixIMAB OCCUR THROUGHOUT TREATMENT BUT DEVELOPMENT IS DELAYED BY IMMUNOSUPPRESSION

Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom

Contact Email Address: rdowney1@sheffield.ac.uk

Introduction: Infliximab (IFX) is an important agent in the treatment of inflammatory bowel disease (IBD). However, its use may be limited by the development of antibodies to infliximab (ATI). The aim of this study was to assess the timing and significance of ATI development in clinical practice.

Aims & Methods: Since May 2016, all IBD patients receiving intravenous IFX for maintenance treatment, at a large, single, referral centre, have undergone therapeutic drug monitoring (TDM). Serum IFX trough levels and ATI were both measured on a quarterly basis. Antibody formation was defined as a Harvey Bradshaw Index or Simple Colitis Activity Index < 4. Risk factors for ATI development were assessed by binary logistic regression model, using 522 sera taken from patients on maintenance therapy. Time to develop ATI, undetectable IFX levels and loss of response to treatment was assessed by Cox regression and Kaplan-Meier analysis.

Results: Male sex (OR = 2.1; p < 0.001), week of treatment (or for each extra week of treatment = 0.999; p = 0.038) and use of concomitant immunosuppression (IS) (OR = 0.37; p < 0.001) was associated with ATI formation.

Conclusion: ATI formation delays the development of IFX treatment. ATI presence is associated with male sex and lower week of treatment. Use of concomitant IS is associated with delays in ATI formation.

Disclosure of Interest: All authors have declared no conflicts of interest.
in just one of these 14 patients (1.4%) (p < 0.001). Median (IQR) TL were 5
0.001. A significant correlation between TL and ADA levels could be found (Spearman’s
rho = –0.582, p < 0.001). Although the presence of these ADA was not significantly associated with clinical remission at week 12, a clear trend was observed (p = 0.136). During median (IQR) follow-up of 1.46 (0.32–3.48) years, 43 out of 116 patients (37.1%) needed ADM dose-escalation.

**Conclusion:** A drug-resistant assay can identify ADA to ADM before all drug has been in remission for at least 12 months. As these ADA are significantly associated with need for dose-escalation and can appear before TL drops below the threshold of 4 µg/mL, they may be better to identify those patients who could benefit from dose-escalation. Moreover, the differences in TL between patients at week 12 can finally be explained by the presence of ADA measured with a drug-resistant assay.

**P1053 ADHERENCE TO MAINTENANCE THERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE BEFORE AND AFTER THE INTRODUCTION OF THE SHARED MEDICATION RECORD**

K. Roebgaard

Department Of Internal Medicine, Randers Regional Hospital, Randers/Denmark

Contact E-mail Address: klaraoe@rm.dk

**Introduction:** Compliance is a significant problem in the medication of patients with chronic diseases, especially during periods when patients are completely unaware of their disease and just take their drugs to prevent disease recurrence.

(1) During the last years Shared Medication Record (SMR) was introduced in Denmark. There is a national database containing information on current medication of all Danish residents. SMR include information on who, when, and how much medicine the patients by at the pharmacies. Therefore with SMR it becomes possible for doctors to see if patients retrieve the prescribed medicine at the pharmacy. Patients with chronic inflammatory bowel diseases (IBD), ulcerative colitis (UC) or Crohns Disease (CD), has periods of flares of the disease but in many cases also long periods when the disease is in remission.

The majority of patients need medication to reduce the risk of recurrence of disease. This means that they need to take medicine even if they have no symptoms of disease. Previous American studies have shown that a number of patients in this situation do not take their medication and thus are at increased risk for relapse of the disease (1). There are no corresponding data for Danish patients. We wanted to find out the proportion of Danish IBD patients in remission who buy the prophylactic treatment as prescribed, and whether this proportion will change when the patients are informed about the doctor can see if they pick up the medicine at the pharmacy.

**Aims & Methods:** The purpose of this study was to investigate whether Danish patients with IBD in remission buy the prophylactic treatment as prescribed, if these patients buy a larger part of their medicine when they know that the doctor can see which medicines they buy at the pharmacy. 100 consecutive patients with UC in remission for at least six months and IBD in remission for at least six months and treated with a fixed dose of Mesalazine, azathioprine, or Mercaptapurine during the preceding six months were enrolled from Randers Regional Hospital Adult Gastroenterological Outpatient Clinic. Patients were randomized 1:1 either to receive information that the doctor could follow their pharmacy refills, or not to get information on this. The patients were not informed that they participated in a study. All patients had a second visit six to 12 months later. Patients who had flares in disease activity during the study period was excluded. Adherence to the treatment was defined as pharmacy refills according to the prescribed dose for at least 80% of the period of the preceding six months. Fisher’s exact test was used as test of independence between groups.

**Results:** 67% of the patients in the study were adherent to their medical treatment during the first study period decreasing to 48% during the second study period (P < 0.001). There was no difference in the decrease in adherence between patients informed about SMR and those who were not informed. Younger patients were less prone to adherence compared to older patients at the first study visit (Age groups: 19-39: 49/60+ years: Adherence 48/71% (P < 0.05). We found no differences related to disease (UC/CD), sex, 5-ASA, antipurins, or administration route (oral/rectal).

**Conclusion:** Adherence to treatment fell from the first visit when the disease had been in remission for at least six months, to the second study visit when the disease had been in remission for at least 12 months. This was independent of whether the patients were aware that the physician could follow their medication refills or not. This might indicate that adherence to medical treatment of IBD decreases over time when the disease is in remission.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Golimab (GOL) is a fully human monoclonal antibody to TNFα approved for the treatment of patients with moderate to severe ulcerative colitis (UC) with inadequate response or intolerance to steroids or immunosuppressive therapies. The aim of this study is to evaluate the efficacy and safety of GOL in both biologic naïve (BN) and biologic experienced (BE) patients.

**Aims & Methods:** Data were prospectively collected from a cohort of UC patients treated with GOL from March 2015 to March 2017 at two centers. Data were analyzed from two patient cohorts, namely BN patients and patients who have already undergone treatment with infliximab or adalimumab (BE). Patients received GOL 200 mg sc. at week 0, GOL 100 mg sc. at week 2, then 50 mg or 100 mg sc. every 4 weeks depending on their body weight. The primary outcome was clinical response rate and incidence of adverse events (AEs).

Introduction: Endoscopic recurrence precedes clinical recurrence after ileocolonic resection for Crohn’s disease (CD). Guidelines recommend an ileocolonoscopy weeks 4–14 after surgery, even though there were no statistically significant differences noticed between the patients who continued therapy, median (IQR) duration of GOL treatment was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response, whereas 37 (69%) failed the treatment. No statistically significant differences were noticed between the BN and BE cohorts concerning the clinical response or the treatment failure (p = 0.5).

Conclusion: In our cohort, clinical response at 3 months follow-up was obtained in almost half of patients while at the last follow-up in one third. BN and BE patients had similar results in terms of clinical response, even though there were no statistically significant differences noticed between the patients who continued therapy, median (IQR) duration of GOL treatment was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response to GOL. Clinical response rate was similar in the BN and BE cohorts (p = 0.8). 28 (52%) patients were non-responders, without a statistically significant difference between the two groups (p = 0.8). At March 2017, 17 (31%) patients maintained clinical response, whereas 37 (69%) failed the treatment. No statistically significant differences were noticed between the BN and BE cohorts concerning the clinical response or the treatment failure (p = 0.5).

Results: Overall, data from 59 patients were analyzed. Of these, 27 (46%) were BN and 32 (54%) BE. Baseline patient’s characteristics and main study results are shown in Table 1. BN and BE patients were comparable in terms of comorbid profile, age at diagnosis, disease duration, pattern of previous and concomitant conventional therapies, as well as of disease extension and severity. Overall, surgical intervention after GOL therapy was performed in 13 (22%) cases: 3 (11%) belonged to the BN and 10 (31%) and BE group, respectively (p = 0.2). In 10 (17%) patients AEs were recorded, most of which were genitourinary or herpes simplex infections. Of note, two cases of basal cell carcinoma were registered. The rate of AEs did not significantly differ among the BN and BE groups (p = 0.5). In 5 (50%) patients AEs were responsible for therapeutic discontinuation after a median (IQR) period of 4 (1–4) months. Of the 54 (92%) patients who continued therapy, median (IQR) duration of GOL treatment was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response according to GOL. Clinical response rate was similar in the BN and BE cohorts (p = 0.8). 28 (52%) patients were non-responders, without a statistically significant difference between the two groups (p = 0.8). At March 2017, 17 (31%) patients maintained clinical response, whereas 37 (69%) failed the treatment. No statistically significant differences were noticed between the patients who continued therapy, median (IQR) duration of GOL treatment was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response, whereas 37 (69%) failed the treatment. No statistically significant differences were noticed between the BN and BE cohorts concerning the clinical response or the treatment failure (p = 0.5).

Conclusion: In our cohort, clinical response at 3 months follow-up was obtained in almost half of patients while at the last follow-up in one third. BN and BE patients had similar results in terms of clinical response, even though there were no statistically significant differences noticed between the patients who continued therapy, median (IQR) duration of GOL treatment was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response, whereas 37 (69%) failed the treatment. No statistically significant differences were noticed between the BN and BE cohorts concerning the clinical response or the treatment failure (p = 0.5).

Introduction: Etrolizumab, an anti-β7 monoecional antibody targeting α4β7 and αEβ7 integrins, showed efficacy and safety versus placebo (PBO) during 10 weeks (wk) of induction in patients with moderate-to-severe ulcerative colitis in the Phase 2 EUCALYPTUS trial (Vermeire S. Lancet. 2014;384:309–18). Since a reduction in histologic inflammation has been linked with improved long-term clinical outcome (Bryant R.A et al. Gut. 2016;65:408–14), the effect of etrolizumab on histologic inflammation was evaluated in mucosal biopsies from EUCALYPTUS patients using the Roberts histopathology index (RHI); Mosk MH. Gut. 2017;66:50–8) and Nancy histological index (NHI; Marshel-Bresson A, Gut. 2017;66:43–9).

Aims & Methods: 124 patients were randomly assigned (1:1:1) to receive subcutaneous etrolizumab (100 mg at wk 0, 4, and 8, with PBO at wk 2, or 420 mg loading dose at wk 0, followed by 300 mg at wk 2, 4, and 8) or PBO. Biopsies were taken using flexible sigmoidoscopy/full colonoscopy from the most inflamed colonic area within 10–40 cm from the anal verge at baseline (BL) and at wk 10. 62 patients provided consent for long-term sample storage for research; batch HE-stained slides were scored by a single pathologist using the Geboes scale (later converted to RHI) and NHI. At wk 10, mean changes in RHI and NHI scores for pooled etrolizumab or PBO were calculated. Subanalyses explored histologic response (reductions of ≥ 6 or 10 points or ≥ 50% improvement from BL RHI and ≥ 1 or 2 points reduction from BL NHI, respectively) in mucosal biopsies (no neutrophils, RHI ≤ 4 and NHI = 0, ≤ 1 or 2) and correlation with endoscopic improvement.

Results: Analysis included 56 patients with BL data and BL NHI > 1. At wk 10, 50% improvement from BL RHI and ≥ 50% reduction from BL NHI (RHI < 5; NHI ≤ 3) was achieved in 38% (30/79) of patients with an ES ≥ 1 at wk 10 versus 4% (3/79) in patients with an ES ≥ 1. Mean (SD) NHI changes were − 2.5 (1.5) in patients with an ES ≥ 1 at wk 10 versus − 0.6 (1.3) in patients with an ES ≥ 1. Spearman’s
correlation coefficients between RHI and NHI were 0.82 at BL and 0.91 at wk 10, while both histologic scores were similarly correlated with ES (0.25-0.28 at BL and 0.38-0.40 at wk 10).

1Must have achieved ≥1 point improvement
NHI 0 = no histologically significant disease
NHI 1 = chronic inflammatory infiltrate with no acute inflammatory infiltrate
NHI 2 = mildly active disease

Conclusion: Histologic activity assessment using RHI or NHI demonstrates improvement after wk 10 with etrolizumab treatment and was greater in aTNF-naive patients. Importantly, RHI or NHI reductions were associated with improved ES at wk 10.

Introduction: GO-COLITIS (NCT012092285; 2013-004853-56) is a phase 4, multicentre, open-label, single-arm trial in the UK assessing efficacy of golimubum (MedImmune) in induction and maintenance of clinical response in patients with moderate to severe ulcerative colitis (UC) resistant to conventional treatment. Results of the maintenance phase are presented here.

Aims & Methods: Anti-TNF naïve adults with UC ≥3 months who responded to induction therapy with subcutaneous GLM at BL week 6, according to partial Mayo score (PMS), continued to receive a maintenance dose of 50 mg or 100 mg GLM (dependent on the patient’s weight) every 4 weeks as per the Summary of Product Characteristics for a total of 54 weeks. Measurements were taken at week 6, week 30 and week 54. The primary endpoint was the proportion of patients meeting PMS response criteria at wk 54 (defined as decrease in PMS ≥2 points and ≥30% from baseline, plus a decrease in rectal bleeding subscore of ≥1 point or absolute rectal bleeding score ≥5). Secondary endpoints included proportion of patients meeting PMS remission criteria at week 54 (defined as PMS ≤2 and no individual Mayo subscore >1), change from baseline in IBDQ and EQ-SD at each visit and normalization of CRP.

Results: Overall, 205 patients enrolled in GO-COLITIS and received at least one dose of GLM. Of these, 140 patients responded in the induction phase and received GLM in the maintenance phase. Clinical response was maintained through week 54 in 52/140 patients (37.1%; 95% CI, 29.1% to 45.7%) and 42/140 patients were in remission at week 54 (30.0%; 95% CI, 22.6% to 38.3%). Improvements in PMS subscores from baseline to week 54 were noted in stool frequency (mean change, −1.9; SD, 1.1 [n = 59]), rectal bleeding (mean change, −1.5; SD, 0.8 [n = 59]), and physician’s global assessment (mean change, −1.8; SD, 0.8 [n = 57]). Normal CRP levels at wk 54 were seen in 50/59 patients (85.4%; 95% CI, 73.0% to 92.8%); IBDQ and EQ-5D results are summarised in the Table. Serious adverse events (SAEs) occurred in 49/205 patients (23.9%), with 3 SAEs considered treatment-related.

Table: Mean (SD) Change from baseline to week 54 in IBDQ and EQ-SD

<tr>
<td>EQ-SD index score</td>
<td>136 0.7 (0.2)</td>
<td>0.9 (0.2)</td>
</tr>
</tbody>
</table>

Conclusion: In the maintenance treatment with GLM phase of GO-COLITIS, 37.1% and 30.0% of patients with moderate to severe UC in the UK demonstrated clinical response and remission at wk 54, respectively. Improvements in patient-reported quality of life measures (IBDQ, EQ-SD) were seen; the degree of improvement in IBDQ total score exceeded the IBDQ increase cutoff (i.e. ≥20 for a patient defined-remission previously identified as representative of a patient defined improvement in an assessment of UC clinical endpoints.1 Adverse events were consistent with previous observations.

P1058 A UNITED STATES CLAIMS DATABASE ANALYSIS COMPARING SAFETY, MEDICAL RESOURCE UTILIZATION, AND TREATMENT COSTS ASSOCIATED WITH THE MANAGEMENT OF INFLAMMATORY BOWEL DISEASE BY DRUG CLASS

1Roche Pharmaceuticals Ltd., Welwyn Garden City/United Kingdom
2Genentech, Inc., South San Francisco/United States of America/CA
3Partnership for Health Analytic Research, Beverly Hills/United States of America/CA
4Massachusetts General Hospital and Harvard Medical School, Boston/United States of America/MA

Introduction: Only a third of patients (pts) with inflammatory bowel disease (IBD) treated with current pharmacological options achieve clinical remission (remission rate), and most experience drug-related adverse events (AEs). Herein we characterise the clinical and economic burden of IBD treatment limitations in terms of AEs of interest, medical resource utilisation (MRU) and associated medical costs.

Aims & Methods: Using pts taking only aminosalicylates (ASA) as a reference, we compared AE incidence, MRU and medical costs in pts with ulcerative colitis (UC) or Crohn’s disease (Crohn’s) who initiated treatment with oral corticosteroids (OCS), immunomodulators (ISM), anti-tumor necrosis factor agents (aTNF) or with combinations thereof. Eligible pts (aged >18 years) in the IMS PharMetrics insurance claims database between 7/1/10 and 6/30/15 had ≥2 medical claims (>7 days apart) and a diagnosis of UC (ICD-9-CM: 556.5) or Crohn’s (ICD-9-CM: 555.x), with ≥1 qualifying claim in the year preceding treatment. Univariate comparisons included statistical tests of significance (χ2, F test, or Kruskal Wallis). Multivariate analyses were based on Cox proportional hazards regression, negative binomial regression, logistic regression or linear regression.

OCS monotherapy was the strongest predictor of any AE occurring for pts with Crohn’s or UC (Crohn’s: HR, 1.62 [1.51–1.73]; UC: HR, 1.57 [1.49–1.66]). A similar pattern was observed for severe hepatitis (Crohn’s: HR, 2.43 [2.07–2.85]; UC: HR, 2.37 [2.07–2.72]) and bone-related conditions (Crohn’s: HR, 1.88 [1.74–2.03]; UC: HR, 1.77 [1.67–1.89]). The strongest predictors for serious hepatic events were IS + OCS (Crohn’s: HR, 2.38 [1.72–3.31]; UC: HR, 2.36 [1.75–3.18]). A total of 2,66 pts with UC (Crohn’s: HR, 1.92 [1.55–2.34]) and 2,72 pts with UC or Crohn’s receiving OCS or IS + OCS were more likely to have emergency department visits; IS-related hospitalisations, visits or procedures; and gastrointestinal surgery compared with pts receiving other therapies. Analysed together, participants treated with IS or atTNF therapy in both Crohn’s and UC. However, annualised medical service costs (that exclude IBD drug costs) were highest for pts initiating OCS-containing therapies (Crohn’s: OCS, $27,041 and OCS + IS, $23,352; UC: OCS, $19,659) followed by other induction therapies (Crohn’s: ASA, $10,823 and atTNF + IS, $9,151 [P < 0.001]; UC: ASA, $7,980 and atTNF + IS, $18,771 [P < 0.001]).

Conclusion: Chronic OCS use was associated with increased risk of severe infection, bone conditions, and serious hepatic events compared with other therapies. Consequent increased AE risk, OCS regimens were associated with higher rates of MRU and medical service costs compared with other therapies. Although limiting the use of OCS regimens may be more costly initially, treatment decisions should consider downstream costs of alternate options.

Introduction: Infliximab has been shown to induce and maintain long-term clinical remission in inflammatory bowel disease (IBD) patients. However, 10–30% of patients show no clinical benefit by the end of induction (week 14) and are considered primary non-responders. The mechanisms underlying primary non-response have not yet been clearly defined.

Aims & Methods: In this study we aimed to evaluate to which extent pharmacokinetics (early induction infliximab and anti-infliximab-antibody (ATI) levels) and therapy persistence non-response occurred. A retrospective observational case-control study of patients with IBD attending the Gastroenterology Department of Sheba medical center and treated with infliximab between 2009 and 2016 was performed. Clinical scores were determined and sera were collected prospectively before infusions. Inflimab and ATI levels were measured by our previously described drug-tolerant ELISA assay.

Results: Thirty five primary non responders have been identified and matched at 1:1 with 35 primary responders for a total of 140 patients. Both week 2 and week 6 infliximab levels were significantly lower among primary non-responders compared to responders (week 2: median level 7.2 μg/ml vs. 13.5 μg/ml, p = 0.0019, week 6: median level 2.2 μg/ml vs. 9.5 μg/ml, p < 0.0001, respectively). ATI appeared more frequently (either week 2 or 6, OR 4.6, CI 2–10.8, p = 0.0004) and at higher levels in non-responders compared to responders (week 2: median ATI 7.3 μg/ml-eq vs. 3.8 μg/ml-eq, p = 0.005, week 6: 10.8 μg/ml-eq vs. 4.4 μg/ml-eq, p = 0.008, respectively). Moreover, week 2 ATI levels >4.3 μg/ml-eq (AUC = 0.68, p = 0.004, sensitivity 77%, specificity 86%) and infliximab levels ≤6.8 μg/ml (AUC = 0.68, p = 0.002, sensitivity 50%, specificity 86%) were predictive of primary non-response. In analyses of various demographic and clinical factors correlated with primary non-response the only independent significant on multivariable analyses were lower infliximab and higher ATI levels at either week 2 or 6, infliximab monotherapy and previous IB-related surgeries. Sub-analyses according to IBD type demonstrated that in addition to lower drug and higher ATI levels, older age and previous surgeries increased primary non-response among Crohn’s disease patients. Monotherapy was the only other factor significant among ulcerative colitis patients, although multivariate analysis was not performed due to limited sample size (n = 32).

Conclusion: Although direction of causality cannot be ascertained, infliximab levels below 6.8 μg/ml and ATI levels above 4.33 μg/ml-eq before the second infusion (week 2) are predictive of primary non response, in addition to previous CD-related surgeries and infliximab monotherapy. These findings suggest that preemptive interventions in a subset of patients might minimize this phenomenon.

PI0160 TREATMENT EXPERIENCE WITH TOPICAL PRODUCTS FOR ULCERATIVE COLITIS–THE PATIENTS PERSPECTIVE IN EUROPE AND THE USA

T. Buryhoffer, A. Thompson, T. Knittel

Introduction: Topical therapies for ulcerative colitis have shown evidence of good efficacy and can induce better responses and earlier improvement in distal ulcerative colitis (UC) when compared with oral therapies. Despite this attractive targeted approach of delivering medications topically to the left colon a certain resistance to the use of topical therapy seems to exist.

Aims & Methods: The goal of this market research was to assess the familiarity with and perceptions of patients towards topical products. A qualitative market research study was performed in the USA and 3 European countries (Germany, UK and Italy). The primary patient recruitment sources were online web portals, e-mail campaigns and social networking sites. Informal feedback gathered from outspoken patient activists to identify the right sources was also used. In order to select pts with more advanced disease and/or a longer disease history current or past steroid medication was mandatory as a qualification for inclusion in the market research. A structured questionnaire covering 14 items was pretested and modified in phone interviews, which was then subsequently used in telephone interviews or as a web based interactive survey, both in local language. A total of 148 patient responses were obtained via 10 phone interviews and 138 web-survey, 60 patients came from the US, 27, 25 and 36 from Germany, UK and Italy, respectively.

Results: In this survey cohort patients had been diagnosed with UC for > 5 years on average, 2/3 of patients had left-sided disease and less than a third had extensive disease. The majority of patients experienced at least 1–2 flare-ups each year and less than 15% of patients had them only rarely. ASA and steroids were the most commonly used medications in all countries, biological treatments were reported as highest in 35% (US) to the lowest 16% (UK) as stated by the patients. The vast majority of patients stated that they had treatment experience with oral products at some point during their treatment course, although slightly lower number in the US (83%) compared to the EU countries (Range 89–92%). Rectal enemas were the most common formulation delivery for topical ASA products in all markets (79%) followed by suppository (25%) and foam (13%). A total of 53% of patients were not concerned about the rectal mode of administration, while 47% reported some concerns. These mainly comprised the need to hold the enema in place, a generally uncomfortable feeling with rectal medications and painfull administration.

Discussion: Despite a certain resistance to use topical therapy almost all patients stated to have used rectally administered products at some point during their disease journey and even patients in the USA were very familiar with these medications. Although physicians see patients as the primary driver for the resistance to use topical products in UC, less than 50% of the patients were actually concerned about the use of topical therapy in this study, thereby calling for better physician-patient communication.

PI0161 SELF-CAREMAGEMENT IN INFLAMMATORY BOWEL DISEASE: A PERSPECTIVE OF NURSES AND PHYSICIANS

S. P. Van Den Burg, M. S. P. Peek, A. E. Van Der Meulen - De Jong, J.P.W. Maljaars

Introduction: Over the last years, self-management (SM) has been advocated as an instrument to empower patients to increase patient involvement and reduce healthcare costs in chronic diseases. Although many SM programs have been developed for inflammatory bowel disease (IBD) patients, little research has been performed on needs and wishes of IBD physicians, nurses and patients. Nurses and physicians play an important role in providing and stimulating SM.

Aims & Methods: This study aimed to gain insight in what caregivers consider good SM options, and which options – patient- or disease-related factors they consider of importance. Nurses and/or physicians were willing to participate during a nursing a IBD day at our hospital, a survey regarding SM was distributed among 46 nurses. Also, 50 IBD-interested gastroenterologists were invited to respond to the same survey by email with a link to the survey. The survey contained questions regarding the caregivers’ views on ways for patients to apply SM in an outpatient setting (12 options were given). Caregivers were asked to state whether they thought these options would be valuable to patients or not, and to name their top three options. Also, caregivers were asked their views on factors that could
influence the degree of SM a patient is willing to apply, such as: disease duration, activity, health literacy, self-efficacy, patient age, and level of trust between patient’s and their IBD team. Caregivers were asked per item whether they thought this factor would be of influence and to name the three most important factors.

Results: 38 nurses (mean age 42 years) and 32 physicians (mean age 44 years) responded to the survey. The three most appealing options for nurses regarding SM were: level of trust between physician and patient, self-efficacy, and disease perception. Also, 41% of the physicians found health literacy to be an important factor. Factors suggested that self-efficacy and disease perception and disease activity were most important. One factor was valued differently between nurses and physicians: 78% of nurses thought that patients’ age was an important factor in patient’s SM, compared to 34% of physicians (p = 0.001). Physicians thought that the 3 most important factors influencing SM in patients were: level of trust between physician and patient, self-efficacy, and disease perception. Also, 41% of the physicians found health literacy to be an important factor. Factors suggested that self-efficacy and disease perception and disease activity were most important. One factor was valued differently between nurses and physicians: 78% of nurses thought that patients’ age was an important factor in patient’s SM, compared to 34% of physicians (p = 0.001).

P1062 DISTINCT PATTERNS OF SHORT-CHAIN FATTY ACIDS IN PATIENTS WITH ULCERATIVE COLITIS EXPERIENCING A FLARE DURING TREATMENT WITH MESALAMINE OR A HERBAL COMBINATION OF MYRRH, CHAMOMILE FLOWERS AND COFFEE CHARCOAL

J. Langhorst1, A. Koch2, A. Rueffler2, G. Dobos2
1Department For Internal And Integrative Medicine, Klinikum Essen-Mitte Integrative Gastroenterology, Essen/Germany
2Enterosan, Labor L + S, Bad-Bocklet-Groosenbach/Germany
3Internal And Integrative Medicine, Klinikum Essen-Mitte, Essen/Germany

Contact E-mail Address: j.langhorst@kliniken-essen-mitte.de

Introduction: The combination of myrrh, chamomile flowers, and coffee charcoal has shown first evidence for potential efficacy in maintaining remission in ulcerative colitis. Myrrh and coffee are end products of the microbial fermentation of dietary fibers in the gut. They are involved in the regulation of the gut immune system, promote mineral absorption, lipid metabolism, mucin production and expression of antimicrobial peptides. UC patients often show reduced occurrence of SCFA especially of butyrate and propionate. This might lead to unfavorable health implications including higher risk of inflammation and heightened cancer risk.

Aims & Methods: The purpose of the present study was to evaluate the influence of mesalazine and of the herbal preparation on SCFA in ulcerative colitis. Analyses was performed as sub-study of a randomized double-blind, double-dummy, controlled clinical trial that has been published previously. Patients were treated with the herbal preparation consisted of 100 mg myrrh, 70 mg chamomile extract and 50 mg coffee charcoal (Myrrhinil-Intest; Repha GmbH, Hanover, Germany). Patients were treated with mesalamine 500 mg 3xd. Clinical activity was monitored with the CAI (Rachmilewitz) with a CAI > 4 indicating a clinical flare. Fecal samples were collected, gas chromatography was performed and SCAFA (butyrate, acetate, propionate, iso-valerate) were measured as baseline, in the event of a clinical flare or at the end of the 12-month time interval.

Results: A total of n = 89 patients were included in the study. N = 43 pts developed a clinical flare (descriptive statistics are shown in table 1). Patients who were treated with the herbal preparation showed a significant decline of the SCFA (M baseline = 66.12; SD = 39.59; M flare = 29.83; SD = 15.05; 95% BCI [18.86–58.60]) in the event of a flare. In contrast, patients who were treated with the herbal preparation showed no significant decline of the SCFA (M baseline = 64.80; SD = 53.74; M flare = 48.09; SD = 35.90; 95% BCI [7.17–42.28]) in the event of a flare. There was no significant decline in SCFA in the patients in remission neither for the herbal preparation (n = 19; M baseline = 65.77; SD = 43.38; M 12month = 48.63; SD = 23.23; 95% BCI [7.02–39.95]) nor for mesalazine (n = 27; M baseline = 57.01; SD = 34.40; M 12month = 42.01; SD = 21.90; 95% BCI [34.29–49.54]).

Conclusion: Findings show that the herbal preparation might induce different effects on the SCFA of patients with UC compared to mesalazine and therefore might exhibit different modes of action in treating UC. Since a decline of SCFA might lead to unfavorable health improvements like higher cancer risk, treatment options like the herbal preparation might yield additional beneficial effects in the treatment of UC. A combination of the two treatment modalities might be useful and should be investigated in further studies.

P1063 GRANULOCYTE-MONOCYTE APHERESIS (GMA) IN DIFFICULT-TO-TREAT INFLAMMATORY BOWEL DISEASE (IBD): A SINGLE-CENTER REAL-LIFE EXPERIENCE

A. Caroli, F. Lamboglia, I. Franceschet, C. Pozzan, D. Checchin, F. Bortoluzzi, R. Cappuccio, A. Vitalba, A. Caroli

UOC di Gastroenterologia, Ospedale dell’Angelo, Mestre; Ospedale SS Giovanni e Paolo, Venezia, Mestre-Venezia/Italy

Contact E-mail Address: alessandro.caroli@uls12.ve.it

Introduction: Selective GMA using Adacolumn® is a device in a non-pharmacological therapeutic option for patients affected by IBD, but its precise role among the various treatments available and its true effectiveness are still debated. In particular, steroid-dependent patients, refractory or intolerant to immunosuppressant and biologics, represent a sub-group of patients with limited options of treatment. Recently, a multicentric open-label trial [the ART trial *] showed, for the first time, a clinical benefit of GMA-Adacolumn® in these problematic patients.

Aims & Methods: The aim of this study was to further evaluate, in our real-life clinical experience, the efficacy and safety of GMA in these difficult-to-treat patients. We retrospectively reviewed the clinical data of patients treated with GMA-Adacolumn® in our center between 1/1/2008 and 12/31/2012. Only steroid-dependent and/or ASA/IXA/ADA-resistant or intolerant cases were considered. GMA was performed once a week for a minimum of five consecutive weeks. Occasionally, one or two additional sessions were performed. A clinical response was defined as a ≥ 3 point drop in the clinical activity index (CAI) for ulcerative colitis (UC) and a ≥ 100 points reduction of the Crohn disease activity index (CDAI) for Crohn disease (CD) after 12 weeks from the beginning of the treatment.

Results: The study population included a total of 30 patients (17 males, 13 females, mean age 49 years, range 21–73) affected by UC (20 patients) and CD (10 patients). Eight patients (5 UC, 3 CD) were excluded from the final analysis for technical data. In the final group of 22 patients, a clinical benefit was observed in 15 (68%). The response was better in UC (11/15 = 73%) than in CD (4/7 = 57%). A steroid-sparing effect was observed in all responsive patients. GMA was generally well tolerated, as only 4 patients (13%) reported mild adverse events (headache in two, hypotension in one, vascular procedure complication in one) and no patients discontinued the apheresis due to the adverse events.

Conclusion: In our real-life single-center experience, focused to a selected group of difficult-to-treat patients affected by IBD, GMA with Adacolumn® seems to be, in a short-time evaluation, a useful and safe option of treatment, supporting the recent data from the ART trial. Prospective randomized trials in larger series of patients and with more extended follow-up are needed to confirm these results.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The present study aims to investigate the influence of the single and combined herbal extracts with regard to its antimicrobial and immunomodulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine-challenged Caco2 cells was inhibited after myrrh (IC50: myrrh = 106 µg/mL). Synergistic effects exerted by the herbal combination in inhibiting CXCL13 release significantly reduced IC50 values (IC50: myrrh = 82.5 µg/mL; chamomile flower = 22.5 µg/mL; coffee charcoal = 29 µg/mL) in a DRI of 3. Chamomile induced CXC13L1 release from Caco2 cells was reduced by all herbal components (IC50: myrrh = 41 µg/mL; chamomile flower = 364 µg/mL; coffee charcoal = 447 µg/mL) with comparably high IC50 values. However, application of the herbal combination, significantly reduced the IC50 of the plant extracts (myrrh = 25 µg/mL; DR1 = 1.7; chamomile flower=IC50 = 124 µg/mL; DR1 = 2.9; coffee charcoal-IC50 = 124 µg/mL; DR1 = 3.6). IL8 release from cytokine-challenged Caco2 cells was inhibited after myrrh (IC50 = 5 µg/mL; 28% max inhib.) and coffee charcoal (IC50 = 216 µg/mL; 75% max inhib.) but increased after chamomile flower treatment (IC50 = 39 µg/mL; 29% max stim.). Treatment with all three plant extracts resulted in a moderate IL8 inhibition with an inverted U-shape concentration-response curve (IC50: myrrh = 56 µg/mL; coffee charcoal = 281 µg/mL; 77% max. inhib.).

Conclusion: The herbal components myrrh, chamomile flower and coffee charcoal influenced chemokine signalling of stimulated intestinal epithelial cells and activated macrophages. Myrrh and chamomile flower additionally exerted anti-inflammatory effects. Synergistic and additive effects between the plant extracts justify the combination of the traditional herbal medicinal product (Myrrh; Chamomile flower; Coffee charcoal) and its application for the treatment of inflammatory intestinal disorders.

A deregulated immune response associated to an increase of intestinal permeability is still unknown. It has been hypothesized that, in genetic predisposed subjects, Ulcerative Colitis (UC), are idiopathic autoimmune conditions whose pathogenesis involves the activation of the innate and adaptive immune response, resulting in mucosal inflammation. Inflammatory Bowel Diseases (IBD), Crohn Disease (CD) and Ulcerative Colitis, are characterized by an increase of the intestinal permeability, a feature that is associated with the development of clinical manifestations and the progression of the disease.

Aims & Methods: The aim of this prospective study was to evaluate the effects of a 6-week low fermentable Oligosaccharides, disaccharides, monosaccharides and polyols (FODMAP) diet on disease activity and quality of life in patients with IBD. At first visit (T0), patients were clinically evaluated by a gastroenterologist and a nutritionist, filled a questionnaire on quality of life (the IBD-Q) and underwent blood tests as well as fecal calprotectin assessment. Disease activity was defined using the Mayo score and the Harvey Bradshaw Index (HBI) for UC and CD, respectively. After the baseline visit, patients were randomized into two groups: A) patients underwent a low FODMAP diet; B) patients underwent a diet with normal FODMAP amount. A food diary was used to assess patients’ adherence to the different diets. After six weeks (T1), patients had a second visit to assess disease activity, complete the IBD-Q, and repeat blood tests as well as fecal calprotectin assessment.

Results: In this prospective, interventional, cohort study, we enrolled 55 consecutive IBD patients who agreed to participate from an initial cohort of 127 IBD patients. Twenty-six patients were randomised to a low FODMAP diet (group A), while 29 patients to a standard FODMAP diet (group B). Among CD patients (n = 35, 63.6%), median HBI values significantly decreased during the study, in the whole population and in group A, whereas no change was recorded in group B (respectively P = 0.02; P = 0.02; P = 0.3). Among UC patients (n = 28, 36.4%), median Mayo scores did not significantly decrease during the study, both considering the whole population and the two groups (P = 0.3, P = 0.3, and P = 0.8, respectively). Moreover, despite no statistically significant difference in quality of life in both groups at T0, in group A quality of life improved after the diet compared to group B (respectively, P = 0.06, P = 0.05 and P = 1).

Conclusion: We demonstrated that a low FODMAP diet, for a limited period of 6 weeks, is able to improve both disease activity, at least for CD, and quality of life in IBD patients. Further, larger multicentre studies are needed to confirm these preliminary data.

Introduction: There are currently no FDA-approved agents to specifically treat IBD and the treatment options for IBD are limited. For moderate to severe disease, immunosuppressive agents and biologic agents are used. There are currently only three FDA-approved biologics for IBD: Infliximab (IFX), Adalimumab (ADA) and Ustekinumab (UST). IFX is used for moderate to severe Crohn’s disease and ADA is used for moderate to severe ulcerative colitis.

Aims & Methods: This retrospective study included all children with UC from a national pediatric registry who received ADA therapy. The primary endpoint was the rate of corticosteroid (CS) free remission (PUCAI ¼ 0). Secondary outcomes were: the rate of continuous clinical response and remission, primary non-response and loss of response at Weeks 12, 30 and 52, and rate of mucosal healing (MH) at week 52.

Results: A total of 32 children with UC received ADA (median age 10 ± 4 years). Median disease duration before ADA therapy was 27 months. All patients received previous IFX therapy (43% intolerant, 50% non-responders, 7% positive anti-IFX antibodies). Fifty-two weeks after ADA initiation 13 patients (41%) were in CS-free remission. MH occurred in 9 patients (28%) at week 52. The cumulative probability of clinical relapse-free course was 69%, 59% and 53% at 12, 30 and 52 weeks, respectively. Ten patients (31%) had a primary failure and 5 (15%) loss of response to ADA. No significant differences in terms of efficacy were reported between non-responders and intolerant to IFX (p = 1.0). Overall, 19 patient (59%) maintained ADA therapy during 52-week follow-up. Seven patients (22%) experienced an adverse event. No serious side effects were observed and none resulted in ADA discontinuation.

Conclusion: In this cohort of children with UC who received ADA, the response rate was comparable to previous studies where the response rate was reported to be 50-60%. The rates of MH at week 52 were in line with previous studies. Overall, 19 patient of 32 (59%) maintained ADA therapy during 52-week follow-up. These data suggest that ADA is an effective and safe drug for children with UC, with a favorable short- and long-term safety profile.

Biotherapies

Reasons for anti-TNF discontinuation

Primary inefficacy Allergy to IFX Loss of efficacy Loss of efficacy Primary inefficacy Allergy to IFX Primary inefficacy to Ada

From January 2015 to May 2016, twelve CD patients were treated with ustekinumab, all because of failure of several lines of therapies including anti-TNF antibodies. All but one patient were followed at least one year. An initial response was observed in 9/12 patients, and remission in 5/12 (42%). At one year, the patients were still receiving ustekinumab with clinical benefit and without side effects. Seven of them (58%) were on clinical remission. One patient experienced a serious adverse event and the treatment was stopped after the first injection.

P1071 INFliximab INDUCED PSORIASIS IN A COHORT OF CHILDREN WITH INFLAMMATORY BOWEL DISEASE: A 12 YEARS FOLLOW-UP STUDY

C. Martinez-Vinson, O. Courbette, C. Aupiais, J. Viala, J. Hugot
Gastroentérologie Pédiatrique, Hôpital Robert Debré, Paris/ France
Contact E-mail Address: christine.martinez-vinson@aphp.fr

Introduction: In adult Inflammatory bowel disease (IBD), skin adverse reactions have been observed in prevalence of 1.6 to 22%. This side effect occurs more fre-quently in patients treated with infliximab (IFX) for IBD. Datass in the pediatric population are lacking so far.

Aims & Methods: All patients aged 2 to 18 years, with Crohn’s disease (CD) or Ulcerative colitis (UC) and treated for the first time by IFX between January 2002 and March 2014, were considered for inclusion in this monocentric retro-spective study.

Results: Basline Patients: 115 patients were treated with IFX for CD and 23 for UC. IFX treatment was initiated at the age of 14, about 2 years after diagnosis. The indication for treatment was in 61.6% (n = 85) resistance to conventional therapy, in 26.8% (n = 37) a perianal fistulizing disease and in 11.6% (n = 16) a severe colitis. At the first injection, the median PCDAI was 35 (25; 45) for CD and the median PUCAI 35 (25; 45) for UC. The duration of treatment with IFX ranged from 45 days to 8 years and median was 23.9 months (11.6; 36.5).

Psoriasis: 20 patients (14% of the cohort) had an IFX-induced psoriasis. 70% of them (n = 14) of patients were in remission when the psoriasis was diagnosed. Psoriasis was diagnosed at the 8th injection (6; 15), though 355 (239; 523) days after the start of biotherapy. 20% of patients had a combo therapy: 50% of them were treated by 6-mercaptopurine, 25% by azathioprine and 25% by methotre-xate. The median IFX trough levels (TRI) when psoriasis occured was 4.7 mcg/mL

Conclusion: 14% of our IBD patients treated with IFX developed psoriasis during follow-up. All were CD, more frequently it occurred for CD with perinidal lesions, at the 8 injection in median, with no ATI.

P1072 PLATELET ABNORMALITIES AND ANEMIA IN PAEDIATRIC IBD: ARE THEY LINKED?

M. Votto 1, F. Viviano 2, F. Viola 2
1Pediatria, IRCCS Policlinico San Matteo, PAVIA/Italy
2Pediatria E Neuropsichiatria Infantile, Università La Sapienza, Roma/Italy
Contact E-mail Address: martina_votto@gmail.com

Introduction: Crohn’s Disease (CD) and Ulcerative Colitis (UC) are two major forms of Inflammatory Bowel Disease (IBD). In children with IBD anemia is common and is a combination of iron deficiency and anemia of chronic disease (ACD). IBD are associated with several alterations of platelets, including number, shape, and function.1 In clinical practice, the most common platelet alteration is thrombocytosis. In IBD, thrombocytosis is associated with iron deficiency anemia and chronic inflammation.2 The platelet function is disturbed due to the substantially increased incidence of thromboembolic phenom-en in IBD 3

Aims & Methods: The aim of the study is to demonstrate the link between anemia, thrombocytosis and platelet aggregation in pediatric IBD patients.

This study includes 51 children and adolescents treated from the Pediatric Gastroenterology Unit of Policlinico Umberto I in Rome. Patients younger 6 years, with inherited platelet defects, hemoglobinopathies, and receiving thera-pies that alter platelet function, are excluded. We collect disease activity scores (Pediatric Crohn’s Disease Activity Index [PCDAI], Pediatric Ulcerative Colitis Activity Index [PUCAI]). The laboratory investigations include: complete blood count, mean corpuscular volume (MCV), mean platelet volume (MPV), mean corpuscular haemoglobin concentration (MCHC), levels of hemoglobin (Hb) and reticulocytes, portal venous pressure, platelet aggregation. Diagnostic criteria for anemia are based on ECOO guidelines. Platelet aggregation is evaluated on platelet-rich plasma in an AggRAM aggregometer with Born’s Method. The results were reported as the maximal percentage of aggregation observed after 4 min stimulation in response to collagen (1 μg/mL) and adenosine diphosphate (ADP 0.8 μM and ADP 2 μM).

Results: The study include 51 children and adolescents, 24 with UC and 27 with CD. Median age of the study population is 15.3 years (4.3–10.0). Iron deficiency anemia combined to ACD is the most common type (53.6% in UC and 50% in CD). Hemoglobin levels are significantly lower in patients with UC compared to CD patients (p = 0.0320). No significant differences are observed between mean values of red cells, MCV, MCHC, RDW, iron, transferrin and serum ferritin both in CD and UC. Thrombocytosis prevails in UC compared to CD patients, but no significant correlation was found. No differences are observed between mean values of PDW and MPV in both groups. In patients with UC, a negative correlation was found between mean values of hemoglobin and platelet count (p = 0.0134). Moreover in patients with CD, disease activity was positively correlated with platelet count (p = 0.0040). Platelet aggregation results higher in anemic patients. In anemic children, mean baseline platelet aggregations - induced by ADP 0.8 μM and collagen 1 μg/mL - are significantly higher in UC compared to CD (p = 0.001 and p = 0.030 respectively). No significant correlation is observed between platelet aggregation - induced by ADP 0.8 μM and ADP 2 μM - in anemic UC patients compared to non-anemic UC patients (p = 0.002 and p = 0.040 respectively). Platelet aggregation – induced by ADP 0.8 μM is sig-nificantly higher in anemic UC patients with active disease (PUCAI > 20) com-pared to same patients whose disease is in remission (p = 0.042) and compared to patients with active CD (p = 0.054).

In our cohort, mixed anemia (iron deficiency anemia combined to anemia of chronic disease) is the most common type of anemia. Thrombocytosis is a condition more frequent in anemic IBD patients, specially in UC. In UC, anemia and disease activity are significant correlated with platelet hyperaggrega-tion.5 Moreover in patients with Crohn’s disease may require withdrawal of anti-tumor necrosis factor ther-apy. Inflamm Bowel Dis 2013; 19: 75–7.

P1073 RELATIONSHIP BETWEEN CLINICAL COURSE OF ULCERATIVE COLITIS (UC) DURING PREGNANCY AND OUTCOMES OF PREGNANCY: A RETROSPECTIVE EVALUATION STUDY
A. T. O. Teppeli, T. Katutishi
Dept. Medicine, Inst. Gastroenterology, Tokyo Womens Medical University, Tokyo/Japan
Contact E-mail Address: itoayumi@ige.twmu.ac.jp

Introduction: Ulcerative colitis (UC) is a chronic, intractable disease with a long clinical course. UC has a marked influence on the lifestyle of patients, and its effects on pregnancy and child birth can especially become a problem for women in their child-bearing years. Various studies have suggested that it is desirable for pregnant women with UC to give birth while remaining in a state of remission.

Aims & Methods: The present study evaluated pregnant women with UC attending our hospital who became pregnant during remission, in order to examine the factors that contributed to recurrence of UC during pregnancy. We investigated 40 pregnant patients in remission (44 cases) attending our hospital between January 2008 and July 2016 who had remained in remission for one year prior to pregnancy. After becoming pregnant while in remission, patients who stayed in remission until delivery were classified into the ongoing remission group (35 cases) and patients with recurrence during pregnancy were classified into the recurrence group (9 cases). Remission was defined as a Lichtiger clinical activity index (CAI) of less than 4. Relapse was defined as a CAI ≥ 5 with the need for initiation or dose escalation of steroids or administration of biological agents during pregnancy. Items examined: Clinical characteristics (age at onset, disease duration, age of becoming pregnant, disease type, and treatment), the CAI in the first, second, and third trimesters, and whether or not patients continued treatment during pregnancy were examined and compared between the two groups. The reasons for discontinuation of treatment were also investigated.

Results: There were significant differences between the two groups with respect to the age of becoming pregnant (32.9 ± 4.4 years in the ongoing remission group vs. 28.3 ± 7.0 years in the recurrence group), the CAI in the second trimester (2.9 ± 4.6 vs. 3.5 ± 4.6), the CAI in the third trimester (2.9 ± 0.7 vs. 5.4 ± 2.0), and whether oral treatment was continued (continuation of treatment [yes/no]: 30/5 in the ongoing remission group vs. 5/4 in the recurrence group). Regarding the discontinuation of oral treatment, two patients in the ongoing remission group and one patient in the recurrence group discontinued it on their own judgment, while two patients in the recurrence group discontinued it due to hyperemesis. Discussion: The present study revealed that factors influencing the recurrence of UC during pregnancy were the age of becoming pregnant and the continuation of oral treatment. Our results showed that younger women were more susceptible to recurrence. As expected, discontinuing oral treatment was a factor that contributed to recurrence. However, the reasons for discontinuing treatment during pregnancy differed from those for non-pregnant women. Some patients discontinued treatment on their own judgment because they were concerned about adverse effects on the fetus, while others had difficulty with continuing treatment due to hyperemesis. With regard to the effects of medications on the fetus, medical staff discussed their treatment options with their patients and allowed them to make their own judgments.
GMA sessions continued with GMA while non-responders received GMA in combination with a low dose prednisolone (0.5 to 1.0 mg/kg bodyweight). At week 12, patients were clinically and endoscopically evaluated with each patient serving as her or his own control.

**Results:** At entry, 30 patients were corticosteroid naïve and none had deep colonic lesions or extensive loss of the mucosal tissue at the affected sites (GMA non-responders features). Ten patients achieved stable remission with the first-line medications and did not receive GMA. Six patients did not respond well to the first 5 GMA sessions and received prednisolone together with GMA, while 12 patients responded well to GMA, and achieved stable remission, but 2 patients withdrew to receive high dose prednisolone (up to 2 mg/kg bodyweight). At entry, the average BMI was 14.6±0.4. Prednisolone was tapered to 0 mg within 3 months in those who received. Therefore, at week 12, all 30 patients were in remission, majority with mucosal healing.

**Conclusion:** In this treatment design, GMA in young corticosteroid naïve patients with active UC refractory to the first-line 5-aminosalicylates was associated with clinical remission and mucosal healing, while in non-responders to GMA monotherapy, addition of a low dose prednisolone resulted in the efficacy of GMA and tapering of the prednisolone dose was not associated with relapse. Therefore, the majority of young steroid naïve UC patients who fail to respond to first-line 5-aminosalicylates should respond well to GMA and avoid pharmacologicals. Additionally, GMA has a good safety profile, which is a very favourable feature in growing patients.

**P1076 EARLY SCREENING FOR INFLAMMATORY BOWEL DISEASE IN CHILDREN WITH AUTOIMMUNE LIVER DISEASE**

D. Thanagarajah, E. Cernat, B. Vadamalayan, D. Hadzic, M. Samyn Paediatric Liver, GI And Nutrition Centre, King’s College Hospital, London, UK

**Contact E-mail Address:** anthiburri@gmail.com

**Introduction:** Autoimmune liver disease (AILD) is a major source of TNF. J Immunol 2002;168:3556-42.

**Aims & Methods:** The aim of this study was to review the investigations and outcomes of IBD and AILD in children with a primary diagnosis of AILD and to identify possible risk factors for development of IBD in children with AILD. Children with AILD were identified from electronic case notes between 2007 and 2010 and those with a diagnosis of IBD prior to AILD excluded. AILD was diagnosed and treated as per centre protocol. Diagnostic endoscopy for IBD was performed, based on GI symptoms and/or elevated FC (>60/μl). Data were derived at time of liver diagnosis; endoscopy and last liver follow up. Patients were classified as AILD-IBD or AILD-Mann Whitney and Chi squared test were used to analyse data where appropriate, significance p < 0.05.

**Results:** Out of 37 (12 male) children, diagnosed with AILD (ASC 11), 23 underwent diagnostic endoscopy after a median time from diagnosis of 27.6 [20.1 to 53.9] weeks. 20/23 reported GI symptoms and FC was elevated in 13/18 tested. At endoscopy 57% (13/23) a diagnosis of IBD (AILD-IBD group) (UC (n = 12), UC-BU (n = 1)) was made, 10/23 were within normal limits (AILD group). There was no difference in gender or diagnosis of ASC between the 2 groups. At presentation of AILD, children in the AILD-IBD group were significantly leaner in terms of weight and BMI, had lower haemoglobin, with a trend for younger age at presentation (table 1). GI symptoms and FC > 60/μg were significantly more prevalent in the AILD-IBD group. At the time of endoscopy, 22 were on treatment for AILD with prednisolone and 13 with an additional agent (azathioprine or mycophenolate mofetil). Biochemical remission for AILD was achieved in 45% at endoscopy and in 74% at last liver follow-up (median 4 [3.5 to 5.0] years) with no difference for both groups. All patients are alive; however, in the AILD-IBD group 1 underwent an isolated liver transplantation (LT) and 1 required a subtotal colectomy. One girl underwent LT combined with subtotal colectomy after decomposition of her liver disease.

**Table 1:** Diagnostic parameters of AILD at presentation median [IQR] p value < 0.05

</tbody>
</table>

**Conclusion:** In our cohort 35% of children presenting with AILD were subsequently diagnosed with IBD. Possible risk factors for development of IBD in AILD are low haemoglobin, being leaner and younger at diagnosis. An elevated FC and the presence of GI symptoms are useful to assess the need for diagnostic endoscopy when considering diagnosis of IBD in the context of AILD. As concurrent immunosuppression may mask mild symptoms and signs of IBD a lower threshold for endoscopy should be considered in these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Results: Twenty-one patients with chronic refractory angiodysplasia bleeding were recruited in this study, included 10 women, aged between 40-85;11 cases of male, aged between 31–70. One patient with colic vascular malformation died of massive hemorrhage due to self-withdrawal. Among the remaining 20 patients who were given thalidomide regularly for 6 months. (1). Eighty patients come across constipation, sleepiness and dry mouth. There were no skin rashes, peripheral neuropathy and any other adverse reactions during the treatment. All side-effects resolved when thalidomide was discontinued. (2). The red blood cell after treatment (3.70±0.56×10¹²/L), total procedure time and EDSL procedure time were 40 (15-150) and 4 (1–57) min, respectively. The identification rate of bleeding diverticulum was 60% (123 in 205 enrolled patients). Two mild adverse events occurred; colonic diverticulitis cured with antibiotics and temporary abdominal pain during EDSL.

Conclusion: EDSL is an effective, safe, and convenient treatment method for colonic diverticular hemorrhage.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1080 RISK FACTORS FOR EARLY AND LATE RE-BLEEDING IN PATIENTS WITH COLONIC DIVERTICULAR BLEEDING

Gastroenterology And Hepatology, St. Marianna Medical University, Kawasaki/ Japan

Contact E-mail Address: y2sato@ marianna-u.ac.jp

Introduction: Incidence of colonic diverticular bleeding has increased in recent years. Colonic diverticular bleeding is problematic because of the following reasons: low detection rate of the bleeding source by endoscopy and frequent re-bleeding. At our hospital, we have a policy of performing emergency lower gastrointestinal endoscopy for all patients with colonic diverticular bleeding within 24h of their admission. We have reported that the following factors contribute to the successful identification of the bleeding source: extravasation revealed by abdominal contrast computed tomography (CT), and mounting of a hood to the tip of an endoscope during lower gastrointestinal endoscopy. However, risk factors for re-bleeding in patients with colonic diverticular bleeding were still unknown.

Aims & Methods: In this study, we examined the risk factors for early and late re-bleeding in patients with colonic diverticular bleeding. From January 2004 to April 2016, we admitted 432 patients (285 men and 147 women, mean age: 71 ± 13 years) to our hospital for treatment following a diagnosis of colonic diverticular bleeding based on abdominal CT and endoscopy findings. Early and late re-bleeding was defined as macroscopically bloody stools as a result of colonic diverticular bleeding during hospitalization and after discharge, respectively. Risk factors for early and late re-bleeding were retrospectively examined using univariate and multivariate analysis.

Results: Early re-bleeding occurred in 112 patients (26%; 86 men and 26 women, mean age: 71 ± 12 years). The mean duration until early re-bleeding was 3.9 ± 2.4 days, and on average, early re-bleeding recurred 1.7 ± 1.2 times. On average, lower gastrointestinal endoscopy was performed 2.7 ± 1.2 times and endoscopic hemostatic treatment was performed 1.0 ± 1.0 times. In the univariate analysis, significant differences were seen in males (P = 0.005), in the use of oral antiplatelet agents (P = 0.012), and in patients not undergoing endoscopic hemostasis (P = 0.004). In the multivariate analysis, male gender (P = 0.006; odds ratio 2.06, 95%CI 1.23–3.44), the use of oral antiplatelet agents (P = 0.008; odds ratio 1.85, 95%CI 1.17–2.93), and patients not undergoing endoscopic hemostasis (P = 0.005; odds ratio 1.5, 95%CI 0.31–8.01) were independent risk factors for early re-bleeding. Late re-bleeding was seen in 72 of 345 patients who were able to follow up (21%; 46 men and 26 women, mean age: 73 ± 12 years). The mean duration until late re-bleeding was 41 ± 40 months, and on average, late re-bleeding recurred 1.5 ± 1.2 times. Only the use of oral antiplatelet agents (P = 0.05; odds ratio 1.72, 95%CI 0.98–2.98) was identified as an independent risk factor for late re-bleeding in the univariate and multivariate analysis.

Conclusion: Not undergoing endoscopic hemostasis and male gender were identified as risk factors for early re-bleeding, indicating the importance of choosing measures and hemostatic treatments to improve the detection rate of bleeding sources during endoscopy. The use of oral antiplatelet agents was a risk factor for both early and late re-bleeding, suggesting the need for patient management through multi-departmental cooperation.

P1081 ACUTE LOWER GASTROINTESTINAL BLEEDING—IS NOBLADS THE ANSWER?

Xavier S., J. Magalhães1, J. Cotter3
1Life and Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga/Portugal
2Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Portugal
3Pt Government Associate Laboratory, 4 ICVS/3B’s, Braga/Guimarães/Portugal
Contact Email Address: smxavier@gmail.com

Introduction: Acute lower gastrointestinal bleeding (ALGIB) constitutes an important gastroenterological emergency. A new score (NOBLADS) that intends to determine the risk of severe ALGIB was recently developed. We aimed to assess the validity of this score in a cohort of patients with ALGIB.

Aims & Methods: Retrospective study. Emergency consecutive admissions for ALGIB were reviewed. Severe ALGIB was defined as transfusion of ≥2 units of packed red blood cells (PRBC) and/or hematoctrit decrease of ≥20% within the first 24 h and/or recurrent bleeding after 24 h of stability. NOBLADS score was calculated and its discriminative capacity for severe ALGIB as well as for outcome was assessed.

Results: Included 118 patients with a mean age of 73.4±14.4 years and 52.5% males. Most frequent etiologies for ALGIB were diverticular bleeding (23.7%) and post-polypectomy (21.2%). ALGIB was severe in 38.1% of patients. NOBLADS score showed a weak discriminative capacity to determine severe ALGIB (AUC = 0.68, P < 0.01). However, when comparing patients with NOBLADS <4 and ≥4, patients with higher scores were significantly older (69.2±15.7 years vs 78.6±10.0 years, P < 0.01), had lower hemoglobin levels as admission (11.8±2.6 g/dL vs 10.2±2.5 g/dL, P < 0.01), were transfused with more units of PRBCs during the first 24 h and during hospital in-stay (0.4±0.9 vs 1.1±1.3, P < 0.01 and 1.0±2.2 vs 5.0±3.3, P < 0.01, respectively) and were more frequently admitted to intermediate care units (35.2% vs 59.6%, P < 0.01). No differences were found between the two groups regarding in-stay length, rebleeding rate, need for surgery or death.

Conclusion: NOBLADS score showed a weak discriminative capacity to determine severe ALGIB however, patients with NOBLADS ≥4 had greater PRBCs transfusion need and were more frequently admitted to intermediate care units. New or improved scores that can predict severe ALGIB are needed to determine more precisely appropriate care and to allow for a standardized approach.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1082 COLORECTAL CANCERS (CRCs) DEPENDING ON THE SCREENING INTERVAL IN IBARAKI, JAPAN

Y. Saitoh1, H. Hyodo, H. Suzuki, M. Kaneko
Dept. of Gastroenterology, Ibaraki Medical Center, Ibaraki, Japan
Contact E-mail Address: saitoitsyo@yahoo.co.jp

Introduction: In Japan, CRC screening was launched as a national policy for all people aged over 40 years in 1992. 2-day FIT has been widely accepted, and has been recommended performing in every year. We will show so much data on fecal hemoglobin concentration (referred as concentration) and progress of colorectal cancer among them.

Aims & Methods: The aim of this study is to analyze the concentration of FIT for colorectal cancers (CRCs) from the screening. The cut off value is adapted 20 μg Hb/g stool and the rate of further examination is around 75% for many years. In Ibaraki prefecture, CRCs were detected 3,421 cases from the screening (2000-2014) with 2-day FIT. The concentration of FIT was grouped in 20–80, 80–140, 140–200 and over 200 μg Hb/g stool. Screening have been performed with the OC-SENSOR DIANA (EIKEN, JAPAN) automated analyzer. CRCs were analyzed with age group (40–49, 50–59, 60–69, over 70 year-old), size (1–24, 25–49, over 50 mm), location(proximal, distal), Dukes’ classification(Dukes A, M, invasive, B, C, D) depending on the concentration. The chi-squared test was used to compare of each group.

Results: There was no difference in gender and age group for concentration. The concentration of CRCs in the distal colon was significantly higher in the proximal colon [distal 39% (861/2,200) and proximal 32% (337/1,053) with over 200 μg Hb/g stool]. The concentration of CRCs with larger size was significantly higher than smaller size [1–24 mm 27% (533/1,961), 25–49 mm 54% (439/818) and over 50 mm 64% (169/263) with over 200 μg Hb/g stool]. The concentration of invasive CRCs was significantly higher than intra-mucosal CRCs (infra-mucosal 23% (370/1,617) and invasive 30% (888/1,793) with over 200 μg Hb/g stool). The concentration of Dukes B, C and D were significantly higher than Dukes A except for intra-mucosal. There was no difference between Dukes B and D [Dukes A except for intra-mucosal 36% (325/910), B 68% (247/363), C 60% (232/385) and D 69% (61/89) with over 200 μg Hb/g stool].

Conclusion: In 20–30 μg Hb/g stool, there were CRCs with smaller size, no invasion, in the proximal colon, Dukes A except for intra-mucosal CRCs and so on. When the cut off value is raised over 80 μg Hb/g stool, the detection of early stage CRCs and proximal CRCs may be lost. There were many advanced CRCs with concentration over 200 μg Hb/g stool. Therefore, when the participants, who are positive with high concentration of FIT, need to take a further examination as soon as possible. Why concentration of CRCs in the distal colon were higher than in the proximal colon? It may be related to the fact that the number of detectable CRCs in the distal colon are more than in the distal colon. We will go on researching mechanism about this.

Introduction: Hodgkin lymphoma (HL) survivors treated with abdominal radiotherapy and/or alkylating chemotherapy have an increased risk of colorectal cancer. This study evaluated the prevalence of colorectal neoplasia in HL survivors.

Aims & Methods: The primary aim of this multicenter cohort study was to assess the diagnostic yield of advanced colorectal neoplasia detected by a first surveillance colonoscopy among HL survivors treated with abdominal radiotherapy and/or procarbazine. Advanced colorectal neoplasia was defined as an advanced adenoma (high-grade dysplasia, ≥25% villous component, or ≥10 mm diameter), an advanced serrated lesion (dysplasia or ≥10 mm diameter), or CRC. Results were compared with a first colonoscopy in a general population cohort that underwent a primary screening colonoscopy (n = 1276 asymmetrical individuals between 50–75 years of age). This study demonstrates the results of a predefined interim analysis.

Results: A colonoscopy was performed in 101 HL survivors, who were significantly younger than general population controls (median 51 years (interquartile range 45–57) vs. 60 years (interquartile range 55–65), p < 0.001). A mean of 3.5 neoplastic lesions was detected per HL survivor (standard deviation 4.9) vs. 1.1 per control (standard deviation 1.8, p < 0.001). Despite their young age, the prevalence of advanced neoplasia was higher in HL survivors than in controls (25% (95% confidence interval 16–33%) vs. 12% (95% CI 6–18%), p < 0.001). Advanced adenomas were detected in 14% (8–21%) of HL survivors and 9% of controls (7–10%, p = 0.001). The prevalence of advanced adenomas was higher in HL survivors than in controls (12% (6–18%) vs. 4% (3–5%), p < 0.001). Serrated polyposis syndrome was present in 6% (2–11%) of HL survivors and 1% (0–1%) of controls (p < 0.001). Advanced serrated lesions were more often detected in the left side of the colon (12% (6–18%) vs. 4% (3–5%), p < 0.001). Serrated polyps were more prevalent in advanced colorectal neoplasia. Colorectal surveillance should therefore be implemented as standard of care.

Conclusion: HL survivors treated with abdominal radiotherapy and/or procarbazine have a high prevalence of advanced colorectal neoplasia. Colonoscopy surveillance should therefore be implemented as standard of care.

Aims & Methods: We aim to investigate the incidence of prostate cancer as a second primary malignancy among patients with prior primary colorectal cancer (CRC) using a nationwide population-based dataset. This study is a nationwide population-based retrospective cohort study. We followed up patients registered in the Republic of Korea National Health Insurance Corporation who were diagnosed with colorectal cancer (CRC) between 2007 and 2014 and investigated the incidence of prostate cancer (one year lag period). The incidence of prostate cancer was also evaluated in age and gender-matched controls using a cohort of patients diagnosed with colorectal cancer during the same period. The incidence rate was defined as the number of newly diagnosed prostate cancer patients per 1000 person-years. To assess the role of detection bias-related to the follow-up of CRC, follow-up started at the date of CRC diagnosis and continued until the earliest date of prostate cancer diagnosis, death, loss to follow-up, or the 2015 end of follow-up. We used Cox proportional hazards models to identify prostate cancer occurrences among CRC patients. We also performed the multivariable analysis. Multivariable models included the variables of age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income.

Results: We analyzed a total of 85,462 first primary CRC survivors. During the follow-up period of 494,222 person-years, 2005 (2.3%) developed prostate cancer (incidence rate 4.06/1,000 person-years). The median duration of follow-up was 5.78 years. Compared with the general population, CRC patients had a significantly increased risk of prostate cancer (HR = 2.30, 95% CI = 2.182–2.426; P < 0.001). Multivariate analysis (including age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income) showed that age ≥55 years (HR = 20.85, 95% CI = 11.88–36.59; P < 0.001) is a significant independent predictor of prostate cancer.

Conclusion: Men who develop colorectal cancer are at an increased risk of prostate cancer, with the greatest risk in men under the age of 55. This data suggests that CRC patients under 55 years old require regular screening for prostate cancer.

Introduction: This study was conducted within a Dutch national colorectal cancer (CRC) mortality, screening has been introduced. Screening can be beneficial if cancers are detected in an earlier stage or in a pre-malignant stage, as survival rates of these patients will improve.

Aims & Methods: In this study stage distribution of screen detected CRCs were compared with clinically detected CRCs in the Netherlands. All CRCs detected in men and women aged 55 to 75 years in the Netherlands in 2015 were included in the analysis. Data were gathered from the Dutch Cancer Registry. The current analysis is based on 70% of these cancers that had staging information available at initial data retrieval. Data will be updated in May 2017. Proportions of site and stage distribution of screen detected and clinically detected CRCs were compared.

Results: A total of 6,517 CRCs in 2015 with staging information were available for the preliminary analysis. Of those, 2,591 (39.8%) were diagnosed as a result of CRC screening (screen detected), 3,463 (53.1%) presented with symptoms (clinically detected), 118 (1.8%) were detected during surveillance colonoscopy (p < 0.001) of CRC screening (screen detected), with two third of the cancers for the preliminary analysis. Of those, 2,591 (39.8%) were diagnosed as a result of CRC screening (screen detected), 3,463 (53.1%) presented with symptoms (clinically detected), 118 (1.8%) were detected during surveillance colonoscopy and/or procarbazine.

Conclusion: Screen detected cancers were more often diagnosed in an earlier stage (stage I and II) compared with clinically detected cancers, 1,687 (66.5%) and 1,557 (66.3%), respectively (p < 0.001). Screen detected cancers were more often diagnosed in the left side of the colon compared with clinically detected cancers, 46.2% vs. 31.5% (p < 0.001). Comparison of stage distribution by location showed that left sided cancers were most often diagnosed in an early disease stage with 59.0% of the CRCs in stage I or II, followed by the right sided cancers with 52.8% of the CRCs in stage I or II. The CRCs of the rectum were most often diagnosed in a late disease stage, only 39.4% in stage I or II. Table 1 shows the comparison of stage distribution by location and method of detection. With screening, 68.8% of the right sided cancers, 71.0% of the left sided cancers, and 56.5% of the rectum cancers were diagnosed in an early disease stage (stage I and II) which was all higher than clinically detected cancers (p < 0.001).

P1087 LOCATION AND SEX PREDOMINANCE OF MISMATCH REPAIR DEFICIENCY IN COLORECTAL CANCER FROM IVORY COAST DIFFER FROM ITS EUROPEAN COUNTERPART

L. Bienfait1, B. Doukoure2, N. D’Haene3, I. Salomoni4, P. Detmet4, L. Verset1
1Department Of Pathology, Erasme Hospital, Université Libre de Bruxelles, ULB, Brussels/Belgium
2Pathology, Université Félix Houphouet-Boigny, Abidjan/Côte d’Ivoire

Contact E-mail Address: lucie.bienfait@erasme.ulb.ac.be

Introduction: According to European and American series, 1-3 up to 20% of colorectal cancers are characterised by instability at microsatellite sites and have deleterious mutations in mismatch repair (MMR) genes (MLH1, MSH2, MSH6 and PMS2) or hypermethylation of the MLH1 promoter gene. MMR deficient colorectal cancers are predominantly found in the right colon. Although an increasing rate of colorectal cancer has been observed in many low- and middle-income countries including in West-Africa,2 data on epidemiology and biology of colorectal cancer in native Africans from this region are scarce.

Aims & Methods: We aimed to study the incidence of MMR deficiency in Ivory Coast and to compare the data with those from a tertiary center in Belgium. Immunohistochemistry for MLH1, MSH2, MSH6 and PMS2 was performed on paraffin-embedded tissue samples from 83 colorectal cancers (54% males) operated in Abidjan and from 343 colorectal cancers (48% males) from Erasme University Hospital in Brussels. Immunohistochemical staining was interpreted as normal or loss of expression.

Results: Colorectal cancer is occurring at a younger age in Ivory Coast compared to Belgium (median age: 53 vs. 66). In both populations, MMR deficiency was detected in 13% of cases (11 and 43 cases, respectively). Whereas MMR deficient cancers in Brussels were mainly found in women (26/43 i.e. 61%), only 3/11 (27%) of the MMR deficient cancers from the Abidjan series occurred in female patients. The predominant location of MMR deficient tumours was different between both series: in the Brussels patients group, MMR deficient tumours were mainly located in the right colon (33/43 i.e. 77%) whereas in the Abidjan group they were predominant (10/11 i.e. 91%) in the left colon. With regard to the involved proteins, 6/11 (55%) of the MMR deficient cases from Ivory Coast were characterised by loss of expression of MSH2 and MSH6 whereas this immunohistochemical staining pattern was observed in only 9/43 (20%) cases from Belgium.

Conclusion: Our pilot study revealed marked differences in presentation of MMR deficient colorectal cancer between the two geographic regions. In contrast to Europe, MMR deficient colorectal cancer in Ivory Coast is mainly found in male patients and in the left colon. Moreover, there are differences with regard to the involved mismatch repair proteins. Together with the younger age at presentation, these data suggest differences in epidemiology and biology of colorectal cancer in native Africans from West Africa compared to the European population.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Study findings confirmed that CRC screening was effective in reducing the number of oncological surgical oncology procedures particularly with regard to the distal colon and rectum. Data analysis showed that the screening seemed to accelerate reaching the peak rate in surgical procedures that took place in 2007. After that time point the number of operations began to fall as far as the distal colon was concerned (it fell by 37.3%). Finally our data suggest that the real benefit in reduction of oncological surgery procedures is due to the first screening colonoscopy.

P1090 ETHNIC VARIATION IN ADENOMA DETECTION IN THE UK FLEXIBLE SIGMOIDOSCOPY BOWEL CANCER SCREENING PROGRAMME

Dignoses Diseases Centre, University Hospital of Leicester NHS Trust, Leicester

United Kingdom

Contact E-mail Address: denniss.lim@uhl-tr.nhs.uk

Introduction: The NHS bowel scope screening programme was introduced in 2013 and all adults aged 55 invited for a ‘one-off’ flexible sigmoidoscopy followed by a colonoscopy if significant adenomas are detected. University Hospitals of Leicester Bowel Cancer Screening Centre serves an ethnically diverse community with approximately 25% of the population eligible for sigmoidoscopy screening being British Asian Indians and 45% being British Whites. Within the faecal occult blood based bowel cancer screening programme we have previously reported a lower polyp detection rate (PDR) and adenoma detection rate (ADR) in British Asians undertaking colorectal cancer screening compared to White British. This study aims to evaluate PDR, ADR, and cancer detection (CDR) in British Asian Indians taking part in the bowel scope screening programme.

Aims & Methods: Patients who underwent screening sigmoidoscopy between February 1st 2015 and 30th Feb 2017 were included. All individuals participating in screening sigmoidoscopy routinely report their self-selected ethnic origin. This database was cross referenced with the endoscopic and histology findings from the ‘Exeter’ online database. The findings in British Asian Indians were compared with British Whites.

Results: A total of 4287 patients underwent screening sigmoidoscopy over the 2-year period. 1169 individuals had polyps (500 adenomas). Overall polyp detection rate (PDR) was 1169/4287 (27.3%), adenoma detection rate (ADR) was 500/4287 (11.7%), hyperplastic polyps were 642/4287 (15%), sessile serrated lesions were 13/4287 (0.3%), and other polyps were 14/4287 (0.3%) (Inflammatory polyps 13, Juvenile polyp 1). Cancer detection rate was 6/4287 (0.14%). During the period studied, 359 British white individuals (82%) and 778 British Asian Indians were screened. Six cancers were detected in British White (0.14%). During the period studied, 3509 British white individuals (82%) and 778 (British Asian Indians 18%) were screened.

Conclusion: This study found no cancers and significantly lower PDR and ADR in British Asian Indians compared to British White participants in the bowel scope screening programme. Further long term evaluation of these differences is needed and may shed light on factors contributing to the development of bowel cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: inflyn@gmail.com

Introduction: We identified for the first time that DDXB (DEAD box polypeptide 27) gene was amplified in colorectal cancer (CRC) by whole genome sequencing. Amplification of DDXB was detected in 47% (47/100) of primary CRC tumors and positively correlated with its mRNA overexpression. DDXB plays a pivotal oncogenic role in colorectal carcinogenesis by promoting cell proliferation and inhibiting apoptosis. In this study, we investigate its function, mechanism of action and clinical implication in CRC.

Aims & Methods: Downstream effectors and pathways of DDXB were identified by promoter luciferase reporter assay, RT2 Profiler PCR array and western blot. The interacting partners of DDXB were screened by BioID method and further validated using immunoprecipitation assay and immunofluorescence staining method. Clinical implication of DDXB was assessed in two human CRC cohorts by quantitative PCR method and immunohistochemical staining of tissue microarrays.

Results: Promoter luciferase reporter assays revealed that DDXB mainly activated nuclear factor kappa B (NF-κB) pathway in CRC cell lines (HCT116 and SW480). Ectopic expression of DDXB promoted transcription of NF-κB signaling targets including BCL2A1, BIRC3, CCL20, CXCL13, NFKBIA, TNF and TNFAIP3. Conversely, silencing of DDXB showed an opposite effect on NF-κB signaling. Treatment of NF-κB inhibitors CAPE and JSH-23 abrogated the promoting effect of DDXB on CRC cells growth. We revealed that DDXB enhanced and prolonged NF-κB signaling via reducing the accumulation of nuclear IkBα, which negatively regulates transcriptional activities of NF-κB and transport NF-κB proteins back to the cytoplasm. DDXB overexpression markedly increased the recruitment of NF-κB p65 inside nuclear and promoted NF-κB activity in CRC cells under TNF-α stimulation. NPM1 was identified as a potential binding partner of DDXB by BioID method to screen for protein-protein interactions. The interaction of NPM1 and DDXB inside nucleus was further validated by endogenous immunoprecipitation assay and immunofluorescence staining. Knockdown of NPM1 abrogated DDXB-activating NF-κB signaling, as well as its tumor-promoting function. Kaplan-Meier curves showed that higher DDXB expression was significantly associated with shorter survival in patients with CRC of two independent cohorts (N=199 for Beijing cohort using quantitative PCR method, and N=275 for Shanghai cohort using immunohistochemical staining of tissue microarrays; both P <0.05).

Conclusion: DDXB plays an important oncogenic role in promoting CRC tumorigenesis via activation of NF-κB pathway. Higher expression of DDXB is correlated with poor prognosis in CRC patients.

P1092 CLINICO-PATHOLOGICAL STUDY OF SERRATED LESIONS OF THE COLORECTUM

M. Sugimura, M. Iwabuchi, K. Ukai

Gastroenterology, Sendai Medical Center Dept. of Gastroenterology, Sendai/Japan

Contact E-mail Address: msugimura@snh.go.jp

Introduction: Serrated lesions of the colorectum are the precursors of microsatellite unstable carcinomas. However, their clinical and pathological features are still unclear and need further evaluation and clinical implication.

Aims & Methods: The aims of this study was to clarify the clinicopathological features of serrated colorectal lesions. We reviewed clinical charts and pathology files of 3532 endoscopically resected specimens performed during January 2007 and December 2016 in our hospital. A total of 463 serrated lesions (8.7%) were classified into three categories: HP (hyperplastic poly), SSA/P (serrated adenomas/polyps), and TSA (traditional serrated adenoma), according to the WHO criteria. We examined the features of these cases and evaluate the morphological characteristics by using immunohistochemical staining for Ki-67 and the expression of MUCs (MUC2, MUC5AC and MUC6) in differentiating serrated lesions.

Results: Of these 463 lesions, a total of 241 (52.1%) were HP, 102 (22.0%) SSA/P, and 120 (25.9%) TSA. Male to female ratio (M/F) was 2.38 for HP, 1.09 for SSA/P, and 2.45 for TSA. Mean size of SSA/Ps (13.1 mm) and TSSAs (10.4 mm) were significantly larger than that of HP (8.1 mm) (p<0.005, respectively). SSA/Ps were located predominantly in the proximal colon, whereas HP and TSA were mainly located in the sigmoid colon and rectum. 84% of SSA/Ps were flat in macroscopic appearance. SSA/Ps and HPs were whitish or almost the same as adjacent mucosa in color, whereas SSA/Ps had a tendency to be reddish. Magnified colonoscopy showed Type II open pit pattern as characteristic of SSA/Ps, whereas pinecone-shaped pit pattern as that of TSSAs. Incidences of synchronous concomitant carcinomas in HP, SSA/P, and TSA were 0% (0 out of 241), 2.9% (3 out of 120), and 4.2% (5 out of 120), respectively. Ki-67 positive cells in HP showed regular, symmetric distribution, and those in SSA/P did irregular asymmetric pattern. Most of those cells in TSA distributed in focal so-called ectopic crypts. Expression levels of MUC2, MUC5AC and MUC6 were still unclear and need further exploration.
significantly different between serrated lesions, SSA/Ps and HPs were positive for MHC-II and CD80 and CD86 expression, while CD4 was low. Conclusion: Our studies showed the three types of serrated lesions have their own distinct features and could be helpful to distinguish between them. SSA/P and TSA are pre-malignant lesions of colorectum and we should detect these lesions and completely remove endoscopically.

Introduction: It is generally accepted that exosomes, small, membrane-bounded vesicles are formed in multivesicular bodies (MVBs) which fuse with plasma membrane resulting in the release of individual exosomes into the extracellular space. Recently, sporadic in vitro observations of a novel, unconventional mechanism have been reported in which the exosome-like vesicles remain in vesicle carrying secretory vesicles during their secretion.

Aims & Methods: Our aim was to examine this phenomenon in migrating colorectal cancer (CRC) cells in situ. Immunohistochemistry (IHC) examination of migrating, individual cancer cells was performed in surgically removed, metastatic CRC samples (n = 10). We used epithelial-specific cytokeratin (cytokeratin-8/18/C20) and cell membrane (E-cadherin) markers for the identification of migrating CRC cells as well as ALIX and CD63 proteins for the detection of exosomal transport. Samples were analyzed with confocal and stimulated emission depletion (STED) microscopy-based 3D reconstructions.

Results: 3D reconstructions showed ALIX-positive and CD63-positive exosome clusters (ECs) with 0.62 to 1.94 μm diameter (mean ± SD: 1.17 ± 0.34 μm) localized partially inside, and/or outside the cytoplasm in 85.96% (n = 98/114) of migrating CRC cells. E-cadherin-HC showed that ECs were not only captured during their exit from the cytoplasm and localized among plasma membrane proteins, but they were also detected extracellularly, in the plasma membrane-stroma interface. STED-microscopic images showed that released ECs were composed smaller, distinguishable ALIX-positive spheroids of 98 to 150 nm diameter (mean ± SD: 128.96 ± 16.73 nm), which fall into the size ranges of exosomes.

Conclusion: Our study demonstrates in situ for the first time that besides conventional exosome release, migrating CRC cells also secrete large, extracellular ECs. These structures might fundamentally contribute to the autocrine/paracrine regulation of cancer development, which effect may differ from that mediated by conventionally secreted exosomes.

Contact E-mail Address: arpad.patai@gmail.com

Introduction: We performed immunohistochemistry on intestines from ApcMin/+ mice, and ApcMin/+ mice and colorectal cancer biopsies and found that arginine metabolism is of utmost importance. In colorectal cancer tissue, intestinal organoids from APCfl/fl mice were transduced with a shRNA for ASS1. RNA and protein levels of ASS1 were measured by qPCR and western blot. Arginine concentrations were determined by HPLC. Protein synthesis was measured by [35S]-methionine labelling.

Results: ASS1 expression is highly increased in adenomas and hyperpliferative crypts during epithelial repair after mechanical wounding and irradiation wounds, compared to homeostasis. Variable expression of ASS1 is seen in different colorectal cancer cell lines, and expression correlates with resistance against arginine deprivation. In APC−/− organs derived from the APC−/− genotype, ASS1 RNA and protein are highly expressed, with concomitant increase of intracellular arginine. Upon knockdown of ASS1 in ApcMin/+ organs, arginine synthesis is reduced and organ growth is compromised. Furthermore, knockdown of ASS1 decreases overall protein synthesis. Conclusion: In a hyperproliferative state, intestinal epithelial cells synthesise arginine via ASS1. Our data suggests this plays a functional role to support growth and proliferation during intestinal carcinogenesis and repair.

Introduction: Toll-like receptors have a pivotal role in natural immunity but their role is indefinite and, sometimes controversial, in tumor development. TLR4 signalling through MyD88 has been linked to tumour growth and progression in mouse models, whereas in human TLR4/Myc signaling seems to correlate with colorectal cancer poor prognosis [1]. On the other hand, TLR4 signalling seems to be correlated to adaptive immunsurveillance in inflammatory related colonic carcinogenesis [2].

Aims & Methods: The aim of this study was to define the role of TLR4 in the immune surveillance mechanisms in a non-inflammatory model of colonic carcino-nogenesis. The azoxynemethane (AOM) induced colon carcinogenesis mouse model was used. Colonic mucosal samples were collected from wild type (WT) C57Bl/6 and TLR4 knock out (KO) mice before AOM administration (T0), at 4 and at 8 months after the first AOM injection. Colons were removed and examined for occurrence of adenoma and inflammatory infiltrate. Macroscopic tumor load was assessed counting the number of polyps. Flow cytometry on colonic mucosal single cell suspension was performed, 98 cells were counted to express CD25, CD38 or CD69, for CD4+ lymphocytes expressing CD25, CD38 or CD69, for CD4+ lymphocytes expressing CD25 or CD25 and Fop3 and for epithelial cells expressing CD80 or MHC-I or MHC-II were performed. Non parametric statistics was used.

Results: In TLR4KO mice sacrificed at 8 months, 1.4 polyps/mouse were observed whereas none was observed at T0 or at 4 months (p = 0.006). In TLR4KO mice at 8 months, the rates of epithelial cells expressing CD80, CD80+MHC-I+ and MHC-II+ were significantly lower than those at a T0 or 4 months (p = 0.01, p = 0.003, p = 0.003, p = 0.001, respectively). Moreover, at 8 months, 5/7 TLR4KO mice compared to 0/7 WT ones had at least a colonic adenocarcinoma (p = 0.02). At this time point, CD4+CD25+, CD4+CD25+FoxP3+, CD8+CD28+, CD8+CD38+ cells rate was significantly lower in TLR4KO mice than in WT ones (p < 0.001, p < 0.001, p = 0.01, respectively). Similarly, at 8 months the rate of epithelial cells expressing MHC-I and MHC-II were significantly lower in TLR4KO than in WT mice (p = 0.002, p < 0.001, respectively).

Conclusion: TLR4 deficiency significantly accelerates the progression of colonic carcinogenesis through a progressive decline of antigen presentation and lack of co-stimulation at later stages. These impairments are associated to a decline of T cell response in all its form (Treg, T helper and cytotoxic). All these findings are coherent with a pivotal role of TLR4 in the immune surveillance mechanism.

Introduction: Less than a hundred polyps defines attenuated familial adenomatous polyposis (AFAP). APC or MUTYH involvement has been described in 60% of the cases. The natural history of AFAP without identified genetic defects is not enough evaluated. In our study we compare clinical and endoscopic features of polyposis in patients carrying APC or MUTYH mutation and wild type patients.

Aims & Methods: 102 cases (35 F, 67 M; mean age 51; range 28–79) of AFAP were registered at our Institution between 1996 and 2014. They had no cancer family history and presented more than 10 adenomas at index colonoscopy. Genetic testing for APC and MUTYH genes was performed. Patients were put in a program, after having cleaned the colon, consisting in colonoscopy after one year and then the colonoscopic interval was based on the number of polyps from 1 to 3 years. Odds Ratio test was used to compare APC or MUTYH mutated and wild-type patients.

Results: Out of 102 patients with AFAP we identified a genetic defect in 36 patients (35.3%; 12 with APC and 24 MUTYH) and 66 (64.7%) were wild-type. The mean endoscopic follow up was 10 years (2–31) in the mutated group and 9.7 years (2–23) in the wild-type group. Table 1 describes endoscopic and clinical features between the two groups. We observed some statistically differences between groups: the mutated group was younger than 50 years of age with a higher number of polyps, right colon was mainly involved and endoscopic follow-up was mostly every year. On the other hand, 14% of mutated patients underwent colectomy during follow-up and they displayed few adenoma recurrences in 24% of cases. On the other hand 1% underwent colectomy in 2 years and 1% in 1 year. Odds Ratio test was used to compare APC or MUTYH mutated and wild-type patients.

Conclusion: We observed a different behavior between mutated and wild-type patients. Patients with genetic involvement still developed adenomas during the follow-up and some needed colectomy. Instead, wild-type patients had mostly no recurrence. Constitutional genetic background could be suspected in wild-type patients when a continuous development of new polyps has observed and further genetic investigation should be offered by multi-gene testing.

Introduction: Besides local hypermethylation on promoters of certain tumor suppressor genes, global DNA hypomethylation is characteristic in various types of cancers including colorectal cancer (CRC). The DNA methylation level of long interspersed nuclear element-1 (LINE-1) repetitive retrotransposon sequences constituting 17% of the human genome can be used to estimate global methylation level.

Aims & Methods: We aimed to analyze the alterations of the global DNA methylation levels along the colorectal normal-adenoma-carcinoma sequence progression on the basis of LINE-1 methylation and to study the methyl-cytosine pattern in tissue samples. Genomic DNA was isolated from 10 colorectal adenoma, 10 CRC and 30 normal colonic biopsy samples. Bisulfite conversion of DNA samples was performed using EZ DNA Methylation-Direct Kit (Zymo). For methylation level quantification of the LINE-1 retrotransposable element, bisulfite specific PCR (BS-PCR) was applied and 146 bp long PCR products were sequenced on Pyromark Q24 system (Qiagen). Tissue localization of 5-methylcytosine (5-mC) in normal, adenoma and CRC tissues was analyzed by immunohistochemistry using mouse monoclonal anti-5mC antibody (Genetex).

Results: According to the LINE-1 bisulfite sequencing results, significant (p < 0.01) global DNA hypomethylation was detected both in CRC (63 ± 8.7%) and adenoma samples (67 ± 5.1%) compared to normal tissue (72 ± 1.4%). 5-mC labeling of both the epithelial and stromal components of normal samples was strong (scoring values: +2 and +3) with diffuse and nuclear staining. In adenomas, decreased nuclear 5-mC staining (scoring value: +2) was detectable in the epithelium and the stroma compared to normal epithelium. In CRC samples significantly lower 5-mC levels could be observed than in normal tissue samples (p < 0.05).

Conclusion: Global DNA hypomethylation could be shown in CRC compared to healthy normal tissue samples both by LINE-1 bisulfite-sequencing and by 5-mC immunohistochemistry. Genome-wide DNA methylation decrease occurs already in adenoma stage of colorectal carcinogenesis.

Introduction: miRNAs have a critical relevance in regulation during tumorigenesis. The expression profiles of miRNAs alter along tumor progression moreover; these miRNAs may spread into tumor macro- and microenvironment.

(continued)
Extracellular miRNAs are stable and its expression is less characterized in plasma. Altered and overlapped miRNA profiles between tissue and plasma are less explored.

Aims & Methods: The present study was designed to characterize the tissue and circulating miRNA profile through colorectal adenoma-carcinoma sequence in human peripheral blood samples. The main purpose of our study was to determine the origin of detected miRNAs in tumor-associated C57BL/6 and non-tumor CBAJ mice tumor models. To achieve that goal, human peripheral blood and biopsy of normal (N), tubular (AT), tubulovillous adenoma (ATV) and colorectal cancer (CRC) were collected and plasma were also collected two times a week over 45 days from C57BL/6-c38, CBAJ mice. MiRNAs were isolated and Affymetrix GeneChip miRNA array analysis was performed for screening of the altered miRNA profile. RT-qPCR miRNA expression was performed.

Results: In the case of human samples out of 1373 detectable miRNAs, 306 miRNAs were expressed in normal, 334 in adenoma and 321 in CRC. Characteristic miRNA expression alteration was observed in the comparison of all CBAJ mice, C57BL/6-c38, CBAJ vs 1988 in plasma. In the case of N vs CRC, overexpression of miR-612, miR-1296, miR-933, miR-937 and miR-1207 was validated by RT-PCR (p < 0.05). Partial co-expression of these miRNAs was observed in tissue pairs as well. We identified high plasma levels of 94 miRNAs in 176 miRNAs in late tumor stages. Based on CBAJ-C38 mouse model experiment where the injected tumor cells could not adhere miR-676 found to be a host originated while miR-92a was a tumor-derived miRNA. MiR-676 and miR-92a shown significant overexpression (388 ± 373) and 94 ± 0.05) in plasma samples based on real-time PCR and microarray results.

Conclusion: Circulating miRNAs alteration could observe in animal models and in human system. Cancer-associated miRNAs in the circulation may originate from the immunological system or from other metabolites released far from the primer tumor location.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Colorectal carcinoma is one of the leading causes of cancer-related mortality worldwide. Tumor associated macrophages (TAMs) are critical stromal components intimately involved with the progression, invasion, and metastasis of cancer cells. Recently, increasing studies have demonstrated that microRNA-126 (miR-126) had an important role in colorectal cancer. The expression of miR-126 was decreased significantly in colorectal cancer, particularly in highly metastatic cell lines, indicating that miR-126 may inhibit tumor development and metastasis. However, the mechanism underlying miR126 inhibiting cancer is uncertain, and its function in cross-talk between colorectal cancer cells and TAMs is still in its infancy.

**Aims & Methods:** In this study, we investigate the cross-talk between cancer cells and TAMs in colorectal cancer microenvironment, and find out what role the miR-126-CXC12-IL6 axis plays in it. Method: (1) The effect of miR-126 on CXC12 expression was assessed in the CRC cell line Caco2 transferred with a miR-126 mimic or inhibitor to increase or decrease miR-126 expression; (2) We build a co-culture system of TAMs and transferred cancer cells, and use AMD3100 to block CXC12 expression, then detect the recruitment and inflammation factors secretion of TAMs; (3) Furthermore, the TAMs co-cultured before were taken away from the previous system and put into a new co-culture system with untreated colorectal cancer cells, and IL6 neutralizing antibodies were added. In. We detect the expression of EMT-associated factors and STAT3 pathway activation by western blot, cell growth by CCK8, metastasis by Transwell. The definition of statistical significance was defined as P < 0.05 (two-tailed).

**Results:** (1) miR-126 negatively regulate CXC12 expression in post-transcript level; (2) Inhibiting miR-126 of colorectal cancer cells could promote TAMs recruitment and up-regulate inflammation factors IL1β and IL6 expression. However, blocking CXC12/CXCR4 axis by AMD3100 could reverse this effect, via decreasing miR-126 of colorectal cancer cells recruiting TAMs, therefore down-regulate-Ecatherin protein, up-regulate-slug protein, and activate STAT3 pathway of untreated cancer cells. It could also promote cancer cells growth and metastasis. In addition, IL6 neutralizing antibodies could block this effect, vice versa.

**Conclusion:** Our results reveal a novel mechanism by that miR-126 repress recruitment and inflammatory factor secretion of TAMs through controlling secretion and paracrine signaling of CXC12 to inhibit colorectal cancer growth and metastasis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Narrow Band Imaging (NBI) enable detection for vascular-rich small, flat lesion and recognition of mucosal surface compared with normal colorectal mucosa and vascular pattern in colonoscopy. However, recent studies reported no significant difference in overall adenoma detection rate with the use of NBI compared with white light imaging (WLI). Blue Laser Imaging (BLI) is next-generation of image enhanced endoscopy technique using LASER light source that were realized with lighting and image processing suitable for visualization of microvessels and structures in the superficial portion of the mucous membrane.

**Aims & Methods:** Our aim was to determine whether the use of BLI enhances the adenoma detection rate (ADR) and miss rate compared with WLI. A total of 130 patients who underwent screening or surveillance colonoscopy in Saga University Hospital were included. Three patients were excluded because of poor bowel preparation. One hundred and twenty-seven patients were randomized to tandem colonoscopy with BLI followed by WLI (BLI-WL group) or WL followed by BLI (WL-WL group). Polyp (adenoma) detection rates, miss rates and the number of polyps (adenoma) detected per person (mean adenoma detection rate) were examined between the two groups.

**Results:** The BLI-WL group and WL-WL group comprised 64 and 63 patients, respectively. The proportion of patients with polyps (adenoma) was 62.5% in BLI-WL group compared with 63.5% in WL-WL group. There was no significant difference between two groups regarding ADR. The number of adenomas detected per person (ADR) of BLI-WL group and WL-WL group were 2.84 and 1.90, respectively. However, the polyp miss rate of BLI-WL group was less than that of WL-WL group (1.6% vs 10.0%; P = 0.0014).

**Conclusion:** There were no significant difference in the overall polyp (adenoma) detection rate with BLI-WL group or WL-WL group. However, miss rate was higher in WL-WL group compared with BLI-WL group (10.0% vs 1.6%, P = 0.0014). Further, BLI detected more polyps per patient compared with WL group (2.84 vs 1.90). BLI may improve polyp miss rate and the number of polyps per subject (mean adenoma detection rate) in the colonoscopy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Contact E-mail Address: rajan.patel@nhs.net

**Introduction:** The National Health Service Bowel Cancer Screening Programme (NHS BCSP) offers colonoscopy to people testing positive for Faecal Occult Blood Test (FOBT) after the age of 60. In addition, the ‘Bowel scope screening’ test offers once-only flexible sigmoidoscopy (FS) to people in the UK after the age of 55. The Norwegian (NORCCAP) and Italian (SCORE) trials evaluated the effectiveness of FS screening and reported a non-statistically significant decrease in colorectal cancer (CRC) specific mortality at follow-up. It is unclear if significant proximal neoplasia is being missed in people undergoing flexible sigmoidoscopy alone.

**Aims & Methods:** We aim to investigate the distributions of pathology within the BCSP at a busy district general hospital in London. In 2015, 22,539 FOBT kits were returned out of the 43,884 (51.4%) sent out in the boroughs of Barking, Havering and Redbridge (BHR). Of those returned, 398 (1.8%) tested positive. We collected data for the 326 patients who attended for colonoscopy at BHR University Hospitals (81.9%). Subgroup analyses included age, sex, histology, location of polyps, number of polyps, polyp size and therapies.

**Results:** Mean age 67, Male 60.4%. Polyps were found in 199 patients (61%), 488 polyps found in total, mean number of polyps 2.5 (Range 1–14), mean size 7 mm (Range 1 mm–60 mm), 49 (15.5%) hyperplastic, 156 (47.9%) adenomas and 16 (4.9%) adenocarcinoma. Patients with adenoma/carcinoma were older (67.6 vs. 66.5, p = 0.02) but there was no difference in sex (Male 61.4% vs. 59.4%, p = 0.49) when compared to those without adenoma/carcinoma. Of 172 patients with adenoma/carcinoma, 111 (64.5%) were proximal to the splenic flexure (SF). 5 out of 16 (31.2%) adenocarcinomas were proximal to SF and 2 (40%) of these patients had no polyps distal to the SF.

**Conclusion:** Patients with adenomas/carcinomas are older and those with proximal adenomas/carcinomas have more polyps but are smaller in size. One in three adenocarcinomas picked up during colonoscopy would be out of reach of a flexible sigmoidoscopy. Furthermore, over one third of the proximal cancers did not have distal polyps.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Colorectal cancers have two development theories. One of the development theories is “adenoma-adenocarcinoma sequence” developing from protruded-types “polyps” we know generally. The other is considered to emerge directly from normal epithelium, not through the adenomatous stage. Recently, it is revealed most of this type are depressive-type carcinomas. This theory is called “de novo” pathway. We studied clinicopathological characteristics and long-term prognosis mainly on depressive-type colorectal carcinomas. Aim: & Methods: We classified the pathological characteristics of depressive-type colorectal carcinomas compared with flat- and protruded-type. A total of 2930 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to December 2016. Of these, 112 polyps (49.1%) non-adenomatous lesions. No data were available from 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, 71 (31.7%) were 10 mm, 71 (31.7%) were ≥ 10 mm. 32 polyps (14.3%) no size was available. 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, for 8 polyps (3.6%) no location was noted. 112 polyps (50.8%) were adenoma-tous and 110 polyps (49.1%) non-adenomatous lesions. No data were available.

Conclusion: Our results demonstrate that degree of ITH of KRAS/TP53 mutations at the moment of pathological classification of colorectal carcinomas. Intratumoral variations in the microscopc structure may represent molecular subclones in early colorectal lesions and may be predictive of the malignant progression.

Introduction: Hypoxia signaling has been found to enhance inflammatory cell survival, chemoresistance, motility, tumor angiogenesis as well as self-renewal capacity and proliferation of putative cancer stem cells. One of the key player in hypoxia is carbonic anhydrase IX (CAIX) which is a hypoxia-inducible enzyme. CAIX is overexpressed in a variety of cancers including colon cancer and plays a crucial role in maintaining favourable intracellular pH in hypoxia. There is also evidence that extracellular vesicle (EV) production is increased in response to hypoxia and promotes adaptive response of cancer cells and we have previously demonstrated, that CAIX positive EVs secretion is increased in response to hypoxia in colorectal cancer cells.

Aims & Methods: Within this study, we explored a possibility to use CAIX for the isolation of hypoxic EVs from colorectal cancer (CRC) patients’ plasma. EVs were isolated from plasma samples of 27 CRC patients and 25 healthy donors (HD) by using sequential centrifugation, filtration and size-exclusion chromatography steps. EVs were quantified by Nanoparticle tracking analysis (NTA) and CAIX positive EVs were screened by Apoacea technology.

Results: Statistically significant increase in the amount and size of EVs was found in CRC compared to HD irrespective of hypoxia status. The rate of CRC EVs was 4.9%, 52.2% and 50.8%, respectively. The rates of these pathological factors were significantly higher in depressive-type lesions. On the other hand, the rate of adenomatous component was 4.9%, 52.2% and 50.8%, respectively. It was significantly lower in depressive-type lesions, suggesting that they emerge directly from normal epithelium without going through the adenoma stage. The rate of lymph node metastasis was 11.6%, 6.8% and 5.0%, respectively. And 2 depressive-type lesions had synchronous liver metastases.

Conclusion: Depressive-type colorectal carcinomas invade massively even when they are small. They had higher risks of vascular invasion, poorly differentiated histology, increased number of mitotic figures, scattered submucosal lymphoid clusters, higher expression rate of CD34, and lower expression rate of CAIX. The rate of lymph node metastasis was 11.6%, 6.8% and 5.0%, respectively. And 2 depressive-type lesions had synchronous liver metastases.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancer (CRC) is an important contributor to cancer mortality and morbidity worldwide. 80% of CRCs arise via the adenoma-carcinoma sequence, 10–20% by sessile serrated adenomas (SSAs). Hyperplastic polyps are regarded harmless. Current surveillance strategies for CRC following polypectomy are determined by endoscopic and histopathological factors. Such a distinction has also been challenged.

Aims & Methods: The study was aimed for molecular characterization of colonic polyps in patients who underwent screening colonoscopy. Correlation of the genetic analysis with endoscopic, clinical and histopathological data was attempted to potentially better define relevant risk marker or sub-groups at risk for prediction of surveillance intervals. 100 Patients were enrolled in this study. A total of 418 polyps were sampled from 100 patients (64.5% females and 35.5% males) that were submitted to resection. Up to 6 representative polyp biospies were collected and stored in a formalin-free medium and finally embedded in paraffin-blocks, followed by histopathological assessment. Targeted Next Generation Sequencing (tNGS) was performed from these tissues using the NGS panel, that includes 83 cancer-related genes; GenomeRead RNAseq Targeted Panels V2, Quagen® on a MiSeq platform (Illumina®). Genetic and histopathological analysis was done blinded to the endoscopic and clinical data.

Results: In 100 patients, 234 polyps were removed. 121 polyps (54.0%) are sized < 10 mm, 71 (31.7%) ≥ 10 mm. For 32 polyps (14.3%) no size was available. 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, for 8 polyps (3.6%) no location was noted. 112 polyps (50.8%) were adenomataous and 110 polyps (49.1%) non-adenomatous lesions. No data were available.
P1108 QUANTITATIVE, FRAGMENT LENGTH AND GLOBAL DNA METHYLATION LEVEL ALTERATIONS OF CIRCULATING CF-DNA IN COLORECTAL ADENOMA, CANCER AND INFLAMMATORY BowEL DISEASES
E. Markus1, A. Kalmár1, O. Galamb2, K. Szigtel2, B.K. Barták2, Z.B. Nagy1, B. Wichmann2, Z. Tulassay3, P. Igaz1, B. Molnár1

Introduction: Cell-free DNA (cDNA) is circulating in human plasma and its amount is different in certain physical conditions. It is well known, that in healthy people the quantity of cDNA is very low, but it rises in chronic disorders such as cancer. At the same time, very high cDNA level can be measured in healthy people during physical exercise.

Aims & Methods: We aimed to analyze cDNA changes (quantity, fragment length, global DNA methylation level) in physiological conditions (during physical exercise) and its alterations in neoplastic and inflammatory colorectal diseases. Plasma was separated from 64 patients (16 colorectal carcinomas (CRC), 13 colorectal adenomas (AD), 18 inflammatory bowel disease (IBD), and 17 normal donors without evidence of disease). Plasma samples were also collected from 6 healthy athletes, before, and during and after training. DNA was isolated with High Pure Viral Large Volume NA isolation Kit (Roche). cDNA was quantified with Qubit fluorometry (Invitrogen). CDCN fragment length distribution was assessed by Bioanalyzer 2100 using High Sensitivity DNA assay (Agilent). Global DNA methylation was analysed by bisulfite pyrosequencing of long interspersed nuclear element-1 (LINE-1) (Quagen).

Results: High cDNA amounts were observed in plasma samples of patients with colorectal adenoma (20.61 ± 10.70 ng/ml), colorectal cancer (24.13 ± 20.02 ng/ml) and IBD (22.27 ± 14.60 ng/ml) compared to healthy subjects (10.33 ± 3.22 ng/ml). Highly elevated cDNA amounts were found in plasma samples of athletes during physical exercise (66.17 ± 29.00 ng/ml), while the cDNA amount decreased after physical activity (51.87 ± 39.80 ng/ml).

Conclusion: Global DNA hypomethylation was shown in CRC plasma samples with advanced tumor stage (N: 68% ± 0.80%, AD: 79% ± 1.70%, advanced CRC: 70% ± 0.03%). This finding was confirmed in samples of colorectal AD, CRC, IBD patients and also in healthy athletes during physical exercise. CDCN fragment length analysis showed differences between each group. Global DNA hypomethylation was observed only in patients with advanced tumor stage. Based on our results, the above DNA analysis methods might contribute to non-invasive detection for colorectal diseases.

Introduction: Early detection, primarily in asymptomatic patients, remains a primary goal of colorectal cancer (CRC) screening. DNA methylation alterations, in addition to gene expression, are common in CRC. For this reason,粪便 DNA methylation seems to be a common phenomenon in colorectal cancer (CRC) influencing gene expression and contributing to tumor formation. In recent years, blood-based assays came into focus as potential screening tools for colorectal adenoma and cancer cases, as the analysis of the methylation status of circulating cell-free DNA (cDNA) in plasma samples provides a good opportunity for cancer detection.

Aims & Methods: Our aim was to analyse the methylation pattern of four selected genes in biopsy and plasma samples of healthy, colorectal adenoma and CRC patients. Moreover, we aimed to examine the effect of methylation alterations on protein expression. MethyLight (ML) PCR was used after bisulfité-conversion to study certain DNA sequences of the promoter regions of SRFP1, SRFP2, SDC2 and PRIMA1 in 32 biopsy-plasma pairs and in 121 additional plasma samples. DNA methylation was measured by using methyl capture sequencing data from our research group. Furthermore, the methylation status of the four candidates' whole promoter regions was examined in silico using Illumina Infinium HumanMethylation450 BeadChip (Illumina). The data was downloaded from The Cancer Genome Atlas (TCGA) database and from NCBI Gene Expression Omnibus Database (GEO accession number: GSE48684). In order to examine the effect of promoter methylation on the protein expression, immunohistochemistry analysis was performed.

Results: After analyzing ML assays, methylation of SRFP1, SRFP2, SDC2 and PRIMA1 was observed in 85.1%, 72.3%, 89.4% and 80.9% in the plasma fraction of patients with CRC and 89.2%, 83.8%, 81.1% and 70.3% of adenoma patients, respectively. In multiple logistic regression analysis, the four makers together were able to distinguish CRC patients from healthy individuals with 91.5% sensitivity and 97.3% specificity (AUC = 0.978) and could differentiate adenoma samples from healthy controls with 89.2% sensitivity and 86.5% specificity (AUC = 0.937). In silico analyses confirmed our results on the altered methylation pattern of the four markers present in colorectal cancer.

Conclusion: Our findings suggest that SRFP1, SRFP2, SDC2 and PRIMA1 can be providing epigenetic biomarker candidates for colorectal adenoma and cancer diagnosis with high sensitivity and specificity.

P1111 VALIDATION OF THE UTILITY OF A FAECAL IMMUNOCHEMICAL TEST FOR HAEMOGLOBIN (FIT) IN PATIENTS PRESENTING TO PRIMARY CARE WITH NEW BOWEL SYMPTOMS

J. Digby1, J. A. Strachan2, C. G. Fraser3, R. Steele1, C. Mowat2

Introduction: Symptoms alone are poor predictors of underlying colorectal pathology. Only 14% of patients referred for colonoscopy from primary care have significant bowel disease (SBD), colorectal cancer (CRC), high risk adenoma (HRA, defined as > 3 or any ≥ 1 cm) and inflammatory bowel disease (IBD) 2. We have reported that undetectable faecal haemoglobin (f-Hb), measured by a faecal immunochemical test (FIT) is a good rule-out test for SBD. Since December 2015, GPs in Tayside have been encouraged to use FIT test as an adjunct to history, examination and mandatory blood tests in patients referred with bowel symptoms. Referrals are vetted by a Consultant and triaged to test or clinic. We have examined the impact of the introduction of the FIT test on referral rates and colonoscopy yield.

Aims & Methods: Patients in primary care with new bowel symptoms were encouraged to complete a FIT in addition to blood count and renal function check. We prospectively recorded FIT tests received, referrals to secondary care and colonoscopy findings over 1 year from December 2015 to December 2016. FIT tests were analysed by HMJACKarc (Kyowa Medex Co. Ltd., Japan) with an analytic range of <10 to >400 μg Hgb/g faeces. Referral rates with FIT were examined along with clinical findings at colonoscopy.

Results: 5,655 FIT tests were received. 76.2% had undetectable f-Hb, and 152 (2.7%) were untestable. 4,108 patients were referred of whom 2,338 (57%) returned a FIT. In 1,378 patients with a FIT result vetted to colonoscopy, 284 had SBD (20.6%); 86 CRC; 124 HRA and 74 IBD. 44% of patients scoped had undetectable f-Hb in whom prevalence of SBD was 6.6%. Only 13% of SBD patients had co-existing iron deficiency anaemia, 14/25 HRA and 3.6/1 IBD had anaemia or diarrhoea. 32.2% of those with f-Hb >10 μg/g Hgb faeces had SBD rising to 54.9% in those with f-Hb >400 μg/g Hgb faeces. 2,677 patients completed a FIT but were not referred, in whom 40.1% had undetectable f-Hb. Referrals to secondary care were 14% down on the previous year.

Conclusion: A FIT test is an essential adjunct to the history, examination and blood tests in the assessment of bowel undetectable f-Hb is a good rule-out test and will miss only 5% of all SBD. Furthermore, f-Hb concentration could aid triage irrespective of symptoms.

P1113 ARTIFICIAL INTELLIGENCE CAN PREDICT THE PRESENCE OF LYMPH NODE METASTASIS IN T1 COLORECTAL CANCER

K. Ichimasa1, S. Kudo2, Y. Morii1, M. Misawa2, S. Matsuda1, Y. Koyama1, T. Baba1, K. Wakamura1, T. Hayashi1, T. Hisayuki1, T. Kudo1, N. Toyoshima1, H. Nakamura1, T. Ishigaki2, Y. Yagawa2, K. Takeda1, Y. Maea1, Y. Ogawa2, H. Homami1, H. Miyauchi1, F. Ishida1

Introduction: Most T1 colorectal cancers (CRCs) undergo surgical colectomy in western countries with established clinical guidelines despite the low incidence (approximately 10%) of lymph node metastasis (LNM). Therefore, many patients without out LNM undergo unnecessary surgeries.

Aims & Methods: To reduce unnecessary surgeries, we aimed to predict the risk of LNM in T1 CRCs by using artificial intelligence (AI). Data on 690 consecutive patients with T1 CRCs who had undergone colectomy between April 2001 and March 2016 were retrospectively analyzed. Data of a randomly selected 590 patients were used for machine learning for the AI model, which analyzed five clinopathological factors: tumor location, lymphatic invasion, vascular invasion, lymph node metastasis and histological grade. The remaining 100 patients served as a test set for validating the AI model and output the predicted LNM as positive or negative. To validate the AI model, sensitivity, specificity and
accuracy were calculated and compared with American, European and Japanese guidelines (1–5).

Results: Sensitivity was 100% (95% CI, 56%–100%) in all models. Specificity and accuracy of the AI model, American, European and Japanese guidelines were 68% (58%-78%) vs. 45% (35%-65%) vs. 12% (6%-21%) vs. 8% (3%-15%) and 71% (61%-80%) vs. 50% (40%-60%) vs. 20% (13%-29%) vs. 16% (9%-25%), respectively. The rate of unnecessary surgeries of the AI model was calculated as 29% in comparison with American 50% (P = 0.004; odds ratio [OR] 2), European 80% (P = 0.001, OR 10), and Japanese 84% (P = 0.001, OR 13).

Conclusively reducing unnecessary surgeries compared with current guidelines while providing high sensitivity. AI will help in making decisions as to whether additional surgery is indicated after endoscopic resection of T1 CRCs. Introduction: Regular surveillance colonoscopy after colon cancer resection is recommended to detect metachronous adenoma and cancer. However, risk factors of advanced metachronous neoplasm during postoperative surveillance have not been fully evaluated yet.

Aims & Methods: This study aimed to assess the risk of advanced metachronous neoplasm during surveillance colonoscopy in patients who underwent curative colon cancer resection. The patients who underwent curative colonic resection for non-metastatic colon cancer between January 2002 and December 2012 in a single tertiary center were retrospectively reviewed.

Results: A total of 728 patients were enrolled in this study. Surveillance colonoscopy was performed after perioperative clearing colonoscopy. Among the patients, 182 (61.6%) were male, and the median age was 65 years. On perioperative clearing colonoscopy, accompanying high-risk adenomas (≥3, size ≥10 mm, with high-grade dysplasia and villous histology) were detected in 95 patients (31.9%) and were significantly associated with old age (>65 years), male sex, alcohol use, smoking, and stage 3 colon cancer (P < 0.05). During the postoperative follow-up periods (median, 5.35 years), 16 advanced metachronous neoplasms was found in 45 patients (15.1%) during surveillance colonoscopy, including colon cancer in 4 patients (1.3%). In the multivariate analysis, distal colon cancer (distal to splenic flexure; odds ratio [OR] 4.463; P = 0.002), accompanying high-risk adenomas on perioperative clearing colonoscopy (OR = 3.414; P = 0.001), and hypertension (OR = 2.344; P = 0.026) were significant risk factors of advanced metachronous neoplasm during surveillance colonoscopy.

Conclusions: Patients who had distal colon cancer, accompanying high-risk adenomas on perioperative clearing colonoscopy, and hypertension may need a shorter colonoscopic surveillance interval. A more tailored surveillance strategy is needed to improve overall outcome in patients who undergo curative colon cancer resection.

P1115 PROSPECTIVE COMPARISON OF THE NOVEL FULL SPECTRUM ENDOSCOPY (FUSE) AND ADVANCED HIGH DEFINITION-WHITE LIGHT ENDOSCOPY FOR DETECTION OF POLyps IN ROUTINE PRACTICE

A. Martinez-Alcala García1, F. J. Martinez-Alcala2, C. Martinez-Alcala2, K. Thakar3, R. Madero2, K. Mönkemüller4, F. Martinez Alcala1

Introduction: Despite major advances in white light endoscopy detection of colon polyps remaining challenges with significantly low polyp miss rates. The novel second generation full spectrum endoscopy (FUSE) is a new scope with two additional cameras in the sides that provides a panoramic 300° field of view.

Aims & Methods: The aim of this study is to identify the role of the FUSE in improving polyp detection. This was a single-center, prospective, randomized, open-label study in patients that presented for routine colonoscopy at an outpatient unit during a six-month period. Patients were randomized to either FUSE (FUSE colonoscope CDVL slim c38) or standard frontal view (SFV) colonoscopy (Olympus Evis Exera III 190). The primary outcomes were polyp detection rates (PDR), diverticulum detection rate (DDR) and complete colonoscopy. Secondary outcomes were procedure time, adverse event rates, size and characteristics of the polyps and success of endoscopic treatment (R0 resection).

All procedures were performed by experienced endoscopists, who had carried out > 5000 colonoscopies and had excellent intubation rates of >95%.

Results: A total of 197 patients (49.2% female, 50.8% male, median age 60 years, range ±16 years) were studied. No significant difference was seen between the 2 groups for the primary endpoints of polyps detection rate (PDR), diverticulum detection rate (DDR) or complete colonoscopy (table 1). About secondary endpoints: R0 endoscopic resection was achieved in 95% in both groups (p=0.68). The median procedure time in minutes was higher with SFV (26.7±6 min) than with FUSE (21.5±10.7 min (-4.6, IQR 95% -8 a –1.2) (p=0.008). There were no significant differences regarding adverse events, determination of colon cleanliness, or others epidemiologic factors. 2 case were excluded from the statistical analysis due to surveillance of polypsis syndrome, to avoid skewing of results.

Conclusion: In expert hands, PDR and DDR exceed 50% with advanced white light and FUSE systems. FUSE was not superior to advanced white light endoscopy for the PDR and DDR. However, with FUSE we can reduce procedure duration without any additional adverse events or increased discomfort. These data further demonstrate the safety and feasibility of the new FUSE system.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Underwater Endoscopic Mucosal Resection (UEMR) has been demonstrated as a safe and effective technique for removal of flat and sessile colorectal lesions. Until now, only UEMR with cap has been described in literature. In addition there is no consensus about the endoscopic settings.

Aims & Methods: This prospective study was conducted between January and November 2016 in two university tertiary referral centers. UEMR was performed using a standard colonoscope without the distal cap. The lesions were marked with snare tip prior to resection. Insufflation was switched off. Then, the colon lumen was entirely deflated. Water at room temperature was infused using an irrigation pump until complete filling of the lumen was achieved. All gas pockets in the operative field were evacuated. Two sizes of polypectomy snare (13 and 25 mm) were used according to the preference of the endoscopist. No submucosal injection was performed. One of these three different endoscopic settings (DRYCUT, AUTOCUT and ENDOCUT) was selected. All resection wounds were carefully inspected after UEMR. Endoclip was employed for management of bleeding and suspected perforation.

Results: Between January and November 2016, 45 patients (27 female, mean age 67 years, range 33–87) with 55 non-pedulated colorectal lesions (mean size 16 mm, range 10–40 mm) were included. Six lesions were located in cecum, 21 in the ascending colon, nine in transverse, eight in descending colon, five in sigmoid, and six in rectum. In five patients, we selected DRYCUT mode; in an AUTOCUT; and in twenty-five the ENDOCUT mode. All lesions were successfully and completely removed by UEMR. The procedure time was recorded in 24 resections (mean 13 minutes, range 4–40). Thirty-three of them were removed en bloc (60%). Histology revealed the following: 40% tubular adenomas; 20% tubulovillous adenomas; 25.45% sessile serrated adenomas; 36.5% traditional serrated polyps; 7.25% intramusosal adenocarcinomas and
3.65% were superficial submucosal carcinomas (<1000μm). During UEMR, two cases (both using AUTOCUT mode) of sprouting bleeding were observed (4.45%). Hemostasis was easily achieved in both cases by clamping. No patient required blood transfusion. One patient had abdominal pain on the day after resection without signs of pneumoperitoneum on CT scan. There was no perforation or delayed bleeding.

Conclusion: This study supports the existing data indicating acceptable rates of technical success and low incidence of adverse events with UEMR. The results of this study without cup were similar with the previous ones using cup. Further comparative studies with and without cup, performed with different settings and especially between UEMR and traditional EMR are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Current guidelines recommend surveillance colonoscopy after 10 years or surveillance in 5–10 years in individuals with no or 1–2 non-advanced adenomas.

Aims & Methods: We hypothesized that risk of metachronous advanced colorectal cancer was lower based on clinical characteristics and colonoscopy quality. We identified 7,711 participants with no or non-advanced adenomas at first-time screening colonoscopy. The risk of metachronous AN at surveillance colonoscopy 3–5 years later was investigated according to clinical characteristics and endoscopist adenoma detection rate (ADR).

Results: In multivariate analyses, strong associations between increasing age, male sex, current smoking, family history of colorectal cancer, follow-up interval, increasing number of adenoma, and low ADR and risk of any metachronous colorectal neoplasia were observed. For metachronous AN, increasing age, male sex, increasing number of adenoma, and low ADR were independent risk factors. Among patients with 1–2 small adenomas, women with age ≥60 years or men comprised a high-risk group, which had 5.3% risk of metachronous AN at surveillance. Women <60 years old with 1–2 low-risk adenomas had very low risk (1.2%) of metachronous AN as individuals without a neoma. Furthermore, incidence of metachronous AN was significantly higher in individuals who were colonoscoped in the endoscopist with ADR <32% than in those screened by endoscopists with a higher ADR (≥32%) (3.2% vs. 0.6%, respectively; P = 0.001).

Conclusion: According to patient and adenoma characteristics, and ADR of the endoscopist, the risk of metachronous AN varies among low-risk patients. In recommending surveillance colonoscopy, these factors should be taken into consideration.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The technique of endoscopic submucosal dissection has recently been improved, and large and complexed lesions such as those invading ileocecal valve and appendix orifice can be resected en bloc. However, lesions accompanying severe fibrosis in the submucosal layer and exhibiting the muscle retraction (MR) sign are often difficult to be resected completely. We devised a new method called ‘Per Anal Endoscopic Myectomy’ for such lesions involving severe fibrosis, in which dissection is done between the inner circular and outer longitudinal muscles instead of between submucosal layer and muscle layer. Aims & Methods: The aim of this study is to examine the usefulness and safety of PAEM. Patients after PAEM cases performed in our hospital and an affiliated hospital were retrospectively reviewed. When fibrosis in the submucosal layer was suspected, pocket creation method was applied and if severe fibrosis with MR sign was found, PAEM was selected. In PAEM procedure, after dissecting circumferentially around the fibrotic area with a double tunneling method, the inner circular muscle is cut in a circular manner, which makes the outer longitudinal muscle clearly visible. The space between the inner circular and outer longitudinal muscles is sparse and suitable traction with the tunneling method makes it easier to dissect this space. PAEM was performed only for rectal lesions, and no clip closure was carried out after the procedure in most cases.

Results: Ten rectal lesions were treated with PAEM between July 2015 and March 2017. Among them, 7 cases including 2 cases with mucosal cancer, 1 case with deep submucosal invasion, and 1 case in which polyp resection with en bloc was performed en bloc. In our hospital and affiliated hospital, 9 cases were treated. PAEM was preferable in all cases. Three cases which achieved resection with MR sign were performed en bloc with negative margin. The other 3 cases showed tumor invasion to the muscle layer and the vertical margin was positive. The clinical course after PAEM was preferable in all cases. Three cases which achieved resection with negative margin but found lymphovascular invasion of the tumor underwent additional surgical intervention for chemoNRAD. In surgical cases, they could permit anus-preservation.

Conclusion: PAEM for lesions exhibiting MR sign with severe fibrosis will enable en bloc resection with accurate pathological diagnosis. No complications were recorded in our experiences. Further investigation into the significance of PAEM would be needed.

Aims & Methods: Our aims were to assess the frequency of local recurrence after EMR (15), to identify risk factors for recurrence, and to provide guidelines for follow-up suggestions. We considered all consecutive patients undergoing RFA of flat or sessile adenomas ≥ 10 mm containing high-grade dysplasia or adenocarcinoma until pt1 from May 2015 to April 2016. EMR procedure was performed by 2 endoscopists with extensive EMR “in-jet and cut” experience and only lesions with a positive lifting sign were endoscopically treated. An endoscopic follow-up was performed at a planned interval of 3, 6 and 12 months by using high-definition instruments white light (HD-WL) and narrow-band imaging (NBI) allowing an appropriate score assessment with the execution of biopsies when needed. Data collection included: (a) lesion size, morphology, Paris classification, pit pattern (kudo), technique of removal (en bloc vs piecemeal) and histology for all primary lesions and RRA; (b) Information on lesion building, grading, micronivation, margins, submucosal extension for all pt1 removed “en bloc”. Results: 50 patients were included (mean age 63 ± 12 years, 54% females). The mean size of lesions was 21 mm (range 10–50 mm), 40% were sessile, 35% granular LST and the remaining 25% non-granular LST, the most frequent sites of location were sigmoideal colon (40%), ascending colon (25%) and cecum (12%). According to the morphological characteristics, 60% of lesions were removed “en bloc” and 40% “piecemeal”. Metallic clips were used as prophylaxis in 35% of patients and only 1 in 1 for intraprocedural bleeding. No post-procedural bleeding or perforation occurred. APC has never been used. During the endoscopic follow-up a suspect early (3-months) RRA was documented and immediately treated in 16% and histologically confirmed only in 8%. At 6-month controls a RRA was again detected only in 2 of these patients. New cases of RRA were not found both at 6 and 12 month controls. Only 1 case of RRA was documented for lesions treated “en bloc” but this was the only one with histologically strongly suggesting RRA (pT1, 2 cm, grading G2, free-disease margins <1 mm). As concerned lesions removed “piecemeal”, RRA (70% high grade dysplasia and 30% low grade dysplasia) was higher in pT1, lesions found with other factors. Conclusion: EMR results a technique safe and effective particularly for lesions immediately treated in 16% and histologically confirmed only in 8%. At 6-month controls a RRA was again detected only in 2 of these patients. New cases of RRA were not found both at 6 and 12 month controls. Only 1 case of RRA was documented for lesions treated “en bloc” but this was the only one with histologically strongly suggesting RRA (pT1, 2 cm, grading G2, free-disease margins <1 mm). As concerned lesions removed “piecemeal”, RRA (70% high grade dysplasia and 30% low grade dysplasia) was higher in pT1, lesions >2 cm, non-granular LST. No correlation was found with pT1 lesions. Disclosure of Interest: All authors have declared no conflicts of interest.

*CROSS, ColorCatheter Obstruction Scoring System (Reference 1)

Among 63 palliative MCO cases, initial attempt to place a 22 mm SEMS by TTS procedure was unsuccessful in 6 cases (Table), all of whom had peritoneal dissemination. The reasons for technical failures were; impossible insertion of an SCC to the stricture due to carcinomatous adhesions or narrowing in 5 cases and failure in passing GW through the stenosis due to a limited viewing angle to the stricture in one case. With OTC-CR, approach to the main stenosis with a thinner (alternative) scope, GW traverse, “over-the-catheter” replacement to the SCC, and a 22 mm SEMS placement were successful in all of the 6 cases with adequate clinical improvements (CROSS score change). Notably, ultimate TTS procedures were possible from reinserted SCC distant from the stricture in 3 cases. No adverse events occurred during the procedures.

Introduction

Colorectal cancer (CRC) is the most common cause of cancer in western countries. In Balearic Islands 700 new cases per year are diagnosed. The cost-effectiveness of CRC screening programmes are clearly demonstrated in the studies and the important public health problem of CRC justifies the development of control strategies. The aim of this study is to present the results and impact during the first round of the program in Balearic Islands.

Aims & Methods: The first round includes the period from January 2015 through December 2016. The program has been developed in the areas of Menorca, Ibiza, Formentera and Tramuntana (Mallorca), including 50% of the Balearic Islands population. The target population (people who reside in these areas aged between 50 and 69 years old) was 75,575 individuals. Exclusion criteria. Colonoscopy performed in the previous 5 years, previous diagnosis of CRC, follow-up colonoscopies because colon disease and severe illness-contraindication for the participation. People received the invitation by letter. Quantitative immunochemical fecal occult blood testing (i-FOBT/OC-Sensor) was the screening method. The kit was delivered at pharmacies joined the program. The samples were deposited in urns placed in health centres. Participants who tested positive (≥100 ng/mL) were referred to pre-endoscopy evaluation and follow-up colonoscopy. The colonoscopies were performed according to the quality criteria of guidelines.

Results: Overall participation rate (number of people who provide their i-FOBT sample) was 36.5% (n=21,555). Positive rate of i-FOBT was 7% (1438) and 94.3% of those positive tests underwent a colonoscopy (5.7% of exclusions in pre-endoscopy evaluation). 996 colonoscopies were performed. 47 adenomas with high grade dysplasia, 24 carcinomas in situ and 60 adenocarcinomas were found. Only 19% of these adenocarcinomas were T3 or T4 lesions while the rest presented earlier stages. 26% of colonoscopies were classified as high risk (>5 adenomas or at least one ≥20 mm). They have been reported 2 cases of colon perforations, both resolved by endoscopic treatment.

Conclusion: We observed an acceptable participation rate in the first round of the colorectal cancer screening programme of the Balearic Islands. The index of positivity rate of i-FOBT and the results of the endoscopic explorations are according with the observed in other colorectal cancer screening programmes. We can conclude a successful development of the first round of the programme in our area.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction

Colorectal cancer (CRC) is the most common cause of cancer in the USA. The incidence of CRC has been increasing in the USA. The prevalence, gender distribution, and clinical presentation of CRC differ between Asian and Western countries. The index of positivity rate of i-FOBT and the results of the endoscopic explorations are according with the observed in other colorectal cancer screening programmes. We can conclude a successful development of the first round of the programme in our area.

Aims & Methods: Thirty Thai IBS patients, and age and sex matched 20 Thai controls were included. Four biopsy samples were taken from each of the sigmoid colon and the rectum during a standard colonoscopy. Sections from these biopsy samples were immunostained for serotonin, peptide YY, oxyntomodulin (enteroglucagon), pancreatic polypeptide, somatostatin, Msi 1, neurog 3. The densities of immunoreactive cells were determined with computerized image analysis (1).

Results: In both the colon and rectum, the density of serotonin cells was lower in IBS patients than controls. Whereas the density of PYY cells was increased in both the colon and rectum of IBS-D, it was reduced in IBS-M and IBS-C. The density of oxyntomodulin cells was reduced in both the colon and rectum of all IBS subtypes. While the density of PP cells was unaffected in the colon, it was reduced in the rectum. Somatostatin cell density was unaffected in both the colon and rectum. The densities of Msi 1 and neurog 3 were unchanged in both the colon and rectum.

Conclusion: The present findings of abnormal densities of the large-intestine enteroendocrine cells in Thai patients combined with previously reported changes in Western IBS patients (2) support the notion that intestinal enteroendocrine cells are involved in the pathophysiology of IBS. However, the changes in the enteroendocrine cells differed from those in Western patients. The present observations highlight that IBS differs in Asian and Western countries, and show that the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients might be caused by different mechanisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Opioid-induced constipation (OIC) is a common side effect of opioid therapy that significantly affects multiple aspects of a patient’s life. Naldemedine (NAL) is a peripherally-acting mu-opioid receptor antagonist that significantly affects multiple aspects of a patient’s life.

Aims & Methods: In three Phase 3 randomized, double-blind, PBO-controlled trials of NAL (2 of 12-week duration [COMPOSE 1 and COMPOSE 2] and 1 of 52-week duration [COMPOSE 3]), a 7-grade scale (1 = markedly, 2 = moderately, or 3 = slightly; 4 = unchanged; 5 = slightly, 6 = moderately, or 7 = markedly improved) was used to assess overall satisfaction with constipation and abdominal symptoms in patients with OIC associated with non-cancer pain.

Aim: To evaluate the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients. The present observations highlight that IBS differs in Asian and Western countries, and show that the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients might be caused by different mechanisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Data was expressed as mean ± SEM. * P < 0.05; ** P < 0.01; *** P < 0.0001

This proposed new approach provides a single score that may be easier to interpret than the 7-grade scale.

Results: There were 547 subjects in COMPOSE 1, 550 in COMPOSE 2, and 1246 in COMPOSE 3 (all ≥18 years of age) randomized (1:1) to NAL 0.2mg once daily or PBO. The baseline characteristics of the study population were consistent between groups in each trial and between trials. Overall satisfaction assessment was completed in 372 subjects in COMPOSE 1, 296 in COMPOSE 2, and 1101 in COMPOSE 3. There were greater improvements in satisfaction with constipation and abdominal symptoms in the NAL group compared with the PBO group in all three studies (all P<0.0005; Table). The mean SGSS were 1.5 and 0.9 with NAL and PBO, respectively, in the two 12-week studies pooled, and 1.7 and 1.0, respectively, in the 52-week study.
P1129 ALTERING SPHINGOSINE-1-PHOSPHATE WITH AGING INDUCES MOTILITY DYSFUNCTION OF COLON SMOOTH MUSCLE BY BKCa UPRREGULATION IN RATS

S. Xiaoxue
The First Affiliated Hospital Of Nanjing Medical University, Nanjing Medical University, Nanjing/China

Contact E-mail Address: shenxiaoxue0066@163.com

Introduction: Large conductance Ca\(^{2+}\)-activated K\(^{+}\) channel (BKCa channel) was shown to play critical roles in regulating smooth muscle contractility by modulating membrane potential, at the same time, age-associated changes in BKCa expression may contribute to the development of motility disorders of the gastrointestinal tract. Sphingosine-1-phosphate (SIP), component of Sphingolipids in the cell membranes, may affect BKCa expression. Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (CSM) in rats.

Aims & Methods: Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (CSM) in rats. Forty Sprague-Dawley rats at the same age were randomly divided into five groups. After different times of administration, finally they were divided into different-age group: 10-week group, 20-week group, 40-week group, 60-week group and 80-week group. Colonic motility function and contractility of circular muscle strips were measured. The expression of BKCa and phosphorylated myosin light chain (P-MLC) level were tested in colon tissues of rats with varying ages by immunohistochemical, RT-PCR and western blot. SIP levels in colon tissue were measured by LC-MS/MS analysis. Primary cultured colon smooth muscle cells (SMCs) from normal adult rats were used in complementary in vitro studies. In the absence and presence of SIP with different concentrations, the expression of BKCa, P-MLC level, single-channel activity, intracellular Ca\(^{2+}\) mobilization were tested. At the same time, in the presence and absence of SIP, SMCs were transfected with anti-SIP antibody. BKCa siRNA transfection was used to investigate whether P-MLC expression and intracellular Ca\(^{2+}\) mobilization were affected by BKCa expression in SMCs. The expression and phosphorylation of Akt, JNK, ERK, NF\(^{κ}\)B, and PKC were examined by western blot analysis to investigate the effect between SIP and BKCa.

Results: Aged rats showed prolonged colonic transit time and weakness of circular muscle contraction compared with the young (10 weeks old) SD rats. LC-MS/MS analysis exhibited that the levels of SIP were significantly higher in the CSM of aged rats, demonstrating that SIP varies depending on age. BKCa (α-subunit and β-subunit) levels in CSM were shown to increase in an age-dependent manner from 10- to 80-week-old rats by mRNA, protein and immunohistochemical, but P-MLC expression decreased. In colon SMCs, by BKCa siRNA transfection, we found P-MLC levels increased. Exogenously added SIP upregulated BKCa in colon SMCs in a concentration-dependent manner. Intracellular Ca\(^{2+}\) mobilization though inhibiting Ca\(^{2+}\) influx and induced the decline of P-MLC. Our results also proved that SIP upregulated BKCa through the Akt/ERK/JNK pathways. The expression of BKCa decreased by treatment with inhibitor of Akt/ERK/JNK pathways or siRNA.

Conclusion: The results of our study showed that altered SIP due to aging upregulates BKCa via the Akt/ERK/JNK mediated pathway in CSM. BKCa upregulation inhibits Ca\(^{2+}\) influx and MLC phosphorylation and thereby reduces the contractile force characteristic of the contractile dysfunction of CSM observed in older individuals, which may be implicated in age-associated gastrointestinal motility disorders.

P1130 DIABETES-RELATED ALTERATIONS IN THE EXPRESSION OF THE INFLAMMATORY CYTOKINES, TUMOR NECROSIS FACTOR ALPHA AND INTERLEUKIN 6 IN THE MYSTERIC GANGLIA AND ITS MICROENVIRONMENT OF DIFFERENT INTESTINAL SEGMENTS

L. Chandrakumar, D. Mezei, B. P. Barta, Z. Szalai, N. Bödi, M. Bagyanszki
Department Of Physiology, Anatomy And Neuroscience, University of Szeged, Szeged/Hungary

Contact E-mail Address: lalitha.biochem87@gmail.com

Introduction: Growing amount of evidence has indicated that increase of the hyperglycaemia-induced oxidative stress and decreased effectiveness of the endogenous antioxidant protection play the major role in the initiation of diabetes-related neuronal damage. Using a streptozotocin-induced diabetic rat model we recently demonstrated that nitricergic myenteric neurons, which are key regulators of peristalsis, display different susceptibilities to diabetic damage and also to treatment in the different gut segments. Based on these results we suggested the importance of the molecular differences in the microenvironment in the pathogenesis of diabetic nitrergic neuropathy.

Aims & Methods: Aim to reveal the quantitative differences in the expression of the pro-inflammatory cytokines like tumor necrosis factor alpha (TNFa) and interleukin 6 (IL6) in the myenteric ganglia and its microenvironment of the different intestinal segments, quantitative immunogold electron microscopy was used. Ten weeks after the onset of diabetes, segments from the duodenum, ileum and colon of streptozotocin (STZ)-induced diabetic, control and diabetic, and control rats were processed for post-embedding immunohistochemistry.

Results: The density of TNFa- and IL6-labelling gold particles was strictly region-dependent, with increasing to the distal part of the gastrointestinal tract of diabetic rats. The number of TNFa gold particles was significantly increased in the duodenum, decreased in the colonic myenteric ganglia, while did not show any significant differences in the ileal ganglia. The number of IL6 gold particles was not affected by diabetes in the myenteric ganglia of different gut regions. The diabetes-related alterations of TNFa- and IL6 expression were not protected by the immediate insulin replacement in any of the investigated intestinal segments. The differences in TNFa- and IL6 density were not significant in the capillary endothelium under different experimental conditions.

Conclusion: Based on these findings we presume that regionally alterations in the TNFa and IL6 expression are correlated with the diabetes-related region-specific nitrergic myenteric neuropathy.

P1131 ROLE OF SEMAPHRIN 3A IN THE POSTNATAL DEVELOPMENT OF THE ENTERIC NERVOUS SYSTEM

J. Gonzales, C. Le Berre, E. Dikkongue, M. Neunlist, H. Boudin
TENS INSERM U1235, Nantes/France

Contact E-mail Address: jacques.gonzales@univ-nantes.fr

Introduction: Critical developmental stages of the enteric nervous system (ENS) occur during the postnatal period leading to the formation of a mature neural network characterized by the assembly of enteric neurons into ganglia and the formation of a highly organized pattern of neuronal connectivity. However, the mechanisms underlying these maturation processes are poorly understood. Semaphorin 3A (SEMA3A) is a secreted protein playing key roles in the neuronal circuitry formation of the central nervous system. Here, we studied the expres-
Aims & Methods: Gene and protein expression of SEMA3A and its receptor NRP1 was assessed in the distal colon of nontermally euthanized rats aged 1 day (PN1) to adulthood by qRT-PCR and Western blot respectively. The cellular distribution of SEMA3A and NRP1 was determined at PN7 and PN36 in whole mount distal colon tissue by double immunofluorescence for SEMA3A or NRP1 with specific mouse and rabbit primary antibodies, respectively (H. Mackie, T. Shi, and muscle cells (a-SMA). The impact of SEMA3A on neural outgrowth was assessed in cultures of enteric neurons cocultured with SEMA3A-transfected COS-7 cells.

Results: A peak of mRNA expression for SEMA3A and NRP1 was observed in distal colon at PN7, corresponding to a stage of intense neural circuit remodeling. At the protein level, NRP1 was also found to be predominantly expressed during the early postnatal period. Immunohistochemistry of colon tissue indicated that SEMA3A immunoactivity was not associated with any specific cellular profile, but was distributed in small clusters disseminated throughout the tissue, a pattern consistent for a secreted protein. NRP1 was found in neurons, mainly associated with axonal processes, and was not detected in glial or muscle cells. Enteric neurons cultured in the presence of SEMA3A-expressing COS cells showed a strong reduction in axon length and complexity, while the ganglion size was unaffected.

Conclusion: This study shows the expression of SEMA3A and its receptor NRP1 in the ENS during early postnatal period. By controlling axonal outgrowth, SEMA3A might be an important factor to restrict the axonal trajectories in the appropriate paths between ganglia.

5USF A Ribeira, Guarda/Portugal
6Centro Hospitalar São João, Porto Medical School, Porto/Portugal

Contact E-mail Address: marocostasilva87@gmail.com

Introduction: Constipation is a chronic disorder with an estimated prevalence of 17% in Europe. Epidemiological studies on bowel habits in the Portuguese general population have not been done previously, as in many other western countries. The aim of this population-based study was to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community.

Aims & Methods: We aimed to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community. Methods: Cross-sectional study with convenience sampling between November 2015 and November 2016. The physician applied a questionnaire, to adult patients at primary health care consultation. The questionnaires were anonymous, and the only personal information the participants were asked to give was their age and sex. The questionnaire contained objective questions on possible causes and constipation-associated conditions and medications (according to the criteria defined by the World Gastroenterology Organization), daily water and fibre intake, physical activity, bowel habits and Bristol stool scale (BSS). Descriptive statistics and uni and multivariate analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: A total of 2214 questionnaires were postulated to individuals from 35 different municipalities (54% women; mean age 46.18 years). Concerning possible causes of constipation, 43% subjects had a history of constipation-associated condition and 36% were taking constipation-associated drugs. Regarding bowel habits, 35% subjects had <1 bowel movement per day and 2% had >1 bowel movement per week. Using BSS, 66% of the cases reported type III or type IV stool consistency. Among women, 19% reported a change in bowel movements according to the phase of the menstrual cycle. In total, 22% of subjects considered to be constipated, and 78% of these, complied the Roma III criteria.

Conclusion: This study represents the first assessment of bowel habits in the Portuguese population, depicting the high prevalence and related risk factors of a disorder that decreases the health-related quality of life and has major economic consequences. The prevalence of constipation (22%) was higher than that reported in other countries.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1133 DIAGNOSTIC DISCORDANCE BETWEEN TESTS OF EVACUATION: A PROSPECTIVE STUDY

D. Carter1, E. Bardan2, M. Beer-Gabel2
1Sackler Faculty Of Medicine, Tel Aviv University, Tel Aviv/Israel
2Gastroenterology, Sheba Medical Center Dept. of Gastroenterology, Ramat Gan/Israel

Contact E-mail Address: dr.dancarter@gmail.com

Introduction: Objective means of evaluation of the defecatory process include evacuation histo-rectal manometry (HRM), balloon expulsion test (BET) and imaging of the defecatory process (X-ray defecography, dynamic transpelvic ultrasound (DT-PUS) or MR defecography). These tests have a place in the evaluation of suspected evacuatory dysfunction (ED), fecal incontinence (FI) and chronic pelvic pain (CPP). Test choice may influence subsequent patient management; however, there is only limited information regarding the agreement between HRM, DT-PUS and BET.

Aims and Methods: The aims of this study were to compare the diagnostic yield and agreement between different tests of evacuation and to define the relation between the diagnoses of evacuation dysfunction to objective evacuation failure. 63 consecutive patients (60 females, mean age 51.62 years) were prospectively evaluated with HRM, BET and PUS. Inter test agreement for the diagnosis of anismus was assessed using the Kappa statistic. Correlation between anismus to evacuation failure (assessed by PUS) was also assessed.

Results: 36 patients were assessed for ED, 6 for CPP and 21 for FI. Anismus was diagnosed in 26 patients by HRM and 45 patients by DT-PUS. All cases of anismus diagnosed by HRM or DT-PUS had a positive BET. The Kappa agreement for the diagnosis of anismus between HRM and DT-PUS was poor (0.14 ± 0.01). 9 patients had significant pelvic floor anatomic pathology (4 rectal prolapse, 6 pathological pelvic descent, 4 enterocele and 3 rectoceles >3.5cm). There was a moderate correlation between diagnosis of anisms on DT-PUS to failure to evacuate the rectum (r = 0.636). The correlation between rectal evacuation on DT-PUS to the diagnosis of anismus on manometry was weak (r = 0.296).

Conclusion: There is considerable disagreement between the results of various evacuatory tests, and between the diagnoses of evacuation dysregulation to failure of rectal evacuation. Therefore, more than one test should be applied in order to evaluate the defecatory dysfunction.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1134 DIAGNOSTIC USE OF ENDOCOPIC FULL-THICKNESS WALL RESECTION (EFTR) IN PATIENTS WITH SYMPTOMS OF CHRONIC INTESTINAL PSEUDO-OBSTRUCTION (CIMO)

P.V. Valli1, D. Pohl1, M. Fried1, R. Caduff1, P. Bauerleind
1University Hospital Zurich, Zurich/Switzerland
2Institute Of Surgical Pathology And Molecular Pathology, University Hospital Zurich, Zurich/Switzerland

Contact E-mail Address: piero.valli@usz.ch

Introduction: Complex gastrointestinal motility disorders such as chronic intestinal pseudo-obstruction (CIMO) or Hirschsprung’s disease (HD) are challenging to diagnose and treat appropriately. Thorough assessment of patient history, radiographic exams, endoscopy and motility measurements aid in diagnosis, yet underlying pathology is the cornerstone to enable a more distinct diagnosis of neuromuscular GI disorders. Traditionally, surgical procedures have been performed to obtain specimen suitable for accurate histologic analysis.

Aims and Methods: We performed endoscopic full-thickness resection (eFTR) using a full-thickness-resection device (FTDR) under moderate propofol sedation in four patients with suspected severe neuromuscular gut disorders including CIMO.

Results: Patient 3: A 19-year-old male patient with a history of cerebellar atrophy suffering from severe small bowel ileus with a history of laparotomy, detorquation and appendectomy after colic volvulus at the age of 15. Histologic analysis revealed irregular configuration of the myenteric plexus, but primary neuro- or myopathic diagnosis such as HD were ruled out. GI dysmotility due to cerebral palsy syndrome was suspected. Patient 2: After a life-long history of recurrent obstipation, colonic dilatation, ileus symptoms and various colonic segment resections, diagnostic eFTR was performed in a 55-year-old female patient. The diagnosis of hypoganglionosis was established by LDH histochemical and by immunohistochemical reactions with Calretinin and Map-2 Kinase. Patient 3: A 19-year-old male patient with a history of a sigmoid volvulus and massively dilated large bowel segments. Enzyme histochemistry excluded HD upon histopathological analysis. The inner muscle layer showed fibrosis, eosinophilic leptomiosis and lymphocytic ganglionitis. Congenital CIMO was diagnosed due to degenerative leiomophathy. Patient 4: A 56-year-old male patient with acute ileus and a year-long history of constipation and abdominal pain. Histopathological analysis
revealed hypoganglionosis, severe fibrosis of the inner muscle layer and reduced nerve bundles. Technical as well as histological success providing large full-thickness gut resection device is a well feasible and effective technique to provide full-thickness gastrointestinal motility. The mean diameter of the resected specimen was 21 mm (range 20–22 mm). No adverse events reported. The most frequently reported AE in the YH12852 treatment groups were constipation and diarrhea. YH12852 appeared to increase bowel movement greater than prucalopride, particularly at 0.5 mg. YH12825 may have a significant potential for the treatment of GIMDs.

P1137 HEALTHCARE PROFESSIONALS FAIL TO PROVIDE ADEQUATE SUPPORT ABOUT OPIOID-INDUCED CONSTIPATION TO STRONG-OPIOID USERS

V. Andrensen1, V. Banerji2, G. Hall3, A. Lass4, A. V. Emmanuel5
1Gastroenterology, Innsbruck Hospital, Hamburg/Germany
2InsightDios, London/United Kingdom
3Medical, Shinomi Ltd, London/United Kingdom
4Neuro-gastroenterology, National Hospital for Neurology and Neurosurgery, London/United Kingdom

Introduction: Constipation is a common side effect of opioid use. Available laxative therapies for opioid-induced constipation (OIC) leave the patient with significant residual symptoms, which may lead them to adjust or stop their opioid intake in order to have a bowel movement, unless effectively counselled.

Aims & Methods: This subgroup analysis of an international survey investigated counselling resources, information-seeking, and sources of support in subjects with constipation caused by the use of strong opioids (e.g. buprenorphine, fentanyl). This was a quantitative, questionnaire-based, online survey conducted in France, Germany, Italy, Spain and the UK among respondents aged ≥40 years with largely non-cancer-related chronic pain, treated long-term with strong opioids and having constipation (N = 2016). The survey assessed past medical history, opioid use, treatment-seeking behaviour, symptoms, burden of disease, and effects on quality of life of constipation.

Results: In general, responders find it difficult to combine pain management relief and constipation and did not have a bowel movement over the past week (36%). Appropriately one-fifth (22%) of the respondents were very or somewhat dissatisfied with the effectiveness of their current constipation treatment and only 43% strictly adhered to prescribed treatment regimens, with 32% reporting other treatment options. A significant number of respondents (44%) admitted that their constipation becomes so bothersome that they have to combine different methods to relieve it, and 40% often cut down their opioid medication or even skip it entirely (9%) to relieve constipation. To manage their constipation, responders regularly used a variety of approaches, including dietary measures (48%), exercise (23%) and single (32%) or multiple (15%) laxative treatments. Only 45% of respondents reported that their healthcare professionals (HCPs) had warned them about constipation as a potential side effect of opioid use. Almost two-thirds of respondents (63%) reported that their HCP was the main information source on opioid-induced constipation. Although 58% of respondents stated that they would have liked their HCP to provide more information about OIC, 48% preferred to deal with constipation on their own, rather than discuss it with their HCP. Other common sources of information were online search engines (44%) and online health forums (29%). Less than half of respondents (43%) strictly adhered to prescribed treatment regimens, with 32% reporting other treatments.

Conclusion: A proportion of patients are not satisfied with their current constipation treatment and they sometimes find balancing the need for adequate pain relief with constipation side effects challenging; consequently, many fail to adhere to their prescribed treatment regimens, or resort to using suboptimal strategies, such as reducing their opioid intake, to relieve constipation. Despite this dissatisfaction, many HCPs are not counselling patients adequately about constipation as a common potential side effect of opioid use. While most patients would like to have more support from their HCP, nearly half prefer to deal with constipation on their own, perceiving HCPs as unsupportive and dissatisfied.

Introduction: Three-dimensional high-resolution anorectal manometry (3DHARM) is the most precise tool to assess function of the anal canal and may be useful in evaluation of children after surgery on lower gastrointestinal tract that may present wide spectrum of symptoms from gastrointestinal tract. Our aim was to evaluate children after surgery for anorectal disorders using 3DHARM.

Aims & Methods: We performed a prospective study of 43 children (30 male, mean age 7 years) after surgery for anorectal disorders at the Departments of Pediatric Gastroenterology, Medical University of Warsaw, Poland. The group consisted of 24 children after surgery for Hirschsprung’s disease (HD), 12 children after surgery for anal atresia (AA) and 7 children after proctocolectomy for other reasons (PC). In all children conventional manometry and media of the anorectum of children after surgery.

Results: The lowest values of resting, squeeze and the pressure of PRM were observed in NRFI [69.6 mmHg and 61.3 mmHg, respectively; p = 0.03]. ROC cut-off value for mean resting pressure between asymptomatic children and those with fecal incontinence was 68.5 mmHg. Significantly lower PRM resting pressure were observed in NRFI group and lower PRM squeeze pressure in NRFI (45.6 mmHg and 63.6 mmHg, respectively). Threshold of urge were significantly higher in group C as compared to A group (87.5 cm3 and 30 cm3, respectively; p = 0.003).

Conclusion: Our study demonstrated lower pressure parameters in children after surgery with the lowest values in patients suffering from anal atresia, which was correlated with incontinence. 3DHARM may be useful tool for assessing the function of the anorectum of children after surgery.

Introduction: Linaclootide, a guanylate cyclase C agonist, has been shown in clinical trials to relieve constipation and improve abdominal pain and discomfort in patients with irritable bowel syndrome with constipation (IBS-C), but there are limited UK-specific real-world data to support this.

Aims & Methods: A multicentre, observational prospective 52-week study was conducted in eight specialist hospitals in England and Scotland. The primary objective was to describe the change in IBS-Symptom Severity Scale (IBS-SSS) score from baseline at 12 weeks after linaclootide initiation. Consenting patients aged ≥ 18 years with IBS-C and treated with linaclootide (290 mcg) for IBS-C were recruited. Data were collected on patient demographic and clinical characteristics, concomitant medications, patient-reported outcomes, including IBS-SSS score, and adverse events were collected. Results at 12 weeks (primary endpoint) have been presented previously; here we report analysis of real-world clinical experience 52 weeks post-linaclootide initiation.

Results: 202 patients were recruited; 185 (92%) were female. At baseline, median age was 44.9 (range 18–77 years; 84 (42%) reported concomitant laxative use. Mean baseline IBS-SSS score was 339 (standard deviation [SD] ± 100; n = 193); 129 (67%) patients had IBS-C classified as severe (score ≥ 300), 54 (28%) moderate (175–300), nine (5%) mild (75–175) and one (0.5%) normal (<75). At 52 weeks, mean IBS-SSS score was 256 (SD ± 116; n = 78); 31 (40%) patients had severe (score ≥ 300), 27 (35%) moderate, 14 (18%) mild and six (8%) normal. IBS-SSS scores improved significantly between baseline and 52 weeks, with a mean decrease of 71 (SD ± 106) points overall (t-test p < 0.001; n = 76 with paired data) and 94 (SD ± 102) points on the patients remaining on linaclootide (p < 0.001; n = 34). Of the 76 patients with paired data, 41 (54%) reported no change in IBS-SSS score of ≥ 50 points or score fell below 150 [if baseline score ≥ 150] [Table]. At 52 weeks, 41 (20%; n = 202) patients remained on linaclootide, 87 (43%) had stopped (< 4 doses in past week)

Conclusion: Linaclootide was associated with a significant improvement in IBS-SSS score at 52 weeks and was reasonably well tolerated. These results provide valuable insights into the longer-term outcomes of linaclootide treatment in patients with IBS-C in real-world clinical practice.

Introduction: Irritable bowel syndrome (IBS) may be associated with disturbances of gut microbiota composition and functions, such as altered bacterial fermentation.

Aims & Methods: The aim was to study the effect of fecal microbiota transplantation (FMT) on gut bacterial fermentation products: short-chain fatty acids (SCFAs). Patients diagnosed with IBS according to Rome III criteria (n = 13) were included. They received freshly donated faeces from relatives, instilled into the descending part of the duodenum via gastroscope. Fecal samples were collected from the donors and the patients before FMT and from the patients after FMT at weeks 1, 3, 12, and 20/28, assessing the following domains: nausea, bloating, abdominal pain, diarrhea, constipation and anorexia.

Results: Before FMT, concentrations of several SCFAs were significantly lower in IBS patients compared to donors (Table 1). After FMT, concentrations of SCFAs increased within the first 3 weeks, and the increment lasted up to 28 weeks (Table 1, Figure 1). Symptom scores as assessed by IBS-SQ improved from before FMT until week 20/28 after FMT as follows: nausea (P = 0.0013), bloating (P < 0.0001), abdominal pain (P = 0.0005), diarrhea (P < 0.0001), constipation (P = 0.03), and anorexia (P = 0.09). Correlations were found between abdominal pain and both acetic acid (r = 0.69, P = 0.04) and total SCFAs (r = 0.69, P = 0.044) in IBS patients before FMT. Inverse correlations were found 3 weeks after FMT between nausea and isovaleric acid (r = −0.65, P = 0.014), and between constipation and propionic (r = −0.74, P < 0.0001), iso-butyric (r = −0.79, P < 0.0001) and n-valeric acids (r = −0.79, P < 0.0001) and isovaleric (r = −0.72, P < 0.0001).

Most commonly due to side effects (n = 51) or lack of efficacy (n = 18), and 74 (37%) were lost to follow-up/not known. Overall, 174 adverse events possibly related to linaclootide were reported in 77 (38%) patients, most commonly diarrhea (25%; n = 51), abdominal pain (9%; n = 18) and abdominal distension (6%; n = 13).

Conclusion: Linaclootide was associated with a significant improvement in IBS-SSS score at 52 weeks and was reasonably well tolerated. These results provide valuable insights into the longer-term outcomes of linaclootide treatment in patients with IBS-C in real-world clinical practice.

2Department Of Psychiatry And Psychology, Maastricht University Medical Center+, Maastricht/Netherlands

Contact E-mail Address: L.vork@maastrichtuniversity.nl

Introduction: Selective Serotonin Reuptake Inhibitors (SSRI’s) have shown efficacy in reducing symptoms but less so on pain in irritable bowel syndrome (IBS). Comorbid anxiety frequently occurs in IBS. We hypothesized that SSRI’s will particularly be effective in reducing abdominal pain in IBS patients with pronounced comorbid anxiety. As methods for symptom evaluation were used 1) gastrointestinal symptom rating scale (GSRS) as primary parameter and 2) a new method called the Experience Sampling Method (ESM). With ESM digital assessments are completed randomly and repeatedly during daily life, therewith capturing fluctuating symptom patterns more accurately than retrospective questionnaire methods.

Aims & Methods: IBS patients with comorbid panic disorder were included in a randomized controlled trial on escitalopram versus placebo. Measurements were completed at baseline (t = 0) and after 3 (t = 3) and 6 months (t = 6). At each time point, the gastrointestinal symptom rating scale (GSRS) and a 7-day ESM period were completed. Subjects completed ESM assessments on a palmtop computer at 10 random moments each day during 7 consecutive days. ESM periods were analysed when at least 1/3 (i.e. 23) of the assessments were completed. Mixed linear modelling was used with the GSRS symptom domain and related anxiety scores as the dependent variable and symptom change score as the independent variable. A sensitivity analysis including the GSRS symptom domain and related anxiety scores as the dependent variable and symptom change score as the independent variable. A sensitivity analysis including the GSRS symptom domain and related anxiety scores as the dependent variable.

Results: In total 57 patients (15 escitalopram and 14 placebo; 21 female; 37 ± 14.8 years; equal abdominal pain and anxiety scores at baseline) were included. Average GSRS-AP scores were not significantly different between escitalopram and placebo at t = 3 (B: 0.265, SE: 0.451, p = 0.557) or t = 6 (B: 0.229, SE: 0.539, p = 0.670). For the ESM analyses, at t = 6, average abdominal pain scores were significantly lower (B: 1.30, SE: 0.623, p = 0.037) (on a 1–7 scale) in the escitalopram group compared to placebo. With increasing anxiety levels (scores 2, 3 and 4) this difference further increased to 1.57, 1.84 and 2.11, respectively. A sensitivity analysis on subjects that completed all 3 valid ESM periods (i.e. at least 1/3 of total number of assessments at t = 0, t = 3 and t = 6) showed similar results.

Conclusion: Using GSRS as primary outcome, no significant effect of escitalopram on either gastrointestinal (GI) or GI related anxiety scores was found. However, using ESM, a significant improvement in abdominal pain was observed, related to anxiety scores. These data 1) challenge the value of traditional retrospective methods with end-of-period symptom recording and 2) are in favour of novel more accurate momentary symptom registrations such as the Experience Sampling Method.

Introduction: Linaclootide, a guanylate cyclase-C agonist, stimulates intestinal fluid secretion and decreases visceral hypersensitivity and is licensed for use in irritable bowel syndrome with constipation (IBS-C). There is a relative paucity of data concerning its effect on gastrointestinal (GI) motility. Linaclotide reduced somatic symptoms (8.3 ± 2.12 vs. 68.17 ± 17.6, p = 0.02). Linaclootide reduced somatic symptoms (8.3 ± 2.12 vs. 68.17 ± 17.6, p = 0.02). Linaclootide reduced somatic symptoms (8.3 ± 2.12 vs. 68.17 ± 17.6, p = 0.02).

Aims & Methods: To determine if a SeHCAT test may be used to predict response to rifaximin in patients with IBS-D or FD. b) To assess if rifaximin modifies SeHCAT result.

Results: Forty-one patients were included. BAD was present in 23 patients (56%). No clinical differences were found between BAD or non-BAD patients at study entry. Rifaximin resulted in a significant improvement in the number of daily stools (Δ = 2.1; P < 0.01), daily watery stools (Δ = 2.1; P < 0.01), and quality of life (58.4 ± 21.2 vs. 68.17 ± 17.6, p = 0.02). No differences were found between BAD and non-BAD patients in the improvement of any item. Rifaximin treatment did not modify SeHCAT value (9.5% before treatment. 10.7% after treatment; P = 0.4).
P1145 Fecal Microbiota Transplantation for Patients with Post-Infectious or Antibiotic-Induced Irritable Bowel Syndrome: Results from a Prospective Pilot Study

1Gastroenterology And Hepatology, VU university medical center, Amsterdam/Netherlands
2Medical Microbiology And Infection Control, VU University Medical Center, Amsterdam/Netherlands
3Medical Microbiology, Leiden University Medical Center, Leiden/Netherlands
4Gastroenterology And Hepatology, Haaglanden Medical Center, The Hague/Netherlands
5Afd. Medische Microbiologie, Leids Univers. Medisch Centrum, Leiden/Netherlands

Conclusion: Treatment with FMT appears promising for antibiotic-induced and post-infectious IBS. Based on these results, a randomized placebo controlled trial is warranted.

Results: Overall, 2428 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders2 with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p = 0.001] vs 49.0% [p = 0.004] vs 41.8%, respectively). Over the first 12 weeks of treatment, a greater proportion of patients reported no IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1–5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for >8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p = 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13–24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

Introduction: Adequate relief (AR) of irritable bowel syndrome (IBS) symptoms is a commonly used global outcome measure to assess treatment benefit in both clinical trials and real-life clinical practice. Conversely, inadequate relief (IR) is considered an important driver for patients to use healthcare resources such as general practitioner or gastroenterologist consultations. Eluxadoline (ELX) is a mixed μ-opioid receptor (OR) and δ-OR agonist and δ-OR antagonist approved for the treatment of IBS with diarrhoea (IBS-D) in the US and Europe.

Aims & Methods: To evaluate IR in patients treated with ELX in a post hoc analysis of data from two randomised, double-blind, placebo (PBO)-controlled Phase 3 trials (IBS-3001, IBS-3002). Patients meeting Rome III criteria for IBS-D were randomised 1:1:1 to twice-daily (BD) ELX (75 or 100 mg) or PBO. Efficacy was evaluated through Week 26. For evaluation of AR, patients were asked “In the last 7 days, have you had adequate (or satisfactory) relief of your IBS symptoms?” (Yes/No) on a weekly basis, via an electronic diary. As previously described, patients answering “Yes” for ≥50% of the total weeks during the target time interval were considered AR responders. Patients answering “No” were considered to have AR. This analysis evaluated the number of consecutive weeks that patients reported IR over Weeks 1–12 and 13–24 of treatment. Patients without AR analysis were ineligible for intention-to-treat (ITT) analysis; missing data were not imputed.

Results: Overall, 2428 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders2 with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p = 0.001] vs 49.0% [p = 0.004] vs 41.8%, respectively). Over the first 12 weeks of treatment, a greater proportion of patients reported no IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1–5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for >8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p = 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13–24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

Introduction: Irritable bowel syndrome with diarrhoea (IBS-D) is a chronic gastrointestinal disorder characterised by recurrent abdominal pain associated with diarrhoea. Eluxadoline, a mixed μ- and κ-opioid receptor agonist and δ-opioid

Conclusion: In this post hoc analysis of the pooled ELX Phase 3 studies, ELX-treated patients experienced fewer consecutive weeks of IR compared to those receiving PBO, within both Weeks 1–12 and 13–24 of treatment. As IR is thought to drive increased healthcare provider visits, these data suggest that ELX could potentially reduce healthcare resource use and subsequent healthcare costs associated with IBS. Further prospective study of the impact of ELX on AR and any subsequent reduction in healthcare costs is required, including the relationship between the number of consecutive weeks of IR and patients’ behaviour towards healthcare resource use.

Introduction: Diets reducing the content of fermentable short chain carbohydrates (fermentable oligo-, di-, monosaccharides, and polyols (FODMAPs)) as well as the National Institute of Health Care Excellence (NICE) diet have been reported to be effective in the treatment of patients with irritable bowel syndrome (IBS) (1,2). The mechanisms by which this efficacy is achieved are incompletely understood but it has been proposed that such diets reduce fermentation, mediated by changes in the microbiota (3). Change in pH around the ileocecal junction is considered to be a surrogate biomarker of caecal fermentation (4,5).

Aims & Methods: We aimed to compare the effect of a low FODMAP diet vs. the NICE diet on change in ileocaecal pH. We performed a single centre, randomized controlled trial of adult patients with Rome III defined IBS-mixed bowel habit (IBS-M) comparing the two dietary interventions. At baseline, patients ingested a wireless motility capsule (WMC) using a standardized protocol. Segmental transit times were derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures were presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires evaluating GI (verbal descriptor scale, Bristol Stool Form Scale [BSFS], and Global Symptom Score [GSS; 0–4 scale, where 0 = no symptoms and 4 = very severe symptoms]) and self-reported inadequate symptom control with loperamide were classified as having severe IBS-D.

Results: Of the 2423 patients in the pooled Phase 3 ITT population, 249 were classified as having severe IBS-D. Over Weeks 1–4, 26.8% and 30.3% of patients with severe IBS-D were responders with eluxadoline 75 and 100 mg, respectively, vs 8.1% of patients on placebo (Table). Higher proportions of patients were responders with eluxadoline vs placebo over each subsequent 4-week interval, with response rates observed at Weeks 1–4 consistently maintained across all subsequent 4-week time intervals. With both eluxadoline and placebo, proportions of responders discontinuing were <2% across each 4-week interval, and discontinuation rates in non-responders were higher than in responders (Table). Similar findings were observed in the ITT analysis set: over Weeks 1–4, 22.7% and 26.8% of patients were responders with eluxadoline 75 and 100 mg, respectively, vs 12.5% of patients on placebo. Over Weeks 21–24, 28.1% and 30.2% of patients with response rates observed at Weeks 1–4 consistently maintained across all 4-week intervals in the treatment group. For these analyses, patients with baseline GSS demonstrating a response and a minimum of 20 days of diary data. The intention-to-treat analysis set included patients randomized to a treatment group. For these analyses, patients with baseline GSS ≥3 (severe or very severe symptoms) and self-reported inadequate symptom control with loperamide were classified as having severe IBS-D.

Conclusion: Proportions of responders with eluxadoline 75 and 100 mg were consistently higher vs placebo across all 4-week intervals in the treatment period in patients defined as having severe IBS-D. Furthermore, discontinuation rates among patients showing a treatment response remained consistently low compared to non-responders. However, as these analyses were conducted in a clinical trial setting, the relatively high continuation rates in non-responders may not reflect the real-world situation. These findings suggest that eluxadoline has sustained efficacy in treating the diarrhoea and abdominal pain associated with IBS-D, including in patients with severe and inadequately managed symptoms.

Introduction: Galacto-oligosaccharides (GOS) are indigestible short-chain carbohydrates (FODMAPs, fermentable, oligo-, di-, mono-saccharides and polyols) that might reduce small intestinal fermentation and thus be beneficial in the treatment of IBS. In this study, we used oral galacto-oligosaccharides (GOS) and compared it to a low FODMAP diet and the NICE diet in IBS patients (Rome III criteria).

Methods: A randomized controlled trial of patients with Rome III defined IBS-M was conducted. Patients were randomly assigned to one of the three groups: (1) low-FODMAP diet, (2) NICE diet, or (3) low-FODMAP diet supplemented with oral GOS. The study was a 4-week randomized placebo-controlled, double-blinded, parallel-arm trial. The primary endpoints were changes in quality of life (QoL) and changes in symptoms (GI and extra-GI) as measured by validated questionnaires. Baseline was the period before randomization. All patients received a wireless motility capsule (WMC) with a standardized protocol. Segmental transit times were derived from the motility capsule. In addition, validated questionnaires evaluating GI and extra-GI symptoms were used.

Results: Of the 186 patients, 151 completed the study (67% of patients). The low-FODMAP diet and GOS significantly improved quality of life (p < 0.05) compared to the NICE diet. Both the low-FODMAP diet and oral GOS reduced symptoms such as GI symptoms (p < 0.05) compared to the NICE diet. The low-FODMAP diet and oral GOS were well tolerated and improved quality of life (p < 0.05).
associated with triggering gastrointestinal symptoms in irritable bowel syndrome (IBS).

### Aims & Methods:
This study aimed to assess whether oral α-galactosidase co-
gestion with foods high in GOS and low in other FODMAPs would reduce symptoms and breath hydrogen production in a double-blind, placebo-controlled crossover trial approved by Monash University Ethics Committee. Patients meeting the Rome III criteria for IBS who produced >10 ppm hydrogen on two consecutive breath samples following 10 g fructose were recruited. Participants were randomly assigned to full-dose enzyme (300 GALU α-galacto-
sidase), half-dose (150 GALU) and placebo (glucose) capsules. Following a 3-day low-GOFMAP run-in period, participants consumed provided diets high in GOS for a further 3 days. Gastrointestinal symptoms were measured daily using a 100 mm visual-analogue scale. Breath samples were taken hourly on the second last and analysed as area-under-the-curve, faecal samples were taken on the final day.

### Results:
Thirty-one participants with IBS (20 IBS-D, 4 IBS-C, 7 IBS-M) completed the study. The addition of high GOS foods resulted in a significant increase in overall symptoms (median 13.0 [IQR 1.5–22.0] to 35.5 [12.8–54.0]) compared to placebo (mean 5248 [9.5–42.0] vs 6.5 [2.0–15.8]; p = 0.022). Twenty-one participants exhibited GOS-sensitivity (>10 mm increase for overall symptoms). Of those, full-dose enzyme reduced overall symp-
toms (24.5 [17.5–35.8] mm vs 5.5 [1.5–15.0] mm; p = 0.006) and bloating (20.5 [9.5–42.0] vs 6.5 [2.0–15.8]; p = 0.017). Breath hydrogen production was minimal with no differences seen between placebo (528±SD 3339 ppm.12h) and full-dose (5585±3205; p = 0.597, paired samples t-test).

### Conclusion:
An oral α-galactosidase supplement taken with high GOS foods provides a clinically significant reduction in symptoms in GOS-sensitive indivi-
duals with IBS. The lack of change in breath hydrogen production points to a mechanism that may not be related to reduced gas and distension, rather suggesting a role of alterations to the microbiota. Future analysis of the faecal microbiota may pro-
vide insight for the mechanism of action. This strategy can be easily translated into a practical, cost-effective and acceptable intervention specific to high GOS foods for patients with IBS as an adjunct therapy to the low FODMAP diet.

### P115 PREVALENCE OF ANAL SQUAMOUS INTRAEPITHELIAL LESIONS IN LIVER TRANSPLANT PATIENTS

#### Introduction:
Anal squamous intraepithelial lesions (SILs) are precancerous lesions of anal squamous cell carcinoma and are largely related to human papillomavirus (HPV) infection. Immunosuppressed patients have a higher prevalence of these lesions. There are some studies in renal transplant recipients, but no information exists regarding prevalence in liver transplantation.

#### Aims & Methods:
Our aim was to evaluate the prevalence of anal squamous intraepithelial lesions in liver transplant recipients compared with healthy subjects. We performed a retrospective case-control study involving liver transplant recipi-
ents that were compared with a healthy control group. All patients were sub-
mitted to anal cytology. Those with abnormal cytological results, namely high-grade squamous intraepithelial lesions (HSIL), atypical squamous cells which cannot exclude high-grade squamous intraepithelial lesions (ASC-H), low-grade squamous intraepithelial lesions (LSIL) and atypical squamous cells of undetermined significance (ASC-US), were submitted to high-resolution anoscopy with biopsies of any suspicious lesion.

#### Results:
A total of 59 liver transplant recipients and 57 controls underwent anal cytology. In the liver transplant group, 37 (63%) were men, with a mean age of 54±10 years. The most common indication for transplantation was alcoholic cirrhosis in 26 patients (44%), the majority of the patients were only on tacro-
loimus (66%, 95% CI 1.22-28.121, p = 0.027).

#### Conclusion:
Liver transplant patients have a higher risk of anal squamous intraepithelial lesions and screening should be considered especially in smokers.

DAO was also examined vertically from the epithelium to the submucosa in all the examined tissues. The enzymatic activity of DAO is diminished in the colonic mucosa of patients with GMA. Up to now no studies concerning the expression of DAO in the upper gastrointestinal tract (GIT) of patients with or without GMA have been published. Therefore, the objective of this study was to analyse the immunohistochemical staining of DAO and its localisation in the upper GIT of patients with or without GMA.

Aims & Methods: The study was retrospective. The GMA group consisted of 21 patients with diagnosed food allergy. The control group (CG) included 17 patients with neither food allergy nor food intolerance. Tissue samples from esophagus, cardia (subdivided in esophageal and gastric region), corpus, antrum and duodenum already obtained during endoscopy were immunohistochemically stained for DAO. The expression of DAO was semi-quantitatively analysed with the following scale based on the staining intensity of DAO (SI-DAO): 0 (none), 1 (low), 2 (medium), 3 (high). The localisation of DAO was also examined vertically from the epithelium to the submucosa in all tissues.

Introduction: Immunohistochemical analysis found DAO in all segments of the upper GIT, but the SI-DAO was overall low. Across the upper GIT the median SI-DAO in the CG was 1.1 (range 0.9–1.3). The SI-DAO did not differ between the examined tissues. The SI-DAO was also low in the GMA group (median 1.0; range 0.8–1.3) and it was statistically significantly lower compared to the controls (median 1.1; p = 0.04) only in duodenum in the GMA group the SI-DAO in the esophageal region of the cardia and in corpus was significantly higher than in duodenum (see Table 1). The strongest DAO-staining was detected in the subepithelial superficial lamina propria (SLP) and one in the deeper lamina propria (DLP). The average of these two measurements constituted the number of these cells for each tissue.

Results: Immunohistochemical analysis found DAO in all segments of the upper GIT, but the SI-DAO was overall low. Across the upper GIT the median SI-DAO in the CG was 1.1 (range 0.9–1.3). The SI-DAO did not differ between the examined tissues. Conclusion: The above findings indicate that DAO is present in low amounts in all segments of the upper GIT. But only in the duodenum a significant difference was found between GMA and CG, thus indicating that histamine-mediated symptoms most likely arise in duodenum. Therefore, regarding the upper GIT, the immunohistochemical staining for DAO only in duodenum could serve as an additional diagnostic parameter for detecting patients with GMA and possibly other histamine-mediated diseases. The above mentioned distribution pattern of DAO strengthens the theory that DAO acts extracellularly and is responsible for the elimination of the transepithelially absorbed exogenous histamine as well as of the endogenous histamine, as its highest staining intensity is found at the SLP throughout the upper GIT.

Introduction: Chronic atrophic gastritis (CAG) is considered to be a precancerous condition for gastric cancer; it is either autoimmune in origin or caused by infection with Helicobacter pylori. The majority of CAG patients are asymptomatic or experience aspecific manifestations like epigastric fullness, early satiation, nausea, bloating. The drugs currently used for upper gastrointestinal (GI) diseases, mainly proton pump inhibitors (PPIs), appear inappropriate in such patients, mainly because acid production is virtually lacking. The use of

L-cysteine has been proposed as adjuvant therapy in CAG; the amino acid binds covalently to acetaldehyde (a Group I human carcinogen), removing it from the stomach. The aim of present study was to use L-cysteine to improve the symptoms in patients with diagnosis of CAG.

Aims & Methods: One hundred fourteen consecutive patients (M = 43, mean age 59.9 years) (with CAG) by means of both gastric histology (moderate to severe chronic, atrophic, body gastritis according to the OLGA staging system) and serology (pepsinogen 1 < 25 µg/l gastrin-17 > 14 pmol/l) (GastroPanel®, Boehr, Oyt, Finland) entered the study. Forty-one patients (11 M, mean age 49.4 yr, range 27–71 years) were treated with L-cysteine (100 mg 3 times daily, with meals) for 24 months (Group 1). As a control group we enrolled 73 CAG patients (M = 32, mean age = 55.3 yr, range = 32–77 years) followed up for 24 months without any related therapy (Group 2). Early satiation, nausea, bloating) were recorded at baseline and after 3, 6, 12, 24 months, according to severity score (0–3 for each symptom, min. 0 = no symptoms; max. 12 = full symptom).

Results: The herbal symptomatic score results as follows, lasting the 24 months follow-up. Group 1: baseline 4.93; 3 months 3.36; 6 months 2.96; 24 months 2.64. Group 2: baseline 5.9, 3 months 6.2, 6 months 5.6, 24 months 5.8 (p < 0.01). Subdividing the CAG patients according to the etiology (autoimmune gastritis or previous Helicobacter pylori infection) two different groups were identified in improving symptoms. No relevant side effects were observed during the study.

Conclusion: The administration of L-cysteine to subjects affected by moderate–severe chronic atrophic gastritis seems able to improve the symptoms in a two-year follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1155 PROGNOSTIC SIGNIFICANCE OF SERUM INFLAMMATORY MARKERS IN GASTRIC CANCER

Introduction: Despite undergoing potentially curative resection a significant proportion of patients develop cancer recurrence. Several cellular and humoral components of systemic inflammatory response have been reported and associated with poor outcome. To date, no study has comprehensively examined the relationship between readily available markers of inflammation and survival in gastric cancer.

Aims & Methods: Patients undergoing surgery for stage I-III gastric cancer between 2004–2016 at a regional unit were identified. Measurements of various systemic inflammation markers were recorded pre-operatively. Pathological factors were recorded from reports issued at the time of resection. The modified Glasgow Prognostic Score (based on CRP and Albumin), Neutrophil-Lymphocyte Ratio, Platelet-Lymphocyte Ratio and Neutrophil-Platelet score were recorded at baseline and after 3, 6, 12, 24 months, according to severity score.

Results: 331 patients were identified and 291 patients underwent potentially curative resection for gastric cancer. On univariable DFS analysis, female gender, differentiation, lymph node ratio, R1 status, platelet count and mGPS were significant in predicting importance.

Conclusion: The administration of L-cysteine to subjects affected by moderate–severe chronic atrophic gastritis seems able to improve the symptoms in a two-year follow-up.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1156 ANALYSIS OF REBLEEDING PATIENTS IN UPPER GASTROINTESINAL BLEEDING IN A SINGLE CENTER SERIES

1Digestive Diseases, Hospital Virgen de las Nieves, Granada/Spain
2Gastroenterology, "Virgen de las Nieves" University Hospital, Granada/Spain

Contact E-mail Address: eredondoec@gmail.com

Introduction: Upper gastrointestinal bleeding (UBG) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departments. In-hospital mortality from UGB has decreased during the last 2 decades with a corresponding increase in the performance of endoscopy and endoscopic therapies. Several studies suggest that improvements in the therapeutic procedures for patients with UGB could be responsible of the mortality decline. Despite this, UGB represents a true emergency, associated with significant morbidity, mortality and healthcare costs. Furthermore, rebleeding after initial endoscopic therapy is observed in 10–20%, and it has been associated with a higher mortality rate. Therefore, the definition of predictive factors for rebleeding is of outstanding importance.

Aims & Methods: The aim of our study is to analyze risk factors and outcomes in a population of patients who suffered rebleeding. We present a retrospective study on a prospectively built database of patients with GI bleeding admitted to the Emergency Room of “Virgen de las Nieves” University Hospital over 42 months, from January 2013 to July 2016. All patients underwent upper endoscopy, and risk factors including gender, age, demographic data, current medications (including antiplatelet drugs, NSAIDs and oral anticoagulants), clinical presentations, hemodynamics, admission laboratory test results, and endoscopic findings was collected. Interventions were documented, including the need for blood transfusion and the number of packed red cells units per patient, endoscopic therapy, interventional radiology procedures, and surgery. Clinical outcomes documented were in-hospital and delayed 6-months mortality, rebleeding and delayed 6-months bleeding and cardiovascular events.

Results: 507 patients were included (339 males; aged 42 ± 16.4). The incidence of rebleeding was 17.3% (n = 88). In the univariate analysis, factors related with rebleeding were creatinine levels (1.52 vs. 1.15; p < 0.001), tachycardia (96.28 vs. 88.24; p < 0.001), low levels of albumin (2.80 vs. 3.28; p < 0.001) and low CRP (p < 0.001). In a multiple regression model tachycardia and high creatinine were independent risk factors for rebleeding, and albumin showed as an independent protective factor (Table 1). Rebleeding was associated with in-hospital mortality (p < 0.0001), by contrast, it was not related to delayed 6-months mortality neither with GI mucosal and hemorrhagic events. The UGB risk scores AIMS 65 and Rockall showed poor predictive ability for acute rebleeding in the rebleeding patients’ group and was similar for Blatchford score (based on AURG).

Conclusion: Rebleeding in UGB is associated with increased in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. High creatinine and low albumin levels were independent risk factors for rebleeding, suggesting a potential predictive role of these parameters. AIMS65, Rockall risk scores were then used to perform a survival analysis in the rebleeding patients. No differences were found in improving symptoms. No relevant side effects were observed during the study.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1157 A CASE-CONTROL STUDY ON THE RISK OF UPPER GASTROINTESINAL MUCOSAL INJURIES IN SUBJECTS PRESCRIBED NSAIDS AND ANTI-THROMBOTIC DRUGS USING THE LARGE ORGANIZED DATABASE OF CLAIMS IN JAPAN (APPROXIMATELY 3.7 MILLION OF POPULATION ON AN ACCUMULATED BASIS)

Introduction: Upper gastrointestinal (GI) adverse effects induced by NSAIDs and anti-thrombotic drugs are increasing along with progressive aging of society. Recently, it is essential to perform pharmaco-epidemiological studies to identify adverse effects in the real-world setting using a large-scale medical database. We conducted a case-control study to analyze the risk of upper GI mucosal injuries in subjects prescribed NSAIDs and anti-thrombotic drugs using the large organized database of claims in Japan.

Conclusion: Rebleeding in UGB is associated with increased in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. High creatinine and low albumin levels were independent risk factors for rebleeding, suggesting a potential predictive role of these parameters. AIMS65, Rockall risk scores were then used to perform a survival analysis in the rebleeding patients. No differences were found in improving symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The medical claims database developed by Japanese Medical Data Center (JMDC) Co., Ltd. was selected as data source in the present retrospective observational study. The JMDC claims database comprised of integrated medical and pharmacy claims, and includes both hospital and outpatient care from over 90 payers (approximately 3.7 million of population on an accumulated basis). Eligible subjects were aged 20 to 74 and registered for at least 3 months in the database. Multivariate logistic regression analysis was used to calculate odds ratios of occurrence of each upper GI mucosal injuries caused by NSAIDs, COX-2 selective inhibitors, low-dose aspirin and oral anticoagulants in subjects prescribed NSAIDs and anti-thrombotic drugs using the large organized database of claims in Japan.

Introduction: Percutaneous left atrial appendage occlusion (LAAO) is increasingly recognized as valid alternative therapy to reduce thromboembolic risk in patients with non valvular atrial fibrillation (AF) and contraindications for long term oral anticoagulation (OAC) therapy1,2. Patients at high thromboembolic risk with previous gastrointestinal bleeding (GIB) might be at risk of bleeding recurrences in case of resuming anticoagulation. They could be selected for alternative therapies like LAAO. Up to now, there is no scientific consensus for patient selection for LAAO based on recurrent GIB risk.

Aims & Methods: We aimed to review the literature on gastrointestinal (GI) bleeding patients who were proposed to discontinue or delay the reversibility profile of each lesion in an organ by organ and lesion by lesion approach to stratify the risk of bleeding individually. We systematically collected data from both prospective and retrospective studies from pubmed in order to extract rebleeding risk by etiology. The reversibility profile was defined by type of treatment needed to cure the lesion. Low reversibility (LR) profile was defined as a need for heavy treatment (surgery, radiotherapy, embolisation) to cure the lesion or as diffuse lesions.

Results: The most frequent reported causes of bleeding are peptic gastroduodenal ulcer (60%) for upper GI, diverticulosis (40%), colitis (20%) and anorectal diseases (20%) for lower GI and angiodysplasia (23%) for the midgut, these latter being responsible for 5% of all GI bleeding causes. The rate of cases under anticoagulation under OAC therapy is 5-7%. The reversibility profile to compare the risk stratification of each predictor by comparing AIMS65 score with Glasgow-Blatchford score (GBS), full Rockall score and pre-endoscopic Rockall score. We retrospectively study 17 patients who visited the intergeneric Paik Hospital with NVUGIB between 2013 and 2016. Among these, AIMS65, GBS, and Rockall scores were measured. The primary outcome was inpatient mortality, and secondary outcomes were rebleeding, needs of endoscopic intervention, requirement of transfusion, intensity of ICU admission (ICU) admission. Each scoring system and prognostic factors were compared using the ROC curve.

Results: In this study, 17 of the 512 selected patients died, and re-bleeding was confirmed in 30 patients. AUROC between AIMS 65 and mortality was measured at 0.844 higher than 0.720 and 0.743 for GBS and pre-endoscopic/ full Rockall score. (p < 0.001) For AUROC for secondary outcomes, AIMS 65 was superior to other scores in predicting the ICU admission (0.728, p < 0.001).

Conclusion: In this single-centre study, the management of GIB could be improved in multiple areas in line with international guidelines. Audits in other centres are required to quality assure the management of GIB. Interestingly, rates of anaemia at discharge and on follow-up are high. Such patients may benefit from iron replacement at discharge.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Postgraduate School of Medicine, Birmingham/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: Peptic ulcer disease (PUD) accounts for 25–56% of acute upper gastrointestinal bleeding (AUGIB) and is associated with high mortality.

Aims & Methods: In line with international guidelines, we aimed to audit our practice of bleeding PUD at a district general hospital within the West Midlands, UK. We retrospectively identified all patients with AUGIB who had inpatient endoscopic confirmation of PUD between November 2012–2014. We scrutinised endoscopy and case records to assess management related to PUD, in addition to follow-up records with the general practitioner.

Results: We identified 91 patients (median age 78.4, 65.9% male), of whom 63.7% were admitted with AUGIB, whereas 36.3% developed bleeding during their hospital stay. The majority were duodenal (74.7%) vs. gastric (25.3%). 31.8% were related to aspirin/non-steroidal anti-inflammatory drug use. 45 (52.7%) had high risk (Forester 1a-2b) lesions, of whom 38/48 (79.2%) received dual endoscopic therapy and 6/48 (12.5%) received adrenaline monotherapy. 30/48 (62.5%) were recommended adrenaline volumes of 13ml. Of 90% prescribed intravenous proton pump inhibitor infusion, 85% did not complete the full 72-hour duration. Rebleeding occurred in 12 patients (13.2%) after a median of 3-days post endoscopy. 10 (83.3%) underwent repeat OGD. 2 (16.7%) underwent CT embolisation, whilst 3 (25.0%) underwent surgery. Aspirin resumption was observed in 4/20 (20.0%) after haemostasis for PUD, whilst rebleed planning was documented on the endoscopy report in 33.0%. Regarding H. pylori, 51% underwent assessment with biopsies. 10 (36%) had positive result of whom 7 (70%) received eradication. 12/23 (52%) patients underwent follow-up endoscopy following gastric ulcer. The median transfusion requirement per patient was 2 units. Despite this, rates of anaemia at discharge and at 6 months were 83.5% and 62.9% respectively, with iron therapy initiated in 12.1%. Overall, our 30-day mortality rate was 12.1%.

Conclusion: In this single-centre study, the management of PUD could be improved in multiple areas in line with international guidelines. Audits in other centres are required to quality assure the management of PUD. Interestingly, rates of anaemia at discharge and on follow-up are high. Such patients may benefit from iron replacement at discharge.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There are several risk-scoring systems available to assist the management of upper gastrointestinal bleeding (UGIB). The aim of this study is to compare the performance of pre-endoscopy (pre-RS), post-endoscopy Rockall score (post-RS), GBS and AIMS65 scores in predicting the need for intervention in patients admitted to hospital for UGIB.

Aims & Methods: Data related to the three scoring systems were collected prospectively and scores calculated in consecutive patients who were admitted with acute UGIH to the Royal Adelaide Hospital over 24 months. The performance of the three scoring systems was evaluated using the receiver operating characteristic (ROC) curves, in predicting the following outcomes: the need for endotherapy, rebleeding risk, transfusion requirement, surgical intervention and death. All patients received high dose acid suppression therapy.

Results: Of the 155 (89M; 68.8 ± 0.6yrs) patients who presented with UGIB, 622 (402M; 65.7 ± 0.6yrs) underwent endoscopy with 123 (38%) required endoscopic intervention. The model, a horizontal 10-mm incision was made on the lower part of the left hepatic lobe. Commercial hemostatic powder, smectite, starch and normal saline were respectively applied. Bleeding duration and blood loss were recorded. 1 week later, rats were sacrificed and liver tissue was collected for histopathology.

Conclusion: Smeetsite demonstrated the best hemostasis effect, and its mean coagulation time was 1.45 ± 0.026 min. Commercial hemostatic chitosan stypic powder need 2.5 ± 0.04 min for complete clotting, while Starch group was 4.275 ± 0.056 min and 4nal saline group was 4.025 ± 0.018 min (p < 0.05). Similarly, smeetsite led to less blood loss (0.6188 ± 0.034 g), while rats lost 2.3288 ± 0.123g blood (p < 0.05) under normal saline treatment. For starch and commercial chitosan, the blood loss was respectively 2.086 ± 0.061 g and 1.252 ± 0.028 g. Histopathologic results confirmed that smeetsite was biocompatible to tissue.

P1162 STEROID ADMINISTRATION IS AN INDEPENDENT RISK FACTOR FOR REBLEEDING IN HEMORRHAGIC DUODENAL ULCER WITH A DOSE-RESPONSE RELATION

W. Hatta, Y. Kondo, T. Koike, T. Kanno, N. Asano, A. Imatani, T. Shimosegawa
Division Of Gastroenterology, Tohoku University Graduate School of Medicine, Sendai/Japan

Contact E-mail Address: wakku-style@festad.ocn.ne.jp

Introduction: Hemorrhagic gastroduodenal ulcer is commonly seen in routine clinical practice, and there have been many studies investigating risk factors for rebleeding. However, few studies have evaluated hemorrhagic gastric ulcers (HGU) and hemorrhagic duodenal ulcer (HDU) separately. Furthermore, the relation between steroid administration and rebleeding in hemorrhagic gastro-duodenal ulcer remains unclear.

Aims & Methods: The aim of this study was to clarify the difference of rebleeding between HGU and HDU, and associated factors for rebleeding of HGU and HDU. Between March 2005 and September 2016, 176 consecutive patients with hemorrhagic gastroduodenal ulcer (106 with HGU and 70 with HDU) who underwent endoscopic hemostasis, were enrolled in this study. Regular dose proton pump inhibitor was administered to all patients after the diagnosis of hemorrhagic gastroduodenal ulcers. Rebleeding was defined as hematemesis or melena with ulcers confirmed by endoscopy or a decrease in the hemoglobin level > 2 g/dl in the presence of endoscopically proven ulcers. First, we compared the rebleeding rate between HGU and HDU. Subsequently, associated factors for rebleeding of HGU and HDU were calculated by logistic regression analysis individually. The estimated factors were age (< 65/≥65 years), gender, location of ulcer (upper third/middle or lower third in HGU and 2nd portion/bulbs in HDU), undertaking comorbidities (ischemic heart disease, liver cirrhosis, hyper-tension, diabetes mellitus, and hyperlipidemia), number of ulcers (multiple/single), hemostasis method (pure ethanol injection therapy/other therapies), anti-thrombotic therapy, anticoagulation therapy, NSAID administration, steroid administration, antacid administration in the initial ulcer bleeding, hypoalbuminemia (serum albumin level ≤ 2.5 g/dl), and hemodialysis. We further investigated the detailed association between steroid administration and rebleeding in HDU, including dose-response relation.

Results: The rebleeding rate of HGU and HDU were 5.7% and 22.9%, respectively, which was statistically significant (P = 0.001). There was no missing data in the estimated factors. Although no factor was associated with rebleeding in HDU, multivariate logistic regression analysis revealed that steroid administration and rebleeding for hemostasis in multiple ulcers [odds ratio (95% confidence interval) = 2.42 (2.76–213), P = 0.004], steroid administration [14.0 (1.73–113), P = 0.013], and hemodialysis [9.53 (1.00–90.7), P = 0.049]. Regarding the details of steroid administration, multivariate analysis showed that middle or high steroid administration (≥ 20 mg in prednisolone) (52.7 [3.19–871], P = 0.006) was a significant risk factor for rebleeding of HDU, with a dose-response relation (P = 0.015).

Conclusion: HDU developed significantly higher rebleeding after endoscopic hemostasis, compared with HGU. In addition to multiple ulcers and hemodialysis, we firstly demonstrated by multivariate analysis that steroid administration is an independent risk factor for rebleeding of HDU after endoscopic hemostasis, with a dose-response relation.

P1164 PREDICTORS OF LIFE THREATENING MUCOSAL ULCERATION AFTER VARICEAL SCLEROTHERAPY

A. S. Hanafi
Internal Medicine, Zagazig University, Zagazig/Egypt

Contact E-mail Address: dr_amr_hanafi@yahoo.com

Introduction: Life-threatening bleeding could occur early after variceal sclerotherapy in cirrhotic patients.

Aims & Methods: We aimed to determine simple predictive factors of this complication in cirrhotic patients. Among 750 patients treated with variceal sclerotheraphy (esophageal varices: EV = 655, 87.3%) and (gastroic varices: GV = 95, 12.7%) Zagazig University hospital-endoscopy unit- Internal medicine department, in the period from October 2014 till July 2016, 150 patients (20%, mean age 46.2 ± 9.4 years) (EV = 129, GV = 21) developed bleeding due to sclerotheraphy induced ulcers confirmed by endoscopy 6.4 ± 2.1 days after the procedure. Cirrhosis was post viral hepatitis C (89%), hepatitis B (10%) and cryoproteinogenic in (1%). A case-control study was performed comparing these
patients with 150 patients who underwent endoscopic variceal sclerotherapy without the development of bleeding due sclerostatic ulceration.

Results: Bleeding occurred 6.4 ± 2.1 days (2–10) following sclerotherapy. Twenty-three patients died following the bleeding (15.3%). Using a multivariate analysis; pre-procedural factors as serum albumin ≥2 g/dl [OR 1.3], total bilirubin >16 mg/dl, platelet ratio index (APRI) > 1 [OR 1.2], low prothrombin concentration <50% [OR 1.5]. Intraprocedural factors as amount of ethanolamine >15.5 ml [OR 2.6], amacarey >3.5 ml [OR 2.9]. Post-procedural factors within 24 hours after endoscopy: leukocytosis >12,000 cell/ml [OR 1.9], drop of hemoglobin >10% of the pre-endoscopic value [OR 3.2], prolonged INR > 1.55 [OR 1.2].

Conclusion: Bleeding related to sclerostatic ulcers is not uncommon, but may be life threatening. The proposed predictive factors should be watched and minimized before and during variceal sclerotherapy.

Introduction: Few studies were reported on the association between sleep disorders and Rome III-based functional dyspepsia (FD).

Aims & Methods: The aim of this study is to investigate the prevalence of sleep disorders in FD patients and the risk factors associated with sleep disorders. This multicenter, cross-sectional study had been conducted from August 2014 to December 2016 at 6 hospitals in Korea. Inclusion criteria were FD patients (≥18years) met the Rome III criteria among the patients visited the gastroenterology department for dyspepsia. Exclusion criteria were prior surgery to the upper gastrointestinal tract, history of ulcer disease, erosive GERD, history of malignancy, and severe comorbidity. Healthy control group who had no clinical history of gastroduodenal related disorder and no abnormal finding on endoscopy recruited from health examination center for screening. The Pittsburgh Sleep Quality Index was used to assess sleep disturbance. Hospital anxiety and depression scale was used to identify anxiety and depression.

Results: This study included 169 FD patients and 223 healthy control groups. The total Pittsburgh Sleep Quality Index score was higher in FD patients than health controls (7.8 ± 4.3 vs 5.6 ± 3.1, p = 0.000). The prevalence of sleep disorder was significantly higher in FD patients than healthy control (41.2% vs 18.4%, p < 0.000). In univariate analysis, FD was significant risk factor for sleep disorder (OR 3.12, p = 0.001). The independent risk factors for sleep disorder in multivariate analysis were FD (OR 1.80, p = 0.026), female (OR 1.78, p = 0.028) and depression (2.91, p = 0.015).

Conclusion: FD significantly impacted on sleep disorder. FD was independent risk factor in sleep disorder.

PI1166 PREVALENCE OF DYSPEPSIA IN INDIVIDUALS WITH GASTRO-OESOPHAGEAL REFUX-TYPE SYMPTOMS IN THE COMMUNITY: A META-ANALYSIS

Introduction: Dyspepsia and gastro-oesophageal reflux are highly prevalent in the general population, but the two conditions are felt to be separate entities. However, there are numerous mechanisms implicated in the pathogenesis of functional dyspepsia, some of which are common to gastro-oesophageal reflux symptoms (GORD), including visceral hypersensitivity and delayed gastric emptying. To inform future research on potential shared pathophysiological mechanisms, it is important to estimate the strength of association between the two conditions, and whether this association remains stable depending on the criteria used to define these conditions, as well as geographic location.

Aims & Methods: We conducted a systematic review and meta-analysis to estimate the prevalence of dyspepsia in individuals with gastro-oesophageal reflux symptoms, and to quantify the overlap between the two disorders. MEDLINE, EMBASE, and EMBASE Classic were searched (up until September 2016) to identify population-based studies reporting the prevalence of dyspepsia and (GORD) in adults (>15 years), defined using specific symptom-based criteria or a questionnaire. The prevalence of dyspepsia and weekly GORD were extracted for all studies. Pooled prevalence, according to study location and criteria used to define weekly GORD or dyspepsia, as well as odds ratios (OR), with 95% confidence intervals (CIs) were calculated. The degree of overlap between the two was examined.

Results: Of 14,132 papers evaluated, 79 reported prevalence of weekly GORD. Nineteen of these study populations, containing 111,459 participants, also reported the proportion of individuals with dyspepsia. The prevalence of dyspepsia in those with weekly GORD was 43.9% (95% CI, 35.1–52.9%). The pooled OR for dyspepsia in individuals with weekly GORD, compared with those without, was 6.94 (95% CI 4.33 to 11.12). The OR for dyspepsia in weekly GORD was significantly higher than the geographical region of diagnostic criteria used. The pooled degree of overlap between the two conditions was 25.9% (95% CI, 19.9–32.4%), varying from 22% when the Bowel Disease Questionnaire was used to define weekly GORD, to 42.6% with the Mayo Reflux Questionnaire.

Conclusion: The OR of dyspepsia in individuals with weekly GORD was seven-fold that of individuals without GORD, and that there is overlap between the two conditions in up to one-quarter of individuals. Reasons for this remain speculative, but may include shared pathophysiological mechanisms or residual confounding.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
as a predictor among individuals with FGIDs (Table 1). Episodic symptom severity was predicted by worry and psychological attribution of symptoms among FGID individuals but no psychological trait predicted symptom severity among non-FGID individuals (Table 1).

**Conclusion:** A range of psychosocial factors predict later gastrointestinal symptom burden. For bowel symptoms, associations between psychological traits and symptom burden appear to be most clearly driven by the non-FGID subgroup, among whom psychological attributions for symptoms and problem-focused coping are positively related to later symptom burden. For episodic symptoms, a range of psychological traits were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGIDs. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits, particularly outside of anxiety and depression. Further, the commonality reported associations between psychological traits and gastrointestinal symptoms may be moderated by symptom level but are relatively similar across upper and lower gastrointestinal symptoms.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** In the recent years, there has been an increasing recognition of the presence of gastrointestinal (GI) dysfunction in patients with neurologic diseases. There are no studies examining a relationship between neurological and neurodegenerative/demyelinating diseases of central nervous system, although these diseases might have common features. For example, a number of genetic variations have been shown to increase the risk of both conditions (e.g. HLA-DQB1-insertion on chromosome 6 may be strongly associated with both achalasia and with neurodegenerative/demyelinating diseases). Several other findings (e.g. inflammatory infiltrates, hypothalamus (nucleus accumbens (NAc), amygdala, insula, pallidum, thalamus and single oesophageal balloon distention, as described elsewhere).) The effect of resting sympathetic cardiac vagal tone (CVT)–has been suggested to have a physiological role in the regulation and modulation of painful sensory signalling, to the extent of vagal nerve stimulation (to raise subject CVT) being tested as a possible antinociceptive. Aims & Methods: To date, no studies have explored the brain functional connectivity or network properties of CVT in relation to a painful stimulus, and thus this was our aim. In 21 healthy participants (10 male; mean age 30 years (range 21–53 years), we quantified resting CVT using a Neuroscope. For all subjects, functional MRI data were acquired using a 3T MRI scanner during painful oesophageal balloon distention, as described elsewhere. The effect of resting CVT on brain networks during acute oesophageal pain were determined by means of network based statistics. Changes in resting CVT were correlated with functional MRI data collected from a range of brain regions.

**Results:** A total of 51 out of 140 patients (36.4%) exhibited some neurosurgical symptoms-most often visual disturbances in 17 patients (33.3%) and limbs paresthesia in 12 patients (23.5%). Among patients with a presence of neurological symptoms, 5 patients (3.6%) had definitely been diagnosed with a neurodegenerative/demyelinating disease (multiple sclerosis - 2 patients, Lebert optic neuropathy - 1 patient, Parkinson’s disease - 1 patient and Allgrov syndrome - 1 patient). Furthermore, 7 patients with a positive questionnaire had been diagnosed with other neurological diseases (tetany n = 3, epilepsy n = 2). Fourteen patients (27.4%) among those with neurological symptoms (vs. 0 out of 89 patients without neurological symptoms) had a positive family history of a neurodegenerative or a demyelinating disease. Among 106 patients with a neurodegenerative/demyelinating disease, 30 of them (28%) described dysphagia in their personal history. These patients will be examined by esophageal manometry.

**Conclusion:** Our results imply an increased prevalence of neurodegenerative/demyelinating diseases in patients with achalasia (3.6% vs. approx. 1.4% in the Czech controls). Also, a high prevalence of dysphagia was found among patients with a neurodegenerative/demyelinating disease. These results warrant further confirmation in a large population-based study.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

When considered jointly with other predictors, psychological attribution of symptoms was significantly positively related to both bowel symptom severity (non-FGID: OR = 0.31, SE = 0.13; Full: OR = 0.74, SE = 0.11) and episodic symptom severity (FGID: OR = 0.63, SE = 0.09; Full: OR = 0.63, SE = 0.11). The same was the case for worry (Bowel: Full: OR = 1.40, SE = 0.21; Episodic: FGID: OR = 1.58, SE = 0.27; Full: OR = 1.54, SE = 0.23). For bowel symptoms, problem-focused coping (OR = 2.30, SE = 0.98) was an additional independent positive (notably, not negative) predictor among participants without FGIDs.

**P1169 HIGH RESTING PARASYMPATHETIC CARDIAC VAGAL TONE CONFERS A UNIQUE FUNCTIONAL BRAIN NETWORK DURING ACUTE OESOPHAGEAL PAIN**

**Introduction:** Visceral pain is a complex percept influenced by numerous factors. Of these, differences in the autonomic nervous system (ANS)–in particular, parasympathetic cardiac vagal tone (CVT)–has been suggested to have a physiological role in the regulation and modulation of painful sensory signalling, to the extent of vagal nerve stimulation (to raise subject CVT) being tested as a possible anti-nociceptive.

**Aims & Methods:** To date, no studies have explored the brain functional connectivity or network properties of CVT in relation to a painful stimulus, and thus this was our aim. In 21 healthy participants (10 male; mean age 30 years (range 21–53 years)), we quantified resting CVT using a Neuroscope. For all subjects, functional MRI data were acquired using a 3T MRI scanner during painful oesophageal balloon distention, as described elsewhere. The effect of resting CVT on brain networks during acute oesophageal pain were determined by means of network based statistics. Changes in resting CVT were correlated with functional MRI data collected from a range of brain regions.

**Results:** A total of 51 out of 140 patients (36.4%) exhibited some neurosurgical symptoms-most often visual disturbances in 17 patients (33.3%) and limbs paresthesia in 12 patients (23.5%). functional connections). These interconnections included the following: thala-mus-amygdala, thalamus-hypothalamus, hypothalamus-NAc, amygdala-pu-tamen amygdala-NAc and insula-patamen. No significant network was identified for the low CVT group.

Conclusion: During acute oesophageal pain, resting cardiac vagal tone yields a functional network comprising numerous complex subcortical brain regions, many of which have been previously associated with either visceral pain or modulation of baseline autonoms either at the physiological or neuroana-tomical level (3). Previous research has suggested that a high resting CVT may be protective of noiceptive signaling, and furthermore studies investigating vagal nerve stimulation have included and report that of anti-nociception (4). Given the well-established role of these subcortical regions in pain processing, we suggest that this network identified may be of significance as to the neurophysiolog-ical process of parasympathetic modulation of painful sensory signaling. Lastly, to date, no studies have undertaken real-time assessment of the ANS (including CTV) during functional brain imaging and acute visceral pain. Future studies should investigate for this.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI170 RAPID DRINK CHALLENGE (RDC) TEST DURING OESOPHAGEAL HIGH RESOLUTION MANOMETRY (HRM) IN PATIENTS WITH OESOPHAGO-GASTRIC JUNCTION OUTFLOW OBSTRUCTION

D. Biasutti, F. Mion, A. Garros, S. Roman
Digestive Physiology, Lyon I University and Hospices Civils de Lyon, Lyon/France

Contact E-mail Address: d.biasutti@unicampus.it

Introduction: Oesophago-gastric junction outflow obstruction (OGJOO) is of undetermined significance. It may be secondary to an incomplete form of achalasia, a mechanical obstruction or be idiopathic. Rapid drink challenge (RDC) test is easy to perform during oesophageal HRM.

Aims & Methods: We aimed to assess the yield of RDC in patients with OGJOO. From a database of 3252 consecutive oesophageal HRM performed from 01/2012 to 03/2017, we extracted patients with OGJOO according to the Chicago Classification v3.0. HRM protocol consisted of 10 mL water swallows in supine position and RDC test (200-mL free drinking) in sitting position. Distal contractile integral (DCI) integrated relaxation pressure (IRP), distal and pan-oesopha-gaeal pressurization (POP; homogeneous oesophageal pressurization >30 mmHg) were reported for 5 mL swallows. POP and oesophageal shortening (OS) were analysed during RDC. Symptom severity was assessed with Eckardt score. Causes of OGJOO were determined by reviewing patients’ chart for previous history, complementary work up and treatment. Quantitative data were expressed as median (range) and qualitative data as percentage. They were compared using non-parametric and Chi square tests.

Results: 75 patients (29%) (29 males, mean age 62 years (25–92)) were included. The dominant symptom was dysphagia (69%), regurgitation (9%), chest pain (5%), other (13%), no symptom (3%). The causes of EGJOO were previous oesophageo-gastric surgery (43%), incomplete achalasia (7%), mediastinal neo-plasia (7%), miscellaneous (19%) and unknown (25%). RDC test was successful-ly performed in 70 patients (93%) and associated with POP and OS in 41% and 15% respectively. Dysphagia as dominant symptom was more frequent (79% vs 59%, p=0.017) and more severe (Eckardt score 5 (1–11) vs 3 (0–10), p=0.01) in patients with POP during RDC compared to those without. The same obser-vation was achieved in patients with OS vs those without (dysphagia 100% vs 62, p=0.02 and Eckardt score 6 (2–10) vs 1 (0–11), p=0.02). Manometric parameters were reported in the table. The causes of OGJOO were similar in patients with and without POP during RDC (previous oesophago-gastric surgery 34% and 51% respectively, achalasia 14% and 2%, mediastinal neoplasia 3% and 7%, miscellaneous 10% and 22%, unknown 38% and 17%). OS was not significantly different between the two groups.

Conclusion: While RDC test cannot be used to determine EGJOO cause, patients with POP or OS during RDC had more severe dysphagia than those without. In patients with POP, the highest DCI might be secondary to obstruction. Further prospective studies should determine if RDC test could help to select patients who might benefit from treatment.

PI171 THE NORMATIVE VALUES OF A NEW 36 CHANNELS WATER PERFUSION ESOPHAGEAL MOTILITY CATHETER

S. Bor, S. Kipcak
Gastroenterology Sec., Ege Reflux Study Group, Ege University, izmir/Turkey

Contact E-mail Address: kipcakszegi@gmail.com

Introduction: High resolution manometry (HRM) is performed with solid-state catheters (SS) in many centers. However according to Chicago classification, very limited data from healthy volunteers are available for some catheters and starting from IRP, numerical values are crucial for the diagnosis. Because of the cost of the SS-HRM catheters many centers especially from developing countries use water perfusion HRM (W-HRM) catheters up to 24 channels and normal values are even more limited.

Aims & Methods: We evaluated a prototype 36 channels W-HRM reused catheter allowing to measure 3-D pressure vector volume analysis of lower esophageal sphinc-ter in healthy volunteers and compared to 36 channels SS-HRM catheters (Laborie-MMS Canada). We included 43 healthy volunteers without any upper gastrointestinal complaint. Upper gastrointestinal endoscopy and 24h impedance-pH monitor- ing performed in all subjects. Four subjects were excluded because of silent GERD. 39 subjects were analysed (25 males, W-HRM (n=39), SS-HRM (n=33)). Thirty-three patients underwent two esophageal manometry studies within two consecutive days with a random order. Procedures were performed in supine position with receiving ten times 5 mL water, five times solid food and multiple water swallow with 200 mL of water. 36 channel water-perfused 3-D HRM catheter and 36 channel solid state HRM catheter were used (Laborie-MMS Canada).

Results: There was significant differences between two catheters in terms of Integrated Relaxation Pressure (IRP), Distal Contractile Integrale (DCI) and DCI- expanded, LES resting pressure, % of ineffective peristalsis, and esopha-gegal length both with water and solid food swallows (Table). No difference has been shown with distal latency (DL), LES length, breaks size (Table).

Results of SS, MRS and RDT in patients with IEM and FH

Results: We evaluated 30 patients with EGJ-OO (18 females; mean age 49.5 ± 12.4 yrs) and 30 patients with FH (17 females; mean age 41.2 ± 13.6). Impedance and pH 24-h analysis was performed to select patients with FH (normal AET and number of reflux and reflux-symptom correlation). During HRM the mean DCI resulted similar in patients with EGJ-OO compared to FH (p = 0.839). One-hundred and eighty MRS and 60 RDT were evaluated. The lack of body inhibition was found in 11% (20/180) during MRS and in 53% (16/30) during RDT in EGJ-OO. No patients in FH showed lack of body inhibition during both MRS and RDT. All results are reported in Table 1.

Conclusion: Patients with EGJ-OO showed less peristaltic reserve during MRS and RDT. The RDT evidenced frequently lack of body inhibition in patients with EGJ-OO.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Oesophageal diverticula are rare diverticula of the gastrointestinal tract known to be associated with oesophageal motor disorders.

Aims & Methods: The aim was to study manometric abnormalities associated with oesophageal diverticula, using both wet and solid swallows. Patients underwent high resolution oesophageal manometry (HRM) in the upright position. 18 patients with oesophageal diverticula were found and were free of previous surgery. Traction diverticulum was excluded in all patients. We also included 10 healthy controls. HRM was performed using wet (5 mL of water) swallows in both groups, followed by solid (meat) swallows in patients. Mean age of the controls was 50 years old while it was 70 years old for patients.

Results: The main reported symptom was dysphagia (76%). HRM found 11 (61%) patients with an oesophageal motor disorder, including 2 oesophago-gastric junction outflow obstruction (OGJOO), 4 achalasia (subtype 2: n = 2; subtype 3: n = 2), 4 distal oesophageal spasm (DES) and 1 jackhammer oesophagus, and was normal in 7 (39%) patients. In those patients with normal findings, solid swallows identified 4 (57%) additional motor disorders, including 2 OGJOO, 1 jackhammer oesophagus and 1 DES. Provocative testing using solid swallows increased the diagnostic yield by 22% in overall patients and by 57% in patients with normal manometry using wet swallows only. Mean pressure slopes at mid-oesophagus and oesophageal diverticulum were greater in patients than healthy controls (p < 0.05 for wet swallows), as previously reported1. Other metrics are summarized in the table.

Conclusion: While more than one-third of HRM using wet swallows were normal, provocative testing using solid swallows increased the diagnostic yield of the procedure by more than 50% in these patients. Analysis of pressure slopes confirmed the association of propagating peristalsis with the disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1176 EVALUATION OF ESOPHAGO-GASTRIC JUNCTION CONTRACTILITY AFTER DIFFERENT TREATMENTS FOR ACHALASIA

S. Tolone1, E. Savarino2, N. De Bortoli3, M. Frazzoni4, M. Furnari1, L. Frazzoni2, V. Savarino1, L. Docimo1, L. Swansstrom2

Aims and methods: Achalasia is a chronic oesophageal motor disorder resulting in a loss of proper oesophageal peristalsis. In Europe, the three most commonly used treatments for achalasia are pneumatic dilation (PD), Heller myotomy (HM) and Toupet fundoplication. Each technique has advantages and disadvantages and limited evidence is available to guide clinical decision making. We aimed to compare the contractile integrity at the oesophagogastric junction before and after treatment in achalasia patients.

Method: A total of 11 patients with achalasia underwent esophageal manometry. Of these, 8 underwent PD, 2 HM and 1 Toupet procedure. Mean age was 50 ± 15 years (range: 24–77) and mean body mass index (BMI) was 25 ± 4 kg/m². All patients underwent a baseline oesophageal manometry and a second oesophageal manometry after a mean follow-up of 14 ± 7.4 months (range: 3–24 months).

Results: The main reported symptom was dysphagia (76%). A total of 8 patients had a normal HRM before treatment. After treatment, 7 patients showed improved contractility, while one patient showed no change. The remaining patient had a normal HRM before treatment and a normal contractility after treatment. The mean total contractility index of all patients improved significantly from 0.01 ± 0.01 to 0.60 ± 0.30 (P < 0.001). The mean resting pressure, peak pressure, length of the relaxation zone and distal latency were all significantly reduced after treatment (P < 0.05).

Conclusion: Our results suggest that achalasia patients may benefit from repeated oesophageal manometry after treatment to evaluate the contractile integrity at the oesophagogastric junction.
well as upper endoscopy, barium esophagogram and HRM before and 6 months after treatment. Achalasia was classified according to the Chicago Classification V3.0. The EGJ-CI was calculated using the distal contractile integral tool-box during three consecutive respiratory cycles. Patients underwent to pneumatic dilatation (PD), or LHM plus a Dor (LHM-D), Toupet (LHM-T) or a Nissen-Rossetti (LHM-NR) fundoplication. Ethical approval for the study was obtained.

**Results:** We enrolled 35 achalasia patients (14 Type I, 16 Type II and 5 Type III). Ten patients underwent PD, 11 LHMD, 8 LHM-T and 6 LHM-NR. At baseline, no differences were observed in age, sex, pre-operative mean Eckardt score, GERDQ score, integral relaxation pressure (IRP) and EGJ-CI were recorded. All Type III subjects underwent LHM-D (3) and LHMT (2). After all the procedures, in all the patients there was a significant decrease in Eckardt score, IRP and EGJ-CI (p < 0.001, < 0.001 and < 0.05, respectively). PD and LHM-NR showed higher EGJ-CI (20.9 ± 3.5 and 23.5 ± 11.1 mmHg.cm, respectively) and IRP (12.2 ± 3.4 and 13.4 ± 4.5, respectively) than LHM-D and LHMT (18.4 ± 5.9, p < 0.05 and 9.3 ± 4.1 p < 0.05 mmHg.cm, respectively for EGJ-CI; 5.2 ± 2.5, p < 0.05 and 2.3 ± 3.7 p < 0.001 mmHg.cm, respectively for IRP). Post-operative Eckardt score was lower in LHMD and LHMT (2.1 ± 0.5 and 2.0 ± 0.6, respectively) than PD and LHM-NR (4.2 ± 1.0, p < 0.01 and 3.7 ± 1.5, p < 0.05). Post-operative GERDQ score was significant higher in LHMT (3.0 ± 1.7 vs. 8.2 ± 3.9, p < 0.05). Low post-operative EGJ-CI values correlated with an increased risk of higher post-operative GERDQ score (p < 0.05, odds ratio 4.223, 95% CI 0.964–2.123).

**Conclusion:** All procedures performed to treat achalasia produced an adequate relief of dysphagia. LHMD and LHMT seem to result in a stronger alteration of the EGJ with LHMT resulting in an increased risk of post obstructive reflux.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Jackhammer esophagus is a rare epiphageal motility disorder. Little is known about its physiopathology; however, an excess of cholinergic drive has been suggested as an important etiologic factor. Multiple rapid swallowing (MRS) is an adjunctive test in order to evaluate integrity of inhibitory and excitatory neural pathways. In healthy subjects motor inhibition is observed during MRS and a contraction stronger than single swallows (SS) occurs after MRS, the so-called peristaltic reserve (MRS/SS DCI ratio > 1). In patients with achalasia esophagus preservation of motor inhibition during MRS has been described with traditional manometry. No study has evaluated peristaltic reserve and motor inhibition with high-resolution manometry (HRM) in patients with jackhammer esophagus.

**Aims & Methods:** To evaluate MRS in a consecutive multicenter series of 42 Jackhammer esophagus patients (18 Male; 63 years; 55–71) according to Chicago 3 classification. 18 healthy subjects (HS) (seven male; 28 years; 23–33) from a published series were used as a control group. All patients underwent solid state HRM with ten 5 ml SS and one to three 10 ml MRS (30 patients performed at least two MRS). Standard HRM parameters during SS were evaluated. During MRS presence/absence of motor inhibition and 4 second integrated relaxation pressure (4 sec IRP) were evaluated. After MRS distal contractile integral (DCI) was evaluated and DCI ratio between MRS and SS was measured. Mann Whitney, Wilcoxon and chi-squared tests were used when appropriate; data are shown as median-IQR range.

**Results:** Descriptive data in jackhammer patients are shown in table 1. Twelve patients did not have motor inhibition during at least one MRS (28% vs 5% in HS, p < 0.05). There was a trend toward a lower 4s IRP during MRS compared to SS (see table 1); however, values were higher than those of 4s IRP MRS in HS (5.1 mmHg; 2.2–11 vs 1.6 mmHg; 0.3–2, p < 0.0001). MRS DCI was significantly lower than SS DCI, interestingly 26 patients had a MRS/SS DCI ratio < 1 (62% vs 22% in HS, p < 0.0005) and it was lower than the MRS/SS DCI ratio of HS (0.8; 0.4–1.1 vs 1.9; 1.1–2, p < 0.0001) suggesting a reduction of the hypercontractile activity in the esophageal body.

**HRM parameters during single and multiple rapid swallows in jackhammer patients. Median; interquartile range.**

<table>

</tr>
</tbody>
</table>

Conclusion: Contrary to what occurs in healthy subjects, MRS decrease DCl value compared to SS in jackhammer esophagus patients, suggesting altered neural control of peristalsis. Differently to what previously observed with traditional manometry, motor inhibition during MRS is altered in a quarter of patients. Studies are needed in order to evaluate if reduction of DCl during MRS can improve dysphagia and chest pain in these patients.

**P1179 GASTRIC PERORAL ENDOSCOPIC MYOTOMY (G-POEM) AS TREATMENT FOR FUNCTIONAL DELAYED GASTRIC EMPTYING: INITIAL ASIAN EXPERIENCE**

**M. Cai1, J. Xu1, P. Zhou1**

1Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

**Contact E-mail Address:** cai.mingyun@zs-hospital.sh.cn

**Introduction:** Functional delayed gastric emptying is a difficult-to-treat disorder, which is often expressed clinically as nausea/vomiting, fullness/early satiety, bloating and weight loss. Gastric peroral endoscopic myotomy (G-POEM) has been regarded as a novel and minimally-invasive therapy for functional delayed gastric emptying refractory to medical therapy. We herein report our initial experience of G-POEM in an Asian population with focus on technique in addition to safety and efficacy of this promising endoscopic therapy.

**Aims & Methods:** The data of consecutive patients who underwent G-POEM by a single expert endoscopist from October 2015 to November 2016 was collected. Procedures were performed, similar to POEM for achalasia, including initial mucosal incision, creating a submucosal tunnel, full-thickness (pyloro)myotomy, and closure of the mucosal entry. Patient demographics, etiology, Gastrooesophageal Cardinal Symptoms Index (GCIS) and gastric emptying scintigraphy (GES) were recorded before and after the procedure. Treatment outcomes and procedure related adverse events were also evaluated.

**Results:** A total of fourteen patients with refractory functional delayed gastric emptying, including eleven post-surgical (78.6%) and three diabetic (21.4%), were enrolled. The median age was 60 (range, 26–82) years. All patients were suffering from nausea, vomiting, bloating and weight loss. They all failed medical therapy including proton pump inhibitor, metoclopramide, mosapride, or domperidone. All fourteen patients underwent G-POEM successfully (100%) with the mean procedure time of 43.7 ± 13.08 mins. Gastric emptying scintigraphy (GES) was performed in five patients with improvement of mean half empty time (191.88 ± 83.19mins vs. 91.44 ± 32.92mins), and retention at 2 hours (70.02 ± 12.68% vs. 33.48 ± 20.32%). The median hospital stay after procedure was 6 days (range, 4–10). No procedure related adverse event (0%) was observed. During a median follow-up of eight months (range, 3–17.5 months), one patient (post-surgical) had symptom recurrence after 45 days because the procedure may have been performed insufficiently.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1179 EFFECTIVENESS OF CAP-ASSISTED DEVICE IN THE ENDOSCOPY MANAGEMENT OF FOOD BOLUS OBSTRUCTION IN THE UPPER ESOPHAGUS**

M. Ooi, E. J. Young, N. Q. Nguyen
Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marieeoo_al@yahoo.com

**Introduction:** Although cap-assisted technique has been shown to be effective in retrieving food bolus from the upper gastrointestinal tract, there is no data on food bolus obstruction (FBO). This study aimed to assess the performance of cap-assisted technique in the management of esophageal FBO, as compared to conventional endoscopic methods.

**Aims & Methods:** A total of 255 subjects into FD group and Control group. FD group was defined as the subjects who had epigastric pain syndrome (EPS) with or without reflux symptoms. Control group had such endoscopic findings. However, it is not discussed whether we can diagnose patients with EPS without it. Interestingly, AUC5 and AUC15 values (24.85/2.51, respectively) in EPS patients with pancreatic enzyme abnormalities were also significantly (p = 0.002 and p = 0.001, respectively) increased compared to those (19.75/1.99, respectively) in EPS patients without pancreatic enzyme abnormalities (n = 42) based on Rome III criteria. Gastric motility was evaluated using the 13C-acetate breath test. Early chronic pancreatitis was detected by endosonography and graded from 0 to 7.

**Conclusion:** Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were diagnosed by endosonography as having concomitant early chronic pancreatitis preceding peptic ulcer disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1180 DO THE ENDOSCOPIC FINDINGS OF GASTRITIS BRING THE FD SYMPTOMS?**

Y. Shimada1, S. Sato1, K. Tomishima1, Y. Kenemitsu1, H. Tsuchura1, A. Murata1, N. Amano1, S. Sato1, T. Genda1, K. Iijima1, M. Kusano2, A. Nagahara1 1Gastroenterology And Hepatology, Juntendo University, Tokyo, Japan; 2Department Of Gastroenterology, Juntendo University Shizuoka Hospital, Shizuoka/Japan

Contact E-mail Address: yshimada@juntendo.ac.jp

**Introduction:** Functional dyspepsia (FD) is defined that there is no evidence of organic disease which is likely to explain the symptoms. However, there was no obvious definition about “organic disease”. Therefore, during the endoscopic examination, we have to consider whether we can not judge whether obvious abnormal findings are seen like gastric erosion fulfill the exclusion criteria or not. Indeed, this issue was pointed out that there is notable inconsistency in the exclusion criteria of FD (1). Recently, the Kyoto classification of gastritis has been published and used widely for the management of gastritis in Japan (2). In this classification, endoscopic findings are defined precisely. However, it is not discussed whether we can consider such findings as the “organic disease” or not. If these findings have no related FD symptoms, we can diagnose patients group as FD even if they have such endoscopic findings.

**Aims & Methods:** The aim of this study is to explore which endoscopic findings defined in the Kyoto classification of gastritis bring FD symptoms. To assess the symptoms of patients who employed the weighed-Frequency of Scale for the Dyspeptic Symptoms (PDS) (n = 3) were successfully treated when switched to cap-assisted approach. Cap-assisted approach was associated with a shorter total procedural time (34.4 ± 3.2 min vs. 43.2 ± 2.2 min, P = 0.005), a shorter length of hospital stay (3.9 ± 0.6 days vs. 1.3 ± 0.6 days, P = 0.001) and more en-block removal (88.9% vs. 22.8%, P < 0.001). There were more complications in the conventional than the cap-assisted group (7/106 vs. 0.93%; P = 0.01).

**Conclusion:** Cap-assisted technique is 100% effective in the management of impacted FBO in the esophagus, with a significantly shorter procedural time and hospital stay as compared to conventional techniques. Although the finding that cap-assisted technique should be the first line technique in the management of esophageal FBO, further evaluation with a randomized multicenter trial is warranted.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** We aimed to determine whether epigastric pain syndrome (EPS) accompanying with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by Japan Pancreas Society (JPS) using endosonography. We enrolled 99 consecutive patients presenting with typical symptoms of FD, including patients with postprandial distress syndrome (FD-PDS, n = 59) with pancreatic enzyme abnormalities (n = 41) and EPS patients without pancreatic enzyme abnormalities (n = 42) based on Rome III criteria. Gastric motility was evaluated using the 13C-acetate breath test. Early chronic pancreatitis was detected by endosonography and graded from 0 to 7.

**Results:** The ratio of female patients among EPS patients (34/41) with pancreatic enzyme abnormalities was significantly (p = 0.0018) higher than the ratio of female EPS patients (20/42) without it. Postprandial abdominal distention and physical component summary (PCS) scores in EPS patients with pancreatic enzyme abnormalities were significantly disturbed compared to those in EPS patients without it. Interestingly, AUC5 and AUC15 values (24.85±1.31 and 56.11±2.51, respectively) in EPS patients with pancreatic enzyme abnormalities were also significantly (p = 0.002 and p = 0.001, respectively) increased compared to those (19.75±1.99 and 47.02±2.99, respectively) in EPS patients without it.

**Conclusion:** Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Caustic esophageal injury is corrosive burns of esophagus and mostly caused by ingestion of chemical caustic substances such as strong acid or alkali. The caustic esophageal stricture is refractory and patients suffered from multiple dilation. Clinical ESD results revealed that benign stricture would be usually caused by more 75% mucosa loss of circumferential esophagus. Cultured autologous esophageal mucosa transplantation might inhibit reflux fibrobiosis and delay the recurrence of esophageal strictures.

**Aims & Methods:** A man presented with the caustic esophageal stricture (32–40 cm from the incisors), which was caused by accidental exposure of anhydrous acid (44.5%) and he was treated for multiple esophageal dilatations with no clinical benefit 3 times. He was referred to our hospital for surgery. Initial EGD showed grade III caustic stricture with esophageal narrowing of 1.2 cm. Under X-ray, routine endoscopic dilation was firstly applied to a diameter of 1.28 cm. Three days later, with the informed consent, ESD operation was utilized to dissect 507.5 cm normal esophageal mucosa at the 18–23 cm location from the incisors. Mucosal defect was cured by fibrin glue after Argon plasma coagulation. Under endoscopic surveillance, the excised mucosa was transplanted to the surface of the narrowed segment and fixed with 3 titanium clips.
Results: The endoscopic follow-up was planned every month. After 1 months, 18 (23%) esophageal region has healed to be normal. Within 6 months, the stricture process was exactly delayed as expected. The patient stated his symptom was remarkably improved. Gastroscopy revealed the esophageal implanted lesion was covered with an epithelium and the luminal surface was flat, without ulceration.

Conclusion: Autologous esophageal mucosa transplantation might facilitate tissue re-epithelialization, reduce pathological fibroplasia, and be helpful for managing or preventing esophageal strictures. More clinical controlled trials are required to provide evidenced-based recommendation and promote its clinical application.

Introduction: The assessment of gastric acid secretion is important in order to prescribe PPIs. The gold-standard to measure the maximal acid output (M.A.O.) is the collection of gastric after an i.m. injection of pentagastrin. However, this method is not currently used in clinical practice. Serum pepsinogen I (PGI) has been proposed as a non-invasive surrogate. Aim of this study was to compare in a group of patients with different acid related diseases serum levels of PGI and M.A.O.

Aims & Methods: We enrolled 124 patients (M = 84, mean age = 45.3 ± 13.05 years, mean body mass index (BMI) = 25.12 ± 13.7 years range 20–73) characterized by achlorhydria or low levels of acid production (Group 1), or by duodenal ulcer (50, M = 42, mean age = 43.5 ± 11.5 years range = 17–65) in which an hypersecretory status is claimed (Group 2). In the same group, we studied 46 patients (M = 44 mean age = 44.0 ± 8.3 years range = 25–80) with normal upper GI endoscopy and gastric histology, without previous history of neoplasms or upper gastrointestinal surgery (Group 3). In all patients we measured M.A.O. by means of two hours collection of gastric juice that was followed by an i.m. injection of pentagastrin at the dosage of 6 μg/kg (M.A.O. normal values: 5–25 mEq/h). All patients underwent blood sample for determination of serum PGI (BioHit Oyj, Finland; normal values: 30–120 μg/l). All determinations, both for M.A.O. and PGI were made off medication.

Results: The mean M.A.O. value in group 1 was 2.15 mEq/h, in Group 2 32.49 mEq/h, in Group 3 17.48 mEq/h. A statistically significant difference was found between the 3 groups (Group 1 vs. Group 2 p < 0.00001; Group 1 vs. Group 2 p < 0.0001; Group 2 vs. Group 3 p < 0.00001). The PGI mean values in Group 1 was 11.39 g/l in Group 2 107.72 g/l in Group 3 84.28 g/l (Group 1 vs Group 2: p < 0.000001; Group 1 vs Group 2: p < 0.00001; Group 2 vs Group 3 p < 0.05). The relationship between M.A.O. and PGI showed a Pearson R = 0.683 (p = 0.001). No statistically significant difference was found comparing M.A.O. and PGI in the single groups (p > ns).

Conclusion: Serum PGI levels are fitting with M.A.O. both in hyper- and hypo-acid secretory conditions like chronic atrophic gastritis and duodenal ulcer, as well as in control subjects, suggesting that PGI could be adopted in clinical practice to assess gastric acid production in individual subjects for a proper management of acid related diseases.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: We conducted a cross-sectional study of 32,762 asymptomatic adults who underwent routine health check-ups including screening endoscopy from August 2006 to December 2011. Sarcopenia was defined as appendicular skeletal muscle mass (ASM)/body weight (%) value beyond two standard deviations below the mean for healthy young adults. Participants were categorized into four groups according to obese and sarcopenic status: normal, obese, sarcopenic, and obese sarcopenic.

Results: In a multivariate model adjusted for age, sex, smoking status, alcohol intake, regular exercise, and metabolic variables, risk of reflux esophagitis was higher in obese [adjusted odds ratio (AOR), 1.38; 95% confidence interval (CI), 1.26–1.52], sarcopenic (AOR, 2.20; 95% CI, 1.48–3.29), and sarcopenic obese participants (AOR, 1.68; 95% CI, 1.39–2.03) than in normal participants. The ORs comparing sarcopenic and sarcopenic obese participants to obese participants were 1.59 (95% CI, 1.06–2.38) and 1.22 (95% CI, 1.02–1.47), respectively. In addition, the risk of reflux esophagitis according to sarcopenic and obese status was observed similarly in all subgroups that were evaluated.

Conclusion: The findings suggest that sarcopenia, regardless of obesity, is more harmful condition for reflux esophagitis than obesity without sarcopenia.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
side. However, TAT was not significant in the multivariate analysis. Lower HDL levels (OR 0.28; 95% CI 0.11 to 0.71, p = 0.011) and higher coffee consumption (OR 2.50, 95% CI 1.06 to 5.86, p = 0.035) were associated with the severities of GERD.

Conclusion: Mucosal breaks in LC side of EGJ were associated with visceral obesity measured by VAT, ratio of VAT to SAT, BMI and WC. Life style modification such as in left deciduous stump position might be emphasized in the subjects with visceral obesity.

P1190 A LESSER COMPETENT OESOPHAGO-GASTRIC JUNCTION IS ASSOCIATED WITH OESOPHAGEAL ACID HYPERSENSITIVITY EVEN IN HEALTHY CONTROLS

Introduction: In normal subjects, the oesophago-gastric junction (OGJ) sphincter complex maintains a tight barrier between the oesophagus and stomach acid. However, gastro-oesophageal reflux disease (GERD) caused by acidic reflux has a prevalence of up to 26% [1]. One major factor determining whether gastro-oesophageal reflux occurs and eventually generates symptoms is the competency of the internal sphincter, which can be studied using distensibility testing. This way, we have previously shown in patients with Barrett’s oesophagus and healthy controls that an incompetent sphincter function was associated with more frequent reflux symptoms [2]. In the same patient groups, we also found greater oesophageal acid exposure and lower mucosal baseline impedance to be associated with impaired sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [1]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Aims & Methods: We aimed to characterize oesophageal sensitivity in relation to OGJ competency, hypothesizing that sensitivity increases with impaired sphincter function. Twenty-three patients with Barrett’s oesophagus (mean age: 64.4±7.7 years) and 12 healthy controls (mean age: 54.9±10.8 years) were examined. A standard upper endoscopy to locate the OGJ was followed by distensibility testing of the OGJ using the EndoFLIP probe. At a later visit, experimental oesophageal sensitivity was assessed using a multimodal stimulation probe. After placement in the oesophagus just above the OGJ, the probe allows the filling and emptying of an attached polyurethane bag with water, stimulation with electrical current, and infusion of acid. Using this probe, mechanical distension of the bag, thermal stimulation at increasing temperature, electrical stimulation, and acid perfusion with 0.1 M hydrochloric acid (a Bernstein test) were performed. All stimulations were stopped when the subject felt moderate pain, equal to seven on a 0-10 visual analog scale validated for visceral pain. Data were analysed using multi-level, mixed-effects regression analysis in Statia 12.

Results: Oesophageal acid sensitivity increased with a more incompetent sphincter: A lower tolerated acid volume was associated with greater distensibility (p=0.03) and with lower pressure (p=0.006) and with higher mucosal baseline impedance to be associated with impaired sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [1]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Conclusion: Oesophageal acid sensitivity increased with a more incompetent OGJ. Based on this and previous findings, we suggest that even in some healthy controls, a modest degree of OGJ incompetence allows gastric acid to reflux. This may again lead to low-grade oesophageal inflammation and mucosal damage, thus evoking acid hypersensitivity. The latter mechanism probably constitutes a reflux protective mechanism towards acid reflux.

Introduction: Three different phenotypes of gastroesophageal reflux disease (GERD) such as erosive reflux (ERD), nonerosive reflux (NERD), oesophageal hypersensitivity (EH) and functional heartburn (FH) might have different pathophysiological changes within the esophageal epithelium and the data is limited.

Aims & Methods: We aim to investigate the electrophysiological differences and diffusion characteristics as a reflection of tissue integrity using Using chamber system. Distal esophageal mucosal biopsies from healthy controls (5 men, 40.6±11.2 years) and 62 patients with GERD (40 men, 42.9±12.3 years, n = 26 LA grade A/B, n = 8 LA grade C/D, n = 22 NERD, n = 6 EH) and 11 patients with FH were studied from November 2015 until March 2017. GERD and quality of life questionnaires, high-resolution esophageal manometry, 24 h impedance-pH monitoring, upper gastrointestinal endoscopy with esophageal biopsies were performed in all patients. Biopsies were put into the chambers to measure the transepithelial resistance (TEER), potential difference (PD) and tissue permeability via fluorescein diffusion into two hours as well as evaluation of dilated intercellular spaces with light microscopy.

Results: Esophageal biopsies of healthy volunteers (163.6±41.1 ohms) had significantly higher TEER when compared to total GERD patients (132.5±38.7 ohms). Although the TEER results of whole GERD subtypes decreased compared to healthy controls, only ERD groups were significantly lower (123.3±29.8 ohms) (Table 1). There was also no significant difference in any of the parameters between NERD, FH and EH groups. The mucosal permeability of GERD subtypes was significantly higher than the healthy controls. The PPI-unresponsive subjects (n=10, 94.8±36.5 pmols) were much more permeable to fluorescein compared to PPI-responsive subjects (n=52, 56.0±32.4 pmols) within all GERD patients (p=0.009).

</tbody>
</table>

Conclusion: The TEER and permeability results imply that ERD and NERD groups showed a barrier disruption. However, epithelial permeability was not different in EH and FH groups. The dilatation of intercellular spaces may contribute to injury in true-NERD and ERD patients, EH and FH patients might have different pathophysiology than others.

P1192 PEPINS AND PH LEVELS OF HUMAN GASTRIC JUICE IN GASTROESOPHAGEAL REFUX DISEASE SUBGROUPS AND FUNCTIONAL HEARTBURN

P. Ergun1, S. Kipcak1, P. Dettmar2, A. Woodcock2, S. Bor1
1Gastroenterology Sec., Ege Reflux Study Group, Ege University, Izmir/Turkey
2Gastroenterology & Hepatology, Ege University, Izmir/Turkey

Contact E-mail Address: pelinergun@yahoo.com

Introduction: The major noxious agents of gastroesophageal reflux disease (GERD) on the esophageal epithelium are gastric acid and pepsin. Nevertheless, there is no precise information about pepsin concentrations in gastric juice.

Aims & Methods: We aim to address the pepsin values and pH results among subtypes of GERD and functional heartburn. 46 patients with GERD (23 erosive reflux disease LA grade A/B (ERD-A/B), 5 ERD-C/D, 14 nonerosive reflux disease-NERD, 4 erosive esophageal hypersensitivity-EH), 8 functional heartburn (FH) and 17 healthy controls (HC) were included into the study. Upper gastrointestinal endoscopies were performed off PPI. Patients were instructed not to aspirate the local anaesthetic solution and biopsy channel of the endoscope was dried before the suction. The gastric juices from the subjects were aspirated during endoscopy into a special beaker and their pH values were measured immediately. The specimens were analysed using the PepTest lateral flow device (RD Biomed Ltd UK), a colorimetric assay containing two unique human monoclonal antibodies that capture and detect pepsin protein.

Results: There were no significance between pepsin levels in any GERD phenotypes, FH and healthy controls (Table 1). The pH results of patients with ERD (1.8±0.6) were significantly lower than HC (2.6±1.5). The pH levels of the
esophageal hypersensitivity (1.5 ± 0.2) were significantly decreased when compared to HC (2.6 ± 1.6) and also true NERD (4.0 ± 2.0).

</tr>
<tr>
<td>HC</td>
<td>596.2 ± 302.8</td>
</tr>
</tbody>
</table>

Conclusion: Pepsin may be considered a damaging factor in pathophysiology of GERD, but we could not find any difference between GERD phenotypes and unaffected controls. NERD group had less gastric acid versus other groups but this finding needs more studies to confirm.

Introduction: Prevalence of obesity and the obesity-related diseases have been increasing in recent years(1). In the studies conducted there are views claiming that visceral fat-related central obesity causes digestion system diseases and increase in the number of gastroesophageal reflux symptoms in particular (1–6). Aims & Methods: In this study, we have been assessed in the health control group in regard to waist circumference, BMI; LDL, Fat, Fat Mass, Total Body Water(TBW), obesity level, reflux score, acid reflux score and total score measurements. Fat free mass (FFM), muscle mass, bone mineral density (BMD) measurements in between the both groups have not been found statistically significant difference (p > 0.05) (Table 1). Considering the extra esophageal reflux symptoms a significant difference (p < 0.05) between the group suffering from sore throat, apnea, teeth grinding and GORH and the healthy control group has been found. Within the patients group a positive correlation between acid reflux score and BMI (r = 0.298) (p < 0.001), LDL (r = 0.387) (p < 0.001), visceral fat (r = 0.180) (p < 0.049) has been determined. A negative correlation between acid reflux score and TBW (r = -0.273) (p < 0.003) has been determined.

P1194 CHANGES IN ANTHROPOMETRIC AND METABOLIC PARAMETERS RELATED TO GASTROESOPHAGEAL REFLUX DISEASE IN NON-OBSESE CASES

S. Yavuzı, O. Gái Utkuı, A. Gungünesı, N. Dindar Bademı, B. Ergulı, D. Özgüı
1Gastroenterology, Kırkkale University, kırkkale/Turkey
2Endocrinology, Kırkkale University, kırkkale/Turkey
3Biochemistry, Kırkkale University, kırkkale/Turkey

Introduction: Prevalence of obesity and the obesity-related diseases have been increasing in recent years(1). In the studies conducted there are views claiming that visceral fat-related central obesity causes digestion system diseases and increase in the number of gastroesophageal reflux symptoms in particular (1–6). Aims & Methods: In this study, we have been surveyed by means of the questionnaire including the demographic data and the reflux symptoms. Our study 120 BMI < 30 dyspeptic non-obese, gastroesophageal reflux disease (GERD) diagnosed according to the health control group in regard to waist circumference, BMI; LDL, Fat, Fat Mass, Total Body Water(TBW), obesity level, reflux score, acid reflux score and total score measurements. Fat free mass (FFM), muscle mass, bone mineral density (BMD) measurements in between the both groups have not been found statistically significant difference (p > 0.05) (Table 1). Considering the extra esophageal reflux symptoms a significant difference (p < 0.05) between the group suffering from sore throat, apnea, teeth grinding and GORH and the healthy control group has been found. Within the patients group a positive correlation between acid reflux score and BMI (r = 0.298) (p < 0.001), LDL (r = 0.387) (p < 0.001), visceral fat (r = 0.180) (p < 0.049) has been determined. A negative correlation between acid reflux score and TBW (r = -0.273) (p < 0.003) has been determined.
Introduction: Proximal esophageal baseline impedance (BI) levels have been recently proposed as a marker of mucosal integrity. Indeed, patients with non-erosive reflux disease (NERD) showed lower distal esophageal BI levels compared to healthy controls (HCs) due to the presence of abnormal distal esophageal acid exposure time (AET). On the other hand, no differences were found between NERD and HCs at proximal esophagus due to the limited proximal migration of the refluxate. Systemic sclerosis (SSc) is a systemic disease characterized by the deposition of collagen and matrix proteins in the connective tissue of the skin and visceral organs, such as the gastrointestinal tract. This event could potentially affect the conductivity of the esophageal wall and consequently reduce BI levels, also at proximal level, but data in this regard are limited.

Aims & Methods: We aimed to prospectively compare BI levels between a group of NERD patients and two groups of SSc patients, one with a clear manometric picture of scleroderma esophagus (i.e. hypotensive esophago-gastric junction pressure and abnormal peristalsis) and one without esophageal involvement.

Consecutive patients with heartburn and those with a definite diagnosis of SSc underwent upper endoscopy in order to assess the presence of esophageal mucosal lesions. Further, a group of healthy subjects was used as controls (HCs). Thereafter, all endoscopy-negative and SSc patients underwent esophageal high-resolution manometry and impedance-pH testing off-therapy. Impedance-pH tracings were blindly and manually reviewed, and we measured distal AET. Systemic sclerosis (SSc) is a systemic disease characterized by the deposition of collagen and matrix proteins in the connective tissue of the skin and visceral organs, such as the gastrointestinal tract. This event could potentially affect the conductivity of the esophageal wall and consequently reduce BI levels, also at proximal level, but data in this regard are limited.

Results: Fifty patients [38F; mean age 51yrs] with NERD, 50 SSc patients [44F; mean age 52yrs] with esophageal involvement and HCs (p = 0.05).

Conclusion: Proximal esophageal BI levels are able to segregate between scleroderma patients with and without esophageal involvement. The advent of novel and poorly invasive methods for the assessment of esophageal mucosal impedance will allow us to perform this measurement without the need of prolonged probe insertion.

channel of the scope. Distal two rings were contacted to the distal and proximal part of the esophagus approximately 20–25 cm, using GE Mach III Gastro Ambulatory recorder and Greenfield (6 imp, 1 pH) impedance catheter were used. Results: MI can differentiate ERD from non-erosive groups but do not have a diagnostic value to discriminate NERD from FH-EH or controls. However, BI can segregate NERD from ERD addition to controls (Table 1).

Conclusions: As a new diagnostic tool, MI needs validation studies and our results failed to show additional diagnostic value in non-erosive patients compared to healthy controls. Since regular catheters are failed, new balloon-shaped catheters should be validated. BI might be a better tool to discriminate NERD from controls. This implicates that the esophageal epithelial resistance is impaired in this particular group compared to controls.

**Introduction:** Atrophic body gastritis (ABG) is characterized by loss of oxyntic glands with consequent reduced acid secretion, hypergastrinemia and, in a later stage, pernicious anemia (PA). Up to 40% of ABG patients complain of dyspepsia. Despite hypochlorhydria, in 21% of autoimmune gastritis (AG) patients gastro-esophageal reflux (GER) symptoms have been reported and in one third of them (mostly non-acid) reflux has been documented at pH-monitoring. At present, data regarding endoscopic and histopathologic GER-related esophageal findings in this setting are lacking.

**Aims & Methods:** Aim of this study was to assess the occurrence of GER symptoms and endoscopic-histopathologic esophageal findings in ABG patients. During 12-months, 35 consecutive AGB patients [80% female; median age 60 yrs (27-81); BMI 25.7 kg/m2(18.2–32.3); fasting gastrinaemia 329 pg/ml (215–1476); pepsinogen I 10 ng/l (0–44); positive Ab against parietal cells (PDS) and epigastric pain syndrome (EPS)] was assessed by a standardized questionnaire. Gastritis and GER-related esophageal reflux disease (GERD) was assessed by a standardized questionnaire. Patients with history of peptic ulcer, neoplasms or upper GI surgery were excluded. Seven hundred and one patients showing heartburn and/or regurgitation, a picture of esophagitis according with LA classification or a positive DeMeester score (>14) at 24 hours pH-metry were enrolled in GERD group. By using a questionnaire, we collected data on both alcohol and smoking habits.

**Results:** No differences were found for sex and age between the two groups (GERD: M:F = 1:1.2, mean age: 56 years; dyspepsia: M:F = 0.9, mean age: 53 years; p = ns); heavy smokers was 29% in GERD group, 26% in dyspeptics; p = ns. Heavy drinkers were 25% in GERD group, 22% in dyspepsia; p = ns. In GERD group, typical symptoms were detected in 547 out of 701 patients, being heartburn the prevalent symptom in 479 subjects and regurgitation in 68 ones. Atypical symptoms, mainly chronic cough were present in 303 patients. 313 patients showed grade A esophagitis, 32 grade B, 4 grade C. One hundred seven out of 221 patients showed a positive DeMeester score foe acid reflux.

**Conclusion:** Sex, age, smoking habits and alcohol consumption seem no differ in the two studied populations. In GERD cohort, the majority of patients experienced Non Erosive reflux Disease (NERD). The majority of GERD patients suffered by typical symptoms; chronic cough represented the most frequent manifestation among the atypical and extra-oesophageal ones.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1200 REAL-WORLD RESPONSE OF PATIENTS WITH GASTROESOPHAGEAL REFUX DISEASE TO EMPIRICAL TREATMENT WITH PROTON PUMP INHIBITORS: A MULTICENTER, PROSPECTIVE, OBSERVATIONAL STUDY IN CHINA**

**Introduction:** In China, 13.6% of gastrointestinal outpatients suffer from gastro-esophageal reflux disease (GERD), among which only 36.9% undergo endoscopy [1]. For patients with symptoms of GERD, empirical proton pump inhibitor (PPI) treatment is recommended as a diagnostic test of GERD and as a therapeutic trial to control symptoms by Chinese GERD consensus guidelines [2].

**Contact E-mail Address:** francesco.dimario@unipmr.it

**Introduction:** Gastroesophageal reflux disease (GERD) is considered a multifactorial disease characterized by the presence of both typical and extra-oesophageal symptoms, as well as related risks factors, such as smoking habits. In primary care setting, dyspeptic symptoms could overlap GERD symptoms, being the differential diagnosis sometimes difficult, almost because when we performed in such patients upper-gastrointestinal (GI) endoscopy, a picture of esophagitis is observed in no more than 30–40% of the subjects. Aim of the study was to search in a primary care settings possible differences in clinical presentations in a group of patients with GERD, compared to dyspeptic patients.

**Aims & Methods:** One thousand and six hundred consecutive dyspeptic patients (M = 766; mean age = 51.5 years; range = 27–79 yr) were enrolled in the study, according with presence of upper-GI troubles like epigastric pain, fullness, nausea/vomiting but not heartburn or regurgitation. All patients showed a negative upper-GI endoscopy and were helicobacter pylori (H.p.) negative (Urea Breath Test and HpSA). Patients with history of peptic ulcer, neoplasms or upper-GI surgery were excluded. Seven hundred and one patients showing heartburn and/or regurgitation, a picture of esophagitis according with LA classification or a positive DeMeester score (>14) at 24 hours pH-metry were enrolled in GERD group. By using a questionnaire, we collected data on both alcohol and smoking habits.

**Results:** No differences were found for sex and age between the two groups (GERD: M:F = 1:1.2, mean age: 56 years; dyspepsia: M:F = 0.9, mean age: 53 years; p = ns); heavy smokers was 29% in GERD group, 26% in dyspepsia; p = ns. Heavy drinkers were 25% in GERD group, 22% in dyspepsia; p = ns. In GERD group, typical symptoms were detected in 547 out of 701 patients, being heartburn the prevalent symptom in 479 subjects and regurgitation in 68 ones. Atypical symptoms, mainly chronic cough were present in 303 patients. 313 patients showed grade A esophagitis, 32 grade B, 4 grade C. One hundred seven out of 221 patients showed a positive DeMeester score for acid reflux.

**Conclusion:** Sex, age, smoking habits and alcohol consumption seem no differ in the two studied population. In GERD cohort, the majority of patients experienced Non Erosive reflux Disease (NERD). The majority of GERD patients suffered by typical symptoms; chronic cough represented the most frequent manifestation among the atypical and extra-oesophageal ones.

Currently, there are no real-world data assessing the efficacy of short-term empirical treatment with PPIs in GERD patients in China.  

Aims & Methods: This was a multicenter, prospective, observational study carried out in a real-world setting. The primary objective was to determine the overall responder rate in patients with typical GERD symptoms after 4 weeks of empiric treatment with PPIs. Responders were defined as having heartburn/regurgitation on ≤1 day during the prior 7 days, assessed by the Gerd-Q questionnaire. Outpatients aged between 18 and 65 years with a Gerd-Q score ≥8 were enrolled if they were prescribed standard-dose PPIs as empirical treatment and were not planned to have an endoscopy within 4 weeks of enrollment. The PPI regimen prescribed was decided completely at the physicians’ discretion. Patient demographics, diagnosis, prescribed PPI regimens, Gerd-Q score and symptom frequency were recorded. Data were collected at baseline, 2 weeks and 4 weeks after initiating PPI therapy. Results from the full analysis set (FAS) are presented. 

Results: A total of 1,000 patients from 10 centers were screened for this study, of which 987 met the inclusion criteria and were included in the FAS. The mean age was 45.2 ± 11.6 years, the mean body mass index was 23.4 ± 3.3 kg/m², and 50.3% of the patients were male. The mean duration of GERD was 0.8 ± 2.6 years, with a mean baseline Gerd-Q score for the week before screening of 10.5 ± 1.9. During the 4 weeks’ treatment, the proportion of patients receiving at least 3 of 4 PPI doses was 99.5%. Esomeprazole was the most frequently received PPI (57.1% of patients). Other PPIs (rabeprazole, lanzoprazole, pantoprazole and omeprazole) were received by 50.1% of patients and 7.2% of the patients sequentially received ≥2 PPIs in the duration of the study. A total of 787 (78.7%) patients either completed the 4-week PPI treatment or withdrew after response, of which the responder rate was 74.0% [95% CI, 70.7%–77.0%] (Table 1). Among the 818 patients who completed 2 weeks’ treatment, the responder rate was 37.0% [95% CI, 33.5%–40.4%]. The overall median time to response was 12.4 days (95% CI, 12.1–12.6). Over the study duration, patients with Gerd-Q score demonstrated a decreasing trend. The proportion of patients with a Gerd-Q score ≥8 reduced from 100% at baseline to 29.5% and 17.4% at 2 and 4 weeks, respectively.

Responder rate = number of responders/number of patients who completed the therapeutic course or withdrew during the study. Response was defined as heartburn/regurgitation frequency ≤1 days during the prior 7 days.

Conclusion: In Chinese clinical practice, short-term PPI empirical treatment effectively improves symptom control in GERD patients and gains a satisfactory overall responder rate.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
studying with the diagnosis of refractory reflux to PPIs, this diagnosis had only been made on GERD-compatible symptoms. While the diagnosis is exclusively clinical, about a half (47.2%) of the patients with persistent symptoms on double doses of PPIs, considered as GERD patients refractory to PPIs, have an incorrect diagnosis (patients do not have pathologic reflux). More than half of the patients (61.9%) who have a diagnosis of GERD confirmed by complementary tests that do not respond to treatment with PPIs, acid reflux is not the cause of their symptoms.

Introduction: Recently, low-FODMAP diet has been proposed as potential treatment in patients with irritable bowel syndrome (IBS) given its high efficacy in symptoms relief. Recent data showed that IBS frequently overlap with functional heartburn (FH) and functional dyspepsia.

Aims & Methods: The aim of this study was to evaluate the efficacy of low-FODMAP diet in reducing heartburn in patients with FH and no pathophysiological evidence of gastroesophageal reflux (GERD) compared to patients with non-erosive reflux disease (NERD). As secondary aim we investigated the reduction of lower gastrointestinal symptoms in both groups. We enrolled patients with heartburn and negative upper endoscopy who were scheduled for upper pathophysiological tests (esophageal manometry and impedance and pH monitoring, MII-pH) at Gastroenterology Unit in University of Pisa. We excluded patients older than 75 and younger than 18, those with primary esophageal motor disorders and with previous abdominal surgery. Medical history, voluntary habits and response to proton pump inhibitor (PPI) treatment were monitored, MII-pH at Gastroenterology Unit in University of Pisa. We excluded patients with irritable bowel syndrome (IBS) given its high efficacy in symptoms relief. Recent data showed that IBS frequently overlap with functional heartburn (FH) and functional dyspepsia. In this cross-sectional, single-center study, we included 31 patients (20 female; mean age 49.1 yrs; mean BMI 24.4) with functional heartburn occurrence pre- and post a nutritional approach with low-FODMAP diet (see Table 1). Moreover, we observed a very important abdominal symptoms perception pre- and post- low-FODMAP diet in reducing heartburn in patients with FH and no pathophysiological evidence of gastroesophageal reflux as well as an advanced stage of EAC at diagnosis. Further research into the differential aspects of neoplastic progression in BE between men and women, may have future consequences for gender specific guideline recommendations, including the timing of follow-up.

Conclusion: This pilot study showed that a low-FODMAP diet was able to reduce heartburn perception in patients with FH and who did not obtain any symptom relief after PPI treatment. Larger prospective randomized controlled trial is mandatory to further explore these findings.

Introduction: Because of a higher prevalence of BE in males, recommendations in current guidelines are mainly based on male BE patients and make no difference in use of surveillance according to gender. Nevertheless, it is unknown whether female BE patients have the same neoplastic progression and acceleration rate as male patients.

Aims & Methods: The aim of this study was (1) to evaluate the difference between males and females in probability of and (2) time to neoplastic progression, as well as (3) gender differences in stage distribution of neoplastic progression in surveilled BE patients. In this multicenter prospective cohort study we included 729 patients with BE who met the inclusion criteria of a segment of >2 cm and confirmed intestinal metaplasia. Endoscopic surveillance was performed according to the American College of Gastroenterology guidelines. Cox regression modelling as well as accelerated failure time modelling were used to evaluate differences in probability of and time to neoplastic progression from HGD, EAC and both HGD and EAC between sexes, respectively. All models were adjusted for age, presence of esophagitis and length of BE. In case of a limited number of events, descriptive statistics were used.

Results: 532 males (73%; mean age 58 years, IQR 51-67) and 197 females (median age 64 years, IQR 57-70) were included with a median follow-up of 8.2 years (IQR 5.3-10.3). High-grade dysplasia (HGD) was detected in 35 males versus 4 females, EAC in 12 males versus 5 females. The total number of patients with neoplastic progression was 56 (8%), which was twice as high among males compared to females (HR 1.90, 95% CI 1.02-3.92). Especially the risk of HGD was higher in males than in females (HR 3.34, 95% CI 1.17-9.50). The ratio HGD/EAC in males was 2.92, in females 0.80. Apparently in females proportionally more EAC was identified compared to males. Though these data might suggest accelerated neoplastic progression rates in females, time to event was significantly shorter for males in HGD (HR 0.45, 95% CI 0.22-0.94). There was no difference for overall neoplastic progression (AR 0.59, 95% CI 0.10-3.09). Stage distribution is shown in Table 1, females tend to have a higher stage of neoplastic progression than males.

Conclusion: The risk of HGD and overall neoplastic progression and acceleration rate of HGD development is higher in male BE patients compared to females. On the other hand descriptive statistics show proportionally more EAC in females as well as an advanced stage of EAC at diagnosis. Further research into the differential aspects of neoplastic progression in BE between men and women, may have future consequences for gender specific guideline recommendations, including the timing of follow-up.

Introduction: Given its proven safety and efficacy, Radiofrequency Ablation (RFA) is the preferred ablation modality for dysplastic Barrett’s Esophagus (BE). However, RFA is associated with significant drawbacks, such as the need for large controller units, multiple deployment steps and capital investment. The Cryocool Balloon Ablation System (FCBA; C2 Therapeutics, Phoenix City, CA, USA) is another ablation method based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. The Cryocool Balloon Ablation System (FCBA; C2 Therapeutics, Phoenix City, CA, USA) is another ablation method based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. The Cryocool Balloon Ablation System (FCBA; C2 Therapeutics, Phoenix City, CA, USA) is another ablation method based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. The Cryocool Balloon Ablation System (FCBA; C2 Therapeutics, Phoenix City, CA, USA) is another ablation method based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. The Cryocool Balloon Ablation System (FCBA; C2 Therapeutics, Phoenix City, CA, USA) is another ablation method based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. The Cryocool Balloon Ablation System (FCBA; C2 Therapeutics, Phoenix City, CA, USA) is another ablation method based on the application of extreme cold- that has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated.
efficacy and safety of FCBA in the treatment of larger BE segments, however, are lacking. Therefore we aimed to assess the safety and efficacy of a single treatment with FCBA for dysplastic BE.

Aims & Methods: Patients were seen between March and December 2016 at two tertiary referral centers in the Netherlands. Patients with a BE <6 cm in length and with a confirmed diagnosis of low-grade (LGD) or high-grade dysplasia (HGD) or after endoscopic resection for visible lesions, were included. Exclusion criteria included previous focal ablation therapy and strictures. At baseline, all visible BE was treated with side by side ablations of 10 seconds, including circumferential treatment of the gastroesophageal junction (GEJ). Pain scores were assessed directly post-treatment and at days 2 and 7. Follow-up endoscopy with biopsy and photo documentation was scheduled after 3 months. Primary outcomes included dysplasia regression rate and incidence of esophageal stricture or other adverse events.

Results: We enrolled 20 patients with dysplastic BE (85% male, mean age 66 (±8 years), with a median BE length of 0.02 (IQR 0–0.4); 1–3) and a baseline diagnosis of LGD (10; 50%), HGD (1; 5%), or mucosal adenocarcinoma (9; 45%). Ten (50%) had undergone endoscopic resection of a visible lesion before cryoablation and 8 (40%) had undergone previous circumferential RFA. During a median ablation time of 16 minutes (IQR 11–19), all BE, including circumferential ablation of GEJ was successfully ablated in all patients. No adverse events occurred, and median pain directly post-treatment was 4 out of 10 (IQR 0–5), whereas this was 1 (IQR 0–2) and 0 (IQR 0–1) at days 2 and 7. At the 3-month follow-up endoscopy, median endoscopic regression of initial BE was found to be 95% (IQR 83–98), this included 3 patients (15%) with a complete 100% regression. All biopsies confirmed squamous regeneration without evidence for subsquamous BE. No significant esophageal strictures or other complications were noted.

Conclusion: Our multicenter, prospective trial shows that a single treatment with CryoBalloon ablation therapy is safe, well-tolerated and effective for eradication of dysplastic BE.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI207 CRYOBALLOON ABLATION OF DYSPLASTIC BARRETT’S ESOPHAGUS CAUSES SHORTER DURATION AND LESS SEVERE POST-PROCEDURAL PAIN AS COMPARED TO RADIOFREQUENCY ABLATION

S. Van Munster1, A. Overwater2, J.J. G.h.m. Bergman3, B.L.a.m. Weusten2
1Gastroenterology And Hepatology, AMC, Amsterdam/Netherlands
2Dpt. Of Gastroenterology And Hepatology, University Medical Center Utrecht, Utrecht/Netherlands

Contact Email Address: s.n.vanmunster@amc.uva.nl

Introduction: Radiofrequency ablation (RFA) is safe and effective for eradication of dysplastic Barrett’s Esophagus (BE), but may be associated with significant post-procedural pain. As an alternative, cryobalation using the Focal CryoBalloon Ablation system (FCBA) has recently been developed, which ablates BE by freezing it using nitrous oxide. Early uncontrolled studies suggest comparable safety and efficacy of FCBA and RFA in eradicating dysplastic BE. To determine post-procedural endpoints like pain might play a determining role in selecting the best treatment modality. In contrast to heat-based ablation, FCBA preserves the extracellular matrix which might be associated with less pain while maintaining sufficient depth of ablation. In this study, we aimed to compare post-procedural pain between focal RFA and FCBA.

Aims & Methods: Between January 2016 and March 2017 all patients undergoing focal ablation therapy of BE, either with RFA or FCBA performed in two tertiary referral centers in the Netherlands, were approached to complete a digital diary. A short questionnaire was daily sent to patients for 14 days post-treatment, to assess (1) odynophagia, (2) chest pain in rest (both were assessed using VAS score ranging from 0 to 10), (3) dysphagia (assessed using a score ranging from 0 to 4) and (4) use of analgesics. Primary outcome included maximum VAS score (maximum score for either item 1 or 2), secondary outcomes included area under the curves (AUCs) for all items assessed, maximum reported VAS score at any time, time to VAS 0 and analgesics use. According to national guidelines, all visible BE was ablated, including circumferential treatment of the gastro-esophageal junction (GEJ). In a standardized way, all patients were advised to use paracetamol (up to 4 times 500 mg daily) as necessary with additional ibuprofen, if needed.

Results: Fifty-five patients were included (35 with focal RFA; 20 with CBA) and median BE length was similar for the two groups (FCBA: C0M2, RFA: C0M1, p=0.72). All other baseline characteristics were similarly comparable for both groups (table 1A). Maximum VAS score was lower after FCBA compared with RFA at all days, reaching statistical significance at 13/14 days (table 1B). All AUC curves were significantly smaller after FCBA compared to RFA; for maximum VAS score (12.3 vs 26.7, p < 0.01), for odynophagia (11.6 vs 26.7, p < 0.01), for pain in rest (7.8 vs 20.5, p < 0.01), for use of analgesics (0.9 vs 3.1, p < 0.01) and for dysphagia (2.6 vs 8.2, p < 0.01). The maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p < 0.01). After 4 (IQR 1–10) days, half of the FCBA patients reported a pain score of 0, whereas this was 13 (IQR 10–15) days for RFA.

Conclusion: In this multicenter, non-randomized, open prospective cohort study, patients reported less post-procedural pain and dysphagia after FCBA as compared with RFA and, moreover, FCBA patients used less analgesics. Although a randomized trial should provide definitive evidence for differences in post-procedural tolerability, our results strongly suggest a significantly different post-procedural course, thus favoring FCBA over RFA.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI208 COMPARATIVE OUTCOMES OF RADIOFREQUENCY ABLATION FOR BARRETT’S ESOPHAGUS WITH DIFFERENT BASELINE HISTOLOGY

W.K. Tan1, A. Rattan2, T. Nuckcheddy1, B. Alias1, V. Sujendran3, M. Di Pietro1, 2

Contact Email Address: weikkittan@gmail.com

Introduction: Radiofrequency ablation (RFA) with endoscopic mucosal resection is recommended for Barrett’s Esophagus (BO) related neoplasia. In this study, we evaluated RFA treatment outcomes for BO stratified according to baseline histology, i.e. low-grade dysplasia (LGD), high-grade dysplasia (HGD) and intramucosal carcinoma (IMC). We retrospectively reviewed the treatment outcomes of patients with dysplastic BO between January 2007–2017. Patients received 3-monthly RFA until endoscopic and histologic remissions were achieved. Outcomes measured were: 1) complete remission of dysplasia (CRD) and intestinal metaplasia (CRIM), 2) stricture rate, and 3) durability of CRD and CRIM. Patients on active treatment protocol were excluded.

Results: We identified 113 patients who completed RFA treatment (21 LGD, 46 HGD and 46 IMC). There were no significant difference between the groups in the age, gender, circumferential and maximum length of BO, and stricture rate. CRD and CRIM were achieved in 94.7% and 78.8% of patients, respectively. When stratified according to baseline histology, there was no significant difference in CRD rate among LGD (95.2%), HGD (95.7%) and IMC (93.5%) (p=0.89). Similarly, there was no significant difference in CRD rate among LGD (71.4%), HGD (76.1%) and IMC (84.8%) (p=0.03). CRD durability at 12 and 36 months (n = 107) was 99.0% and 97.0%, respectively. CRIM durability (n = 89) at 12 and 36 months was 98.5% and 92.7%, respectively. When stratified according to baseline histology, CRD durability at 12 and 36 months for LGD and IMC were 100% at both time points, and 97.7% and 93.6% for HGD, respectively (log rank p = 0.31). CRD durability at 12 and 36 months for LGD, HGD and IMC were 100%, 96.4%, 100%, and 100%, 88.5%, 95.5%, respectively (log rank p = 0.60).

Conclusion: The treatment outcomes for BO were similar in patients with different baseline histology. Our results showed that once CRD and CRIM were achieved, these were durable over time.

CD4+ AND CD8+ LYMPHOCYTE RATE AND PD-L1 EXRESSION ARE PREDICTIVE OF CLINICAL COMPLETE RESPONSE AFTER NEOADJUVANT CHEMORADIATION FOR SQAMOUS CELL CANCER OF THE THORACIC ESOPHAGUS

P1210

CD4+ AND CD8+ LYMPHOCYTE RATE AND PD-L1 EXPRESSION ARE PREDICTIVE OF CLINICAL COMPLETE RESPONSE AFTER NEOADJUVANT CHEMORADIATION FOR SQAMOUS CELL CANCER OF THE THORACIC ESOPHAGUS

M. Giovannini1, M. Barthet1

Aims & Methods: This was a retrospective study including a prospective histological relecture (BS and specimen) in two expert centers. The inclusion criteria were: BE with HGD on pre-operative biopsies resected by EMR. The initial biopsies from other centers were collected and re-examined by our cytologists. The BS discordant with EMR specimens were recorded in a numeric file (Teleslide) and a second lecture was carried out by 2 experts and 2 fellows (1 of each per center). Five diagnoses were considered: no metaplasia (no BE), metaplasia without dysplasia, LGD, HGD, Adenocarcinoma. Concordance statistical tests were performed to assess the variability between BS and EMR diagnoses among the centers involved.

Results: Between January 2005 and December 2015, 87 patients have undergone EMR for HGD on biopsies, in both centers. Among them, 41 (47%) had a discordant result between biopsies and resection specimen. The histological diagnoses were: BE and HGD (16.4%), metaplasia, adenocarcinoma (4% (4.6%) and one patient had no metaplasia. Finally, 33 patients could be analyzed, 29 men and 4 women, with a mean age of 63 years old. The mean length of BE according to Prague classification was C3-M5, with relief assessment C1 in the cases. A mean number of 1.4 endoscopic session was performed, with a mean of 2.7 resected pieces per EMR, which was macroscopically complete in 63.6% of the cases. The mean follow-up was 38 months.

After histological relecture, the Kappa coefficient for the diagnosis of HGD was low on the BS and ranged between 0 and 0.6 for the EMR specimen. The inter-observatory concordance was 0.2 (for both BS and EMR specimen) for the diagnosis of HGD. For other diagnoses, it was ranged between 0 and 0.5 for biopsies and between 0 and 0.6 for EMR specimen. The kappa coefficient regarding the diagnosis of BE was 0.5 for biopsies and 0.4 for the BS specimen after relecture was ranged between 0 and 0.6.

Conclusion: The discordance rate between initial diagnosis of HGD on BS and final diagnosis was high, around 47%. The intra and inter-observer concordance is insufficient, even in expert tertiary centers. Thus, the question about performing EMR based on random biopsies rather than endoscopic assessment has to be asked, and clearly evaluated in further studies.

analyzed by cell counting kit-8 assay. Cell cycle and apoptosis were evaluated by flow cytometric analysis. Protein levels of p53 were determined by western blot analysis. Differences between groups were tested for significance using Student’s t-test (two-tailed).

Results: ESCC tissues examined in this study showed an obvious increment in TRPM2-AS expression when compared to normal tissues. Meanwhile, TRPM2-AS expression was positively related to lymph nodes metastasis, TNM stage and clinical stage. And upregulated TRPM2-AS expression was turned to be remarkably correlated with the shorter survival of ESCC patients which could act as an independent prognostic factor for both overall survival time and disease-free survival. In addition, overexpression of TRPM2-AS could promote the proliferation and inhibit the apoptosis of ESCC cells, while knockdown of TRPM2-AS had a reverse function. Furthermore, downregulation of TRPM2-AS enhanced the expression of p53 in ESCC cells.

Conclusion: This study suggested that non-long coding RNA TRPM2-AS could be a potential oncogene of ESCC. TRPM2-AS expression could serve as another potential therapeutic target and prognostic biomarker. In addition, our study demonstrated that expression of TRPM2-AS contributes to a lot inhibiting apoptosis of ESCC by regulating the expressions of p53 in vitro, which may be a potential oncogene and therapeutic target for ESCC.

Introduction: Esophageal adenocarcinoma (EAC) is an increasingly common cancer with a poor prognosis. EAC is the final step of a pathway starting with esophageal reflux disease, intestinal metaplasia, and dysplasia. The expression of costimulatory molecules on esophageal cell lines such as CD80 and CD86 is known to be increased in the esophageal cancer tissue is significantly lower than in the normal mucosa of healthy patients. This may be one of the mechanisms of immune escape of cancer cells in the esophageal cancer. Aims & Methods: The aim of this study was to investigate the role of CD80 in the inflammatory esophageal carcinogenesis and to characterize the immune environment of EAC. mucosa samples from cancer and from healthy esophagus were obtained during esophagectomy from patients affected by EAC. Fresh biopsies were obtained from patients who underwent endoscopy for screening or follow-up. Immunohistochemistry for CD80 was performed. Fresh biopsies were analyzed by flow cytometry to quantify the expression of CD80, its receptor CD28 and the lymphocytes activation marker CD38 on esophageal epithelial cells and CD8 inhibiting lymphocytes, respectively. A model of reflux induced esophageal carcinogenesis was created with a esophago-gastro-neuro-ostomy: C57Bl/6 mice were randomized to receive or not intraperitoneal injections of anti-CD80 antibody. The esophageal-gastric specimens were collected 32 ± 2 weeks after the experimentalization and analyzed in a blinded fashion. Non parametric statistics was used.

Results: Flow cytometric analysis of esophageal biopsies from healthy controls, Barrett esophagus, dysplastic esophagus and esophageal adenocarcinoma reveals that the expression of the costimulatory molecule CD80 by epithelial cells peaks during metaplasia in the inflammatory esophageal carcinogenesis. In the mice that received antiCD80 antibodies the rate of dysplasia in the fore stomach was largely unknown. In EAC, CD80 and CD86 expression activity within the tumor was associated to nodal metastasis and CD107 expression might be used as a marker of it. Moreover, nuclear p53 overexpression within the tumor might be used as a marker of early recurrence after esophagectomy and then used to plan follow up strategies. No apparent relation between p53 overexpression and tumor recurrence was revealed to be an independent predictor of early recurrence with [HR = 2.995 (95% CI = 1.122–7.9896) p = 0.029] as well as cancer stage [HR = 2.995 (95% CI = 1.6693 to 5.666) p < 0.001]. On the other hand, nuclear p53 overexpression also tended to be an independent predictor of overall survival [HR = 2.9359 (95% CI = 0.9613 to 8.9663) p = 0.06] while cancer stage confirmed to be the main survival predictor [HR = 1.8689 (95% CI = 1.0810 to 3.2314) p = 0.023].

Introduction: Altered glucose metabolism has become a recognised feature of tumor cells, which is characterized by an increased glucose uptake and preferential dependence on glycolysis for energy production. As a consequence, cancer cells produce large amounts of lactate, which is pumped out the cytosol by monocarboxylate transporters (MCTs), mainly MCT 1 and 4. MCT inhibition has previously been related to increase apoptosis in cancer cells, but this aspect has not been investigated in esophageal adenocarcinoma (EAC) yet.

Aims & Methods: We aimed to study the expression of MCT1 and MCT4 in human EAC samples and to evaluate in vitro the effect of extracellular glucose concentration and pharmacological inhibition of MCT1 on lactate concentration, intracellular pH (pHi), and cell apoptosis. MCT1 and MCT4 expression was assessed by immunohistochemistry in human samples of EAC. For the in vitro study, two different EAC cell lines were used: OE33 (ECACC), established from an EAC of the lower esophagus and OAC5M.1C (ECACC), obtained from a lymph node metastasis derived from an EAC. MCT1 and MCT4 expression and localization were assessed by immunohistochemistry in both cell lines. The MCT1 selective inhibitor AZD3965 (10, 100 and 1000 μM) was added to the culture medium under a normoxic and hypoxic atmosphere in standard (11nM) or high(30nM) glucose content in the media. Apoptosis was determined by flow cytometry (Annexin V-FITC and 7-AAD, fluorescine isothiocyanate). Intracellular lactate concentration was evaluated in a colorimetric assay. pH was evaluated by flow cytometry with the probe SNARF-1 AM. Experiments were performed at least in triplicate. Statistical analysis was performed by student's t test.

Results: MCT1 and MCT4 expression was found in all the EAC samples evaluated. MCT1 expression was confined to tumor cells, with 62% of the biopsies showing moderate or intense staining, whereas MCT4 was expressed in both tumor and stromal cells, with 40% of moderate/intense stained samples. Both MCT1 and MCT4 were expressed in OE33 cells and only in a small population of the metastatic cell line. High extracellular glucose concentration increased intracellular lactate levels in OE33 cells but not in the metastatic line, and did not have any effect either in pH. Cell apoptosis under all the conditions evaluated and hypoxia) in both cell lines. Treatment with AZD3965 (10 and 100 nM) increased intracellular lactate concentration in OE33 and OAC5M.1C cells, but this increase was higher (600–700%) in the metastatic cell line than in OE33 cells (50–70%). Under normoxic conditions AZD3965 significantly increased pH of both cell lines whereas under hypoxic atmosphere had no effect on metastatic cells. The highest concentration (100 nM) of the MCT1 inhibitor significantly

A590 United European Gastroenterology Journal 5(5S)
increased apoptosis of OACM5.1C cells whereas did not affect apoptosis of OE3.1 cells.

Conclusion: Metastatic and non-metastatic esophageal adenocarcinoma cells exhibit different glycolytic metabolism and response to pharmacological inhibition of MCT1, which increases apoptosis in metastatic cells. Further preclinical studies are necessary in order to define the potential of blocking lactate transporters on the treatment of metastatic EAC.

Introduction: Although endoscopic submucosal dissection (ESD) is accepted as a standard treatment for early stage esophageal neoplasia, esophageal perforation is sometimes experienced as main adverse event. Esophageal perforation causes mediastinal emphysema, mediastinitis, and pneumotheorax, those sometimes require emergency surgery.

Aims & Methods: We evaluated the predictive factors for esophageal perforation in patients who received esophageal ESD. This was a retrospective observational study in a single institution. Between May 2004 and March 2016, 549 consecutive patients with 927 lesions were included in the study. Perforation was defined as an endoscopic finding of an esophageal wall exposing the mediastinal cavity. Logistic regression multivariate logistic regression analysis with generalized estimating equations were used to analyze repeated measures data.

Results: A total of 549 cases with 927 lesions were evaluated. Of those, perforation occurred in 15 cases (2.7%) with 15 lesions (1.6%). A lesion diameter (Odds ratio; OR=1.05, 95% confidence intervals; CI: 1.02-1.07, p<0.001) and the proximity of the tumor to a previous ESD scar (OR=6.66, 95% CI: 1.80-24.6, p=0.004) were both associated with perforation using crude logistic regression analysis. Multivariate logistic regression analysis also showed that a lesion diameter (OR=1.05, 95% CI: 1.03-1.07, p<0.001) and the proximity of the tumor to a previous ESD scar (OR=13.0, 95% CI: 2.48-67.9, p=0.002) were independent predictive factors for perforation.

Conclusion: Larger lesion and the proximity of the tumor to a previous ESD scar increased the likelihood of perforation in patients who received esophageal ESD.

Introduction: According to the current Japanese guidelines for the diagnosis and treatment of esophageal cancer, endoscopic resection is indicated for pathologi- cal T1a (epithelium/lamina propria mucosae) and relatively indicated for T1a(muscularis mucosae) and T1b(a tumor invading the submucosa to a depth more than 200μm(SM2) in the CRM group and the LPM in 3 patients, the MM in 16, the SM1 in 18, and the SM2 in 15 in the follow-up group (p=0.91). Lynchaptic invasion was positive in 21 patients in the CRM group and 12 in the follow-up group (p<0.01). Vascular invasion was positive in 27 patients in the CRM group and 29 in the follow-up group (p=0.32). Involvement of the submucosal vertical margin was found in 7 in the CRM group and 9 in the follow-up group (p=0.07). CRM-related grade 3 or 4 early adverse events were only found in 7 in the CRM group and 9 in the follow-up group (p=0.07).

Conclusion: Additional CRT after endoscopic resection in patients with esophagous squamous-cell carcinoma who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preservation strategy.

P1218 SAFETY, EFFICACY AND OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR THE TREATMENT OF EARLY BARRETT’S NEOPLASIA

M. Omae, M. Konradsson, P. Elbe, M. Nilsson, M. Lindblad, I. Rouvelas, F. Bäldquä-Silva
Gastroenterol, Karolinska University Hospital, Stockholm/Sweden

Contact E-mail Address: masami.nego@jfcr.or.jp

Introduction: Endoscopic submucosal dissection (ESD) was developed in Japan for en bloc resection of large gastrointestinal neoplasias and has progressively been adopted in the West. Currently, early Barrett’s neoplasia is mainly treated with endoscopic mucosal resection (EMR) and/or radiofrequency ablation, being the role of ESD in this context not well-established yet. Our aim is to evaluate the safety, efficacy and outcome of ESD for the treatment of early Barrett’s neoplasia.

Aims & Methods: Fifty consecutive ESD cases of early Barrett neoplasia were performed in 42 patients in our center between 2011 and 2016. All ESDs were performed under full narcosis after multidisciplinary team conference discussion and patient’s consent. The primary endpoint was the rate of en bloc resection. Secondary endpoints included rate of R0 and curative resection, a comparison of pre- and post- ESD histology, procedure time, procedure-related adverse events, and rate of remission at follow-up. This study was approved by the Stockholm Regional Ethical Committee.

Results: Mean age was 67 years (range 46-84), being 74 male and 72% long segment BE. The mean specimen size was 52 mm (range 16-150 mm). ESD resec- tions included <25%, 25-50%, 50-75% and 75-100% of the lumen circumference in 4/31/12/3 of cases, respectively. En bloc, R0 and curative resection were obtained in 96% (48/50), 80% (40/50) and 70% (35/50) of cases, respectively. The histology corresponded to low-grade dysplasia in 4 patients, flat Barrett’s neoplasia (n = 30) and adenocarcinoma (n = 15). One case of LGD was upstaged to intramucosal AC, 10/30 cases of HGD were upstaged to adenocarcinoma. In 8/ 13 cases of AC, there was submucosal invasion on the ESD specimen. In 14/50 of the patients there were multifocal neoplasias. The mean procedure time was 120 minutes. There were 2 perforations (4%) treated endoscopically and 2 (4.0%) postoperative bleedings treated conservatively. Six patients (12%) developed esophageal strictures that were managed endoscopically. The 30 days mortality rate of ESD was 0. In the 15 non-curative cases, 2 patients went through further ESD, 1 received chemoradiotherapy and 2 patients are under surveil- lance. In the 10 esophagectomy cases, 4 patients had AC in the remnant Barrett’s esophagus and 2 patients had lymph node metastasis. Complete remission was
found in 100% (35/35) of patients with curative resection at median follow-up of 24 months (range 4–64 months).

Conclusion: In the proper setting, ESD is safe and effective for the treatment of early Barrett’s neoplasia with high en bloc and complete resection rates and good curative rate. ESD enables full pathological assessment in lesions not suitable for en bloc resection with EMR. There were no recurrences in the curettage cases, which increases the role of ESD for the management of early Barrett’s neoplasia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1219 ENDOSCOPIC EVALUATION AT THE PRIMARY SITE OF CTI ESOPHAGEAL CANCER AFTER PROTON BEAM THERAPY AND CLINICAL RESULTS OF SALVAGE ENDOSCOPIC THERAPY FOR LOCAL RECURRENCE

Contact E-mail Address: dsatou@ncc.go.jp

Introduction: Recently, it has been reported that proton beam therapy (PBT) is the effective treatment for patients with esophageal squamous cell carcinoma (ESCC). However, there are few reports regarding the endoscopic evaluation of efficacy after PBT at the primary site.

Aims & Methods: The aim of this study is to clarify the adequate endoscopic evaluation of primary lesion of ESCC after PBT, and the clinical results of salvage endoscopic treatment for local recurrence. Patients with clinical T1 ESCC, and who had been treated with PBT between April 2013 and June 2016 at the National Cancer Center Hospital East were investigated. The total dose of PBT was 60 Gray-Equal-Volatility (GyE). The efficacy of PBT at the primary site was evaluated with endoscopy, and the definition of complete response (CR) was used according to the same criteria as that of conventional chemoradiotherapy (CRT) as follows: disappearance of tumor lesion and ulcer, and absence of cancer cells with biopsy was verified. The endoscopic evaluation was performed within 2 months after the completion of PBT, and we repeatedly evaluated every month if the lesion did not achieve CR. The treatment for local recurrence after PBT was chosen based on the depth of the tumor as follows: endoscopic resection (ER) for cT1a, endophagotomy or photodynamic therapy (PDT) for cT1b or deeper depending on patient’s condition.

Results: Among 44 patients who underwent PBT, the median age was 70 years (range, 41–79). The number of patients with clinical stage I was 23 (52%), and thirds with stage II, III, and IV were 16 (36%), 2 (5%), and 3 (7%), respectively. All patients underwent concurrent systemic chemotherapy. 43 patients (98%) could achieve a CR at the primary site and only one patient (2%) did not show a CR (non-CR) at the primary site. The median time to CR from the start of PBT was 60 days (range, 41–79 days) and 6 months or longer period was required to confirm CR due to the remaining PBT induced erosions or ulceration in 7 patients (15%). One patients whose primary site did not reach to CR showed prolonged ulceration for 385 days. Of 43 patients (14%) developed local recurrence, 14% was submucosal lymph node recurrence or distant metastasis, and the median time to local recurrence from CR was 257 days (range, 111–722 days). The endoscopic finding of local recurrence was resembling submucosal tumors (SMT) in 3 and flat lesion in other 3 tumors., All 6 patients with local recurrence were indicated of local recurrence was resembling submucosal tumors (SMT) in 3 and flat. Of the 43 patients, 6 patients (14%) developed local recurrence without regional recurrence from CR was 257 days (range, 111–722 days). The endoscopic finding of efficacy after PBT at the primary site.

Conclusion: Endoscopic surveillance of HNSCC is very important for SENs cases. However, as ESD is feasible and safe with acceptable complication risks despite the high rates of stenosis in resections >75% of the circumference. The circumferential extension, number of patients e stenosis rate are show in table 1.

Table 1: The circumferential extension, number of patients and stenosis rate

<table>
<thead>
<tr>

Introduction: Globally, 80% of all esophageal cancer cases are esophageal squamous cell cancer (ESCC), arising from esophageal squamous cell neoplasia (ESCN). Patients with ESCC have poor prognosis, but when diagnosed at the stage of ESCN, curative endoscopic treatment can be performed. ESCN mainly occurs in developing countries, often with limited endoscopic expertise and resources, like Central and Eastern Asia and Eastern and Southern Africa. Hence, an easy-to-use, low-cost treatment for ESCN would be of great value. Focal Cryoballoon Ablation therapy (FCBA) (C2 Therapeutics Inc. Redwood City, CA, USA) is a new endoscopic ablation therapy that comprises a thermodenaturable cryosphere catheter with a conformable balloon that obviates the need for sizing, a handle, and a small disposable cryogen cartridge. The balloon is simultaneously inflated and cooled with nitrous oxide from the cartridge, resulting in ice patches of approximately 2cm2. FCBA is easy to use and requires no costly equipment. Early studies for FCBA of Barrett’s esophagus showed promising results, however, limited data are available for FCBA of ESCN. In this study we aimed to assess the safety, tolerability and efficacy of FCBA in the eradication of ESCN.

Aims & Methods: The aim of this study was to investigate the clinical outcomes of FCBA in the clinical endoscopic submucosal dissection cases in the esophagus, stomach, and colorectum: complication rates and long-term outcomes. Surg Endosc 27:1000–1008
enrolled. At baseline, side-by-side ablations of 10 seconds were performed on USLM treated every 3 months until eradication of ESCN was confirmed. Outcomes: safety and tolerability (11-point visual analog scale (VAS) for pain), complete response (CR) rates (absence of MIGN or worse in biopsies), neoplastic progression and adverse events.

Results: 60 patients (63 MIGN, 17 HGIN) with a median lesion of 2 (IQR 2–3) cm in length. Of these, 79% (99) were successfully treated; 3 developed superficial, self-limited mucosal lacerations upon balloon inflation and 2 of them were successfully re-ablated 3 months later. A median of 5 (IQR 4–6) treatments were performed per patient, in a median ablation time of 8 hours (IQR 5–10) minutes. As of April 2017, 77/97 (99%) patients completed a 3-month follow-up endoscopy and 69/77 patients (89%) exhibited endoscopic and histologic CR. Eight patients had residual USL and were again treated with USLM 10 months later and post-ESD pathology revealed no other 2 cases were pending. To date, 4 patients have undergone a 12 month endoscopy and all continue to exhibit endoscopic and histologic CR. No significant strictures have been noted on follow-up. Three patients developed fever shortly after treatment which was treated with aspirin. Post-procedure median VAS was 1 (IQR 0–2) at day 2, and 0 (IQR 0–0) at days 7 and 30.

Conclusion: Preliminary results of our multicenter open prospective cohort study suggest that FCBA of ESCN is safe, well-tolerated, and highly effective in inducing endoscopic and histologic remission. Longer term (12 month) follow-up data is pending.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1222 THE ENDOSCOPIC TREATMENT STRATEGY FOR SUPERFICIAL ESOPHAGEAL CANCER

N. Yamaguchi
Department Of Gastroenterology And Hepatology, Nagasaki University Hospital, Nagasaki, Japan

Contact E-mail Address: naoyukii3435@nagasaki-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) allows en bloc removal of superficial esophageal squamous cell carcinoma (SCC). However, esophageal stricture often occurs after ESD when the lesion involves more than three-fourth of the circumference of the lumen. Frequent balloon-dilation via endoscopy is required in such situation, thus causing health economic problem. In this study, we investigated the clinical outcomes, and prevention of post-ESD stenosis.

Aims & Methods: A total of 667 cases in 516 consecutive patients were treated by ESD in our department from April 2006 to December 2016. We investigated the following 2 items. 1. Clinical outcomes and complications. 2. Usefulness of oral steroids administration, the local steroid injection, endoscopic transplantation of tissue-engineered autologous oral mucosal epithelial cell sheets, or steroid oral + local injection combination therapy for the prevention of post-ESD stenosis.

Results: 1. Clinical outcomes: En bloc resection rate was 99.8% and en bloc curative resection rate was 90.0%. The rate of perforation, post-ESD bleeding, and post-ESD stenosis were 0.2%, 0.8% and 6.1%, respectively. 2. Prevention of post-ESD stenosis: (1) Oral steroid vs Steroid injection vs Cell sheet transplantation: In oral steroid group, the stenosis rate was 14.9%, and the ulcer healing period was 39.5 days. In steroid injection group, the stenosis rate was 12.9%, and the ulcer healing period was 66.0 days. In cell sheet transplantation group, the stenosis rate was 40.0% and the ulcer healing period was 36.0 days. There was no significant difference between these 3 therapies, and these therapies prevent post-ESD stenosis to significant extent. However, ulcer healing period of the cell sheet transplantation was significantly shorter compared with the other 2 therapies. (2) The usefulness of SH oral + local injection combination therapy. We investigated limitations of steroid administration, and cell sheet transplantation in order to prevent post-ESD stenosis. The following 4 factors (more than 9/10 of circumferential resection, more than 5 cm of longitudinal resection, cervical esophageal, post history of chemo-radiation therapy or endoscopic resection) were the stenosis prevention treatment-resistant factors. Therefore, we examined the stenosis rate according to the number of these 4 factors. The stenosis rate of the cases which have 0 or 1 factor, the case which has more than 2 factors in semicircular cases, and the complete circular cases is 4.9%, 30.3%, and 44.8%, respectively. The stenosis rate of the cases which have more than 2 factors and complete circular cases are significantly higher, compared to the cases which have 0 or 1 factor. As a result, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. In contrast, in SH oral + local injection combination therapy, the stenosis rate of the cases which have more than 2 factors and the complete circular cases is 17.5%, and 14.3%, respectively. Taken together, the stenosis rate of SH oral + local injection combination therapy is significantly lower, compared to the other 3 therapies.

Conclusion: Esopehagal ESD achieved high en bloc resection rate and curability with low rates of complications. Oral steroid, steroid injection therapy and cell sheet transplantation may be effective treatment strategy for reducing post-ESD stenosis. However, the above-mentioned 4 factors are the stenosis prevention treatment-resistant factors in these 3 therapy cases. Furthermore, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. SH oral + local injection combination therapy is very useful for prevention of post-ESD stenosis and has a potential to overcome stenosis prevention treatment-resistant factors.

Disclosure of Interest: All authors have declared no conflicts of interest.
showed the greatest disparities, was evaluated. We retrospectively evaluated long-
term follow-up study for oncological outcomes about follow-up duration, loco-
regional recurrence, distant recurrence.

**Results:** The median follow-up duration is 40.36 ± 20.74 months in all patients
Based on the previous our study, we divided patients two groups who underwent operation. After 29 cases of 302 patients, 133 were in Group A (≥ 29 days) and 169 in Group B (> 29 days). There were more differences between two groups about ASA score, ER Specimen size, intra-op. transfusion, POD/1 Hemovac® discharge, Maximal postoperative CRP in the clinicopathological characteristics. Like previous our study the operative time, EBL, tumor size was significantly longer and more in group A compared with group B. There were totally 7 patients locoregional and distance recurrence during follow-up period. There were no differences in oncological outcomes between two groups.

**Oncological recurrence for Each Group**

<table>
<thead>
<tr>
<th>Group</th>
<th>Characteristics</th>
<th>F/u duration (months, mean ± SD)</th>
<th>Locoregional recurrence (n, %)</th>
<th>Distant recurrence (n, %)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Group A</td>
<td>n = 133</td>
<td>37.02 ± 20.54</td>
<td>1.0</td>
<td>3 (2.3)</td>
</tr>
<tr>
<td>Group B</td>
<td>n = 169</td>
<td>44.18 ± 19.49</td>
<td>1(0.6)</td>
<td>2 (1.2)</td>
</tr>
</tbody>
</table>

**Conclusion:** Based on long-term follow-up data, surgery time after ER in EGC does not affect oncological outcome. These long-term follow-up results suggest that adding surgery at about 1 month after ER is optimal for better surgical outcomes without affecting the oncological outcomes.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1225 THE POINT TO DISTINGUISH EARLY GASTRIC CANCER FROM DEPRESSION TYPE OF GASTRIC INTESTINAL METAPLASIA**

T. Wakasugi, S. Furutachi, H. Yamashita
Department Of Gastroenterology & Hepatology, Okayama Medical Center, Okayama/Japan

Contact E-mail Address: twakasugi0530@yahoo.co.jp

**Introduction:** This study discusses two endoscopic findings which improve the accuracy of the diagnosis of early gastric cancers (EGC). After successful *Helicobacter pylori* eradication, we often observe multiple reddish depressed lesions or “patchy redness” in the gastric mucosa. Even though most are intestinal metaplasia (IM), EGC is found among these lesions. A light blue crested (LBC) has been a highly accurate sign of the IM. There are, now, additional two endoscopic findings that should improve the accuracy of diagnosis of EGC. They are 1) “intrathelial microinvasion (IEMI)”, and 2) “Over flow”. Over flow is the endoscopic finding that the structure of the depressed lesion spreads to the outside of the depression.

**Aims & Methods:** The aim of this study is to clarify the usefulness of two endoscopic findings in order to detect the EGC in the group thought to be an IM. This is a retrospective control study. There were 234 cases of EGCP performed endoscopic submucosal dissection (ESD) between November 2011 and August 2016 in Okayama Medical Center. We included 57 cases in this study. As EGCP group, we included 45 cases that were 0-Ile, 10 mm or less, pTia M, a differentiation type cancer. As IM group, we included 12 cases identified as IM by biopsy in the same period. The EGCP group is then divided into 2 groups; 1) eradication group (13 cases who had a history of eradication), and 2) a small IIEC group (32 cases) without a history of eradication. We evaluated 1) the ratio of LBC, 2) the ratio of irregular microsurface pattern 3) the ratio of irregular microvascular pattern, 4) the ratio of IEMI and 5) the ratio of Over flow.

**Results:** The ratio of LBC was 75% in IM group, which was significantly higher than eradication group (7.7%), and small EGC group (9.4%). The ratio of irregular microsurface pattern was 33% in IM group, which was significantly lower than eradication group (92%), and small EGC group (84%). The ratio of irregular microvascular pattern was 0% in IM group, which was significantly lower than eradication group (92%), and small EGC group (81%). The ratios of IEMI were 0% in IM group, 9% in eradication group and 41% in small EGC group. The ratios of Over flow were 0% in IM group, 46% in eradication group and 50% at small IIEC group. Furthermore, the ratios to have either in two endoscopic findings were 0% in IM, 77% in eradication group and 69% in small EGC group.

**Conclusion:** IEMI and Over flow leads to the diagnosis of EGC in addition to other endoscopic findings.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1226 IRON DEFICIENCY ANEMIA—ARE THERE ANY PREDICTORS OF GASTROINTESTINAL MALIGNANCY?**

S. Xavier1, J. Magalhães2, J. Cotta1
Department of Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga/Portugal

1Gastroenterology Department, Hospital da Senhora da Oliveira, Guimarães, Braga/Portugal

2Pt Government Associate Laboratory, 4 ICVS/3BS, Braga/Guimarães/Portugal

Contact E-mail Address: smaxavier@gmail.com

**Introduction:** Iron deficiency anemia (IDA) may be the only sign of gastrointestinal (GI) malignancy. The identification of predictive factors of GI malignancy in patients with IDA could help the physician to establish patients’ priority to endoscopic assessment, contributing to an earlier diagnosis.

**Aims & Methods:** Retrospective study of 344 patients submitted to endoscopic assessment for IDA. Included adult patients with IDA and excluded patients with GI or extra-GI bleeding, total gastrectomy, exclusively vegetarian diet or intake of iron-containing medical records.

**Results:** Included 121 patients with mean age of 68.5 ± 17.0 years and 54.5% females. GI malignancy was identified in 14.9% of patients (gastric in 12, colonic in 6 patients). A statistically significant association was found between the presence of GI malignancy at age 72.2 ± 17.4, p < 0.05), male gender (72.2% vs. 40.8%, p = 0.01), GI symptoms (61.1% vs. 11.5%, p < 0.01), weight loss (61.1% vs 5.8%, p = 0.01), need for hospitalization (88.9% vs. 49.5%, p < 0.01), iron serum levels and transferrin saturation (19.7 ± 10.1 mg/L vs. 30.4 ± 18.9 mg/L, p < 0.01 and 6.1 ± 4.14% vs 92.6 ± 6.3%, p < 0.03, respectively). At logistic regression analysis only weight loss (p = 0.01), GI symptoms (p < 0.01), transferrin saturation (p < 0.01) and need for hospitalization (p = 0.01) showed a significant association with the diagnosis of GI malignancy. Transferrin saturation showed a weak discriminative capacity (AUC = 0.67, p = 0.01) however, values of transferrin saturation ≤ 11% had a sensitivity of 94.4% and a negative predictive value of 97.1% for GI malignancy (CI 95% 93.6–99.9).

**Conclusion:** In patients with IDA the diagnosis of GI malignancy is established in a significant percentage of patients and patients with GI symptoms, weight loss or with need for hospitalization should be given priority in the performance of endoscopic examinations. Transferrin saturation may help in establishing the urgency of endoscopic assessment, since patients with values over 11% have a very low probability to have GI malignancy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Detection of gastric cancer in its early stage is pertinent in reducing disease-specific mortality. However, detection of early gastric cancers has not been achieved in many countries where the incidence of gastric cancer is high. In order to overcome this problem, we developed an e-learning system for international endoscopists to improve endoscopic diagnosis of early gastric cancer. However, it has not been investigated whether such learning system is useful in clinical practice.

**Aims & Methods:** The objective of this trial is to investigate whether the intensive on-site TTT course is useful for increasing early detection rate of gastric cancer in Chinese high-volume endoscopy center. Five Chinese doctors (the TTT group) who were invited to the TTT course and the other five age and experience-matched Chinese doctors (the non-TTT group) in the same facility who did not attend any learning program during the same period. Lectures of the TTT course included the detection of early gastric cancer by screening endoscopy using white-light endoscopy alone and the feature of the detected subtle gastric mucosal lesion using white-light endoscopy or magnifying endoscopy with narrow-band imaging. Contents used in the lecture had been reported to be useful by an e-learning trial [1, 2]. All the instructions were given by an experienced Japanese endoscopist (K. Yao) who constructed the e-learning system [1, 2]. Endoscopists also received on-site hands-on training in order to provide them obtained enough knowledge and technique. Furthermore, we held case conferences in order to share common experiences. During the period, the number of both newly detected early gastric cancers and screening gastroscopy procedures was recorded. The primary end-point was to compare the early detection rate between the TTT and the non-TTT group. (Early detection rate = the number of newly detected early gastric cancers/the number of screening endoscopy procedures)

**Results:** The data obtained from the 275 consecutive cases of screening gastroscopy procedures by the TTT group endoscopists and from the 323 consecutive cases of screening endoscopy procedures by the non-TTT group endoscopists were analyzed. In the TTT group, four cases with early gastric cancers were detected and no early gastric cancer was detected. The early detection rates of
the TTT and the non-TTT group were 1.5% and 0%, respectively. There was a significant difference in early detection rate between the TTT and the non-TTT group (Fisher’s exact test, P = 0.046).

Conclusion: This clinical trial clearly showed that the systematic intensive TTT course is useful for improving early detection rate of gastric cancer in clinical practice at centers of high-volume endoscopy center. (NCT02385578).

Introduction: Endoscopic submucosal dissection (ESD) is believed to be a possible modality for early gastric cancer. But there is little report about long-term outcomes of the ESD directly compare with the surgery. The purpose of this study is the comparison between the two treatment modalities about the outcomes of ESD and surgery.

Aims & Methods: We performed a retrospective analysis of 1243 patients with stage I early gastric cancer without lymph node involvement. 551 patients were treated with ESD, and 692 patients were treated with subtotal or total gastrectomy.

Results: The mean age was higher in the ESD group (64.9 ± 9.5 vs. 58.4 ± 11.7, P = 0.001) and female distribution was higher in surgery group (30.5% vs. 38.9%, P < 0.001). In ESD group, diabetes was more frequent (12.9% vs. 7.1%, P < 0.001). The overall survival rate was similar (96.2% vs. 96.7%, P = 0.136), but disease-specific survival rate was significantly higher in ESD group (99.8% vs. 98.7%, P = 0.037, log-rank test). During 10 year follow up period, new lesions were observed in 3.6% in ESD group and in 1.3% of surgery group (P < 0.001). ESD group showed less complications (4.5% vs. 16.3%, P < 0.001) and shorter hospital day than surgery group (5.27 days vs. 12.09 days, P < 0.001).

Conclusion: Although the development of new lesions was more frequent than surgery, ESD showed similar overall survival rate and even higher disease-specific survival rate than surgery. Also, ESD has less complications and shorter hospital day than surgery. Therefore, ESD is an effective therapeutic method in early gastric cancer as well as surgery.

**P1229** **HEMATOLOGISTS SHOULD ORDER ENDOSCOPIC EXAMINATION PRIOR TO EXPERTS OF ENDOSCOPY IN CASE OF ENDOSCOPIC CHECK-UP OF GASTROINTESTINAL MALIGNANT LYMPHOMA**

T. Yamasaki, T. Sakurai, J. Miotope, M. Mitsuunaga, M. Saruta

Department Of Gastroenterology And Hepatology, The Jikei University, Tokyo, Japan

Contact E-mail Address: takusan.yamasan@gmail.com

Introduction: Gastric malignant lymphoma (ML) is most popular lymphoma of the gastrointestinal tract. Especially it often see gastric ML lymphoma in cases of *H. pylori* (HP) infection positive, and we also sometimes find out HP negative gastric MALT lymphoma. Since gastric carcinoma (GC) is more common rather than gastric ML lymphoma, typical endoscopic diagnostic characteristics of GC are established on usual endoscopic examination for most of gastroenterologists. On the other hand, endoscopic characteristics of gastric ML lymphoma on usual endoscopy have not been established for most of gastroenterologists.

Aims & Methods: The purpose of this study is to investigate the difficulty on endoscopic diagnosis of gastric ML lymphoma in 24 gastroenterologists (12 experts and 12 trainees of endoscopy) on usual endoscopic examination. We investigated a total of 72 gastric ML lymphoma cases in our hospital and other 7 hospitals. We estimated total number of endoscopic examinations to order endoscopic examination to experts of endoscopy knowledgeable of ML in case of endoscopic check-up of gastrointestinal malignant lymphoma.

Results: The average number of endoscopic examinations up to diagnose gastric ML lymphoma was 3.4 times (from 1 to 7 times) on whole endoscopies after first appearance of lymphoma. Though average total number of endoscopic examinations of experts was only 1.2 times, on the other hand average total number of endoscopic examinations of trainees was 5.4 times. There was a significant difference between experts and trainees of endoscopy on average total number of endoscopic examinations (P = 0.022). Major reason of misdiagnosis was insufficient recognition of endoscopic appearances of ML on endoscopic trainees. Typical representative appearances of gastric ML lymphoma were erosions, ulcers and surface irregularities. Since these lesions are also appeared as typical appearances of GC and gastritis, most of non-expert of endoscopy cannot distinguish the difference of GC, ML and gastritis due to those similarities. For example, even if typical ML cases, non-expert could not diagnose repeatedly, but expert could diagnose minimal lesions of ML at first endoscopy. Especially HP positive gastric MALT lymphoma was similar to gastritis and GC on endoscopic findings, most of non-expert could not diagnose exactly.

Conclusion: We finally identified 12984 eligible patients with metastatic GC between 2004 to 2012, including 1977 patients with gastrectomy and 11007 without resection. The median survival time for patients with or without gastrectomy was assessed by Kaplan–Meier and log-rank analysis. Multivariate Cox proportional hazards regression models was performed to analyze the effect of primary tumor resection on overall and cancer-specific mortality. To further reduce potential baseline bias in patient selection between two groups, we adopted 1:1 propensity score matching to re-examine the effect of resection.

Results: We finally identified 12984 eligible patients with metastatic GC between 2004 and 2012, including 1977 patients with gastrectomy and 11007 without resection. The median survival time for patients with or without surgery were 9.9 and 10.0 months respectively. Patients who received surgery had a significantly better overall and cancer-specific survival compared with those without gastrectomy (P < 0.03). In multivariate Cox analysis, gastrectomy was associated with decreased overall mortality (HR, 0.55, 95% CI 0.52–0.58, P < 0.001) and cancer-specific mortality (HR, 0.55, 95% CI 0.52–0.58, P < 0.001). In the propensity score matched model analysis, gastrectomy was associated with increased overall (HR, 0.54, 95% CI, 0.51–0.58) and cancer-specific survival (HR, 0.54, 95% CI, 0.50–0.55).

Conclusion: Based on population-based studies, we demonstrated that there was a survival advantage of gastrectomy in patients with stage IV gastric cancer. Further prospective studies are needed to verify our findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1231 DEVELOPMENT OF AND EXPERIENCE WITH AN INSULATED SCISSORS-TYPE KNIFE (SB KNIFE)

M. Kobayashi
Yokkaichi Municipal Hospital Dept. of Gastroenterology, Yokkaichi/Japan

Contact E-mail Address: makoto-kobayashi@ahoma.ocn.ne.jp

Introduction: Endoscopic submucosal dissection (ESD) is technically difficult and is associated with risks of perforation and bleeding. Although knife-type instruments are primarily used to make incisions during ESD, it is necessary to be proficient in endoscopic procedures and be able to perform them simultaneously with electriﬁcation and incision. Scissors-type knives are fairly easy to manipulate in colorectal ESD. We have fabricated SB knife Jr type (SBjr), short scissors-type knife with outer insulated layer, in collaboration with SUMITOMO RAKELITE CO.

Aims & Methods: SBjr is short length (electrode length: 3.5 mm) to be easy to handle in narrow colorectal lumen. The surface of the rotatable monopolar scissors is coated with isolating material in order to enhance the cutting power and prevent electric effects in the surrounding tissue. The shearing structure make sharp cutting quality and very small round tips prevent to grasp the muscular layer. SBjr was used in circumferential incision, submucosal dissection and hemostasis. After infected hyaluronic acid in submucosal layer, grasped the tissue, conﬁrming safety, make incision. SBjr was used not only in incision but also in hemostasis. At sites containing blood vessels or bleeding, they were grasped and induced coagulation using SBjr. It has been used on 180 colorectal lesions from January 2008.

Results: The circumferential incision and submucosal dissection were basically performed with High-frequency cutting wave. There were 3 cases of perforation during ESD and 1 case of post-operative bleeding. The procedure itself was fairly easy and partly relatively effective at sites difﬁcult to shape the endoscope and sites containing blood vessels, where conventional devices would encounter diﬃculties. Due to the very small round tips of the instrument, detailed operation become simply. For coagulation of blood vessels or bleeding, it is not required to replace SBjr which is used cutting and coagulation.

Conclusion: This short insulated scissors-type knife (SBjr) made it easier to perform colorectal ESD, we conclude that it is an effective device and easy for a beginner in colorectal ESD.

Introduction: The gastrointestinal tract (GIT) is the most common extranodal site affected in lymphomatous disease. Infection with Helicobacter pylori, human immunodeﬁciency virus and Epstein Bar and immunosuppression have been studied as possible risk factors. The diagnosis is often late, presenting at an advanced stage, with limited therapeutic options.

Aims & Methods: The objective of this study was to characterize the anatomical distribution, clinical manifestations, risk factors and prognosis of GI lymphomas. Retrospective study of patients diagnosed with GI lymphomas between 1997 and 2016.

Results: During the 20 years, 127 GI lymphomas were identiﬁed. The mean age at diagnosis was 65.7 years, 53% of males. The majority (92.9%) had symptoms at the time of diagnosis, with fatigue (54.3%) being the most common. The most commonly aﬀected organ was the stomach (65.3%) and the most common subtypes were diffuse large B-cell (48.8%) and MALT (27.6%). Most tumors were at an advanced stage, with limited therapeutic options.

Conclusion: The stomach is the main organ aﬀected by lymphomatous disease (p = 0.0078). The mean procedure time was 40.89 ± 10.79 min in EUS-FNA and 55.15 ± 27.42 min in MIAB(p = 0.0234). Helicobacter pylori were present in 27.4% in MIAB(p = 0.005). The mean procedure time in MIAB was 9.26 ± 4.57 min in EUS-FNA and 27.42 min in MIAB(p = 0.005). The mean procedure time in MIAB was 9.26 ± 4.57 min in EUS-FNA and 27.42 min in MIAB(p = 0.005). BMI and its effect has dose-dependent pattern.

Disclosure of Interest: All authors have declared no conﬂicts of interest.

P1233 THE EFFECT OF OBESITY ON EARLY GASTRIC CANCER IN PATIENTS UNDERGOING ENDOSCOPIC TREATMENT

Introduction: Previous studies have shown that non-cardiac gastric cancer had no associations with the obesity even if cardiac or gastroesophageal junctional cancer was related with the obesity. These studies have included high portion of advanced gastric cancer. Patients with most advanced cancer already experienced weight loss.

Aims & Methods: We evaluated the effect of body mass index (BMI) on early gastric cancer in patients undergoing endoscopic treatment for early gastric cancer. A total of 748 patients with early gastric cancer undergoing endoscopic treatment (endoscopic submucosal dissection) including age and sex matched healthy controls consist of this case-control study. Body mass index was classified into underweight (BMI < 18.5), normal (BMI 18.5–23), overweight (BMI 23–25), and obesity (BMI ≥25) by Asian-Paciﬁc guideline. Adjusted analysis using odds ratio (OR) and 95% conﬁdence interval (CI) was performed to evaluate the eﬀect of BMI on early gastric cancer.

Results: The mean age was 57 years and male sex was 60% (n = 447). BMI was higher in gastric cancer compared to healthy control (24 vs 23, P < 0.001). The OR of gastric cancer was increased according to the BMI increase; 1.57 (95% CI, 0.89–2.79, P = 0.12) in normal BMI, 1.88 (95% CI, 1.06–3.35, P = 0.03) in overweight, and 2.28 (95% CI, 1.29–4.06, P = 0.005) in obese persons comparing to underweight (BMI < 18.5).

Conclusion: The early gastric cancer was strongly associated with the increased BMI and its eﬀect has dose-dependent pattern.

Disclosure of Interest: All authors have declared no conﬂicts of interest.

P1234 COMPARATIVE STUDY OF THE ENDOSCOPIC ULTRASONOGRAPHY-GUIDED FINE-NEEDLE ASPIRATION VS MUCOSAL-INCISION ASSISTED BIOPSY FOR THE HISTOLOGICAL DIAGNOSIS OF GASTROINTESTINAL SUBEPITHELIAL TUMORS

T. Osoegawa1, N. Harada1, E. Ibara2, Y. Iiboshi1, Y. Sumida1, M. Nakamuta1, Y. Ogawa1

3Medical And Bioregulatory Science, Kyushu University, Fukuoka/Japan

Contact E-mail Address: t.osoegawa@gmail.com

Introduction: Gastrointestinal subepithelial tumors include potentially malignant tumors. When considering the diagnostic yield for subepithelial tumors, it is important to evaluate whether the samples obtained are adequate for histological analysis, as immunohistological analysis is indispensable for a definitive diagnosis. However, it may be difficult to make a correct histological diagnosis with only the endoscopic ultrasonography-guided ﬁne-needle aspiration (EUS-FNA). Therefore, there has been an interest in exploring an alternative modality for tissue sampling as mucosal-incision assisted biopsy (MIAB) based on the endoscopic submucosal dissection.

Aims & Methods: The aim of this study was to compare the usefulness of EUS-FNA and MIAB in the histological diagnosis of gastrointestinal subepithelial tumors (SET). We performed the retrospective study comparing 37 patients who underwent either EUS-FNA (n = 18) or MIAB (n = 19). Diagnostic yield and feasibility and safety of these techniques were compared.

Results: The location of the SET was esophagus (n = 6), stomach (n = 29), and duodenum (n = 2). The histological diagnosis were gastrointestinal stromal tumors (n = 10), leiomyoma (n = 17), aberrant pancreas (n = 3), poorly-differentiated adenocarcinoma (n = 2), metastatic carcinoma (renal cell carcinoma, n = 1), and no-diagnosis (n = 4). There were no signiﬁcant differences in the clinical characteristics- including sex and age- of the patients in the EUS-FNA and MIAB groups. In EUS-FNA, we compared the morphological ﬁndings of the SET by EUS were as follows. The mean diameter of tumor was 29.16 ± 15.6/17.77 ± 7.16 mm (p = 0.0034). The ratio of intraluminal growth was 55.6% / 94.7% (p = 0.0078). The mean procedure time was 40.89 ± 10.79 min in EUS-FNA and 55.15 ± 27.42 min in MIAB (p = 0.0234). Helicobacter pylori were present in 27.42% in MIAB (p = 0.005).

Conclusion: The mean procedure time was significantly longer in MIAB than in EUS-FNA. However, the mean diameter of the tumor was signiﬁcantly smaller in MIAB than in EUS-FNA the higher diagnostic yield in MIAB than in EUS-FNA was borderline signiﬁcant.

Disclosure of Interest: All authors have declared no conﬂicts of interest.

Introduction: In 2012 the reported incidence of gastric cancer in both sexes was 153.3/100,000 but the early detection strictly related to a better survival. Parma area is considered at medium-low incidence of gastric cancer. For early diagnosis, the detection of a precancerous condition like atrophic gastritis seems crucial, but the majority of such patient is asymptomatic. Here we present molecular analysis of non-invasive diagnostic methods like serology, magnifying endoscopy with narrow-band imaging. We also introduce the Chinese TCGA study.

Aims & Methods: Six years (from July 2010 to July 2016) were considered in search for diagnosis of gastric cancer as reported in the archives of the Pathology Department of Parma University. Overall, 816 cases of gastric cancer were found but we chose to consider only the surgically removed cases, therefore the available sample is based on 584 cases. For every cases we classified the cancer in early, following the Kodama classification, and advanced. The presence of atrophic gastritis nearby the neoplasia was assessed according to OLGa classification. In both early and advanced cancer the node status was investigated.

Results: Overall, 584 cases of gastric cancer was detected in the six years considered interval (M = 318, F = 223, mean age 78ys, range 36-105ys). The diagnosis of early gastric cancer was made in 44/584 (7.53%) (M = 24, F = 20 mean age 75.68ys, range 47-92ys). A diagnosis of advanced gastric cancer was established in 540 pts (M = 318, F = 222, mean age 78.20ys, range 36-105ys). The picture of chronic atrophic gastritis was found in more than 95% of the cases, both in early and advanced cases. The node status was also recorded. Early cancers showed a 25% of node metastasis compared with 84.65% in advanced ones. As regards the number of involved nodes, in early presentation of neoplasia we found 98% of pN1 staging whereas in advanced the pN1 cases were only 9.1%.

Conclusion: Cancer diagnosis is still considered as an infrequent and this could account for the high mortality rate for the gastric neoplasia. The search for precancerous condition like chronic atrophic gastritis is therefore mandatory.

Introduction: Promoter hypermethylation plays a vital role in cancer development through transcriptional silencing of tumour suppressor genes. Using Infinium Human Methylation 450 BeadChip (450K) array, we first identified calcium binding protein 39-like (CAB39L) to be preferentially methylated in gastric cancer (GC) and it may function as a potential tumour suppressor gene.

Aims & Methods: In this study, we aim to investigate the biological function, molecular mechanism and clinical implications of CAB39L in GC. Clinical relevance was validated by bisulfite genomic sequencing (BGS), western blot and immunohistochemistry (IHC). In vitro functional assays were carried out by cell viability, colony formation, apoptosis, cell cycle, cell invasion and migration assays in GC cell lines. In vivo tumorigenesis was evaluated in an orthotopic nude mouse model. Pathway analysis was performed using RNAseq and Phosphokinase Antibody Array. The interaction of CAB39L with its protein partners was determined by co-immunoprecipitation.

Results: CAB39L mRNA was down-regulated in 13 out of 14 GC cell lines. Silencing of CAB39L was associated with promoter hypermethylation, and demethylation 5'-treatment using Azadeoxycytidine (5-Aza) restored the expression of CAB39L. In human GC, CAB39L mRNA and protein level (p < 0.0001)
were significantly decreased in GC tissues comparing to adjacent normal tissues both in Chinese cohort (n=48 pairs) and TCGA cohort (n=450). CAB39L hypermethylation was correlated with poor overall survival in Chinese cohort (n=87, p<0.005) and validated in TCGA cohort (n=354, p<0.005), which suggested that CAB39L might function as a tumour suppressor. The functional importance of CAB39L was then experimentally examined. Ectopic expression of CAB39L in three GC cell lines (AGS, BGC823, MKN45) suppressed cell proliferation in vitro (P<0.01) and colony formation assays (p<0.0001). CAB39L induced apoptosis and G1 cell cycle arrest in GC cells, concomitant with the enhanced expression of cleaved caspase-8, caspase-3, p21 and decreased cyclin D3 expression. Cell migration and invasion abilities were inhibited by CAB39L in wound healing and gel invasion assays, respectively. Conversely, CAB39L knockdown in MKN28 demonstrated opposite effects. Orthotopic mouse model also showed inhibited tumorigenicity with CAB39L-overexpressing BGC823 cells. Mechanistically, RNAseq and gene set enrichment analysis (GSEA) revealed that AMPK and ERBB2/ERBB4 signaling were involved in the tumour suppressive role of CAB39L in GC. Consistent with our RNAseq data, the ERRB2 Antibody Array identified AMPK as the top activated kinase; whilst ERK1/2 was the most strongly down-regulated in CAB39L over-expressing GC cells, suggesting that CAB39L up-regulates AMPK concomitant with down-regulation of ERBB2/ERBB4 signaling. Moreover, co-immunoprecipitation experiment identified interaction between CAB39L and LKB1, a bona fide tumour suppressor that functions to activate AMPK to suppress tumorigenesis. Western blot confirmed activation of LKB1-AMPK/β cascade in GC cells expressing CAB39L, while the opposite effect was observed in CAB39L silenced MKN28 cells. Administration of an AMPK activator, AICAR, inhibited growth of control cells but not CAB39L-expressing (thus AMPK activated) cells, suggesting that AMPK activation by CAB39L contributes to tumour suppression. Consistent with novel tumour suppressor gene silenced by promoter methylation in GC, CAB39L inhibits gastric tumorigenesis via LKB1-mediated activation of AMPK/β. CAB39L methylation may serve as an independent prognostic biomarker for GC patients.

PKNOX2 was silenced in 15 out of 18 GC cell lines through promoter reporter assay. PKNOX2 expression was positively correlated with IGFBP5 expression in gastric cancer tissues and the corresponding adjacent non-tumor tissues, as well as its correlation with clinical pathological parameters. In addition, we also verified the results by utilizing bioinformatics analysis. We studied the effects of Hoxc10 on gastric cancer cell cycle control and proliferation through combination of in vitro cell function tests and in vivo nude mouse model. Then, we screened Hoxc10 potential downstream targets by using cDNA microarray and verified the results by RT-qPCR. We studied the effects of Hoxc10 on cell proliferation and its downstream cell cycle-related proteins and validated the correlation of Hoxc10 and p21 expression in vitro and in vivo. By application of dual-luciferase reporter assay and chromatin immunoprecipitation, we explored the role of Hoxc10 in p21 transcription repression.

Results: Hoxc10 mRNA expression were significantly higher in fresh frozen gastric cancer tissues than in matching adjacent non-tumor tissues (91.43%, 64/70, P<0.01). The expression of Hoxc10 was related to the depth of tumor invasion, lymph node metastasis and tumor stage (P<0.01). Using tissue microarray, Hoxc10 protein expression was also found widespread in gastric cancer tissues (91.3%, 137/150, P<0.01) and was closely correlated with patient survival (HR=2.8; 95% CI 2.0–7.2). Besides, in TCGA database of gastric cancer, Hoxc10 was upregulated by 122 times (n=33, P<0.01), and in Kaplan-Meier Plotter database, Hoxc10 expression was associated with poor prognosis of patients with gastric cancer (HR=1.8; 95% CI 1.5–2.16). Hoxc10 overexpressing gastric cancer cells accelerated G1-S phase transformation and proliferation, whereas Hoxc10 knockdown induced cell cycle arrest in G1 phase and repressed cell proliferation. Moreover, over-expression of Hoxc10 accelerated gastric tumor growth in a mouse xenograft model, while knocking-down of Hoxc10 inhibited gastric tumor growth. cDNA microarray showed that Hoxc10 regulates multiple downstream genes including p21, a potent cell cycle regulator. A significantly negative correlation between Hoxc10 and p21 were detected in gastric cancer cells and tissues. Knocking-down of Hoxc10 also altered the expression of some p21 downstream cell cycle related proteins, such as pRB, CDK2 and CDK4. Furthermore, we found that Hoxc10 binds to the p21 promoter directly and could inhibit p21 transcription.

Conclusion: Taken together, our results suggest that Hoxc10 functions as a tumor promoting gene in gastric cancer and may be an important regulator of cell cycle control and cancer cell proliferation. Moreover, Hoxc10 may serve as a useful biomarker for predicting patient prognosis.

Introduction: The relationship between Helicobacter pylori (H.p.) eradication and atrophic changes is debated. Although some studies report a partial restoration of GC serum pepsinogen levels after eradication, it is not clear whether this finding reflects gastric mucosal healing. -Cysteine, reducing acetatedehyde production after food intake, has been proposed for prevention of gastric carcinogenesis in patients with chronic atrophic gastritis (CAG). To assess modifications in gastric function after L-Cysteine administration in CAG by means of PGI and gastrin 17 (G17) serum levels

Aims & Methods: 62 patients (18 men, mean age 47.2 yrs), with histological diagnosis of moderate to severe chronic, atrophic, body gastritis (according to the updated Sydney system) and PGI serum levels < 25 nmol/L, were randomly selected for a gastroenterological endoscopy with gastric biopsy samplings and PGI and G17 measurement by means of Gastropanel®. 22 out of 62 patients had autoimmune gastritis while 40 of them reported previous H.p. infection. All patients, Helicobacter pylori (H.p.) negative at baseline, were treated with L-Cysteine (100 mg three times daily), up to now 24 out of 26 reached 36 months-treatment. Serum PGI and G17 were measured at baseline and after 3, 6, 12, 24, 36 months after starting therapy.

Results: The PGI serum increased level after the starting of L-Cysteine administration, as it follows: PGI mean value at baseline was 8.42 μg/L, but after 3 months therapy was 10.58, after 6 months 11.65, after 12 months 12.19, after 24 months 13.88, and after 36 months was 14.21 (p < 0.0001). The G17 serum level resulted gradually decreased over the 36 months therapy, as it follows: G17 mean value was 51.33 pmol/l at baseline, 43.13 after 3 months therapy, 38.66 after 6 months, 28. 34 after 24 months and 26.03 after 36 months (p < 0.0001).

Conclusion: After L-Cysteine administration, patients with chronic, atrophic, body gastritis showed long-lasting improvements of physiological gastric function, reflected by a significant increase of PGI levels and a parallel decrease of G17 serum levels over a 36 months follow-up period.

P1244 WHAT IS THE YIELD OF ROUTINE D2 BIOPSIES IN THOSE PRESENTING WITH WEIGHT LOSS AT GASTROSCOPY?
M. Yalchin, S. Zonoozi, M. Hussein, N. Jayasooriya, K. Besherdas
Gastroenterology, Barnet Hospital, DJ/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Coeliac disease is a common cause of malabsorption in Western countries. The gold standard method of diagnosing coeliac disease is by way of duodenal biopsy. Weight loss is a symptom of malabsorption. Patients referred for upper gastrointestinal endoscopy with symptoms of weight loss commonly undergo duodenal biopsy to assess for presence of coeliac disease. We hypothesise that those patients with weight loss and who routinely have duodenal biopsies very rarely have coeliac disease unless there are other pointers towards malabsorption.

Aims & Methods: A single-centre, retrospective analysis of consecutive patients undergoing upper gastrointestinal endoscopy for the investigation of weight loss was undertaken within a large associate teaching hospital within North London from 2005–2016. Of these patients, we reviewed those that had duodenal (D2) biopsies and the results. If they proved abnormal, we looked back for additional markers of malabsorption, clinically and biochemically.

Results: 142 consecutive patients, 65 were Male, 77 were female, underwent OGD for weight loss. Out of this cohort, 62% (n = 88) had a duodenal biopsy. 89% (n = 78) of these had a normal biopsy. 11% (n = 10) had an abnormal biopsy.

Conclusion: Our results demonstrate that AR directly regulates CCRK expression in GC. AR and CCRK gene may act as a potential oncogene in gastrocarcinogenesis by playing an important role in promoting of cell proliferation, migration and invasion, which may partially explain the higher prevalence of gastric cancer among males.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
and 6 of these patients had coelac, whilst 4 had other pathology such as granuloma or duodenitis.

For all the patients who had abnormal D2 biopsies, they had other clinical markers of malabsorption, such as abdominal pain and diarrhoea, or biochemical indices such as anaemia or elevated TTG antibodies.

Conclusions: We conclude that A. fungorum reduces the yield of routine duodenal biopsies in patients endoscoped for the sole indication of weight loss is poor. In patients with weight loss in whom coeliac disease is identified on biopsy is always associated with additional symptoms or abnormalities in blood indices. We conclude that there is no need to take biopsies of the duodenum on a routine basis for weight loss alone unless there are other signs of malabsorption. This will save time (both from taking the biopsy and sampling in the lab), lower the cost (forces and pot) and improve the safety (potential perforation and bleeding risk) of the procedure.

Aims & Methods: In this study, we characterized the salivary microbiota in patients with H. pylori-associated gastritis and the potential changes of salivary microbiota after receiving HP eradication. We enrolled subjects who were scheduled for diagnostic upper GI endoscopy. We enrolled patients with peptic ulcer or cancer found on endoscopy, who have received prior HP eradication therapy, and who have recent exposure to antibiotics or acid suppressive therapies. Unstimulated saliva samples were obtained from subjects during fasting state prior to endoscopy. Endoscopically, gastric and salivary HP biopsies were obtained for determination of HP statuses by rapid urease test and histology. Another gastric biopsy was obtained for characterization of gastric microbiota. Serial salivary samples were obtained from HP-infected subjects 8-week after completing HP eradication therapy. Bacterial DNA was extracted for 16s rDNA sequencing by using the MiSeq Platform (Illumina). OTU clustering was performed and taxonomy assigned to the Greengene and HOMD database. Alpha and beta diversity were calculated. Linear Discriminant Analysis Effect Size (LEfSe) was used to identify differentially expressed bacterial DNA in different groups.

Results: We enrolled 16 subjects with confirmed HP gastritis and 14 HP-negative subjects. Baseline salivary samples of all subjects were found to have significantly higher microbial diversity than corresponding gastric samples. The predominant microbial family identified in the stomach is Helicobacteraceae (55.2%) whereas Helicobacteraceae constitutes only 0.1% of salivary microbiota. In contrast, the predominant families in salivary microbiota are Prevotellaceae (23.9%) and Neisseriaceae (20.3%). When compared to HP-negative subjects, salivary microbiota in HP-positive patients showed a significant increase in the Bacteroidetes and Spirochaetaeae, and a decrease in Flavobacteriaceae families. HP eradication therapy resulted in a significant reduction in the relative abundance of family Spirochaetaceae and Flavobacteriaceae.

Conclusion: There was a significant difference in the microbial diversity and compositions between gastric and salivary microbiota in HP-infected subjects, with Helicobacteraceae dominating the gastric microbiota. HP-infected subjects have a distinctive microbiota in the saliva which is reversed by HP eradication therapy. The significance of these microbial alterations in the saliva of HP-infected subjects and its correlation with gastric diseases deserves further investigation.

P1251 THE INVESTIGATION OF MIR-155, MIR-21, MIR-146A AND MIR-223 EXPRESSIONS IN HELICOBACTER PYLORI POSITIVE AND NEGATIVE INDIVIDUALS

N. Uyar Alpaslan1, E. Ucbilek2, I. Ö. Barlas1, O. Sezgin2, S. Yara

Introduction: This study was conducted to determine the differential expression patterns of microRNAs, non-coding RNAs that control gene expression mainly through translational repression, in gastric mucosa of Helicobacter pylori (H. pylori) positive patients. Several miRNA have been associated with promoting the inflammatory response initiated by the H. pylori infection, increasing the malignant progression of the gastric epithelium, and enhancing the invasiveness and migratory capacity of cancer cells. Using serum specimens, expression patterns of hsa-miR-155, hsa-miR-21, hsa-miR-146A and hsa-miR-223 were determined by Real-Time Polymerase Chain Reaction (Real-Time PCR).

Aims & Methods: Patients who underwent upper gastrointestinal endoscopy, in Mersin University Faculty of Medicine, Department of Gastroenterology and diagnosed H. pylori positive and negative were recruited. H. pylori status was assessed by the rapid urease test. Serum specimens of patients, were taken for the determination of hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-miR-223 expressions in serum specimens and nuclear factor-κB (NF-κB) and interleukin-4 (IL-4) level anti-inflammatory interleukin-4 that can be an additional factor of development of an inflammation during H. pylori infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: The incidence and eradication rate of gastric cancer are high in Japan. The International Agency for Research of Cancer (IARC) reported that 80% of gastric cancer is caused by Helicobacter pylori (H. pylori) infection and that the incidence of gastric cancer can be reduced by 30%-40% through H. pylori eradication therapy. The eradication rate of vonoprazan for chronic H. pylori infection was approved for national health insurance in February 2013 in Japan. However, the success rate of H. pylori eradication by conventional primary triple therapy has decreased by resistance to clarithromycin. Vonoprazan, which is a potassium ion-competitive acid blocker (P-CAB), became available in Japan in February 2015, before its release on the world market. There have been some reports on the usefulness of vonoprazan for H. pylori eradication.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Clarithromycin (CLA)-containing quadruple therapy, i.e. concomitant therapy (CT), and bismuth-containing quadruple therapy (BQT) have been suggested as regimens for eradication of H. pylori infection. Both treatments are reported to have an eradication rate higher than 90%. International guidelines recommend that choosing one regimen vs the other should be based on the regional prevalence of antimicrobial resistance, knowledge of patient’s previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. However, this therapeutic approach has never been tested systematically.

Aims & Methods: The primary endpoint of this study was to evaluate the eradication rate in H. pylori-infected subjects naïve to treatment in an area of high (10%-15%) CLA resistance based on knowledge of patients’ previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. Secondary endpoint was to assess any difference between CT and BQT in terms of efficacy, safety and compliance. Because in Italy bismuth compounds are not available, BQT was by using the new third-in-one pill (TiOP).

Results: The primary endpoint of this study was to evaluate the eradication rate in H. pylori-infected subjects naïve to treatment in an area of high (10%-15%) CLA resistance based on knowledge of patients’ previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. Introduction: Potent acid inhibition with acid inhibitory drugs is crucial to the eradication regimen for Helicobacter pylori infection. However, CYP3A5 variant is known to possess a genetic polymorphism (CYP3A5*1 vs. CYP3A5*3) with the potential to influence H. pylori eradication in 2nd line treatment. On the other hand, eradication rates have been decreasing because of resistance to the clarithromycin (CAM). It is known that most antibiotics are not effective under strong acid secretion. So in order to improve the eradication rate, gastric acid must be reduced more rapidly and strongly. Vonoprazan(VPZ) is a new potassium competitive acid blocker and the usefulness is expected in Japan.

Aims & Methods: We investigated the influence of CYP3A5*3 in Japan and wished genotypes and susceptibility to antimicrobial agents for outcome of vonoprazan-contained eradication regimen for 7 days in 105 Japanese: (1) with amoxicillin 750 mg and clarithromycin 20 mg twice daily (bid) as the first-line treatment (n=76); (2) with amoxicillin 750 mg and metronidazole 250 mg bid as second-line (n=29).

Results: Results: The primary endpoint of this study was to evaluate the eradication rate in H. pylori-infected subjects naïve to treatment in an area of high (10%-15%) CLA resistance based on knowledge of patients’ previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. However, this therapeutic approach has never been tested systematically.

Aims & Methods: The primary endpoint of this study was to evaluate the eradication rate in H. pylori-infected subjects naïve to treatment in an area of high (10%-15%) CLA resistance based on knowledge of patients’ previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. Secondary endpoint was to assess any difference between CT and BQT in terms of efficacy, safety and compliance. Because in Italy bismuth compounds are not available, BQT was by using the new third-in-one pill (TiOP).

Results: The primary endpoint of this study was to evaluate the eradication rate in H. pylori-infected subjects naïve to treatment in an area of high (10%-15%) CLA resistance based on knowledge of patients’ previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. Secondary endpoint was to assess any difference between CT and BQT in terms of efficacy, safety and compliance. Because in Italy bismuth compounds are not available, BQT was by using the new third-in-one pill (TiOP).

Conclusion: Vonoprazan is considered to be useful for H. pylori eradication instead of a PPI in first line treatment.

P1256 COMPARISON OF HELICOBACTER PYLORI ERADICATION RATES: VONOPRAZAN VS. PROTON PUMP INHIBITOR

N. Kozawa1, T. Mochida1, A. Igarashi1, C. Kamitsuja1, T. Tsujihi1, M. Ike2, K. Yasuda1, M. Kanihoro1, H. Ikeyamhi1, Y. Fukami1, K. Yoshino1, S. Sakita1

Aims & Methods: Our aim was to investigate the efficacy of the VPZ-based eradication therapy of H. pylori in Japan. The number of first-line regimen of VPZ patients was 109, and the eradication was achieved in 97 patients (87%). RPZ patients were 308, and the eradication was achieved in 228 patients (74%). In the second-line regimen, the eradication was achieved in 377 patients (68%), and the eradication was achieved in 228 patients (68%). In the second-line regimen, the eradication was achieved in 97 patients (87%). RPZ patients were 308, and the eradication was achieved in 228 patients (74%). In the second-line regimen, the eradication was achieved in 377 patients (68%), and the eradication was achieved in 228 patients (68%).

Results: Results: The primary endpoint of this study was to evaluate the eradication rate in H. pylori-infected subjects naïve to treatment in an area of high (10%-15%) CLA resistance based on knowledge of patients’ previous antimicrobial exposure or allergy to amoxicillin, and patient’s wish. such as erosion and diarrhea were reported in 6.6% (9/136) of patients in VPZ, in 7.8% (8/102) in VPZ and in 6.1% (28/456) in LPZ.

Conclusion: The first-line regimen with VPZ was superior to conventional PPI regimen, and was a result not to be inferior in the safety either.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aim: To describe and analyze the prevalence of eradication of H. pylori in patients infected with Helicobacter pylori and treated with a probiotic-based quadruple therapy regimen.

Methods: The study included a cohort of 410 patients infected with H. pylori who were treated with probiotics. The study included patients who had previously been diagnosed with H. pylori infection using breath test or biopsy. The inclusion criteria were: patients who had previously been treated for H. pylori infection and failed eradication therapy. The patients were randomized to receive either probiotics alone or the quadruple therapy regimen. The end-point was to assess the proportion of patients who achieved successful eradication of H. pylori. The results were analyzed using chi-square test and Fisher’s exact test. The safety of the regimen was assessed by monitoring for adverse events.

Results: Of the 410 patients included in the study, 205 were randomized to receive probiotics alone and 205 were randomized to receive the quadruple therapy regimen. The eradication rate of H. pylori was significantly higher in the quadruple therapy regimen (93.4%) compared to probiotics alone (86.8%, P = 0.02). The most common adverse events reported in both groups were gastrointestinal symptoms, such as diarrhea and abdominal pain.

Conclusion: Probiotics alone may have a beneficial effect on the eradication of H. pylori, suggesting a presumable direct effect. However, they cannot be indicated as a therapeutic regimen for the low eradication rate. Further studies are needed to confirm these findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Methods of analysis and inclusion criteria were based on the PRISMA recommendations. Relevant publications were identified by a research in PubMed, MEDLINE, Science Direct and EMBASE. The end-point was to estimate the mean eradication rate and variations of delta value at urea breath test across all studies and, overall, with a pooled data analysis. The data have been reported as proportions, percentages, and 95% confidence intervals (CI) were calculated. For continuous variables, we calculated the weighted mean difference. Odd ratios (OR) were calculated, where available, based on the Mantel-Haenszel method. Data were entered into the RevMan 5.3 software.

Results: Two studies (both randomized clinical trials and open label pilot studies) were selected. In one study patients with peptic ulcers were selected, while in the remaining 9 only dyspeptic patients were recruited. Probiotics eradicated H. pylori in 50 out of 391 cases. The mean eradication rate was 14%, with a 95% CI of 2.25% (p = 0.02). Most of studies investigated a probiotic formulation based on a single lactobacilli strain. Lactobacilli eradicated the bacterium in 30 out of 235 patients, with a mean weighted rate of 16% (95% CI 1–31%). Multistrain combinations were effective in 14 out of 105 patients, with a pooled eradication rate of 14% (95% CI 16–45%). In the comparison probiotics versus placebo, we found an OR = 9.65 in favor of probiotics, with a 95% CI of 1.97–47.36 (p = 0.005). Finally, probiotics induced a mean reduction in delta values of 8.61% (95% 3.88–11.34, p < 0.0001).

Conclusion: Probiotics alone show a minimal effect on the eradication of H. pylori, thus suggesting a presumable direct effect. However, they cannot be indicated as a therapeutic regimen for the low eradication rate.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims and Methods: We aimed to determine eradication rate, the effectiveness and advantage of rebamipide in triple eradication therapy of H. pylori infection. Subjects comprised patients undergoing eradication therapy for H. pylori infection in our clinics. Patients with a history of eradication therapy, gastrectomy, or allergy to medications in triple therapy were excluded. Written informed consent was obtained from the patients. The rates of severe adverse effects of therapy were 7.1% and 2.9% in the mentioned groups, respectively.

Conclusion: Both Clarithromycin-containing triple therapy and Levofloxacin-containing triple regimen do not seem to be suitable options for first-line H. pylori eradication in Iran. We suggest using Charithromycin in quadruple regimens such as hybrid or concomitant therapies and reserve Levofloxacin to be used in second-line eradication regimens, as it is recommended by Maastricht V Consensus Report.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Chemotherapy-induced mucositis is a common complication during anticancer treatment. Epigallocatechin-3-gallate (EGCG), derived from green tea, has been shown to have antioxidant effects and immunomodulatory activities. However, studies on EGCG for chemotherapy-induced mucositis have been scarce.

Aims & Methods: In this study, we aimed to prove the protective effect of EGCG in murine chemotherapy-induced mucositis model. Twenty-four 8-wk-old male C57BL/6 mice were randomized to 4 groups: control, EGCG, 5-Flurouracil (5-FU), EGCG plus 5-FU. Mucositis was induced by intraperitoneal injection of 5-FU (400 mg/kg). EGCG (50 mg/kg) was administered orally for 5 days from the day before administration of 5-FU. After 6 days of 5-FU injection, the mice were sacrificed and intestinal tissue was obtained. WBC count was performed with whole blood from Inferior vena cava of mice. The end points were villus height, villus/crypt ratio, histologic characteristics, and mRNA expression of tumor necrosis factor (TNF-α), and interleukin (IL)-6.

Results: In 5-FU group, neutropenia was confirmed by laboratory test (5-FU, 0.650 K/µL, Control, 5.317 K/µL), indicating significantly decreased 5-FU effect. Histologic findings showed that crypt dilatation, villus stunting, and villus atrophy were reduced in EGCG plus 5-FU group than in 5-FU group (Figure 1). Quantitative analysis of villus height (EGCG group, 352 µm; 5-FU group, 352 µm; 5-FU plus 5-FU group, 319 µm) and villus/crypt ratio (EGCG plus 5-FU, 3.26; 5-FU, 2.31) in EGCG plus 5-FU group, compared with 5-FU treated group, were significantly higher. mRNA expression of TNF-α was significantly lower in EGCG plus 5-FU group compared with 5-FU group (P < 0.05; Figure 2). Figure 1. Effects of EGCG administration on chemotherapy-induced mucositis in mice jejunum (A) Control (B) 5-Flourouricil (5-FU) group with significant villus atrophy and crypt dilatation (c) EGCG group (d) EGCG plus 5-FU group with mild villi destruction and less crypt dilatation. Figure 2. mRNA expression of IL-6 after administration of 5-FU in EGCG plus 5-FU group showed significantly lower 2’dAct/5-FU only group. (** P < 0.05)

Conclusion: EGCG derived from green tea reduced 5-FU induced intestinal mucositis, suggesting a possibility for novel treatment of chemotherapy-induced mucositis.

Introduction: Proton pump inhibitors (PPIs) have become one of the most commonly prescribed medicine for their strong effects of suppressing gastric acid and high curative effects for acid related diseases. On the other hand, their side effects have been attracting more attention. One of them is the increased incidence of infectious intestinal diseases. Those are mostly reported by clinical observations, and the exact mechanism has not been clarified. To investigate whether PPIs can increase the susceptibility to peroral enteropathogenic bacterial infection, we focused on C. rodentium (C. rodentium), a well-known and astonishingly associated pathogen, which is used for the model of human enterohemorrhagic Escherichia coli (EHEC) and enteropathogenic Escherichia coli (EPEC) infection: the major causes of food poisoning.

Aims & Methods: To investigate whether LAZ can influence the steady-state intestinal environment, C57BL/6J mice were divided into two groups, and 8 mg/kg-day of lansoprazole (LAZ group) or saline (control group) were administrated intraperitoneally for two weeks. The intact contents and feces were collected before and after LAZ administration. Genomic DNA of the gut microbiota was analyzed by 16S ribosomal RNA (16sRNA) gene sequencing, and the metabolites were analyzed by a CE-TOFMS platform. To examine the changes of immune cell distribution by LAZ, hematopoietic cells in the lamina propria were analyzed by flow cytometry. The changes of gene expressions of the ileum using a comprehensive analyzing tool, RTACT: a retrospective analysis in 175 patients. Bone Marrow Transplant 2012; 47: 430–438.

Results: After the administration of 5-FU, the body weight, food intake, water consumption, and fecal volume decreased; thus, a systemic influence was observed. The length and villus height of the intestinal tract decreased because of the administration of 5-FU, and mucous production, cell infiltration, and immune response of the intestinal tract were decreased. In addition, we confirmed the protein expressions among the small intestines using anti-LAT antibodies.

Conclusion: After the administration of 5-FU, the body weight, food intake, water consumption, and fecal volume decreased; thus, a systemic influence was observed. The length and villus height of the intestinal tract decreased because of the administration of 5-FU, and mucosal damage with histological change was observed. The number of PAS-positive cells decreased in the small intestinal mucosa, and it was assumed that the defensive function of the epithelial cells had decreased. In addition, an increase in the mRNA expression of IL–1β, IL–6, and TNF-α in the Peyer’s patch along with an increase in the cell infiltration after the administration of 5-FU significantly enhanced the immune response associated with the inflammatory cytokine production. Furthermore, on investigating the mRNA and protein expressions of LAT1 and LAT2 in the tissues of the small intestines, we observed that LAT1 expression significantly increased and LAT2 expression decreased after the administration of 5-FU.

Introduction: Because recent studies have demonstrated that amino acid transporters, which transport amino acids into cells, are correlated to various cancers and are major transporters that supply essential amino acids to tumor cells, these transporters are considered as novel biological tumor markers. On the other hand, because anticancer agents are frequently used clinically, the number of patients suffering from anticancer agent-induced intestinal mucosal injuries is increasing; hence, it is important to take appropriate measures for reducing these side effects. Because the L-type amino acid transporter (LAT) transports a wide range of nonselective amino acids, including essential amino acids, it is considered to be a gastrointestinal transporter that is important for nutrient absorption. Furthermore, the involvement of other amino acid transporters in malignancies has been reported by previous studies.

Aims & Methods: We aimed to clarify the pathophysiological role of an amino acid transporter in gastrointestinal tract inflammation caused by an antitumor agent in this study. The antitumor agent fluorouracil (5-FU) was orally administered to mice. The severity of mucositis was assessed based on the length, villus height, mucus production, cell infiltration, and immune response of the intestinal tract. We measured the mRNA expressions of LATs in the tissues of the small intestines. In addition, we compared the protein expressions among the small intestines using anti-LAT antibodies.

Results: After the administration of 5-FU, the body weight, food intake, water consumption, and fecal volume decreased; thus, a systemic influence was observed. The length and villus height of the intestinal tract decreased because of the administration of 5-FU, and mucosal damage with histological change was observed. The number of PAS-positive cells decreased in the small intestinal mucosa, and it was assumed that the defensive function of the epithelial cells had decreased. In addition, an increase in the mRNA expression of IL–1β, IL–6, and TNF-α in the Peyer’s patch along with an increase in the cell infiltration after the administration of 5-FU significantly enhanced the immune response associated with the inflammatory cytokine production. Furthermore, on investigating the mRNA and protein expressions of LAT1 and LAT2 in the tissues of the small intestines, we observed that LAT1 expression significantly increased and LAT2 expression decreased after the administration of 5-FU.

**Introduction:** Acetyl salicylic acid (ASA) has been used for the secondary prevention of cardiovascular diseases. Especially, the enteric coated ASA is widely used to prevent ASA-induced gastric mucosal injury. Recent technology such as video capsule endoscopy and balloon endoscopy enabled us to look inside the small intestine in more detail. Consequently, not a few cases of ASA-induced small intestinal mucosal injuries have been reported. However, the effective prophylaxis and treatment is not clear yet. Previously, we reported direct detrimental effect of ASA on small intestinal epithelial cells using an in vitro model [1]. However, there are the thick mucus layer between intestinal lumen and epithelial cells. The mucus has been reported to prevent foreign objects such as bacteria, medicine and food from epithelial cells.

**Aims & Methods:** This study was conducted to clarify the role of mucus on ASA-induced small intestinal mucosal injury using a rat model. Male Sprague-Dawley rats, 9 weeks old was used. These rats were divided into four groups; group 1: sham (carboxy methyl cellulose: CMC alone), group 2: polysorbate-80 (P80) alone, group 3: ASA alone, and group 4: P80 plus ASA. CMC and/or 50–200 mg/kg ASA was injected to the proximal duodenum of rats. P80, an emulsifier, which has been reported to reduce mucous thickness [2], was administered via drinking water for 2 weeks before ASA treatment. Indeed, P80 also reduced the thickness of mucous layer in our analyses. One hour after ASA treatment, blue dye was injected into a vein of rats to visualize small intestinal lesions. Ninety minutes after ASA treatment, the entire small intestine was removed for histological assessment. To further investigate the importance of mucus, rebamipide (Reb, 300 mg/kg) or saline were orally administered for one week prior to P80 treatment. Reb is a gastric mucosal-protective drug widely used for the treatment of gastric ulcer, and increases mucus secretion by small intestinal goblet cell.

**Results:** Evans blue method suggested that high-dose ASA (200 mg/kg) induced small intestinal mucosal injury, which was further confirmed by the histological examination. Although lower doses of ASA (50 and 100 mg/kg) did not cause mucosal damage, P80 significantly reduced Evans blue exudate and severe mucosal lesions in jejunum at these concentrations, suggesting the pivotal role of mucus in these phenomena. Moreover, Reb significantly suppressed reducing small intestinal mucus and the exacerbation of ASA-induced mucosal lesions by P80, indicating that mucus is inevitable in the protection of ASA-induced small intestinal mucosal injury.

**Conclusion:** Long-term increasing therapy might be a useful solution for the prevention of ASA-induced small intestinal mucosal injury.

**Introduction:** Intestinal mucosal injury following a course of 5-FU chemotherapy is a severe side-effect of chemotherapy with current deficiency in effective treatments.

**Aims & Methods:** This study investigated three prebiotics, galacto-oligosaccharide (GOS), mannan-oligosaccharide (MOS) and fructo-oligosaccharide (FOS) for their potential to reduce the severity of 5-Fluorouracil (5-FU)-induced intestinal mucositis in rats. Female Dark Agouti rats (n = 8/group) were orally gavaged with either 5% FOS, GOS, MOS or water (controls) for 16 days, and received an intraperitoneal injection of 5-Fluorouracil (5-FU: 150 mg/kg) or saline (controls), on day 13. Rats were housed in metabolic cages for the duration of the study, and metabolic data was recorded daily. Rats were killed on day 16 and visceral organ weights and lengths were analyzed post mortem. Crypt depth, villus height and histological severity scores were quantified in haematoxylin & eosin stained sections. Sucrase and maltoperoxidase (MPO) activity were quantified by biochemical assay. White and red blood cell types were quantified by whole blood analysis. Fecal volatile fatty acids (VFAs), acetic, propionic, isobutyric, butyric, isovaleric and valeric acid were also measured. Statistical analysis was by one-way ANOVA or Kruskal Wallis and Mann Whitney U test, where p < 0.05 was considered statistically significant. Data are expressed as mean ± standard error of the mean.

**Results:** %Bodyweight loss was significantly decreased in all treatment groups following 5-FU injection. Treatment of GOS, MOS or FOS, pre and post 5-FU compared to saline treated controls (p < 0.05). Ileal villus height was significantly higher in GOS treated rats pre 5-FU (284.16 ± 11.95 μm) compared to respective water controls (240.40 ± 8.83 μm; p < 0.05). A small height and crypt depth was significantly decreased in all treatment groups after 5-FU injection (p < 0.05) and prebiotic treatment did not significantly modify this parameter. Similarly, jejunal and ileal sucrase activity was decreased in all groups after 5-FU injection (p < 0.05), correlating with histological measurements. Tissue MPO activity was significantly increased post 5-FU injection, reflecting increased neutrophil activation, and was unchanged by prebiotic treatment. Interestingly, MOS and GOS both lowered %circulating neutrophils pre 5-FU compared to water controls (p < 0.05). Pre 5-FU treatment with GOS significantly increased the fecal VFAs acetic acid (16.76 ± 1.22 mM/L) and propionic acid (4.60 ± 0.99 mM/L) compared to saline treated controls (7.73 ± 0.92 mM/L and 3.05 ± 0.28 mM/L respectively; p < 0.05). MOS and GOS treatment also significantly increased fecal acetic and propionic acid post 5-FU compared to water control (p < 0.05).

**Conclusion:** Our study has found that prebiotics, MOS, GOS and FOS modified some parameters of intestinal health and immune regulation in healthy rats; however, these prebiotics were not protective against 5-FU induced intestinal damage. Furthermore, our findings have demonstrated that prebiotic treatment significantly increases VFA production, suggesting functional changes to the intestinal microbiome. Further studies are needed to investigate prebiotics, both alone and in combination, during the repair phase of intestinal mucositis, and to determine their effect on gut microbial composition.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Food allergy is characterised by a T helper type-2 immune response against a food antigen, manifesting as symptoms including nausea, diarrhoea, vomiting or anaphylactic events. It is estimated that 10% of the Australian population have a food allergy, and common allergens include cow’s milk, shellfish and peanuts. Epidemiological studies have identified antibiotics as a significant risk factor for food allergy in infants.

**Aims & Methods:** We examined how the broad spectrum antibiotic amoxicillin influenced mucosal immune responses to peanut proteins and the development of peanut allergy in mice. Balb/C mice were treated daily with 5 mg/kg amoxicillin or PBS for 5 days (days 0–4). On days 5 and 6 animals received 0.2 mg peanut extract or PBS vehicle by oral gavage. Animals were rechallenged with peanut on day 13 and sacrificed on day 16 and immune responses to peanut challenge in blood and intestinal tissues were assessed by protein, mRNA and histological analysis.

**Results:** The proportion of circulating eosinophils was increased in the blood of mice treated with both antibiotics and peanut. Histological examination revealed an increase in small intestinal eosinophils, predominantly at the villous tips, indicating recruitment to the mucosa. RNA and protein analysis revealed an increase in IL-5 associated with increased Nod-Like Receptor Protein 3 (NLRP3) inflammasome activation.

**Conclusion:** These studies demonstrate that antibiotic treatment prior to food antigen challenge can lead to altered mucosal immune homeostasis, facilitating IL-5-mediated eosinophil recruitment, characteristic of allergic responses. Importantly, we have demonstrated an adjuvant-free model of food sensitisation and small intestinal eosinophilia. These findings contribute to a better understanding of how disruption of mucosal homeostasis by antibiotics contributes to the development of allergic sensitisation and reaction.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1269 THE RELATION OF CHEMOKINE RECEPTOR CXCR3 AND GUT-HOMING MARKERS ON SMALL INTESTINAL LAMINA PROPRIA T-LYMPHOCYTES IN CROHN’S DISEASE PATIENTS

Introduction: Crohn’s disease has been thought to be caused by abnormal immune responses affecting many parts of digestive tract in which Th1 cells and their cytokines are involved. The recruitment and activation of Th1 cells is regulated by interactions of their expression of chemokine receptor CXCR3 and its ligands. There have been many IBD murine models showing the increase of CXCR3 expression and its roles on the disease promotion. However, there are limited evidences in the roles of CXCR3 in human IBD. In fact, a small study in large bowel in a cohort of 10 Crohn’s disease patients showed lower expression of CXCR3 on T lymphocytes, compared to colon cancer patients. In terms of inhibition of T-lymphocyte migration into intestine in IBD patients, anti a4b7 (Vedolizumab) therapy is currently shown to be effective.

Aims & Methods: Our study aimed to assess expression of CXCR3 by different subsets of small intestinal lamina propria T-cells and its association with a4 and b7 integrins (gut-homing (CD) patients and healthy controls). Total of 56 duodenal biopsies were obtained from CD (n = 25), functional dyspepsia (FD) / irritable bowel syndrome (IBS) (n = 24) or iron deficiency patients (n = 17) with ethical approval. Lamina propria (LP) cells were isolated from biopsies using EDTA, collagenase and gravi-fugation centrifugation with Ficoll. Expression of CXCR3, a4, and b7 on isolated T-lymphocytes was examined by flow cytometry. Statistical significance was assessed using T-test or Spearman correlation.

Results: The expression of CXCR3 on CD4 lymphocytes was significantly lower (p < 0.05) compared to 61.6% in control group (FD/IBS deficiency). Although the expression of CXCR3 on CD8 lymphocytes was higher than CD4 lymphocytes, it was not different between CD and other group (75.8% in CD patients vs 82.2% in controls). Similar observation was obtained on the double positive CD4 and CD8 lymphocytes. Interestingly, only expression of CXCR3 on CD4 lymphocytes positively correlated with expression of the gut-homing integrins, a4 and b7.

Conclusion: These observations showed significant expression of CXCR3 across different diseases, with consistently higher expression seen in CD8 lymphocytes compared to CD4 lymphocytes. An unexpected reduction of CXCR3 expression was seen in small intestinal of CD patients, which associated with gut-homing integrins. This result showed CXCR3 expression may play a role in migration of CD4 lymphocytes but not CD8 lymphocytes into duodenum in relation with integrins, a4 and b7. However, CXCR3 expression on CD4 lymphocytes in CD patients’ small intestine may have protective role. This propose further study to clarify.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute Gastroenteritis (AGE) is one of the diseases that most frequently affects paediatric population. Successful treatment in AGE has been shown on the basis of rehydration therapy with different modifications.

Aims & Methods: Our study aimed to assess the methodological quality of clinical practice guidelines (CPG) that recommend their use in the acute gastroenteritis. All the CPGs were obtained from CD (n = 25), functional dyspepsia (FD) / irritable bowel syndrome (IBS) (n = 24) or iron deficiency patients (n = 17) with ethical approval. Lamina propria (LP) cells were isolated from biopsies using EDTA, collagenase and gravi-fugation centrifugation with Ficoll. Expression of CXCR3, a4, and b7 on isolated T-lymphocytes was examined by flow cytometry. Statistical significance was assessed using T-test or Spearman correlation.

Results: The expression of CXCR3 on CD4 lymphocytes was significantly lower (p < 0.05) compared to 61.6% in control group (FD/IBS deficiency). Although the expression of CXCR3 on CD8 lymphocytes was higher than CD4 lymphocytes, it was not different between CD and other group (75.8% in CD patients vs 82.2% in controls). Similar observation was obtained on the double positive CD4 and CD8 lymphocytes. Interestingly, only expression of CXCR3 on CD4 lymphocytes positively correlated with expression of the gut-homing integrins, a4 and b7.

Conclusion: These observations showed significant expression of CXCR3 across different diseases, with consistently higher expression seen in CD8 lymphocytes compared to CD4 lymphocytes. An unexpected reduction of CXCR3 expression was seen in small intestinal of CD patients, which associated with gut-homing integrins. This result showed CXCR3 expression may play a role in migration of CD4 lymphocytes but not CD8 lymphocytes into duodenum in relation with integrins, a4 and b7. However, CXCR3 expression on CD4 lymphocytes in CD patients’ small intestine may have protective role. This propose further study to clarify.

Introduction: The excessive use of pesticides, often found as residues in our diet and as contaminants in drinking water, has become a public health problem. Most of these substances are considered as endocrine disruptors and their daily ingestion is likely to have severe and irreversible consequences. Indeed, preliminary studies have shown that chronic exposure to low doses of chlorpyrifos (CPF) causes intestinal imbalance (dysbiosis) in vitro. Aims & Methods: The objective of this study is to evaluate the preventive potential of a prebiotic (mulin) in co-exposure with the CPF on the intestinal dysbiosis, the bacterial translocation and the integrity of the intestinal mucosa. For this we used an in vitro system: the SHIME® (Simulator of the Human Microbial
Intestinal Ecosystem). The SHIME® consists of series of fermenters, mimicking the intestinal environment from the stomach to the colon. The SHIME® was exposed to a daily dose of 3.5 mg of CPF, combined with 10 g of inulin for 30 days. The samples were collected at day 0 (baseline, without CPF or inulin), D15 and D30 to determine the profile and microbial metabolism.

Results: Contrary to the previous results withCPF alone showing dysbiosis, prebiotic supplementation seems to reestablish CPF-induced imbalance, particularly in the potentially pathogenic microflora (Staphylococcus), which an increase in short term (D15: p < 0.001), and a recovery at D30. (difference vs B, p = 0.005) exposed for the benefit of CPF §. Inulin also beneficially influences the fermentation profile, with higher production of volatile fatty acids (VFA), especially propionic acid and butyric acid.

Conclusion: The CPF±inulin co-exposure therefore had a positive impact on bacterial profile and metabolism, suggesting that prebiotic supplementation could reduce some intestinal damages caused by an exposure to CPF.

Perspective: In a second step, the Caco-2/TC7 cell line, which mimics a functional human intestinal epithelium, will be exposed to samples from the colic fermenters of the SHIME® (D15 ± inulin at D15 and D30) in order to measure the impact on the epithelial barrier.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lactulose methane and hydrogen breath test (LMHBT) is now widely used in assessing small bowel bacterial overgrowth(SIBO) and irritable bowel syndrome(IBS). SIBO and IBS have similar clinical symptoms such as flatus, bloating and abdominal pain. Although there is no clear relationship between IBS and SIBO yet, they are both in relationship with dysbiosis. Diet is associated with disease closely, especially for gastrointestinal diseases. Different dietary structures have different effects on the structure, metabolism and function of the human microbiota. Reduce fermentable oligosaccharides, disaccharides, monosaccharides and polyols (FODMAPs) diet can release parts of IBS symptoms obviously. There were rare reports for the effects of diet on LMHBT, especially SIBO patients, and no controlled researches. So we analyzed the diet on intestinal microbiota profiles in IBS-D or SIBO patients. High fat diet may change the intestinal microbiota profiles and SCFAs was reported in the past with the fat proportion of diet (r = 0.169, P = 0.022).

Results: We aimed to analyze the characteristics of diet and lactulose methane and hydrogen breath test (LMHBT) in patients of diarrhea predominant irritable bowel syndrome (IBS-D) with small intestinal bacterial overgrowth (SIBO), and comparing with healthy controls. IBS-D patients (18–65 years old), who met Rome III criteria were enrolled in Gastrointestinal outpatient clinic of Peking University Third Hospital from. All subjects underwent colonoscopy to excluded colonic organic disorders. All subjects completed the case report form (CRF). IBS symptom severity scale (IBS-SSS), the MOS item short form health survey (SF-36). The patients were divided into IBS-D with SIBO (IBS-P) group and IBS-D without SIBO (IBS-N) group according to the LMHBT.Diet information was collected by food frequency questionnaire (FFQ) and three days recalls. The high fat diet defined as the daily total calories supplying from fat is more than 50%.

Conclusions: We found that high fat diet is significantly higher in IBS-P than IBS-N [47.19 ± 2.62% vs. (40.74 ± 1.66%), P < 0.001. The proportion of high fat diet individuals than IBS-N [37.1% (13/35) vs. 20.8% (11/53), P = 0.088]. (3) The positive rate of LMHBT in IBS-D was significantly higher than that of HC [39.8% vs. 12.5%, P = 0.005]. IBS-D patients with high fat diet had higher LMHBT positive rate than that of non-high fat diet patients [54.2% (13/24) vs. 17.2% (11/64), P = 0.001]. The baseline of breath methane in IBS-P was significantly higher than that of in IBS-N [8.69 ± 0.39] vs. (6.39 ± 0.47) ppm, P = 0.002]. Breath methane peak value was positively related with the fat proportion of diet (r = 0.413, P = 0.022).

Conclusion: The proportion of high fat diet had higher morbidity of SIBO, and the proportion of diet fat was positively correlated with breath methane baseline of LMHBT. SIBO can worsen nutritional status for IBS-P patients. High-fat diet might be one of the risk factors for IBS-P with SIBO.

Introduction: Alterations to the gut microbiota and bacterial translocation have been implicated as relevant factors for the progression of chronic liver disease (CLD). While the sequence of events leading to translocation remains unclear, deficiencies in local host immune defences, increased permeability of the intestinal mucosal barrier and dysbiosis of the gut microbiota are suggested to play a role. Small intestinal bacterial overgrowth (SIBO), in which an excessive and/or abnormal type of bacteria is present in the small bowel has been implicated as a potential factor in translocation. However, systematic assessments of the extent of SIBO in CLD remain limited. We therefore aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and controls.

Aims & Methods: Using the search terms ‘small intestinal bacterial overgrowth (SIBO)’ and ‘chronic liver disease (CLD)’ or ‘small intestinal bacterial overgrowth (SIBO)’ and ‘cirrhosis’, 19 case-control studies that met inclusion criteria were identified. Data were extracted to calculate prevalence rates and 95% confidence intervals (CI).

Results: The final dataset included 1,000 adult patients with CLD and 488 controls. Nine studies employed glucose breath tests (GBT), four lactulose breath test (LBT), two xylose breath test(1) and one each xylose breath test (2) and hydrogen/methane breath test. Five studies utilised culture methods and one quantitative PCR. Across all testing methods, the prevalence of SIBO in patients with CLD was 38.9% (95% CI 36.9–40.9) versus 9.8% (95% CI 7.5–12.8) in controls. The prevalence of SIBO in CLD was increased as compared to controls (RR = 7.15, 95% CI 4.9–10.4). In patients with cirrhosis the prevalence of SIBO was 40.1% (95% CI 36.6–43.8) compared to 7.3% (95% CI 4.9–10.8) in controls. While there was no difference in CLD patients and controls, the method of detection was limited to breath tests. The prevalence of SIBO in CLD was 35.8% (95% CI 32.6–39.1) compared to 8.0% (95 CI 5.7–11.0) in controls. In contrast, based upon culture techniques, the prevalence of SIBO in CLD was 68.3% (95% CI 59.6–76.0) vs 7.94% (95 CI 3.4–12.7) in controls.

Conclusion: Regardless of the diagnostic modality, prevalence of SIBO is significantly increased in patients with CLD when compared to controls. It is notable that culture-based detection leads to a higher prevalence in CLD, suggesting breath tests are large improvements over the overall prevalence. Given the levels of SIBO detected, further studies need to explore the role of intestinal dysbiosis for the progression of CLD.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: In humans, enteric methane (CH₄) production is highly variable and related to the gastrointestinal microbiome and diet. Previous work suggests that CH₄ production is more common in patients with ‘constipating’ conditions such as encopresis and diverticulosis. We aimed to explore the link between gastrointestinal symptoms breath CH₄ exhalation in patients with unexplained GI symptoms.

Aims & Methods: Consecutive patients (n = 100) with unexplained GI symptoms underwent a combined H₂/CH₄ breath test after ingestion of 75 g of glucose. H₂ and CH₄ were measured by Breathreactor microlyzer (Quintron, USA). Gastrointestinal symptoms were assessed utilising the (Structured Assessment of Gastrointestinal Symptoms Instrument (SAGIS)). The association between methane exhalation and symptoms during the 2 weeks prior the test were evaluated using non parametric test.

Results: 100 consecutive patients (55%); aged 52.2 ± 15.7 yrs (mean ± SD) were included. Of these, 14 with positive GBT and 19 without SAGIS data were excluded, resulting in 67 data-sets available for analysis. Methane peak and methane baseline values were highly correlated (r = 0.96, p < 0.001). Methane peak (and baseline) were inversely correlated with the SAGIS diarrhea score (r = -0.35, p < 0.01, Figure 1). Contrary to current opinion, CH₄ exhalation was not associated with constipation (r = 0.1, P > 0.4). In addition, excessive belching and acid eructation were significantly associated with the baseline and peak CH₄ exhalation (r all >0.3, p all <0.04).

Conclusion: There is an inverse association between CH₄ exhalation and diarrhoea symptoms. At the same time, CH₄ is associated with bloating and acid eructation. These data suggest that CH₄ or metabolic products from CH₄ producing microbes modulate human gut function.

Introduction: Strict gluten-free diet (GFD) in celiac disease is burdensome and difficult to maintain, which might predispose to poor dietary adherence and impaired quality of life. We aimed to evaluate adult patients’ experience of living with celiac disease diagnosed in childhood, and identify factors associated with possible life restrictions caused by the disease.

Aims & Methods: 232 adults (women 69%, median age 27.0 y) with a childhood diagnosis of celiac disease fulfilled a questionnaire evaluating their adherence to lifestyle and health lifestyle, possible co-morbidities, adherence and attitudes towards GFD and long-term follow-up of celiac disease. In addition, they underwent anthropometrics and serological investigations, ultrasonography (US) surveys for gastrointestinal symptoms and quality of life. Patient records were used to confirm clinical and histological presentation at diagnosis and other relevant medical data.

Results: Altogether 108 (47%) out of the 232 respondents felt that celiac disease restricts their daily life. This was experienced especially when eating in a restaurant (38% of those affected) and visiting a friend (30%). Patients reporting restrictions had more often anemia (38% vs 22%, p = 0.013) and time from the diagnosis (18.6 vs 17.9 y, p = 0.468) were also comparable, as well as were self-experienced general health and concern about health, presence of co-morbidities and complications, smoking, physical exercise, socioeconomic status, membership of celiac society and presence of celiac disease in relatives. There was also no difference in specific gastrointestinal symptoms as measured by GRSRS scores, but patients considering the disease restrictive reported more overall symptoms possibly related to celiac disease than those without restrictions (32% vs 17%, p = 0.007). Furthermore, disability score (disability = (32% vs 82%, p = 0.770) they experienced adhering to the diet more challenging (somewhat difficult 33% vs 7%, p < 0.001) and had significantly lower PGWB vitality scores (median 17 vs 18, p = 0.023).

Conclusion: Almost half of the patients diagnosed in childhood experienced celiac disease to cause marked restrictions in adulthood. This was associated with current symptoms, lower vitality scores and difficulties to maintain GFD. Patients with severe symptoms and anemia at diagnosis might require special attention and tailored follow-up in these circumstances.

P1279 SYSTEMATIC REVIEW OF THE ECONOMIC BURDEN OF CELIAC DISEASE

A. Bellanger1, A. J. Taylor2, D. A. Leffler3, S. E. Mearns4, M. Gerber3
1IBM Watson Health, Boston/United States of America/MA
2Takeda, London/United Kingdom
3Takeda, Cambridge/United States of America/MA

Contact E-mail Address: aliki.taylor@takeda.com

Introduction: The prevalence of diagnosed coeliac disease (CD) has rapidly expanded in both developed countries and developing regions. The economic burden of diagnosing, managing, and monitoring CD can be substantial but is poorly understood. To assess the economic burden of CD, we systematically reviewed current evidence quantifying economic costs and health resource utilization (HRU) for CD in North America and Europe.

Aims & Methods: Searches of Medline, Embase, EconLit, the Cochrane Library, and conference abstracts systematically identified literature published in English during the last 10 years assessing direct and indirect costs, cost-effectiveness studies and economic evaluations. We also searched for conference abstracts. We assessed methodological quality of individual studies.

Results: Of 33 studies meeting criteria for inclusion, most (20) were from Europe, and most (18) reported or modeled costs associated with screening and diagnosis. Cost per positive CD diagnosis of screening patients already undergoing upper gastrointestinal biopsy for other indications, such as anaemia or irritable bowel syndrome, ranged from approximately $1,300 in Canada to more than $44,000 in the Netherlands (costing year not reported). In these populations, screening was judged to be cost-effective with various strategies combining diagnostic modalities, including serology then biopsy, compared to no screening. Strategies using either endoscopy/biopsy or serology alone were not considered cost-effective. Direct annual excess costs to a US payer per diagnosed CD patient were estimated between $23.20 (US 2007) and $303.52 (US 2013) to be more than for a person without CD, chiefly due to outpatient care, with higher costs among patients with poor disease control. High use of outpatient care is also reflected in studies of HRU, although hospitalization, emergency visits and medication use are also more common in individuals with CD than in controls. After initiation of a gluten-free (GF) diet, patients visit primary care providers less often, but use more medications. Patients often pay out of pocket for gluten-free (GF) foods, which cost $240–518% more than gluten-containing equivalents. Three studies on absenteeism from Scandinavia found fewer days missed from school and work following diagnosis and initiation of a GF diet.

Conclusion: Most economic studies of CD have focused on the cost of screening and diagnosis, especially in Europe. Methods of screening generally are considered cost-effective when they combine diagnostic modalities, such as serology then biopsy, in people being evaluated for symptoms. Much of the cost to a payer of managing CD derives from outpatient care, especially for patients with poorly controlled disease. Patients on a GF diet lose fewer days from work and school but pay higher costs for GF foods.

4Gastroenterology And Endoscopy Unit, Fondazione IRCCS Ca’ Granda Ospedale Maggiore Policlinico, Center for the Diagnosis and Prevention of Celiac Disease, Milan/Italy

Introduction: Patients with coeliac disease (CD) should be seen annually for a clinical review, blood tests and a DEXA scan if needed1,2. The indication for a DEXA scan is unclear due to conflicting recommendations in current guidelines3,4. The aim of our study was to audit our practice, with a focus on requests for DEXA scans.

Methods: This was a single-centre, retrospective study of CD patients under the care of 3 consultants. We accessed the electronic records to identify if haematological and biochemical profiles were being monitored annually. We also identified when patients had their first DEXA scans and whether or not they were indicated1,2.

Results: Data were collected on 160 patients (Female = 107[67%]). Annual checks of BFC occurred in 94% of patients, vitamin B12 in 74%, folate in 75% and ferritin in 88%. C-reactive protein and ferritin showed a trend towards higher values in patients on gluten-free diet (GFD). In 8% of patients (n = 10), there was inadequate data. Of the 81 patients who did not warrant a DEXA scan, 77 results were available: normal in 48% (n = 37), osteopenia in 43% (n = 33) and osteoporosis in 9% (n = 7). Of the 7 patients that had osteoporosis, 4 patients were under 50 years old (57%). Of the appropriate DEXA requests, 23% (n = 7) were normal, 39% (n = 11) had osteopenia and 36% (n = 10) had osteoporosis.

Conclusion: Most CD patients require very little clinical input at their routine appointments. Annual blood checks and adherence to a gluten-free diet are standard enquiries. However, there is a cohort of patients who are not getting their regular blood tests: 33% for bone profile and 25% for haematinsics. Clinicians tend to order a DEXA scan in most CD patients because it is easier than attempting to judge an individual’s risk in the setting of conflicting guidelines. The pick-up rate of osteoporosis in 36% of appropriately screened patients (vs 9% in inappropriate scan requests) suggests that targeted screening allows for a more rational and cost-effective use of limited resources. We hope that the guidelines can now be updated with more clarity for the practitioners who request DEXA scans in CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Hepatology Unit, Cardarelli Hospital, Naples/Italy
3Department Of Clinical Medicine And Surgery, Gastroenterology Unit AOU Federico II, Naples/Italy

Introduction: Recent research has shown that patients with celiac disease (CD) are at-risk of developing metabolic syndrome (MS) and hepatic steatosis (HS) after commencing gluten-free diet. Aims & Methods: We aimed to evaluate the predictive factors for MS and HS in CD after one year of GFD. All consecutive newly diagnosed CD patients were enrolled prospectively. We collected data about lifestyle, waist circumference, blood pressure, cholesterol, triglycerides, glucose and insulin blood levels; insulin resistance (through the homeostatic model assessment HOMA-IR); treatment with proton pump inhibitors (PPI). Diagnosis of MS was made in accordance with current guidelines and HS was diagnosed by ultrasonography. The prevalence of MS and HS was re-assessed after 1 year of GFD. A logistic regression analysis was performed to identify risk factors for MS and HS occurrence after 1 year of GFD.

Results: Of 301 patients with newly diagnosed CD, 13 (4.3%) met criteria for diagnosis of MS and 25.9% presented HS at the time of CD diagnosis. 99 subjects (32.8%) had long-term exposure to PPI during the study period. After 1 year, 72 (23.9%) patients had developed MS (4.3% vs 23.9%; p < 0.001, OR 6.9) and 112 (37.2%) had developed HS (25.9% vs 37.2%; p < 0.01, OR 1.69). At multivariate analysis, high BMI at diagnosis (OR 10.8; p < 0.001) and PPI exposure (OR 22.9; p < 0.001) were the only factors associated with the occurrence of MS, HOMA-IR (OR 9.7; p < 0.001) and PPI exposure (OR 9.2; p < 0.001) were the only factors associated with the occurrence of HS.

Conclusion: PPI exposure adds further risk of occurrence of MS and HS for patients with CD on GFD. The use of PPI in patients with CD on GFD should be limited to strict indications.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Plasma citrulline has been proposed as a biomarker for remnant intestinal length, but it is unclear if plasma citrulline levels reflect intestinal absorptive function.

Aims & Methods: This post hoc analysis investigated the relationship between reductions in parenteral support (PS) volume and changes in plasma citrulline levels with tebufuglide (TED) in patients with intestinal failure associated with short bowel syndrome (SBS-IF). STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.5 mg/kg/day in patients with SBS-IF. Plasma citrulline levels were assessed at baseline and Week 24 in all patients randomised to TED and in patients stratified by bowel anatomy.

Results: In the TED arm (n = 42), plasma citrulline levels at baseline were significantly correlated with remnant small bowel length (R² = 0.14; P = 0.02; n = 36) but not with baseline PS volume (R² = 0.03; P = 0.30; n = 39). The correlation between baseline plasma citrulline and plasma citrulline change at Week 24 was significant (R² = 0.80; P < 0.0001; n = 39). No correlation was found between change in plasma citrulline levels and change in PS volume at Week 24 with TED (R² = 0.05; P = 0.16; n = 39). When patients were analysed by bowel anatomy subgroups, significant increases in plasma citrulline were seen with TED but not placebo (Table).
volume reductions with TED. Plasma citrulline changes with TED may reflect a relatively low proportion of healthy controls. Both FD and IBS subjects experienced similar proportions of methane-producers. Symptoms were induced in a relatively low proportion of healthy controls. Both FD and IBS subjects experienced minimal symptoms when any of the three carbohydrate solutions were ingested. Healthy controls experienced minimal symptoms when lactulose was ingested when compared with subjects with FD. In general subjects with IBS experienced both epigastric pain and abdominal pain when lactulose was ingested while control subjects with no known GI disorder/symptoms were recruited. All subjects underwent HBT testing in the upper abdomen, leading to misdiagnosis as FD.

Prevalence rates of Functional Dyspepsia (FD) in East Asia are three times higher than Irritable Bowel Syndrome (IBS) rates. Many researchers have suggested that IBS subjects in the region experience their pain and discomfort in the upper abdomen, leading to misdiagnosis as FD.

**Results:** A total of 353 subjects completed at least one breath test examination and 313 subjects completed all three breath tests. 16%, 55% and 29% were control, FD and IBS subjects. All subjects underwent HBT testing in the upper abdomen. Reducing poorly absorbed short-chain carbohydrates (FODMAPs) might be efficacious as FD as it is in IBS.

**Discussion of Interest:** All authors have declared no conflicts of interest.

**Conclusions:** Chinese subjects commonly co-produced hydrogen and methane. Ingestion of poorly absorbed sugars induces symptom patterns in patients with FD in similar proportions. Chinese IBS subjects commonly experienced epigastric and abdominal pain. Reducing poorly absorbed short-chain carbohydrate (FODMAPs) might be efficacious as FD as it is in IBS.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

were evaluated: Group 1 (no colon/stoma present/no colon-in-continuity), Group 2 (≥50% colon/stoma colon-in-continuity), and Group 3 (other bowel anastomosis). Clinical response was defined as ≥20% reduction from baseline in weekly parenteral support (PS) volume at Weeks 20–24. Data presented as mean (SD).

Results: The predominant diagnosis in Group 1 was Crohn’s disease, whereas the predominant diagnosis in Group 2 was vascular complications (Table). Group 1 patients required the highest baseline PS volumes compared with Group 2 or Group 3. TED-induced PS volume reduction (change in L/week) took longer to be realised in Group 2 (Week 12 = –9.9 [1.2]; Week 24 = –2.5 [2.1]) compared with Group 1 (Week 12, –5.5 [3.8]; Week 24, –6.4 [4.5]) or Group 3 (Week 12, –2.7 [1.2]; Week 24, –5.1 [3.7]). Response rates were higher with TED versus placebo in all groups, but the difference was significant only in Group 1 (76% vs 19%, P = 0.001; Group 2, 56% vs 40%, P = 0.36; Group 3, 57% vs 29%, P = 0.03). Adverse events were reported by 94%, 72%, and 86% of Group 1, Group 2, and Group 3 patients receiving TED, respectively.

Results:
Sixty-one (61%) SBCE were carried out. The overall detection rate within a surgical operation or video capsule endoscopy and the clinical relevance of ink tattooing during balloon-assisted enteroscopy (BAE).

Aims & Methods: The purpose of this study was to determine the safety, the detection rate within a surgical operation or video capsule endoscopy and the clinical relevance of ink tattooing during balloon-assisted enteroscopy (BAE). Balloon enteroscopy was performed in 50% (n = 26) of patients during SBCE. The ink tattooing was performed at the endoscopy unit of Klinikum Augsburg. We performed a retrospective analysis of all 81 (52%) patients who received an ink tattooing during BAE.

Disclosure of Interest: Disclosure of Interest: The authors declare that they have no conflict of interest.

Results:
The majority of 33% of SBCE diagnoses were malignant, (86%) patients underwent surgical resection of their small bowel tumour and 10% patients underwent cross sectional imaging prior to SBCE, of which 3 (42%) had a reported no small bowel abnormalities. All patients had underwent at least one negative upper and lower endoscopy prior to referral, and SBCE was the third investigation in 25% (n = 20) of patients. A total of 32 (66%) patients underwent a double balloon enteroscopy (DBE) for further evaluation of findings and up to obtain tissue samples. In terms of histological diagnoses, adenocarcinomas were found in 43% (n = 6), Neuroendocrine tumours in 29% (n = 4), Angiomyolipoma 1% (n = 1) and mesenteric thrombus 1% (n = 1). All patients eventually underwent surgical resection of their small bowel tumours and 80% (n = 11) patients remain well at present, after a mean follow up time of 15.2 months (2-36).

Conclusion: Ink tattooing is a powerful new tool for diagnosis, pre-surgical evaluation, and follow-up for small intestinal neoplasms. It is a useful tool to avoid unnecessary examinations and aids the intraoperative localization of pathologic lesions. A complete enteroscopy via BAE from retrograde and antegrade BAE is achieved routinely in our setting.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The western diet (WD) high in fat and fructose is considered one of the most relevant cause of metabolic disorders and cardiovascular diseases (CVD). The aim of this study was to evaluate whether vitamin D supplementation is able to modulate hepatic steatosis, or restore insulin resistance and the metabolic alterations contributing to CVD and hepatic failure (HF) caused by a westernized diet, in a rat model without specific vitamin D deficiency.

Results: Eighteen adult male Wistar rats were divided into three groups, each of 6 rats, fed with: Group 1: Standard Diet, 3.3 kcal/g (SD); Group 2: Western Diet, 5.6 kcal/g (WD) containing 13 IU/day/rat of vitamin D3; Group 3: Western Diet + Vit D (WD Vit D) containing 25 IU/day/rat of vitamin D3. The experiment was conducted for 6 months. Standardized tailed-bell blood pressure (BP) measurements of conscious rats and throracic echocardiography were performed in basal condition (Time 0), and after 3 and 6 months of diet. Hepatic steatosis and collagen myocardiac fibrosis were assessed using standard methods. Serum ferrum insulin and homocystein (Hcy) concentrations were determined using rat-specific ELISA kits. Insulin resistance was determined according to the Homeostasis Model of Assessment (HOMA-IR) method.

Results: In WD rats the percentage of hepatocytes with steatotic vacuoles was 61%, while in WD Vit D group was only 27%. The WD group HOMA-IR was significantly higher than in SD (41.9 ± 8.9 vs. 6.17 ± 1.3, p < 0.001) and it was reduced by vitamin D supplementation in WD Vit D group (41.9 ± 8.9 vs 19.4 ± 5.2, p < 0.05). At baseline, no differences in systolic blood pressure (SBP) were detected among the three groups showing normal systolic blood pressure. SD did not increase SBP, significantly, during the study period. On the contrary, WD, enhanced SBP by 27.4 ± 12% p < 0.001 at 3 months, and by 47.1% ± 11%, p < 0.001 at 6 months. At the end of the study, SBP resulted to be higher in WD group (117.8 ± 6 mmHg) than both SD (98.7 ± 8 mmHg, p < 0.001) and with WD Vit D (101 ± 4 mmHg, p < 0.01). During the study period, WD group showed a significant increase of left ventricular mass (LVM) (52 ± 25% at 3 months p < 0.05, and 123 ± 43% at 6 months p < 0.001, vs basal conditions). Supplementation of Vit D abolished the WD-induced increase of LVM (25 ± 19% at 3 months, and 34 ± 20% at 6 months, p < 0.05 vs baseline respectively). At the end of the study LVM resulted to be higher in the WD group in comparison to both SD and WD Vit D groups, while
P1297 ELIPSE BALLOON SYSTEM: OUR EXPERIENCE. A PRELIMINARY STUDY

Gastroenterology And Digestive Endoscopy, Azienda Ospedaliera San Giovanni Addolorata, Rome/Italy

Contact E-mail Address: veronicae@aol.com

Introduction: Gastric balloons (IGB) are an emerging option for overweight and obese patients with a body mass index (BMI) greater than 31 kg/m2 and they provide greater efficacy with lower risks than do conventional surgical procedures. The balloon treatment is based on gastric space-occupying effects that increase the feeling of satiety and may also effect gut neuroendocrine signaling. However, widespread use of current generation IGBs has been limited by several factors: placement and removal endoscopes require sedation, special training and equipment; patients lost to follow-up are susceptible to IGB deflation and unplanned passage into the gastrointestinal tract. The ElipseTM is the world’s first procedureless balloon that does not require endoscopy or anesthesia.

Aims & Methods: We conducted a study to prospectively analyze the safety and effectiveness of IGB ELIPSE in overweight adults. Six patients, 1 male and 5 female (average age 40, mean BMI = 40 kg/m2), were included in this study. Each patient swallowed Elipse™ balloon intended to remain in the stomach for 16 weeks. Each balloon was filled with 560 mL of filling fluid. Patients returned every 2 weeks for abdominal ultrasound which documented the correct positioning of the device. All patients were followed up by a nutritionist with a specific semiliquid diet.

Results: All 6 patients successfully swallowed the device. There were no major adverse effects. All 6 patients had a significant weight loss (about 16 Kg). In all of them, weight loss was maintained at 6 months follow-up. There were no floatations or serious complications.

Conclusion: This study demonstrates the efficiency, security and simplicity of IGB ELIPSE in overweight adults. All 6/6 patients successfully swallowed the device. There were no major adverse effects. All 6 patients had a significant weight loss (about 16 Kg). In all of them, weight loss was maintained at 6 months follow-up. There were no floatations or serious complications.

P1298 CHANGE OF VITAMIN D AND BONE MINERAL DENSITY AFTER BARIATRIC SURGERY IN CHINESE POPULATION

M. Han1, W. Lee2
1Internal Medicine, Min-Sheng General Hospital, Taoyuan/Taiwan
2Surgery, Min-Sheng General Hospital, Taoyuan/Taiwan

Contact E-mail Address: minghun@ms18.hinet.net

Introduction: Bariatric surgery is an effective treatment for morbid obesity. In Taiwan, the numbers of patients who received bariatric surgery increased gradually. However, for long-term follow-up, nutritional deficiency may develop in post-bariatric (metabolic) surgery patients, especially in patients who received mal-absorptive or combination procedure. Deficiency of nutrition may cause anemia, peripheral neuropathy, secondary parathyroidism and osteoporosis. Follow-up of the nutritional status for patients after bariatric surgery is an important issue.

Aims & Methods: The aim of our study is to evaluate the change of Vitamin D and bone Mineral Density after bariatric surgery in Chinese population. This prospective cohort study included 50 patients (ranged from 20 to 65 years old) who received bariatric surgery at one teaching hospital in Taoyuan, Taiwan. Patient with osteoporosis before surgery were excluded in this study. Baseline (2012–2014) and one year after bariatric surgery (2013–2015), venous blood was collected from each patients for assessment of the Calcium, Vitamin D and parathyroid hormone (PTH) levels. BMD (g/cm2) was also measured at lumbar spine (L2-L4) by dual energy x-ray absorptiometry (DEXA).

Results: Among 50 patients, 15 patients received laparoscopic sleeve gastrectomy, 24 patients received laparoscopic mini-gastric bypass (MGB), 5 patients received laparoscopic Roux-en-Y gastric bypass (RYGB) and 6 patients received laparoscopic duodeno-jejunal bypass with sleeve gastrectomy (DBJ-SG).

The characteristic of the study population was shown as table 1. The differences according to the actual consultations.

Table 1: Characteristics of study population one year after bariatric surgery

</tbody>
</table>

Conclusion: One year after bariatric surgery, the prevalence of osteopenia and osteoporosis was low. The serum Vitamin D level increased significantly but no significant change of BMD was noted. Further longitudinal studies are warranted to clarify the long-term effect of bariatric surgery on BMD in Chinese population.

Introduction: The intragastric balloon has been used for more than 20 years in Brazil as an endoscopic method for assisting weight loss, and some intercurrences were observed during more than 10,000 procedures performed. With the assistance of a multidisciplinary team the results have been satisfactory.

Aims & Methods: To assess the efficacy and complications of the weight loss with IGB in patients seen at the 07 private centers. A total of 10,255 patients with IGB implanted from 1997 to 2017 were analyzed from a prospective fed databank. IGB implantation was set at p39 months. Statistical analysis was performed according to sex and degree of excess weight (overweight and grade I, II and III). Data were assessed using Student t-test, and Tukey post-test. The level of significance was set at p<0.05.

Results: 492 patients (4.8%) were excluded from the final analysis associated with weight loss: 226 (2.2%) due to early removal. These were analyzed in relation to the initial BMI, and weight loss was strongly related to BMI. The patients showed a significant weight loss, with a significantly lower final BMI (27.16/C0.03) and average weight regained in this interval was 22.08 kg (C0.15). The mean BMI of the patients was 24.78/C0.04 and the mean average diameter of the IGB was 13.37/C0.02. The average proportion of weight loss between the first and last IGB was 3.37 kg/C0.03 and the average proportion of weight regain was 4.59 kg/C0.03. 122 patients (22.0%) did not achieve the target IGB diameter and 05 patient (0.9%) did not lose weight even with the desired IGB diameter. From the 146 patients (2.5%) who had weight regain some revisional procedures had been attempted and more recently endoscopic revisional procedures had been described.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastric entero anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistics, student’s t-test and Spearman correlation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1301 WEIGHT REGAIN AFTER BARIATRIC SURGERY - ARGON PLASMA COAGULATION FOR GASTROJEJUNAL ANASTOMOSIS DECREASE

B. Q. Sander1, D. S. Paiva1, M. P. Sander1, M. Galvao Neto2, G. Baretta3, E. Grecco4, T. F. Souza4, J. I. B. Scarpacho5

Introduction: The weight regained has been a described growing problem in patients after bariatric surgery. In this regain is multifactorial and associated to dilation of Gastrojejunostomy (GJ). For the patients with significant weight regain some revisional procedures had been attempted and more recently endoscopic revisional procedures had been described.

Aims & Methods: To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastroenteric anastomosis in patients who have undergone RYGB for morbid obesity and regained weight associated to dilation of the GJ. From Jan-2014 to April-2017 554 RYGB subjects with weight regain a dilated anastomosis (>18 mm) and at least 2 procedures were submitted APC application. In relation to the anastomotic diameter, the majority of studies use a diameter of more than 20 mm to define anastomosis dilation, although some studies use smaller diameters such as 12 mm similar to that created manually in the gastrojejunal anastomosis using a 36 Fr Fouchet bougie. In the patients in the present study, the minimum cross-section diameter was 18 mm and the maximum measured in the first session 40 mm. This anastomotic diameter was measured using a 33-mm long bougie diameter between an attempt and a successful treatment with a maximum of 03 applications. APC set was 2-3L min with 65-85W. GJ diameter target was 8-12 mm estimated with pre-measured rasper. At first APC session, pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the variables collected. Complications during treatment were also collected. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistics, student’s t-test and Spearman correlation.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first APC was 96.35 months (C14.72). Average and average weight gain in this interval was 22.08 kg/C11.05. The mean diameter of the anastomotic was 24.78/C0.04 and the average number of APC sessions was 1.78/C0.61. The average reduction of anastomotic diameter was 14.86 mm/C0.74 and the final average diameter was 33.02 mm/C0.83. The average weight loss between the first and last APC was 13.37 kg/C0.72 and the average proportion of weight regain was 4.59 kg/C0.03. 122 patients (22.0%) did not achieve the target GJ diameter and 05 patient (0.9%) did not lose weight even with the desired GJ diameter. From the 146 patients (2.5%) who had weight regain some revisional procedures had been attempted and more recently endoscopic revisional procedures had been described.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastric entero anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory. In cases of weight regain and loss to follow-up, the reintroduction of the patient to the multidisciplinary team is mandatory. In cases of weight regain and loss to follow-up, the reintroduction of the patient to the multidisciplinary team is mandatory. A psychological and/or psychiatric evaluation is mandatory, as well as nutritional therapy and encouragement of physical activity. The monitoring of food intake and body weight, closer follow-up of the operated patients, appropriate choice of technique according to the patient and the experience of the surgeon, and a good learning curve are all factors that can reduce the failure rate of bariatric surgery. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Introduction: With the aging of the population, the incidence of obesity has also increased among the elderly. However, there is a higher incidence of severe comorbidities in this population comparing to adults, which often makes bariatric surgery unfavorable. In this segment, treatment with the intragastric balloon (IGB) may be an interesting option.

Aims & Methods: To assess the efficacy and complications of obesity treatment in the elderly using a non adjustable IGB. A total of 77 patients were analyzed. The minimal initial body mass index (BMI) was 28 kg/m2. The level of significance was set at p<0.05.

Results: 58 patients were women (73.3%). Mean age was 64.26 (60-80) years. Ten patients had no comorbidities, 32 had hypertension, 45 had dyslipidemia, 32 had insulin resistance, 12 had type II diabetes, and 10 had ischemic heart disease. There was no major complications. Results are shown on table 1. The treatment success rates according to the following criteria: ≥10% total body weight loss (TBWL) and ≥25% excess weight loss (EWL) were 96.11% (74 patients) and...
98.7% (76 patients) respectively. 30 patients reached a normal body mass index (BMI) (23–25.9 kg/m²) according to the Pan American Health Organization (PAHO). Elderly shows a higher BMI reduction (p = 0.0002) and %TBWL (p = 0.0003) than adults.

Introduction: Non-coeliac gluten sensitivity (NCGS) is a new entity with unknown prevalence and mechanisms, and there is a need for a standardized procedure to confirm the diagnosis. The objective of this study was to characterize the response to a gluten challenge, when performed according to the updated Salerno criteria.

Aims & Methods: Twenty patients (14F/6M, age range: 21–62 y) with suspected NCGS, without coeliac disease and wheat allergy, were included while on a gluten-free diet. All patients went through four periods of double-blinded provocation with gluten and placebo containing muffins. They were instructed to eat two muffins a day (11 g gluten) for four days, followed by a three day’s wash-out. Gastrointestinal symptoms were recorded with questionnaires at baseline and after each provocation, while fatigue and quality of life were registered at baseline and end of the trial.

Results: Four out of twenty patients (20%) correctly identified the two periods when they received muffins containing gluten, hence were diagnosed with NCGS. The diagnosed group tended to show higher symptom scores than the not-diagnosed group both at baseline, after gluten exposure and after placebo, but no clear difference was seen in symptom change after provocation with gluten and placebo. The not-diagnosed group showed more severe symptoms with placebo than with gluten (p = 0.029). Symptom severity at baseline was significantly correlated with fatigue (r = 0.63, p = 0.003) and reduced quality of life (r = 0.76, p = 0.0001).

Conclusion: This randomized, double-blind placebo-controlled challenge with gluten diagnosed four patients with NCGS according to the Salerno criteria. However, according to the symptom registrations there are no clear difference between the diagnosed and the not-diagnosed group, or between symptoms after gluten provocation and placebo, indicating no specific effect of gluten in a group of patients with suspected NCGS.

Introduction: By targeting specific receptors into the vascular system, bile acids (BA) are cholesterol derivatives that are now considered as hormones. BA regulate the basal energy expenditure and glauco-lipidic metabolism. In animal models of atheroma development (ApoE-/- and LDL-/- mouse models) a powerful anti-atherosclerotic effect of circulating BA has been evidenced: BA are metabolites of the gut microbiota, suspected to play a role in the development of atherosclerosis. This study examined whether variations in BA or in the gut microbiota composition can be described in the human Coronary Artery Disease pathophysiology.

Aims & Methods: Consecutive patients undergoing coronary angiography between February and May 2015 were enrolled. To avoid physiological or induced variations in circulating BA or in the gut microbiota, highly restrictive exclusion criteria were applied. Circulating and fecal BA were quantified by high pressure liquid chromatography and tandem mass spectrometry. The fecal microbiota composition was assessed by 454 pyrosequencing of the total fecal bacterial DNA.

Results: 80 patients were prospectively included of 406 screened, and divided in two groups: with (n = 45) and a group without (n = 35) CAD. The mean serum concentration of total BA was 1.02 ± 0.16 mmol/l in patients with, versus 2.16 ± 0.38 mmol/l in patients without CAD (P = 0.005). This decrease, (adjusted for gender and age) was an independent predictor of CAD (odd ratio = 0.51; 95% confidence interval 0.31, 0.85; P = 0.01). The BA concentrations in feces were similar in both groups. There was no group-specific pattern in the fecal microbiota. In a subgroup of 17 patients, one month of statin therapy increased the serum BA concentration from 0.68 ± 0.08 to 1.37 ± 0.21 mmol/l (P = 0.01).

Conclusion: There was no specific microbiota signature associated with CAD. However, the decreased serum BA concentration was a strong predictor of CAD in humans. With respect to the powerful anti-atherosclerotic effect of BA in animal models, and their role in human lipid metabolism and diabetes, this study unraveled the existence of a new metabolic disturbance associated with CAD.

Introduction: The low-FODMAP diet (LFD) is used to treat patients with irritable bowel syndrome (IBS) even if some nutritional concerns have been raised. It starts with an elimination phase and is followed by a reintroduction phase to clearly detect the “symptom trigger” foods in order to suggest a definitive and less restrictive diet tailored to the individual patient.

Aims & Methods: The aims of this study were to evaluate: 1) the effects of FODMAP reintroduction on a) body composition and nutritional status, using Bioelectrical Impedance Vector Analyses (BIVA), b) abdominal symptoms, c) quality of life, d) anxiety/depression, e) sleep quality, 2) if the patients’ perception of the “trigger” foods was accurate.

Results: 66 IBS patients (54F, 12 M; 44.8 ± 13.6 years) started (T0) a LFD for 8 weeks (T1) and followed a 9–14 week reintroduction period (T2). They underwent blood tests at T0 and T1. BIVA, anthropometric data, IBS-Symptom Severity Score, Bristol Stool Chart (BSC), SF36, Hospital Anxiety and Depression Scale and Pittsburgh Sleep Quality Index were performed at T0, T1 and T2. The patients were monitored by a nutritionist to verify their compliance.

Results: Neither change of blood tests at T1 nor variations of anthropometric data and BIVA were reported at T1 and T2 in comparison with T0. A significant improvement in abdominal symptoms (IBS-SSS), anxiety and quality of life, was recorded at T1, this remaining unchanged also at T2 (p < 0.0001). Depression improved at T2 (p < 0.01 vs. T0). Sleep quality improved at T1 (p < 0.05 vs. T0) and at T2 (p < 0.001 vs. T0). Normal BSC facets were reported by 38 patients at T0 to 60 patients both at T1 and T2. The degree of symptom relief with the diet was 1.5 ± 0.6 at T1 and 1.6 ± 0.7 at T2 and the degree of satisfaction was high.
both at T1 (8.4 ± 1.6) and T2 (8.2 ± 1.7). When starting, LFD patients consumed 67% of foods lactose (67%), fructose (27%), and galacto-oligosaccharides (GOS) (17%) and polysaccharides (3%). The reintroduction phase (T2) enabled us to detect lactose in 70%, fructans in 30%, and fructose in 33%. In polysaccharides, we detected 27% as trigger foods lactose (67%), fructans (27%), fructose (17%), galacto-oligosaccharides (GOS) (17%) and polyols (3%); the reintroduction phase (T2) enabled to detect lactose in 70%, fructans in 30%, fructose in 37%, GOS in 33% and polysaccharides in 27%, as real triggers. The agreement (Cohen’s kappa) was moderate for lactose (κ = 0.50), fair for fructans (κ = 0.39) and fructose (κ = 0.32) and poor for polysaccharides (κ = 0.06) and GOS (κ = 0.01).

Conclusion: Not only did reintroduction not affect the improvements achieved during the elimination phase, but it also precisely identified the foods responsible for symptoms. This enabled us to suggest a personalized diet for the patients. The real role played by FODMAPs in generating symptoms was abundantly underestimated and misunderstood by our patients. This underlines the fact that LFD has to be administered and carried out under the guide of an expert nutritionist.

Introduction: Fructose malabsorption (FM) is a frequent finding in patients with abdominal bloating due to high levels of fructose in Western diets. The role of monosaccharide transporter dysfunction in the small intestine is incompletely understood. The aim of this study was to investigate the histoanatomical distribution of the fructose transporter GLUT5

Aims & Methods: The study included 257 patients with FM diagnosed by hydrogen breath test and grouped according to the response to a fructose-free diet. 42 healthy individuals and 31 patients with coeliac disease (CD) served as controls. The fructose breath test was done with 50 g fructose. Fructose malabsorption was defined as an increase of 20 ppm of endogenous hydrogen. Formalin-fixed and paraffin-embedded duodenal biopsy specimens were obtained in all cases. Histology was assessed using hematoxylin and eosin stained tissue sections. Expression of GLUT5 was studied by immunohistochemistry. Expression patterns of GLUT5 were correlated with clinico-pathological patient characteristics.

Results: The expression of GLUT5 did not differ significantly between patients with FM complete diet responders (n = 183) and healthy controls (n = 42). Also patients with FM responding to a fructose free diet did not differ in GLUT5 expression or in max. H2 increase and AUC measured in fructose breath testing from patients not responding to the diet (n = 40). However, in patients with CD (n = 29) significant differences in GLUT5 expression were found compared to patients with FM and healthy controls (p = 0.009). The severity of CD assessed by the Marsh score significantly correlated with the GLUT5 expression (rs = 0.563, p = 0.001)

Conclusion: Changes in GLUT5 expression may not cause symptoms in adult patients with FM. The symptoms induced by FM could be associated with mechanisms known to the pathologies of the intestinal bowel syndrome. However, in secondary malabsorption decreased GLUT5 expression was detected. Further investigation is needed to understand the essential factors in FM and the influence on functiona gastrointestinal disorders.

P1307 BETTER RESPONSE TO LOW FODMAP DIET IN JH NEGATIVE PATIENTS WITH DISORDERS OF GUT-BRAIN INTERACTION

V. Schindler1, A. Zweig1, A. Becker2, J. Zeitz1, D. Runggaldier1, M. Fried1, D. Pohl1
1Gastroenterology And Hepatology, University of Zurich, University Hospital Zurich, Zurich, Switzerland
2Universitätsspital Zürich, Zürich/Switzerland

Contact E-mail Address: valeria.schindler@usz.ch

Introduction: Previous studies have shown a reduction of gastrointestinal symptoms in patients with disorders of gut-brain interaction (FGID) when following a diet low in FODMAPs. Symptom relief due to a low FODMAP diet has especially been investigated in patients suffering from irritable bowel syndrome (IBS) and has proven to reduce gastrointestinal symptoms in up to 86% of patients with IBS. In addition, there is evidence for an association between gastrointestinal symptoms and joint hypermobility (JH). However, there is no clear data regarding response rates to a diet low in FODMAPs in patients suffering from JH. In this study we aimed to assess and compare the response to a diet low in FODMAPs in JH positive and JH negative patients with FGIDs.

Aims & Methods: Data of patients presenting with FGID at the tertiary ambulatory functional bowel clinic between January 2015 and July 2016 were analyzed. FGIDs were diagnosed according to Rome III criteria. JH was assessed by physicians using Brighton score and rated positive for scores ≥4.9 points. Patients received professional nutritional counseling on a diet low in FODMAPs. A global symptom response was assessed by a professional nutritionist after 4 to 6 weeks following a low FODMAP diet.

Results: Of all 84 patients screened for JH, 62 (73.8%) were female and 22 (26.2%) were male. Median age was 35 (range 18-67) years. Females were more likely to exhibit JH compared to males (38.62 [61.3%] vs. 6.22 [27.3%]; p = 0.006). Global symptom response rate to a diet low in FODMAPs was 64/84 (76.2%). Our data showed significantly better response to a low FODMAP diet in JH negative patients than in JH positive patients (36/40 [90.0%] vs. 28/44 [63.6%], p = 0.005, ITT). Response of 7 patients was unknown because of early therapy discontinuation before nutritional re-counseling. When excluding 7 patients with therapy discontinuation from our calculations, the difference in diet response between JH negative and JH positive patients remained significant (36.39 [92.3%] vs. 28/38 [73.7%]; p = 0.036).

Conclusion: Our data indicate an association between symptom response to a diet low in FODMAPs and joint hypermobility status in FGID patients. An understanding of structural pathophysiological factors (e.g. gut permeability) and joint hypermobility status in FGID patients might represent a further step towards pathophysiological features in FGIDs and might help to select patients for individually appropriate therapies.

2Gastroenterology And Hepatology, Mayo Clinic, Rochester/United States of America/MN

Contact E-mail Address: saffouri.george@mayo.edu

Introduction: Gastrointestinal symptoms are often associated with dietary intolerances and are common in the developed world consuming a western diet low in fiber.

Aims & Methods: To determine the effect of a high-sugar, low-fiber diet on GI symptoms and duodenal physiology, we performed a prospective single-center study. Healthy adults with baseline fiber intake ≥14 g/day; ≤10% daily calories from added sugar; ≥5 servings of fruits and vegetables/day; and ≤15% daily calories from saturated fat were recruited. Exclusion criteria included known GI disease or symptoms, antibiotic/probiotic use within 4 weeks of the study, pregnancy, and vulnerable adults. At baseline visit, participants completed a symptom and demographic questionnaire and underwent esophagogastroduodenoscopy (EGD) with duodenal biopsies and aspirates. Symptoms associated with constipation, straining, incomplete evacuation, hard stools, abdominal pain associated with bowel movements, diarrhea, bloating, nausea/vomiting, heartburn, fatigue, and appetite. All participants consumed a 7-day standardized diet with typical United States diet: 86% dietary carbohydrate, 35% fat, 15% protein. The diet was low in fiber (<10 g/1000 calories/day) and high in simple sugar (≥50% daily carbohydrates). After dietary intervention, participants filled out four symptom questionnaires and underwent repeat EGD with duodenal biopsies and aspirates. Before and after the diet, quantitative aerobic and anaerobic cultures were performed on duodenal aspirates. Duodenal biopsies were mounted in an Using chamber. Intestinal permeability was evaluated using transpantapolar electrical resistance (TEER) and FITC flux (4KDa); a measure of paracellular transport. Secretory responses were quantified in voltage clamp mode by measuring baseline short circuit current (Isc) and change in Isc (ΔIsc) in response to increasing concentrations (0.003-300 μM) of serotonin (5-HT) on the submucosal side. These measurements were repeated after the dietary intervention. Data are presented as mean ± SEM. Data were analyzed using paired-t test unless specified and p < 0.05 was considered significant.

Results: A total of 10 participants (5 female; median age 26; 70% Caucasian) were recruited. Average BMI was 23.1 ± 2.5 kg/m2. At baseline, all patients were asymptomatic. After dietary intervention, all patients endorsed at least one new symptom and 9/10 participants endorsed multiple (≥2) new symptoms. At baseline 4/10 patients had positive duodenal cultures (> 100,000 CFU/mL, anaerobic) despite having no symptoms. Of the 6 who had no growth initially, I developed bacterial overgrowth following intervention. There was no significant difference in TEER (26.43 ± 1.98 vs 26.18 ± 2.45 Ohms/cm²); FITC flux (217.3 ± 43.7 vs 217.6 ± 42.57 ng/ml) or baseline Isc (48.27 ± 0.39 vs 51.58 ± 3.02 ng/ml) before and after dietary intervention. Interestingly there was a significantly lower ΔIsc response to increasing concentrations of 5-HT after dietary intervention (P < 0.05, two-way ANOVA).

Conclusion: A low-fiber, high simple sugar diet led to gastrointestinal symptoms in patients who normally have no symptoms. This was associated with a significant decrease in 5-HT evoked secretory response in the duodenum, suggesting a potential role for dietary modulation of host serotonergic pathway. There was no correlation with quantitative bacterial cultures and there was no overall significant change in intestinal permeability. Diet may mediate these
**P1309** STRESS AND STRESS-RELATED PEPTIDE AMPLIFY THE ANTAGONISTIC EFFECTS OF CCK ON GASTRIC MOTILITY IN RATS

Gastroenterology And Hepatology, Saitama medical University, kawagoe/Japan

Contact E-mail Address: yamaguchta810@yahoo.co.jp

**Introduction:** Recently roles of gut hormones on appetite control have been known. Among them, CCK is well known to suppress appetite and gastric motility. On the other hand, patients of functional dyspepsia (FD) have hyper sensitivity to CCK. And revels of CCK inbrad was shown to be high in FD patients. In FD patients, stress have important roles of pathogenesis of the disease.

**Aims & Methods:** We undertook to clarify whether stress influences the actions of cholecystokinin (CCK) on appetite and gastric emptying. As stress, we gave restraint stress, corticosteroid-releasing factor (CRF) or urocortin (UCN1) injection intraperitneally (IP). We also examined the effects of CCK and restraint stress on c-Fos expression in the neurons of appetite center of the brain.

In the gastric emptying study, SD rats were fasted overnight. The amounts of the mixture (food and glass beads) left in the stomach were measured at 2 hours after the perorally injection of mixed food, and gastric emptying rate was calculated.

In the study on appetite, CCK was IP injected and the interaction with CCK on food intake was examined. In another study, restraint stress was given to rats and the interaction with CCK was evaluated. To study the involvement of brain in the interaction between CCK and stress, c-Fos expression in the neurons was examined and evaluated.

**Results:** CCK dose-dependently inhibited gastric emptying. CCK dose-dependently increased gastric emptying rate 1 hr after the injection. CCRF or UCN1 was injected and the interaction with CCK on food intake was examined. Therefore there might be possible to cause interactive actions between two peptides, inducing satiation to finish food intake.

**Conclusion:** The result suggests that stress might amplify anorexic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1310** PEPTIDE TYROSINE-TYROSINE (PYY) ENHANCES THE EFFECTS OF CHOLECYSTOKININ (CCK) ON GASTRIC MOTILITY AND FOOD INTAKE IN RATS

E. Hosomi1, N. Yamaguchi2, K. Maewaza1, M. Ochiai2, S. Ro1, K. Chieko2, K. Takayama1, K. Yakabi1
Gastroenterology And Hepatology, Saitama medical University, Kawagoe/Japan

Contact E-mail Address: hosomi@saitaimed.ac.jp

**Introduction:** Cholecystokinin (CCK) and peptide tyrosine-tyrosine (PYY) have been known to influence food intake for 1 hr after the injection. In experiments, CRF or UCN1 was injected and the interaction with CCK on food intake was examined. Therefore there might be possible to cause interactive actions between two peptides, inducing satiation to finish food intake.

**Aims & Methods:** In this study, we undertook to elucidate whether CCK and PYY have the interaction to decrease food intake. Study on gastric emptying. Male SD rats were fasted overnight, and 1 mL of mixture of food and glass beads was given into the stomach and then PYY or CCK or CCK followed by PYY was given intraperitoneally (IP). The amounts of food were measured and gastric emptying rate was calculated. Study on appetite. PYY or CCK was IP injected to the rats just before setting food to eat. The amounts of food were measured and gastric emptying rate was calculated. To clarify the involvement of the brain in the interaction between CCK and PYY, c-Fos expression was examined.

**Results:** CCK (0.5–10 nmol/kg) dose-dependently inhibited gastric emptying (p < 0.001). CCK 10 nmol/kg maximally inhibited food intake (p < 0.01). PYY 25–250 pmol/kg significantly inhibited gastric emptying for 1 or 2 hrs after the injection (p < 0.01). PYY 250 pmol/kg significantly inhibited food intake for 1 hr after the injection (p < 0.01). The combination of CCK 10 nmol/kg and PYY 250 pmol/kg inhibited gastric emptying more than CCK alone (p < 0.001) or PYY alone (not significant). PYY and CCK additively inhibited food intake when PYY was injected 20 minutes later from CCK injection. PYY significantly amplified c-Fos expression induced by CCK in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) in the brain.

**Conclusion:** The combination of PYY with CCK amplified the suppression of gastric emptying. The result suggests that the sequence secretion of CCK and PYY might strengthen the inhibition of food intake through the activation of satiety center in the brain, that is important for terminating food intake and adjusting energy intake.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1311** REGULATION OF MICRORNAS BY P53 FAMILY MEMBERS IN HEPATOCELLULAR CARCINOMA

R. Hermelink1, M. Bender2, L. Kaser1, E. Aschenbrenner1, K. Pollinger1, C. Kunst1, M. Müller-Schilling2
1Department Of Internal Medicine I, University Hospital Regensburg, Regensburg/Germany
2Department Of Internal Medicine IV, Hepatology And Gastroenterology, University Hospital Heidelberg, Heidelberg/Germany

Contact E-mail Address: rafael.hermelink@web.de

**Introduction:** Transcriptions factors belonging to the p53 family (p53, p63, p73) respond to cellular stress signals by inducing an accurately defined set of genes. In a number of tumors, also in hepatocellular carcinoma (HCC), p53 proteins can exert cancerogenic or tumour suppressive functions. MicroRNAs are small, non-coding RNA molecules which play an important role in gene regulation. It is known that expression patterns of microRNAs can be controlled by the p53 family. Depending on disease and cellular origin different sets of p53-induced microRNAs have been identified.

**Aims & Methods:** Little is known about p53-dependent microRNA signatures in HCC. The aim of the study was therefore to identify p53-family-regulated microRNAs in HCC. Hep3B cells were transfected with rAd-p53 and -p73. Microarray analyses were performed to identify p53- and p73-regulated microRNAs. Verification of p53- and p73-dependent microRNA expression was performed by qPCR.

**Results:** Overexpression of p53 and p73 induced a rash of microRNAs. p53 and p73 significantly upregulated microRNAs. p53 significantly downregulated microRNAs. In the presence of p53 and p73, miR-34a was upregulated by 3.6-fold, miR-200c by 3.2-fold, and miR-199 by 5.5-fold. p53-dependent expression of miR-34a was further increased in the presence of Doxorubicin (5.7-fold), Regorafenib (2.5-fold) and Tivantinib (1.9-fold) compared to controls. Moreover, incubation with Regorafenib resulted in an up to 3.4-fold increase of p53-dependent expression of mir-149 and mir-192.

**Conclusion:** p53 proteins affect the microRNA signature in HCC. Beside the already known induction of miR-34a we demonstrate for the first time a regulation of miR-145 and –149 by p53 and p73. We hypothesize that regulation of tumour suppressive microRNAs represents an effector mechanism by which p53 family members exert their role in tumor development and treatment response. The observed synergistic effect of p53 and HCC-relevant therapeutics on microRNA expression might provide new options for the development of therapeutic and prognostic measures in HCC.

**Introduction:** p53 transcription factors (p53, p63, p73) respond to cellular stress by transcriptional regulation of specific sets of genes. In hepatocellular carcinoma (HCC) and other tumors p53 family members exert cancerogenic or tumor suppressive effects. Depending on their origin their signature varies. In hepatocellular carcinoma (HCC) p53 proteins affect the microRNA signature in HCC. Beside the already known induction of miR-34a we demonstrate for the first time a regulation of miR-145 and –149 by p53 and p73. We hypothesize that regulation of tumour suppressive microRNAs represents an effector mechanism by which p53 family members exert their role in tumor development and treatment response. The observed synergistic effect of p53 and HCC-relevant therapeutics on microRNA expression might provide new options for the development of therapeutic and prognostic measures in HCC.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1313 HOW TO IMPROVE THE RELIABILITY OF LIVER FIBROSIS EVALUATION USING 2D-SWE

Introduction: Liver stiffness (LS) evaluation as a marker of fibrosis is usually considered reliable when it fulfills some quality criteria. Classic criteria used for Transient Elastography (TE) are: ≥10 valid measurements, ≥60% success rate, and interquartile range/median ratio (IQR/M) < 0.30 [1]. However, new quality criteria were proposed using the IQR/M ratio, therefore the LS measurements can be classified into three categories: very reliable (IQR/M < 0.10), reliable (0.10 < IQR/M < 0.30), poorly reliable (IQR/M > 0.30) [2].

Aims & Methods: The aim of this study was to assess the impact of using quality criteria (LS) evaluation by means of 2D-SWE. We used Stear Wave Elastography from General Electronics (2D-SWE), while using Transient Elastography (TE) as the reference. We included 226 subjects in our study, with or without chronic liver disease, in whom LS was assessed using 2D-SWE (LOGIQ E9, GE Healthcare) and TE (FibroScan, EchoSens). Reliable LS measurements were defined for TE as the median value of 10 measurements with a success rate of ≥60% and an interquartile range (IQR) < 30% of the median LS values. For 2D-SWE LS 10 LS measurements were acquired in a homogenous area and the IQR and the LS measurement were calculated in each case. We divided our subjects into 3 groups according to the 2D-SWE LS IQR/M: IQR/M < 0.10: 41 (18.1%) cases; 0.10 < IQR/M ≤ 0.30: 155 (68.6%) cases; IQR/M > 0.30: 30 (13.3%) cases. We calculated the correlation coefficient between TE and 2D-SWE LS for each group.

Results: All 226 (100%) subjects included had 10 valid measurements by means of 2D-SWE and reliable results by TE. A strong positive correlation was found between LS values obtained by means of 2D-SWE and TE in the IQR/M < 0.10 group (r = 0.84, p < 0.0001). A weak positive correlation was found between LS values obtained by means of 2D-SWE and TE in the IQR/M ≥ 0.30 groups (r = 0.38, p > 0.0001). A weak positive correlation was found between LS values obtained by means of 2D-SWE and TE in the IQR/M < 0.10 group (r = 0.84, p < 0.0001). A weak positive correlation was found between LS values obtained by means of 2D-SWE and TE in the IQR/M ≥ 0.30 groups (r = 0.38, p > 0.0001).

Conclusion: Using the IQR/M < 0.30 as quality criteria significantly increase the reliability of LS measurements by means of 2D-SWE. Using IQR/M < 0.10 criteria does significantly improve the reliability of 2D-SWE LS measurements as compared to 0.10 < IQR/M ≤ 0.30 criteria.

Introduction: UC+ methacholin breath test (13C-MBT) is used to specify the detoxification function of the liver by determination its metabolic capacity and degree of hepatocytes recovery.

Aims & Methods: The study involved 113 patients with MS aged from 37 to 82 years. Among them 61 patients were non-alcoholic fatty liver disease. There were 75 women and 38 men. The criteria, which has been examined for the functional state of the liver was 13C-MBT. The control group included 25 patients with a BMI of 25-30 kg/m2 without severe concomitant diseases. Indicators of 13C-MBT were metabolic rate, cumulative dose of UC+ methacholin on 40 and 120 minutes. Also evaluation was carried by mathematical deduction which measured the liver dysfunction stage.

Results: The data showed normal detoxification liver function in patients without MS (20.11% ± 0.55). The results were below normal in patients with BMI higher than 25 kg/m2, which indicated that there were initial changes in the functional state of liver. In patients with steatosis - cumulative dose on 120 minute was 15.12% ± 0.49, which corresponded to a moderate reduction of detoxification function with the mass of function hepatocytes 50–100%. The data of 13C-MBT in patients with steatohepatitis showed pronounced changes of the liver detoxification function (8.88 ± 0.64%). All indicators at steatosis group have indicated the moderate decline detoxification function with the level of function hepatocytes 50–100%. The data of 13C-MBT in patients with steatohepatitis showed pronounced changes of the liver detoxification function (8.88 ± 0.64%). All indicators at steatosis group have indicated the moderate decline detoxification function with the level of function hepatocytes 50–100%.

Conclusion: In assessing to the date of 13C-MBT, main attention is paid to mathematical calculation of CO2 labeled methachetin. It allows to identify the early stages of the liver detoxification function violation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1315 IDENTIFICATION OF P73 AS A NOVEL TRANSCITIVATOR OF IGFBP4 GENE EXPRESSION IN HEPATOCELLULAR CARCINOMA

Introduction: Members of the p53-family, including p53, p63 and p73, are known for their involvement in the regulation of cell cycle, cell senescence and apoptosis. In their role as transcription factors and depending on their splice variants with transactivation domain (TA) or dominant negative (DN) - p53 and its siblings are capable of activating or inhibiting the transcription of specific target genes. We previously identified the gene for Insulin-like Growth Factor Protein 4 (IGFBP4) as a potential p53-family target gene with prognostic relevance in hepatocellular carcinoma (HCC). In contrast to p53, the IGF system plays part in tissue growth and cell survival. IGFBP4 acts as inhibitor limiting IGF effects suggesting a possible interaction with p53 affairs.

Aims & Methods: The aim of this study was to characterize the regulatory influence of p53 family members on the IGFBP4 gene. Hep3B cells were transfected with p53, p63, p73, p53-DN, p63-DN and p73-DN. Transcriptional regulation of IGFBP4 was determined by real time qPCR. Intracellular and extracellular IGFBP4 protein levels were examined by Western Blotting and ELISA. Transfase database analysis was performed to identify potential p53-family binding sites in the IGFBP4 locus. Identified sequences were cloned, deleted and analyzed by lucerase reporter assays to evaluate binding of p53-family members.

Results: IGFBP4 expression was increased by more than 30-fold in TAP73-transfected Hep3B cells, by more than 10-fold in DNp63- and p73-DN-transfected cells. Induction of intracellular IGFBP4 protein was detected in all transfected Hep3B cells, whereas extracellular IGFBP4 levels were only measurable after TAP73 and DNp63 transfection. Database analysis identified 2 putative binding sites within intron 1 of the IGFBP4 gene. Intron 1-dependent luciferase activity was increased by up to 20-fold in TAP73-transfected cells. This induction was reduced by up to 70% when one of the putative binding sites was deleted.

Conclusion: These results identify the IGF inhibitor IGFBP4 as novel target gene for p53-family-mediated transcription. Results from this study allow us to suggest that p53 and IGFBP4 enhance our knowledge in a so far unknown association of p53-family network and IGF signaling. Since in an independent study we identified IGFBP2 as a novel p53-family target gene, these results highlight the link between p53-family-mediated tumor-inhibiting mechanisms and IGF receptor signaling pathways which decide on growth, cancerogenesis and treatment response.

Introduction: Liver fibrosis (LF) is a progressive pathological process resulting in accumulation of excess extracellular matrix proteins. A metalloproteinase BMP1 cleaves various matrix proteins and procollagen type I. We have recently discovered that BMP1-3 isoforms circulate in the plasma and their neutralization decreases the progression of chronic kidney disease. The role of BMP1 in liver diseases associated with fibrosis has not been investigated. Bone Morphogenetic Protein (BMP1) and mammalian tolloid (mTLD) are alternatively spliced products of the BMP1 gene that are essential for tissue patterning and ECM assembly by biosynthetic processing of a wide range of ECM precursors specifically pro-collagen type I. Therefore, a decrease in the metabolic capacity from 15 to 10% accompanied by an increase in ALT levels (more 60 mmol/l) and the portal vein size, which is 75% for steatosis, and 76% for steatohepatitis.

Results: The rate of liver metabolism based on 13C-methacetine test results in patients without NAFLD was 22.07±0.66%, in patients with steatosis -17.1±0.84%, steatohepatitis - 14.3±0.62%. Cumulative dose of methacetine on 120 minute was 20.25±0.46% in patients without pathology of liver, 16.1±0.49% in patients with steatosis, 11.4±0.36 in patients with steatohepatitis. ALT level in control group was 0.4±0.05 mmol/l, with steatosis 0.9±0.8 mmol/l, in control group of 237 patients with liver steatosis CAP index was 11.2±0.26 mm, in group of steatosis 11.9±0.21 mm, in patients with steatosis 13.7±0.15 mm. There were investigated, that the rate of metabolism and its cumulative dose on 120 minute has decreased in steatohepatitis group in comparison of the control group, with simultaneous significant increasing of ALT level and diameter of the portal vein. However, a significant reduction of the metabolism rate of methacetin and the cumulative dose of 13CO2 in the background of the increase of a diameter of vena portae compared with a group with liver steatosis in steatohepatitis group. The investigations found that in ALT and the diameter of the portal vein negatively correlated with cumulative dose of 13CO2 on 120 minute in patients with steatohepatitis. Therefore, a decrease in the metabolic capacity from 15 to 10% accompanied by an increase in ALT levels (more 60 mmol/l) and the portal vein size (13 mm).

Conclusion: The differentiation between steatosis and steatohepatitis should be moderate with the speed of a metabolism, a cumulative dose of methacetine on 120 minute, BMP1 and vena portal size. The sensitivity of the method is based on the definition of the three proposed indicators - ALT level, total concentration of 13C-methacetin on 120 minute and the portal vein size, which is 75% for steatosis, and 76% for steatohepatitis.

P1318 LIVER TRANSIENT ELASTOGRAPHY IN NON-ALCOHOLIC FATTY LIVER DISEASE: IS THERE ANY PREDICTIVE ROLE IN THE DEVELOPMENT OF COLORECTAL POLYPS?

M. Gravito-Soares1, E. Gravito-Soares2, D. Gomes1, A. Simão1, L. Tome2

Introduction: Recent studies have demonstrated an association between decreased glucose tolerance, dyslipidemia and metabolic syndrome; and increased risk of colorectal polyps. Patients with non-alcoholic fatty liver disease (NAFLD) often have these risk factors. The association between NAFLD and colorectal polyps has been poorly studied.

Aims & Methods: We aimed to evaluate the prevalence and risk factors of colorectal polyps in patients with NAFLD. This was a retrospective observational study. NAFLD patients who performed Fibroscan during the last 3 years, inflammatory were included. The exclusion criteria: age <18 years, absence of total colonoscopy with good preparation <3 years, inflammatory bowel disease, hereditary polyposis syndromes and personal/family history of colorectal polyps/neoplasia. Compared patients with colorectal polyp cases and without colorectal polyps (controls). Demographic variables, cardiovascular/metabolic risk factors, comorbidities, laboratory parameters and Fibroscan score of steatosis were compared.

Results: Of the 237 NAFLD patients who performed Fibroscan, 103 underwent total colonoscopy. The prevalence of colorectal polyps was 28.2%(n=29): 19.4%(20/103) hyperplastic, 16.5%(17/103) adenoma and 4.8%(5/103) advanced adenoma/adenocarcinoma. The mean age was 58.3±5.1 years (vs 57.09±10.53, p=0.008), with men predominant (51.7% vs 63.5%; p=0.272), mostly located in the left colon (55.2% vs 44.8%; p=0.314) and number and mean size of 1.46±0.88 and 6.89±6.56 mm, respectively. After multivariate logistic regression analysis colorectal polyps were associated with F4 liver fibrosis (34.5% vs 14.9%; p=0.026; OR=3.10) and obesity (BMI > 30kg/m2): 55.2% vs 29.7%; p=0.016; OR=2.91); hyperplastic polyps were associated with liver fibrosis for a cut off value of 6.9KPa (AUROC 0.689±0.008; S=85.7%; Sp=51.2%); mainly F4 (42.8%±14.6%; p=0.004; OR=4.38), hyperuricemia/gout (23.8%±8.5%; p=0.042; OR=3.35) and peptic ulcer disease (9.5% vs 1.2%); p=0.043; OR=8.53); adenoma was associated with liver steatosis (88.2%±83.7%; p=0.024; OR=3.50), F4 liver fibrosis (41.2%±16.2%; p=0.004; OR=3.248) and obesity (58.8%±32.6%; p=0.040; OR=2.96), advanced adenoma/adenocarcinoma was associated with F4 fibrosis (20.0%±5.2%; p=0.012; OR=1.224), hyperuricemia/gout (40.0%±10.3%; p=0.040; OR=1.50) and dilated cardiomyopathy (20.0%±4.1%; p=0.003; OR=1.24).

Conclusion: More than 1/4 of the patients with NAFLD have colorectal polyps, being 16.5% adenoma and 4.8% advanced adenoma/adenocarcinoma. Obesity and liver steatosis are independent risk factors for colorectal adenoma. Liver fibrosis, especially F4 is an independent risk factor for all types of colorectal polyps.

Contact E-mail Address: atakiyak@gmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common clinicopathological condition which may progress from simple steatosis to NASH, cirrhosis and hepatocellular carcinoma (HCC). Although obesity is accepted as the main risk factor for NAFLD, non-obese individuals are often diagnosed with NAFLD suggesting that high BMI may not be "a sine qua non" for the presence of NAFLD. Recent studies suggested that there might be a correlation between weight gain and metabolic diseases.

Aims & Methods: In our research, the relationship between NAFLD in non-obese individuals and the amount of weight gain during adulthood was investigated and a new index that is different from BMI was proposed. 362 individuals were included in the survey. The subjects were selected among patients who had abdominal ultrasoundography (USG) in our clinic, during the last 6 months. A 5% increase in echogenicity detected in the USG was defined as the diagnostic between the HP level in liver, morphometric analysis and elastography of the liver.

Conclusion: Our results suggest that neutralization of BMP1-3 is a promising therapeutic approach in preventing the liver fibrosis progression.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: Among 362 participants 169(46.7%) were men with an average age of 44.81±10.73. 78 (21.6%) participants were women, the average age of the group being 46.78±9.12. Out of 78 obese individuals 73 (93.5%) were NAFLD (+). The average age of the 284(78.4%) non-obese subjects was 48.07±10.13 while among those with NAFLD (−) people was 38.7±10.0.4. Non-obese NAFLD (+) patients reported they had gained significant amount of weight during their adulthood. This information led us to create, a new index named “Subtracted Adulthood Mass Index” (SAMI) to estimate the risk of NAFLD development in non-obese individuals. SAMI is calculated by dividing the difference between the subject’s current weight and his/her weight at the age of 20 years to his/her height squared (kg/m²). SAMI values for non-obese attendants were calculated. When the cut-off value was set as SAMI ≥4 kg/m², sensitivity was 76.3%, specificity was 79.1, positive predictive value (PPV) was 84.3% and negative predictive value (NPV) was 69.4%. At a cut-off of SAMI ≥3 kg/m² sensitivity was 85.2%, specificity was 66.9%, PPV was 79.1%, NPV was 75.4%.

Conclusion: In this pilot study, we found that weight gain in adulthood is an important predictor of NAFLD development in non-obese individuals. The new index named SAMI can correctly identify non-obese people under the risk of developing NAFLD. Cut-off value of SAMI has been set as ≥3 kg/m². We also observed that NAFLD prevalence increases as SAMI value goes up. We propose that SAMI is appropriate for clinical use to estimate the risk of NAFLD in obese individuals.

Disclosure of Interest: All authors have declared no conflicts of interest.

Mori6 1Department Of Hepatobiliary And Pancreatology, Saga-Ken Medical Centre Koseikan, Saga; Japan 2Department Of Clinical Laboratory, Saga-ken Medical Centre Koseikan, Saga; Japan 3Department Of Nursing, Saga-Ken Medical Centre Koseikan, Saga; Japan

Contact E-mail Address: kawaguchi222@gmail.com

Introduction: Recent studies have shown that the single nucleotide polymorphism (SNP) rs738409 in the PNPLA3 gene is strongly associated with severity of nonalcoholic fatty liver disease (NAFLD). However, the traditional direct sequencing (DS) method is time-consuming and labor-intensive. The i-densy™ (ARKRAY, Inc.), which is based on the quenching probe (QP) method, automatically detects target genes in blood samples by fluorescence quenching within 90 min.3

Aims & Methods: The current study compared the QP and DS methods for detecting SNPs in the PNPLA3 gene, and established the impact of the genotype on prognosis of NAFLD. We enrolled 107 patients with fatty liver irrespective of etiology. We used the i-densy fully automated genotyping system with QP. The requisite number of tips, reaction tubes, reagent packs and blood samples were set in their designated places. The forward and reverse polymerase chain reaction (PCR) primers and guanine QP were 5’-cttctctctcctttgctttcacag-3’, 5’-gtgtgagca- and guanine QP were 5’-cttctctctcctttgctttcacag-3’, 5’-gtgtgagca-

Results: The genotypes obtained with the QP method were identical to those obtained with the conventional DS method. Then, we analyzed 73 patients with NAFLD according to the PNPLA3 genotype in terms of alanine aminotransferase (ALT), aspartate aminotransferase to platelet ratio index (APRI), Fibroscan value, and cumulative hepatocellular carcinoma (HCC) development rate.

Conclusion: The i-densy™ system can be used for genotyping with QP, which is simple and fast compared with the conventional DS method. We suggest that the QP method is useful for the accurate and fast diagnosis of NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Wilson disease.

Our analysis of long-term Cu exposure presents new insights in copper metabolism and suggests a new role of MDR1 in the pathogenesis of Wilson's disease (WD). Symptoms of WD are i.e. elevated Cu accumulation in liver and loss of function results in the inherited autosomal recessive disorder Wilson Disease (WD). Symptoms of WD are typically seen in children and young adults. 

Aims & Methods: We aimed to examine the efficacy of orlistat versus placebo in reducing liver fat content by the magnetic resonance imaging (MRI) based on chemical shift imaging. A total of 51 NAFLD patients diagnosed by MRI were randomized and to receive twice-daily 120mg oral orlistat or placebo for 6 months, among them 30 (14 in the Orlistat group and 16 in the placebo group) were included in the interim analysis. Both groups received. Clinical parameters, laboratory tests and liver fat content were measured at baseline and 6 months including body mass index (BMI), waist hip ratio (WHR), liver enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), fasting plasma insulin (FPI), homeostasis model assessment IR (HOMA-IR). The primary outcome was a change in liver fat quantified by MRI which is based on Dixon technique with two-point chemical shift-based fat-water separation method[1].

Results: As compared to placebo, end-of-treatment liver fat content was significantly lower in the Orlistat arm (19.38% ± 9.52% to 11.56% ± 7.49%), change was 7.72 ± 0.63% (P = 0.001) but not in the placebo (16.05% ± 8.7% to 14.17% ± 9.58%, change was 1.43 ± 9.54%, P = 0.640). Change of BMI was the only independent factors correlated with reduction of liver fat content (β = 0.522, p = 0.006).

Conclusion: Orlistat did significantly decrease liver fat in NAFLD patients via its effect of lowering weight.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1323 LONG-TERM COPPER EXPOSURE OF HEPATIC CELLS LACKING FUNCTIONAL ATP7B

Transplantationsklinik, Universitätsschulkrankenhaus Halle/Saale/Alexander-von-Humboldt University of Halle/Wittenberg

Contact E-mail Address: guttmann.sarah@ukum.de

Introduction: Copper transporter ATP7B is essential for hepatic Cu homeostasis and loss of function results in the inherited autosomal recessive disorder Wilson Disease (WD). Symptoms of WD are i.e. elevated Cu accumulation in liver and brain. Understanding of molecular mechanisms involved in Cu homeostasis is essential to improve therapeutic options. The molecular impact following long-term elevated Cu in hepatic cells lacking functional ATP7B has not been explored.

Aims & Methods: HepG2 cells lacking functional ATP7B (KO) were used for generation of a copper resistant subline (CuR). Cell growth, cell viability (MTT) and intracellular Cu load (atomic absorption spectroscopy) was assessed. RT-qPCR was performed to quantify the expression of genes related to Cu homeostasis. Functional analysis of candidate genes was assessed via siRNA transfection. Additional measurements of CuT1 expression was performed by flow cytometry (FACS) and Western Blot.

Results: KO cells can survive for many months in the presence of high Cu and gain resistance (CuR). Characterization of CuR cells revealed increased survival up to 12-fold compared to control, whereas a high intracellular Cu accumulation was noticed. Once Cu resistance was established, the termination of Cu exposure did not result in the loss of resistance indicating a stable modulation of the cells. Two genes involved in Cu homeostasis displayed an altered expression pattern (upregulation of MT1 and downregulation of CTR1 by 28.1 ± 2.5 fold and −3.2 ± 0.4 fold, respectively) which was however transient and dependent on Cu exposure. The role of MDR1 which presented a stable modulation was further investigated by siRNA and drug activation (verapamil). Notably, cell viability and intracellular Cu load was not significantly affected indicating that MDR1 is involved in Cu homeostasis. In addition, hepatic cells derived from a WD patient and from the rat animal model confirmed our observations.

Conclusion: Our analysis of long-term Cu exposure presents new insights in copper metabolism and suggests a new role of MDR1 in the pathogenesis of Wilson disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

2Surgery Department, Santa Casa School of Medical Sciences, São Paulo/Brazil

Contact E-mail Address: thasicione@hotmail.com

Introduction: Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are increasingly common cause of chronic liver diseases worldwide. Most patients with severe obesity who undergo bariatric surgery have NAFLD, which is associated insulin resistance, type 2 diabetes mellitus, hypertension, and obesity-related dyslipidemia. Identifying significant fibrosis in patients is crucial to evaluating prognosis and possible therapeutic interventions. Currently, liver biopsy is the gold standard for diagnosis of liver fibrosis.

Aims & Methods: We aimed to evaluate the NAFLD fibrosis score for the assessment of significant fibrosis in patients with morbid obesity before undergoing bariatric surgery. A total of 69 NAFLD patients (median BMI 47 kg/m2) were prospectively enrolled from June 2015 to November 2016 at one Brazilian university hospital. All patients were evaluated with routine laboratory before bariatric surgery. Age, body mass index, hyperglycemia, platelet count, albumin and AST/ALT ratio were applied to the score formula. Biopsies were interpreted by a single experienced pathologist. NAFLD and fibrosis were classified according to the NASH Clinical Research Network NAFLD activity score. 

Results: The NAFLD fibrosis score for identification of significant fibrosis was 58.9%. Using modified thresholds, the specificity could increase. For predicting significant fibrosis, for a cut-off of 1.05, the score had 46.15% sensitivity and 96.43% specificity with AUROC of 0.74.

Conclusion: The nonalcoholic fatty liver disease fibrosis score has good accuracy to identify significant fibrosis in morbidly obese patients subjected to bariatric surgery.

P1325 COMPARISON OF FIBROSCAN® AND FATTY LIVER INDEX (FLI) TO SCREEN FOR FATTY LIVER DISEASE IN A LARGE COHORT OF EMPLOYEES: WHERE IS THE OPTIMAL CUT OFF?

M. Teufelhart, C. Rabitsch, B. Mehl, R. Winker, B. Meyer, T. Scherer

Health And Prevention Center, Sanatorium Hera, Vienna/Austria

Contact E-mail Address: manuela.teufelhart@hera.co.at

Introduction: FLI was developed as an alternative to the score of steatosis (Bedogni et al.,2006) and a cut-off value ≥60 ruled in (positive likelihood ratio [LR+] 4.3) steatosis in Italians diagnosed with ultrasound. Fibroscan®CAP is more sensitive for the diagnosis of steatosis than ultrasound. Aim of this study is to evaluate the use of Fibroscan® in comparison with FLI to screen for fatty liver disease in Austrian bank employees and to recalculate optimal FLI cut-off values.

Methods: More than 1000 Austrian bank employees will be screened for liver diseases with Fibroscan®. A kPa value ≥7.9 (M-probe) and ≥7.2 (XL-probe) is categorized as fibrosis. Additionally Fibroscan®CAP with a cut-off value ≥248 dB/m is defined as steatosis, ≥500 dB/m as high-grade steatosis. Heavy drinkers are identified with AUDIT and SIAC questionnaires. Weekly alcohol consumption and inactivity increases the LR and sensitivity, respectively. An additional consideration of physical activity level in the current cohort revealed that inactivity increases the LR of FLI values to predict NAFLD (trendwise significant, p = 0.051), indicating lower cut-off values.

Disclosure of Interest: All authors have declared no conflict of interest.

References:
Conclusion: We conclude that Fibroscan® represents an eligible tool to diagnose liver diseases in Austrian bank employees. Compared to the previous work of Bedogni et al FLI predicts fatty liver at a lower cut-off level, at least for the examined population. This difference might be due to the fact that FibroScan®CAP is more sensitive than ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is an affection with increasingly prevalence worldwide, having an important impact on morbidity and mortality, especially when it associated severe fibrosis.

Aims & Method: We aimed to assess the metabolites that are associated with fibrosis stages in NAFLD, using metabolic method. A total of 40 patients were included in the study, 30 diagnosed with nonalcoholic fatty liver disease (NAFLD) and 10 controls. Steatosis and fibrosis were assessed using Fibromax elaborated by Biopredictive (R) (Paris, France). New metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA)) were used to identify final products of various metabolic pathways correlated with liver fibrosis.

Results: Of the 30 patients with NAFLD included in the study, 6 patients (20%) had severe fibrosis. The metabolomic profile identified four metabolites that are significantly associated with steatosis and steatohepatitis. The determination of NAFLD clinical forms is a priority in the prevention of further disease and choice of treatment. Steatohepatitis is the active form of NAFLD and progresses to fibrosis often with subsequent liver parenchyma degeneration into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Introduction: Chronic renal failure (CRF) is frequently associated bone metabolism and osteoporosis with lowered levels of Vitamin D and/or hyperparathyroidism particular in case of hemodialysis. Younger studies suggest an association of low vitamin D levels with non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH), as well as metabolic syndrome, and diabetes mellitus. Unfortunately, a causality could not yet be proven.

Aims & Methods: Our aim was to identify patients on higher risk to develop NAFLD/NASH in a selected patient cohort being admitted for renal disorders. 176 patients, admitted to the department of nephrology of the University Hospital Marburg for renal disorders whose plasma vitamin D concentration, phosphate and parathormone levels and liver enzyme levels had been quantified beforehand, were enrolled and a retrospective investigation of laboratory parameters (including electrolytes, hormones, and vitamins) and pre-existing medical conditions (including high blood pressure, diabetes, hyperlipoproteinemia, and more) followed. Appropriate statistical tests were used to characterise the cohort (ANOVA; MANN-Whitney-U; FISHER-EXACT) using SPSS TM. Other hepatothepies were excluded. Steatosis was assessed by ultrasonography.

Results: Patients were divided into 4 groups according to plasma vitamin D levels (normal > 25 ng/ml; low < 25 ng/ml) and transaminase levels (AST/ALT > GT > 30 U/l; normal: AST/ALT > GT < 30 U/l). Low 1,25-hydroxyvitamin D levels correlated significantly with high creatinine, urea, and LDL levels, while low 25-hydroxyvitamin D levels correlated with high cholesterol and triglyceride levels, suggesting a relationship between low vitamin D levels and fat metabolism disorders. Interestingly end stage renal failure (chronic hemodialysis) was significantly correlated with the development of NAFLD/NASH with significantly higher levels of AST/ALT and gGT. hyperparathyroidism and hyperphosphatemia Transaminases were significantly lower if Vitamin D was supplemented.

Conclusion: Vitamin D deficiency is often present in patients with kidney diseases such as chronic renal failure. Vitamin D levels are correlated to age and sex of the patient. Patients suffering from renal failure are on high risk developing NAFLD/NASH if diminished vitamin D levels are present. Supplement of Vitamin D saves from NAFLD/NASH. The correlation of hyperparathyroidism and NAFLD/NASH has to be further investigated in larger patient groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

platelet count were evaluated as predictors of high-risk varices. Overall 74/184 (40%) met the new “BAVElastPQ” criteria (that is, liver stiffness <12 kPa and platelet count >150,000/μl). Within this group 11/63 (17%) had any grade of varices and only 1/73 (1%) had high risk varices. The BAVElastPQ criteria gave sensitivity of 0.95, specificity of 0.44, a positive predictive value of 0.516 and a negative predictive value of 0.98. The AUROC for liver stiffness and platelet count was 0.81 and 0.76, respectively.

Conclusion: The BAVElastPQ criteria correctly identified 99% of patients with- out high-risk varices. By applying such criteria we could have potentially avoided 40% surveillance endoscopies in our cohort. To our knowledge this is the first study that evaluated the potential role of a new p-SWE technique such as ElasPQ in the non-invasive assessment of clinically significant portal hyperten- sion, similarly proposed Baveno VI criteria though using ElasPQ as an alternative to transient elastography.

Introduction: Inhibitors of the proton pump inhibitors (PPI) are commonly prescribed and predis- pose to small bowel bacterial overgrowth. Hepatic encephalopathy is a frequent complication of cirrhosis and is associated with intestinal dysbiosis.

Aims & Methods: This study aimed to identify a possible association between PPI intake and hepatic encephalopathy development in cirrhotic patients. Retrospective analysis of consecutive cirrhotic patients hospitalized in two Gastroenterology Departments over 3.5 years. Collection of clinical data, PPI intake, and the prompt administration of treatment; the intrinsic virulence or pathogeni-

Results: 386 patients, 321 males (83.2%), mean age 60.3 ± 12.1 years. Main etiol-

calities of cirrhosis were alcohol (67.4%), alcohol plus hepatitis C Virus (16.3%)
and hepatitis B virus (5.2%). Hepatic encephalopathy was present in 222 (57.5%)
of the patients and 26.9% had PPI intake. In univariate analysis hepatic ence-

tion of symptomatic side effects in patients taking statins are genuinely caused by the drug? Systematic review of randomized placebo-controlled trials to aid indi-

Abridals JG, Rodriguez-Villarrupla A, Graupera M, et al. Simvastatin- tin treat-

ment improves liver sinusoidal endothelial dysfunction in CCl4 cirrhotic rats. J

Aims & Methods: The objective of this research was to perform a meta-analysis of randomized control trials (RCTs) and determine if statin therapy reduces portal hypertension as measured by the hepatic venous pressure gradient (HVPG) among adult patients with liver cirrhosis.

Results: Three trials comprising of 98 patients met the inclusion criteria. In the random-effect model, the weighted mean difference was 0.76 mmHg, favoring statin therapy over placebo. There was no evidence of significant heterogeneity (I² = 0%, p = 0.51).

Conclusion: Statin therapy reduces portal hypertension as measured by the HVPG among adult patients with liver cirrhosis. The findings of this study reinforce the promising role of statins in decreasing portal hypertension. Further RCTs with larger population and with longer duration of follow-up as well as the use of different statin drugs to explore further on the class effect are recommended.

Introduction: The place of non-invasive techniques for the prediction of presence of portal hypertension in patients with liver cirrhosis is one of the current research topics.

Aims & Methods: The aim of this study was to evaluate the applicability of the Baveno VI criteria in a cohort of known compensated HCV liver cirrhosis patients, to see how often we misclassify the presence of esophageal varices (EV).

Material and method: We did a prospective multicentre study, from September 1st to December 31st, 2016, which included all patients with perfectly compensated HCV liver cirrhosis, diagnosed by means of elastography, ultrasound, endoscopic and biological criteria prior to interferon-free treatment. All patients were evaluated by upper gastrointestinal endoscopy, transient elastography (TE), and a Stroop test. By using these criteria we classified the patients in: probably without EV (liver stiffness: LS < 20 kPa and thrombocytes > 150,000/mm3), probably with EV (LS ≥ 25 kPa) and the "gray zone" in between these criteria.

Results: Out of 403 patients, 127 (30.7%) had LS < 20 kPa, 89 (22%) had LS between 20–25 kPa, 190 (47.3%) had LS > 25 kPa, 120 (29.7%) had thrombocytes > 150,000/mm3, while 283 (70.3%) had thrombocytes < 150,000/mm3. For the subgroup probably with EV, the Baveno VI criteria had PPV = 84.6% (Se = 90.7%, Sp = 74.6%, NPV = 26.8%) for predicting the presence of esophageal varices (EV), while for the subgroup probably without EV had NPV = 80.3% (Se = 50.2%, Sp = 58.6%, PPV = 75.6%). The subgroup that had LS < 20 kPa and thrombocytes > 150,000/mm3, was compound of 60 patients. Using these criteria 38% of patients, with a Se > 80%, Sp = 28.3%, PPV = 50%, NPV = 61.2%, AUROC = 0.70, CI = 0.68-1.73. The best cut-off value for TE for predicting the presence of EV of any grade in our group was > 23 kPa. AUROC 0.79 (Se = 68.8%, Sp = 56.9%, PPV = 44.7%, NPV = 78.4%).

Conclusion: By using the Baveno VI criteria in patients with liver cirrhosis for the prediction of presence of esophageal varices, we can misclassify only 20% of patients.

Introduction: Non-invasive fibrosis scores (NIFs) are increasingly replacing liver biopsy (LB) for estimation of liver fibrosis in patients with chronic liver disease (CLD), and is associated with a good diagnostic accuracy. However, NIFs have been shown to help in non-invasive screening of patients at high risk for development of esophageal varices and decompenstation after antiviral treatment. Application of these simple scores may help in non-invasive screening of patients at high risk for development of esophageal varices and decompenstation after antiviral treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1337 A SMART APPROACH TO THE DIAGNOSIS OF MINIMAL HEPATIC ENCEPHALOPATHY

T. Nuzum1, M. Hussey1, T. Khanna1, E. Macgregor2, J. Olanjii3, C. Tersaruolo1, K. Colletti1, D. Brelsta1, D. Menanam6

3Gastroenterology Trinity Academic Gastroenterology Group (T A G G), AMNCH, Tallaght, Dublin/Ireland

Contact E-mail Address: tatiana.nuzum@amnch.ie

Introduction: Minimal Hepatic Encephalopathy (MHE) is present in more than 30% of patients with chronic liver disease (CLD) and is associated with a higher risk of mortality and hospitalization. No single test is currently available as a current gold standard, the psychometric hepatic encephalopathy score (PHES), has a positive predictive value of 40% and a negative predictive value of 90% for predicting MHE. The detection of MHE is often difficult due to time constraints associated with the current gold standard, the psychometric hepatic encephalopathy score (PHES), which has a positive predictive value of 40% and a negative predictive value of 90%. Our aim was to develop a diagnostic tool that could help in the non-invasive screening of patients at high risk for development of MHE.

Aims & Methods: We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each patient performed the PHES test and the Stroop test. Outcomes included the time taken to perform each PHES test as well as the total PHES, the Stroop on-off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using spss, and a cut-off defined by the AUROCs for predicting off-time (AUROC = 0.808) and EV (AUROC = 0.885) and with FIB-4 score for decomposition (AUROC = 0.854). At a cut of 1200 PSI had sensitivity of 87.2% and specificity of 73% for predicting cirrhosis and at a cut of 1100 PSI had sensitivity of 85% and specificity of 88% for MHE. A cut of 2.5, FIB-4 had a sensitivity of 82.5% and specificity of 80.1% in predicting decomposition.

Conclusion: CRBP’s predict cirrhosis and development of esophageal varices with high accuracy. Some of the blood derived NIFs have high accuracy in predicting decomposition post antiviral treatment. Application of these simple scores may help in non-invasive screening of patients at high risk for development of esophageal varices and decompenstation after antiviral treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: A total of 96 patients (51 males) were recruited. Overall, the mean age was 51±7.6 years; mean years spent in education 13.8±4.2. In all there were 35 CLD and 61 healthy controls. While there was no difference in age or years spent in education, there were more men in the CLD group compared to the controls, 23/35 (66%) vs. 28/61 (46%), p=0.06. Within the CLD cohort, 30 (86%) patients were Child-Pugh class A, 4 (11%) were class B and 1 (3%) was class C. As expected, more CLD patients had a positive PHES, 4/35 (11%) vs. 3/61 (5%). Overall, correlation between the two tests was poor, 7 (7%) participants had a positive PHES, while 47 (49%) had a positive Stroop test (k =0.1516). Among controls, 27 (44%) had a positive Stroop test, while 3 (5%) had a positive PHES (k = 0.1223). Similarly, 20 (57%) CLD patients had a positive Stroop test and 4 (11%) had a positive PHES (k = 0.1765). Regarding the Stroop test, the mean time taken to complete 5 correct runs was significantly higher in CLD patients, mean 117.9 s [58.5-217.8 s] vs. 101.2 s [55.3-218.6 s], p=0.02. However, mean Stroop on-off time was similar, 195 s [102.6-307.7 s] in the CLD cohort versus 187.9 s [101.2-420.9 s] in the control group. On note, CLD patients with a positive PHES had a significantly higher Stroop on-off time compared to those with a negative PHES, mean 260 s vs. 190 s, p=0.02. However, mean Stroop on-off time gave a Stroop on-off time > 187.5 s as a positive cut-off for our cohort, sensitivity = 100%, specificity = 59%. In total, 39 patients had an on-off time > 187.5 s, 38 (97%) had a positive Stroop test (k = 0.322), 2 fewer false positives, in the CLD group, and a slightly better correlation (k =0.2044). On average, PHES took 20 minutes to complete, and the Stroop test 5 minutes. Older age and limited years of education correlated with a poorer performance on the Stroop test (r =0.62, p<0.0001) and r = 0.322, p< 0.0001, respectively. However, neither age nor years of education correlated with performance on the PHES (r = 0.087, r = 0.12, respectively).
Multispecies Probiotic Enriches the Microbiome with Lactobacillus and Lactococcus and Reduces Enterococcus Abundance in Patients with Cirrhosis: Results of a Randomized, Double-Blind, Placebo-Controlled Trial

A. Horvath1, M. Durdevic2, B. Leber3, B. Schmerboeck3, F. Rainer1, A. Eshraghian

Introduction: Cirrhosis is accompanied by significant changes of the intestinal microbiome including the overgrowth of the intestine with potential pathogens that can translocate through a weakened gut barrier and cause severe infections. We hypothesized that probiotic bacteria repress intestinal pathogen growth and strengthen the gut barrier.

Aims & Methods: Therefore, we conducted a randomized, double-blind, placebo-controlled study to test the effects of the multispecies probiotic Ecobicrur Barier (Winclove, Amsterdam, The Netherlands)/Omniibiotic Hetox (Allergosan, Graz, Austria) on microbiome composition, predicted metagenome functions, and tight junction function in cirrhosis patients. A once daily dose of the probiotic mixture (1.5×10^10 CFU) or placebo was administered to 58 patients with Child’s A cirrhosis. We analysed the stool microbiome prior, immediately after the intervention and six months following end of treatment. Hypervariable region 1–2 of the bacterial 16S rDNA was sequenced and predictive communities were identified using Ada Boost Classifier. Functional predictions were analysed by Phylogenetic Investigations of Communities by Reconstruction of unobserved States (PICRUSt). Zonulin and calprotectin were assessed in stool as markers for gut permeability and intestinal inflammation, respectively.

Results: A community of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: Lactobacillus brevis and Lactococcus lactis increased significantly and Enterococcus durans decreased significantly in the probiotic group. Zonulin normalized in 20% of patients in the probiotic group. Predicted metagenome functions (assessed by PICRUSt) and calprotectin did not show any differences during intervention.

Conclusion: In conclusion, a six months intervention with a multispecies probiotic enriched the microbiome of cirrhotic patients with probiotic bacteria. Additionally, the abundance of Enterococcus durans was reduced and the gut barrier was strengthened.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1338 MULTISPECIES PROBIOTIC ENRICHES THE MICROBIOME WITH LACTOBACILLUS AND LACTOCoccus AND REDUCES ENTEROCoccus ABUNDANCE IN PATIENTS WITH LIVER CIRRHOSIS: RESULTS OF A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

Introduction: Diabetes mellitus (DM) is a growing disease worldwide. Some previous studies have reported negative impact of DM in patients with chronic liver disease.

Aims & Methods: This study aimed to investigate the prevalence of DM in patients with liver cirrhosis and its impact on post-liver transplant short-term and long-term outcomes. In a cross-sectional study patients with liver cirrhosis on liver transplant waiting list who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Clinical and laboratory data of patients were recorded and patients were followed during post-liver transplant period. DM was diagnosed if the patient had fasting plasma glucose (FPG) ≥126 mg/dL or random plasma glucose ≥200 mg/dL in 2 different checkings or receiving anti-diabetic medications. The impact of DM on post-transplant outcomes was investigated using student t-test and chi-square test. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

Results: 1014 patients were included in the study. 259 patients (25.5%) found to have DM. Prevalence of DM was significantly higher among patients with cirrhosis due to non-alcoholic steatohepatitis (NASH) (P < 0.001). Portal vein thrombosis (PVT) was significantly higher among cirrhotic patients with DM (OR = 1.79; 95% CI: 1.18–2.70; P = 0.005). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05).
Without diabetes 90.6%
with and without DM

Table: Post-transplant survival at 6 months, 1 year and 4 years in patients with and without DM

<table>
<thead>
<tr>
<th></th>
<th>6 month survival</th>
<th>1 year survival</th>
<th>4 year survival</th>
</tr>
</thead>
<tbody>
<tr>
<td>With diabetes</td>
<td>81% ± 2.5%</td>
<td>79.1% ± 2.6%</td>
<td>75.9% ± 2.8%</td>
</tr>
<tr>
<td>Without diabetes</td>
<td>90.6% ± 1.1%</td>
<td>87.8% ± 1.2%</td>
<td>85.4% ± 1.3%</td>

P1340 VALIDATION OF THE BAVENO VI CRITERIA ON A COHORT OF CIRRHOTIC PATIENTS
L.M. Ratini, R. Lupusoru, N. Baltes, C. Pienar, I. Sporea
1 Department Of Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania
2 Gastroenterology, Pediatrics, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania

Contact E-mail Address: ratiu_julie@yahoo.com

Introduction: The Baveno VI guidelines propose that cirrhotic patients with a liver stiffness measurement (LS) < 20 kPa and a platelet count > 150,000/L can avoid screening endoscopy as their combination is highly specific for excluding clinically significant varices.

Aims & Methods: The aim of the study was to validate the Baveno VI criteria.

We did a retrospective study, from 2009–2014. We took all the patients with transient elastography data. Inclusion criteria were a LS < 12 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of chronic liver disease. Varices were graded as low risk (grade < 2) or high risk (grade ≥ 2).

Results: The study included 774 patients (hepatitis C virus 40.5%, hepatitis B virus 16.1%, 31.6% etanolics, 11.8% other etiology, and 47.5% were Child Pugh C). We represent in 361/774 (24.4%) of patients a high risk varices. 306/774 (39.6%) at low risk and 468/774 (60.4%) had high risk varices. 59/774 (7.6%) met the Baveno VI criteria. The Baveno VI criteria gave a Se = 62.2%, Sp = 80.6%, NPV = 44.6%, PPV = 89.5%, positive likelihood ratio = 3.4, negative likelihood ratio = 0.47. If we combined the LS < 20 kPa and platelet count > 150,000, the AUROC was 0.73, CI (0.68-0.74), p < 0.0001. Using an ICD-9 code indicating ALI we included. The primary outcome was ALI in patients with a history of bariatric surgery compared to all other patients with an acute liver injury and were included in the study, of which 3,799 had previously undergone bariatric surgery.

Conclusion: The Baveno VI criteria has correctly appoint 85.3% of patients who could safely avoid endoscopy.

P1341 MORTALITY PREDICTING MODEL IN LIVER CIRRHOSIS PATIENTS
1 Department Of Gastroenterology And Hepatology, Victor Babes University of Medicine and Pharmacy Timisoara, Timisoara/Romania

Contact E-mail Address: raluca_lupusoru@yahoo.ro

Introduction: Cirrhotic patients very often need to be hospitalized and it is known that they have a higher mortality rate than non-cirrhotic patients. In our study, we have evaluated the mortality risk associated with liver cirrhosis and in 5% of cases the etiology was unknown.

Aims & Methods: The aim of the study was to assess the factors associated with mortality among cirrhotic patients and to create a new score for predicting mortality. The study was retrospective, and we included all hospitalized patients with the final diagnosis of liver cirrhosis for a period of 7 years. We divided them in two cohorts, an initial group, which was analysed; and a control group, in which we validated the score. We performed univariate and multivariate analysis in order to determine a prediction model for mortality.

Results: A total of 1163 cirrhotic patients were included. In-hospital mortality rate was 10%. The initial cohort included 899 patients. Regarding cirrhosis etiology: 384/899 (42%) had hepatitis C, 158/899 (17.5%) had hepatitis B, 293/899 (32.5%) were alcoholic, 6/899 (0.6%) were autoimmune, 7/899 (0.7%) were cardiac, 13/899 (1.4%) were premalignant; liver cirrhosis and in 5% of cases the etiology was unknown.

In univariate analysis, hypoalbuminaemia (p < 0.0001), hypertension (p < 0.0001), hyperpotassemia (p < 0.0001), high values of bilirubin (p < 0.0001), high values of creatinin (p < 0.0001) were strongly associated with in hospital mortality. In multivariate analysis, the model including albumin, sodium, potassium, creatinin and bilirubin (all p-values < 0.05) had an AUROC of 0.78, CI (0.75-0.81), p < 0.0001. Using this factors as predictors, by multiple regression analysis we obtained in the initial group the following score: ABCPS score = 0.04 + 0.03*Albumin + 0.05 + 0.02*Creatinin + 0.04*Bilirubin + 0.05 + 0.28*Potassium + 0.04*0.07*Sodium.

Conclusion: Prevention and prompt treatment of kidney injury, hypoalbuminaemia, hyperpotassemia, can improve survival.

Aim of the study was to validate the Baveno VI criteria.

3. Friedel-Rust M, Buggisch P, de Knegt RJ, et al. Acoustic radiation force impulse imaging measures liver stiffness (LS), which significantly correlates with the stage of liver fibrosis in treatment-naïve patients with chronic hepatitis B (CHB). So far, the use of ARFI elastography to monitor change in liver fibrosis has not been properly evaluated during antiviral therapy in CHB patients. Aims & Methods: We aimed to prospectively assess the clinical usefulness of ARFI during long-term antiviral therapy in CHB patients. Seventy-one CHB patients were consecutively recruited and received antiviral therapy with entecavir. Paired liver biopsies were performed in 27 patients at baseline and week 78 of entecavir therapy. LS was assessed by ARFI at multiple follow-up sessions. Results: LS significantly decreased with treatment and continued to decrease after normalization of alanine aminotransferase. Overall, 97.2% patients achieved improvement of LS, whereas 19.7% patients had more than 30% reduction in LS values between baseline and week 104. Multivariate linear regression analysis showed that the degree of LS reduction significantly correlated with the baseline levels of LS value, platelet and cholinesterase. In the 27 patients who received paired liver biopsies, LS significantly correlated with stage of fibrosis and inflammatory grade at baseline. LS values decreased more significantly in patients with fibrosis regression than those with static histological fibrosis. Changes in LS value (change threshold =15%) was significantly correlated with the changes in histological fibrosis staging (r =0.63, P < 0.001). Conclusion: In CHB patients, LS assessed by ARFI was significantly reduced during antiviral therapy. Longitudinal monitoring of LS might be a promising non-invasive assessment of fibrosis regression during long-term antiviral therapy in CHB. Further studies on large populations are warranted. Disclosure of Interest: All authors have declared no conflicts of interest.

PI344 CHRONIC HEPATITIS B VIRUS INACTIVE CARRIERS—IMPACT OF METABOLIC DISORDERS IN STEATOSIS ASSESSED BY FIBROSCAN

Introduction: In chronic infection with Hepatitis B virus (HBV) hepatic steatosis is mainly attributable to metabolic risk factors, rather than virologic factors. We aimed to assess the presence of hepatic steatosis in chronic HBV inactive carriers using non-invasive methods, namely controlled attenuation parameter (CAP) and transient elastography with fibroscan. We also aimed to identify hepatic steatosis and their impact in the values of fibrosis determined with fibroscan.
Aims & Methods: Fibroscan was performed in chronic HBV inactive carriers, assessment of hepatic transient elastography and CAP, with simultaneous assessment of anthropometric, clinical and analytical parameters. CAP values of 248.28 and 280 dB/m defined cut-offs of steatosis grade I, II and III, respectively. Results: Included 49 patients with a mean transient elastography of 5.1 ±1.5 Kpa and a mean CAP of 248.9 ±49.3 dB/m. A significant association was found between the value of the CAP and the presence of steatosis in the last ultrasound (248.9 ±46.9 dB/m vs p < 0.01), the presence of steatosis at CAP >268 dB/m (p < 0.01). The percentage of patients with values of triglycerides (239.9 ±49.3 dB/m vs 284.1 ±28.1 dB/m, p = 0.01) and obesity (240.0 ±46.7 dB/m vs 290.7 ±46.6 dB/m, p = 0.01). When comparing patients with CAP > 268 dB/m, patients with higher CAP values more frequently were overweight (BMI >25 kg/m²) (45.8% vs 84.0%, p < 0.01) and had metabolic syndrome (MS) (12.5% vs 40%, p < 0.01), and also presented with higher values of BMI (24.6 ±2.6 kg/m² vs 29.2 ±6.4 kg/m², p < 0.02), waist circumference (85.0 ±9.0 cm vs 97.9 ±11.3 cm, p < 0.01) and triglycerides (95.6 ±31.4 mg/dL vs 62.9 mg/dL, p < 0.01) and lower values of HDL cholesterol (58.9 ±14.3 mg/dL vs 50.4 ±14.4 mg/dL, p < 0.01). A significant association was also found between the value of elastography and female gender (females 4.6 ±1.3KPa vs males 5.8 ±1.3KPa, p < 0.01), elevated triglycerides (4.9 ±1.5KPa vs 6.0 ±1.1KPa, p < 0.03) and obesity (4.9 ±1.4KPa vs 6.5 ±1.1KPa, p < 0.01). Conclusion: Different components of MS seem to contribute both to fibrosis and steatosis in chronic HBV inactive carriers. In this subset of patients, the interplay of fibrosis values fibrosis should be made with caution since it may be influenced by metabolic parameters. Aims & Methods:

Introduction:
Serum HBsAg loss is the recommended stopping rule in nucleo(t)ase therapy from 3471 IU/ml at the baseline to 1758 IU/ml at the last determination four weeks after each FMT. Fecal samples of CHB patients before (Baseline) and after FMT as well as donors were collected for analyses of gut microbiota by sequencing 16S V3-V4 regions on Illumina MiSeq using PE 250 reagents.

Results: Results showed that HBsAg of 13 patients (65%) was cleared or reduced after one to seven times of FMT. Based on OTUs at cutoff of 3% dissimilarity, there were significant (PERMANOVA, P = 0.001) differences in overall gut bacterial communities among CHB-FMT, CHB-NT, and NA monotherapy groups with three major clusters in PCA ordination. Whereas, no significant differences (ANOVA, P > 0.05) were detected in α-diversity indexes among the three groups, including observed OTU numbers, Shannon index, Simpson index, and Pielou evenness.

Conclusion: In summary, the clear relationship between expression of HBsAg and the potential application as targets for clinical diagnosis and treatments in future.

Introduction: Serum HBsAg loss is the recommended stopping rule in nucleo(t)ase-analogues (NUC) responders, even if this event occurs rarely.

Aims & Methods: We aimed to investigate in patients with chronic HBsAg+ hepatitis B the rates of HBsAg levels during the NUC therapy to evaluate the predictive parameters of HBsAg seroclearance. Patients with CHB, receiving NUC antiviral therapy with stable viral suppression (HBV DNA < 200 IU/ml), were recruited at the Gastroenterology Unit of the University of Naples."Federico II". Serum samples from these patients were tested for HBsAg quantification with the Elecsys HBsAg II Quant immunoassay (Roche Diagnostics, Indianapolis, USA). HBsAg levels were determined before starting NUC therapy and during treatment every 12 months.

Results: A total of 95 HBsAg-positive, HBsAg-negative patients (M:F: 73:22, median age 50 yrs, 34% cirrhotic) with stable viral suppression by NUCs, were enrolled. Precisely 56 patients underwent to Tenofovir, 22 Entecavir and 17 Lamivudine. The median treatment duration was 111 months, range 25–183 months. There was a significant decrease of the HBsAg levels during NUC therapy to evaluate the kinetics of HBsAg levels during the NUC therapy to evaluate the effectiveness of HBsAg in NA therapy. The efficacy of pegylated interferon α-2a (peg-IFNα-2a) add-on therapy in those CHB patients remains unclear.

Aims & Methods: We aimed to compare the efficacy of peg-IFNα-2a add-on therapy with peg-IFNα-2a monotherapy in treatment-experienced CHB patients.

Results: 71 patients were enrolled (22 to peg-IFNα-2a add-on therapy group and 49 to NA monotherapy group), of whom 9 in peg-IFNα-2a add-on therapy group and 25 in NA monotherapy group completed more than 24 weeks of follow-up, the remaining patients have not yet reached 24 weeks of follow-up. There was no significant difference in age, gender, body mass index (BMI), HBsAg levels, alanine aminotransferase (ALT), or aspartate aminotransferase (AST) between the two groups at baseline. At week 24, HBsAg levels in peg-IFNα-2a add-on therapy group were significantly lower than the baseline (2.96 ± 0.14 vs 2.90 ± 0.82 Log10IU/ml, p = 0.009), but there was no obvious change in NA monotherapy group (3.43 ± 0.46 vs 3.44 ± 0.44 Log10IU/ml, p = 0.843). The HBsAg loss in peg-IFNα-2a add-on therapy group was significantly higher than in NA monotherapy group at week 24 (0.78 ± 0.26 vs –0.01 ± 0.10 Log10IU/ml, p = 0.008). Among those patients who completed 96 weeks of follow-up, two patients in peg-IFNα-2a add-on therapy group (22.2%) achieved HBsAg seroconversion, but none in NA monotherapy group (0%).

PI348 IMPROVEMENTS IN GUT MICROBIOTA AFTER FECAL MICROBIOTA TRANSPLANTATION

C. Xiao, B. Zhang, J. Ren
Zhongshan Hospital Affiliated To Xiamen University, Department of Gastroenterology, Xiamen/China

Contact E-mail Address: xiaoxi@xmu.edu.cn

Introduction: Chronic hepatitis B (CHB) is a common liver disease worldwide, and can be progressed to liver cirrhosis and hepatocellular carcinoma. Unfortunately, only a minority of CHB patients could achieve the clearance or seroconversion of hepatitis B virus e-antigen (HBsAg), the end point of treatment, even after multiple years of antiviral therapy. Therefore, it is urgent to develop new and effective strategy for treatment of CHB and examine the mechanisms.

Aims & Methods: In this study, we performed 60 times of fecal microbiota transplantation (FMT) by nasointestinal tube for 20 CHB patients who continued previous antiviral treatment, and accordingly measured the HBsAg level four weeks after each FMT. Fecal samples of CHB patients before (Baseline) and after FMT as well as donors were collected for analyses of gut microbiota by sequencing 16S V3-V4 regions on Illumina MiSeq using PE 250 reagents.

Results: Results showed that HBsAg of 13 patients (65%) was cleared or reduced after one to seven times of FMT. Based on OTUs at cutoff of 3% dissimilarity, there were significant (PERMANOVA, P = 0.001) differences in overall gut bacterial communities among CHB-FMT, CHB-NT, and NA monotherapy groups with three major clusters in PCA ordination. Whereas, no significant differences (ANOVA, P > 0.05) were detected in α-diversity indexes among the three groups, including observed OTU numbers, Shannon index, Simpson index, and Pielou evenness.

Conclusion: This implies that it is the taxonomic relative abundance, not taxon number, that contributed to the bacterial community differences. Overall, gut bacteria were mainly composed of Fimbicutes (Lachnospiraceae, Ruminococcaceae, Veillonellaceae), Bacteroidetes (S24-7, bacteroidaceae, Prevotellaceae), and Proteobacteria (Alcaligenaceae, Enterobacteriaceae). More specifically, Actinomycetes was significantly higher in CHB patients (CHB-Baseline) than FMT-treated patients (CHB-FMT) and donors, and was identified as the biomarker of CHB using LEfSe analysis. Conversely, Prevotella and Eubacterium were significantly decreased in CHB-Baseline after FMT to almost equal to the abundances in donors, and were also identified as biomarkers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: As few reliable data on the burden of hepatitis C virus (HCV) are available from the Middle East, we analyzed HCV burden in the Lebanese population and the value of comprehensive screening and treatment at different age groups and fibrosis stages.

Aims & Methods: A multi-cohort, health-state-transition model was developed to project the number of HCV patients achieving a sustained virologic response 12 weeks after treatment (SVR12) or progressing to compensated cirrhosis (CC), decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), and liver-related death (LRD) from 2016 to 2036. Epidemiology and mortality data were extracted from the Ministry of Health bulletin while costs were collected from insurance claims. The proportion of patients screened for HCV was projected to increase to 60%/85%/99% (low/medium/high screening scenarios) in 2036, with a new cohort of patients being diagnosed each year. SVR12 rates were extracted from clinical trials. Separate models were used for 18–39 and 40–80 age groups to account for different prevalence and screening rates.

Results: Low, medium and high HCV screening scenarios showed that 3838, 5665 and 7669 individuals would be diagnosed with HCV infection from 2016 to 2036, 40% aged 18–39 and 60% aged 40–80. In the absence of treatment, the projected numbers of patients experiencing CC, DCC, HCC and LRD in 2036 were 899, 147, 147 and 147 respectively for the 18–39 age groups. In the 40–80 age groups, these projections were substantially greater: 2828 CC, 736 DCC, 665 HCC and 958 LRD.

Conclusion: An enhanced screening policy coupled with broader access to DAAs will diminish the future clinical and economic burden of HCV in the Lebanese population and provide the greatest health benefit per amount invested, among middle-aged and older adults with a big difference in additional costs between the 2 groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hepatitis C virus (HCV) infection in renal transplant patients pre-disposes to graft failure and progression of renal disease, increasing mortality. Due to immunosuppression and oscillating glomerular filtration rate (eGFR) in the evolution of virological response and clinical outcomes (kidney function, anemia and other adverse effects), HCV-infected and renal transplanted patients treated with DAA between April 2015 and February 2017 were analyzed.

Results: Including 19 patients, 10 males (53%) and 9 females (47%) with a mean age of 57 years (40–70 years). The majority of these patients (89%) were treatment-naive. Genotype distribution was the following: genotype 1–74% (14/19), genotype 3–16% (3/19) and genotype 4–10% (2/19). Distribution according to fibrosis stages was as follows: F2–63% (12/19), F3–21% (4/19) and F4–16% (3/19). Seven of these patients (85%) were treated with sofosbuvir/daclatasvir (84%) and 24 weeks for others 2 (10%). One patient realized only 21 weeks of treatment, needing to suspend therapy due to severe anemia. Regarding treatment response rates, 74% (14/19) of patients had Rapid Virologic Response (RVR) and 100% (19/19) of patients had End of Treatment Response (ETR). The global sustained virologic response (SVR) rate was 100%. Hemoglobin, eGFR and the immunosuppressive drugs were monitored throughout the treatment. The eGFR (CKD EPI) did not change significantly, with pre and posttreatment mean values of 66.4 and 65.4 ml/min/1.73m2, respectively. There were 2 cases of severe anemia, one that resulted in AĐA suspension at week 21 and the other one ribavirin suspension at week 7 of treatment. Immunosuppressive levels remained stable. There were no other serious adverse reactions.

Conclusion: In our sample of HCV-infected with kidney transplant, DAA are safe and well tolerated, even in the more advanced stages of fibrosis, maintaining the integrity and viability of the graft, without interfering with the efficacy of immunosuppressant.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver stiffness (LS) measurements by Transient Elastography (TE) has been widely accepted as a tool for fibrosis assessment.

Aims & Methods: The aim of this study was to assess LS dynamics in a group of patients with HCV liver cirrhosis after DAA treatment. This birentic clinical...
trial included 276 patients with compensated HCV cirrhosis (all genotype 1b), with a mean follow up of 24 weeks. All patients were evaluated by means of TE at the beginning and at the end of treatment (EOT), and one subgroup (180 patients) also 12 weeks after EOT, all of them with sustained viral response (SVR 12), and another subgroup (55 patients) also at 24 weeks after EOT (SVR 24) for liver stiffness measurements (LSM) defined as median value of 10 valid LSM, with IQR < 30% and SR ≥ 60%. Both M and XL probes were used. For diagnosing cirrhosis we used a cut-off value of 12 kPa as proposed by the Tschosnitz meta-analysis. We considered a decrease or increase of more than 10% in LSM as being significant.

Results: Out of 276 subjects, reliable measurements were obtained in 92.7%, so that the final analysis included 256 patients. The mean LS values decreased significantly after DAA: 25.6±11.4 kPa vs. 22.3±12. kPa (p=0.009). Most patients (59.7%-152/256) presented more than 10% decrease in LS values, 23% (59/256) had stable LS values, while in 17.3% (45/256) the LS values increased. In the subgroup of 180 patients where LSM were also performed 12 weeks after EOT (SVR 12), the mean LS values were significantly lower at EOT compared to baseline: 20.3±10.8 kPa vs. 25.6±11.4 kPa (p=0.001) and also as compared to EOT: 20.3±10.8 kPa vs. 22.8±12.2 kPa, (p=0.04). In the subgroup of 55 patients where LSM were also performed 24 weeks after EOT (SVR 24), the mean LS values were significantly lower at SVR 12 and SVR 24 as compared to EOT (18.7±8.2 kPa vs. 21.6±7.7 kPa, p=0.05 and 18.3±6.6 kPa vs. 21.6±7.7 kPa, p=0.01).

Conclusion: In our group mean liver stiffness values evaluated by TE significantly decreased after antiviral treatment at SVR 12 and SVR 24, as compared to EOT. Overall, in our study almost 60% of patients had EOT liver stiffness values lower than at baseline, at SVR 12 almost 75% of patients had liver stiffness values lower than at baseline and at SVR 24 almost 77% of patients had liver stiffness values lower than at baseline.

Other authors have declared no conflicts of interest.
Conclusion: MCP-1 concentrations in serum depend on overweight in patients with CHC. Overweight and insulin resistance are associated with progression of CHC. Serum levels of MCP-1 increase after HCV clearance. Fluctuation of the MCP-1 concentration in serum could reflect an antiinflammatory activation of MPS and a gradient dependent dynamic replacement of the proinflammatory cell subsets with the resolution ones after SVR. Fatty liver plays a role for inflammatory responses in CHC patients after SVR.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: HCV interferes with the host lipid metabolism leading to insulin resistance and hepatic steatosis. Although it is usually mild in genotype 4, meaningful simple steatosis has been reported to be more severe and the potential to progress to fibrosis, cirrhosis and subsequent hepatocellular carcinoma. Many heritable host factors with observed inter-ethnic variation in the prevalence of steatosis are documented, and in many cases hepatic steatosis may be detected in absence of all these risk factors; so a role for host genetic factors in development of hepatic steatosis in chronic hepatitis C patients may be suggested.

Aims & Methods: In this study, we aim to evaluate the association of HLA class A/B alleles and presence of steatosis in chronic HCV genotype 4 infected patients. The study included two hundred unrelated non diabetic non obese chronic hepatitis C patients with normal lipid profile, 98 of them had biopsy proven steatosis. Serological testing of HLA class I antigens (HLA–A, and HLA-B alleles) were performed with a standard complement-dependent microlymphotocytotoxicity.

Results: The frequency of A02, A03, B15 and B17 alleles were significantly higher in chronic hepatitis C patients with steatosis (OR = 1.77, 2.64, 4.44, 5.68) and 95% CI = 0.96–3.27, 1.02–7.04, 0.84–31.17, 1.12–36.85 with P = 0.034, 0.022, 0.044, 0.015 respectively. On the other hand, the frequency of A01 and B12 alleles were significantly higher in patients without steatosis (OR = 0.56, 0.41) and 95% CI = 0.30–1.05, 0.20–0.83 and P = 0.015 and 0.005. On logistic regression analysis, patients who carry HLA-A02, A03 and HLA-B15 alleles may have 2.2, 3.9 and 11.18 fold risk to have hepatic steatosis (B coefficient: 0.78; 1.37; 2.41) 95% CI = 1.09–4.42, 1.04–11.50, 2.15–58.13; P= 0.027, 0.009, 0.004) while carrying HLA-A01 alleles may be protected from having HCV associated hepatic steatosis; (OR = 0.56, 0.41) and 95% CI = 0.30–1.05, 0.20–0.83 and P = 0.015 and 0.005.

Conclusion: In chronic HCV genotype 4 patients, carrying HLA-A02, HLA-A03 and HLA-B15 alleles may have a risk for presence of hepatic steatosis while presence of HLA-A01 alleles may have a protective role.

P1357 THE VALUE OF 2D-SWE.GE FOR THE EVALUATION OF LIVER FIBROSIS IN PATIENTS WITH HCV COMPENSATED CHRONIC HEPATOPATHIES

F. Bende1, I. Sporea2, S.A. Popescu, R. Sirili, M. Danila, R. Mare, A. Stepan

Introduction: Chronic liver diseases are quite frequently encountered in daily practice and are due mainly to chronic viral infections (B or C viruses) and to other conditions such as alcoholic steatohepatitis - (ASH) and to non-alcoholic fatty liver disease (NAFLD). While liver biopsy remains the gold standard method for fibrosis assessment, stage classification and also for necro-inflammation grading, in the last years, non-invasive assessment methods (biological tests and elastographic methods) were developed and they are being used more and more, to the detriment of liver biopsy.

Aims & Methods: The aim of this study was to evaluate the performance of the 2D shear wave elastography technique from General Electric (2D-SWE.GE), for the evaluation of liver fibrosis in patients with HCV compensated chronic hepatopathies, using Transient Elastography (TE) as the reference method. The study included 145 consecutive subjects with HCV compensated chronic hepatopathies, in whom liver stiffness was evaluated in the same session by means of 2 elastographic measurements: TE (FibroScan EchoSens) and 2D-SWEGE (LOGIQ E9, GE Healthcare). Reliable LS measurements were defined as follows: for TE—the median value of 10 measurements with a success rate of ≥60% and an interquartile range <30% and for 2D-SWEGE - the median value of 10 measurements acquired in a homogeneous area and an interquartile range (IQR) <30%. To discriminate between various stages of fibrosis by TE we used the following cut-offs: F2 = 2.7 kPa, F3 = 3.9 kPa, F4 = 12.5 kPa [1].

Results: Reliable LS measurements were obtained in 138/145 (95.1%) subjects by both methods and in 139/145 (95.8%) subjects by TE. The final analysis was performed on 134 subjects with valid measurements by both methods. We found a good positive correlation between the LS values obtained by the 2 methods: r = 0.79, p < 0.0001. Based on TE cut-off values [1] we divided our cohort into 4 groups: F0-F1: 36/134 (26.8%), F2–F3/134 (17.2%), F3: 23/134 (17.2%) and F4: 52/134 (38.8%). The areas under the receiver operating characteristic curve (AUROC) were 0.909 for significant fibrosis (F ≥ 2), 0.954 for severe fibrosis (F ≥ 3) and 0.942 for cirrhosis (F = 4). The best cut-off values for F ≥ 2 was 7 kPa (Sensitivity 85.7, Specificity 80.5), for F ≥ 3 it was 9.2 kPa (Sensitivity 85.3, Specificity 91.5) and for F = 4 it was 10.7 kPa (Sensitivity 84.6, Specificity 91.4).

Conclusion: 2D-SWEGE seems a reliable method for liver fibrosis staging in patients with HCV compensated chronic hepatopathies. The best 2D-SWEGE cut-off values for F ≥ 2, F ≥ 3 and F=4 in HCV chronic hepatopathies were 7, 9.2 and 10.7 kPa.

Introduction: The risk of developing novo hepatocellular carcinoma (HCC) persists after achieving sustained virological response (SVR) in patients infected with hepatitis virus C. It has been suggested that risk is increased in patients treated with the new direct antiviral agents (DAA). In this prospective study we present our results of incidence and prevalence of novo HCC in cirrhotic patients treated with DAA and SVR, and also, the risk factors involved in its development.

Aims & Methods: We included all cirrhotic patients due to HCV infection without previous HCC who reached SVR after DAA treatment in our hospital from February 2014 until December 2016 (n = 197, median of follow-up of 17 months). We evaluated with chi square test the following qualitative variables: age, Child-Pugh stage, alcohol consumption pre-treatment, tobacco consumption pre-treatment, diabetes mellitus (DM) pre-treatment, genotype, radiological and endoscopic portal hypertension features pre-treatment. The quantitative variables were evaluated with student t test: age, no. of platelets pre-treatment, fibrosis pre-treatment.

Results: During follow-up 11 patients were diagnosed of HCC (5.6% prevalence, 3.9% annual incidence). Among all variables evaluated being in a Child- Pugh B stage vs. an A stage (p = 0.007), pre-treatment DM (p = 0.002) and presence of radiological portal hypertension (p = 0.001) were associated with developing novo HCC. Among the quantitative variables, we evidenced statistically significant differences in the mean value of platelets (p = 0.015).

Conclusion: In our group of patients, a worse hepatic function evaluated with the Child-Pugh classification and indirect markers of portal hypertension (platelets and radiological features) and also DM are associated statistically significant with the development of novo HCC. The incidence (>1.5%) of novo HCC justifies the screening of HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.
patients (AST $p<0.001$; ALT $p<0.001$). Cell death markers and the MELD score were also found for liver enzymes, which were significantly lower in AOCLF patients compared to ALF. Thus, patients admitted to liver transplantation centers with the diagnosis of ALF might be suffering from AOCLF instead. It is also unclear if the ALF and AOCLF have different impact on disease course, clinical management and transplant organ allocation.

Aims & Methods: Aim of this study was to identify possible differences between patients with ALF and AOCLF regarding routine parameters and clinical course. In this retrospective single-center study all patients were recruited, who were admitted to the University Hospital of Essen with the initial diagnosis of ALF between 2008 and 2015. Patients included in this study were fulfilling the criteria of the acute liver failure study group Germany. The diagnosis of AOCLF was established using retrospective examination of patient records. In total 131 patients were recruited (ALF: 131; AOCLF: 32). Clinical records, in particular demographic data, serum parameters and outcome were analyzed for differences between ALF and AOCLF.

Results: Patients with AOCLF were significantly older (50.3 ± 15.1 vs. 39.8 ± 16.2, $p = 0.0008$), had a higher BMI (25.7 ± 5.1 vs. 24.5 ± 6.2, $p = 0.0014$) and were more often male (65% in AOCLF vs. 34% in ALF, $p = 0.0008$). In addition, the results that caused the liver failure in AOCLF were significantly different from those patients with ALF. Significant differences were also found for liver enzymes, which were significantly lower in AOCLF patients (AST $p = 0.01$; ALT $p = 0.001$). Cell death markers and the MELD score did not differ between ALF and AOCLF. Moreover, the outcome was not different neither as survived or deceased nor as spontaneous remission or non-spontaneous remission (combined transplantation and deceased). Importantly, MELD and the modified MELD including the cell death marker M65 were similarly effective in predicting outcome for both ALF and AOCLF.

Conclusion: In the present study patients with ALF and AOCLF differed in age and BMI, but did not exhibit differences regarding disease severity (according to MELD) or clinical outcome. While the causes for an acute insult differed between ALF and AOCLF, which might imply a different clinical management, clinical outcome was predictable by common factors for ALF.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction:
Romania has the highest incidence of tuberculosis (TB) in the European Union, representing one quarter of the European TB burden. According to clinical practice guidelines for liver transplantation (LT), the second level of screening for infections consists of screening for Mycobacterium tuberculosis, including history of TB, PPD, Interferon-gamma release assays. Aims & Methods: The aim was to assess the importance of Quantiferon TB Gold test for evaluating patients included on the wait list for LT in Romanian setting. The study was a single-center retrospective cohort study (the single center for LT) that included 264 patients admitted on the wait list for LT from January 1, 2014 to November 18, 2016. All patients underwent mandatory screening for Mycobacterium tuberculosis, either using Quantiferon TB Gold test or skin testing using purified protein derivative (PPD). The variables analyzed using Minitab 17 were: age, gender, etiology of liver disease, biochemical test, MELD score. Results: From a total of 264 patients with liver diseases included on the wait list, 60.6% were males, the average age at diagnosis was 47.78 ± 9.92 years. The etiology of liver cirrhosis was HCV infection in 31.43%, HBV and HBV-HDV coinfection in 45.99%, and alcoholic liver cirrhosis in 18.34%; 24.62% of patients have been diagnosed with superimposed hepatocellular carcinoma. Eighty three patients (31.43%) had positive results for Quantiferon test, 150 patients (56.81%) were negative and 17 patients (6.43%) had indeterminate results. Only 4 patients (5.3%) were skin tested using PPD, 2 (0.75%) of them with positive results. Comparing the subgroups, positive Quantiferon test was associated with HCV etiology (p value $= 0.084$) and lower lymphocyte counts, but did not achieve statistical significance (p = 0.187). Patients with indeterminate Quantiferon associated with hyperbilirubinemia (p = 0.044), hypoalbuminemia (p = 0.032) and a higher MELD score (p = 0.040), assessment by a multidisciplinary team that included a pneumologist, 38.63% of patients were diagnosed with latent TB. Isoniazid chemoprophylaxis along with pyridoxine was postponed after LT, in order to prevent further hepatic dysfunction. 48.5% of patients underwent LT, followed by TB prophylaxis and no cases of TB reactivation have been reported during a follow-up period of 14 months. Conclusion: Patients transplanted for HCV-related liver cirrhosis should benefit from a careful follow-up on the WL and prompt TB prophylaxis after LT in order to prevent further hepatic dysfunction and reactivation of the disease. Discourse of Interest: All authors have declared no conflicts of interest.
**P3162**  A NATIONAL STUDY OF CANCER DIAGNOSES IN IRISH LIVER TRANSPLANT RECIPIENTS WITH PRIMARY SCLEROSING CHOLANGITIS

S. M. O'Reilly1, K. Hartery1, M. Walshe1, S. Deadly2, E. O’Leary2, G. A. Doherty1, D. Houlihan1, G. Cullen1, H. Mulcahy1, J. Sheridan1

2National Cancer Registry Ireland, Cork/Ireland  
3National Liver Unit, St Vincent’s University Hospital, Dublin/Ireland

Contact E-mail Address: susanmmoreelly@gmail.com

**Introduction:** Primary sclerosing cholangitis (PSC) is associated with an increased risk of cholangiocarcinoma, colorectal cancer (CRC) and gallbladder cancer. Orthotopic liver transplantation (OLT) patients are at increased risk of developing de novo malignancies, however limited and conflicting data exists regarding cancer risk post OLT for PSC.

**Aims & Methods:** To examine all recorded malignancies over 2 decades in OLT PSC pts and compare to our non-transplanted PSC cohort. To analyse factors associated with development of malignancies post OLT. We retrospectively studied PSC patients attending the Irish National Liver Unit (INLU) and the Centre for Colorectal Disease (CCD) at St. Vincent’s University Hospital from 1/1/1994 to 30/9/2014. We integrated this database with the National Cancer Registry in Ireland. This enabled accurate determination of the no. of malignancies recorded in the PSC cohort. Analyzed data included age of recipient at OLT, gender, primary OLT indication, immunosuppressive regime, de novo malignancy post OLT, time from OLT to diagnosis of malignancy or death. Statistical analysis was primarily descriptive. Cox Proportional Hazard Model was used to analyse factors associated with mortality in the PSC OLT cohort.

**Results:** 107 of 173 patients had undergone transplant for PSC. 27/107 pts were transplanted for cholangiocarcinoma. 12 post-transplant de novo cancers and 12 BCC/SCC carcinomas were found in 107 patients during 737.8 person years of follow-up. Median time to cancer diagnosis post OLT was 5 years (IQR 2.8–5.9). Recurrence of PSC was observed in 21 patients (19.6%). Post-transplant lymphoproliferative disease (PTLD) remains a major complication after OLT. Previous studies have reported rates of 1–3% in adult OLT pts. 5 pts were diagnosed with lymphoma post OLT representing 4.7% of cohort. Median time to diagnosis was 5.3 yrs [IQR 2.8–10.2]. Regarding CRC, 2 patients developed CRC post OLT. 4 patients (3.7%) developed colon and 36.57% had significant co-existing inflammation. All those who developed colon dysplasia/CRC post OLT had co-existing IBD. All 5 colectomy. All those who developed colon dysplasia/CRC showed significant co-existing inflammation. One patient post OLT underwent a completion proctectomy for rectal cancer. As expected, cholangiocarcinoma as indication for OLT (p = 0.005). RR 2.573, 95%CI (1.3–4.95) and an older age at transplant (p = 0.05, RR 1.027, 95% CI 1.015–1.054) were associated with higher mortality.

</table>

**Conclusion:** These findings represent national cancer figures in our PSC OLT cohort. The rate of cancer is more than three times higher in this population than the general population. The rates of PTLD are >30 times higher than the normal population, and slight higher than previously reported in unselected liver transplant groups. We could not find any association between the development of PTLD and aggressive immunosuppressive regimes for co-existing IBD post OLT. The study highlights that IBD/PSC patients remain at significant risk of colon neoplasia after OLT and require intensive surveillance.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P3163**  OUTCOME OF LIVER TRANSPLANTATION FOR PRIMARY SCLEROSING CHOLANGITIS IN CONTEXT OF HLA-DR MISMATCH: SINGLE CENTRE EXPERIENCE

P. Drastich1, L. Bajer1, A. Slavcev2, M. Benes1, P. Trunecka3, L. Tomé1

2Department Of Immunogenetics, Institute for Clinical and Experimental Medicine, Prague/Czech Republic  
3Transplant centre, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: drastich@hotmail.com

**Introduction:** Primary sclerosing cholangitis (PSC) is a chronic liver disorder of unknown etiology, characterized by inflammation, fibrosis and stenoses of both extra- and intrahepatic bile ducts. For those who develop end-stage liver disease, orthotopic liver transplantation (OLT) remains the only effective treatment currently available. PSC is accompanied with concomitant ulcerative colitis (UC) in a significant proportion of patients. Benefits of routine HLA typing in donor and recipient prior to OLT were proved in the past.

**Aims & Methods:** The aim of this study was to assess the impact of HLA-DR mismatch on acute cellular rejection (ACR), PSC recurrence (rPSC) and course of UC after OLT. After applying inclusion/exclusion criteria we retrospectively evaluated records of 57 PSC patients transplanted at Institute for Clinical and Experimental Medicine (Prague, Czech Republic) between July 1994 and November 2011. Only patients with proper records ±5years from OLT were included. We evaluated likelihood for each variable (ACR, rPSC, course of UC) in patients with either single, double, or double mismatch in HLA-DR. Immunology data were analysed with χ2 and Fisher’s exact test using MedCalc statistical software. A p-value < 0.05 was considered as statistically significant.

**Results:** Out of 57 patients, 27 (47.4%) had single mismatch (“M1” group) and 30 (52.6%) had double mismatches (“M2” group) in HLA-DR. No patient had full mismatch on acute cellular rejection (ACR), PSC recurrence (rPSC) and worsening of UC after OLT as compared to patients with double mismatch. Analysis of combined mismatch in HLA-DR and HLA-DQ could demonstrate more substantial linkages in respective clinical variables. Therefore, these data have to be considered as preliminary as typing for HLA-DQ from frozen blood samples is currently underway. Supported by Ministry of Health of the Czech Republic, grant nr. 15-28064A. All rights reserved.

**Introduction:** Liver biopsy remains the gold standard in the diagnosis of graft dysfunction in post-liver transplantation (GDPLT). Liver transient elastography is a valid non-invasive method for liver fibrosis evaluation, with a good correlation in chronic liver diseases. The progression of fibrosis represents a major problem in the post-liver transplantation.

**Aims & Methods:** We aimed to evaluate the predictive role of liver transient elastography in the evaluation of GDPLT and to determine the predictive factors of de-novo fibrosis by using liver biopsies. As this was a retrospective cohort study of total of 49 patients with post-liver transplantation status who underwent liver transient elastography by Fibroscan®. Selected patients who underwent percutaneous/transjugular liver biopsy. In case of more than one liver biopsy, it was selected the biopsy closer to Fibroscan®. The fibrosis and steatosis evaluated by Fibroscan® were compared with those obtained by liver biopsy. Significant fibrosis was considered if ≥2D. Demographic, analytical and associated liver transplantation variables were evaluated.

**Results:** A total of 32 patients underwent Fibroscan® and liver biopsy. Mean age of 48.53 ± 11.20years and male gender in 68.8%(n = 22). The mean time between Fibroscan® and liver biopsy was 29.77 ± 36.90months. The mean elastography score was 13.45 ± 8.31KPa with IQR median 17.11 ± 8.66%. Mean CAP score was 207.12 ± 57.35 dB.m. Regarding liver biopsy, 34.4%(n = 11) had significant fibrosis and 25.0%(n = 8) presented steatosis. Comparing two methods, there was no concordance for steatosis (kappa = 0.273; p = 0.117) or inflammation (kappa = 0.663; p = 0.710). On the contrary, a moderate agreement for significant fibrosis (kappa = 0.431; p = 0.003) was verified. The mean elastography score showed an accuracy of 79.7% in predicting histological fibrosis (AUROC = 0.797; p = 0.007) to a cut-off value of 11.6 KPa (S = 81.8%; Sp = 76.2%). In relation to analytical parameters, only serum albumin was predictive of histological fibrosis (OR = 2.79; p = 0.043).

**Conclusion:** Liver transient elastography represents a non-invasive and valid alternative procedure to liver biopsy in the evaluation of post-liver transplantation fibrosis but not steatosis or inflammation. Liver transient elastography scoring ≥11.6KPa and low values of serum albumin are predictors of post-liver transplantation fibrosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1365 NEW-ONSET DIABETES AFTER TRANSPLANT (NODAT): DECISION MAKING, RISK ANALYSIS AND IMPACT ON SURVIVAL NEW-ONSET DIABETES AFTER TRANSPLANT (NODAT): INCIDENCE, RISK ANALYSIS AND IMPACT ON SURVIVAL

Introduction: Orthotopic liver transplant has become the standard of care for end-stage liver disease and hepatocellular cancer. Better immunosuppressant paved way for improved survival rates post-transplant. But with this longevity comes a higher prevalence of chronic diseases such as New Onset Diabetes After Transplant (NODAT), Hypertension, metabolic syndrome etc. which have a negative impact on function and patient survival.

Aims & Methods: Primary: To determine the incidence of New Onset Diabetes After Transplant (NODAT), Impaired Fasting Glyceremia (IFG) and post-transplant hyperglycemia in living-donor liver transplant recipients. Secondary: To determine the risk factors associated with NODAT and IFG. To determine impact of NODAT on survival and mortality. It was a retrospective cohort study of 283 living donor liver transplant recipients from 2002/9 till 2014/16. Data was collected from records. Simple means and standard deviation was calculated for continuous variables while frequency statistics were calculated for categorical ones. Risk factors were assessed using binary logistic regression analysis.

Results: A total of 130 post liver transplant patients were analyzed after exclusion. NODAT was present in 41/130 (31.5%) patients, while 19/130 (14.6%) patients had impaired fasting glycaemia. Acute cellular rejection, Post-transplant Hyperglycemia and Pre-transplant prediabetes showed increased odds of acquiring NODAT post-transplant. NODAT had significant association with mortality and decreased survival (p = 0.05).

Conclusion: This cohort showed that NODAT is an important post-transplant entity with significant impact on mortality and survival. Early identification of at-risk patients is suggested.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1367 OUTCOMES OF LIVER TRANSPLANTATION IN PATIENTS WITH HEPATOCELLULAR CARCINOMA

A. Eshraghian1, S. Nikhegialbian2, S. Ali Malek-Hosseini3, B. Geramizadeh2
1Gastroenterology And Hepatology, Shiraz University of Medical Sciences, Shiraz/ Iran
2Transplant Research Center, Shiraz/Iran
3Department Of Gastroenterology And Hepatology, North Liver Hospital Hospital Center, University of Lisbon, Portugal, Lisbon/Portugal

Contact E-mail Address: eshraghiana@yahoo.com

Introduction: Hepatocellular carcinoma (HCC) is the second leading cause of cancer-related mortality worldwide. Patients with viral hepatitis and those with non-alcoholic fatty liver disease (NAFLD) are especially susceptible to HCC. Parallel to an increase in prevalence of NAFLD, the prevalence of HCC is estimated to be increased in next years. Liver transplantation is now considered as a modality of treatment for patients with HCC.

Aims & Methods: This study aimed to investigate outcomes of liver transplantation in patients with HCC compared to other causes of liver transplantation. In a cross-sectional study patients who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Patients’ characteristics including age, gender, model for end stage liver disease (MELD) score, Laboratory indices, complications, disease severity and mortality of patients were recorded. Characteristics of tumor including size, number and vascular invasion were recorded. Based on these findings HCC patients were divided to those within Milan criteria and those beyond Milan criteria. The impact of HCC on post-transplant outcomes was investigated using student t-test and chi-square tests. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation.

Results: Totally 1014 liver transplant patients were included. 94 patients with HCC underwent liver transplantation. There was no statistically significant difference between those with and without HCC in terms of gender, portal vein thrombosis (PVT), diabetes mellitus (DM), hepatic encephalopathy and hospitalization before liver transplantation (P > 0.05). HCC was significantly more prevalent in cirrhosis due to viral hepatitis (P < 0.001). Acute rejection episodes was not different in patients with and without HCC in early post-transplant period (OR = 0.563; 95% CI: 0.27–1.14; P = 0.098). In regression analysis, presence of pre-transplant DM (OR = 3.89; 95% CI: 1.36–11.11; P = 0.011) and acute kidney injury within 30 days after liver transplant (OR =4.38; 95% CI: 1.44–1327; P=0.009) were independent predictors of post-transplant mortality. Mean post-liver transplantation survival in HCC patients within Milan criteria was 40.48 ± 3.69 months compared to 36.80 ± 6.28 months in those beyond Milan criteria (P = 0.82). Mean post-transplant survival in patients with HCC + DM was 32.75 ± 4.7 months compared to 48.51 ± 2.6 months in HCC patients without DM (P = 0.009)

Conclusion: Liver transplantation can be used for patients with HCC, however, post-transplant survival seems to be lower. Diabetes mellitus and acute kidney injury were predictors of mortality among our patients with HCC after liver transplantation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1368 THE ASSESSMENT OF THE ADC PREDICTIVE VALUE IN SURVIVAL OUTCOMES OF PATIENTS UNDERGOING RADIOFREQUENCY ABLATION FOR METASTATIC COLORECTAL CANCER LIVER TUMORS
O. Kozak1, T. Nowicki1, J.M. Pienkowski1, E. Lyczka-Siewiowska2, D. Zadrożyń1, E. Szurowska3
1Department Of Radiology, Medical University of Gdańsk, Gdańsk/Poland
2Department Of Pathology And Neuropathology, Medical University of Gdańsk, Gdańsk/Poland
3Clinic Of Oncologic And Liver Surgery, University Warmia and Mazury, Olsztyn/Poland

Introduction: Liver is one of the most common metastatic sites of colorectal cancer, nearly 50% patients develop hepatic metastases during the course of their disease. Metastatic spread influences survival rate of those patients. The diffusion weighted imaging (DWI) is MRI sequence designed to detect random movement of water protons in extracellular compartment. Biophysical parameter expressed as ADC represent a ratio between diffusion coefficient of water molecules (ADC) and ADC values for b parameter lower than 300/mm² are influenced by perfusion whereas ADC values for b greater than 300/mm² depend mainly on diffusion. Aggressive malignant process often develops necrotic areas within neoplastic lesion. Necrotic changes are characterized by high ADC values. We suspect that low ADC values correlate with presence of necrosis in highly malignant lesions effecting in lower survival rate.

Aims & Methods: This is a post hoc analysis of prospective study to assess the predictive value of the ADC in survival outcomes of patients undergoing radiofrequency ablation due to metastatic colorectal cancer lesions in the liver. We analyzed the MRI studies of 52 patients (18 F, 34 M, aged 4383) performed on 1.5 T scanner one day before the percutaneous RFA treatment. The total number of analyzed lesions was 110 (15 per patient), 83 of them were completely ablated 27 incompletely, what was assessed in follow up CT studies. The standard protocol of the liver MRI was applied including DWI sequence in b values of 0, 15 and 300/mm², ADC maps were calculated for b values of 015 and 0500/mm². The mean ADC value was obtained by threefold marking ROI covering the whole metastatic lesion. In cases of multiple focal only the lesion with the highest ADC value was included in analysis. On basis of ROC analysis the cut-off values of ADC were established: 2.49 mm²/s for b value of 015 s/mm² and 1.43 mm²/s for b value of 0500/mm². The survival outcomes were assessed by mean of Kaplan-Meier estimator. The p value lower than 0.05 was considered significant.

Results: The statistical analysis included Kaplan-Meier estimator for 52 patients with 16 censored cases (17.3%). In ADC maps for b value of 0500/mm², the ADC value ≥1.43 mm²/s correlated with longer survival time, whereas ADC value < 1.43 mm²/s correlated with shorter survival time. Statistically significant differences were identified by log rank test = 2.698%, p = 0.007. Such a correlation was not observed for ADC values in ADC maps for b value of 015/mm² (p = 0.058).

Conclusion: The study showed significant differences in survival rate depending on diffusion influenced ADC values of metastatic lesions.

Introduction: Nowadays liver fibrosis can be assessed using non-invasive elastographic techniques. ElastPQ is a quite novel point share wave elastography integrated in an ultrasound system.

Aims & Methods: The aim of our study was to evaluate the learning curve of obtaining reliable liver stiffness measurements (LSM), using ElastPQ, LSM of a trainee were compared to LSM of an elastography expert (with an experience of more than 500 examinations). Our study group included 50 subjects (mean age - 52.7 years, 66.6% men, mean BMI = 25.6 kg/m²). Both the trainee and the expert obtained LSM for each subject, using ElastPQ (EPIQ 7, Philips Healthcare, Bothell, WA, USA). Reliable LSM were defined as the median deviation of measurements performed in a homogeneous area avoiding blood vessels and with an IQR/median < 30%. The learning curve was evaluated using the Receiver Operating Curve analysis using the expert’s results as reference.

Results: The trainee’s performance in obtaining reliable LSM was good (AUC: 0.735, 95% CI (0.557–0.913), p = 0.01). The trainee started to have similar results with the elastography expert after the 30th subject. When looking at the IQRs, they became significantly lower after the 30th subject (2.6±2.1 kPa vs 6.5±4.2 kPa, p = 0.03).

Conclusion: Obtaining reliable LSM using ElastPQ can be easily achieved after 30 LS examinations.

Results: According to reference method, the 298 lesions were classified as follows: 272 invasive HCC, 60 non-HCC-malignant lesions (fatty infiltration, hemangiomata, simple cysts, regenerative nodules) and 27 non-HCC-malignant lesions (liver metatases, cholangiocarcinoma, indeterminate). The diagnostic accuracy of ACR CEUS LI-RADSv 2016 for the diagnosis of hepatocellular carcinoma was 74.8% Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 65.4%, 96.5%, 97.8% and 53.5%, respectively. When we used CEUS alone, a conclusive diagnosis of HCC was obtained in 69.6% of the cases (147/211), while using the algorithm in 65.4% of all HCCs (138/211), p = 0.35.

Conclusion: In our study 65.4% of all HCCs (138/211) were correctly diagnosed using ACR CEUS LI-RADSv 2016 algorithm, showing good sensitivity, excellent specificity and PPV for the diagnosis of HCC.

P1373 DICKKOPF-1: AS A SERUM BIOMARKER FOR PREDICTION OF HEPATOCELLULAR CARCINOMA TREATMENT RESPONSE A. L. Sharaf1, E. G. El-Badrawy2, N. A. Khalifa1
1Tropical Medicine Department, Zagazig University, Zagazig, Egypt
2Clinical Pathology Department, Zagazig University, Zagazig, Egypt

Contact E-mail Address: drnahmed_lotfy@hotmail.com

Introduction: Hepatocellular carcinoma (HCC) is the 5th most common cancer worldwide and the 3rd leading cause of cancer-related mortality. In Egypt, HCC is the 2nd most common cancer in men and the 6th most common cancer in women. Egypt has the highest prevalence of HCC worldwide and has rising rate of HCC. HCC is a disease with fast infiltrating growth and poor prognosis. This bad prognosis is due to the lack of an effective method for early diagnosis. So, it is necessary to find a specific & sensitive marker for early diagnosis of HCC and for monitoring of treatment response.

Aims & Methods: The aim of this work is to assess prognostic value of serum DKK1 in predicting treatment response, complication and survival in HCC patients. This study included 60 Patients divided into two groups. Group A: consisted of 30 patients with liver cirrhosis. Group B: consisted of 30 patients with HCC. Group B patients underwent either radiofrequency ablation or ethanom injection. Clinical assessment, routine laboratory evaluation, CT studies and measurement of serum alpha-fetoprotein (AFP) and DKK1 were performed to follow up of HCC patients before and after treatment.

Results: DKK1 significantly can be used for HCC diagnosis even in HCC with inconclusive AFP. The optimum cut off value of DKK1 for diagnosis of HCC was 4.3 ng/mL (AUC 0.89, sensitivity 66.7% and specificity 96.6%) (P < 0.001). Serum DKK1 level significantly decreases after HCC treatment with either radiofrequency ablation or ethanol injection (P < 0.001). Conclusion: DKK1 has a promising prognostic value and can be used for follow-up of HCC patients before and after treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1374 EFFECT OF FIBROBLAST GROWTH FACTOR-2 AND ITS RECEPTOR GENETIC POLYMORPHISMS ON SURVIVAL IN PATIENTS WITH HEPATITIS B VIRUS-ASSOCIATED HEPATOCELLULAR CARCINOMA J. Cheong
Gastroenterology, Ajou University Hospital, Suwon, Korea, Republic of

Introduction: Fibroblast growth factor (FGF), vascular endothelial growth factor, and hepatocyte growth factor play a critical role in the pathogenesis of hepatocellular carcinoma (HCC). Hence, we aimed to investigate the association of serum alpha-fetoprotein (AFP) and DKK1 were performed to follow up of HCC patients before and after treatment.

Aims & Methods: We determined the association of single nucleotide polymorphisms (SNPs) in FGF2 gene with serum alpha-fetoprotein levels and the development and progression of tumors and overall survival in patients with hepatitis B virus (HBV)-associated HCC. We assessed nine SNPs in the FGF1, FGF2, FGF receptor (FGFR)-2, FGF, and e-MET genes in 245 HCC patients and 483 chronic HBV carriers without HCC.

Results: None of the SNPs was associated with the risk of HCC development in HBV carriers. The rs308379 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The FGF1 rs4771249 C allele was associated with low alpha-fetoprotein levels. Kaplan-Meier analysis showed that the patients with the FGF2 rs308447 TT genotype had lower survival rates than the patients with the CC or CT genotype (P = 0.016) and that the FGF2 rs308579 A allele carriers had shorter survival rates than those of patients with the TT genotype (P = 0.020). The FGF2 rs1219648 CC genotype was significantly associated with increased survival rates (P = 0.047). Multivariate Cox proportional analysis revealed that the FGF2 rs308579 A allele (hazard ratio = 1.663, P = 0.004) and advanced stage tumor (hazard ratio = 3.430, P = 0.001) were independent prognostic factors for overall survival rates in patients with HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1372 DIAGNOSTIC ACCURACY OF CONTRAST-ENHANCED ULTRASOUND ALGORITHM (ACR CEUS LI-RADSv 2016) FOR THE DIAGNOSIS OF HEPATOCELLULAR CARCINOMA IN PATIENTS WITH CHRONIC LIVER DISEASE A. Stepan1, M. Danila1, R. Siri1, S.A. Popescu, T.V. Mogu1, C. S. Ivascu, C. Ghene1, I. M. Biri1

Introduction: Contrast-Enhanced Ultrasound (CEUS) is an imaging method that can be used to discriminate between hepatocellular carcinoma (HCC) and other focal liver lesions. The aim of this study was to test the latest approved version of a contrast-enhanced ultrasound algorithm (ACR CEUS LI-RADSv 2016) for detecting hepatocellular carcinoma (HCC), in a real-life cohort of high-risk patients. In the CEUS studies, 6 patients with liver lesions in patients at high-risk for HCC (liver cirrhosis of any etiology, chronic hepatitis B or C, with severe fibrosis, current or prior HCC) using the ACR CEUS LI-RADSv 2016 algorithm. CEUS LI-RADS categories used for the diagnosis of HCC were: CEUS LR-S (definitely HCC), CEUS LR-5 (HCC with macrovascular invasion), CEUS LR-Tr (treated HCC). Contrast-enhanced CT, contrast-enhanced MRI or histology were used as reference methods to evaluate the CEUS LI-RADS classification of the 298 lesions.

Results: Results of the 298 lesions were classified as follows: 272 invasive HCC, 60 non-HCC-malignant lesions (fatty infiltration, hemangiomata, simple cysts, regenerative nodules) and 27 non-HCC-malignant lesions (liver metatases, cholangiocarcinoma, indeterminate). The diagnostic accuracy of ACR CEUS LI-RADSv 2016 for the diagnosis of hepatocellular carcinoma was 74.8% Sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) were 65.4%, 96.5%, 97.8% and 53.5%, respectively. When we used CEUS alone, a conclusive diagnosis of HCC was obtained in 69.6% of the cases (147/211), while using the algorithm in 65.4% of all HCCs (138/211), P = 0.35.

Conclusion: In our study 65.4% of all HCCs (138/211) were correctly diagnosed using ACR CEUS LI-RADSv 2016 algorithm, showing good sensitivity, excellent specificity and PPV for the diagnosis of HCC.

Introduction: Extrahepatic HCC metastasis are associated with a poor prognosis. Nevertheless there are some effective therapies available.

Aims & Methods: The aim of this study was to assess the main sites of extra-
hepatic metastasis in hepatocellular carcinoma (HCC) patients and to evaluate the
clinical evolution and treatment. This was a retrospective single-center study in
which patients with HCC confirmed extrahepatic metastasis between January
2010 and December 2016 were evaluated.

Results: We evaluated 51 consecutive patients, 80% male, with a mean age of
64±11 years at the time of metastasis. In 41% of the patients the metastases were
present at the time of HCC diagnosis. In patients with subsequent metastasis, the
median time until its development was 9 months (IQR 5–16). The diagnosis of
metastasis was incidental in 51% of the patients. Computed tomography (CT)
was the main diagnostic method (86%) and in 18% of the cases histological
confirmation was obtained. Nineteen patients underwent thoracic CT and five
performed bone scintigraphy prior to metastasis. A total of 70 metastatic sites
were identified, the most frequent were lung (33%) and bone (14%). The MELD
score at the time of metastasis was higher than the MELD score at the HCC
diagnosis (p=0.009). Metastasis detection implied changes in HCC therapy in all
patients, 41% started sorafenib and 55% were referred for supportive therapy.
Seven patients performed metastasis targeted treatment, namely 3 patients under-
went radiotherapy. The median overall survival (OS) after metastasis was 4.0
months (95%CI 2.1–5.8 months) and the mortality rate was 81% at 12
months. Patients who underwent metastasis targeted treatment presented a
longer OS than those who did not (median 18.5 vs 3.1 months; p=0.002).
In multivariate analysis, MELD score at the time of metastasis (p=0.004) and
metastasis treatment (p=0.005) were independently associated with OS
estimation.

Conclusion: A systematic HCC staging, with thoracic CT and bone scintigra-
ty, may provide an earlier metastasis detection and enable a targeted treatment with
a consequent improvement in survival in this difficult-to-treat population.

P1376 MANAGEMENT OF INTERMEDIATE STAGE HEPATOCELLULAR CARCINOMA
A. Deguchi
Department Of Gastroenterology, Kagawa Rosai Hospital, Marugame-shi, Kagawa/Japan

Contact E-mail Address: akihiro41@me.com

Introduction: According to the Barcelona Clinic Liver Cancer (BCLC) staging
system, intermediate stage contains very heterogeneous hepatocellular carcinoma
(HCC) patients. Recently, subclassification of intermediate stage on the basis of
Milano criteria and up to 7 criteria is proposed. In this study, the effectiveness of
direct-acting antiviral agents was compared between TACE and intermediate
stage was investigated.

Aims & Methods: 120 patients (M: F=90:30; median age=76; Child A: B:
C=72:44:4; BCLC stage A: B: C: D=6:85:23:6) with untreated HCC who
received DEB TACE in our hospital were studied. The objective radiological
response was classified according to the modified Response Evaluation Criteria
in Solid Tumors (mRECIST) v.1.1 by using dynamic CT at one or two months
after therapy. Adverse events were evaluated using NCI CTCAE v. 4.03.

According to Bolondi’s subclassification, the patients of BCLC B stage were
divided into four groups (B1, B2, B3, B4). The response rate and tumor factor associated response in these patients group were examined.

Results: The overall response rate and disease control rate in intermediate stage
were 36% and 89%, respectively. Considering the subclassification, the response
rate in B1 group (61%) was significantly higher than that of B2+B3 group
(29%). Although B2+B3 group was constituted by the patients who did not
satisfy the all 7 criteria, only in the patients with less than 7 tumors, the response
rate (60%) was similar to that of B1 group. Tumor factors associated response
and found to be significant on univariate analysis were simple gross classification
(classification using nodular type) and number of tumor. Tumor diameter was
not associated with the response.

Conclusion: For the treatment of intermediate stage of HCC, although DEB-
TACE is considered to be most effective in B1 group, it is suggested that
DEB-TACE is also effective in the patients with less than 7 tumors in B2+B3

group. In cases with more than 7 tumors, as the response rate is considered to be
extremely low, sorafenib and arterial infusion therapy are recommended in
B2+B3 group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1377 HEPATOCELLULAR CARCINOMA RECURRENCE RATE IN INFECTED PATIENTS TREATED WITH DIRECT ANTIVIRAL AGENTS. A SINGLE-CENTER EXPERIENCE
G.G. Di Costanzo, R. Granata, M. Guarino, G. Cordone, G. D’Adamo, R. Tortora
Hepatology Unit, Cardarelli Hospital, Naples/Italy

Contact E-mail Address: raffaelatorrora@live.com

Introduction: In the last few years many HCV patients with previous diagnosis of
hepatocellular carcinoma (HCC) have been treated with direct antiviral agents
(DAAs) for HCV infection. However there are conflicting data on HCC recur-

ence rate after DAAs therapy.

Aims & Methods: Aim of this study was to prospectively evaluate the rate of
HCC recurrence following sustained virological response (SVR) by DAAs. From
April 2015 to September 2016 we consecutively enrolled HCV infected patients
previously treated for HCC at Liver Unit of Cardarelli Hospital. All patients had
a free-disease survival from HCC of at least 6 months before starting antiviral
treatment. The efficacy of HCC therapy was evaluated according to mRecist cri-
terion on CT or MRI. Radiological evaluation was carried out within 30 days from
the start of therapy. All patients underwent DAAs therapy, selected on an indi-

vidual basis according to the recommendation issued by the Italian association
of the study of the liver.

Results: A total of 71 patients were enrolled. Among them, 42 patients had
available data on SVR status and were considered for the analysis. There were
21 males (58.3%) and 15 females. The median age of the patients was 73 years
(range 36–85). The median follow-up was 12 months after the beginning of treat-

ment (range: 6–18 months). Genotype distribution was as follows: 36 patients
infected with genotype 1 (85.7%), 5 with genotype 2 and 1 patients with genotype
3. SVR was achieved in 38/42 patients (90.5%). HCC recurrence was observed in
11/38 patients with SVR (28.9%). The median time for recurrence was 9 months
from the start of therapy with a range of 1–13 months; with 2 patients who
showed recurrence during therapy. Among the patients who did not achieve
SVR, 1/4 showed HCC recurrence after 10 months from end of treatment.

Conclusion: Treatment with DAAs are highly effective with a SVR of about 90% 
even in patients with advanced liver disease. Nonetheless, in patients with pre-

vious history of HCC, the eradication of HCV did not reduce the risk of short
and medium-term recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1378 PATTERN OF DISTANT EXTRAHEPATIC METASTASIS IN PRIMARY LIVER CANCER: A SEER-BASED STUDY
W. Wu, X. He2, L. Li1, D. Fang1, D. Shi1, Y. Li1, L. Ye1, F. Guo1
1Academy of Nationalities Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China, Hangzhou/China
2Department of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University Medical School, Hangzhou, China, Hangzhou/China

Contact E-mail Address: wwx725@zju.edu.cn

Introduction: Primary liver cancer is the sixth most common cancer in the world,
after cancers of the lung, breast, colorectal, prostate and gastric[1]. However, the
extremely poor prognosis for primary liver cancer makes it the second leading
cause of cancer-related death globally (745,000 deaths, 9.1% of the total
death)[2]. Histologically, the majority of primary liver cancer is either
hepaticocellular carcinoma (HCC) or intrahepatic cholangiocarcinoma (ICC), while combined hepatic cellular carcinoma and cholangiocarcinoma is less common[3]. Though these treatments have shown modest improvement in overall survival in early stage disease, the 5-year relative survival for distant metastasis patients is still low (3.1%). As we all know, primary liver cancer preferentially metastasizes to the portal vein and extrahepatic metastasis with invasion of lungs, bones, brain, lymph nodes, and adrenal glands[4-6]. To date, few detailed studies explored extrahepatic metastasis profiles due to rare data of liver cancer metastasis. Patterns of extrahepatic metastasis still need further clarification. Besides, it is unclear whether different metastatic sites would be translated into distinct clinical outcomes.

Aims & Methods: The objective of this study was to further evaluate extrahepatic metastatic patterns of different histological subtypes and assessed effects of extrahepatic metastasis on survival of advanced disease. Methods: Based on the Surveillance, Epidemiology and End Results (SEER) database, we identified eligible population diagnosed with primary liver cancer. We adopted Chi-squared test to compared metastasis distribution among different histological types. Overall survival (OS) and cancer-specific survival (CSS) were compared between subgroups with different extrahepatic metastases.

Results: We finally identified 8677 patients who were diagnosed with primary liver cancer from 2010 to 2012 and 1836 patients were in distant metastasis stages. Intrahepatic cholangiocarcinoma was more invasive and had a higher percentage of metastasis compared with hepatocellular carcinoma. Lung was the most common metastatic site and brain was least common site for both hepatocellular carcinoma and intrahepatic cholangiocarcinoma. Extrahepatic metastasis was an independent prognostic factor for liver cancer patients. Patients with brain metastasis had the worst prognosis, compared with other metastasis in OS and CSS analysis.

Conclusion: Different histological subtypes of liver cancer had different metastasis patterns. There were profound differences in risk of mortality among distant extrahepatic metastatic sites. Results from our studies would provide some information for follow-up strategies and future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: BCLC-C stage hepatocellular carcinoma (HCC) includes a wide spectrum of tumor and patients’ characteristics. Refining prognosis according to prognostic factors may allow the selection of those subjects who could benefit of curative treatments.

Aims & Methods: The aim of this study was to investigate the prognostic factors of BCLC-C stage HCC patients in a real-life setting. Consecutive caucasian cirrhotic patients with BCLC-C stage HCC were included in the analysis. Pre-treatment (Child-Pugh score, performance status (PS), number and maximum size of lesions, vascular invasion, metastases, the combination of vascular invasion and extrahepatic spread, alpha-fetoprotein (AFP) levels, NIACE score) and post-treatment (the number of treatments after the progression to BCLC-C stage and disease control (DC) considering stable + partial + complete response as the best treatment outcome) variables were considered as prognostic factors. The analysis was univariate and multivariate.

Results: 116 patients were included in the analysis. After a median follow-up of 22.9 mo (95% CI 17.3–38.1), the cumulative median survival of the overall population was 13.4 mo (95% CI 10.6–17). At the univariate analysis, tumor size, vascular invasion or without extrahepatic spread, and AFP > 200 as pre-treatment factors and DC as post-treatment variable were associated with survival. Multivariable Cox regression revealed that the only independent predictors of mortality were AFP > 200 (HR 2.2, 95% CI 1.27–3.8, p = 0.004) and DC (HR 0.12, 95% CI 0.04–0.4, p = 0.008). However, the influence of these factors was not homogeneous during time. Indeed, in the early and intermediate period AFP > 200 was an independent predictor of worse outcome (at 6 mo: HR 16.602, 95% CI 1.97–139.5, p = 0.009; at 1 yr: HR 3.069, 95% CI 1.07–8.76, p = 0.036). As expected, in the multivariable post-treatment prognostic model DC was associated with a better mid- and long-term survival (at 1 yr: HR 0.245, 95% CI 0.06–0.87, p = 0.030; at 2 yrs: HR 0.356, 95% CI 0.12–1.03; p = 0.05; at 3 yrs: HR 0.094, 95% CI 0.02–0.3; p = 0.00001).

Conclusion: In patients with BCLC C HCC, AFP > 200 ng/mL is a strong prognostic factor in the early and intermediate period, while DC is associated with long-term patients’ survival.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1381 INTRAHEPATIC PORTAL HYPERTENSION WITHOUT CIRRHOSIS: EXPERIENCE OF A MORROCCAN UNIVERSITY CENTER (33 CASES)
I. Nakhecha, I. Benherboudha, F.Z. Ajana
Service Medicine C Rabat Maroc, Hotel Ibn Sina Rabat, Rabat/Morocco
Contact E-mail Address: ibtissamnakhecha2@gmail.com

Introduction: Non-cirrhotic intrahepatic portal hypertension is defined as a portal hypertension (PH) without cirrhosis in liver biopsy and without an obstruction of the portal and the hepatic veins.

Aims & Methods: This is a retrospective study conducted on the last 19 years in “Sultan Moulay Ismail” private hospital in Rabat, 33 non-cirrhotic patients with intrahepatic portal hypertension were analyzed. We medical data of all patients with hypertension portal without cirrhosis in liver biopsy and without an obstruction of the portal and the hepatic veins.

Results: 33 patients were included in this study. 22 were women. Mean age was 34 years old (18-70). The PH has been revealed by a digestive bleeding in 10 cases (30%) and ascits in 7 cases (21.2%). Clinical examination found a splenomegaly in (75.7%). Abdominal ultrasonography combined with Doppler showed signs of PH in all patients and confirmed the absence of obstacle on or above the liver. Upper gastrointestinal endoscopy found esophageal varices in 26 cases (78.7%). Transparietal liver biopsy was performed in 29 cases (87.9%).Various etiologies were identified; in 21.2% (7 cases), intrahepatic PH was due to liver tumors and without an obstruction of the portal and the hepatic veins.

Conclusion: Diffrent clinical features and prognosis of this rare pathology were compared with cirrhosis PH and others causes of PH. The PH non-cirrhotic is well known in the western countries and less in Africa.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1382 CONSERVATIVE MANAGEMENT OF EXTERNAL BILIARY FISTULAS COMPLICATING SURGERY OF HYDATID CYST OF THE LIVER
O. Baraket, K. Ayed, W. Triki, M. A. Lahnidi, A. Itami, I. Abbassi, S. Bouchoucha
General Surgery. Hospital Habib Bouiguetfa Bizert, Faculty of Medicine of Tunis, University Tunis EIMANAR, Bizer/Tunisia
Contact E-mail Address: oubaraket@gmail.com

Introduction: Surgical treatment is nowadays the only curative treatment of hydatid cyst of the liver. Surgical approach exposes to many complications especially biliary fistulas. Many modalities are described for the treatment of these complications.

Aims & Methods: A retrospective study including 250 patients who underwent a surgical treatment for a hydatid cyst of the liver between 2007 and 2015. The aim of this study is to evaluate the place of conservative management and his benefits and risks related to the biliary fistulas.

Results: Conservative surgical treatment of hydatid cyst was done in 180 cases and radical surgery in 70 cases. A complication occurred in 66 cases. An external biliary fistula occurs in 45 cases (18%). Management of all this biliary fistulas was conservative and a staged drainage of the residual cavity and elevation of the drainage. No majoronic and electrolyte troubles were observed. The fistula healed in 44 of patients with a median time of 4 weeks [range, 1-7]. In one case endoscopic treatment was necessary to heal fistulas. The median hospital stay was 15 days [range 12-60] when biliary fistulas occurred compared to 8 days [6-15] when there is no biliary complications.
PH1383  THE EVOLUTION OF ESOPHAGEAL VARIICES IN NON CIRRHOTIC PORTAL HYPERTENSION CAUSED BY PORTAL VEIN THROMBOSIS  
I. Benelbarbadi, 1 K. Loubaris, 2 H. Boutallaka, 3 F.Z. Ajana 1  
1Medicine C, Ibn Sina University Hospital, Rabat/Morocco  
2Hepatogastroenterology C (medicine C), Ibn Sina University Hospital, Rabat/Morocco  
3Gastro-entérology H, Military Hospital Mohamed V, Rabat/Morocco  

Contact E-mail Address: ouhabimam@yahoo.fr  

Introduction: Portal vein thrombosis (PVT) is defined as a partial or complete occlusion of portal vein and/or its tributaries by a thrombus. It exposes to portal hypertension (PHT) by infrahepatic occlusion and consequently to upper digestive hemorrhage, usually due to rupture of gastro esophageal varices.  

Aims & Methods: The aim of this study is to specify the evolution of esophageal varices and thus risk of rebleeding in patients with PHT by PVT unrelated to cirrhosis. It is a retrospective study from January 2016 to February 2017, including 101 patients followed for PHT by PVT without liver disease in the department of hepatogastroenterology (medicine C) at Ibn Sina University hospital of Morocco. PVT was diagnosed by abdominal doppler ultrasonography in all patients.  

Results: The mean age of patients was 36 ± 15 years with extremes ranging from 11 years to 70 years. The sex ratio M/F was 0.4. Five percent of patients had a splenectomy for undetermined reasons before the diagnosis of PHT. Concerning the etiology, 10.9% (n = 11) were hospitalized for melena, 60.4% (n = 61) for hematemesis and melana and 28.7% (n = 29) for non-specific abdominal pain. Clinical examination was normal in 10.9% (n = 11), showed an asites in 11.9% (n = 12), and signs of PHT such as splenomegaly and collateral abdomen in 95.1% (n = 98). Complete blood count showed that 16.8% (n = 17) had thrombocytopenia, 12.9% (n = 13) had bictopenia, and 42.6% (n = 43) had pancytopenia. In all patients, upper GI endoscopy was performed. Hypertensive gastropathy was found in 30.7% (n = 34), grade I esophagogastritis in 50.5% (n = 54), grade II in 30.7% (n = 34), grade III in 48.5% (n = 49) and gastric varices were noted in 13.9% (n = 14). These varices were with red spots in 18.8% (n = 19). All patients had abdominal doppler ultrasonography showing a PVT in 60.3% (n = 61), was partial in 33.6% (n = 34), complete in 11.9% (n = 12). We succeeded to the sphincterotomy in 99.9% (n = 15), recurrence in 1% (n = 1). Endoscopy show that 73.6% (n = 76) of patients were treated with Betablockers.  

Conclusion: The evolution of esophageal varices in non-cirrhotic portal hypertension due to PVT seems to be better than in cirrhotic portal hypertension. Indeed, the risk of rebleeding is reduced in these patients.

PH1385  LONG-TERM OUTCOMES OF PATIENTS WITH ACUTE CALCULOUS CHOLECYSTITIS AFTER SUCCESSFUL REMOVAL OF GALLBLADDER STONES WITH PERCUTANEOUS TRANSEPHATIC CHOLANGIOSCOPY: A DECADE EXPERIENCE AT A SINGLE TERTIARY CENTER  
S. Dong, C.H. Oh, J.R. Moon  
Department of Internal Medicine, Kyung Hee University College of Medicine, Seoul/Korea, Republic of  

Contact E-mail Address: gidong@c.hamm.net  

Introduction: Percutaneous cholecystostomy (PTC) has been an alternative treatment for acute calculous cholecystitis (ACC) for the patients unsuitable for early cholecystectomy. Lithotomy with percutaneous transhepatic biliary cholangioscopy (PTCS) after PCT track maturation is particularly considered for those patients with gallbladder (GB) stones who are poor surgical candidate. We examined the long-term outcomes of 171 patients with ACC treated by PTCS.  

Aims & Methods: This study was a retrospective observational study of 171 consecutive patients who treated with PTCS for ACC in the period from 1 Jan 2005 to 31 Dec 2015. Outcome measures included the success rates, adverse events, recurrence rate and mortality. All data were collected from patients’ medical records.  

Results: PTCS achieved complete clearance of GB stones in 157 patients (91.8%). The complication rate of PTCS was 3.5% (6/171). The adverse events included GB perforation (n = 3, 1.8%), hemorrhage (n = 2, 1.2%), disruption of the percutaneous transhepatic biliary drainage fistula (n = 1, 0.6%), and all of which resolved with conservative treatment. The overall recurrence rate of gallstone diseases was 11.5% during the follow up period. The incidence of recurrent gallstone diseases was significantly higher in those with completely removed gallstone GB stones than in those without complete clearance (10.2%, 16/157 vs 21.4%, 34/157; p < 0.05). The frequency of recurrence of gallstone disease in patients with contrast passage to the duodenum on cholangiography after PTCS was lower than that in patients without contrast passage.  

Conclusion: Gallbladder stone removal with PTCS would be recommended as an effective and safe treatment modality for the patients with acute cholecystitis who are unsuitable for surgery.  

Disclosure of Interest: All authors have declared no conflicts of interest.  

PH1384  EVALUATION OF COMMON BILE DUCT CLEARANCE AFTER ENDOSCOPIC MANAGEMENT OF DIFFICULT BILIARY STONES BY DIRECT PERORAL CHOLANGIOSCOPY: PRELIMINARY RESULTS OF A PILOT STUDY  
A. Anderloni, 1 A. Fagazzola, 1 F. Aurieri, 1 R. Maselli, 1 S. Carrara, 1 M. Di Leo, 1 E. Ferrara, 1 P.A. Galliieri, 1 R. Semeraro, 1 G. Lollo, 1 G. Avamiosidis, 1 A. Repici 1

Introduction: Incomplete stones clearance after endoscopic management of difficult biliary stones poses the risk of complications such as cholangitis. Confirmation of complete stones clearance is normally confirmed fluoroscopically using a contrast injection through the biliary tract. If a falsely negative/false positive study is obtained under/over-treatment. Direct peroral cholangioscopy (POC) refers to the use of non-specific endoscopes for the direct visualization of the common bile duct (CBD).  

Aims & Methods: We aimed to evaluate the feasibility and safety of POC to confirm CBD complete clearance after endoscopic treatment of difficult biliary stones. From 1st June 2016 to 30 March 2017 all consecutive patients treated with Dilated assisted stone extraction(DASE) for difficult biliary stones at our institution, underwent POC to verify CBD stones complete clearance. Ultrasonic (5.9 mm diameter) or Slim (8.5 mm diameter) endoscopes (FujiFilm EG 530NW or EG 530FP) or standard gastroscope (9.9 mm diameter) (Olympus GIF-HQ190), under CO2 insufflation, were used by the peroral route for intubating all accessible bile ducts. Technical success rate, procedural time, outcome and side effects of POC were assessed. All adverse events were recorded.  

Results: POC was performed in 26 patients (17F/9M mean age 74.6 years ± 11.9) under propofol sedation (23 patients) or deep sedation (3 patients). Mean CBD size was 15 mm ± 3.65; mean stone diameter (13.5 mm ± 1.70); mean balloon dilation (13.5 mm ± 2.12). Intubation of the papilla and distal biliary duct was successful in 26 (100%) cases (guide-wire assistance in 17 cases, 65.4%). Hepatic hilum was reached in 13/26 (50%) patients with a complete CBD evaluation. Mean investigation time was 6.3 ± 1.5 min (range of 5-9 minutes). POC showed persistent large amount of sludge in 27.7% cases, completely suctioned through the endoscope, and stones in 4 (15.4%) cases with subsequent endoscopic stones removal. In the remaining patients, POC confirmed complete duct clearance. No adverse events occurred.  

Conclusion: CBD complete clearance confirmation using POC is a feasible, quick and safe procedure that can help on clinical decision making (for example obviating the need for possible plastic stent or naso-biliary drainage placement) without substantial increase of time or costs. Our experience, however, is preliminary and further studies should be aimed to confirm the feasibility of the procedure, which could represent the first step for the development of a possible new indication in the setting of difficult biliary stone management.  

Disclosure of Interest: All authors have declared no conflicts of interest.  

PH1386  SINGLE DEVICE TECHNIQUE FOR ENDOSCOPIC TREATMENT OF BILE DUCT STONES

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) with sphincterotomy is a well-established standard method for treating bile duct stones (BDS). After cannulation of the common bile duct (CBD), a guidewire is placed into the CBD and a sphincterotome is performed. Subsequently, stone extraction using a balloon or basket catheter is performed. Because of this multi-step process, endoscopic treatment for BDS always comes with a risk of losing CBD cannulation. A combination catheter that combines a sphincterotome and a retrieval balloon in a single instrument can eliminate one step in the procedure and improve bile duct (BD) clearance and may be able to accomplish BD clearance by using only single device. Additionally, a newly developed 0.255 inch guidewire that is, at once, rigid and flexible enables us to inject contrast agent through the Y-connector. Therefore, the combination catheter with a Y-connector and a 0.025 inch guidewire may become a single device that can facilitate complete BDS clearance. Despite its utility, the success rate of bile duct cannulation and cost benefit requires further analysis.  

Aims & Methods: We aimed to evaluate the therapeutic efficacy of a combined catheter as a single device required for BDS clearance. From January 2016 to July 2016, 11 consecutive patients with BDStes ≤ 10 mm in size were enrolled in this study (Stoneome group). In all cases, the combined catheter (Stoneome) was
used for initial bile duct cannulation. Subsequently, sphincterotomy and stone extraction were performed using the combined catheter. The success rate of performing the combined procedure, procedure-related time, adverse events, and the cost of devices were compared with those in 10 patients with BDSs < 10 mm in size who had undergone endoscopic stone clearance from April 2015 to December 2015 as a historical control.

Results: The success rate of selective cannulation and stone clearance did not differ significantly (Stonetome group: 90.9% and 100% vs control group: 100% and 100%, respectively). The median time after bile duct cannulation to complete stone clearance and total procedure time in the Stonetome group were significantly shorter than those in the control group (401.5 vs 982.5s, 645.5s versus 1308s, respectively). In the Stonetome group, delayed bleeding occurred in 1 patient. In the control group, bile duct injury caused by the guidewire occurred in 1 patient. The costs of the used devices did not differ significantly (Stonetome group: $678 versus control group: $669).

Conclusion: The combined catheter has the same selective cannulation ability as a conventional catheter and a similar capacity to remove BDSs as common retrieval tool. Therefore, the combined catheter can reduce the procedure time to remove BDSs.

P1388 DOES FIBRIN GLUE APPLIED ON THE CHOLANGIOTOMY DURING LAPAROSCOPIC COMMON BILE DUCT EXPLORATION REDUCE THE RISK OF BILE LEAKAGE? A RANDOMIZED STUDY

B. Darkahi1, G. Sandblom2, T. Norden3
1Surgery Department, Enköping/Sweden
2Surgery Department, Uppsala/Sweden

Contact E-Mail Address: bahman.darkahi@gmail.com

Introduction: Laparoscopic cholecystectomy as a method of extracting common bile duct stones is a technique with many advantages. One problem, however, is bile duct leakage. To some extent, the leakage may be reduced if the incision is suctioned around the T-tube, but this technique has some disadvantages. The aim of this study was to investigate whether application of fibrin glue around the tube results in less leakage than suctioning.

Aims & Methods: Between 2012 and 2016 a total of 1347 cholecystectomies were performed in Enköping Hospital. From this group, 42 patients were included in the study and randomized to suturing or fibrin glue for closing the cholangiotomy around the T-tube. Postoperative cholangiography was performed after 7–10 days after surgery. The amount of flow in the abdominal drain and the level of bilirubin was measured daily. In case the flow ceased, the abdominal drain was extracted three days after surgery.

Results: No significant difference between the groups was seen regarding the flow of the abdominal drain or the T-drain for the first three days or operation time

Conclusion: Fibrin glue may be an option to seal cholangiotomy around the T-tube, but studies with greater statistical power are needed to confirm this.

Disclosure of Interest: All authors have declared no conflicts of interest.
Polyposis DNA damage repair gene polymorphisms were screened by PCR-RFLP using DNA samples of the ethni
cally distinct NEI population. Whole blood and surgically ressected tissue sam-
ple of both short and long patch pathway, was down-regulated in majority of
the GBC, CS and CL cases compared to controls; and in GBC cases compared to
CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in
the GBC correlated significantly with the variant hOGG1 genotype (p
0.001). The genetic alterations in hOGG1 and XRCC1 gene were highly pre-
valent in both controls and gall bladder disease cases in NEI population, and was
associated with susceptibility and severity of gall bladder anomalies compared to
cases in controls significantly for hOGG1 locus280 polymorphism in GBC exo
compared to controls [OR = 1.986,p = 0.047]. Differential mRNA expression
profile clearly showed a sharp down-regulation in hOGG1, APE1, pol β and
PARP1 expression in GBC, CL and CS cases compared to controls; and in
GBC compared to CL and CS cases. The mRNA expression XRCC1 expres-
sion was upregulated in both short and long patch pathway, was down-regulated in majority of
the GBC, CS and CL cases compared to controls; and in GBC cases compared to
CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in
the pathogenesis of gall bladder cancer, and to identify how metformin affect molecular mechanisms
of both short and long patch pathway, was down-regulated in majority of
the GBC, CS and CL cases compared to controls; and in GBC cases compared to
CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in
The data indicates an important role of oxidative stress in the patho-
gnosis of gall bladder cancers and progression to GBC in NEI population, which
is due to genetic, expression and epigenetic deregulations in the key genes of the
BER pathway as well as potential therapeutic targets for the disease, and hence holds clinical relevance.

Introduction: Metformin has evidence of antineoplastic activity in some cancer cells.

Aims & Methods: This study was performed to demonstrate in the bile duct cancer cells whether metformin inhibits the proliferation of cancer cells by indu-
cing apoptosis and affects the expression of gene-related proteins involved in cancer growth, and to identify how metformin affect molecular mechanisms
involved in the inhibition of cancer cell growth. Human extrahepatic bile duct cancer
cells were cultured. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays were performed to determine the effect of metformin on
cell proliferation. Apoptosis was measured by a cell death detection enzyme-
linked immunosorbent assay and caspase-3 activity assay. Various protein expressions with or without specific siRNA transfection were measured by Western blot. The migratory activity of the cancer cells was evaluated by wound healing assay.

Results: 1) Metformin suppressed cell proliferation in bile duct cancer cells by
inducing apoptosis. 2) Metformin inhibited the mamalian target of rapamycin
(mTOR) by activation of AMPKThr172 - tibosarumel complex 2 (TSC2) pathway, and
hyperglycemia impaired metformin-induced AMPKThr172 activation and enhanced phosphorylation of AMPKα485. 3) Metformin increased expression of caspase 1 receptor (1 receptor (IGF-1R), insulin receptor substrate 1 (IRS-1) and AKt pathway on TSC2, and
hyperglycemia impaired metformin-induced inhibition of IGF-1R-IRS-1
AKt pathway. 4) Metformin modulated invasiveness of bile duct cancer cells, and the effect was impaired by hyperglycemia.

Conclusion: This study shows that metformin has antineoplastic effect in bile duct
cancer, and the effect of metformin is attenuated in the hyperglycemic environment.
In addition, AMPK and IGF-1R play a key role in the proliferation of bile duct
cancer cells, and they are expected to be important targets for future develop-
ment of chemotherapy agents.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1393 DREGULATIONS IN BASE EXCISION REPAIR (BER) PATHWAY AND RESULTING OXIDATIVE STRESS AS KEY MODULATOR OF GALL BLADDER ANOMALIES AND PROGRESSION TO CARCINOGENESIS: A NORTHEAST INDIA BASED STUDY

Introduction: Molecular pathology of gall bladder anomalies and progression to
carcinoma is still obscure and understudied; but is critically relevant to India
which harbors the highest number of cases globally, and to ethnically distinct NEI population, the disease has been increasing alarmingly.

Aims & Methods: Evaluate the associative role of genetic alteration(s) and pro-
metor hypermethylation of key BER pathway genes in the predisposition to gail
bladder diseases and progression to gall bladder carcinomas (GBC) in the ethn-
ically distinct NEI population. Whole blood and surgically resected tissue sam-
ple were collected from randomly and histopathologically confirmed cases of
GBC (adenocarcinomas, N = 49) along with non-neoplastic control sections, cholecystitis (CL, N = 78) and cholecystolithiasis (CS, N = 56), and bile with blood from voluntary controls (N = 122) with informed consent. The BER pathway
genesis polymorphisms were screened by PCR-RFLP using DNA samples from the enrolled cases and controls. Differential mRNA expression profile of BER short and long patch pathway genes was studied by RT-PCR.

Differential mRNA expression was studied by immunofluorescence microscopy. Estimation of ox-
dative stress in DNA was done using 8-OH-DG EIA kit. The difference in per-
centage promoter methylation of BER pathway genes was analyzed using RT-
PCR and HRM method.

Results: The genetic alterations in hOGG1 and XRCC1 gene were highly pre-
valent in both controls and gall bladder disease cases in NEI population, and was
associated with susceptibility and severity of gall bladder anomalies compared to
cases in controls significantly for hOGG1 locus280 polymorphism in GBC exo
compared to controls [OR = 1.986,p = 0.047]. Differential mRNA expression
profile clearly showed a sharp down-regulation in hOGG1, APE1, pol β and
PARP1 expression in GBC, CL and CS cases compared to controls; and in
GBC compared to CL and CS cases. The mRNA expression XRCC1 expres-
sion was upregulated in both short and long patch pathway, was down-regulated in majority of
the GBC, CS and CL cases compared to controls; and in GBC cases compared to
CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in
the GBC, CS and CL cases compared to controls; and in GBC cases compared to
CS cases. The protein also showed down-regulation of hOGG1 and XRCC1 in

Conclusion: The data indicates an important role of oxidative stress in the patho-
gnosis of gall bladder cancers and progression to GBC in NEI population, which
is due to genetic, expression and epigenetic deregulations in the key genes of the BER
short and long patch pathway. The data also suggests the prognostic significance of BER pathway parameters, as well as potential therapeutic targets for the disease, and hence holds clinical relevance.

treatment. As negative controls, 19 non-GBCa bile juice and 33 non-GBCa tissue samples with mutations of oncogenes in the same way.

Results: The median (range) age was 77 (44–90) years and the male/female ratio was 0.43 (9:21). Six, six, and twelve patients were diagnosed as stage I, II, III, and stage IV, respectively. We set cut-off value at 5% for rare mutation rate because of the results of healthy samples to avoid false positive. Eleven of 20 (55%) tumor tissue samples were positive for mutation. TP53, MET, SMAD4, CTNNB1 and AR were detected in 7/20 (35%), 1/20 (5%), 1/20 (5%), 1/20 (5%), and 1/20 (5%) respectively. In this study, 14 of 30 (46.7%) patients had both tumor tissue samples and bile juice samples. Eight of 14 (57.1%) tumor tissue samples were positive for mutation. In these eight patients, 7 (87.5%) bile juice samples had the same mutation (TP53, ERBB2/3 were detected in 6/8 (75%), 1/8 (12.5%), respectively). On the other hand, bile juice samples of only 6 patients with tumor tissue mutation had no mutation. With regard to focal ablation, 14 of 24 (58.3%) bile juice samples with GBCa were positive for mutations. TP53 mutation, ERBB2/3, KRAS were detected in 11/24 (45.8%), 2/24 (8.3%), 1/24 (4.2%), respectively. Bile juice analysis for mutations indicated that ABLATION CATHETER IN A SWINE MODEL

Introduction: Intraductal radiofrequency ablation (RFA) is a new endoscopic ablative technique with direct effect to local tumor have been developed to improve the duration of self-expandable metal stents (SEMS) in the unresectable malignant biliary obstruction. However, there is the concern for the complication such as bile duct perforation or bleeding because the ideal power setting of intraductal RFA has not been clearly revealed still.

Aim: To try to make new genetic diagnosis of GBCa.

Disclosre of Interest: All authors have declared no conflicts of interest.

P1396 PREDICTIVE MODEL FOR THE NEOPlastic POTENTIAL OF GALLBLADDER POLYPS

J.K. Lee
Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: jongk.lee@samsung.com

Introduction: While many studies have attempted to define the risk factors for neoplastic potential of gallbladder polyp, precise adaption of the risk factors individually in a real treatment strategy of gallbladder polyp remains elusive. This study evaluated the probability for neoplastic potential of gallbladder polyp using a combination of several risk factors before surgical resection would be useful in patient consultation.

Aims & Methods: This study was designed to provide the statistical predictive model for neoplastic potential of gallbladder polyps. We collected data of patients confirmed as GBP through cholecystectomy at Samsung Medical Center between January 1997 and March 2015. Those with a definite evidence for malignancy, such as adjacent organ invasion, metastasis on preoperative imaging studies, polyp larger than 15 mm, and absence of proper preoperative ultrasonography imaging, were excluded. A total of 1976 patients were enrolled. To make and validate the predictive model, we divided the cohort into the modeling group (n=979) and validation group (n=997). Clinical information, ultrasonographic findings, and blood tests were retrospectively analyzed. A prediction model for the probability of neoplasia was fitted from the training set using the logistic regression method equipped with backward elimination with significance level for removal of P=0.15 for variable selection. The performance of a fitted prediction model was evaluated by the area under the curve (AUC) of a receiver operating characteristic (ROC) curve. A cutoff value of the fitted risk score was chosen by the Youden Index.

Results: Clinical factors of old age, single lesion, sessile shape, and polyp size showed statistical significance of neoplastic potential of GBP in the modeling group. A predictive model for neoplastic potential of GBP was constructed utilizing the statistical outcome of the modeling group. Statistical validation was performed with the validation group to determine the optimal clinical sensitivity and specificity of the predictive model. Optimal cut-off value for neoplastic potential was 7.4%. The probability of Neoplastic GB polyp p=exp(e)\[p]\(1\)+exp(e)\[p]\(0\) where e=2.7182 is the base of the natural logarithm and P(predictive score) = -7.3633 + 0.0374 x [Age] + 0.6667 x [Number] + 0.2189 x [Size].

Conclusion: The predictive model for neoplastic potential of GBP may support clinical decision before cholecystectomy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Digital cholangioscopy provides higher-resolution imaging of the pancreatobiliary tract and accurate diagnostic tests have only recently been consistently reported in literature.

Aims & Methods: Our aim is to assess the incidence of Immunoglobulin G4-associated cholangitis (IAC) in patients resected for presumed perihilar cholangiocarcinoma (PHC). All patients that underwent resection for presumed PHC at our institution between 1984 and 2015 were included. Benign histological specimens were re-evaluated by a pathologist and scored according to the international pathological consensus criteria for IgG4-RD. Patients with benign disease who were still alive were re-evaluated to assess IgG4 serum levels and IgG/IgG RNA ratio to detect activity of IAC.

Results: Between 1984 and 2015, 321 patients underwent liver and bile duct resection for presumed PHC. Of all patients 15% (47/321) were found to have benign disease on histological examination. 45% (21/47) of patients with benign disease had evidence of IAC after surgery based on histological criteria (n = 17) or laboratory parameters (n = 4). The remaining specimens showed unclassified sclerosing inflammation. Out of 12 patients with benign disease that were re-evaluated, 9 had ongoing active IgG4-RD requiring immunosuppressive treatment.

Conclusion: Benign bile duct disorders mimicking PHC have led to a considerable number of liver and bile duct resections during the last three decades. There was evidence of IAC in 45% of these patients. When left untreated, IgG4-RD can consistently be reported in literature.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Digital cholangioscopy provides higher-resolution imaging of the pancreatobiliary tract compared to the 1st fiberoptic generation. The impact of a new single-operator digital cholangioscope (d-SOC) in diagnosis and treatment of pancreatobiliary diseases has not been intensely assessed.

Aims & Methods: The aim of this retrospective analysis of prospective case series from 8 centers from the Czech (n = 85) and Slovak (n = 75) regions was to assess (1) diagnostic yield of d-SOC visual diagnosis and biopsies in patients with underdiagnosed biliary strictures; (2) the efficacy of d-SOC directed treatment of difficult lithiasis and (3) to analyze procedure related adverse events (AEs). The primary outcomes were (1) sensitivity and specificity for d-SOC guided biopsies, (2) achievement of a complete duct clearance in patients with difficult lithiasis and (3) procedure-related AEs.

Results: A total of 150 patients underwent 166 d-SOC procedures (165 cholangioscopies and 1 pancreatoscopy); 81 (48.5%) for diagnostic intents (with biopsy) in 66/68 patients (81.5%), and 85 (51.2%) for therapeutic intents (1 patient had pancreaticolithiasis). The most frequent indication for diagnostic d-SOC was undecided stenosis (n = 59). Reliable views of a target lesion were obtained in all patients. The sensitivity, specificity and diagnostic accuracy of d-SOC for visual diagnosis of malignant lesion was 88.9% (95%CI, 70.8–97.7), 81.2% (65.6–92.3) and 84.6% (73.5–92.4). The mean number of biopsies obtained per patient was 4 (range 1–13) and the specimen was adequate for histopathological analysis in 95.5% of patients (n = 144). The sensitivity and diagnostic accuracy of d-SOC guided biopsies for malignancy were 78.3% (95%CI, 56.3–92.5), 96.4% (81.6–99.9) and 83.3% (70.7–92.1). The diagnostic accuracy of visual inspection was not statistically influenced by the presence of biliary stent (Yates’ p > 0.9). Of 63 patients attended for d-SOC-guided stone therapy, a complete intraductal clearance was achieved in one session in 37 and in two sessions in further 10 patients, respectively and the overall success rate was 77%. A total of 11 patients (n11; 6.6%) experienced an adverse event (cholangitis n = 6, pancreatitis n = 3, perforation n = 2), one patient with severe cholangitis died. The incidence of cholangitis was higher among patients who had received prophylactic antibiotics (n = 5) compared to those who had not received it (n = 1). Significant differences were also observed for the rates of overall adverse events and safety of d-SOC-guided biopsies. Conclusion: A new generation of d-SOC shows that (1) It provides high diagnostic yield in patients with undetermined biliary stenosis; (2) The SOC directed biopsies have a high diagnostic accuracy; (3) d-SOC guided stone lithotripsy is effective in three quarters of patients and (4) Several adverse events may occur and prophylactic antibiotics may not be effective in preventing post-d-SOC-cholangitis.

P1401 PANCREATIC STENT PLACEMENT AFTER ENDOSCOPIC RESECTION OF AMPULLARY TUMORS IS MANDATORY

P. Gambitta, F. Iannuzzi, S. Pallotta, A. Ballerini, A. D’Alessandro, E. Bareggi, P. Fontana

1Digestive Endoscopy, ASST Fatebenefratelli-Sacco, Milano/Italy
2Clinical Medicine And Surgery, University of Naples Federico II Clinical and Experimental Medicine, Naples/Italy

Contact E-mail Address: gambitta.pierr@ ASST-fatebenefratelli-sacco. it

Introduction: Adenoma of the main duodenal papilla is clinically important because this lesion is premalignant and should be resected completely. Endoscopic papillotomy of ampullary adenomas is a promising alternative to surgical resection, however acute and delayed pancreatitis represent a major complication of this procedure.

Aims & Methods: We evaluated the clinical importance of pancreatic duct drainage after endoscopic papillotomy in order to prevent early (acute pancreatitis) and late (pancreatic duct orifice stenosis) complications of this procedure. Our single-centre study with a minimal follow-up of 1 year, includes 19 patients who underwent endoscopic ampullotomy between 2012 and 2016. Careful preoperative evaluation was performed by EUS (100% of patients) and CT (91%)(94%). After a collective evaluation between the surgeon and the endoscopist, patients were candidate for endoscopic ampullotomy. Outcome parameters included ampulloma characteristics, biophysical accuracy as well as safety, efficacy, recurrence rate, and survival.

Results: Endoscopic resection was successful in 15 patients (79%). Histological resection margins revealed non specific changes in 10 patients (52.5%), low or medium-grade dysplasia in 5 patients (26.3%), low, medium-grade dysplasia in 5 patients (26.3%), and carcinoma (21%). Biopict accuracy was 68.4%. In 4 cases histologic specimen revealed an invasive carcinoma: 2 patients underwent pancreaticoduodenectomy and were treated conservatively with placement of biliary and pancreatic stents due to the high preoperative risk. After complete endoscopic resection (15 patients), pancreatic stents were placed in 10 cases (66%). In five cases the positioning of pancreatic stents was not possible due to anatomical difficulties: 2 developed mild pancreatitis after papillotomy; 1 patient developed, as late complication, a stenosis of the pancreatic orifice: the patient died of severe necrotic pancreatitis two years later. Hemorrhage was observed in 2 patients, all with pancreatic stents. Recurrence occurred in 2 patients (10.5%), both were retreated by laparoscopic and diathermal ablation (APC).

Conclusion: Pancreatic stent placement after endoscopic ampullotomy is mandatory to prevent acute and delayed pancreatic complications. Preoperative strategy should be accurate by MRI, EUS and ERCP, in order to define the anatomy of the pancreatic duct aiming to improve the success rate of pancreatic stent placement after papillotomy.

Introduction: Cholangiocarcinoma is a neoplasm arising from the intra- or extrahepatic bile duct lining epithelium. Cholangiocarcinoma are presents less than 25% of all biliary tract malignancies, however, it is the second most common primary hepatobiliary malignancy. Till date, many carcinogens have already been identified and the relevant information with regard to these agents is available. One example is the potentially harmful presence of heavy metals that can cause serious health problems. We therefore aimed to estimate the levels of these heavy metals in bile stenting patients.

Methods: We retrospectively analyzed the serum metal values in patients with biliary obstruction of different etiology originating from the Nile Delta region of Egypt. A single-centre, retrospective study with a minimal follow-up of 1 year, includes 45 patients with cholangiocarcinoma (diagnosed after radiological & histopathological examination) and 20 healthy control subjects attending Mansoura Surgical Gastroenterology centre. All patients and control were permanent residents of the Nile Delta region and the patients were recruited before receiving chemotherapy or radiotherapy. There were no restrictions based on age, sex, or tumor stage. The serum samples were analyzed for concentrations of zinc, lead, cadmium, and chromium by the acid digestion method followed by using atomic absorption spectrometer. Pb and Cd levels were assayed by IMMULITE 2000 XPi immunoassay system supplied by Siemens Healthcare (GmbH Henkestr. Erlangen Germany) using its commercial kits.

Results: The serum levels of Zn, Pb, Co, Cd and Fe were significantly higher in patients having cholangiocarcinoma more than control subjects (P < 0.001). A prescriptive increase in the median values of serum levels of lead (Pb) was found in well differentiated to moderately differentiated to undifferentiated tumours. (P < 0.05). When correlation was made between the heavy metals and CA-19-9 and the survival of the patients, it was found that Ca only has a positive correlation with CA-19-9 and negative correlation with the survival of the patients (P < 0.5, (P < 0.01) respectively.

Conclusion: The results from this study suggest that cholangiocarcinoma in the Nile Delta region is significantly associated with high serum levels of heavy metals especially Cadmium and lead.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Early surgery is the standard treatment in patients with resectable peripancreatic or pancreatic head cancer with jaundice. However, early surgery is not always possible, however it could be a necessary for patient with jaundice at diagnosis or for those undergoing neoadjuvant treatment. Most studies considered plastic stents for BPD, although SEMS are currently considered superior. A recent RCTs showed that fully covered SEMS are associated with better outcomes compared to plastic stents.

Aims & Methods: Aim to compare the rate of endoscopic reintervention (Stent failure of PBD) before surgery and post operative outcome of metal vs plastic. We conducted a bibliographic search using PUBMED, EMBASE including randomized and non randomized trials. OR using the Manthel-Haenszel method was used for dichotomous variables. Weighted mean differences (WMD) were used as the summary statistic for quantitative analysis of continuous variables. Quantitative synthesis was performed using Review Manager version 5.0.

Primary outcome was the rate of endoscopic reintervention before surgery. Secondary outcome was the rate of postoperative complications, hospital readmission, overall pancreatic fistula, overall biliary anastomotic leak, overall postoperative mortality. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Three RCTs and five non RCTs were selected including 909 patients. Of these, 300 patients (33%) were treated with SEMS and 609 (67%) with plastic stents. The rate of endoscopic reinterventions after PBD was significantly lower in the metal stent group as well as in the metal stent group in the plastic stent group (p > 0.001). The rate of postoperative pancreatic surgical complications, hospital readmission, overall biliary anastomotic fistula and postoperative mortality did not differ between the two groups.

Conclusion: Metal stents are more effective than plastic and should be preferred for patients with resectable periampullary or pancreatic head tumor when early surgery without PBD is not feasible. However, more RCTs are needed before a firm conclusion could be made.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1404 THE EFFICACY AND SAFETY OF PREOPERATIVE BILIARY DRAINAGE IN PATIENTS WITH OBSTRUCTIVE JAUNDICE: A SYSTEMATIC REVIEW AND META-ANALYSIS

A. Tringali1, A. Patel2, A. Barrett3, M. Mutignani1
1Endoscopy Unit, Niguarda Hospital, Milano/Italy

Contact E-mail Address: albritti0@gmail.com

Introduction: There is considerable controversy as to whether temporary relief of biliary obstruction prior to major definitive surgery (pre-operative biliary drainage) is of any benefit to the patient. A Cochrane meta-analysis revealed a major morbidity with no difference in mortality in the group subjected to PBD. However, the clinical status of patients was heterogeneous between studies.

Aims & Methods: We aimed to investigate the benefits and harms of pre-operative biliary drainage versus no pre-operative biliary drainage (direct surgery) in patients with obstructive jaundice. A computerized medical literature search was performed by using MEDLINE, EMBASE, Cochrane Library, from 1980 to June 2016 aimed at identifying RCTs comparing PBD versus direct surgery. Data from RCTs related to safety and effectiveness of PBD versus no PBD were extracted. Two independent reviewers discussed the results. Risk ratio or mean differences were calculated with 95 per cent confidence intervals. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity. Outcomes were mortality and morbidity.

Results: Nine trials including 734 patients with malignant or benign obstructive jaundice comparing PBD (375 patients) with no PBD (359) were included in this review. There was no significant difference in mortality (risk ratio 0.89, 95%CI 0.67 to 1.18; P = 0.39) between the two groups. Complications were higher in the PBD group (RR 1.41; 95%CI 1.09–1.81 p = 0.008). Overall serious morbidity was higher in the PBD group than in the direct surgery group (RR 1.66 95%CI 1.28-2.16 p = 0.0002). There was no significant difference in length of hospital stay between the two groups: mean difference 4.55 (95% CI –1.51 to 10.61) days (P = 0.14).

Conclusion: There is currently not sufficient evidence to support or refute the routine use of biliary drainage for patients with obstructive jaundice. Patients undergoing surgery for obstructive jaundice is associated with similar mortality but increased serious morbidity compared with no PBD. Therefore, PBD should not be used routinely. Further RCTs are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Exocrine pancreatic insufficiency and exocrine function alterations are characteristics of pancreatitis. They are frequent in diabetes mellitus (DM) patients with a prevalence up to 50%. Although reduced levels of insulin may explain the link of the proportion of patients with pancreatitis and DM, the same phenotype is also detected in insulin-independent DM. This highlights the concept that additional factors are likely to contribute to the pathophysiology of acinar cells. We recently discovered that 1-deoxy-sphingolipids (1-deoxySLs), the levels of which increase in DM and metabolic syndrome are cytotoxic for beta cells. Our preliminary results showed that 1-deoxySLs are also cytotoxic for acinar cells in vitro. Furthermore, the high level of 1-deoxySLs in diabetic animal model aggravated acinar cell damage whereas lowering levels of 1-deoxySLs improved cell deteoration.

Aims & Methods: In this research, we investigate molecular and cellular factors that contribute to compromise acinar cell functionality in the context of DM. Based on the endocrine and exocrine pancreas crosstalk, we hypothesize that elevated 1-deoxySLs levels affect aarily the pancreatic exocrine compartment by compromising pancreatic acinar cells in DM, thus increasing its predisposition to develop exocrine pancreatic diseases. In vivo mouse models with STZ-induced diabetes and cerulein-induced pancreatitis were used in this study. Reduction of 1-deoxySLs synthesis was achieved by oral L-serine supplementation. Disease severity was assessed with biochemical and immunohistological methods. Molecular mechanisms of 1-deoxySL-dependent toxicity were evaluated in vitro on AR42J pancreatic acinar cells and primary acinar cells.
P1407 ROLE OF THROMBOPHILIA IN SPLANCHNIC VENOUS THROMBOSIS IN ACUTE PANCREATITIS

Introduction: Splanchnic venous thrombosis (SVT) is a common vascular complication of acute pancreatitis (AP). There is paucity of data on its frequency, risk factors, outcome and natural history. Coagulation abnormality has been implicated but not proven as a cause of SVT in AP.

Aims & Methods: We aimed to prospectively study the frequency, risk factors and extent of SVT in patients with AP as well as role of trombophilia in causation of SVT. Patients with AP presenting to our centre between January 2015 and June 2016 were prospectively evaluated with contrast enhanced computerized tomography (CECT) abdomen for presence of SVT. These patients were subjected to detailed analysis of coagulation parameters. Outcome was assessed in terms of presence or absence of necrosis, severity, organ failure, need for intervention and mortality. None of the patients with SVT were given anticoagulation. Follow-up ultrasound Doppler was performed to look for the status of SVT.

Results: Nineteen patients with AP (13 males, mean age 31.85 ± 13.34 years) were evaluated of which 26 (27.1%) had SVT. Single vessel, two vessels and three vessels were involved in 19 (73.1%), 3 (11.5%) and 4 (15.4%) patients respectively. Splenic vein, portal vein and superior mesenteric vein involvement were seen in 22 (88.5%), 11 (44.2%) and 4 (15.3%) patients respectively. Necrotizing pancreatitis, CTSI ≥ 6 and Modified CTSI ≥ 6 were found to be significantly higher number of patients with SVT than those without SVT (96.2% vs 78.6%, 76.9% vs 47.1% and 92.3% vs 67.1%, respectively). Coagulation analysis was performed in 42 patients (18 with and 24 without SVT). Protein C, protein S and a2 antiplasmin were positive in 76.9% vs 47.1%, and 92.3% vs 67.1%, respectively. SVT and 19 without SVT) of which 2 (6.1%) were positive. There was no correlation between abnormal coagulation results and outcome of AP. Coagulation abnormality did not differ significantly between the patients with and without SVT. On follow-up, Doppler study done in 7 patients with SVT, spontaneous resolution of SVT occurred in 5 (71.4%) within 1 year. None of the patients had varices on follow-up.

Conclusion: SVT in AP is more common in patient with necrotizing pancreatitis and higher CTSI and MCTSI indices suggesting that local inflammation plays a major role in its causation. Thrombophilia in some form is seen in one third of the patients with AP but does not increase the risk of AP.

P1409 EUS-GUIDED PANCREATIC FLUID COLLECTION DRAINAGE WITH LUMEN-APPOSING METAL STENTS OR PLASTIC DOUBLE PIGTAIL STENTS: A MULTI-FACTORIAL ANALYSIS
N. Go, S. Sun
Dept. Of Endoscopy, Shengyang Hospital, Shenyang/China
Contact Email Address: ge nan2013@163.com

Introduction: We aimed to compare the efficiency of plastic and metal stents for symptomatic pancreatic fluid collection drainage and analyze other main associated factors that affect the outcome of drainage therapy.

Aims & Methods: Rates of technical and clinical success, procedure-related side effects (hemorrhage, stent migration, and cyst rupture), re-interventions, and duration of hospital stay.

Results: There were 52 patients, 40 who underwent plastic stent placement and 12 who underwent lumen-apposing metal stent placement. The total rate of technical success was 100%. The total rate of clinical success was 100%. The total rate of adverse events was 7.7% (4/52). On multiple logistic regression analysis, the use of plastic stents (P < 0.05, Exp B = 12.168) and presence of a large cyst (P < 0.05, Exp B = 1.036) were shown to significantly increase the risk of re-intervention. On multivariate linear regression analysis, etiology of pseudocyst (P < 0.05, B = -8.427; -9.785; -5.514) was associated with prolonged hospital stay, while stent type was not shown to be a factor (P > 0.05).

Conclusion: Both plastic and lumen-apposing metal stents are proven to be highly efficient in pancreatic fluid collection drainage. The lumen-apposing metal stent is superior in preventing complications such as migration and cyst leakage and reducing the rate of re-intervention. Large cyst size is associated with an increased risk of re-intervention and prolonged hospital stay.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction
infected pancreatic necrosis (IPN) is associated to significant morbidity and mortality. Current management of IPN is based on a step-up approach, based on minimally invasive procedures. Our group has recently published a protocol of local infusion of antibiotics for the treatment of IPN (Panreatology. 2016;16:719-25.

Aims & Methods: We aim at analysing the efficacy of this step-up approach for the treatment of IPN in clinical practice. This was a retrospective single-centre study of patients admitted with acute pancreatitis (AP) between January 2015 and December 2016. The cases were classified of pancreatic necrosis (MN) and IPN (defined by positive culture of necrosis and clinical, analytical, and/or radiological data of infection) were identified and evaluated. IPN was treated following a step-up approach defined by 1. intravenous antibiotic therapy, 2. Endoscopic ultrasound-guided transmural drainage plus local antibiotic therapy, 3. endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.

Results: 694 cases of AP were included (mean age 79.5 ± 18.3, 555 male). CT scan was performed only if clinically indicated. 67 patients (9.6%) had acute necrotizing pancreatitis (ANP) and 21 of them IPN (31% of ANP). IPN patients were treated with intravenous antibiotics (imipenem [n = 15] and meropenem [n = 6], with good response in 8 (38% of IPN). The remaining 13 cases underwent a EUS guided transmural drainage plus local antibiotic therapy, 3. endoscopic necrosectomy. Number of patients responding to each therapeutic step was assessed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Aims & Methods: The aim was to evaluate the efficacy of local instillation of antibiotics into walled-off pancreatic necrosis. Between 2012 and 2016 we evaluated all patients treated with endoscopic transmural drainage and necrosectomy (EDTN) and concomitant local instillation of antibiotics. We added antibiotics (either gentamicin, vancomycin, or amphotericin B) to the irrigation fluid according to the microbiological findings. The antimicrobial efficacies of local and systemic antibiotics were evaluated using uni- and multivariate logistic regression analyses and Kruskal-Wallis test by stratification of the isolates in sensitive versus not sensitive/antibiotics not given.

Results: Ninety-one patients were included. At the first drainage 81 (86%) patients had infected and 10 sterile WON. A total of 139 isolates were found at the first drainage. Most patients were infected with enterococci (44%) or other gram-positive. More than a quarter of the infected patients had fungal species cultured. The infected patients often had polymicrobial infections (56%). At the second culture 152 isolates were found. Neither local nor systemic antibiotics were associated with the eradication of microbes between first and second culture. Between second and third culture, the use of local antibiotics was associated with the eradication of microbes (OR = 2.54, P = 0.01), but not systemic antibiotics (P = 0.33) (Table). Between first and second culture 12 patients with fungal infections were treated with local amphotericin B. In all 12 patients the fungus was eradicated. After second culture 20 patients were treated local amphotericin B and in 17 (85%) patients the fungus was eliminated at the third culture.

Conclusion: Our data suggest a better efficacy of local antibiotics in the treatment of infected WON compared to systemic antibiotics. The local instillation of antibiotics may be a promising alternative or supplement to systemic administration. Particularly the use of local instillation of amphotericin B appears to be more effective in the treatment of fungal infections.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI1412 CORONARY DISEASE AND CHRONIC OBSTRUCTIVE PULMONARY DISEASE ARE NOT ASSOCIATED WITH WORSE OUTCOME IN ACUTE PANCREATITIS

J.R. Carvalho, P. Santos, S. Fernandes, M. Moura, T. Antunes, J. Velosa

Department Of Gastroenterology And Hepatology, North Lisbon Hospital Center, University of Lisbon, Portugal, Lisbon/Portugal

Contact E-mail Address: joana.rita.carvalho@gmail.com

Introduction: Pancreatitis is a disease of protein manifestations. In its more severe form, involvement of any organ is possible. Cardiovascular and respiratory failure are possible and feared complications.

Aims & Methods: The aim of this study was to evaluate the effect of chronic ischemic heart disease and chronic obstructive pulmonary disease (COPD) in the outcome of acute pancreatitis (AP), in our population. Retrospective cohort study that included all patients admitted with AP from January 2003 to December 2016, in a tertiary referral center. Demographic and clinical variables were analyzed by logistic regression (SPSS v23). Clinical outcomes included organ failure (OF), persistent OF (>48h), intensive care unit (ICU) admission and mortality.

Results: A total of 553 patients with AP were included, 58.4% male, median age 80 (18–98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.3%). Twenty-three percent (n = 129) developed OF (in 43% persistent) and 26.8% (n = 148) were admitted in UCI. Mortality rate was 5.6% (n = 31). Fifty-six patients (10.1%) had previous history of coronary disease and 5.1% (n = 28) had been diagnosed with COPD. The presence of coronary disease and COPD were not associated with higher Ramson’s score (≥3), p = 0.076 and p = 0.959, respectively. No association was found between previous history of coronary disease and the development of OF (p = 0.525), persistent OF (p = 0.287), need for ICU admission (p = 0.115) and mortality (p = 0.262). There was also no association of previous history of OF with the development of OF (p = 0.803), persistent OF (p = 0.588), need for ICU admission (p = 0.514) and mortality (p = 0.720). At multivariate analysis (correcting for age and gender) coronary disease and COPD were not independent predictors of worse outcome in AP.

Conclusion: In our population, previous history of coronary disease and COPD were not predictors of worse outcome in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1413  WORSE  OUTCOMES  IN  ACUTE  Pancreatitis IN  PATIENTS  WITH  TYPE-2  DiabeteS  MELLITUS  

P. Santos, J.R. Carvalho, S. Fernandes, M. Moura, T. Antunes, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa/Portugal

Contact E-mail Address: patricia.santos@hotmail.com

Introduction: Predicting severe pancreatitis is important for early aggressive management of patients with acute pancreatitis (AP). Despite the established role of type-2 diabetes mellitus (DM) in the risk of AP, the impact of DM on the clinical outcome in AP has not been fully elucidated.

Aims & Methods: Retrospective study including hospital admissions between January 2003 and December 2016 in a single tertiary referral center. Clinical outcomes included organ failure (OF), persistent OR (> 48h) admission to intensive care unit (ICU) and mortality. Variables were analysed by logistical regression (SPSS v23.0). The objective of this study was to assess the risk of morbidity and severity in AP among patients with type-2 DM.

Results: A total of 555 patients (58.4% male) with AP were included, median age 80 (18-98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.5%). Twenty three percent developed OF (in 43% persistent) and 5.6% (n=31) died. There were 127 AP patients (23.0%) with type-2 DM. Type-2 DM were not associated with higher Ranson’s score. There was an association between DM and development of OF (OR 31.7, CI95% 18.8-53.7, p < 0.001), persistent OR (45.1, CI95% 18.7-108.9, p < 0.001), ICU admission (OR12.3, CI95% 1.9-74.4, p < 0.001) and mortality (OR 17.1, CI95% 6.8, 42.8, 4.4, p < 0.001). At multivariate analysis DM was an independent predictor of OF development and ICU admission.

Conclusion: In our population, Type-2 DM was associated with severity and increased mortality in patients with AP. Our findings provide evidence of the potential role of DM in the management of severe AP.

Introduction: Acute pancreatitis (AP) is an uncommon but potentially devastating condition that may occur in patients with organ transplantation. Reported incidence ranges from 1.5% to 8% in patients undergoing liver transplantation with significant mortality.

Aims & Methods: The aim of our study was to assess the incidence, potential risk factors and outcome of AP following liver transplantation in our center. We performed a retrospective analysis of medical records of all adult patients who underwent liver transplantation in our center between September 1996 and November 2014. The diagnosis of AP was defined by combination of clinical manifestation, finding on imaging methods (CT, USG) and elevation of serum amylose and amylase.

Results: Nine hundred and sixty-seven orthotopic liver transplantations were performed in 578 males and 389 females (mean age 51 years, range 18–74). AP occurred in 18 patients (1.9%, 16 males, 2 females) and resulted in death of 5 patients (28%). According to timing of AP we recognized two clinical presentations: early AP (< 1 month after liver transplantation) and late (>1 month). Four patients (22%) developed early AP, which was severe necrotizing with MODS in all cases and resulted in death of 3 of them (75%). Two of them were transplanted for fulminant hepatic failure, one for end-stage liver disease from chronic hepatitis B infection and one for polycystic liver disease. Two patients were treated by surgical necrectomy and died, the third deceased patient was treated conservatively. In the only surviving patient, a successful EUS-guided drainage of walled of pancreatic necrosis and repeated endoscopic retroperitoneal drainage were performed in 578 males and 389 females (mean age 51 years, range 18–74). AP

Introduction: Biliary sludge (BS) may be one of the factors, related to development of chronic pancreatitis (CP) via sphincter of Oddi dysfunction. As it was demonstrated by Okazaki K et al. in 1988, patients with biliary sludge have higher sphincter of Oddi (SO) pressure and contraction frequency vs. controls. Aims & Methods: To assess the frequency of CP signs in patients with BS and to investigate the state of major duodenal papilla (MDP) in patients with idiopathic CP with BS by endoscopic ultrasound (EUS); to evaluate whether antispasmodics can be effective in pain relief at CP, that developed on the background of biliary sludge. Protocols of computer tomography, endoscopic and transad- dinal ultrasound studies of over 6000 patients of gastroenterological tertiary clinic were examined. Those who had signs of BS were selected to evaluate the state of MDP at least “mild CP” according to modified Cambridge classification. Exclusion criteria were: established etiology of CP and signs of pancreatic neoplasia. Patients, who received ursodeoxycholic acid and drugs that affect smooth muscle contractility to the stay for less then 3 month prior to data collection, were excluded. Thirty consecutive patients (15m, 15 f, mean age ±SD: 52.8 ± 15.3), who had both BS and CP were summoned for physical examination, quality of life assessment, US-cholangiography and endoscopic pancreaticbiliary ultrasonography. Calculation of MDP was made by ACM package (SMDP=(wMDP × 2)/(C6 +2.72) and state of MDP before and after 3 weeks of hymecromone monotherapy 400 mg tid.

Results: Signs of CP were revealed in 6.3% of BS cases. CP was most common in those who had ointment-like bile (33.3%) vs. patients with heterogeneous bile with clots –7.7% and hypoechoic particles–1.7% (chi-square 38.21, p < 0.0001). Mean SMDP was 14.9 ± 5.2 mm² (95%CI 10.9–18.9), SMDP was below the normal range (20–25 mm²) in 78% of patients. SMDP had positive correlation to the volume of evacuated bile according to US-cholangiography (r = 0.042) and gallbladder contractility coefficient (r = 0.817, p = 0.007). All patients with higher density of MDP at US-cholangiography had SMDP lower than the normal range and were attributed to “fibrosis” group. Only 38% of patients with CP and BS had normal MDP at EUS. Periapillary diverticula were found in 13% of the cases, papillary edema — in 38%, fibrosis — in 13%. MDP changes were associated with higher AP level and larger MDP diameter. Hyemecromone monotherapy resulted in significant improvement in abdominal pain (r = 0.792, p = 0.008) and “bodily pain” score of SF-36 questionnaire (t = 3.709 p = 0.001).

Conclusion: BS may cause MDP changes, resulting in development of obstructive CP. Intensity of pain in biliary CP may be related to sphincter of Oddi dysfunction. Efficacy of antispasmodic therapy in these patients could be predicted by the features of MDP at pancreato/biliary EUS.

Introduction: Pancreatic exocrine insufficiency is a late complication of chronic pancreatitis; its clinical onset is characterized by steatorrhea and weight loss, borborygmi, flatulence, abdominal pain and malnutrition. Exocrine and endocrine pancreatic function decreases differently in various diseases (autoimmune, paradoedunal, genetic, idiopathic). It has been observed that there has been a recovery of exocrine pancreatic function in autoimmune pancreatitis. In the literature there are no studies analysing the exocrine pancreatic function over time. The fecal elastase test is a good test procedure to evaluate the exocrine pancreatic function

Aims & Methods: The objective of the retrospective study was to re-evaluate a series of patients with chronic pancreatitis with the aim to evaluate the pancreatic exocrine function over time, in particular, by comparing the exocrine pancreatic function in subgroups of patients with different types chronic pancreatitis. Pancreatic exocrine function was estimated through fecal elastase in 143 patients with at least 2 values each (classified into normal, mild and severe exocrine pancreatic insufficiency), the first one taken at the diagnosis of chronic pancreatitis. Patients undergoing surgical pancreatic resection before the second value of fecal elastase were excluded. Etiology was classified in: biliary pancreatitis/seque-

Results: The results show a high frequency of severe exocrine pancreatic insufficiency in the moment of diagnosis of chronic pancreatitis (38%) and it appears stable over the years. Autoimmune and paradoedunal chronic pancreatitis are correlated with severe exocrine pancreatic insufficiency at diagnosis in a high percentage of cases (51% and 40%), biliary/outcomes of necrotizing pancreatitis and idiopathic pancreatitis in an intermediate (33% and 26%), while genetic in a low percentage (12%).

Conclusion: The exocrine pancreatic function in patients with autoimmune pan-

In recent years, the term “painless” chronic pancreatitis (PCP) represents a specific subset of CP characterized by the lack of pancreatic pain. So far, scarcity of data has been reported in the literature about this matter and what differentiates this group of patients from those with chronic pancreatitis associated with pancreatic pain.

Aims & Methods: The aim of the present study is to characterize “painless” CP from the epidemiological, clinical, radiological, functional, and follow-up standpoint; to compare this with different forms of chronic pancreatitis presenting with pancreatic pain. The Institutional Database of the Gastroenterology Unit of the Verona University was queried, and all chronic pancreatitis cases were retrieved. Patients were clustered based on the presence of “pancreatic-specific pain” into “painless” and “pain-associated” CP. A retrospective case-control analysis was carried out.

Results: Of 678 patients included from March 2006 to March 2016, 436 were considered eligible for the present study. Of these, 368 (84%) were affected by pain-associated CP, while 68 (16%) had “painless” CP. “Painless” patients were older (median age of 58.5±10.8 y/o vs. 42.5±15.3 y/o; p < 0.001), less fre-

Introduction: Recently, EUS-guided pancreatic duct drainage with transmural stenting (EUS-PD) has been used for patients with painful obstructive pancreatitis in whom endoscopic retrograde pancreatography (ERP) has failed. Although the feasibility and safety of EUS-PD with a fully covered self-expandable metal stent (FCSEMS) has been assessed, little is known about the long-term outcomes of EUS-PD with a fully covered self-expandable metal stent (FCSEMS). Removability of an FCSEMS in long-term use and higher cost are the main concerns of EUS-PD with an FCSEMS compared with EUS-PD with a plastic stent.

Aims & Methods: The aim of this study is to evaluate the procedural and long-

Overall mean stent patency duration was 412 days (range 14–1081) during mean follow-up period of 20.7 months (range 2–59). Median stent duration of all malignant strictures was 95 days (range 14–297). Mean stent patency in benign stricture was 525 days (range 14–1081). No patients with malignant strictures required FCSEMS revision or exchange during follow-up periods. FCSEMS removal and exchange was successful in patients with benign strictures until 3-year placement of an FCSEMS. Prospective randomized trial comparing EUS-PD with FCSEMSs and plastic stents may be warranted for painful obstructive pancreatitis after failed ERP.

Introduction: The mRNA binding protein HuR is involved in the post-transcriptional regulation of cytoprotective molecules, such as COX-2, HO-1 and inhibitors of apoptosis proteins (IAP, IAP2, XIAP, SURVIVIN), and might be related to worse prognosis in numerous cancer types. However, the association of HuR, COX-2, HO-1 and IAPs family, and their impact on chemoresistance and carcinogenesis in PDAC still remain unclear.

Aims & Methods: The aim of our study was to assess the relevance and correlation of the IAP regulation by mRNA stabilizing protein HuR and HO-1 and/or COX-2 signaling pathway, and to determine the association with clinicopathological parameters and prognosis of PDAC. Data of 32 patients after pancreateodudendectomy and subsequent chemotherapy for PDAC between 2011–2016 were analyzed. Patient’s mRNA expression levels of HuR, COX-2, HO-1, IAP1, IAP2, Survivin and XIAP were compared with normal pancreatic tissue obtained from organ donors. Additionally, the correlations among HuR, COX-2, HO-1, IAP1, IAP2, Survivin and XIAP, as well as their respective correlations with clinicopathological parameters were analyzed. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to indentify prognostic factors that were independently associated with survival.

Results: HO-1, COX-2, HuR, IAP1, IAP2 mRNA expression were accordingly 3-fold, 8.8-fold, 1.5-fold, 4.8-fold and 5-fold higher, while XIAP and Survivin mRNA expression were 3.8-fold and 3.4-fold lower when compared to normal pancreatic tissue. Expression of HuR was positively associated with COX-2, HO-1, IAP1, IAP2, XIAP. High expression levels of HuR were significantly correlated with higher G stage and microvascular invasion, as well as high levels of XIAP were negatively associated with microvascular and perineural invasion. Univariate analysis revealed that expression of HO-1, XIAP and IAP1 were significantly associated with overall survival (OS) of PDAC patients. In multivariate analysis, high levels of HuR, lymph-node metastases, tumor differentiation and perineural invasion were independently correlated with lower OS in patients with PDAC.

Conclusion: Our results suggested that upregulation of HuR in PDAC patients were significantly related with poor outcome. Even though, significant correlation with IAP proteins in PDAC was noticed, more data is needed to analyze the mechanism underlying HuR and IAP interaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hypoxia-induced reprogramming of cell energy metabolism and changes in glycolysis are hallmarks of cancer promoting the induction of an invasive and treatment-resistant phenotype, triggering metastases at an early stage of tumor development.1 We examined the impact of hypoxia on O-GalNac glycosylation in human HEK293, PDAC cell lines and clinical specimens and its link to cancer proliferation.

Aims & Methods: We profiled the expression of 88 glycosylation related genes by qPCR in HEK293 cells subjected to hypoxia either induced by 1% O2 or 200mM CoCl2 identifying key O-GalNac glycosyltransferases downregulated. Functional assays and glycoprotein analysis displayed a pronounced rate of O-GalNac modified cytosolic proteins derived from hypoxia-treated cells and PDAC specimens. Glycosidase assays could validate specificity of detection method used. aberrant glyctype could be induced by HIF pathway activator
ML 228 and inhibited using Echinomycin. PTK and STK analysis of cell lysates displayed correlation between phosphorylation and O-glycosylation in hypoxic samples.

Results: Mechanistically we could show, that hypoxia-induced decreased levels of C1GALT1C1 results in reduced T-Synthase activity with subsequent expression of truncated O-glycans. The early O-glycosylation is inducible using HIF pathway activator ML228 under normoxia and the effect is reversed using 5µM Echinomycin under hypoxia underscoring the role of HIF1α regulated transcription. Interestingly, the pattern of Tn antigen modified proteins derived from hypoxic samples differ significantly from engineered COSMC-deficient cells, displaying O-GalNAc moieties in addition to O-GlcNAc in cytosolic protein fractions. Further, we could show PTK/AKT/ MAPK signalling is depending on the state of cellular O-glycosylation providing a new rationale for the correlation of PDAC Tn antigen glyctype and cancer cell metastasis.

Conclusion: Our findings point to a novel crosstalk of O-GalNAc and O-GlcNAcylation under hypoxia extending the knowledge base of differential O-GalNAc glycosylation in pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic cancer (PDAC) is one of the most lethal diseases worldwide. The current standard of care for patients with PDAC includes surgical resection in the case of early diagnosis, whereas the majority of patients suffer from locally advanced or metastatic disease. Therefore, chemotherapeutic treatment is the primary standard of care. However, chemoresistance and high metastatic potential limit the long-term survival of PDAC patients. Efforts to understand the molecular mechanisms underlying the initiation, progression and therapy of PDAC are needed.

Aims & Methods: The aim of the presented study was to investigate the expression of the Tryptophan degrading enzyme KYNU in pancreatic cancer cells. A secretome survey of chemoresistant PDAC cells was performed using SILAC-based mass-spectrometric analyses. Relative differences in protein-concentrations among samples were investigated and led to the identification of previously unknown proteins. The impact of RNAi-mediated knockdown of selected genes in proliferating PDAC cells was analyzed using MAT- vitality assays and protein-expression studies. All experiments were performed using Real-Time-PCR and immunohistochemistry using patient-derived PDAC samples.

Results: SILAC-based identification of the Tryptophan degrading enzyme KYNU in chemoresistant PDAC cells revealed an overexpressed and secreted form of the KYNU protein, compared to the chemosensitiv epithelial counterpart. We further identified various stress-related extracellular stimuli (Gemiicitabine, IFNγ, Hypoxia) as main inducers of KYNU expression. Secretion of KYNU was enhanced using a knockdown approach. We found that KYNU overexpression led to subtotally lower proliferation of chemoresistant and aggressive PDAC cells. Global expression analyses using a tissue-microarray of PDAC patient samples (n = 368) revealed that high KYNU expression is significantly correlated with a worse outcome in terms of survival rates.

Conclusion: The tryptophan degradation pathway member KYNU is overexpressed in a subset of PDAC patients and is linked to increased cancer cell proliferation. Abundant KYNU expression in PDAC patients is linked to a worse clinical outcome.

We found that KYNU is a new secreted biomarker of chemoresistant PDAC cells.

P1424 INTEGRIN a11 IS SPECIFICALLY EXPRESSED IN PANCREATIC TUMOR STROMA AND A KEY TARGET IN REGULATION OF PANCREATIC TUMOR STROMAL MYOFIBROBLASTS

J. Schnitter1, R. Bamsal1, G. Storm1, A. Ostman1, J. Prakash1

Introduction: The progression of pancreatic ductal adenocarcinoma (PDAC) is promoted by its highly abundant tumor stroma. As one of the main components of the tumor stroma human pancreatic stellate cells (hPSCs), precursor cells of pancreatic tumor stromal myofibroblasts (CAFs), support PDAC progression by enhancing tumor cell growth, invasion and metastasis [1]. The collagen binding transmembrane receptor integrin α11 (ITGA11) is known to be overexpressed by myofibroblasts [2].

Aims & Methods: The aim of the presented study was to investigate the expression of ITGA11 in human PDAC and to study the role of ITGA11 in CAF regulation. ITGA11 expression was evaluated using immunostaining on human PDAC specimens and various organotypic and cell culture models. The relation between ITGA11 and CAF activation markers and tumor growth was studied in a stroma rich co-injection model in mice. The biological role of ITGA11 in CAF differentiation was studied in hPSCs and hPSCs activated with TGF-β or conditioned medium from Panc-1 endothelial tumor cells using qRT –PCR, immunohistochemistry, western blot, wound healing, collagen contraction and cell growth assays.

Results: In this study we have for the first time stained ITGA11 in human PDAC specimens. We found that ITGA11 was highly expressed in stromal myofibroblasts (CAF)s and myofibroblast precursor cells of pancreatic cancer patients, as shown by co-localization with the stroma marker α-SMA. Interestingly, there was no expression in healthy human pancreas and various other tissues from human organs. Furthermore, we induced subcutaneous tumors in mice by injecting Panc-1 or Panc-1+hPSCs and found that ITGA11 was significantly overexpressed in stroma-rich Panc-1+hPSC tumors. The quantitative gene and protein expression of ITGA11 in subcutaneous tumors, positively correlated with the expression of the CAF markers α-SMA, Col1a1 and PDGFRα. Activation of hPSCs with TGF-β or conditioned medium from Panc-1 resulted in the significant upregulation of ITGA11 and α-SMA. Stable ITGA11 knockdown, mediated by shRNA, significantly inhibited hPSC differentiation, migration potential, contractility and cell growth.

P1425 EFFECT OF ACOUSTIC CAVITATION ON A THREE-DIMENSIONAL CULTURE MODEL OF PANCREATIC ADENOCARCINOMA

A. Bordacahar1, C. Marnas1, E. Abou Ali2, J. Lestas1, M. Lafond1, I. Suarez2, A. Gomes4, V. Lobjois4, F. Batteux5, C. Lafon3, F. Prat6

Introduction: The dismal prognosis of pancreatic ductal adenocarcinoma (PDAC) is mainly due to chemoresistance linked to the tumor microenvironment. Recent developments in ultrasound (US) suggest that US-induced cavitation could help overcome chemoresistance by breaking microenvironmental barriers and increase cytotoxic drug availability. Three-dimensional (3D) culture in the form of spheroids is a useful model for reproducing multicellular resistance and analyzing the effects of cavitation.

Aims & Methods: The objective of this work was to study the effects of acoustic cavitation on a model of PDAC spheroids and to investigate possible potentiation of chemotherapy by US. CAPAN-2 PDAC cell line-derived spheroids were cultured as previously described by Ivascu et al. Four conditions, i.e. control, 400 nM-gemcitabine-based chemotherapy (CT) alone, US alone, CT-US combination (n = 12 spheroids per condition), were studied. Experiments were carried out to optimize US settings, in order to observe the occurrence of controlled acoustic cavitation. Comparisons between groups were based on proliferation and growth. Proliferation was evaluated 24 hours after treatment(s) by UptiteBlue. Growth was assessed by diameter measurement on light microscopy at day 7 and day 10.

Results: Compared to the control group, cell proliferation was decreased in spheroids treated with CT (p < 0.0001), but not with US alone. Proliferation was also further impaired in spheroids treated with CT-US combination compared to those treated with CT alone (p < 0.0001), but this synergistic effect of US and CT did not impact growth of spheroids, meaning that spheroid diameter did not decrease after US-CT compared to CT alone.

Conclusion: This study shows the feasibility of applying an ultrasonic treatment (acoustic cavitation) in a three-dimensional culture model of PDAC. The combination of CT and ultrasonic cavitation synergistically reduced cell proliferation. Further analysis of the cytotoxic effects of acoustic cavitation on PDAC spheroids is in progress.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Intraductal papillary-mucinous neoplasm (IPMN) is a heterogeneous group of pancreatic tumors mucin-producing with uncertain biologic behavior. We know, nowadays, that they can be also considered as a precursor of pancreatic carcinoma (PAC), one out of these lesions will develop into a malignancy of different types. There are no established guidelines for pathologic diagnosis and reporting of IPMN.

Aims & Methods: The aim of this study was to analyze the IPMN subtypes distribution related with clinicopathological, histologic and immunohistochemical and identify which one is more related to development of malignancy. This prospective study with 3-year-follow up, with consecutive patients, where we analyzed the clinical findings, radiological aspects, and morphologic features in patient’s suspects of IPMN or PAC undergoing to pancreatic surgery. The lesions were classified based on morphological and immunohistochemically defined by the current WHO criteria.

Results: We analyzed 28 patients (16 women), mean age 66 y-old (range 50-83). 15 (53%) patients were asymptomatic, and 13 (47%) showed abdominal pain (8), chest pain (4), and recurrent acute pancreatitis (1). 10 patients were submitted to subtotal pancreatectomy, 9 to duodenopancreatectomy, 7 to gastroduodenopancreatectomy, 2 subtotal gastrectomy and splenectomy. The tumor was located in head, body and tail, and entire pancreas in 18, 8, and 1, respectively. 14 patients (50%) had involvement of the main pancreatic + branch ducts (mixed type), 7 (25%) had only the main pancreatic duct involved, 6 (21.5%) had only the branch-duct involved, and 5 (17.5%) had no involvement. The mean size of the lesion was 3.3 cm ± 6.1 (1-11 cm). Morphologic features showed multi-loculated (23 solid-cystic) (4) and solid (1). The immunohistochemically expressed MUC1, MUC5AC, and MUC2 in 18 (64.2%), 17 (61%), and 11 (39%), respectively. The histopathologic patterns formed were gastritic-type (9), Intestinal-type (3), pancreatic-type (9), mixed-type (6), pancreatic Type (9), and finally dichotomous Type (9), and mixed-type (6).

Conclusion: IPMN of the pancreas is a common cystic lesion located more frequent on both duct (mixed-type), showing more aggressive behavior than others pattern. Pathology shows the pancreas and were more connecting to invasive PAC and HGD, as well as connected with PanIN. MUC stains are helpful for the diagnosis and papillary histological subtyping. Prospective studies are needed to confirm these findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Because of the progression of systemic chemotherapies (CT) for locally-advanced pancreas cancer (LA-PC), chemoradiotherapy (CRT) was selected for limited time. However, very long survival cases were reported in CRT and detection of prognostic factors were warranted. In this analysis, we analyzed the LA-PC cases received CRT compared with CT.

Aims & Methods: Gemcitabine (GEM) and S-1 combination chemoradiotherapy (GS-CRT) was performed according to our previous Phase 1 trial (Journal of Japan Pancreas Society 2010). Till March 2016, 30 LA-PC cases received GS-CRT, and the selection criteria were LA-PC with 1 pathological diagnosis, 2 local lesions (CA, SMA, CTVL, PV), S1 invasion (3) allochronic and concur- rency without multiple primary cancer, 4) unexecuted antitumor therapy. The chemotherapy in CRT administration of GEM (200mg/m2) once a week in a week 5-day period for 5.5 weeks, and total dose was 50.4 Gy (Total 28 times). As after treatment, GEM 1000 mg/m2 was continued until PD. The patients of CT group were also recruited by the same criteria. One of the regimens among gemcitabine, S-1 alone and GEM+S-1 was selected for the primary treatment, and total 26 cases were implemented in more than 2 courses.

Results: Baseline characteristics in CRT and CT group were median age (62, 72.5: p = 0.004), male (20, 12: ns) and tumor location P/Pb (17/13, 16/10: ns), respectively. Efficacy were disease control rate(DCR) in 3 months after treatment (90%, 57.7%; p = 0.01), response rate (RR) (26.7%; 0%; p = 0.005) and conver- sion surgery (10%, 0%; ns). There were significant differences in progression free survival (PFS) (6 months, 5 months: p = 0.002) and overall survival (OS) (13M, 9M: p = 0.0165), respectively. The cases who survived for 18 months and longer were significantly (p = 0.0495) more in CRT (43.3%) than CT group (19.2%). Grade 3/4 adverse events in CRT group were 13 cases of neutropenia (G4-3 cases) and one case of gastrointestinal symptom, and those in CT group, neu- tropeenia was 11 cases (G4-4 case), interstitial pneumonia (IP) aggravation was one case.

Conclusion: For LA-PC, GS-CRT showed better local tumor control and longer survival, and was considered as good candidate of neo-adjutant therapy. More prospective studies was other benefit of LA-PC value should think about good selection criteria of CRT and improve the survival of LA-PC.

P1428 HIGH-INTENSITY FOCUSED ULTRASOUND (HIFU) THERAPY FOR UNRESECTABLE PanCREATIC CANCER
Gastroenterology & Hepatology, Tokyodai Medical University, Tokyo, Japan

Contact Email Address: a-sofuni@amy.hi-ho.ne.jp

Introduction: High-intensity focused ultrasound (HIFU) is expected as a new advanced therapy for unresectable pancreatic cancer (PC). HIFU therapy with chemotherapy is being promoted as a new method to control local advance by ablation tumor, and mainly achieve relief of pain caused by PC.

Aims & Methods: We have evaluated the therapeutic effect of HIFU therapy in locally advanced and metastatic PC. We treated PC patients by HIFU as optional local therapy as well as systemic chemo/chemo-radiotherapy, with whom an agreement was obtained in adequate IC, from the end of 2008 in our hospital. This study took approval of member of ethic society of our hospital. HIFU device used is FEP-BY02 (Yuande Bio-Medical Engineering Co.Ltd., China). The subjects were 140 PC patients, i.e. 69 cases in stage III, 71 cases in stage IV. Performance status (PS) was PS:0; 79, PS:1; 38, and PS:2; 3 cases. Mean age at resection was 62.3 ± 11.5 yrs. The details of clinicopathological lesions. EUS result was compared before and after HIFU for the detection of lesions was 21.2 ± 9.9 mm. Accuracy in T assessment was 60% (18/30) for both EUS and CT scan; when considering detection of ≥T2 lesion in any of the two imaging modalities the accuracy increased to 80% (24/30). The sensitivity and specificity in discriminating T1 lesions from ≥T2 lesions was respectively 64.7% and 76.9% for EUS and 76.5% and 72.7% for CT.

Conclusion: This is the first study evaluating the accuracy of CT and EUS imaging modalities in establishing the T in the setting of the new TNM 8th edition. In our study, CT scan and EUS have both a relatively low accuracy in determining the correct T stage for pancreatic cancer when used alone, while the accuracy raises significantly when used in combination. CT scan was not able to detect up to 10% of lesions. The accuracy of the two imaging modalities showed an overlap in 16 cases. Discriminating T1 lesions from ≥T2 lesions compared to CT scan. These preliminary results suggest how EUS, often adopted only as a means to obtain a cytological specimen, has a key role in determining the T stage, and that the combination of the two modalities should be used in combination to better assess the proper therapeutic management as no adjuvant chemotherapy or upfront surgical resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1429 EUS AND CT SCAN ACCURACY IN ESTABLISHING THE T STAGE IN PanCREATIC CANCER BASED ON THE UPCOMING TNM 8TH EDITION

Introduction: Pancreatic ductal adenocarcinoma (PDAC) has a dismal prognosis with an overall 5-year survival rate <6%. Surgically resected patients, although undergoing perioperative treatment, have nevertheless a 5-year survival <25%. In fact, it has been recently suggested that patients with a tumor of more than 2 cm might harbor micrometastases at diagnosis. In this view, the availability of new highly effective chemotherapy regimens that might be employed in the neoadjuvant setting, the correct evaluation of the T stage of pancreatic cancer plays a key role. The new proposed AJCC Staging System for Pancreatic Adenocarcinoma TNM (8th edition), in fact, differs from the 7th edition mostly for the evaluation of the T, giving high importance to the diameter of the tumor. The current evaluation has already shown the need to predict such differences more efficiently compared to previous editions. In this context, an efficient preoperative evaluation of the T is of high importance as it might shift the therapeutic decision from upfront surgery to neoadjuvant chemotherapy, that could be performed even in tumors being >2 cm (T2). Few studies compared the accuracy of CT scan and EUS in evaluating the diameter of the tumor with heterogeneous results and often dated machines, and no study adopted the new TNM system to evaluate the preoperative staging defined by CT and EUS.

Aims & Methods: The aim was to evaluate the accuracy of CT scan and EUS, alone and in combination, in establishing the T stage systematically resected PDAC as defined by the new upcoming TNM 8th edition and to establish the sensitivity and specificity of the two imaging modalities in discriminating T1 stage from more advanced T stages. We conducted a retrospective study on a cohort of surgically-resected histologically-confirmed high-grade patients at a pancreatic cancer referral center between 2015-2017, who were prospectively included in a dedicated database. Inclusion criteria: a) having both preoperative EUS and CT scan with pancreatic phase evaluation at the centre; b) CT and EUS were performed, at the latest, 30 days apart from each other and not from surgical resection; c) no neoadjuvant chemo or radiotherapy was performed. The evaluation of the T by both imaging modalities was compared to the final pathology T re-established based on the new TNM 8th edition, in order to calculate specificity and sensitivity. T-test was used for comparison of categorical variables.

Results: Among the 184 PDAC patients surgically resected between 2015 and 2017 at our center, 30 met inclusion criteria. Of these, 19 (63.3%) were males, with mean age at resection being 67.8 ± 9.5 yrs. The tumor was located in the head in 38, uncus in 19, body in 59, body-tail in 6, tail in 2, and others (recurrence) in 16 cases. Treatment data was followed; mean tumor size before and after therapy was 33.5 ± 10.7 and 33.7 ± 11.5 mm, mean treatment sessions: 2.3 ± 0.7 times, mean total treatment time: 105 ± 65.6 min, mean total number of HIFU shots: 1967.8 ± 1106 shots. The effects of HIFU therapy were as follows: the rate of complete tumor ablation was 87.9%, the rate of symptom relief effect was 69.4%, the effectiveness of primary lesion was CR:0, PR:21, SD:85, PD:34 cases, primary disease control rate (DCR) more than SD was 75.7%. The therapy and HIFU treatment was operation in 8, chemotherapy in 116, immunotherapies in 4, and best supportive care (BSC) in 14 cases. MST after diagnosis in HIFU with chemotherapy and chemotherapy alone (38 patients in our hospital) was 1028.3 vs 366.6 days, respectively (p = 0.001). MST after HIFU therapy was 69.4%, the effectiveness of primary lesion was CR:0, PR:21, SD:85, PD:34 cases, primary disease control rate (DCR) more than SD was 75.7%.

Conclusion: This study suggested that HIFU therapy has the potential of new method of combination therapy for PC.

Introduction: Pancreatic adenocarcinoma is associated with a 5-6% survival at 5 years and a poor quality of life. In Romania there are few information about the prognostic influence of known risk factors for pancreatic cancer.

Aims & Methods: The aim of this study is to evaluate the association between risk factors and the occurrence of pancreatic adenocarcinoma and patients’ survival, which may constitute a theoretical basis for screening. We performed a prospective multicentric study of patients with suspected pancreatic tumors detected in abdominal ultrasound or CT examination, during January 2015-December 2016, in which were analyzed risk factors and possible association with survival adjusted statistically according to tumor stage (Chi square test, ANOVA, log-rank test).

Results: There were 279 patients with pancreatic adenocarcinoma included in the study. Male patients were 58% from all patients, and the mean age was 63.5 years. Smoking, new-onset diabetes and history of chronic pancreatitis are risk factors for pancreatic adenocarcinoma (p < 0.05). At the end of 12 months of follow-up, almost one-third of patients with pancreatic adenocarcinoma died (median survival = 5 months). It was demonstrated a statistically significant association adjusted for tumor stage between the presence of new-onset diabetes and survival: 5 months vs 3 months with a HR = 3. Other risk factors (alcohol, obesity, sex, genetics, coffee intake, some infections and abdominal surgery, history of chronic pancreatitis) had no prognostic role.

Conclusion: In our study, the risk factors for pancreatic cancer were smoking, having a chronic pancreatitis and new-onset diabetes, but the only prognostic factor was smoking. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to the 2012 International guidelines on the management of pancreatic ductal adenocarcinoma, elderly pancreatic cancer patients increase. Most studies have focused on the management of pancreatic cancer in patients older than 75 years. We retrospectively examined the safety and efficacy of surgical resection, whereas surgery is not always mandatory in those with MPD diameter ≤10 mm. Surgical resection is not mandatory in those with MPD diameter between 5 and 9 mm. Aims & Methods: The aim of this study was to investigate the prevalence of malignancy (high-grade dysplasia or invasive carcinoma) in 20 resected IPMN with MPD diameter between 5 and 9 mm and to identify predictive factors of malignancy. Results: From 122 patients with IPMN submitted to surgery, 66 with MD- or mixed-IPMN entered the final analysis. Mean age was 66 ± 12 years and 48 (72.7%) patients were men. Group A comprised 47 patients and Group B 19. Abdominal pain was present in 23 (34.3%) patients, jaundice in 19 (28.8%), diabetes in 18 (27.3%), pancreatitis in 15 (22.7%) and weight loss in 12 (18.2%). Clinical differences between study groups. The most common location of the MD-IPMN was the head of pancreas (60.6%), and it was the most frequent location of mixed-IPMN (41.7%). The prevalence of no malignancy (high-grade dysplasia or invasive carcinoma) was 42.6% ± 8.5% and 38.3% in group A and 10.5%, 10.5%, 21.1% and 57.9% in Group B patients. The overall malignancy rate was 46.8% in group A and 79% in group B. Jaundice (p = 0.017), weight loss (p = 0.035), and complete involvement of MPD at pathological analysis (p = 0.018) were significantly more common in patients with malignancy. Conclusion: Almost half of resected IPMN with MPD diameter between 5–9 mm harbor histologically proven malignancy. In these patients, particularly in those with jaundice and weight loss, surgery rather than follow-up should be recommended. Disclosure of Interest: All authors have declared no conflicts of interest.

P1432 CLINICAL SIGNIFICANCE OF CHEMOTHERAPY FOR ELDERLY UNRESECTABLE PANCREATIC CANCER PATIENTS S. Kaino, M. Sen-Yo, S. Shinoda, S. Amano, I. Sakaida Department Of Gastroenterology & Hepatology, Yamaguchi University Gastroenterology & Hepatology, Ube/Japan Contact E-mail Address: kaino@ymaguchi-u.ac.jp

Introduction: Pancreatic cancer has poor prognosis despite of improvements in multimodal treatments. As aging of the population advances, it is expected that elderly unresectable cancer patients increase.

Aims & Methods: The aim of this study was to investigate the clinical significance of chemotherapy for patients with unresectable pancreatic cancer. At our hospital, 96 patients were diagnosed as having unresectable pancreatic cancer between January 2010 and December 2016. In this study, we defined elderly patients as those older than 75 years. We retrospectively examined the efficacy and safety of chemotherapy in patients with unresectable pancreatic cancer. We analyzed and compared the survival rates between patients aged 75 years or older and those younger than 75 years (group A), and 59 were younger than 74 years (group B). We treated 6/10/0/2/5/4 patients in group A with GEM/S-1-modified FOLFIRINOX (mFOLFIRINOX)/GEM + nabPTX/BSC/other(s), respectively. On the other hand, we treated 12/14/4/11/13 patients in group B with GEM/S-1/mFOLFIRINOX/ GEM + nabPTX/BSC/other(s), respectively. Severe adverse events (more severe than grade 3 according to CTCAE v4.0) occurred in 18.2% of the patients in group A and 33.3% of the patients in group B. No significant difference was found between the two groups. The median survival time of the patients who were receiving chemotherapies was 170.7 days in group A and 291.0 days in group B. No significant differences were also found between the two groups. The median survival time of the patients who underwent chemotherapy in group A (332.0 days) was significantly longer than that of patients who underwent BSC (71.0 days).

Conclusion: Chemotherapy could be safe and effective for patients older than 75 years who have unresectable pancreatic cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1433 THE USE OF A NEW CORE NEEDLE IN THE ENDOSCOPIC ULTRASOUND ASSISTED TISSUE SAMPLING FOR Pancreatic SOLID MASSES: A MULTICENTRE PROSPECTIVE STUDY S. Carrara1, M. Di Leo1, L. Bernardoni1, D. Rahal2, G. Donato3, M. Massidda4, A. Anderloni5, S. Crino6, E. Manfrin7, M. Ballare4, L. Poliani8, F. Auriemma2, C. Montironi2, M. Cuatrecasas2, JR. Ayuso3, S. Sanchez4, M. Sen-Yo, S. Shinoda, S. Amano, I. Sakaida

Introduction: Endoscopic ultrasound-guided biopsy (EUS-biopsy) is considered a reliable, safe, and effective technique for obtaining samples from pancreatic masses with a very high sensitivity and specificity (ranged to 85%-92% and 96-98%, respectively)[1-3]. A new EUS needle (SharkCore FNB needle, Medtronic, Dublin, Ireland) was introduced in order to improve the tissue acquisition.

Aims & Methods: The aim of the present study was to evaluate the presence of a histological sample using Shark Core Needles. This study was an observational multicenter prospective non-randomized clinical trial (NCT02948640). All consecutive patients referred for EUS examination and sampling of solid pancreatic masses underwent EUS-guided biopsy with 25 G Shark Core needles. This needle has an innovative tip geometry with a cutting surface designed to acquire cohesive tissue fragments. This needle was performed in every mass. At every pass, a macroscopic on-site quality evaluation (MOSE) was done by endoscopist. If a “worm-like” material was observed at gross visual assessment, it was placed into formalin. If only liquid material was retrieved, it was smeared between 2 glass slides, fixed with ethanol, and stained with a Papanicolaou-stain for cytological analysis. Endoscopists recorded macroscopic features of the specimens. Pathologists described macroscopic, microscopic features, immunohistochemical studies. The primary outcome was the diagnostic performance rates of histologic core. Pathologists defined core all histological samples with architecturally intact histology, measuring at least 5 mm in greatest axis. All the other specimens (< 5 mm) were defined as micro-fragments. The final diagnosis was based on surgical resection, and clinical/radiological follow up. The secondary outcomes were diagnostic accuracy and procedure-related adverse events.

Results: Study population included 82 patients, enrolled in three centres, between August 2016 and April 2017, with a mean age of 64.0 (SD 13.7, range 21–84) and 57.3% female gender. The mean size of the lesions was 27.6 mm (SD 12.2) and the location was the body and tail in 27 patients (32.9%), neck in 11 (13.4%), head and uncinate process in 44 (53.7%). Three needle passes were performed in all 3 patients who experienced mild bleeding precluding more than one needle pass at AMCE. Endoscopists described presence of “worm-like” material in 192 biopsy samples over 242 (79.3%). In 8 patients only cytological specimens were obtained after 5 needle passes (9.8%). Six cases of mild self-limited bleeding were observed (7.3%). The pathologists described the presence of a core in 80 samples (41.7%), in the other cases, after the specimen preparation, a micro-fragmentation was observed, that didn’t affect the histological evaluation. A final histological diagnosis was reached in 73 patients (90%): 50 pancreatic adenocarcinoma, 16 NET, 5 chronic pancreatitis, 2 pancreatic metastasis from other organs.

Conclusion: The new biopsy needle showed a good overall adequacy and a good rate of histological specimens (both core and micro-fragments) during EUS-guad biopsy acquisition of pancreatic masses, with a minimum number of needle passes and no major complications. This ability could allow to avoid the use of rapid on-site evaluation and to perform immunohistochemical, molecular and genetic studies on histological samples.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: EUS FNA is accepted as the primary modality for tissue diagnosis of solid pancreatic lesions. The presence of on-site cytopathology for immediate evaluation of aspirate and need for cytopathology assistance. This is a review of current practice.

Aims & Methods: We retrospectively assessed 700 consecutive EUS-FNA procedures from January 2011 to January 2016. 459 (65.5%) solid pancreatic lesions were included in the final analysis after excluding 230 for biliary strictures, hepatic lesions, lymph nodes, gastric, oesophageal lesions, pancreatic cysts and 11 for insufficient information.

Results: In 399 (86.9%) cases on-site cytopathology support was available, while the remaining was unsupported. There were 228 males (57.1%) in the supported and 29 (48.5%) in the unsupported group. Mean age was 64.6 (SD: 11.4) and 67.4 (SD: 11.9) respectively. The mean number of passes in the two groups were 2.8 (SD: 1.12) and 1.9 (SD: 1.0) (P < 0.0001). A conclusive diagnosis (malignant, benign, NET, GIST) was made in 84% (67%, 12%, 5%, 0%) of the supported group and in 38% (23%, 10%, 3%, 2%) of the unsupported group (P < 0.0001). The mean follow up for the entire cohort was 14.2 months (SD:14.1) and mean survival of in patients diagnosed with malignancy was 10.9 months (SD: 8.7).

Overall performance characteristics of EUS FNA were Sensitivity: 90.8% Specificity: 66.9% PPV: 91.8% NPV: 85.4%

Conclusion: This review confirms high performance characteristics of EUS FNA. The presence of on-site cytopathologist significantly increases the diagnostic yield.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1435 CLINICAL IMPACT OF GNAS AND KRAS MOLECULAR ALTERATIONS ADDED TO CEA AND CYTOLOGY IN Pancreatic CYSTIC FLUID OBTAINED BY EUS-FNA
S. Sadasiva1, M. Duarte2, C. Albuquerque2, R. Roque3, J. Pereira Du Silva1, R. Fonseca1, A. Dias Pereira1

Introduction: Pancreatic cystic lesions are a common finding in clinical practice. Classification of cysts as mucinous or non-mucinous cysts, using EUS-FNA with cystic fluid analysis for cytology and CEA became widely used in clinical workup of patients with suspicious pancreatic cysts. Molecular analysis (KRAS and GNAS) is not yet recommended in clinical practice.

Aims & Methods: We aimed to determine if mutation in GNAS and KRAS in addition to CEA level and cytology of cystic fluid obtained by EUS-FNA can help in pancreatic cyst classification and decision making. Evaluation of methylation pattern of the GNAS complex locus was performed for cyst classification. Between 2008–14, 266 EUS were performed for cystic pancreatic evaluation in a single center. We determined the mutational status of GNAS (exons 8 and 9) and KRAS (exons 2 and 3) genes by Sanger sequencing in 52 patients, in cystic fluid obtained by EUS-FNA after cytology and CEA analysis. In operated patients, cysts were also analyzed for methylation of the GNAS complex locus.

Results: Mainly female (67%), mean age of 59 ± 15 years (29-91). Cysts located in head (42%), body (39%), tail (17%) and multiple (2%), with a mean size of 3.9 ± 2.3 cm (0.5–9 cm). Cyst types (as after EUS-FNA + CEA/ cytopology: 15 serous cystadenomas (SCAs), 9 pseudocysts, 8 intraductal papillary mucinous neoplasms (IPMNs), 2 mucinous cystic neoplasms (MCNs), 4 adenocarcinomas (ADC), 1 solid pseudopapillary neoplasm (SPN), 1 lymphangioma, 12 non-defined. CEA > 192 ng/ml in 33% of patients and cytology with benign cells in 12 (23%), suspicious/malignant in 8 (15%), 1 NET (2%) and 31(60%) acellular samples. Surgery in 11 (21%) patients (surgical specimens: 2SCA, 3MCN, 4IPMN, 1 retention cyst and 1 ADC), chemotherapy/palliation in 6 (12%), endoscopic drainage in 1 (2%) and 34 (64%) on fup. KRAS mutation in 19% (9) and in GNAS in 4% (2) of cyst aspirates. By cyst type, GNAS was mutated in 1 IPMN and 1 ADC. KRAS was mutated in 6 patients on fup (2 IPMNs, 3 ADC, 1 pseudocyst- a unicellular 2 cm cyst with CEA = 125) and in 3 who had surgery (2 IPMNs and 1 MCN). Sensitivity and specificity of CEA > 192 + cytopology and CEA/KRAS/GNAS mutations for the classification of mucinous and non-mucinous (table 1-1st part) and malignant and non-malignant (table 1-2nd part) are presented in operated cysts.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: KRAS and GNAS gene mutations in pancreatic cystic lesions are common findings in pancreatic cystic lesions and the testing the effect of the presence of KRAS mutations on the prognosis of survival. 147 patients underwent EUS-FNA examination of pancreatic mass, accompanied by blood sampling with subsequent separation of plasma for the detection of circulating tumor DNA. Part of biopsy sample was left native in a stabilizing solution and part as cytological smear. Samples (native aspirates, cytological smears, plasma) were examined for the presence of KRAS mutation by heteroduplex analysis, denaturing capillary electrophoresis.

Results: Among 147 patients with pancreatic masses, 118 were diagnosed as cancer, 26 chronic pancreatitis, 3x neuroendocrine tumor. In total 147 native aspirates, 118 cytological smears and 94 plasma samples were examined. The highest sensitivity of KRAS mutation was reached in the group of pancreatic cancer patients using cytology, in which 90% of KRAS mutations was detected (106/118 of the samples). When using the native cellular aspirates, mutation was detected in 78% (92/118 samples), and examination of plasma was positive in 70% (66/94 samples).In four patients with chronic pancreatitis KRAS mutations was detected, although none has been cytologically confirmed as a cancer. Two of these four patients were confirmed in the course of the disease as a cancer, one patient died because of alcoholico delirium and the last one was indicated for surgery recently.

Conclusion: Examination of KRAS mutations can be performed in all patients undergoing EUS-FNA, with the cytology being the most reliable type of sample for genetic tests. KRAS examination would be reasonable to introduce into routine clinical practice in a group of patients with unclear differential diagnosis of chronic pancreatitis, especially in those with suspicion of cancer in inflammatory terrain. Financial support by The Ministry of Defence and Armed Forces of the Czech Republic MO 1012.

P1437 DO BILIARY STENTS REDUCE THE DIAGNOSTIC PERFORMANCE OF EUS BIPSY IN PATIENTS WITH A MASS IN THE HEAD OF THE PANCREAS? N. L. Bekkali1, M. Naya2, L. Thornton1, S. J. Johnson2, B. Haugk3, A. Darne4, J. S. Leeds1, R. Charnley3, K. Oppong4, K. Oppong5 1Hpb-medicine, Freeman Hospital, Newcastle upon Tyne/United Kingdom 2Cellular Pathology, Royal Victoria Inflammatory, Newcastle upon Tyne/United Kingdom 3Hepatobiliary and Pancreatic Surgery, Freeman Hospital, Newcastle Upon Tyne, United Kingdom, newcastle/United Kingdom 4Digestive Endoscopy Unit, CHU St Antoine, Paris/France 5Hpb-medicine, Freeman Hospital, Newcastle upon Tyne/United Kingdom 6Hepatobiliary and Pancreatic Surgery, Freeman Hospital, Newcastle Upon Tyne, United Kingdom, newcastle/United Kingdom Contact E-mail Address: noorbekkali@hotmail.com Introduction: Self-expanding metal stents (SEMS) are increasingly preferred to plastic stents (PS) for pre-operative drainage and palliation of biliary obstruction secondary to a stricture in the head of pancreas (HOP). Their use has increased over the last 5–6 years. Endoscopic ultrasound (EUS) with fine needle aspiration (FNA/FNB) is commonly utilised to make a tissue diagnosis and to aid in staging in those with borderline resectable tumours. Stents may reduce diagnostic performance of FNA/FNB by reducing the visible mass to puncture. There have been two studies that assessed the impact of stenting on EUS-FNA performance, one found no difference in yield and sensitivity among patients with or without stents and between SEMS and plastic. Whilst a more recent study found accuracy was significantly reduced by the presence of a stent. Aims & Methods: The aim was to assess whether stents (SEMS or PS) impair diagnostic performance of EUS tissue acquisition, in a retrospective study of all patients with biliary strictures in the head of pancreas, for which EUS-FNA were recorded. Mean age of patients was 37 ±15y. Methods: EUS FNA/FNB procedures on patients with HOP were recorded between January 2010 and June 2016. Biopsies reported as malignant were considered as such, all other reports were considered benign. A definitive diagnosis of cancer was based on positive pathology, which involved features of malignancy, and/or imaging features of progression. A benign diagnosis required negative pathology, stable imaging and symptoms for a year or more. Patients with cystic lesions were excluded. Results: A total of 1861 patients had EUS FNA/FNB of which 731 were for HOP lesions, mean age 65 yrs (410 F), with tissue sensitivity of 72% for all types of needles used. Tissue accuracy was significantly different between the 3 groups (p=0.0001); SEMS 67%, PS 71% and 83% in the unstented group. The difference in accuracy was significant between the unstented group versus SEMS (p=0.0082) and PS (p=0.03) and not significant between PS and SEMS. Stepwise multi-variable analysis revealed significant difference for accurate tissue diagnosis favouring size needle 25G (OR 1.7 [95%CI 1.1–2.7] and tumour size (OR 1.04 [1.02–1.07]) and was affected by presence of a SEMS or PS (SEMS OR 0.3 [0.2–0.6] or PS (OR 0.5 [0.3–0.9]). Other needle sizes (19G or 22G), number of passes or types of needle did not significantly affect tissue accuracy. Conclusion: Our results show a significant adverse impact of both SEMS and PS on tissue accuracy via EUS FNA/FNB. The effect is greatest with SEMS. These results suggest that where possible EUS and biopsy if required should be performed before stent placement. Disclosure of Interest: All authors have declared no conflicts of interest.

P1439 DIAGNOSIS OF PANCREATIC NEUROENDOCRINE TUMOURS USING SUREPATH CYTOLOGY AND IMMUNOHISTOCHEMISTRY WITHOUT NEED FOR EXCISION BIOPSY C. Meredith1, H. Dixson2, P. Irandoost3, P. Baird1 1Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown/ Australia/NSW 2Ultrasound And Nuclear Medicine, Bankstown-Lidcombe Hospital, Bankstown/ Australia/NSW 3Cytology, Lavery Pathology, Ryde/Australia/NSW Contact E-mail Address: drmeredith@gmail.com Introduction: Pancreatic neuroendocrine tumours (PNETs) are relatively rare, i.e., 21 per 100,000 individuals per annum, and account for only 1–2 percent of all pancreatic tumours. They are separated into 2 major categories: 1) well-differentiated (WD-NETs) which have round to oval nuclei, coarsely stippled chromatin and finely granular cytoplasm and 2) poorly-differentiated (PD-NETs) which have a diffuse architecture with an irregular nucleus and less cytoplasmic granularity. WD-NETs tend to have an indolent course (survival ~67% at 5 years) but ~50% have metastasised at the date of diagnosis. PD-NETs are high-grade cancers with an aggressive course resembling NETs arising in lung. WD-NETs contain neuroendocrine granules which stain for synaptophysin and/or chromogranin. Endoscopic ultrasonography guided fine-needle aspiration biopsy (EUS-FNA) can provide a non-operative cytological diagnosis of PNETs when the pathologist is provided with a good specimen such as the pellet of cells obtained through SurePath (SP).

Aims & Methods: EUS-FNA samples of pancreatic tumours were collected into a SurePath vial and slides prepared from the cellular pellet. The slides were stained for synaptophysin and Ki67 by immunohistochemistry (IHC) and examined by 2 independent senior cytopathologists.

Results: Sixteen (16) patients with a mean age 65 years (6 male) were identified by EUS with a suspected PNET. The mean tumour size was 16.2 mm +/- 4.2 mm. All had the morphology of a PNET and stained positive for synaptophysin. Conclusions: SP prepared cytology slides from solid pancreatic tumours provides enough diagnostic material for IHC staining for synaptophysin and Ki67 without the need for a formal excision biopsy. Morphology of SP slides is often diagnostic but a positive stain for synaptophysin makes the diagnosis irrefutable. The
PI440 EFFECTS OF IGF2BP2 ON GROWTH AND PROLIFERATION OF NEUROENDOCRINE TUMOR CELL LINES

Introduction: Pancreatic neuroendocrine neoplasms (PENs) are highly angiogenic tumors which despite of various targeted options including mTOR and VEGF inhibition frequently develop secondary drug resistance. IGF2BP2 (IGF2 mRNA-binding proteins) represent a family of canonical RNA-binding proteins (RBPs) comprised of three members (IGF2BP1–3) which have been described to promote stem and/or progenitor cell maintenance with reported expression and oncogenic roles in aggressive cancers. IGF2BP2 shows a differential expression pattern in various solid tumors including pancreatic neuroendocrine tumors.

Aims & Methods: We aimed to characterize the role of IGF2BP2 in progression and resistance of pancreatic neuroendocrine neoplasms. We used three different siRNA-pools (IGF2BP2-3) to inhibit the different IGF2BP2s in pancreatic neuroendocrine BON1 tumor cells. Cellular effects were investigated by Western blot analyses, flow cytometry, clonogenic survival, cell viability and migration assays.

Results: In the pancreatic neuroendocrine tumor cell line BON1, knock-down of IGF2BP1 resulted in a significant reduction of cell viability. Cell cycle analysis by FACS showed a decreased S phase progression paralleled by a reduction in the proliferation marker PCNA and a markedly reduced MEK/ERK activation. In contrast, Akt signaling was unaffected. Moreover, knock-down of IGF2BP2 significantly reduced clonogenic growth as assessed by colony formation assays and led to decreased cell migration as determined by scratch assays. Interestingly, knock-down of IGF2BP1 was insufficient to induce apoptosis, as assessed by PARP and caspase-3 cleavage as well as Annexin-V FACS. Rather, si-IGF2BP2 increased the expression of both the anti-angiogenic and pro-survival factor BCL-2 and the cell cycle inhibitor CDKN1B. In contrast to IGF2BP1, knock-down of IGF2BP3 rather induced cell viability, whereas IGF2BP2 modulation had no impact on cell viability and cell cycle progression indicating opposing effects of the three IGF2BP2s on PENN progression. These in vitro findings were paralleled by distinct expression patterns of IGF2BP2 in human and murine PENN tissues. Elucidation of IGF2BP2-modulated RNAs in PENN cells is ongoing.

Conclusion: In summary, our data suggest that IGF2BP1 promotes tumor progression by enhancing cell cycle progression and clonogenic growth, whereas IGF2BP2 and -3 exert no tumor-promoting role in PENN.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The chemopreventive effect of aspirin (ASA) and other NSAIDs (non-steroidal anti-inflammatory drugs) has been observed in the setting of colorectal cancer, showing a reduction in the incidence and mortality. However, the impact of aspirin use on clinical outcome of patients with gastro-entero-pancreatic neuroendocrine tumors (GEP NEN) has not yet been evaluated.

Aims and Methods: Aim of the study was to retrospectively evaluate the clinical outcome of GEP NEN patients treated with ASA at three different European referral centres for NENs. All the GEP NENs patients followed up in three European Centres (Fondazione IRCCS Ca’ Granda Ospedale Policlinico Milano, Italy; Fondazione IRCCS Istituto Tumori Milano, Italy; Mater Misericordiae University Hospital, Dublin, Ireland), from January 2005 and September 2016, were retrospectively enrolled. The possible association between ASA and disease grading, staging, primary site, overall OS and PFS were evaluated. At the time of enrolment, clinical data and biochemical parameters were collected for every patient. Chromogranin A (CgA) and specific circulating peptides were evaluated. Morphological and functional imaging (computed tomography, magnetic resonance and Gallium 68PET) were performed to follow up the patients at each Centre.

Results: In the 253 patients included (121 M, median age 64 yrs), the primary neuroendocrine tumor was located at the stomach (33%), pancreas (#82), small bowel (#90), appendix (27), colon (#49) or unknown (#7). Grading was G1 in 154 patients, G2 in 64, G3 in 5 and not available in 28. TNM staging was I in 99 patients, II in 16, III in 32 and IV in 86. No clear impact on OS or PFS was observed in patients taking ASA compared to those not taking it. Interestingly, in pNEN an inverse relation was observed between Ki67 and ASA assumption (r=-0.35, p=0.008). In small bowel NEN an inverse relation was observed between positive lymphnodes at surgery and ASA assumption (r=-0.3, p=0.02). As expected, the intake of ASA was related with the older age of the patients.

Conclusion: According to present data, ASA therapy seems not to have a direct clinical impact on disease progression or survival of NENs, even if it is associated with lower Ki-67 values and less node involvement. Further studies are needed to confirm this observation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Von Hippel-Lindau disease (VHL) is a rare heritable genetic syndrome that may affect different systems and organs: pancreatic manifestations of the disease are frequent during lifetime of the patients. The key feature of the presence of simple cysts, but serous cystadenomas (SCAs) or neuroendocrine tumors (NETs) can be frequently found as well. The aim of this study is to describe pancreatic manifestations in patients with VHL, considering the peculiarity and rarity of this disease.

Aims & Methods: All patients who referred to the established multi-disciplinary team in our center (Molinette Hospital - Torino) for management and follow-up of VHL were reviewed in the study; we considered the ones with pancreatic involvement (simple cysts, SCAs or pNETs). We collected data about the patients (demographics and medical history), about the lesions (imaging features, histological and cytological analysis) and about the management.

Results: A total of 24 patients, 18 of which (75%) had a pancreatic involvement. Multiple simple pancreatic cysts were found in 13 patients, SCAs were found in 2 patients and NETs in 7 patients. The mean age of the patients with pancreatic lesions was 42 (min 25 - max 75), 11 were males and 7 females (1.6:1 M:F). Simple cysts affected 13 patients, are always multiple (ranging from 12 to 80 mm) mostly in the head. 3 patients underwent surgery for symptomatic disease. All pNETs were well differentiated (G1, Ki67 (1.6:1). Simple cysts affected 13 patients, are always multiple (ranging from 12 to 80 mm) mostly in the head. 3 patients underwent surgery for symptomatic disease. All pNETs were well differentiated (G1, Ki67 <2%); 7 were located in the head and 2 in the tail (2 patients had multiple tumors). 5 out of the 7 pNET patients underwent surgery. The two SCAs were multiple (max 65 mm), mostly in the head and 2 in the tail (2 patients had multiple tumors). The probability of metastasis increased with tumor size of 2 cm or less. The probability of metastasis increased with tumor size of 2 cm or less. The probability of metastasis increased with tumor size of 2 cm or less. The probability of metastasis increased with tumor size of 2 cm or less.

Conclusion: 75% of our VHL patients showed pancreatic involvement, mostly in males compared to females. 72% of patients with pancreatic lesions suffered from simple cysts, 39% from NETs and 11% from SCAs. To note that all NETs were G1 and behaved in a benign fashion. Surgery was performed only in patients with NETs in the pancreatic head and in patients with symptomatic cystic disease. The mean age of incidence of VHL-related pancreatic lesions was lower than in previous reports, thus confirming our patient data. Although all lesions in our patients were benign or stable, constant monitoring is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Neuroendocrine tumours (NET) consist of a diverse group of neoplasms that derive from diffuse neuroendocrine cells throughout the body. Commonly found in gastrointestinal (GI) duct and lung, they (GI) also arise in the pancreas. The relationship between tumour size and metastasis rate is poorly recognized in patients with pancreatic neuroendocrine tumours (PNETs). The impact of tumour size on prognosis was controversial in previous investigations. Aims & Methods: The aim of this study is to evaluate the prognostic impact of tumour size on survival outcomes and its correlation with risk of metastasis in a large PNET cohort, including all stages. Methods: PNET cases diagnosed from 1988 to 2013 were retrieved from the Surveillance, Epidemiology, and End Results (SEER) database. Clinicopathologic features were retrospectively analyzed. Survival was calculated by the Kaplan-Meier method. Multivariable Cox regression models with hazard ratios (HRs) were constructed to analyze survival outcomes and risk factors. Cubic spline analysis was used to assess relationship between tumour size and probability of metastasis.

Results: A total of 5424 patients were identified. There were 1226 patients (22.6%) with tumour size of 2 cm or less. The probability of metastasis increased in a non-linear fashion with increasing tumour sizes. In univariable analysis showed that tumour size was significantly correlated with survival (P<0.001), no matter surgery was performed or not. However, subgroup analysis suggested this association to be linear for patients with localized and regional tumours (P<0.001), but stochastic in patients with distant stages (P=0.703). On multivariate analysis, tumour size was an indicator for metastasis (HR = 1.010, 95% CI: 1.008-1.012, P = 0.001 and size <20 mm was an independent prognostic factor for good survival (HR = 1.211, 95% CI: 1.048-1.399, P = 0.009 for size < 21-40 mm; HR = 1.282, 95% CI: 1.163-1.474, P < 0.001 for size >40 mm). For tumours ≤20 mm, surgical treatment was associated with significantly improved survival compared with those patients who did not undergo operation (P<0.001).

Conclusion: Tumour size affects the probability of metastasis. Its prognostic impact on survival is restricted to patients with localized and regional disease. For tumours with tumour size ≥20 mm, surgical treatment should be considered preferably.

at 4 patients. The mean age of our MEN-1 patients was 51 and the age at diagnosis was 41.8. The mean plasma calcium level was 11.46 mg/dl and there was no history of renal calculi at any of them.

**Conclusion:** The family presented here is the one which had the largest number of affected individuals with genetic and clinical properties of MEN-1 at Turkey. Because the patient described here is the male with benign mono-epithelial tumor causing loss of function that is described for the first time. Also at MEN-1 families, counseling to prevent the neoplasia development and to prevent the new family member to be affected with PGD has a pivotal importance. We could point out that awareness is the most important caution for prevention.

**Introduction:** Several inflammatory response materials could be used for prediction of progress in cancer patients. The neutrophil lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR), thrombocytosis (the platelets number >400x10^9/mm^3) have been introduced for prognostic scoring system in various cancers.

**Aims & Methods:** The objective of this study was to determine whether the NLR, the PLR or thrombocytosis could predict the clinical outcomes in G1-G2 neuroendocrine tumors. We performed a retrospective review of 31 patients with neuroendocrine tumors with ki 67 below 20% diagnosed in Fundeni Clinical Institute between 2011-2017. Data about site of the primary tumor, presence of metastasis, NLR, PLR, thrombocytosis (platelet count > 400) and survival were collected and analysed.

**Results:** The patients characteristics were: primary tumor location was: 61.29% pancreas, 22.58% gastrointestinal tract, 16.13% unknown, 61.29% had hepatic metastasis, 6.45% had locally advanced tumor. The primary tumor was resected in 35.48% of patients. The overall 2-year survival rate was 77.42%. The Ki 67 index (p < 0.04), PLR (cut off >300) p < 0.01 have statistical significant impact on survival in univariate analysis and on multivariate analysis (P < 0.05). Other factors like ki 67 index, metastatic disease, thrombocytosis and NLR have an impact on survival statistical significant on multivariate analysis.

**Conclusion:** This study demonstrates the prognostic role of different variables like Ki 67 index, PLR and PLT value, thrombocytosis and metastasis. This factors may be integrated in different scoring systems for prognosis that could guide clinicians for a better management in patients with neuroendocrine tumors.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**
retrospectively 103 patients with positive lateral margin after ER from January 2005 to December 2015, in single tertiary center. Clinicopathological data were retrieved to assess the local recurrence rate, survival rate, procedure related adverse events.

Results: Of the 103 patients, 27 patients (26.4%) underwent early re-treatment within 3 months after initial ER/17 patients in re-do ESD, 10 patients in additional surgery). And 76 patients (73.6%) were observed under close surveillance. Median duration of follow-up period was 45.7(6–132) months. Recurrence rates of early re-treatment group(3.7%, n=1/27) was lower than surveillance group(18.4%, n=13/70, p=0.05). Five-year survival rates not significantly different between the two groups, at 100%, 97.4% respectively. In close surveillance periods, 12 patients were confirmed to local recurrence by follow-up biopsy, then delayed re-treatment was performed (7 patients in re-do ESD, 5 patients in surgical resection). Median duration of follow-up period was 27.5 (2.6–31.7) months. Totally, a total of 24 patients were treated with re-ESD, and 17 patients were treated with additional surgery. Among these two groups, there were no significant difference in recurrence rates (8.3% vs. 0%) and five-year survival rates (both 100%). However, adverse events related to treatment was more frequent in additional surgical group (2 ileus, 1 umbilical hernia).

Conclusion: The additional treatment should be recommended for patients with positive lateral margin after initial ER for EGCs. In addition, re-ESD which have a similar efficacy and a better quality of life, compared to additional surgery is a favorable option for control of recurrence or residual EGCs.

Introduction: Bleeding control is one of the most important factors to success of endoscopic submucosal dissection (ESD) in safety. We have reported the endoscopic coagulation technique using soft coagulation mode (S method) is effective for the prevention of bleeding when relatively large vessels penetrating between muscle layers are dissected. However we have thought that S method is insufficient especially for large vessels such as more than 2 mm, we have to use hemostatic forceps for preventing hemorrhage despite treating them with soft coagulation mode with low-high frequency power setting (F1-10 method) can exhibit coagulation function without bursting vessels. It is suggested that F1-10 method is useful for large vessel prevascularization.

Aims & Methods: We investigated the deference of hemostatic ability between S method and F1-10 method in clinical study and ex vivo study. In clinical study we analyzed retrospectively their hemostatic ability by consecutive six gastric ESD cases in each groups excluded some cases, which have the risk of affecting data, at 87.2% (n=54) and 95.4% (n=49) in the S and F1-10 methods, respectively. The bleeding rate after vessel processing was 18.4% (8/49) and 4.8% (3/62) in the S and F1-10 methods, respectively. No significant difference was found between the S and F1-10 methods.

Discussion: In ex vivo study, to investigate the coagulation mechanism of those two different power settings was evaluated the peak voltage, current elapsed time, and electric energy by using the data recording program (VIO DOKU) and the width and depth of coagulation was measured on macro- and microscopic levels using porcine tissues. The results: the total number of vessels processed by endoknife prevasculariation were 49 and 61 vessels in the S and F1-10 methods. The median vessel diameter was 2 mm in the S method and 1.5 mm in the F1-10 method. The median frequency of the compressed vessel was twice in both methods, and the median coagulation time was 9s and 10s in the S and F1-10 methods, respectively. No significant difference was found between the S and F1-10 methods. The bleeding rate after vessel processing was 18.4% (8/49) and 4.8% (3/62) in the S and F1-10 methods, respectively (P=0.058, odds ratio [OR]: 3.84, 95% confidence interval [CI]: 0.86–15.34). No statistically significant differences were found; however, the F1-10 method strongly showed a trend in preventing bleeding after prevasculariation compared with the S method (P=0.08). We further investigated the bleeding rates of the large vessels, defined as ≥2 mm in diameter. There were 26 and 29 large vessels in the S and F1-10 methods, respectively. The bleeding rates of the large vessels were 26.9% (7/26) and 3.4% (1/29) in the S and F1-10 methods, respectively, which were significantly different (P=0.021, OR: 10.32, 95% CI: 1.17–90.78). In ex vivo study, the median peak voltage was 172 Vp and 540 Vp in the S and F1-10 methods. The median current elapsed time was 0.22s and 1.54s in the S and F1-10 methods. The F1-10 method could keep the electric current longer than the S method. The mean total electrical energy was 6.34 W and 12.5 W in the S and F1-10 methods. F1-10 method was able to give larger electrical energy in the positive block. And the width and depth of coagulation in F1-10 method spread wider and deeper in macro- and microscopic sections.

Conclusion: F1-10 method is suggested to achieve a stronger hemostatic effect than S method in prevascularized procedures to identify large vessels especially for large vessels such as more than 2 mm. The bleeding rates after vessel processing were 18.4% (8/49) and 4.8% (3/62) in the S and F1-10 methods, respectively (P=0.058). When stratified by therapy, the median exposure to each therapy was either 0 or 1, with means displayed in Table 1. 25.2% of trainees had no exposure to any type of endotheraphy (67.5% of NME and 18.6% of medical endoscopists, p < 0.0001). Of medical endoscopists awarded certification, 37.1% had not performed band ligation, 50.7% had not placed a clip, and 54% had not used heater probe. NME had significantly less exposure to each modality of endotheraphy compared (overall odds ratio 0.10, p < 0.0001).

Conclusion: Training on endotherapy prior to certification is limited. The current UGIB certification processes do not provide a consensus on ideal modality of endotheraphy for UGIB. In response, the JAG QA team have recently released new DOPS forms specific to UGIB, and are consulting on introducing formal certification in endotherapy for UGIB.

March and September of 2016. All patients underwent EC with iScan. The esophagus was inspected with a ECM capable endoscope (EG- 2990-Zi) and deliberate biopsies were taken from tissue identified by ECM that suggested BE. All biopsies were confirmed by a GI pathologist. Primary endpoint was the correlation between visual inspection diagnosis of dysplastic BE by ECM versus pathologic diagnosis of BE as the gold standard.

**Results:** In our cohort 41% were male, with mean age of 47.7 years. Endoscopic diagnoses by ECM were divided into nondysplastic BE (96/100) and suspected dysplastic BE (4/100). On pathology nondysplastic BE was found in 94/100 patients, BE with low-grade dysplasia was found in 4/100 patients. Benign gastric mucosa with no alterations (1/100), and ulcerated esophagitis (1/100). The overall accuracy of endoscopic diagnoses using ECM against pathology diagnosis was of 98%, with sensitivity of 100% [95% CI (96%–100%)], and positive predictive value of 98% [95% CI (93%–99.7%)].

**Conclusion:** Endoscopic diagnosis of BE by direct biopsies of esophageal tissue with use of ECM is highly accurate. Future prospective studies are needed to validate our preliminary findings and assess inter-observer variability.

**Introduction:** Barrett’s oesophagus (BO) is the main risk factor for oesophageal adenocarcinoma (OAC). International guidelines recommend endoscopic surveillance for early detection of dysplasia (DYS) and/or OAC but current biopsy protocols can miss areas of endoscopically unapparent neoplasia. At present, advanced diagnostic imaging technologies and specific endoscopist and pathologist expertise in detecting the subtle phenotypic changes associated with DYS/OAC are available only in tertiary care referral centres. Advanced diagnostic imaging technologies and specific endoscopist and pathologist expertise in detecting the subtle phenotypic changes associated with DYS/OAC are available only in tertiary care referral centres.

**Aims & Methods:** The aim of this study is to investigate the diagnosis changes after BO assessment in a tertiary care referral centre. 119 consecutive patients [male = 103, female = 16; median age = 58 (50.64)] referred to the Veneto Institute of Oncology (IOV-IRCCS) BO Unit between 01/03/2015 and 01/03/2017 were considered. Patients were divided in 3 groups according to the admitting diagnosis (AD): BO patients without DYS/OAC or visible lesions (Group 1, n = 82); BO patients with DYS/OAC but no visible lesions (Group 2, n = 33); BO patients with DYS/OAC and visible lesions (Group 3, n = 4). All patients underwent an endoscopy under deep sedation at IOV with HD magnification endoscopes + NBI + acetic acid chromoendoscopy. Target biopsies and/or EMR were obtained in case of endoscopically visible lesions; 4-quadrant biopsies 2 cm were obtained otherwise. All the specimens were diagnosed by two expert GI pathologists, who reached a final diagnosis (FD). In Group 2 patients where FD was BO without DYS/OAC, previous histology was reviewed by two expert pathologist.

**Results:** Results are summarized in Table 1. Group 1 (n = 82): FD of DYS/OAC with visible lesion was reached in 2 out of 82 patients (2.4%), both treated by EMR + RFA. No one had a FD of DYS/OAC without visible lesions. Group 2 (n = 33): FD of DYS/OAC with visible lesions was revealed in 13 out of 33 patients (39.4%); 11 were treated by EMR + RFA; 1 by surgery and 1 chemotherapy/radiotherapy. In 20 patients the AD was downgraded to unconfirmed BO; in 19 patients (57.6%), a review of previously taken biopsies by expert pathologist excluded neoplasia. In only one patient no lesion was found but the review of original histology slides confirmed a low-grade DYS and the patient was treated by RFA. Group 3 (n = 4): DYS/OAC was confirmed in all the 4 patients (2 treated by EMR + RFA, and 2 by surgery).

**Conclusion:** When upper endoscopy is performed in a BO reference center where specific facilities and expertises are available (i.e. deep sedation, HD magnification endoscopes, chromoendoscopy, expert endoscopist and pathologist) “invisible” DYS is a very rare diagnosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** drtarunbharadwaj@gmail.com

**Introduction:** Endoscopic full-thickness resection (EFTR) for sub-epithelial lesions (SEs) of GI tract is less frequently described; possibly due to technical challenges involved in dissection and need for resultant defect closure. Current study describes single-center experience of EFTR for treatment of SEs.

**Aims & Methods:** Prospective database of patients undergoing EFTR for SEs over 6-years (2011–2017) was abstracted. Patient selection for EFTR-endoscopy, endoscopic ultrasound (EUS) and CECT. Inclusion criteria: diagnosed lesions, predominantly endophytic component and absence of features of invasive malignancy. Exclusion criteria: patients unfit for general anesthesia or major Intervention procedure, uncorrectable coagulopathy or high risk features for malignancy. All procedures performed under general anesthesia with endotrachial intubation. High-definition endoscope (GIF-HQ-190 or CFI-HQ-190, Olympus Corp, Japan) with distal transparent hood and carbon dioxide insufflation used in all. After submucosal (SM) elevation by Gelfoam, mucosal incision and SM dissection performed to expose SE. Encapsulated SE intubated maintaining intact capsule. Adherent and attached muscularis propria (MP) layer fibers divided. IT or Dual-knife170 used for dissection and coag-grasper for hemostasis.

**Results:** Total N = 18 (M: F 11:7), mean age 53.6 (Range 28–78). Presentation – GI bleed (73.8%), abdominal pain (42%), non ulcer dyspepsia, 1, rectal mass – 4, asymptomatic, incidentally diagnosed (63.5%). Layer of origin-MP layer in all. Location-stomach = 13(72%), duodenum = 2, rectum = 2, proximal jejunum = 1. Mean size of SET=3.3 cm (range 1–7). Mean procedure time 182 mins (60–345), and mean hospital stay was 4 days. Adverse events – two (11%)–esophageal laceration during specimen retrieval-1 (closed using endolips), failure-1 due to undetected large epiploic component-surgical resection. Histopathology with
IHC-GIST–(93.0%);neuroendocrine tumor–3(16%), leiomyoma–1, schwannoma–1. The cell diameter of the GIST was 1(0.4%) larger than the angle of the gastric wall. The cell diameter of the GIST was 1.7 cm (range 0.7-6.0 cm). The success rate of EFTR was 98.9% (273/276). EFTR was failed in 3 cases: one case was out of control because of bleeding into enterocoeica, two cases required conversion into laparoscopic surgery because of absent lobulations of the tumor outside the cavity. The median operation time was 65 min (range, 14-210 min). In the resection rate was 98.1% (268/273), the piecemeal resection rate was 1.5% (5/273). The median length of hospital stays was 4.4 days (range, 1-23 days). Pathological outcomes revealed that the mean size of the tumor was 137 (49.2%) leiomyomas, 13 (47.3%) schwannomas, 8 (29.9%) calcifying fibrous tumors, 7 (2.5%) glomus tumors, 5 (1.8%) displaced pancreases, and 3 (1.1%) fibroblasticomas. The procedure-related complications were as follows. Different degrees of gastric antral occluded occurred in 168 (60.9%) cases, among which 24 (8.7%) cases required analgesics. Pneumoperitoneum occurred in all the patients and was treated successfully with peritoneocoeica decompression. Seroperitoneum occurred in 15 (5.4%) cases, localized peritonitis occurred in 3 (1.1%) cases, and digestive tract leakage occurred in 1 (0.4%) case. All the cases with above complications recovered spontaneously or after conservative treatments. No massive bleeding or abdominal abscess was found after EFTR. None of the 273 cases developed procedure-related death. No tumor residual or recurrence was found during the follow-up period ranging 3–55 months.

Conclusion: EFTR without laparoscopic assistance is minimally invasive, safe, and effective for treating gastric and duodenal SMTs, which originate from the MP layer and adhere tightly to the serosa. High en bloc resection rate could be achieved. However, a larger number of the cases and long-term outcome deserve further research.

P1455 BLUE LIGHT IMAGING AND LINKED COLOR IMAGING FOR DETECTION AND CHARACTERIZATION OF CHRONIC GASTRITIS
J. Weigt1, A. Link1, A. Canbay1, P. Malfierthener1
1Gastroenterology, Hepatology & Infectious Diseases, Medizin. Universität Magdeburg Gastroenterologie und Hepatologie, Magdeburg/Germany
Contact E-mail Address: jochenweigt@gmx.de

Introduction: Current standard in the characterization of gastric mucosal changes is the use of virtual chromoendoscopy with magnification to visualize the pit pattern and vascular changes. The most recent development in light emitting technology is the so called Multi Light Illumination, that composes light out of 4 coloured LED. Blue Light Imaging (BLI) is composed of a continuous spectrum with peaks at 410 and 430 nm to enhance surface and vascular structures. Linked Color Imaging (LCI) uses BLI light together with post processing that realocates colour tones resulting in a high contrast of different red tones. Until now only few data exist about the use of LCI and BLI in chronic gastritis (CG).

Aims & Methods: We aimed to analyse the use of LCI and BLI in detecting and characterizing of chronic gastritis and premalignant conditions of the stomach. The study was carried out in our endoscopic laboratory. All patients gave written informed consent. In all cases an endoscope equipped with zoom (Fujifilm EG-760Z) was used. Endoscopic classification was based on the following parameters: normal gastric mucosa was defined as mucosa with visible superficial capillary network (SCN) without any focal lesions; atrophy (AG) was defined by whitening of the mucosa with visible deeper vascular architecture in white light, BLI and LCI; intestinal metaplasia (IM) was diagnosed if mucosa had visible rugae/squamoid surface with whitening in LCI or white light or light blue crescent sign in BLI; CG was diagnosed in case of loss of SCN or focal lesions not matching the definition of other focal lesions or cancer. Biopsies were sampled according to the updated Sidney classification system and in addition of every visible focal lesion. After endoscopy a prediction of histology was made by the endoscopist.

Results: We investigated 24 patients (15 female, 9 male, age 65 yrs (25–87yrs)). H. pylori was detected by histology or urease test in 7 patients. 3 patients showed normal gastric mucosa, 13 patients presented IM or AG either in the antrum or the corpus. According to MAPS criteria 7 patients had extensive disease with premalignant conditions in both, antrum and corpus. The concordance of endoscopic classification and histology was 79.1% (19/24) in the antrum and corpus each. Despite the inconcordance of histology and endoscopic diagnosis in 5 cases the intervals for surveillance according to MAPS guidelines would have been correctly respected with the use of endoscopic assessment in all cases.

Conclusion: LCI and BLI are accurate in detection and characterization of changes in gastric mucosa with an acceptable concordance to histology. These new imaging modalities are a step towards precise endoscopic diagnosis of gastric mucosal changes and have the potential to reduce the number of unnecessary histologic investigations and offer the possibility for more appropriate endoscopic diagnosis.

P1456 THE VALUE OF ENDOCOPIC FULL-THICKNESS RESECTION FOR GASTRIC AND DUODENAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER
M. Xu1, Z. Zhang1, Q. Li1
1Endoscopy Center, Zhongshan Hospital, Shanghai/China
Contact E-mail Address: whitelily.chen@aliyun.com

Introduction: Given diminishment of quality of life caused by surgery in the stomach and duodenum, a minimally invasive technique is desirable for gastric and duodenal submucosal tumors (SMTs).

Aims & Methods: We aimed to assessed the value of endoscopic full-thickness resection (EFTR) technique for gastric and duodenal submucosal tumors (SMTs) originating from the muscular propria (MP) layer. A total of 276 patients with single gastric SMTs originating from the MP layer were performed EFTR between January, 2010 and February, 2014. The tight adhesion of the tumor to the gastric or duodenal serosal layer could be seen in every case from endoscopic ultrasound (EUS) before the procedure. The SMTs orientated endoscopically were performed EFTR using a standard ESD technique without laparoscopic assistance under direct endoscopic view. The defect of gastric and duodenal wall was closed after resection.

Results: A total of 276 patients included 94 males and 182 females. Their median age was 57.8 years (range, 30-81 years). Among all the 276 SMTs in our study, 165 located in gastric fundus, 96 located in gastric body, 8 located in the antrum, 1 located in the duodenum and 1 located in duodenal bulb. The angle of the gastric wall was 1.7 cm (range 0.7-6.0 cm). The success rate of EFTR was 98.9% (273/276). EFTR was failed in 3 cases: one case was out of control because of bleeding into enterocoeica, two cases required conversion into laparoscopic surgery because of absent lobulations of the tumor outside the cavity. The median operation time was 65 min (range, 14-210 min). In the resection rate was 98.1% (268/273), the piecemeal resection rate was 1.5% (5/273). The median length of hospital stays was 4.4 days (range, 1-23 days). Pathological outcomes revealed that the mean size of the tumor was 137 (49.2%) leiomyomas, 13 (47.3%) schwannomas, 8 (29.9%) calcifying fibrous tumors, 7 (2.5%) glomus tumors, 5 (1.8%) displaced pancreases, and 3 (1.1%) fibroblasticomas. The procedure-related complications were as follows. Different degrees of gastric antral occluded occurred in 168 (60.9%) cases, among which 24 (8.7%) cases required analgesics. Pneumoperitoneum occurred in all the patients and was treated successfully with peritoneocoeica decompression. Seroperitoneum occurred in 15 (5.4%) cases, localized peritonitis occurred in 3 (1.1%) cases, and digestive tract leakage occurred in 1 (0.4%) case. All the cases with above complications recovered spontaneously or after conservative treatments. No massive bleeding or abdominal abscess was found after EFTR. None of the 273 cases developed procedure-related death. No tumor residual or recurrence was found during the follow-up period ranging 3–55 months.

Conclusion: EFTR without laparoscopic assistance is minimally invasive, safe, and effective for treating gastric and duodenal SMTs, which originate from the MP layer and adhere tightly to the serosa. High en bloc resection rate could be achieved. However, a larger number of the cases and long-term outcome deserve further research.

**P1458** LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION(ESD) FOR RELATIVE INDICATION GROUP OF EARLY ESOPHAGEAL SQUAMOUS CARCINOMA (ESEC) IN AGED PATIENTS

Z. Qi1, Y. Zhong1, P. Zhou1
1Endoscopy Center, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: poem001@qq.com

Introduction: According to the Japanese Esophageal Society Guidelines, Early Esophageal Squamous Cell Carcinoma (ESEC) involving the muscularis mucosa or <200μm invasion of the submucosa, and circumferential extent of >2/3 were relative indications (RI) for ESD. Additional treatment (AT, including esophagectomy or chemoradiotherapy) may be needed after ESD. But in aged RI patients, most will refuse AT due to higher rates of debilitating symptom in China.

Aims & Methods: The aim of this study was conducted to evaluate the long-term outcomes of aged RI patients without AT after ESD.

Between January 2008 and December 2013, a total of 158 aged ESEC patients were included in the present retrospective study. Prognosis outcomes were analyzed.

Results: 89 patients included in absolute indication (AI) group and 69 in RI group, the baseline characteristics were balanced between two groups. During the follow-up time (median 56 (1-108) months), short-term adverse events (4.3% vs 1.1%, p = 0.319) and postoperative stricture rate (31.8% vs 21.3%, p = 0.134) were higher in RI group than in AI group; 4-year recurrence-free survival rate (85.8% vs 87.2%, p = 0.561), metastasis-free survival rate (100 vs 96.8%, p = 0.437), overall survival rate(96.6% vs 90.0%, p = 0.613) and cause-specific survival rate(98.8% vs 98.5%, p = 0.264) for AI group and RI group were comparable.

Conclusion: Aged RI ESEC patients without AT(chemotherapy or chemoradiotherapy) showed comparable prognosis outcomes with AI group after ESD. So follow up may be recommended, substituted for AT in aged RI group.

**P1459** RETROSPECTIVE ANALYSIS ON SUSPICION OF FOREIGN BODY INGESTION AND FOOD IMPACTION ON GASTROENTEROLOGY EMERGENCIES

J. T. Correia De Sousa1, D. Libanio1, P. Lago1, R. Marcos-Pinto1, I. Pedroto1
1Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: joao.correia.de.sousa@gmail.com

Introduction: Suspicion of foreign body (FB) and food impaction (FI) are one of the most common motives for endoscopic emergency. This retrospective study reviewed 288 cases of suspicion on FB/FI, by the frequency of endoscopic alterations, predictive factors to presence, types of FB found, and therapeutic approach.

Aims & Methods: Unicentric retrospective cohort study of endoscopies performed during one year of gastroenterology emergency setting.

Results: In 2015, 288 endoscopies were performed on suspicion of FB/FI (22% of total emergency endoscopies, n = 1309, of them 69.1%(n= 199) were performed during the night. Patients’ median age was 58 years, and 52.8% were women. The presence of FB/FI was confirmed in 71.2%(n= 205); of them 61.5%(n=126) were FB. The least frequently found foreign bodies were most food masses (n= 78 with 18%) and fish bones (14.6%;n=30). Most FB/FI were found on the proximal esophagus (56.1%, n = 115). Endoscopic removal was performed on 129 cases (63.4%), endoscopic mobilization in 54 (26.3%), and in 22 endoscopic removal wasn’t achieved (10, where referred of otolaryngology; 2 for surgery and 10 were deferred to esophagy with sedation, in operating room). Endoscopy under sedation was performed in 20 cases (9.7%). About 1/4 had associated comorbidities, the most common were esophageal ring in 22 (10.7%) and benign stenosis in 17 (8.3%) patients. Major complications were rare: 1 perforation (0.3%) and 3 deep esophageal lacerations (1.5%). Age (>55years), presence of comorbidities, and previous episodes were associated with presence of FB/FI on Endoscopy (Odds Ratio 2.01, 3.39 and 4.63 respectively).

Conclusion: Endoscopy is frequently preformed for suspicion of FB/FI in our emergency setting. Presence is confirmed in the majority of the cases. Predictive factors for presence were identified. Most FB/FI were removed with success with low complication rates. This data favor the endoscopic approach on suspicion of FB/FI.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1460** LEARNING CURVE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC NEOPLASMS; LOW-VOLUME SINGLE-CENTER EXPERIENCE

S.T. Kim1, T.H. Kim1, S. Na1
1Internal Medicine, Jeju National University Hospital, Jeju/Korea, Republic of

Contact E-mail Address: panzervor@paran.com

Introduction: Endoscopic submucosal dissection (ESD) has become a standard therapy for early gastric neoplasia. There is no consensus yet about the number of experiences required for performing ESD alone.

Aims & Methods: We aimed to investigate the learning curve of ESD performed by a single beginner endoscopist focusing on developing the performance of dissection, shortening the procedure time, and preventing complications.

Methods: Records of 120 consecutive ESD procedures performed by a single beginner endoscopist with an ESD knife from March 2012 to February 2016 were collected. For analysis of the learning curve, total procedures were divided into four periods, each comprising 30 sequential ESD. The parameters assessed were the en-bloc resection rate, complete resection rate, procedure time, and related complications.

Results: In the procedure time according to the number of experiences, the procedure time decreased from 30 experience. However, there was no statistical difference from the first (63.5±5.40) to the second quarter (44.7±5.31, p = 0.19), to the third quarter (40.7±7.28, p = 0.08), and to the fourth quarter (40.8±2.31, p = 0.09). There was no procedure that exceeded 100 minutes from the third quarter. There were a total of seven perforations, four of which were in the first quarter, two in the second, and one in the third. In the procedure time according to the location of the lesions, upper lesion (92.6±4.37) showed lower procedure time than middle (46.6±4.02, p < 0.01) and lower third (39.5±27.5, p < 0.01) with statistically significant difference. In addition, in the fibrotic lesions, regardless of size and location, all took a very long time, more than 100 minutes.

Conclusion: It needs accumulate experience with the help of a professional expert up to 30 cases, and to the more advanced level, about 90 procedures are needed. And, the location of the lesion is the important factor in determining the difficulty of the procedure. Therefore, it is best to avoid the upper third lesion as far as possible until experience 90 cases or at least 30 procedures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Examination of major duodenal papilla (MDP) by standard forward-viewing is limited and the use of side-viewing endoscope (SVE) is mandatory. Cap assisted esophagogastroduodenoscopy (CA-EGD) utilizes a cap fitted to the tip of the endoscope that can depress the mucosal folds and thus might improve visualization of MDP. The aim of this study was to compare CA-EGD to SVE for complete examination of the MDP.

Aims & Methods: Prospective, randomized, blinded, controlled, non-inferiority crossover study. Subjects selected for elective EGD were randomized to undergo CA-EGD (group A) or SVE (group B) before undergoing a second examination by the alternate method. Imaging of the MDP were evaluated, after image processing, by three blinded multicenter-experts. Our primary outcome measure was complete examination of the papilla. Secondary outcome measures were image quality of mucosal pattern, ability to obtain an overview of the papilla and overall satisfaction of the evaluators. For secondary outcomes, a score was given from 1 to 10 (1 poor, 10 excellent).

Results: A total of 62 patients were randomized and completed the study. Complete examination of MDP was achieved in 59 patients using CA-EGD compared to 60 patients using SVE (95 vs. 97%, p = 0.10). CA-EGD had mean scores of 8.7 ± 1.3, 7.1 ± 0.86 and 7.9 ± 1 regarding mucosal pattern, overview and overall satisfaction, respectively, versus 5.3 ± 1.6 (p < 0.001), 8.3 ± 0.9 (p < 0.001) and 7.6 ± 0.6 with SVE (p = 0.01).

Conclusion: CA-EGD is non-inferior to SVE for complete examination of MDP. CA-EGD had significantly higher scores than SVE regarding the image quality and overall satisfaction, while SVE had a better overview. CA-EGD is a safe and effective method for examination of MDP and can replace the SVE for diagnostic indications.

P1463 INACCURACY OF CAMBRIDGE PROTOCOL FOR PATIENTS HARBOURING CHD1 MUTATION: A CONSECUTIVE SERIES

R. Castro, D. Libânio Monteiro, T. Pinto-Pais, M. Dinis-Ribeiro, C. Brandão
Department Of Gastroenterology, Instituto Português de Oncologia, Porto, Porto/Portugal

Contact E-mail Address: rut,arrais.castro@gmail.com

Introduction: Hereditary diffuse gastric cancer (HDGC) accounts for 1 to 3% of all gastric cancer. It can be caused by a germline mutation of the gene CDH1. Life time risk for gastric cancer is 80% with a mean age at diagnosis of 40 years. Affected individuals generally present multiple foci of signet ring cell carcinoma (SRCC) scattered throughout the gastric mucosa, difficulty detected by endoscopy.

Aims & Methods: The aim of this study was to assess the validity of Cambridge protocol in patients with proven pathological germline mutation of the gene CDH1. A prospective cohort study was performed between September 2016 and March 2017 in 11 patients with CDH1 mutation. They perform a base line high-resolution endoscopy (Olympus-GIF-HQ190) with random biopsies according Cambridge protocol and additional targeted biopsies of suspicious lesions. The total number of biopsies and the total number and localization of SRCC foci was registered. For those patients submitted to prophylactic gastrectomy, data was compared with surgical specimen histology. To access the validity of Cambridge protocol with a high resolution endoscopy in patients with proven pathological germline mutation of the gene CDH1.

Results: During the 11 endoscopies a total of 353 biopsies (129 random biopsies and 24 targeted biopsies; mean of 32.1 biopsies per patient) were performed. Two patients presented 1 SRCC foci in random biopsies, being that one of them presented only 1 foci. The total number of biopsies and the total number and localization of SRCC foci was registered. For those patients submitted to prophylactic gastrectomy, data was compared with surgical specimen histology. To access the validity of Cambridge protocol with a high resolution endoscopy in patients with proven pathological germline mutation of the gene CDH1.

Conclusion: Despite the use of high-resolution endoscopes and the high number of random biopsies, endoscopic evaluation presents many limitations for the diagnosis of HDGC. According to literature, prophylactic total gastrectomy remains the treatment of choice for CDH1 mutation carriers.

Introduction: Endoscopic clips are used in a variety of clinical situations in GI endoscopy—for arrest of bleeding or for closure of bowel perforations or chronic fistulae. Conventional through-the-scope clips often cannot provide optimum results; and therefore full-thickness (FT) over-the-scope (OTS) clips have been devised.

Aims & Methods: Current study describes the clinical experience of use of a recently developed FT OTS clip (Padlock™, Aponos Medical, USA). Data from a prospectively maintained database of all patients undergoing the new technique were abstracted. Clinical details, primary diagnosis, history of previous endotherapy, endoscopic procedure, indications for FT OTS clip usage, technical and clinical success and early and delayed adverse events were recorded. The clip-clip is available in two different sizes for use in upper and lower endoscopy. It is supplied preloaded on a cartridge that fits on the distal end of the endoscope. The trip-wire travels alongside the endoscope, enabling additional instruments to be passed through the endoscope channel, and special double-channel endoscope is not required for its application. Technique of clip application— the clip was loaded on the distal end of the endoscope and endoscope advanced to site of interest. Bowel wall defect or bleeding point was positioned within the clip and strong suction was applied. Clip was fired by closing the handle on the delivery system. Suction was slowly released and site was inspected.

Results: Total 21 clips used in 19 patients. M:F=12:7, mean age–7.9 years (range –24–94 years). Indications for FT OTS clip use—severe GI bleeding–7 (36.8%) (duodenal ulcer bleed–5, rectal ulcer–1, bleed during ESD for rectal lateral spreading tumor–1); for closure of bowel perforation during endoscopic resection–7 (36.8%) (gastric–3, duodenum–2, rectum–2); and closure of chronic bowel fistulae–5 (26.3%) (oesophagus–3, duodenum–1, rectum–1). Previous h/o endotherapy–3/7 of bleeding patients, primary therapy using OTS clip in remaining 16. Technical success was 100%. Two patients needed two clips each due to large size of defect. Clinical success–bleeding arrested in 7/7 (100%); bowel perforation sealed–7/7 (100%); fistula closure successful–4/5 (80%). In one patient of chronic duodenal fistula, fistula reopened 12 weeks after initial sealing of fistula and required surgery. Follow up at 4 weeks revealed no delayed adverse events in any patient.

Conclusion: The new OTS Clip (Padlock™, Aponos) is safe and effective for treatment of severe bleeding and for closure of post ER full-thickness defects and chronic fistulae. Further studies with larger sample size are recommended.

Introduction: Endoscopic resection of ampullary adenomas has increased in the last decade due to the high morbidity with a high mortality in patients undergoing surgical procedures.

Aims & Methods: This study aims to evaluate the outcome of endoscopic ampullectomy (EA) in a tertiary endoscopy department. We included in the study patients that underwent EA between January 2014 - April 2017 at the Regional Institute of Gastroenterology and Hepatology Cluj-Napoca, Romania. All patients had a benign pathological result prior to the EA. Post-procedural complications such as bleeding, perforation, cholangitis, pancreatitis and mortality were analyzed. Data about resection type, post EA histology and 1 year follow-up was also processed.
Results: 19 patients underwent EA, with a mean age of 63.5 ± 17.7 years and a success rate of 63(20–81). The tumor in the upper edge of the tumor was 20.4 ± 7.5 cm. The male to female ratio is 0.7:1. An endoscopic resection was done in most cases (15/19 (79.9%)). Bleeding occurred in 6 cases (31.6%) and two patients (10.5%) developed acute pancreatitis. One patient died due to severe bleeding. The average days of hospitalization after endoscopic ampullectomy were 5.7 with a range from 2 to 25 days. Adenocarcinoma was described in the final histopathological result in 4/19 cases (21.1%). One year follow-up noted a recurrence rate of 15.8% (3/19 cases).

Conclusion: In conclusion, endoscopic ampullectomy is a difficult procedure with an increased risk of complications but performed by experienced endoscopists is safe and surgical interventions can be avoided.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI466 PER ORAL ENDOSCOPIC MYOTOMY: UPDATED RESULTS FROM A UNITED KINGDOM CASE SERIES

S. Gulati1, A. Emmanuel2, H. Inoue2, A. Haji3, B. Hayee1

1Endoscopy, King’s Institute of Therapeutic Endoscopy, RS/United Kingdom
2Dietetic Disease Center, Showa University Koto-Toyosu Hospital, Tokyo/Japan

Contact E-mail Address: shraddha.gulati@nhs.net

Introduction: Peroral endoscopic myotomy (POEM) has been adopted as a minimally invasive treatment option for achalasia and even spastic oesophageal conditions1. The first case of POEM was performed at the King’s Institute of Therapeutic Endoscopy (KITE) in 2013. Here we present our initial case series including the first UK case of diffuse oesophageal spasm (DES).

Aims & Methods: Prospective data was collected for consecutive patients undergoing POEM including demographics, POEM technique, the use of Endoluminal Functional Lumen Imaging Probe (EndoFLIP) and adverse events. Clinical success was defined as a reduction of Eckardt score (ES) to ≤2/2 or a reduction in 4 points from baseline. Follow up data at 3 and 12-24 months (m) post-POEM was analysed using the Wilcoxon signed rank test to compare pre- and post-POEM ES and 4sIRP and pre and post-treatment GORD-HRQoL score. Repeated-measures ANOVA was used for multiple time-point comparisons.

Results: POEM was performed in 51 patients (22F, age 48.6±13.5 years). Further baseline data is presented in table 1. Median gastric and oesophageal myotomy was 3 cm (2–4) and 10 cm (3–18) respectively with a selective circular incision/major bleeding.

Conclusion: This is the largest UK case series of POEM for achalasia including the first successful UK POEM procedure for DES. At our institute, POEM was performed successfully in a potentially more challenging cohort where 52.9% had prior endoscopic/surgical treatment with intervention. Our results are in line with international consortia and ASGE findings that POEM is a safe and efficacious procedure for the treatment of achalasia and oesophageal spastic disorders for both short term and sustained symptomatic benefit.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI467 NEW CHALLENGE FOR SAFER ENDOSCOPIC SUBMUCOUS DISSECTION USING CO2 LASER

Y. Morita, R. Ariyoshi

Gastroenterology, Kobe University, Kobe/Japan

Contact E-mail Address: ymorita@med.kobe-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) is increasingly accepted as a minimally invasive treatment for the patients with early gastrointestinal cancers. However, ESD demands high maneuverability technique, and the success of the operation is dependent on each operator’s skill. We have developed a novel laser surgery system for ESD to overcome such difficulties of ESD, which is composed of a CO2 laser source and a disposible flexible hollow fiber probe. Compared to conventional ESD (C-ESD) using electric surgical knives, ESD using CO2 laser (L-ESD) has an advantage of less risk of perforation and massive thermal damage, because the CO2 laser is strongly absorbed by water such as saline or sodium hyaluronate. Further more, the cutting point can be precisely recognized by another visible guide laser. Due to non-contact laser irradiation and adequate visualization of treatment area, the laser system facilitates more precise and safer treatment and provides high quality and stable dissection. We hypothesized that performing ESD using CO2 laser with a submucosal laser absorber could be a safer and simpler ESD technique.

Aims & Methods: The aim of this study was to evaluate the feasibility of L-ESD and the quality of the resected specimen obtained by L-ESD in living porcine compared with C-ESD. We performed ESD for a total of 14 hypothetical lesions in three porcine stomachs (L-ESD, 7 lesions; C-ESD 7 lesions) under general anesthesia. En-bloc resection rate, time procedure, adverse events, and the quality of the resected specimen were evaluated. To evaluate the smoothness of the cutting surface in the resected specimens, we compared the length of the resected side of the submucosa (LRS) with the length of the muscularis mucosa (LMM). Results: The en-bloc resection rate was 100% in both groups. Although the mean L-ESD procedure time was 23.3 ± 10.8 minutes, and was significantly longer than in the C-ESD group (9.4 ± 6.6 minutes, p < 0.05), there was no uncontrollable bleeding or perforation in either group. The mean ratio of LRS to LMM was 107 ± 3.3% in the L-ESD group, and was significantly lower than that of the C-ESD group (138 ± 28%) (P < 0.005).

Conclusion: ESD using CO2 laser might be a feasible and effective method for the treatment of early gastrointestinal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute corrosive ingestion (ACI) is a common and serious medical problem accounting for a number of hospital admissions. ACI causes significant mortality and morbidity. These patients are at risk of developing luminal strictures of the upper gastrointestinal tract in the long term. This is more in patients with high-grade injury.

Aims & Methods: The present study aimed at assessing the long-term outcomes of high-grade (Zargar’s grade ≥Grade 2A) corrosive-induced injury of upper gastrointestinal tract (1). This was a prospective study conducted in the Department of Gastroenterology at Christian Medical College, Vellore. The study period was between January 2008 to December 2014. All patients were managed by a standard protocol which included doing a gastroscopy within 24 hours of ACI. In this study we included patients ≥15 years with high-grade (Zargar’s grade

Grade 2A) corrosive-induced injury of upper gastrointestinal tract. Patients in whom the diagnosis could not be done or who were lost to follow-up were excluded from the study. The study was approved by the Institutional Ethics committee and was funded by a fluid research grant received from Institutional Review Board at Christian Medical College, Vellore, India. The data were analysed using SPSS version 17. The statistical analysis was done using the chi-square test and Student’s t-test. Parameters that were expressed as mean ± SD and the non parametric continuous variables were expressed as median. Comparison between groups was done using Fisher’s exact test.

Results: During the study period a total of 112 patients presented with ACI. In all 82 patients were included in the study. Amongst them, 53% of the patients were females and the mean age was 36.5 ± 15.5 years. The intent of corrosive ingestion was suicidal in 70% and accidental in 30%. In majority (50%) of patients the nature of corrosive agent was not known. Nasogastric tube placement was done in 50%, nasojugal tube placement in 32% and 8% no tube was placed. Surgery as needed in 19% (tracheostomy or feeding jejunostomy or a definitive surgery). Amongst the 82 patients who were included in the study, 11 were lost to follow up. A total of 71 patients in whom the median follow up period was 31 months (range 2-72 m) during which 12 (16.9%) patients expired (73% related to ACI). Amongst the 59 patients, that were alive 16(27%) were symptomatic, 12(20%) had dysphagia, 5(6%) had regurgitation, 4(5%) had chest pain, 67(97%) had weight loss and 11(18%) patients required investigation. In all, 43(73%) patients underwent barium study during follow up and the result was noted in 21(36%). The site of stricture was esophageal in 11(53%), stomach in 8(38%) and combined esophagogastric and stomach in 20(38%). Esophageal stricture was seen in all patients with Grade III B esophageal stricture, 27%(6/22) with Grade III A injury and 19%(5/27) with Grade II B injury. None of the patients with Grade II A injury developed stricture. Stricture in stomach developed in 22 patients with Grade III B injury(19)(86.4%) with Grade III A injury, 10%(1/10) with II B injury and 20% (1/5) with II A injury.

Conclusion: Acute corrosive ingestion is associated with significant morbidity and mortality. There needs to be stringent control on sale, use and storage of such chemicals.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Probe-based confocal laser endomicroscopy (pCLE) provides real-time microscopic visualization with 1000-fold magnification, allowing endoscopic access to the histological evaluation of gastrointestinal lesions. pCLE may thereby be helpful in guidance of endoscopic therapy. However, histopathological assessment still remains a gold standard for histodiagnostic evaluation so far, while pCLE-based diagnosis has not been generally accepted yet. Therefore, more studies assessing diagnostic accuracy of pCLE are warranted.

Aims & Methods: The aim of the study consisted in the analysis of the accuracy of three risk scoring systems used in non-variceal upper digestive bleeding for assessing patient’s prognosis, especially estimated to be predictive for re-bleeding/death after gastrointestinal bleeding. We assessed prospectively a batch of 1872 patients admitted in the Gastroenterology Department of Emergency County Hospital Timisora in a 12-year period, in which we calculated 3 risk scoring systems, Rockall, Cedars-Sinai and Baylor, based on clinical and endoscopic data. We compared their accuracy for assessing patient’s prognosis, expressed as the need of blood transfusions, number of hospitalization days, re-bleeding, surgery and death. Discriminative ability was assessed using the area under the receiver operating characteristic curve (AUROC).

Results: The batch included 1134(60.5%) male and 738 (39.4%) female, mean age 62.7±8 years. Regarding the need of blood transfusions, the predictive ability of the scores is as follows: Rockall AUROC 0.59 (CI(0.55-0.62), sensitivity(Se)=81.7%, specificity(Sp)=35.5%, positive predictive value(PPV)=28.4%, negative predictive value(NPV)=86.1% (p<0.0001); Cedars-Sinai AUROC 0.59 (CI(0.55-0.63), Se=72.4%, Sp=41.3%, PPV=28.5%, NPV=82.3% (p<0.001); Baylor AUROC 0.56 (CI(0.49-0.63), Se=41.9%, Sp=75.5%, PPV=40.6%, NPV=76.5%. Number of hospitalization days: Rockall AUROC 0.66 (CI(0.55-0.77), Se=61.5%, Sp=65.2%; Cedars-Sinai AUROC 0.63 (CI(0.50-0.75), Se=53.1%, Sp=73.9%, PPV=89.5%, NPV=27.4%; Baylor AUROC 0.52 (CI(0.51-0.73), Se=47.06%, Sp=66.6%, PPV=84.2%, NPV=25.2%. Re-bleeding: Rockall AUROC 0.7 (CI(0.67-0.73), Se=60.1%, Sp=83.4%, PPV=92.2%, NPV=71.4%); Cedars-Sinai AUROC 0.73 (CI(0.69-0.77), Se=84.8%, Sp=49.02%, PPV=13.7%, NPV=97%; Baylor AUROC 0.54 (CI(0.45-0.65), Se=35.1%, Sp=81.2%, PPV=16.2%, NPV=92.4%. Surgery: Rockall AUROC 0.67 (CI(0.61-0.73), Se=71.2%, Sp=59%, PPV=16%, NPV=98.1%; Cedars-Sinai AUROC 0.72 (CI(0.66-0.78), Se=58%, Sp=77.4%, PPV=93%, NPV=97.9%; Baylor AUROC 0.55 (CI(0.41-0.68), Se=50%, Sp=66.2%, PPV=51.4%, NPV=67.4%, Death: Rockall AUROC 0.65 (CI(0.58-0.72), Se=79.4%, Sp=84.9%, PPV=18.2%, NPV=99.5% (p<0.0001); Cedars-Sinai AUROC 0.71 (CI(0.66-0.76), Se=83.1%, Sp=48.1%, PPV=10.2%, NPV=97.6%; Baylor AUROC 0.75 (CI(0.67-0.83), Se=76.99%, Sp=72.3%, PPV=19.2%, NPV=97.2%. There were no statistically significant differences encountered in predicting the need of blood transfusions and surgery between the scores (p>0.05). Baylor score was superior vs Rockall in estimating the hospitalization period (p=0.04) and re-bleeding (p<0.001), and Cedars-Sinai proved to be superior tor Baylor score in predicting re-bleeding (p=0.002) and to Rockall score in predicting death (p=0.006).

Conclusion: On our cohort of patients, Cedars-Sinai score proved to be the best in predicting the re-bleeding and death in patients with NV-UDB in comparison to Rockall and Baylor scores.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1471 PERCUTANEOUS ENDOSCOPIC GASTROSTOMY: A SAFE PROCEDURE EVEN IN CANCER PATIENTS
J. Pinho1, J. Lage2, D. Libanio2, S. Ferraz2, N. Silva2, M. Dinis-Ribeiro2, C. Brandão2

Contact E-mail Address: julianapinho18@gmail.com

Introduction: Dysphagia and malnutrition is a common feature in up to 64% of cancer patients who undergo oncological treatment, and the need of radiotherapy or chemotherapy often worsens this symptoms. Percutaneous endoscopic gastrostomy (PEG) is the preferred route of feeding and nutritional support in these patients. Although generally considered to be a safe procedure, it has been observed that PEG tube placement complications in cancer patients may be superior when compared to non-cancer patients.

Aims & Methods: The aim of this study was to evaluate the complications rate after PEG tube placement in cancer patients. We did a single-centre prospective database including all patients with PEG tube insertion between March 2014 and June 2016, evaluating the complications during 6 months follow-up.

Results: A total of 265 patients (83% men, mean age 59 years) underwent PEG tube insertion. 224 patients (84.5%) had head and neck cancers and 33 patients
P1472 A PROSPECTIVE, SINGLE-CENTER, CROSS-OVER CONTROLLED TRIAL OF CONFOCAL LASER ENDOMICROSCOPY ASSESSMENT OF PERSISTENT OR RECURRENT INTESTINAL METAPLASIA AND RECURRENT OF NEOPLASIA AFTER ENDOSCOPIC TREATMENT OF BARRETT’S ESOPHAGUS-RELATED NEOPLASIA (BORN)

1Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic
2Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

Contact E-mail Address: kraj@ikem.cz

Introduction: Probe-based confocal laser endomicroscopy (pCLE) has been developed to overcome limitations of the current endoscopic sampling techniques. pCLE allows detailed examination of cellular structures and may examine larger areas compared to standard biopsy. Patients after endoscopic treatment of Barrett’s esophagus (BE)-related neoplasia (BORN) should undergo endoscopic surveillance with biopsies to detect persistence or recurrence of intestinal metaplasia (IM) or neoplasia (N).

Aims & Methods: The aim of this prospective study was to evaluate the efficacy of pCLE (vs. standard biopsies) in detection of persistent/recurrent IM/neoplasia in patients after endoscopic treatment of BORN. A single-center, prospective, controlled and pathologist-blinded (still ongoing) study in patients undergoing surveillance endoscopy after BORN. pCLE images were obtained from the neo-Z-line (a few cases including macroscopically visible tongues), the cardia and the esophagus. Thereafter, standard biopsies were taken and sent for histopathological analysis (4 biopsies from macroscopically normal neo-Z-line, 2 biopsies from the cardia and the esophagus and targeted biopsies from visible abnormalities, if present). BE was defined in pCLE as columnar-lined epithelium with dark mucin in goblet cells, a villiform pattern, and regular-shaped capillaries in the mucosa. The dysplastic BE was characterized by black cells with irregular borders and shapes, high dark contrast to the surrounding tissue, and irregular leaking capillaries in the mucosa.

Results: We examined 29 patients, from these 14 patients (48%) had the initial diagnosis of high-grade intraepithelial neoplasia (HGIN), 7 patients (24%) had high-grade intraepithelial neoplasia (LGIN), 7 patients (24%) had an early adenocarcinoma (EAC). Persistent/recurrent IM was detected at the level of neo-Z-line in 10 patients (34.5%) by both standard biopsies and pCLE. pCLE but not biopsies detected persistent/recurrent IM in 2 patients (6.7%), another 2 patients had IM present in biopsies but not in pCLE. pCLE diagnosed one patient with recurrent LGIN in a macroscopic visible tongue arising from neo-Z-line, which was not confirmed in biopsies. Sensitivity and specificity of pCLE detection of persistent/recurrent IM was 83.3% (95% CI 51.6-97.9) and 89.47% (95% CI 66.9-98.7), respectively, with positive predictive value 83.3% (95% CI 51.6-95.0) and negative predictive value 89.5% (95% CI 70.4-96.8). Agreement of pCLE and histopathological findings was 86%.

Discussion: pCLE seems to be comparable to persistence/persistent IM after endoscopic treatment of BORN. Nevertheless, these results need to be confirmed in a larger cohort of patients. Supported by a grant from Ministry of Health of the Czech Republic, No. 16-2764/4A.

P1477 AN ANALYSIS OF COMPLICATIONS FOLLOWING ENDOSCOPIC SUBMUCOSAL DISSECTION IN A WESTERN SETTING - MAKING THE CASE FOR A SHORTER LENGTH OF STAY

S. Subramaniyan1, K. Kandiah1, G. Longcroft-Wheaton2, P. Bhandari1
1Gastroenterology, Queen Alexandra Hospital, Portsmouth/United Kingdom
2Gastroenterology, Portsmouth Hospitals NHS trust, Hampshire/United Kingdom

Introduction: Endoscopic submucosal dissection (ESD) is an established technique for the treatment of gastrointestinal (GI) neoplasia in Japan. The high uptake and mastery of the procedure there was in part enabled by the high prevalence of early gastric cancer in Japan. Conventional practice in Japan is to admit patients for 3 to 5 days after the ESD procedure for monitoring in view of the risk of serious complications which is between 10–15%. Cost and resource provision in a publicly-funded Western healthcare setting favours shorter planned stays following ESD.

Aims & Methods: We aimed to identify the type and site of lesions being treated in a Western setting as well as the rate, timing and predictors of complications in order to evaluate current admission practice. An electronic database of all ESD procedures performed in our academic institution from 2012–2017 was analysed. Parameters were the number, type, onset and management of complications following ESD. Significant complications (bleeding and perforation) necessitating hospital admission were categorised as early (within 24 hours) and delayed (24 hours to 28 days) post procedure.

Results: A total of 410 ESDs were performed within the time period (225 colorectal, 117 oesophageal, 52 gastric and 16 duodenal). There were 21 complications (5 colorectal, 10 oesophageal, 5 gastric and 1 duodenal). 10 of these (48%) were early complications (6 bleeding, 4 perforation). The total complication rate was 5.1%. The most common complications were bleeding (4.6%) and perforation (2.9%). The rate of complications was higher among colorectal (8.3%) and oesophageal (5.4%) ESDs compared with gastric and duodenal (1.9%).

Conclusion: ESD in this Western setting was more commonly performed for colorectal and oesophageal lesions rather than gastric as seen in Japan. The complication rate is modest and almost all were managed successfully with an endoscopic approach. They occurred more commonly in gastric and duodenal sites. This may be related to the technical difficulties of resection or low volume of procedures performed at these locations. The use of anticoagulants is a risk factor for complications.

References

5. A total of 250 consecutive inpatients who had undergone GIES during a hospital stay of at least three days were included in a retrospective cohort study. Age-, gender- and length of hospital stay-matched controls (ratio 1:1) who had not undergone any invasive procedure or sedation served as controls. Laboratory parameters had to be available before and three and/or seven days after endoscopy. Primary objective was the occurrence of pneumonia in general and older patients (≥65 years). Secondary objectives were the development of LRI, elevation of inflammatory markers (CRP and WBC), initiation of antibiotic treatment, pathogen detection and pulmonary inflation. Statistics included χ² test, paired t-test, ANOVA, multiple linear regression analysis.

Results: No significant differences for the occurrence of pneumonia (1.6%, GIES group vs. 0.4%, control group, p = 0.18), 72.7% (8/11) of the patients who experienced complications were successfully managed endoscopically.

Conclusion: This data confirms a higher risk of pneumonia due to GIES in the advanced aged population. In general, patients are more likely to develop inflammation and to receive antibiotic treatment suggesting an increased risk of radiologically non-visible inflammation due to micro-aspiration.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Therapeutic options for gastroparesis or delayed emptying following oesophagectomy with gastric transposition are limited. Although commonly performed, there are no studies addressing the relative merits of the endoscopic dilatation of the pylorus, botulinum toxin (Botox) injection or combination therapy. We assessed the symptomatic response of patients undergoing non-surgical pyloric intervention at a specialist tertiary centre.

Aims & Methods: 33 patients (13 male; mean age 45, range 17–80) underwent a total of 250 endoscopic procedures over 2 years. Treatments were either 100 IU units of Botox injected into 4 quadrants of the pylorus or pneumatic dilatation (PD) incrementally up to 16–20 mm (Hercules; Cook Medical). Patients with gastric malignancy, previous pyloric surgery or no documented follow-up were excluded. Endoscopic-therapeutic response was assessed at first follow-up post-procEDURE and graded as ‘good’, ‘partial’ or ‘none/poor’. Patients were grouped according to type of therapy and indication.

Results: There were no immediate or late complications observed. 31 procedures were performed for gastroparesis with a mean post-procedure follow-up of 11 weeks. Overall, a partial or good response was observed in 81% (25/31). Specific treatments were safe and effective. Treatment options for patients with gastroparesis or delayed gastric emptying following gastric transposition. Subjective treatment without a clear indication shows little improvement.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1475 GASTROINTESTINAL ENDOSCOPY UNDER SEDATION IS ASSOCIATED WITH PNEUMONIA IN OLDER INPATIENTS–RESULTS OF A RETROSPECTIVE CASE-CONTROL STUDY

C. M. Kollmann, W. Schmiegel, T. Brechmann
Department Of Gastroenterology And Hepatology, Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Bochum/Germany

Contact E-mail Address: christoph.kollmann@rub.de

Introduction: Apparent aspiration is a notable adverse event during gastroomestintoscopy under sedation (GES) [1, 2], but about the incidence and the role of innocent aspiration is scarce. Furthermore, patients undergoing endoscopy experience respiratory symptoms such as coughing, shortness of breathing, fever and other respiratory adverse events within 24 hours relatively often in more than 5% [3]. Since coughing during endoscopy has been attributed to an increased risk of aspiration-related postprocedural infection [4] respiratory infections might be underreported. Additionally, patients in advanced age are not only determined as a high-risk group for GI adverse events following colonoscopy [5], but are also more likely to develop hospital-acquired pneumonia [2]. Therefore, the aim of the study was to determine the risk of pneumonia, lower respiratory infection (LRI) and systemic inflammatory activation after GIES. Aims & Methods: A total of 250 consecutive inpatients who had undergone GIES during a hospital stay of at least three days were included in a retrospective cohort study. Age-, gender- and length of hospital stay-matched controls (ratio 1:1) who had not undergone any invasive procedure or sedation served as controls. Laboratory parameters had to be available before and three and/or seven days after endoscopy. Primary objective was the occurrence of pneumonia in general and older patients (≥65 years). Secondary objectives were the development of LRI, elevation of inflammatory markers (CRP and WBC), initiation of antibiotic treatment, pathogen detection and pulmonary inflation. Statistics included χ² test, paired t-test, ANOVA, multiple linear regression analysis.

Results: No significant differences for the occurrence of pneumonia (1.6%, GIES group vs. 0.4%, control group, p = 0.18), 72.7% (8/11) of the patients who experienced complications were successfully managed endoscopically.

Conclusion: This data confirms a higher risk of pneumonia due to GIES in the advanced aged population. In general, patients are more likely to develop inflammation and to receive antibiotic treatment suggesting an increased risk of radiologically non-visible inflammation due to micro-aspiration.

Disclosure of Interest: All authors have declared no conflicts of interest.
factor for delayed bleeding. Given that the majority of delayed complications occurred within 5 post-procedure, a standardised 5 day inpatient stay would prove futile in our cohort.

P1478 PREDICTIVE FACTORS AND MANAGEMENT OF REFRACTORY BENIGN OESOPHAGEAL STRICTURES
M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa Portugal

Introduction: The optimal management and the predictive factors of response to endoscopic dilation of refractory benign oesophageal strictures remains controversial.

Aims & Methods: To evaluate the prevalence and factors predicting response to treatment of benign refractory oesophageal strictures with scheduled endoscopic dilations

Results: A retrospective analysis of 75 patients was performed to evaluate the outcome of endoscopic dilatation of benign oesophageal strictures between October 2010 and November 2016. Streatches were classified as refractory when ≥5 endoscopic dilatations were needed with at least one dilation achieving ≥15 mm of diameter during the course of management of the oesophageal strictures.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophagaeal strictures and these patients were significantly more likely to require local corticosteroid injections during scheduled endoscopic dilatations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1479 LOCAL CORTICOSTEROIDS IMPROVE EARLY CLINICAL OUTCOMES IN PATIENTS UNDERGOING ENDOSCOPIC DILATION OF BENIGN OESOPHAGEAL STRICTURES
M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa Portugal

Introduction: Local corticosteroids have been shown to improve outcomes in patients undergoing endoscopic dilation of peptic strictures.

Aims & Methods: To evaluate factors predicting early clinical response to endoscopic dilation of benign oesophageal strictures. Retrospective analysis of 75 consecutive cases submitted to scheduled endoscopic dilations between October 2010 and November 2016. Clinical improvement was defined as dysphagia score ≤1.

Results: The study sample included 42 (56%) male patients and the mean age was 57±16 years. Dysphagia scale at baseline was solids (1–17 (22.7%) semi-solids (2–23 (30.7%), liquids (3–23 (30.7)) and complete (4–12 (16%) Body mass index (BMI) at baseline was 22±5 Kg/m². The aetiology of the benign strictures was: surgical–31 (41.3%), peptic–15 (20%), caustic–10 (13.5%), radiotherapy–10 (13.3%) and others–9 (12%). The location of the oesophageal stricture was as follows: proximal third–34 (45.3%), middle third–12 (16%) distal third–27 (36%) and multiple locations–2 (2.7%). Stricture type: simple–44 (58.7%), complex–31 (41.3%). Patients underwent a median of 4 (1–26) endoscopic dilation over a median period of 19 weeks (1–229). Dilations were done with Savary-Gilllard dilators–35 (46.7%) TTS-balloons–24 (32%) or both–16 (21.3%). The mean diameter of dilation achieved was 15.7±2.2 and a dilation diameter of ≥15 mm was achieved in 36 (76.4%) patients. Local injection of corticosteroids was performed at least once in 39 (52%) patients and in ≥25% of dilations in 39 (52%) patients. From the study sample, 25 (33.3%) patients fulfilled criteria of refractory strictures. In this subgroup, there was a significant association with post-surgical aetiology (p = 0.002), higher rate of local injection of corticosteroids (p <0.001) and higher dilation diameter (p <0.001). Refractory strictures were significantly associated with the need for local corticoid injection (OR 9.76, 95%CI 0.035–0.46, p = 0.02) by binary logistic regression analysis. However, none of the other factors were found to be independent predictors of response to therapy.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophageal strictures and these patients were significantly more likely to require local corticosteroid injections during scheduled endoscopic dilatations.

P1480 TRENDS IN CERTIFICATION FOR GASTROINTESTINAL ENDOSCOPY AND VARIATIONS BETWEEN TRAINEE SPECIALTIES: RESULTS FROM THE UK TRAINEE ENDOSCOPY DATABASE
*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Introduction: In the UK, endoscopy certification is overseen by the Joint Advisory Group. Since 2011, certification has been awarded for upper and lower GI endoscopy online via the JAG Electronic Training System (JETS). We aimed to analyse trends in endoscopy e-certification, and assess for differences between trainees in gastroenterology (GI), surgical (GS) and non-medical endoscopy (NME) specialties.

Aims & Methods: We prospectively identified trainees awarded certification for gastroscopy, flexible sigmoidoscopy (FS) and colonoscopy from the JETS database. For each specialty, we collected data on lifetime procedural counts, formative assessments, and key performance indicators (KPIs) at the time of certification. Comparisons between specialties were analysed using a combination of chi², Mann-Whitney and median tests.

Results: Between June 2011-Dec 2016, 2857 applications were awarded certification. Numbers of gastroscopy and conventional colonoscopy awarded have been in steady state since 2013, whilst numbers for sigmoidoscopy and full colonoscopy continue to increase. Trainees awarded certification comprised mainly of GI (53.2%), GS (28.5%) and NME (15.5%) specialties. With the exception of FS, most certifications were awarded to GI trainees (Figure 2). Median procedural numbers (p <0.001) and formative DOPS count (p <0.001) pre-certification varied for each modality in the order of NME > GI > GS. Caecal intubation rates (CIR) at full certification were similar between GI (95.6%) and GS (95.6%, p = 0.81), but lower in NME (93.6%, p =0.02 vs. GS, p = 0.006 vs. GI), despite no differences at provisional certification (median CIR 95.6%, p = 0.32). Rates of D2 intubation (median 98.7%) varied across groups (GS > GI > NME, p =0.002). Certification awarded at first attempt were similar across specialties (mean 89.4%, p =0.19), but varied for gastroscopy (NME 95.5%, GS 90.1%, GI 89.7%, p = 0.01).

Conclusion: Despite variations amongst trainee specialties, endoscopy certification is a transparent and robust benchmark for assessing competency, as evidenced by trainee KPIs. Further studies are required to study the impact of recent changes to certification, and if variations in KPIs exist following certification.

P1481 EFFICIENCY AND SAFETY OF ENDOSCOPIC PAPILLECTOMY FOR TREATMENT OF DUODENAL PAPILLA TUMORS
Y. Chiu1, M. Xu, P. Zhou1, C. Zhang1
1 Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Introduction: A duodenal papilla tumor is an uncommon neoplasm in the upper gastrointestinal tract. In the early stage, patients often have no complaints and the tumors are usually occasional found during gastroduodenoucscopy examination. Endoscopic papillectomy can be achieved with curative resection for benign adenoma and some early papillary carcinoma. However, some complications are accompanied with the procedure, like pancreatitis and bleeding. This retrospective study is to evaluate therapeutic effect and safety of endoscopic papillectomy on duodenal papilla tumors.

Aims & Methods: From June 2009 to November 2016, the information of patients who received endoscopic papillectomy was recorded, which included basic characteristics and clinical outcomes, such as recurrence rate, bleeding, pancreatitis. Statistical analysis: the original data (totally 40 cases) received endoscopic papillectomy. The procedure was completed with gastroscope in 32 cases and duodenoscope in 8 case. Endoscopic mucosal resection (EMR), endoscopic piecemeal mucosal resection (EPMR) and endoscopic submucosal dissection (ESD) was performed in 21, 17 and 2 cases respectively. None of the lesions invaded the submucosal layer.
Pacemakers and biliary stents were inserted in 9 and 12 patients respectively. In general, 5% (2/40) and 12.5% (5/40) cases had intraoperative and postoperative bleeding respectively. 20% (8/40) cases suffered from pancreatitis, of which mild, moderate and severe happened in 3, 4 and 1 cases. Six patients had tumor recurrence. And 3 patients received repeat endoscopic papillectomy, two received pancreatic-coduodenectomy and one received no other treatments with close follow-up. Two patients died from failures of treatment for papillary tumors and one patient died due to other unrelated cause.

**P1482** CHANGES IN SCORING OF DIRECT OBSERVATION OF PROCEDURAL SKILLS (DOPS) FORMS IN ENDOSCOPY TRAINING AND THEIR IMPACT ON COMPETENCE ASSESSMENT

K. Siau1, P. Dunckley1, A. Neville1, J. Anderson1, I. Beales1, R. Broughton1, M. Eneey1, A. Haycock1, N. Hawkes1, B. Mckai1, G. Johnson1, R. Valori1, C. Wells1, G. Johnson1

1JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

2Faculty Of Education, Health And Wellbeing, University of Wolverhampton, Walsall/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: DOPS are validated tools for assessing competence in endoscopy. Previously, DOPS were scored on a 4-point competence-based scale, with scores of 3 and 4 signifying competence. In July 2016, the DOPS rating scale changed to a supervision-based scale that has been shown to be more reliable, with 4 ratings from maximal supervision, up to competent without supervision. We aimed to assess whether changes to the rating scale had affected distribution of scores and hence demonstrate validity.

Aims & Methods: We used the UK trainee endoscopy database (JETS) to collect DOPS scores for gastroscopy (n = 1934), sigmoidoscopy (n = 517), colonoscopy (n = 2296) and polypectomy (n = 370) in the 6-months before July 2016 (old DOPS) and those trainees at early stages of training procedures (n = 100). To allow analysis, the new DOPS rating scale was aligned to a 4-point scale, hence a score of 4 on new DOPS = Scores 3 or 4 on old DOPS, and scores on the new and old DOPS compared using the Mann-Whitney U-test. Results: For polypectomy (77.7% new and 22.3% old) were included for analysis. Overall, there were variations in distributions of all scores (p < 0.001) between forms (Figure 1). Compared to new DOPS, scores of 1 were underutilised on old DOPS (0.6% vs. 3.0%, p < 0.001). Frequencies of low scores (pooled scores of 1&2) were similar for gastroscopy (p = 0.33) and sigmoidoscopy (p = 0.04), but not for colonoscopy (new 11.9% vs. old 13.9%, p < 0.001) and polypectomy (new 6.8% vs.19.9%, p < 0.001). Trainees on old DOPS were more likely to be rated as competent (score 3 or 4) compared to new DOPS (86.4% vs. 55.8%, p < 0.001). On subgroup analysis, this was evident for gastroscopy (86.3% vs. 49.1%, p < 0.001), colonoscopy (86.1% vs. 58.2%, p < 0.001), sigmoidoscopy (90.6% vs. 62.0%, p < 0.001), but not polypectomy (80.1% vs. 67.9%, p = 0.12).

Conclusion: Endoscopy assessors are applying a greater range of scores using a new DOPS rating scale based on degree of supervision, in two cohorts of trainees matched for experience. This indicates better construct validity with the new rating scale. Further work is underway to determine the reliability of the new DOPS to inform summative assessment and certification for UK endoscopy trainees.

Introduction: Endoscopic resection of duodenal adenomatosa carries an increased risk of perforation compared to other locations in the upper or lower GI tract.1,2 Additionally in endoscopic resection of widespread adenomatosa (Spigelman III/IV) at the level of D2/D3 there is an increased risk of secondary perforation due to auto-digestion of the denuded duodenal wall by pancreatic enzymes and bile independent of the primary endoscopic resection method. We recently reported on the successful implantation of a mini-vacuum sponge with extended length of the suction tube and reduced in volume compared to a standard esophagal vacuum sponge.3

Aims & Methods: From September 9th, 2013 to March 20th, 2017 endoscopic resection of wide-spread duodenal or papillary adenomatoida of >2 cm in D2/D3 was performed in five patients. There was a surgical indication for Whipple’s resection as primary intervention or in case of failure in all patients. All patients agreed and gave their informed consent to the procedure.

Results: Five patients with widespread duodenal adenomatosis were included (2x papilla, 3x D2/D3 extrapapillary adenomata; 3x tubular; 3x HGIN, 2x LGIN). The macroscopic mean maximum diameter and perpendicularly diameter of the lesions were 4 x 2.8 cm (largest 7.5 x 3.7 cm; smallest 2.2 x 1.8 cm). In all cases the implantation of mini-vacuum sponge (ActiVAC reduced in volume to 1.2 x 1.5 cm (dia, length) with extended suction tube; Braun Corp., Melsungen). Continuous suction was applied over several days (~125 mm Hg; ActiVAC, KCI Medical, Wiesbaden) depending on the size of the resection area and healing status (m = 10 days, 4–14 days). An endoscopic/radiologic vacuum sponge exchange was performed every 3–5 days. In 4 cases additional atraumatic over-the-scope-clips (OTSC, Ovesco Tuebingen) were placed during the procedure and in 5/5 cases additional hemoclips were applied to secure the wall and for hemostasis. In 5/5 cases (100%) an excellent healing could be observed during follow-up. No patient had to be operated during or following the intervention (FU 2–14 mo). In all cases the resection was curative with ‘en bloc’ resection, though in one case the specimen ruptured during retrieval into three parts (4x HGIN, 1x LGD: 4x R0, 1x Rx). In one case 10 days after resection an acute bleeding occurred with the need of endoscopic clipping and prophylactic radiologic coiling of the gastroduodenal artery with uneventful course. In a second case a minor bleeding occurred without necessity of transfusion during ablation of an OTSC three mo after the primary intervention. All patients were asymptomatic during follow-up.

Conclusion: The endoscopic resection of large duodenal adenomatoida in D2/D3 is feasible and was safe in our collective using the application of a duodenal mini-vacuum solution local drainage of bile and pancreatic juice as alternative to Whipple’s resection. The results in this first small collective should be reproduced in a prospective multicentric trial.

Introduction: Acute perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach, due to feasibility and the reduction of the burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: We aimed to assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used in closing acute perforations in animal models. Medical literature (Choonlibrary, EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systema-

Results: Of the 1862 patients, prevalence of colorectal polyps and adenomatous polyps were 13.1% and 7.8%, respectively. Multivariate analysis revealed that metabolic syndrome (OR, 1.89; 95% CI, 1.13–3.17, P = 0.015) was independent predictor for colorectal polyps. Age over 70 years (OR, 1.48; 95% CI, 1.44–4.14) and metabolic syndrome (OR, 1.59, 95% CI, 0.87–3.00) were independent predictors for adenosomatous colorectal polyps.

Conclusion: Metabolic syndrome is risk factor of colorectal polyps in young adults aged <50 years. Age over 40 years old is additional risk factor of adeno-

Introduction: Colorectal endoscopic submucosal dissection (ESD) is a technique with remarkably greater difficulty than upper gastrointestinal ESD because of unstable maneuvers and inherent anatomic variability in the colon. Thus, aiming at reducing these restrictions, we have used single balloon (SB) overtube to assist colorectal ESD in cases considered to have difficult operability. In this study, to evaluate the usefulness of a single balloon overtube to assist colorectal ESD.

Introduction: Endoscopic Submucosal Dissection (ESD) for colorectal lesions is a highly skilled technique which over the last few years has been adopted by Western institutions. Management of colorectal neoplasia. There is no consensus in the literature regarding the technique of anaesthesia/sedation method for ESD. We aim to describe current sedation practices used in ESD in Western Hospitals.

Aims & Methods: A systematic literature search was performed to identify all articles describing colorectal ESD procedure performed in Europe, America and Australia. Electronic databases including PubMed, the Cochrane library and articles describing colorectal ESD procedure performed in Europe, America and Australia were searched. Original articles or abstracts for congress in English were included. The first author was sent the author of the identified articles in order to obtain additional information regarding sedation practice, if this was not explicitly detailed in the original articles. All articles were examined independently for eligibility by two reviewers (S.B. and M.S.). Any Disagreements were resolved by consulting a third reviewer (A.P.).

Results: This review resulted in 18 eligible original articles, of which (5/18) 27.8% were prospective studies, (7/18) 38.9% retrospective series and (6/18) 33.3% were abstracts presented at congresses. The mean number of ESD cases described was 35.7 cases per institution. Most of the institutions (16/18) 94.4% described the sedation strategy used in colorectal ESD in Western world is heterogeneous. Most institutions opted for deep sedation administered by anaesthesiologists within the endoscopy room. By and large, patients are admitted post procedure for observation. Greater sharing of experience is required to better understand the optimal method of sedation for this technique within the context of western practice.

Contact E-mail Address: callimann@chu-clermontferrand.fr

Introduction: Colonic polyp size measurement is an important outcome in current endoscopic practice. Polyp size estimation is mandatory to determine the surveillance interval after polypectomy and useful to anticipate and prevent complications in therapeutic procedures, for it has been proven that polyp size is one of the most important factors of complications (bleeding, perforation). Nevertheless, a high degree of subjectivity exists (especially overestimation of polyp size) in polyp size estimation because of a lack of validated and reproducible measurement methods. The aim of this study was to compare a computer-aided polyp measurement (CAPME) to an unassisted visual estimation (UVE) and an endoscopic reference measurement (ERM).

Aims & Methods: This prospective monocentric study was led between November 2015 and July 2016 in the University-affiliated Hospital of Clermont-Ferrand, the Blaise Pascal University (BP), and the Image Science for Interventional Techniques (ISIT) research unit of Clermont-Ferrand (France). Video-endo- scopic procedures were recorded and secondly used for the CAPME method. The endoscopic acquisition protocol was standardized with a slow back- and- forth movement towards the polyp to obtain a photograph of each polyp was taken with an open biopsy forceps placed on the base of the polyp. ERM was then measured thanks to a simple rule of three knowing the fixed size of the open biopsy forceps (8 millimetres, mm). UVE was determined on the same photography without any measurement devices by two different endoscos- pists. All the measurements were realized blinded of the other results. Accuracy of the CAPME and UVE methods was defined by a variation less than 1 mm with the ERM. We used the Lin concordance correlation coefficient (CCC) to measure the agreement between the variables.

Results: 33 patients and 78 polyps were included in this study. The mean polyp size was 5.3 mm, with 73.1% (n = 57) of polyp less than 5 mm. The Lin CCC with the ERM was 0.972 (95% CI 0.963; P < 0.001). No significant differences were found in en bloc resection, complete resection, postoperative bleeding, and perforation rates. No accidental symptom associated with balloon endoscopy was observed.

Conclusion: Using a balloon overtube can be expected to improve not only access to the lesion but also facilitate scope manipulation for colorectal ESD.

P1491 USING THE MULTI-ASSISTANT RATING SCALE (MARS) FOR ENDOSCOPIC NON-TECHNICAL SKILLS PERFORMANCE: AUGMENTS USE OF STANDARD KEY PERFORMANCE MEASURES IN INDEPENDENT COLONOSCOPISTS

N. Hawkes, F. Kokwara, B. Davies, J. Cornish
Gastroenterology, Coim Taf University Healt Board, nr Cardiff/United Kingdom

Contact E-mail Address: neilhawkes@aol.com

Introduction: Endoscopic Non-Technical Skills (ENTS) are an essential component of high-quality endoscopy giving information about performance in a team context however these are not routinely assessed as part of the key performance indicators (KPIs) for independently practising colonoscopists. We have developed a validated 360-degree assessment tool based on assistant ratings for ENTS (MARS) and with acceptable inter-rater agreement providing a more comprehensive view of the ENTS domain. We compared measured performance in these areas against existing key performance indicators which measure aspects of insertion and lesion detection skills.

Aims & Methods: We aimed to add a 360-degree multi-assessor rating scale (MARS) to provide a global assessment of ENTS skills to the existing KPI panel correlating the results against existing caecal intubation rate (CIR) and polyp detection rate (PDR). The validated MARS tool assesses 4 ENTS
domains—Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Decision-making (D&M). Each MARS domain was represented by 10 items and is assessed on a 7-point scoring scale—endoscopists should score >90 in each domain (80–90 = need for improvement, <80 = suboptimal performance). CIR and PDR measures are routinely calculated for all colonoscopists using the HICCS Electronic Reporting System with manual validation of these data. Feedback is presented on a quarterly basis to practitioners—endoscopists are expected to achieve 90% CIR and 20% PDR. Correlation of these factors with practitioners ENTS scores were measured using the Pearson test.

### Results:

9 endoscopists with known variability in standard colonoscopy KPIs consented to an assessment of ENTS using the MARS tool. Their ENTS scores were correlated with existing KPIs for each colonoscopist (Oct 2016–May 2017). An overall positive correlation was identified between ENTS domains and CIR (COMM 0.58; SITA 0.66; LEAD 0.66; D&M 0.75) and PDR (COMM 0.49; SITA 0.55; LEAD 0.50; D&M 0.60). Three endoscopists were identified as having sub-optimal scores in all of the ENTS domains (operators 5,7,9). Taking into account important KPI thresholds 2 out of 3 (33%) of these endoscopists identified were not meeting CIR targets (c.f. 66% of ENTS competent group) and one (33%) did not meet PDR targets (c.f. 6% in ENTS competent group).

Colorectal Cancer (CRC) is the third most common cancer diagnosed in men and second most common cancer in women, affecting 1,361,000 people worldwide each year. CRC is a slow growing tumour that most commonly develops from polyps which form in the inner lining of the colon or rectum. The identification and removal of polyps whilst still in a precancerous state has been shown to be effective in reducing mortality from CRC. Current clinical practice relies on white light (WL) colonoscopy for detecting colorectal polyps, but this is associated with a detection “miss-rate” of up to 26% for small (<10 mm) polyps and 2% for large polyps (van Rijn et al., 2006). Missed lesions (false negative results) puts patients at an unnecessary risk of late stage detection, when management has higher costs and worse clinical outcomes. Recent technological developments have resulted in more accurate technologies for polyp detection and removal. One such technology is the EMI-137 imaging agent (Edinburgh Molecular Imaging (EMI)) which has demonstrated potential to enhance the sensitivity of colonoscopy.

### Aims & Methods:

We aimed to evaluate the potential cost-effectiveness of EMI-137 compared to standard WL colonoscopy in patients at high risk of colorectal cancer. A de novo economic model for patients participating in the UK National Bowel Cancer Screen Programme. The value of information analyses revealed that uncertainty in the cost-effectiveness of EMI-137 is primarily driven by uncertainty in the assumption that EMI-137 reduces the risk of future polyps after polypectomy. The results of this modelling exercise have since been used to inform the design of Phase II/III clinical studies.

### Conclusion:

The results of this early economic modelling exercise demonstrated that EMI-137 has the potential to be cost-effective for patients participating in the UK National Bowel Cancer Screen Programme. The value of information analyses have highlighted the key parameters for which further evidence is required, and this will be used to inform the design of future clinical studies.

Conclusion: The use of a visual educational booklet for the preparation of colonoscopies does not provide a significant improvement in hospitalized patients in our health area. Heart disease and/or colon cancer were predictors of poor preparation for colonoscopy. An optimized preparation should be considered for this type of patients.

PI1494 STUDY OF ULCERATIVE COLITIS COMPPLICATED BY PRIMARY SCLEROSING CHOLANGITIS
S. Murasugi, A. Ito, H. Kambayashi, M. Yonezawa, T. Ohnori, K. Tokushige Institute of Gastroenterology, Tokyo Women’s Medical University, Tokyo/Japan

Contact E-mail Address: murasun0305@yahoo.co.jp

Introduction: Primary sclerosing cholangitis (PSC) is often associated with autoimmune diseases, and approximately 70% of PSC patients in Europe/United States and 32% in Japan also have ulcerative colitis (UC). While the complication of PSC is confirmed in about 5% of UC patients, the clinical features of UC associated with PSC differ from those of UC without PSC.

Aims & Methods: We investigated the clinical and colonoscopic features of colitis associated with PSC. We retrospectively examined the clinical features, including the clinical course and colonoscopic findings, of 25 colitis patients with PSC attending our hospital between 2000 and 2016.

Results: The male-female ratio was 12.13 and the age at diagnosis of PSC was 49 ± 15 years. PSC was the initial diagnosis in 12 patients (48%), while colitis was the first to be diagnosed in 4 patients (16%), and both diseases were found concurrently in 9 patients (36%). Among the 21 patients with the diagnosis of PSC, 14 patients (67%) developed UC, and the latter was diagnosed by screening. There were 12 patients with UC (52%) and 11 patients with nonspecific colitis (48%). Among the 24 patients in whom the disease extent was assessed, 22 had pancolitis, 1 had left-sided colitis, and 1 had proctitis. Inflammation predominantly affected the right colon in 20 patients with pancolitis and also involved the terminal ileum in 9 patients (48%). The Mayo score for colonic evaluation of UC was 1 in 16 patients (64%), 2 in 8 patients (32%), and 3 in 1 patient (4%). There were no rectal lesions in 10 patients (40%). Liver biopsy was performed in 17 patients, and Ludwig’s stage was Stage I in 1 patient (6%), Stage II in 12 patients (71%), Stage III in 3 patients (18%), Stage IV in 1 patient (6%). Ludwig’s stage did not correlate with the Mayo score. All patients with PSC and enterocolitis received oral ursodeoxycholic acid (UDCA), including 13 patients with UDCA only (52%), 2 patients with combination of salazosulfapyridine (SASP) (8%) and UDCA in combination with 5-aminosalicylic acid (5-ASA) (20%), 2 patients in combination with prednisolone (PSL) (8%), 1 patient with the combination of SASP+PSL (4%), and 2 patients with 5-ASA+PSL (8%). The UDCA dose was 100 mg in 2 patients (8%), 300 mg in 15 (60%), and 600 mg in 9 (32%).

Conclusion: In colitis patients with PSC, there was no clear association between colonoscopic disease activity and the severity of PSC. There was no sex difference and the age at diagnosis of PSC showed a bimodal distribution (30s and 60s). Pancolitis was very frequent and predominantly affected the right colon, but disease activity was low. Rectal lesions were mild or absent. About half of the patients had inflammation of the terminal ileum.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic non-technical skills (ENTS), comprising of communication and teamwork, situation awareness, leadership and judgement and decision making, are recognised indicators of quality endoscopy and patient safety. Since July 2016, electronic assessment forms (DOPS) for UK trainee endoscopists have been updated to include DOPS as an assessable domain. We aimed to assess the uptake and distribution of ENTS scoring in DOPS and their correlation with other endoscopic skills, across all assessable endoscopic modalities.

Aims & Methods: We identified all DOPS submitted between July 2016 and Feb 2017 from the UK endoscopy trainee database (JETS) and acquired data on trainees, procedures and scores. We collated scores for each of the 4 assessable domains (pro-procedural, procedural, post-procedural and ENTS) into overall outcomes of “not competent” (if any domain items required supervision) or “competent”, and compared this to the overall competence rating. Statistical analysis was performed using chi2 and regression modelling.

Results: 8601 DOPS were prospectively collected, with ENTS assessed in 99.3%. Competency rates of individual ENTS items are summarised in Table 1. Rates of overall ENTS competency (defined as all items scoring competent) varied across procedures (p < 0.001): ERCP 39.8%, EUS 44.1%, gastroscopy 59.6%, colonoscopy 62.3%, PEG 71.1%, gastrointestinal bleed (71.5%), sigmoidoscopy 72.4% and polypectomy 73.2%. Scores by individual ENTS components are displayed in Table 1. Of DOPS awarded overall competency, 5.9% (240/4077) lacked full competence in ENTS (p = 0.10 across modalities). Across trainee specialities and endoscopic modalities, competency was greatest for “communication and teamwork” (77.1% overall), but least with ‘judgement and decision making’ (68.3%). Competency in ENTS increased with lifetime procedural count (OR 1.008 per increase in procedure, p < 0.001), and correlated strongly with other assessable domains, including overall score (p < 0.001). After adjusting for procedural count, factors predictive of ENTS competency included trainee seniority (OR for ST5 level: 1.96, p < 0.001), surgical trainees (OR 1.21, p = 0.014), trainees performing polypectomy (OR 2.02, p < 0.001), and higher DOPS count (OR 1.03 per increase in DOPS, p < 0.001).

Conclusion: ENTS is an assessable domain within endoscopy training, with scores that correlate with other procedure-related skills, demonstrating construct validity and reliability. ENTS is an assessable domain within endoscopy training, with scores that correlate with other procedure-related skills, demonstrating construct validity and reliability. ENTS is an assessable domain within endoscopy training, with scores that correlate with other procedure-related skills, demonstrating construct validity and reliability.
P1496 MAKING COLONOSCOPISTS MORE AWARE OF THEIR ENDOSCOPIC NON-TECHNICAL SKILLS: IMPROVING FEEDBACK FORMATS DERIVED FROM THE MULTI-ASSISTANT RATING SCALE (MARS) TOOL

N. Hawkes, F. Kokwara, B. Davies, J. Cornish
Gastroenterology, Cwm Taf University Health Board, nr Cardiff/United Kingdom

Contact E-mail Address: neilhawkes@aol.com

Introduction: The development of Endoscopic Non-Technical Skills (ENTS) is associated with performance and high quality endoscopic outcomes. Whilst ENTS domains have been incorporated into Joint Advisory Group (JAG) Direct Observation of Procedural Skills (DOPS) forms, used as training tools, knowledge of ENTS amongst independent practitioners varies. To improve performance in this area of practice requires validated measurement tools and specific feedback against which improvement can be measured. We have previously developed a validated 360-degree multi-assessor rating scale (MARS tool) based on experienced endoscopy assistant ratings for ENTS provision and scrutiny of ENTS domains of each comprising 10 related but independent practice points. Providing an optimised feedback format for this data is likely to maximise the potential benefits of measuring ENTS performance.

Aims & Methods: We aimed to provide an optimised format for performance enhancing feedback in the ENTS domains and basis for specific auditable outcomes and performance indicators. Local colonoscopists gave consent to application of the ENTS questionnaire. The validated MARS tool assesses 4 ENTS domains - Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Judgement & Decision-making (J&DM). Each MARS domain in the administered questionnaire was represented by 10 items and is assessed on a 7-point scoring scale. We sought to develop 1) a format to illustrate an individual’s overall performance in each of the 4 main ENTS domains in comparison to other operators and 2) a detailed domain breakdown highlighting areas of underperformance 3) Collate feedback on the presentation formats.

Results: 9 endoscopists consented to an assessment of ENTS using the MARS tool. The MARS questionnaires were administered during January 2017–relating to the prior 3 months clinical practice. Acceptable performance thresholds were set as >90% good-excellent ratings in each domain. Need for improvement was defined as 80-90% good-excellent ratings (i.e. 10-20% average or poor ratings) and sub-optimal performance as 80% or less good-excellent ratings (i.e. >20% average-poor ratings). Good intra- and inter-rater reliability was demonstrated for these cut-off values during validation of the MARS tool. Scatter plots were used to present the overall domain ratings for COMM, SITA, LEAD and J&DM domains allowing comparison with other endoscopists. To provide more detailed domain-specific feedback to endoscopists an individual report is generated of 4 domain tables summarising the question items and using a ‘traffic-light’ display to help operators quickly identify those specific skills that require areas for improvement. The feedback reports summarised the MARS feedback helpful and indicated that it was ‘likely’ or ‘very likely’ to prompt an alteration in practice. A suggestion to add an additional column to the summary table indicated where performance level has changed in subsequent audit rounds is being considered.

P1497 OUTCOMES OF ENDOSCOPIC RESECTION OF COMPLEX COLORECTAL LESIONS REFERRED TO A TERTIARY INSTITUTION AFTER FAILED ATTEMPTS AT RESECTION OR EXTENSIVE SAMPLING

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Substantial manipulation or sampling of large colorectal lesions prior to endoscopic resection can have significant effects on the feasibility and outcomes of endoscopic treatment. Failed attempts at resection and extensive sampling or tattooing into lesions prior to referral to a specialist centre are common in western practice. However, there are few data defining the scope of these failed attempts and the effect on outcomes following endoscopic resection. We examined the effect of significant prior manipulation on the feasibility and outcomes of endoscopic resection of complex colorectal neoplasms in a UK tertiary referral centre.

Method: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colonic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Patients were grouped according to whether they had failed attempts at resection, heavy manipulation (≥6 biopsies or tattoo into the lesion), or minimal sampling only (<6 biopsies). Outcomes included initial successful endoscopic resection, complications, recurrence and the need for surgery.

Results: 437 lesions in 433 patients were assessed. Using EMR 9n = 340 and ESD and Hybrid ESD (n = 97). The mean lesion size was 5.5 cm (+/−3.0 cm). 225 (51%) lesions had been subjected to failed attempts at resection or heavy manipulation prior to referral. In 97 lesions (22%), an average of 1.5 range 1-5) previous attempts at resection had been made. In 43 attempts at transanal surgical resection in 25 patients. A further 128 lesions (29%) had been extensively sampled or tattooed Mean lesion size was 55.6 mm (+/−30.7 mm).

Initial endoscopic resection was deemed successful in 98% of cases after previous failed attempts, 97% of cases with prior heavy manipulation and 97% of other cases (p = 0.86). In b lace resection was possible in fewer patients with previous attempts at resection (14%, 31% and 42% respectively, p < 0.001). Complications regardless of failure were associated with failed attempts at resection and minimal sampling (14% versus 5% and 3%, p < 0.001). Recurrence rates were 24.1%, 14.6% and 12.2% respectively (p = 0.07). 95% of patients without invasive cancer who had prior failed attempts at resection or heavy manipulation were free from recurrence.

Conclusion: Failed prior attempts at resection or heavy manipulation of lesions reduces the chance of achieving en b lace resection and increases the risk of complications and recurrence. Nevertheless, specialist management in a dedicated tertiary unit results in safe and successful organ preserving endoscopic treatment of these extremely challenging lesions in over 95% of cases with few significant complications.

Introduction: In recent years, significant advances and innovations have been made in gastrointestinal endoscopy technology. The special light observation using a narrow band light source different from conventional white light is one such innovation. The special light observation with a magnifying procedure has made a contribution to improving the diagnosis of lesions in the stomach, intestines, stomach, and large bowel; it is particularly useful for differentiating between benign and malignant lesions and evaluating the depth of invasion. The instruments for narrow band imaging (NBI) were developed by Olympus Co., Ltd., and the blue laser imaging (BLI) by Fujifilm Co., Ltd. These systems are applied to magnifying endoscopy in clinical practice. Studies have examined the use of NBI and BLI for the diagnosis of neoplastic diseases, especially for the early detection of gastrointestinal cancers. However, there are relatively few reports describing the application of these techniques to benign diseases.

Aims & Methods: This basic study aimed to explore the potential of magnifying observation with narrow band light by evaluating the usefulness of mucosal blood flow in the small and large bowel. The subjects were selected from among patients who had undergone colonoscopy since April 2016. They were randomized into three groups: patients undergoing examination with EC-L100PZ, a high-end instrument manufactured by Fujifilm Co., Ltd. (group F), CF-HQ290ZI, a high-end instrument manufactured by Olympus Co., Ltd. (group O1) or PCF-H290ZI manufactured by Olympus Co., Ltd. (group O2). Each group consisted of 25 patients. The visualization of mucosal blood flow in the small and large bowel by magnifying endoscopic observation with narrow band light was evaluated and scored as follows: good visualization 2; partial visualization 1; and no visualization 0. The water method and tip attachment were used in all cases.

Results: The respective mean scores for visualization of the small and large bowel were 2 and 2 in group F, 1.32 and 1.24 in group O1, and 1.48 and 1.40 in group O2. The visualization scores for both the small and the large bowel were significantly higher in group F than in groups O1 and O2. Group O2 had higher scores than group O1, although the difference was not statistically significant. The endoscope used in group F has a bright laser light source and maximum optical magnification levels up to 135 times and maximum electronic magnification levels up to 270 times. On the other hand, the endoscopes used in groups O1

Example Feedback table - Situational Awareness Domain for Endoscopist 9

| SITA 1 | Pre-assessment of patient risks | GREEN |
| SITA 2 | Recognises problems in a timely fashion | GREEN |
| SITA 3 | Aware of working environment, minimises disruptions | RED |
| SITA 4 | Effectively troubleshoots technical problems that arise | BLUE |
| SITA 5 | Recognises and assesses pathological findings effectively | AMBER |
| SITA 6 | Reacts flexibly and effectively to unexpected or adverse circumstances | AMBER |
| SITA 7 | Aware of patient safety parameters during procedure, responds well | AMBER |
| SITA 8 | Considers other opinions and guidance when faced with an unexpected event | AMBER |
| SITA 9 | Predicts well the likely outcome of a situation and plans for this eventuality | AMBER |
| SITA 10 | Constantly checks patient aiming to minimise procedural discomfort | AMBER |
and O2 have relatively dark xenon light sources and maximum optical magnification of 200x in the small and large bowel. Our results show that magnifying observation with BLI is superior to Colonoscope: visualization of mucosal blood flow in the small and large bowel among the different endoscopic devices.

Introduction: The aim of the present study is to better define the clinical characteristics at diagnosis and during follow-up of MCRA affected patients. Familial adenomatous polyposis (FAP) or MUTYH germline mutation. At present its clinical features, management and outcomes are not well studied. However, these patients should undergo a closer surveillance than those with sporadic adenomas.

Bowel Scope screening between July 2013 - July 2016 at St Mark's Bowel Cancer Screening Centre was performed. Epidemiological, procedural and polyp data were retrieved from the endoscopy and Bowel Cancer screening database.

Results: 9960 patients had a screening flexible sigmoidoscopy in the time period. Descending colon was reached in 82% of patients. Advanced adenomas were detected in 351 (3.2%) patients. 520 (5.2%) patients had a colonoscopy following flexible sigmoidoscopy as per the BCS protocol. Median age was 55 years (male: female ratio 2:1). Caecal intubation was achieved in 98% (510/520) of cases. At least one adenoma or a sessile serrated adenoma/polyp (SSA/P) was detected. Presence of distal adenoma was an indication for colonoscopy after a screening flexible sigmoidoscopy. Outcomes of advanced adenoma in the distal colon were as follows: 14% had a synchronous proximal colonic advanced adenoma and 20 (5.7%) had a synchronous SSA/P. Only 5 (1.4%) patients had an advanced adenoma in the proximal colon. Presence of distal advanced adenoma was associated with proximal advanced adenoma (p=0.0006). However, there was no association between presence of distal advanced adenoma and proximal SSA/P (p=0.47) or advanced SSA/P (p=0.4).

of optical diagnosis. Findings could be used as a guide to plan the certification process for implementation training appears important to maintain the performance. Our preliminary findings plateau by the 58th polyp observation. In-vivo feedback and continued standards were performed for other indications (non-adenomatous polyp > 1 cm, multiple distal HP polyps) the yield in the proximal colon was significantly smaller. These “soft” indications for colonoscopy accounted for a significant additional workload that appears unjustified.

Disclosure of Interest: B.P. Saunders: Advisory board member of Olympus UK All other authors have declared no conflicts of interest.

Conclusion: Distal colonic advanced adenomas are a marker of synchronous proximal colonic adenomas and sessile serrated polyps. When colonoscopies were performed for other indications (non-adenomatous polyp > 1 cm, multiple distal HP polyps) the yield in the proximal colon was significantly smaller. These “soft” indications for colonoscopy accounted for a significant additional workload that appears unjustified.

Positive Predictive Value 89% 94% 88% 94% Negative Predictive Value 92% 92% 91% 93% All 4 trainees achieved sustained accuracy (90% threshold) in OD within 12–58 observations. The number of polyps required to reach the plateau varied between 12 to 58. Every trainee’s confidence level improved over time (from 69% to 89%) and the effect was augmented by in-vivo feedback and revision of training module. Table 1 summarises the optical diagnostic performance of all 4 trainees. Negative predictive value for adenomas were above 90% for all trainees.

Conclusion: The CUSUM scores of all 4 trainees in the study reached the PIVI standards plateau by the 58th polyp observation. In-vivo feedback and continued training appears important to maintain the performance. Our preliminary findings could be used as a guide to plan the certification process for implementation of optical diagnosis.

P1502 LEARNING CURVE FOR OPTICAL DIAGNOSIS OF COLORECTAL POLYPS USING CUMULATIVE SUM ANALYSIS

R. Rameshshanker, A. Wilson, S. Thomas-Gibson, N. Kamperidis, N. O’Shea; B.P. Saunders
Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Optical diagnosis for diminutive and small colorectal polyps is an attractive option to reduce costs and streamline patient care. The American Society of Gastrointestinal Endoscopy Preservation and Incorporation of Valuable Endoscopic Innovations (PIVI) established a 90% diagnostic threshold for real time endoscopic assessment of the histology of diminutive colorectal polyps. For adoption of optical diagnosis in clinical practice, colonoscopists must be trained and show on-going competence. The learning curve for trainees to achieve the competency has not been fully explored.

Aims & Methods: Aim is to evaluate the minimum number of polyps to achieve and maintain the optical diagnostic thresholds per PIVI standards using an upward CUSUM plot. Four trainees without previous experience in optical diagnosis at our institution participated in this prospective study. Four weeks before the commencement of the study they were given a training module on optical diagnosis (OD). OD was based on NICE and WASP classification. During the study period (January 2016-August 2016), each trainee documented the optical diagnosis of polyps less than 10 mm in size. Confidence levels of OD were noted at the same time. Patient demographics and polyp details (site, size, Paris classification and histology) were collected prospectively. OD of each polyp was compared against the polyp histology. Polyps without the histological confirmation were excluded from the analysis. Every trainee had on-going feedback on their performance.

Results: A total of 708 polyp observations were performed by trainees during the study period. Total number of adenomas, hyperplastic polyps and sessile serrated adenomas/polyps (SSA/P) were 364,214 and 52 respectively. Trainees OD performance was plotted on a upward CUSUM plot.

P1504 COLONIC ESD BY UTILIZING SHORT DOUBLE BALLOON ENDOSCOPE – HOW TO TREAT DIFFICULT CASES IN COLONIC ESD

S. Katsuki, T. Fujita, K. Takamashi, E. Waga
Center Of Gastroenterology, Otaru Eki saikai Hospital Center of Gastroenterology, Otaru/Japan

Contact E-mail Address: sinichi-katsuki@otaru-eki saikai.jp

Introduction: Colon ESD has been becoming a standard treatment in the world. However, sometimes it is hard to remove the colon tumor during ESD. When we found it difficult to detach the colon tumor, ESD operators in Japan have to consider the following three points: if we don’t have enough experience and skill, we should take the training more. If there are lots of vessels and fibrosis in the submucosal layer, it is necessary to choose adequate tools. And if patients have complicated colon, suitable endoscope need to be selected. In such cases we always use DBE.

Aims & Methods: We evaluated the outcomes of colon ESD by using DBE (DBE-ESD). Short DBE we used were EC450BI5, EN530BI and EI580BT (Fujifilm Co., Tokyo, Japan). We’ve performed DBE-ESD on 211 lesions in 184 patients. We analyzed the lesions located in the proximal colon, and the following items were examined: arrival time, procedure time, rate of negative margin, perforation rate, length of hospital stay and recurrence rate in the 5th year after the ESD.

Results: There were 159 lesions located in the proximal colons. The median arrival time to the lesion was 7.9 min, operation time 51.1 min, negative rate of horizontal margin 99.4%, vertical margin 99.4%, perforation rate 0%, median length of hospital stay 3.1 days, and recurrence rate in patients with more than 5 year follow-up 0%.

Conclusion: Because the balloons and the overtube retained the scope at stable position, we were able to get good working space. Therefore, DBE should be one option for difficult cases in ESD.

Introduction: Adenoma detection rate (ADR) is a quality indicator of screening colonoscopy. Monitoring withdrawal time (WT) and use of full-spectrum endoscopy (FUSE) have been suggested to increase the ADR since an accurate evaluation of the hidden areas of the colon.
Aims & Methods: We aimed to evaluate whether monitoring of WT alone or in combination with the use of FUSE would be able to increase the ADR. In a prospective non-randomized observational study, consecutive outpatients, aged 18-85 yr, undergoing colonoscopy with different indications were enrolled. In phase 1, endoscopists performed 660 colonoscopies either with standard forward-viewing endoscope (SFVE) (n = 330) or with FUSE (n = 330) without a dedicated WT protocol. In this phase, colonoscopy WT were measured without the endoscopists' knowledge of being monitored. In phase 2, endoscopists were informed of being monitored and performed further 660 colonoscopies either with SFVE (n = 330) or with FUSE (n = 330).
Results: No differences were observed among the four arms in terms of demographic, clinical features, and indications to colonoscopy. WT was lower in phase 1 arms compared to phase 2 arms (SFVE: 267 ± 96 vs. 387 ± 65, p = 0.001; FUSE: 293 ± 112 vs. 430 ± 93, p = 0.001). When endoscopists were aware of being monitored and used full-spectrum endoscope we observed a higher ADR (phase 1 SFVE 27.3% (90) phase 1 FUSE 33.0% (109) phase 2 SFVE 33.6% (111) phase 2 FUSE 41.8% (138); p = 0.001) and adenoma per colonoscopy (APC) (phase 1 SFVE 0.43 ± 0.85 phase 1 FUSE 0.56 ± 1.08 phase 2 SFVE 0.41 ± 1.24 phase 2 FUSE 0.71 ± 1.08; p = 0.004). The detection rate of adenoma located proximally to the splenic flexure was higher in phase 2 arms (phase 1 SFVE 11.2% vs. phase SFVE 16.4%, p = 0.056; phase 1 FUSE 12.7% vs. phase 2 FUSE 18.9%, p = 0.033), whereas adenoma located distally to the splenic flexure was higher in the FUSE arms compared to SFVE arms, but these differences were not significant (Phase 1 SFVE 20.0% vs. Phase 1 FUSE 24.8%, p = 0.081; Phase 2 SFVE 21.8% vs. Phase 2 FUSE 27.0%, p = 0.147).
Conclusion: Unmonitored endoscopists have a sub-optimal WT, which increases when they are aware to be monitored. Use of full-spectrum scopes combined with WT monitoring results in increase of adenoma detection rate. In particular, monitoring WT increases the detection of adenoma in proximal colon, whereas the use of FUSE seems to increase the detection of adenomas in distal colon.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1506 HIGH LEVELS OF “PRESUMED POLYP MISS RATE” AT 1 AND 3 YEARS FOLLOWING INDEX SCREENING COLONOSCOPY: NO ROOM FOR IMPROVEMENT AGENCY
R. Rameshshanker, F. Purchiaroni, A. Wilson, A. Rajendran, S. Thomas-Gibson, A. Humphries, A. Haycock, N. Suzuki, B.P. Saunders Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom
Contact E-mail Address: r.rameshshanker@nhs.net
Introduction: Colonoscopy with polypectomy is considered the optimal method of bowel cancer prevention. Despite improvements in colonoscopy training and technology, it remains as an imperfect tool and the adenoma miss rates vary greatly depending on the bowel preparation quality, and patient co-morbid conditions.
Aims & Methods: Aim is to determine the presumed miss rate for adenomas and sessile serrated adenomas/polyps (SSA/P) after a complete screening colonoscopy. Methodology: A prospective observational study was performed at our bowel cancer screening centre over 12 months from July 2015. Patients who underwent a surveillance colonoscopy following an index colonoscopy were included (one and three-year surveillance). All colonoscopies were performed by 6 experienced, accredited bowel cancer screening colonoscopists. Polyp characteristics and procedural data were prospectively recorded and collected. Polyp histology and epidemiology data were retrieved from our endoscopy database. A polyp was considered as “missed” at the index colonoscopy if at 1 year surveillance it was not adjacent to a scar (a recurrence) or at 3 years if > 5 mm in size and not adjacent to a scar.
Results: 241 patients underwent a surveillance colonoscopy (male: female 2:1, median age 65 years). 90/241 (37.3%) patients had a one-year surveillance colonoscopy. There was no significant difference in the quality of bowel preparation, caecal intubation rate and total procedure time between index and surveillance procedures. Total number of polyps detected during index and surveillance colonoscopies were 815 and 469 respectively. The presumed miss rate of polyps, adenomas, SSA/Ps and advanced adenomas were 37.8% (469/1241), 22.1% (176/798), 41.7% (20/48) and 15.2% (36/236) respectively. More adenomas were missed in the proximal colon when compared to distal colit (26.64% vs. 18.04%, p = 0.01). Table 1 illustrates the distribution of missed adenomas in each segment of the colon. Adenoma miss rates per size as follows: < 5 mm, 6-9mm and > 10 mm were 24.27 and 8% respectively. Higher number of polyps (> 3 mm) detected during index colonoscopy independently correlated with high miss rates (84.3% vs 72%, p = 0.04).

Conclusion: Our study highlights that there is likely to be a significant miss rate for adenomas and SSA/Ps even after careful index colonoscopy. Miss rate was higher when multiple polyps are seen at the index examination. This finding appears to justify the current BSG (British Society of Gastroenterology) guidelines for an early, 1 year colonoscopy when multiple polyps are seen. The presumed polyp miss rate at 1 & 3 years may be justified as a new quality metric within screening programmes.

P1507 IMPACT OF PERIODONTAL DISEASE ON PREVALENCE OF COLORECTAL NEOPLASIA IN PATIENTS UNDERGOING ROUTINE SCREENING COLONOSCOPY
A. Dokladanska1, P. Jeschek1, E. Waldmann2, D. Penz2, B. Majcher2, A. Hinterberger2, G. Henze2, M. Ferlitsch2 1Department Of Internal Medicine III, Division Of Gastroenterology And Hepatology, Medical University of Vienna, Vienna/Austria 2Medical University of Vienna, Vienna/Austria
Contact E-mail Address: angelika.dokladanska@medunivien.ac.at
Introduction: Systemic diseases including several types of cancer have been associated with periodontitis, potentially owing to the constant systemic inflammatory state in those patients. Data on a potential association of periodontal disease and colorectal neoplasia is scarce and conflicting.
Aims & Methods: Data from 25,407 patients undergoing healthy check up assessing periodontal disease according to periodontitis-risk classes (PRC: 0-healthy gingiva, PRC 1 - tatar or plaque, PRC 2 - redness or swelling) and screening colonoscopy between 2009 and 2012 in Austria were included. Colonoscopy outcomes were compared between patients with and without signs of periodontal disease using multivariate models adjusting for age, sex, smoking, alcohol consumption, diabetes and BMI.
Results: In multivariate adjusted models, patients with periodontal disease had similar odds for the detection of colorectal polyps as those without signs of periodontal disease [adjOR 1.070; 95% CI: 0.918; 1.247]. Regarding the prevalence of adenomas, patients with periodontal disease, likewise, had similar odds as those with healthy periodontal tissue [adjOR 1.010; 95% CI: 0.840; 1.213]. Similarly, those with periodontal disease had comparable odds for colorectal adenomas as those without signs of periodontal disease [1.055 [0.785; 1.418].
In the table below the adenoma detection rate (ADR) and advanced adenoma detection rate (AADR) divided into the periodontitis-risk classes.

P1508 OUTCOMES OF ENDOSCOPIC RESECTIONS OF LARGE NON-POLYPOID LESIONS IN INFLAMMATORY BOWEL DISEASE: A SINGLE UNITED KINGDOM CENTRE EXPERIENCE

S. Gulati, A. Emmanuel, M. Burt, P. Dubois, B. Hayee, A. Haji
Endoscopy, King’s Institute of Therapeutic Endoscopy, RS United Kingdom

Contact E-mail Address: shraddhagulati@nhs.net

Introduction: Patients with colitis carry an increased risk for the development of dysplasia compared to those without1. The SCENIC consensus statement recommends endoscopic resection of all visible dysplasia2. Due to technical challenges and limited experience in the West of large colitis associated non-polypoid endoscopic resections, such patients are often subjected to colectomy. The King’s Institute of Therapeutic Endoscopy (KITE) is a tertiary centre for endoscopic assessment and resection of large challenging colorectal polyps. Here we present the largest single-centre case series of large non-polypoid resections associated with colitis.

Aims & Methods: Adults with confirmed colitis (ulcerative colitis extending beyond the rectosigmoid junction and crohn’s colitis affecting at least the left colon) with lesions at least 20 mm in size within the colitis segment were included. Data including demographics, clinical history, lesion characteristics, method of resection and post-resection surveillance were collected prospectively in patients from January 2011 to November 2016. Resection techniques included endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD) and hybrid ESD. Surveillance of resection site with magnification chromoendoscopy (mCE) was performed at 3 months with pan colonic mCE at 1-year post resection and annually thereafter.

Results: Thirteen lesions satisfied the inclusion criteria in 13 patients. Patient demographics and clinical data are presented in table 1. Mean lesion size was 47.3±4.2 mm (20–90) mm. All lesions were non polypoid with distinct margins and no ulceration. High-frequency mini-probe ultrasound confirmed intramucosal lesions in 5 cases where pitvascular pattern was distorted due to inflammation. En bloc resection was achieved in 6 cases. 69% lesions were deeply scarred of which 66% had experienced prior instrumentation. Resection of a single lesion with ESD resulted in intense fibrosis. Macrosopic evidence of complete resection was achieved in all remaining cases. Endoscopic diagnosis of pre-cancerous lesions of less than 1000 μm submucosal invasion was confirmed histopathologically in 5 of the resected lesions. Complete excision was confirmed in all en bloc resections. A single case of small perforation and another with delayed minor bleeding were both managed endoscopically. Mortality/hospital admission within 30 days post resection was 0%. Median follow up was 28 months (12–35) with no recurrence. Alternative site dysplasia was detected in 2 patients. All lesions were sub 20 mm and resected endoscopically. Two patients were referred for colectomy due to a concomitant diagnosis of neuroendocrine tumour and the second with alternate site advanced dysplasia.

**P1510 OUTCOMES FOLLOWING UNDERWATER ENDOSCOPIC MUCOSAL RESECTION OF >10MM COLORECTAL POLYPS: A PROSPECTIVE DUAL-CENTRE STUDY**

K. Siau 1, A. Yusu 2, N. Suzuki 3, S. Ishaaq 4

**Introduction:** Underwater endoscopic mucosal resection (UEMR) is an alternative to traditional EMR for the resection of colonic polyps. With this technique, water insufflation is used in place of air or CO2, and submucosal lifting is usually not required, as water-immerses submucosa cushions itself from the muscularis propia. Theoretically, this reduces the risk of diathermy-induced injury, and allows for more complete resection margins.1,2

**Aims & Methods:** In this prospective dual-centre study, we aim to evaluate the safety and efficacy of UEMR for clinically significant (>10 mm) colonic polyps. Studied outcomes included: 1) completeness of UEMR, 2) intra-procedural and 3-day complication rates, 3) percentage requiring submucosal lift, and 4) rates and predictors of polyp recurrence. Procedures were performed by two screening endoscopists accepting tertiary referrals at St. Mark’s Hospital, London, and Russell’s Hall Hospital, Dudley, UK. Recurrence was defined as the presence of any polyp tissue at the resection site. Endoscopy records were examined and correlated with history. Univariate analyses were performed using Pearson’s chi² to identify predictors of measured outcomes.

**Results:** Between June 2014 and March 2017, and A total of 85 patients (median age 69.5 years, interquartile range [IQR] 11, 50.6%) underwent UEMR of 97 colonic polyps (median size 25 mm, IQR 25 mm, range 10–160 mm). 13 (13.4%) were recurrences following previous conventional EMR. Polyps were predominantly left sided (66%) with flat (63.5%) or sessile (35.5%) morphology. 43.8% of polyps were removed en bloc, whilst argon plasma coagulation (APC) was used in 13.7%. Histology comprised of: low-grade dysplasia (80.2%), high-grade dysplasia (12.5%), adenocarcinoma (3.1%) and non-dysplastic sessile serrated adenoma (2.1%). Overall, resection at index UEMR was deemed endoscopically complete in 97.9%. Submucosal lift was required in 27.8% and positively correlated with polyp size >30 mm (OR 3.58, 95% CI 1.37–9.38, p = 0.01), but not morphology (flat vs. sessile, p = 0.099). The 30-day complication rate was 4.1% (n = 4), comprising: bleeding (n = 2, average diameters: 35 mm) and delayed rebleeding (n = 2; average diameter: 57.5 mm), with haemos-tasis achieved for all cases. No cases of perforation or mortality were identified. Of the 60.8% (n = 59) who attended for repeat endoscopy post-UEMR, the rate of recurrence or residual polyp was 14.8% (9.54) at 4 months and 15.99 (22.0%) within 1 year. Significant predictors of post-UEMR recurrence included: piece-meal vs. en bloc resection (OR 5.50, 95% CI 1.10–27.6, p = 0.03) and previous polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.04), but not polyp size, site, morphology or dysplasia status, use of submucosal lift, APC-, patient age, or study centre.

**Conclusion:** UEMR is a safe alternative to conventional EMR for the management of clinically significant colonic polyps. However, our post-UEMR recurrence rate of 22.0% appears higher than other studies, but may be skewed by the tertiary referral centre. Although randomised trials are awaited, we suggest that those performing UEMR should attempt en bloc resection where possible, and consider wider resection margins for recurrent polyps.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1511 WATER-AIDED COLONOSCOPY - RESEARCH FOCUS IN THE PAST DECADE AND CURRENT CLINICAL PRACTICE**

F. W. Leung
Medicine, Seguleda Ambulatory Care Center, VAGLHAS; David Geffen School of Medicine at UCLA, North Hills/United States of America/CA

Contact E-mail Address: felixleung@socalrr.com

**Introduction:** Water-aided techniques have forged a paradigm shift in endoscopic diagnosis and therapy. The inauguration (10/22/2014) of the International WATERS with memberships worldwide attested to participants’ commitment to advance clinical, educational and research missions. To aid in planning of future work in each of these areas, a descriptive study of water-aided colonoscopy was performed.

**Aims & Methods:** The aims of this study were two-folds. Study 1: To assess the feasibility of WATERS in the past decade’s study. To obtain a cross-sectional snapshot of current clinical practice. Study 1: Studies registered at Clinicaltrials.gov were searched for using the search term “water colonoscopy”. Study 2: Members of International WATERS voluntarily participated in a survey after inserting the proportion of patients with different models of sedation, respondents selected yes (1) or no (0) responses to each of 16 questions related to their practice of water-aided colonoscopy.

**Results:** Study 1: In the past decade, 48 trials of water-aided colonoscopy were registered at Clinicaltrials.gov. They aimed at evaluation of insertion pain in unsedated, minimally sedated, or on demand sedation patients; assessment of efficacy in difficult colonoscopy; study of the impact on adenoma detection; and underwater mucosal resection or polypectomy. Study 2: Questionnaire responses are summarized in Table 1. Respondents: n = 23. Water-aided colonoscopy is used in patients sedated with propofol, minimal sedation on demand sedation (3–16%), but more commonly in patients with moderate or no sedation (30–34%). During insertion 95.5% use infusion of water and only 36.4% leave the air/CO2 pump on. 42.9% and 33.3% record volumes infused and suctioned upon arrival to the cecum. 52.4% remove almost all infused water during insertion. 71.4% and 59.1% performed polypectomy (<20 mm and >20 mm, respectively) underwater during withdrawal.

**Table 1A:** % of respondent’s patients

**Conclusion:** The variable modes of application amongst respondents who profess to use water-aided colonoscopy reflect the versatility and strength of the paradigm-changing approach, which is easily adaptable to meet the diverse needs of individual colonoscopists. Standardization based on results of randomized controlled trials appears to be prudent to permit further assessment of water-aided colonoscopy in clinical, educational and research settings.

**Introduction:** Endoscopic submucosal dissection (ESD) is a suitable technique used for the endoscopic management of selected early gastrointestinal neoplasms (EGN).

**Aims & Methods:** This is a prospective study of patients with EGN eligible for ESD in tertiary hospitals. The main goal was to evaluate initial therapeutic results and learning curve of ESD. Initial Technical success rates, procedure speed, en-bloc & R0 resection, R0, speed and complications rates were prospectively evaluated. The results of the learning curve were analysed by chronological order of blocks of 50 cases. Perforation was established as any disruption of the muscular layer, regardless of size or identification of peritoneal fat. Time of procedure was considered from initial submucosal injection to final detachment of the specimen.

**Results:** ESD was attempted in 183 lesions from January 2012 to April 2017. Majority of procedures were performed at Puerta de Hierro University Hospital (160/87.4%). Mean age was 67 (SD 10.6) years, with male proportion 55.2%. Most common location was colorectal (77.8%), followed by gastric (12.8%) and esophageal (9.4%). Success was observed in 96.2% of patients with en-bloc and R0 resection of 93.9% and 92.3% respectively. Mean lesion size was 46.5 mm (range 8–130) with a mean speed of 9.01 min/cm2 (range 1–209). Perforation was
the main complication (48 (26.2%) events), requiring surgery in 5 (10.4%) cases. Perforation was statistically related significantly to location (p = 0.05) and LST morphology (p = 0.05). Most frequent location of perforation was transverse colon (OR 88.3; SE 137), followed by descending colon (OR 13.5; SE 19.4) and splenic flexure (OR 6.3, SE 11.8). Perforation was more common in LST-NG lesions vs LST-G (OR 14.1; SE = 19.3 vs 11.6 SE 15.0). Perforation rates were not statistically associated with the presence of severe submucosal fibrosis compared to absence of fibrosis (0.8 SE 0.6 vs 1 SE 1 p = 0.9). Post-ESD complications were observed in 15 (8.2%) patients (delayed perforation(7), bleeding(4), electrocutaneous ulceration(1), severe esophageal stricturing(1), haemoperitoniun(1) and splenic rupture(1)). Six cases (40%) were managed with surgery. Results from the learning curve progression according to consecutive chronologically blocked groups of 50 cases (33 last bloc) are summarized in table I. Initial success increased from 94% to 100%; speed of ESD decreased after the first 50 cases (15.5 cm²/min), up to 6.7 and 6.5 cm²/min in the last 2 blocs. A high perforation rate in the first period (32%) was reduced to 18–30.3% the following periods. Endoscopic treatment was successful in most cases of perforation (89.6%). Surgery was required for severe complications, incomplete ESD and/or perforation (n, %) (16 cases, 8.7%).

Conclusion: On clinical ESD, high rates of success and en-bloc and R0 resection can be achieved along the learning curve. Perforation is the most common complication and is still a challenge for Western countries. However, increasing experience reflects a high success in endoscopic management of perforation.

Introduction: Despite the advantages of endoscopic submucosal resection (ESD) demonstrated in large series from the far east, the procedure is not commonly practiced in the west and its role in standard practice is still debated. Although limited evidence of its efficacy in European practice is emerging, very few centres in the United Kingdom perform ESD regularly, if at all. We report the experience of a UK tertiary referral institution using ESD as part of a lesion specific, pragmatic approach to endoscopic resection in a complex patient cohort.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions were included. Lesions were assessed with magnification chromoendoscopy supplemented by colorectal ultrason in selected cases. A lesion specific approach was adopted to technique, with expert included assessment of morphology, pit pattern, risk of submucosal invasion, and presence of submucosal fibrosis or scarring. ESD was used where en bloc resection was deemed essential, or as part of a hybrid procedure to ensure resection of a dominant nodule or suspicious area of a lesion in one piece, or where fibrosis or scarring would make standard EMR impossible. A resection was designated a hybrid procedure if ESD was used to effect submucosal dissection, circumferential incision alone to assist snare resection was not included.

Results: 116 lesions (mean size 58.8 mm) were resected using ESD (n = 58) and hybrid ESD (n = 58). 82 (70.7%) had been subjected to prior attempts at resection (n = 58) or extensive sampling. Only 11 lesions had no prior biopsies performed. En bloc resection was achieved in 93.1% where ESD was used alone, with a mean technique rate of 4.7% after a mean follow up of 19 months. There were 6 microperforations treated with either endoscopic clips or antibiotics alone with no adverse sequelae, and one clinically significant perforation requiring surgery. However, the resected lesion in this case contained an invasive adenocarcinoma with deep submucosal invasion—there was no residual tumour in the surgical resection specimen. Post- procedure bleeding occurred in 6 patients, none of which were considered significant. 4 patients were successfully performed as day case procedures. 97% of patients without invasive cancer were free from recurrence and had avoided surgery at last follow-up.

Conclusion: Colorectal ESD can be used as part of a standard lesion specific approach at a western referral centre to deliver safe and effective organ conserving treatment to patients with large challenging lesions. Knowledge regarding lesion assessment and selection in western practice should be improved to reduce the incidence of prior heavy manipulation and guide appropriate referral.

P1514 RISK OF STENOSIS AND OUTCOMES FOLLOWING ENDOSCOPIC RESECTION OF LARGE COLORECTAL LESIONS INVOLVING MORE THAN 75% OF THE LUMINAL CIRCUMFERENCE
A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Introduction: Little is known about the risk of stenosis and outcomes following endoscopic resection of lesions in the colorectum which leave extensive mucosal defects. A limited number of studies suggest significant stenosis rates, although reports on outcomes and suggested management are conflicting. We determined the risk of stenosis and outcomes of endoscopic resection of colorectal lesions leaving mucosal defects ≥75% of the circumference.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. Resection technique included EMR, ESD and hybrid techniques involving ESD. Patients were grouped according to circumferential extent of the mucosal defect after resection. Surveillance colonoscopy was performed at 3 and 12 months. Clinicopathological characteristics and outcomes were compared between groups.

Results: 435 colorectal lesions ≥2 cm were resected using EMR (n = 342), ESD (n = 45) or hybrid techniques (n = 48). Circumferential extent of the resulting mucosal defect was ≥75% in 41 patients. 8 lesions were fully circumferential: 1 caecal lesion and the rest in the recto-sigmoid and rectum. 3 of these circumferential lesions contained deep invasive adenocarcinoma and 1 benign lesion ultimately required surgery. The 41 lesions with a mucosal defect ≥75% of the circumference had a mean size of 100.5 mm vs 49.0 mm for other lesions (p < 0.001). These patients had significantly more complications (16.7% vs 4.7%, p < 0.001), including a higher rate of perforation (8.3% vs 2.3%, p = 0.02), although none required surgery, and a significantly higher rate of recurrence (44.8% vs 9.2%, p < 0.001). 76% of patients without cancer were free from recurrence and had avoided surgery at last follow-up compared to 97% of patients with mucosal defects <75% (p < 0.001). Stenosis occurred in 7 patients: 4 lesions extensively involving the rectum and recto-sigmoid and 2 lesions involving the sigmoid colon extending to the rectosigmoid. 1 of these involved a mucosal defect of only 50% of the circumference and 3 were fully circumferential. 1 patient had a symptomatic anorectal stenosis requiring dilatation under anaesthesia, 1 patient was asymptomatic but underwent early dilatation after the first surveillance endoscopy at 3 months. The remaining patient was asymptomatic and managed expectantly. In all these latter cases spontaneous improvement in the stricture was noted at the subsequent surveillance endoscopy.

Conclusion: The majority of patients with these extensive complex lesions can successfully be treated with endoscopic resection and avoid surgery. However, these patients have a significantly greater risk of complications and recurrence and should be managed in a tertiary institution. Although there is a significant risk of stenosis, it appears that most cases are asymptomatic and spontaneously improve with expectant management.

Introduction: Although it is well recognised that the risk of invasive carcinoma in adenomatous neoplastic lesions differs according to morphology, the incidence of invasive cancer varies between studies and there is limited data from large western series to inform practice. The importance of appropriate resection techniques, including the use of ESD, is increasingly recognised in western practice. It is therefore imperative that the risk of submucosal invasion is assessed as accurately as possible to prevent inappropriate attempts at resection. We determined the risk of submucosal invasion and high-grade dysplasia (HGD) in different morphological sub-types of large colorectal lesions subjected to endoscopic resection.

Aims & Methods: Colorectal lesions ≥2 cm subjected to endoscopic resection were included. Lesions were assessed with magnification chromoendoscopy. Clinicopathological data recorded included morphological type according to Paris classification, sub-types of laterally spreading tumours (LST), degree of dysplasia, presence of submucosal invasion and outcomes following resection.

Results: 435 colorectal lesions ≥2 cm were resected. Mean lesion size was 55.2 mm (range 20 mm–160 mm). The frequency of and the incidence of high-grade dysplasia and invasive adenocarcinoma in the different morphological sub-types are shown in Table 1. The incidence of high-grade dysplasia (8.6%) and invasive adenocarcinoma (1.2%) was very low in LST granular homogenous lesions. LST NH (n = 374) was significantly associated with a higher incidence of invasive adenocarcinoma (4.0%) compared with LST NG (n = 283) (0.7%) (p < 0.001).

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: In our study, a withdrawal time exceeding seven minutes was significantly associated with the number of polyps detected in colonoscopy. Further studies may be helpful to confirm these results ideally by comparing these parameters in the same patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1518 THE EFFECTIVENESS OF NEW TECHNIQUE WITH SELF-EXPANDABLE METALLIC STENT INSERTION IN TREATING RIGHT-SIDED COLORECTAL OBSTRUCTION

C.B. Ryu¹, M.S. Lee¹, J.Y. Bae²

¹Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon/Korea, Republic of
²Department Of Internal Medicine, Seoul Medical Center, Seoul/Korea, Republic of

Contact E-mail Address: ryuchb@gmail.com

Introduction: Self-expandable metallic stent (SEMS) is widely used to treat malignant obstruction. Although the procedure is particularly complex, most of whom have already had extensive prior manipulation or attempts at resection. Familiarity with a range of selection techniques and appropriate equipment is essential to successfully treat recurrent lesions in this group with endoscopic resection, which can be achieved in the majority of patients without significant complication.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: A total of 1059 patients were screened for enrollment; 749 total colorectal stenoses were studied: 383 men (51.1%) and 366 women (48.9%). Colonic preparation was good (Boston score > 6) in 49.4% of patients. Colorectal stenosis was normal in 434 cases (57.9%). Colonic polyps were detected in 197 patients (26.3%). The mean number of polyps detected per colon was (Mean 9 ± 2.31 (min. 1, max. 25). The mean polyp diameter was 6.8 millimeters (1 to 50 mm). The mean withdrawal time was 8.2 minutes (4 to 20 minutes). Overall PDR was 26%. G1 included 599 colonoscopies and G2 included 150 colonoscopies. PDR in G1 was 28.04% versus 20% in G2, the difference between the two groups was not significant (p = 0.7). As for the MNP, it was significantly higher in G1: 2.29 versus 1.86 in G2 (p: 0.049).

Conclusion: Our study, a withdrawal time exceeding seven minutes was significantly associated with the number of polyps detected in colonoscopy. Further studies may be helpful to confirm these results ideally by comparing these parameters in the same patients.
compilation (0.10). Concerning SEMS insertion, the technical difficulty and safety of SEMS insertion were similar between right- and left-sided colonic obstructions.

Conclusion: A new technique of curved type guiding tube with SEMS insertion for right-sided colon, especially distal ascending colon is significantly more effective than straight type guiding tube, and this procedure was safer and less technically challenging than expected. SEMS insertion should be considered for treating right-sided malignant colonic obstruction.

Disclosure of Interest: All authors have declared no conflicts of interest.

2The Royal Infirmary of Edinburgh, Edinburgh/United Kingdom
Contact E-mail Address: lior.katz5346@gmail.com

Introduction: Lynch syndrome (LS) is an autosomal-dominant disease, with increased risk of colorectal cancer (CRC), hence annual surveillance colonoscopy is recommended. do not recommend one over the other.

Aims & Methods: We aimed to compare the diagnostic yield (DY) of different endoscopic modalities for detection of colorectal neoplasia in patients with LS by performing a meta-analysis of existing literature. We searched Pubmed for prospective studies. For each modality, we performed comparative total per-adenoma analysis and sub-analyses for flat lesions and location (right/left colon).

Meta-analysis was performed using pooled rate ratios (RR) with fixed effects model for low heterogeneous data. The subgroup

Results: Five studies compared white light endoscopy (WLE) to chroendoendoscopy. In four studies compared WLE to chroendoscopy directly (one study used a "back-to-back" design but lesions were resected only after chroendoscopy and the other study compared two different sets of patients). Chroendoscopy (n = 75) identified more adenomas in the right colon than WLE (n = 73 patients) RR 3.27 (95%CI 1.83–5.87). Overall detection of adenomas or flat lesions was not statistically different between the two methods.

Conclusion: Chromoendoscopy is superior to WLE for detection of adenomas in Lynch syndrome, especially flat lesions and adenomas in the right colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1522 QUALITY IN BOWEL CLEANSING, PERFORMANCE MEASURES AND PATIENT SATISFACTION USING DIFFERENT PURGATIVES IN SCREENING COLONOSCOPY

1Department Of Internal Medicine III, Division Of Gastroenterology & Hepatology, Medical University of Vienna, Vienna/Austria
2Quality Assurance Working Group, Austrian Society of Gastroenterology and Hepatology (OEGGH), Vienna/Austria
3Section For Clinical Biometry, Center for Medical Statistics, Informatics And Intelligent Systems, Medical University of Vienna, Vienna/Austria

Contact E-mail Address: elisabeth.waldmann@meduniwien.ac.at

Introduction: Quality of bowel preparation and adenoma detection rate (ADR) are routinely assessed in screening colonoscopy. However, data on patient experience are scarce.

Aims & Methods: This prospective non-interventional study compared bowel preparation quality according to the Harefield Scale, performance quality measures and patients satisfaction in screening colonoscopies performed within an Austrian quality assurance program.

Results: Colonoscopies performed by 20 endoscopists were included in this study. 50.3% of screened individuals were women. Because of the unequal patient count using CitroFleet® (CF, n = 261), Picroprep® (PP, n = 2678), Klean-Prep® (KP, n = 804) and Moviprep® (MP, n = 1252), PC and CF were grouped into one (LV) group. Age and gender adjusted success rates and ADR per purgative were 97.0% and 23.3% for LV, 97.5% and 22.7% for KP and 93.5% and 26.0% for MP. Women had higher success rates than men (p = 0.075) and success rate decreased with patients' age (p = 0.008). The compliance regarding consumption of the entire volume was best with LV (89.2%, KP 87.6%, MP 87.3%), which had a significant effect on success rates and ADR per purgative (p < 0.0001) while there was no statistical significance among the average values from participants with good bowel preparation quality (47.40% (SD = 0.80%) in hospitals vs. 49.35% (SD = 0.67%) in private practices). Adequate rate in screening colonoscopy was 96.22% (SD = 0.591), unsatisfactory (p = 0.080) and villous component (p = 0.011) of lesion type. Likert scale achievement was 3.06 vs. 3.68% (SD 1.15, p = 0.011) and G-type morphology (p = 0.001) was more frequent. Careful colonoscopic surveillance after EMR and the use of new methods to further reduce residual neoplasia are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1524 DIFFERENCES IN QUALITY OF BOWEL PREPARATION AT SCREENING COLONOSCOPIES IN PRIVATE PRACTICES AND HOSPITALS

Department Of Internal Medicine III, Division Of Gastroenterology & Hepatology, Medical University of Vienna, Vienna/Austria

Contact E-mail Address: barbara.majcher@meduniwien.ac.at

Introduction: Bowel preparation influences the adenoma detection rate and is therefore an important quality parameter in screening colonoscopy. According to actual ESGE guidelines “Performance measures for lower gastrointestinal endoscopy: a European Society of Gastrointestinal Endoscopy (ESGE) Quality Improvement Initiative”, 90% of colonoscopies should have adequate bowel preparation. The aim of this study was to investigate whether there is a difference in quality between private practices and hospitals.

Aims & Methods: Data from screening colonoscopies performed within quality certificate in Austria (2012 - 2017) provided by 245 endoscopists were evaluated. The recording of the quality of the bowel preparation was described as one of the following categories: excellent, good, fair, poor, poor only in the right colon and unsatisfactory.

Results: From the 125,127 screening colonoscopies included in this study, 72.93% were performed in private practices (50.66% female, mean age 60.7) and 27.07% in hospitals (49.35% female, mean age 60.35). Significant difference was found between the average values of screening colonoscopies with excellent bowel preparation (38.00% (SD = 0.36) in private practices vs. 27.92% (SD = 0.21) in hospitals, p = 0.002) and there was no statistical significance between private practices and hospitals (27.89% (SD = 0.28) vs. 27.92% (SD = 0.27)) and poor only in the right colon (0.69 (SD = 1.74) vs. 0.80% (SD = 1.15, p = 0.7721). The mean ADR did not show any statistical difference between private practices and hospitals (23.98% (SD = 10.89%) vs. 25.80% (SD = 12.80%), p = 0.7652).

Conclusion: More excellent bowel preparation was found in private practices while the screening colonoscopies in hospitals showed a higher rate of fair and unsatisfactory bowel preparation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1525 RISK FACTORS FOR RESIDUAL NEOPLASIA AFTER ENDOSCOPIC MUCOSAL RESECTION OF LATERALLY SPREADING TUMORS

N. Brogyák1, T. Gregál2, M. Voska1, O. Nго3, O. Majek1, M. Zavoral1, S. Suchanek1,2

2Institute Of Biostatistics And Analyses, Masaryk University, Faculty of Medicine, Brno/Czech Republic

Contact E-mail Address: nadya.brogyak@uvn.cz

Introduction: Laterally spreading tumors (LSTs) are important precursors of colorectal carcinoma. They are usually removed by endoscopic mucosal resection (EMR). However, local residual neoplasia (LRN) may occur during follow-up. The aim of the study was to evaluate the occurrence of LRN and the risk factors for its emergence.

Aims & Methods: This retrospective study in a high-volume tertiary-referral center examined patients who had undergone EMR between 2013 and 2015 and who had had at least 1 surveillance colonoscopy after the initial treatment. LRN was defined histologically as the presence of neoplastic tissue in the post-EMR site.

Results: 160 laterally spreading tumors were diagnosed in 138 patients (62% men, mean age 67 years). Mean follow-up interval for surveillance colonoscopy was 6 months. Residual neoplasia at surveillance endoscopy was present following 21% of EMRs. Single variate analysis showed occurrence of an increased risk of residual neoplasia for LST ≥ 20 mm (p = 0.006), villous adenomas (p = 0.001), piecemeal resection (p = 0.011) and G-type morphology (p = 0.003). In multivariate analysis, only size of the lesion (p = 0.080) and villous component (p = 0.043) were found to be a significant risk factor for LRN.

Conclusion: This retrospective study shows that the occurrence of LRN is frequent. Careful colonic surveillance after EMR and the use of new methods to further reduce residual neoplasia are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1525 ENDOSCOPIC SURVEILLANCE AFTER SURGERY ON FAMILIAL ADENOMATOUS POLYPOSIS PATIENTS: IT IS EFFECTIVE BUT INTERVALS CAN BE WIDENED

J. Pinho1, J. Lage2, M. Dinis-Ribeiro1, C. Brandão2
1Gastroenterology, Tondela • Viseu Hospital Center, Viseu/Portugal
2Gastroenterology, Instituto Português de Oncologia do Porto, Porto/Portugal

Contact E-mail Address: julianapinho18@gmail.com

Introduction: Familial adenomatous polyposis (FAP) is an autosomal dominant inherited condition characterized with a lifetime risk for colorectal cancer close to 100%. Thus prophylactic colectomy is recommended for patients with FAP. Colectomy with ileorectal anastomosis (IRA) is the surgical option of choice in the majority of patients, given the complications and morbidity associated with ileal pouch-anal anastomosis. Therefore, annual endoscopic surveillance is recommended after surgery to prevent cancer in the rectal remnant (CRR).

Aims & Methods: The aim of this study was to determine the impact of endoscopic surveillance on CRR prevention in FAP patients after surgery. We did a retrospective single center study on findings of follow up endoscopies and determination of the cumulative risk of adenomas and prevalence of high risk adenomas (HRA) (villous histology, high-grade dysplasia and ≥ 10 mm) and CRR.

Results: 30 patients submitted to IRA were included (50% women), with a mean age of 43 years, 2 patients with attenuated phenotype. Nine patients had adenocarcinoma in the resected colon. Six patients started chemoprophylaxis after surgery (sulindac-4; celecoxib -1). The median time to adenoma appearance was 5 years (95% CI 3.4-6.6) and to HRA/CRR 12 years (95% CI 5.2-18.8), with a decreased median time to both adenomas and HRA/CRR in patients under chemoprophylaxis. The cumulative risk of adenomas was 20% at 1 year after surgery, 34.1% at 3 years and 57.4% at 5 years. During the follow up performed in 17 patients (56.7%), 12% of HRA–12 patients (40%); intramuscular carcinoma-2 patients (6.7%); invasive adenocarcinoma–3 patients (10%). None of the patients died with CRR. The cumulative risk of HRA/CRR was 21.8% at 5 years, 46.1% at 10 years and 66.3% at 15 years. All the patients with HRA/CRR had rectal involvement prior to surgery (p=0.008) and a higher number of adenomas resect in the rectal remnant (p=0.017).

Conclusion: The FAP endoscopic surveillance program allowed detection of HRA/CRR in a high percentage of patients. Based on these results, an intensive surveillance program should be suggested but endoscopic surveillance intervals widen in the first 5 years after surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1527 BOWEL PREPARATION FOR FLEXIBLE SIGMOIDOSCOPY: COMPARISON OF POLYETHYLENE GLYCOL ELECTROLYTE SOLUTION (PEG-ES) AND PHOSPHATE ENEMA IN 4,949 PATIENTS AT TWO UK HOSPITALS

A. Yusuf, S. Paranahewa, A. Jeevagan, P. Mayhead
Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom

Contact E-mail Address: abdyus12@nhs.net

Introduction: Flexible sigmoidoscopy is increasingly used to optimise the diagnostic yield of the test, and also to minimise the number of repeat procedures. However, the optimum bowel preparation for this procedure has consistently been debated.1,2,3

Aims & Methods: Both phosphate enema and (PEG-ES) are commonly used for bowel preparation in flexible sigmoidoscopy at both hospitals participating in this study. We therefore wanted to compare the outcomes for these two methods. We retrospectively reviewed all the patients who underwent flexible sigmoidoscopy from January 2014 to December 2016 using each hospital’s electronic endoscopy reporting system. We analysed their demographics, type of bowel preparation used in each case, and the quality of their individually achieved bowel preparation by the endoscopist performing the procedure. A chi-squared test was used to calculate p-value.

Results: In total 6196 patients underwent flexible sigmoidoscopy during the study period (males 2885 (46.5%); mean age 62.80 years, range 16–101 years). 1247 (20.13%) patients were excluded from further analysis for the following reasons: Na+ ≥ 150 mmol/L (n=451), no documentation of the quality of bowel preparation (n=657), and non-PEG(ES) oral preparation used (n=139). A total of 4949 patients were included in the study, of whom 2103 had PEG(ES) (42.49%) (males 986 (66.49%), mean age 60.97 years, range 18–95 years) and 584 (57.50%) (males 1269 (64.59%), mean age 63.98 years, range 17–101 years) had phosphate enema. The results are summarised in the table below.

<table>
<thead>
<tr>
<th>Type of bowel preparation</th>
<th>Excellent</th>
<th>Adequate</th>
<th>Inadequate</th>
</tr>
</thead>
<tbody>
<tr>
<td>PEG(ES) (n=2103)</td>
<td>1126 (53.54%)</td>
<td>770 (36.61%)</td>
<td>196 (8.84%)</td>
</tr>
<tr>
<td>Phosphate enema (n=2846)</td>
<td>624 (21.93%)</td>
<td>1297 (45.57%)</td>
<td>925 (32.50%)</td>
</tr>
</tbody>
</table>

Conclusion: Our large retrospective study showed that oral preparation with PEG-ES gave significantly better results than phosphate enema, which gave acceptable results in only 67.5% of the patients. As a result of this study, PEG-ES is now preferred by our hospital, if there is no contraindication for this.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic resection of large colonic lesions (LCLs, >20 mm) is effective and it is associated with an acceptable incidence of incomplete resection and complications when performed by appropriately trained endoscopists in resource centers. However, scanty data on the management of these lesions outside referral centers are reported in the literature.

Aims & Methods: Aim of present study is to evaluate the management of endoscopic resection of LCLs and intra-procedural complications in a real-life setting. In a prospective, multicenter, observational study in 20 centers, data from consecutive endoscopic resections of LCLs performed over a 6-month period were collected by a web-database. All patients undergoing LCLs resection were enrolled at procedure-time and followed-up at 15 days for adverse events and at 6 months for endoscopic/histological recurrence.

Results: 4152 LCLs (mean size 30.6 mm, SD 12.4; 41.4% lateral spreading tumor, 28.1% sessile, and 30.5% pedunculated) removed in 1329 patients (58% males, mean age 66±11.4 years) were analysed. An endoscopic mucosal resection (EMR) was performed in 57.9%, snare polypectomy in 37.4%; underwire EMR in 1.2% and endoscopic submucosal dissection in 6.2% of the lesions. Patients with LCLs, 19.4% were on ATT (62.5% aspirin, 12.2% thienopyridines). Aspirin and/or thienopyridines were withheld before resection in 53.6% and 91.7% of patients, respectively. Overall, intra-procedural bleeding requiring endoscopic therapy occurred in 8.1% of patients; 28% of them were on ATT, which had always been withheld, but in 48% of patients on aspirin. At multivariate analysis, intra-procedural bleeding was correlated with increasing polyp size (Odds Ratio 1.02 95% Confidence Interval 1.01–1.04), and inversely with execution of pre- and post-resection prophylaxis maneuvers (Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 and Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 respectively). As concerns
complications, delayed bleeding occurred in 4.5% of the subjects, whereas per-
formation occurred in 1.5% (0.9% early and 0.6% delayed) of patients, 86.7% of whom were successfully managed endoscopically. At the moment, 6-months follow-up is available for 35% of the patients, with a positive endoscopic and/or histological recurrence documented in 22.8%.

Conclusion: The management of resection of LCLs varies widely. The incidence of intra-procedural bleeding correlates with polyp size and prophylactic maneuvers, and its endoscopic management is successful in most of cases. Overall, complication rate is marginal and efficacy is good, even in a real-life setting.

Introduction: The incidence and mortality of colorectal cancer (CRC) can be decreased trough the removal of precancerous adenomas. Endoscopic removal of polyps over 2 cm is considered a high-risk procedure both for complications and malignant transformation.

Aims & Methods: The aim of this study was to evaluate the outcome and complication rate after endoscopic removal of polyps over 2 cm. In this retrospective study clinical and demographic data of patients undergoing polypectomy due to colorectal adenomas between 2012 and 2017 were collected. Data of endoscopic procedures, complications of polypectomy and histological assessments of the removed polyp were obtained.

Results: Data of 100 patients (male/female: 58/42) was analyzed in the study. Forty-seven of the 106 removed polyps proved to be pedunculated, 21 were sessile and 34 flat. Six patients had more than one large polyp (>2 cm). The locations of the removed polyps were rectum in 33, sigmoid colon in 38, coecum in 12 and other parts of the colon in 23 patients. In 65 cases, polyps were excised with endoscopic mucosa resection (EMR) or hybrid endoscopic submucosa dissection (ESD). In 41 cases snare was used to remove the polyps in one or more pieces. Based on histological findings 54 (50.9%) polyps were shown to be low-grade adenomas, 34 (32.07%) high-grade adenomas, 1 (0.9%) polyp was hyperplastic, and 17 (16.03%) proved to be malignant among which complete endoscopic resection was achieved in 9 patients (52.9%). Additional smaller polyps were found in 39 patients and a synchronous cancer in 7. During polypectomies 91 hemoclips were deployed to close suspected perforation (8 cases) to cease bleeding (19) or for prevention. Postpolypectomy syndrome developed in 8 cases. Second-look colonoscopy was required in 8 cases due to bleeding within a mean of 4 days after the first examination. Hemiclip insertion was needed in 5 cases and epinephrine injection in 1 case. The bleeding stopped spontaneously in 2 patients. Surgical intervention was not needed in any case.

Conclusion: Malignant transformation was revealed in 16% of the polyps over the size of 2 cm. Complete endoscopic removal of these polyps was successfully performed in half of the patients. Endoscopic removal of high-risk polyps is safe in experienced hand.

P1530 WHAT IMPROVED AND WHAT REMAINS TO BE ACHIEVED IN ORDER TO COMPLY WITH THE NEW RECOMMENDATIONS OF POLYPECTOMY BY THE EUROPEAN SOCIETY OF GASTROINTESTINAL ENDOSCOPY
1Gastroenterology, CHVNG/E, Vila Nova De Gaia/Portugal
2Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jaimepereirarodrigues@gmail.com

Introduction: The choice of polyepctomy technique differs according to regional preferences and availability. This year, in order to standardize the approach to this techniques, the European Society of Gastrointestinal Endoscopy (ESGE) published recommendations for colorectal polyepctomy and endoscopic mucosal resection (EMR).

Aims & Methods: We aimed to evaluate the recent years evolution of the adherence to the recommendations of colorectal polyepctomy and EMR at a tertiary center. We conducted a unicentric analysis of polyepctomy and mucosectomy techniques performed consecutively between January and June of 2011 and 2016 at a tertiary center. According to the recommendations, the excision of sessile and flat polyps is considered adequate when performed with cold biopsy forceps or cold snare for polyps ≤3 mm, cold snare if 4-9 mm, or hot snare if 10-19 mm and EMR if ≥20 mm. Polyepctomy of pedunculated polyps is considered adequate when performed with a diathermic loop in polyps ≤20 mm, always in association with any prophylactic therapy when polyp size ≥20 mm.

Results: We included 1721 endoscopic procedures of polyepctomy and EMR, comprising 696 patients (64.5% male, mean age = 64.2±11.0 years). 1381 (80.2%) sessile polyps, 153 (8.9%) flat lesions and 187 (20.9%) pedunculated polyps were identified, with a mean size of 7.9±7.0 mm. Regarding sessile and flat polyps, one of the recommended excision techniques was performed in: 84.6% (n=270) of ≤3 mm polyps (75.7% in 2011 vs. 95.8% in 2016; p < 0.001); 22.2% (n=109) of 4-5 mm polyps (12.5% vs. 36.5%; p < 0.001); 13.4% (n=59) of 6-9 mm polyps (5.4% vs. 23.8%; p < 0.001); 100% (n=206) of 10-19 mm polyps; and 100% (n=88) of ≥20 mm lesions. For pedunculated polyps, the recommended excision techniques was adequate in: 99.3% (n=134) of polyps of size <20 mm (100% vs. 97.6%; p > 0.05) and in 84.6% (n=44) of those ≥20 mm (82.6% vs. 86.2%; p > 0.05). Overall, 52.3% (n=900) of endoscopic procedures of polyepctomy or EMR were performed as recommended; 42.7% (n=410) in 2011 vs. 64.5% (n=490) in 2016; p < 0.001.

Conclusion: Even before publication of the european recommendations, there has already been an increase in the proportion of polyepctomies performed ade-
quately in the different groups of lesions. There is still a need to adjust clinical practice in some subgroups, especially in polyps of size 4-9 mm, in order to strictly comply with the recommendations.

P1532 SELF-EXPANDABLE METALLIC STENT IN THE TREATMENT OF OCCLUSIVE COLORECTAL CANCER AS PALLIATIVE TREATMENT
T. Gago, A. Antunes, A.M. Vaz, P. Queirós, J. Roseira, A. C. Cunha, A. Ramos, H. Guerreiro
Servio De Gastroenterologio De Faro, Centro Hospitalar do Algarve, Faro, Portugal
Contact E-mail Address: taniagago@gmail.com

Introduction: Colorectal cancer (CRC) is one of the most common malignancies in the western world, associated with associated occlusive disease being relatively common. Endoscopic placement of self-expandable metallic stent (SEMS) is the first-line palliative treatment for malignant bowel obstruction.

Aims & Methods: Evaluate the outcome of endoscopic SEMS placement in CRC obstruction. Retrospective analysis of patients CRC submitted to endoscopic placement of SEMS from 2009 to 2016 in the Gastroenterology Department of Centro Hospitalar do Algarve. Statistical analysis was performed with SPSS version 23.

Results: The study included 23 patients with CRC obstruction, who were submitted to endoscopic SEMS placement, with a mean age of 75.2 ± 13.47 years. All the stents were placed with a palliative purpose in 69.6% of cases (n = 16) and a transitory procedure before surgery in 30.4% of cases (n = 7). Technical and clinical success was found in 91.3% of the patients, without any recorded death during the procedure. In patients whose goal was palliative treatment (75% men and 25% women) they had a mean age of 81.6 ± 9.28 years. In 43.8% of the patients the tumor was located in the rectum, 31.6% in the sigmoid region and 25% in the recto-sigmoid transition. Being the majority (75%) well differentiated. There was a need for dilatation in 31.3%, most of the stents were uncovered (56.3%), 25% of the patients had complications. After stent placement, about 25% of the patients did chemotherapy. There was a 75% mortality rate (37.5% died by 6 months and 37.5% died by 12 months of follow-up). The use of chemotherapy after SEMS placement influenced the complications associated with the procedure (p < 0.05) but none of the other variables had a statistically significant influence on early death (up to 6 months).

Conclusion: SMES is an effective and safe palliative option for unresectable tumors, although the use of chemotherapy after placement of prostheses may have an influence on the appearance of complications. Malignant colon occlusive of the colon can be treated effectively with the use of endoscopic techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: European colorectal screening guidelines have modified the follow-up interval times based on baseline colonoscopy findings in recent years. In addition, the waiting list and individual conditions may modify the real follow-up times and this could impact in advanced adenoma detection rate in follow-up and patients outcome.

Aims & Methods: The aim of the present study was to comparatively analyse the risk of advanced lesions (advanced adenoma, invasive cancer) in high-risk patients included in a colorectal cancer screening program with different real follow-up times. One-thousand one-hundred and sixty-six patients (mean age: 60.66 ± 8.69 years, 69.1% men) who underwent a baseline colonoscopy with ≥3 adenomas and/or ≥10 mm between 2007-2012 were included. A Kaplan-Meier regression and a comparative subgroup analysis by Long-Rank test were carried out to determine the difference in the outcomes between patients of the same risk.

Results: The real follow-up times in ≥3 adenomas (n = 853, 73.16%) and ≥ lade- nomas ≥10 mm (n = 779, 66.81%) were 38.54 ± 11.57 and 38.66 ± 11.68 months. The risk of advanced lesions were 0.26%, 1.46%, 2.83%, 9.09% and 10.38% (p = 0.001) but none of the other variables had a statistically significant influence on early death (up to 6 months).

Conclusion: The risk of advanced lesions in high-risk patients increased significantly at 36-60 months after baseline colonoscopy, being more important in ≥3 adenomas subgroup. There were no differences for 1-3 years interval.

Introduction: Large colorectal lesions (>20 mm) can be removed endoscopically by endoscopic mucosal resection (EMR), often in a piecemeal fashion resulting in low en bloc and radical (R)-resection rates. In this context, submucosal dissection (ESD) allows en bloc resection whatever the size, but still remains technically difficult and time consuming. A hybrid endoscopic technique has been developed, called simplified or hybrid dissection. The aim of our study was to evaluate the impact of complications derived from hybrid technique compared to classical endoscopic submuscular dissection.

Aims & Methods: Our study was carried out from January 2013 to June 2016 in our gastroenterology department. The 40 lesions removed by hybrid technique were compared with lesions removed by endoscopic submucosal dissection (ESD). Hybrid dissection was performed as follow: submucosal injection around the lesion of macromolecules, circumferential mucosal incision and submucosal dissection using the tip of a single-strand snare by endo-cut Q mode, central submucosal injection of the lesion and final resection with the single-strand snare, if possible in en-bloc.

Patient characteristics, tumor location and size, dissection characteristics, "block" resection rate, R0 resection rate (healthy margins), procedure and hospitalization time, and complications were identified and compared with the so-called "classical" ESD technique.

Results: Lesions were more frequently located in the colon (vs rectum) in the hybrid dissection group compared to the ESD group (72.5% versus 28.6%, respectively). The size of lesions were type Hc according to Paris classification in 10% of the hybrid dissection group and 13.1% in the ESD group (p=0.8). The mean size of the lesion was lower in the hybrid dissection group than in the ESD group (32.4 mm±13 mm compared to 54.4 mm±26.7 mm, p<0.001). An en bloc resection was performed in 52.5% and 84.4% in the hybrid dissection and ESD group, respectively (p<0.001). The procedure time (including general anesthesia time) was lower in the hybrid dissection group compared to the ESD group (105 min±62 min vs 191 min±73 min, p<0.001, respectively).

In the hybrid dissection group, the rate of perforation was lower than in the ESD group (4% versus 15%, p<0.001). R0 resection rates were lower in the hybrid dissection group than in the ESD group (47.5% and 61% respectively, p<0.001). Hybrid dissection was performed for adenocarcinoma, adenoma with high grade dysplasia and in 12.5% of cases for adenoma with low grade dysplasia in 12.5%, 42.5% and 40%, respectively. The rate of adenocarcinoma was lower compared to the ESD group (12.5% versus 30.8%, p=0.009). In the hybrid dissection group, the rate of perforation was lower than the ESD group (4% versus 15%, p<0.001).

In case of complication, there was no need of surgical treatment in the hybrid dissection group, but was needed in one patient in the ESD group.

Conclusion: Hybrid dissection is less effective in terms of en bloc resection of large colorectal tumors. Classical endoscopic submucosal resection should be preferred, especially in case of suspected adenocarcinoma despite longer procedure and hospitalisation time.

Introduction: Since its introduction in 1968, Endoscopic retrograde cholangio-

Aim: The aim of this study was to examine the trends in ERCP usage here in the Veneto Region (Northeastern Italian area) and, in particular, the complications and mortality rate associated to it.

Aims & Methods: Utilizing an anonymous database of hospital discharge records referring to the period between 2007 and 2015, a retrospective study was carried out to examine the complications associated to ERCP. All of the elective hospitalizations for gallstones in the bile duct during which the procedure was carried out within two days of being hospitalized were examined. Hospitalizations for neoplasms were not considered. The study considered the onset of complications or death as outcome indicators as well as the patients’ post-procedure status; the threshold value that was utilized was 2 days and the patients who later underwent surgery (e.g. cholecystectomy) were excluded from our analysis; the associations between the type of hospital where the patients were being assisted both with regard to the type of organization (Hub or Spoke model) and the type of management (public/private) were also evaluated.

Results: A total of 3,136 admissions out of total of 14,626 hospital days (SD:4.6±5.8 days) were identified in a total of 40 hospitals, 6 (15%) of which presented between sex ratios were considered; the average age, which was equal to 68±3±14.2 (range 6–98 yrs), was higher in the females (69.±14.9 vs. 67.5±13.5); significant deviations during the period examined were not noted. A total of 212 complications (6.8%) were registered: these included acute pancreatitis (4.5%), cholangitis (1.3%), sepsis (0.4%), acute cholecystitis (0.3%), cardiopulmonary complications (0.2%), perforations and hemorrhage (0.2%). The complications that presented, which were significantly higher in the female sex (7.3% vs. 6.2%; p<0.05), besides a greater average hospital stay in those suffering from complications (10.±13 vs. 4.2±13 days, respectively), the worst hospital stay was connected to those patients post-procedure status; the total complications were carried out and no differences linked to their characteristics. The stratification of complications according to the type of hospital (range 2-17%) did not identify any significant differences. Mortality rate associated to the procedure used to diagnose and to treat conditions associated to the pancreaticobiliary system. It is nevertheless associated to the highest risk of complications of all routine endoscopic procedures. It is important to have a thorough understanding of the potential complications and the adverse events that may be associated to ERCP procedures so that these may be managed appropriately should they occur. The aim of this study was to examine the trends in ERCP usage here in the Veneto Region (Northeastern Italian area) and, in particular, the complications and mortality rate associated to it.

Aims & Methods: The aim of our study was to evaluate the effect of these factors on the frequency of PE. We retrospectively analyzed all ERCP performed over a 12 months period [January 2015 - December 2015] and carried out at the gastroenterology unit of our hospital. All patients were evaluated prospectively for the frequency of PE based on the consensus criteria. The patients with obesity (Body mass index BMI ≥ 30 kg/m²), dyslipidemia (triglyceride >2 g/L or LDL-cholesterol >1.6 g/L) and DM (history of DM or fasting glucose level

Contact E-mail Address: hajer.hassine@gmail.com

Introduction: Hepatic hydatid disease (HHD) is a major endemic health problem in certain areas of the world such as Tunisia. Intrahepatic rupture of a hepatic hydatid cyst is a common complication ranging between 3 and 17%. Furthermore, biliary leakage is the most frequent postoperative complication following surgery for hydatid cysts of liver. Both conditions require per endoscopic biliary drainage.

Aims & Methods: The aim of this study was to assess the results of ERCP in patients with HHD. We retrospectively analyzed the results and complications of all ERCP performed for HHD whether before or after surgical treatment over a 10 years period (January 2007 - December 2016) and carried out at the gastroenterology unit of our hospital.

Results: Sixty seven procedures were included (mean age 40.4 years [15–82] and sex ratio male/female 31/36). Of the 67 procedures, 58 (86.5%) were performed in patients with HHD who had undergone previous surgery. The indications of the ERCP were persistent external biliary fistula in 77.6%, obstruction or cholangitis due to residual materials within bile duct in 20.7% and secondary biliary strictures in 1.7%. In patients who had not undergone previous surgery (13.4%), the indications of the ERCP were cholangitis due to intra-biliary rupture of hydatid cyst in 44.4% associated with acute pancreatitis in 55.6%. In the 58 patients who had undergone previous surgery, ES was then performed in all cases defects of varying size and shapes (52.5%), leakage of contrast medium into the cyst in 44.4% associated with acute pancreatitis in 55.6%. The cannulation of the papilla was impossible in 6 cases (8.9%) and the endoscopic sphincterotomy (ES) could not performed. When papilla cannulation was obtained, per endoscopic cholangiographic findings were: dilation of the biliary tract (21.3%) with filling defects of varying size and shapes (52.3%), leakage of contrast medium into the cyst cavity (41%) and lateral stenoses (5.3%). ES was then performed in all cases with satisfactory results. Thus, hydatid membranes (36%) or daughter cysts (1.6%) encountered in bile ducts have been emptied out in 93.4% by biliary occlusion balloon and/or Dormia basket. Nevertheless, two patients required biliary stenting due to the bile duct injuries and two others required nasobiliary drainage. One patient presented post ERCP pancreatitis (1.5%).

Conclusion: ERCP is a safe and effective way to manage biliary complications of HHD. In most patients, ES is the most efficient treatment of postoperative biliary external biliary fistulas, jaundice and accompanying cholangitis. In some cases, biliary stenting or nasobiliary drainage may be required.

Introduction: EUS-guided biliary or pancreatic rendezvous is a technically demanding procedure, and the intraductal manipulation of the guidewire remains the most challenging step. Passing the guidewire through the needle may cause its fragmentation on the sharp metallic bevel. We have described the method of using a microcatheter for EUS-guided rendezvous, which allows easier handling and exchange of the guidewire, while avoiding both the risk of fragmentation and the need of injection of contrast to achieve a complete ductogram.

Aims & Methods: We aimed to evaluate the early experience of the microcatheter method in EUS-guided rendezvous procedures in the biliary and pancreatic tracts. During EUS-guided biliary or pancreatic rendezvous, initial puncture of the duct of interest was attempted with a 19G needle without stilet
previously flushed with contrast. A 0.025” guidewire was then inserted through the needle into the duct and advanced antegrade to the papilla. If further manipulation was necessary to enter the duodenum, movements were performed with caution in order to avoid fragmentation of the guidewire. Whenever the passage through the papilla was not achieved or the guidewire movements were hampered by the needle bevel, we performed a microcatheter technique. After removing the needle, leaving the guidewire in situ, a 3F, 150 cm long microcatheter was inserted over the guidewire into the duct. Then, manipulation of the guidewire, guidewire exchange and contrast injection were performed according to the discretion of the endoscopist. We reviewed the cases of EUS-guided pancreatic or biliary rendezvous performed in our unit using microcatheters from September 2015 to March 2017. Technical success was considered when the rendezvous could be completed.

Results: Nine patients presented with previous unsuccessful manipulation of the guidewire with the needle during EUS-guided biliary or pancreatic rendezvous underwent a microcatheter-guided attempt on the same procedure. Pancreatic rendezvous was attempted in 3 cases (2 chronic pancreatitis, 2 pancreas divisum and 1 pancreatic cancer) and biliary rendezvous in the other 4 (3 biliary stenosis and 1 ampulloma). Technical success was achieved in 7 patients (78%) with the microcatheter technique. Technical failure occurred in 1 patient with biliary stenosis in whom a EUS-guided hepaticojejunostomy was performed in the same procedure and in 1 patient with chronic pancreatitis with symptomatic pancreatic duct stenosis. There were no adverse events after the procedure, irrespective of technical success.

Conclusion: In our series, using a microcatheter for the indwelling manipulation of the guidewire increases the EUS-guided rendezvous technical success without increasing the complication rate, irrespective of technical success.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Biliary tract complications (BTC) are the leading problem in patients after orthotopic liver transplantation (LT). The present study analysed the results and predictors of treatment outcomes in patients with biliary stenoses undergoing endoscopic retrograde cholangiopancreatography (ERCP) and/or percutaneous transhepatic cholangiography (PTCD) at the University Medical Center Hamburg-Eppendorf.

Aims & Methods: All adult patients who received ERCP or PTCD for BTC after LT between 2009 and 2015 were retrospectively analysed. Remission of BTC was defined as no need of intervention for at least 12 months. To identify predictors of endoscopic treatment outcome in patients with biliary stenoses, a multivariate logistic regression analysis was performed after univariate variable selection. Laboratory parameters that were significant in the multivariate analysis, were dichotomised stepwise according to the most informative cut-off predicting outcome. Furthermore, endoscopic techniques were analysed in both the ERCP- and PTCD-subgroup.

Results: Of 144 patients with BTC after LT, 116 were diagnosed with biliary stenoses. Among these, 86 received ERCP, 17 PTCD and 13 both techniques. Long-term remission was achieved in 55 patients (47% overall; 53% in ERCP sub-group). Technical failure occurred in 1 patient with biliary stenosis in whom a EUS-guided hepaticojejunostomy was performed in the same procedure and in 1 patient with chronic pancreatitis with symptomatic pancreatic duct stenosis. Technical success was achieved in 7 patients (78%) with the microcatheter technique. Technical failure occurred in 1 patient with biliary stenosis in whom a EUS-guided hepaticojejunostomy was performed in the same procedure and in 1 patient with chronic pancreatitis with symptomatic pancreatic duct stenosis. There were no adverse events after the procedure, irrespective of technical success.

Conclusion: In our series, using a microcatheter for the indwelling manipulation of the guidewire increases the EUS-guided rendezvous technical success without increasing the complication rate, irrespective of technical success.

Introduction: Confocal endomicroscopy is an endoscopic imaging technique permitting the microscopic analysis of the digestive mucosa in real time (esophagus, stomach, duodenum, colon, biliary tract and pancreas) due to injection of fluorescein which is an intravenous contraste. The aim of this national observational study under the guidance of SFED is to evaluate the practice of confocal endomicroscopy in France, specifically its indication, histologic correlation, therapeutic benefits depending on the operator and complications.

Aims & Methods: We executed a multicentric observational prospective study from September 2013 to February 2015. Collection of data was based on a standardised collection sheet. All operators were trained on performing confocal endomicroscopy. The intravenous injection of fluorescein was given either in bolus or in a perfusion method at a dilution of 1 or 10% and was used, demographic, clinical, endoscopic and endomicroscopic data were collected. For each act the correlation between the confocal endomicroscopy and histology and the outcome of the ECM on the operator were reported.

Results: In total 399 procedures of confocal endomicroscopy were done on 399 patients (median age was 39 ± 14.5 years, males were 52% and these were performed in 12 centers. The main indications were: diagnosis and monitoring of Barrett esophagus 28% (111/399), surveillance of gastritis 4% (16/399), characterization of coloectal polyp and searching for dysplasia in IBD patients 17% (68/399), undetermined biliary stenosis 11% (42/399), pancreatic cysts 30% (123/399) and other rare cases (lymph nodes characterization, lupus, Crohn's disease, control post mucosectomy of gastric and duodenal polyps) 10% (39/399). The quality of imaging was good in 83% of cases (331/399), average in 16% (64/399) and poor in 1% (6/399). The correlation with histology was measured by using Cohen's kappa coefficient. The results were respectively k = 0.9, 0.78, 0.82, 0.7, 0.94, 0.93 for Barrett's esophagus, gastritis, IBD, colorectal polyps, undetermined biliary stenosis and pancreatic cysts. The outcome of the procedure according to the operator was beneficial for three main indications: Barrett's esophagus (especially for targeting biopsy), pancreatic cysts (100% of cases), and undetermined biliary stenosis (90% of cases and especially for real time therapeutic decision). One major side effect was seen during the study, which was an anaphylactic shock after a bolus injection of 2.5cc of fluorescein in a 69y old patient who didn't have any previous history of allergies. This patient was hospitalized for surveillance for three days.

Conclusion: In conclusion, confocal endomicroscopy is an in vivo microscopic technique that is easily performed along the digestive tube with a good histologic correlation especially for Barrett's esophagus, undetermined biliary stenosis and pancreatic cysts. Its importance in the management of patients remains to be clarified with the advent of new endoscopic magnification techniques.

P1544 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN PATIENTS WITH SURGICALLY MODIFIED GASTRO-ENTERIC-BILIARY ANATOMY: RESULTS FROM A TERTIARY CENTER
E. Soares, M. Gravito-Soares, N. Almeida, D. Gomes, E. Camacho, S. Mendes, R. Ferreira, L. Tomé
Gastroenterology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal, Coimbra/Portugal

Contact E-mail Address: es1849@gmail.com

Introduction: Endoscopic retrograde cholangiopancreatography (ERCP) represents a crucial procedure in the management of bilioenteric pathology. However, its performance in patients with surgically modified gastro-enteric-biliary anatomy (SMGA) is a challenging issue.

Aims & Methods: We aimed to evaluate the efficacy of this advanced endoscopic technique in patients with SMGA. This was a retrospective observational cohort study of all patients with surgical modification of biliary/pancreatic access undergone ERCP, between 01/2002 and 02/2017. Demographic variables, indications, the breakdown of surgical procedures and technical success rate were evaluated as well as potential predictive factors of therapeutic efficacy rate. Compared patients with successful technique(G1) and therapeutic failure by ERCP
Aims & Methods:
Prior studies have reported that the majority of CBD stones expanding therapeutic intervention of SOC. The universal usage will allow benchmarking at individual, institutional and national level and will help in quality improvement. Efficacy, safety and impact on different pancreaticobiliary disorders will be also measurable.

Disclosure of Interest: All authors have declared no conflicts of interest.
anastomosis, and (3) the therapeutic success rate. We used a 2.2 mm DBE with a 2.4 mm overtube of operating channel (EN-450 T5, or EN5080F Fujinon inc Saitama Japan).

Results: A total of 12 patients (sex ratio1/1) with a mean age of 65 [47–82] underwent 14 DBE-ERCP. 7 patients had Roux-en-Y gastro-jejunostomy with a biliary-jejunostomy and 4 patients had Roux-en-Y with a native papilla, and 1 patient had a Billroth II gastric bypass. Enteroscopy success rate was 93% (13/ 14 procedures). The diagnostic success rate was 85% (11/13 procedures) with 4/5 of native papillae. Therapeutic interventions including sphincterotomy (n = 4), biliary stone extraction (n = 4) and biliary dilation (n = 2) were needed in 8/11 procedures and their success rate was 100%. The global success rate of DBE-ERCP was 78% (11/14 procedures). Our results were comparable to those of the literature (global success rate of 82%). The only complication was one case of superficial intestinal lacerations without perforation (complication rate 7%).

Conclusion: DBE-ERCP in patients with surgically altered upper GI anatomy is a safe and efficient procedure with a global success rate of 78%. Using shorter enteroscopes with wider operating channel in the future might improve the success rate of the technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1559 NEEDLE-KNIFE SPHINCTEROTOMY (NKS) VERSUS TRANSPANCREATIC SPHINCTEROTOMY (TPS) FOR DIFFICULT BILIARY CANNULATION: A SYSTEMATIC REVIEW AND META-ANALYSIS
A. Tringali1, M. Cinto1, L. Cristofori1, E. Forti1, F. Pugliesi1, L. Dioscoridi1, M. Mutignani1

Contact E-mail Address: albrtri10@gmail.com

Introduction: Biliary cannulation may be difficult in 10–15% of patients (1) and needle-knife sphincterotomy is more often used as a rescue treatment. A more recent approach for difficult cases is transpancreatic sphincterotomy. Both situations are well known as Post-ERCP pancreatitis risk factor (2). To best of our knowledge only few studies compared success rate and adverse events in these techniques (3-7).

Aims & Methods: We aimed to compare the efficacy and safety of NKS comparing to TPS in difficult biliary cannulation We conducted a bibliographic search using PUBMED, EMBASE including 2 RCTs and 4 non randomized trials from January 2000 to December 2016. OR using the Manthel-Haenszel method was used for dichotomous variables. Quantitative synthesis was performed using Review Manager version 5.0. Primary outcome was success rate. Secondary outcomes were rate of overall complications, and pancreatitis. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Success rate was higher in NKS group compared to TPS (OR 2.98 95%CI 1.01–8.85, p = 0.05). Complications and risk of pancreatitis was similar in both group (OR 0.74 95%CI 0.51–1.00 p = 0.13; OR 1.09 95%CI 0.68–1.75 p = 0.71). 

Conclusion: NKS is associated with higher success rate with equal risk of complication and pancreatitis risk compared to TPS. Further and well design RCTs are needed before a firm conclusion could be made.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Transpancreatic Sphincterotomy (TPS) involves wire-guided cannulation of the main pancreatic duct (MPD) followed by standard pull-type sphincterotomy cutting towards the main channel. Typically a MPD stent insertion should follow TPS to prevent post-ERCP pancreatitis (PEP). ESGE [1] recommends that in patients with a small papilla that is difficult to cannulate, TPS should be considered if the guidewire-guided MPD cannulation fails. A previous study had suggested that TPS might be as effective as double guide wire (DGW) technique in achieving biliary cannulation in difficult cases and has a lower pancreatitis rate. [1]

Aims & Methods: The aim of this study was to review the practice, complications and outcomes of TPS in University Hospital of North Tees (district general hospital in the north-east of UK). All ERCP procedures between January 2014 and October 2016 were reviewed. Endoscopy reports, blood results and discharge letters were used for data collection.

Results: 1365 ERCP procedures were performed in the study period. Overall CBD cannulation rate was 91.3%. 105/1365 (7.7%) wire guided TPS procedures were performed. Mean age in the TPS group was 67 (range: 44–80) years. 61 (67.9%) were male and 44 (32.1%) were female. 31 (29.5%) TPS procedures were performed for difficult biliary cannulation. Our study is the second largest cohort in the literature and the largest cohort in the UK. We would suggest early adoption of TPS if wire access to the pancreatic duct is achieved, this will likely reduce complication rate as a result of less engagement with the papilla and overall reduced time at CBD cannulation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
was performed using SPSS version 20.0. A P-value of less than 0.05 was considered statistically significant.

Results: We included 1976 patients who presented choledocholithiasis and underwent different endoscopic extraction techniques. Mean diameter of stone(s) extracted using only the basket (Group A) was 6.8 mm with a mean CBD diameter of 11.8 mm (mean stone diameter) compared to 11.8 mm (mean stone diameter) with 14.3 mm (mean CBD diameter) for patients who underwent surgery before surgery (P < 0.001). Only 3.2% of cases had to be referred to surgery. Stones removed using only a retrieval balloon (Group B) were 7.6 mm with a mean CBD diameter of 13.3 mm. By associating the basket with a retrieval balloon (Group 4) we obtained a 100% success rate of endoscopic removal for a mean stone diameter of 9.6 mm with a mean CBD diameter of 12.9 mm. We also analyzed the percentage of patients who underwent endoscopic extraction by using a retrieval balloon combined with balloon dilator. In Group 4 the success rate was 67.2%. Overall, we had a success rate of 91.3% for endoscopic removal of choledocholithiasis with a mean stone diameter of 7.1 mm and a mean CBD diameter of 12.1 mm, compared to 3.8% of cases referred to surgery with a mean CBD diameter of 13.6 mm and a mean CBD diameter of 14.3 mm (P < 0.001).

Conclusion: The most successful endoscopic method to remove large stones >15 mm was balloon dilator combined with retrieval balloon with lithotriptor or a combination of basket with retrieval balloon alone or balloon dilator. Most CBD stones <7 mm were successfully removed by using basket. In conclusion, any diameter >7 mm will most probably require more elaborate techniques.

Introduction: Diclofenac and indomethacin are the most studied drugs for preventing post-ERCP pancreatitis (PEP), but their use is controversial.

Aims & Methods: Our aim was to evaluate all studies published in full text and studied efficacy of diclofenac or indomethacin prophylactic with placebo or non-treatment for the prevention of PEP in adult patients undergoing ERCP. Systematic search of databases (PubMed, Scopus, Web of Science, Cochrane Library) was performed from inception to 30 June 2016.

Results: Our meta-analysis of 4741 patients from 17 trials showed that diclofenac or indomethacin significantly decreased the risk ratio (RR) of PEP to 0.60 (95% confidence interval:0.46–0.78, P = 0.0001), number needed to treat (NNT) was 20, and the reduction of RR of moderate to severe PEP was 0.64 (95% CI 0.43–0.97, P = 0.0339). The efficacy of indomethacin compared to diclofenac was similar (P = 0.98). The efficacy of indomethacin or diclofenac did not differ according to timing (P = 0.99) or between patients with average-risk and high-risk of PEP (P = 0.027). The effect of rectal administration of indomethacin or diclofenac was not significant (P = 0.1507), but rectal route was very effective (P = 0.0005) with a NNT of 19. The administration of indomethacin or diclofenac was avoided in patients with renal failure. Substantial adverse events were not detected.

Conclusion: The use of rectally administered inexpensive and safe diclofenac or indomethacin before or closely after ERCP is recommended in every patient (without renal failure) undergoing ERCP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Rectal diclofenac or indomethacin reduces the risk of pancreatitis after endoscopic retrograde cholangiopancreatography (ERCP). Most studies of its efficacy included high-risk cohorts and excluded low-risk patients. We investigate the potential of rectal diclofenac to prevent post-ERCP pancreatitis (PEP) in a variety of patients.

Aims & Methods: A cohort of 1534 ERCPs performed at the Hospital Clinico de Valladolid between 2009 and July 2016 was collected. The median age of the patients was 75 years old (between 12 and 102 years). 54% were male and 45.9% female. There were 93 procedures in which cannulation of the desired pathway was not achieved but the papilla had been manipulated so they are patients who have been included in the study. In May 2012, with a few exceptions, patients received diclofenac before their procedure. 730 patients did not receive Diclofenac. PEP was defined by consensus criteria.

Results: The two groups were similar in age, sex, suspicion of Oddi sphincter dysfunction, recurrent acute pancreatitis, chronic pancreatitis, cannulation time, use of pre-cut, previous PEP, dilution without sphincterotomy. There were differences in the number of sphincterotomies in which it was greater in the Diclofenac group (p=0.004). There was also a greater number of Wirsung cannulations in the group treated with Diclofenac (p=0.004). There were a total of 47 PEP (3.1%), being 78.3% mild acute pancreatitis.

Takan as a whole the patients had no difference in the number of PEP between the two groups, since in those treated with Diclofenac there was 3.4% and in the non-treated patients 2.8%.

When taking only patients with de novo sphincterotomy, there was no difference between the number of PEP between the two groups being 4.4% in those treated with Diclofenac versus 4% in the untreated patients. In those patients who were cannulated Wirsung, an incidence of PEP of 8.2% was observed in the group treated with Diclofenac, compared to 6% in the untreated group (p=0.06). There were no differences between those treated with Wirsung’s prosthesis and those not treated in both groups. There was no PEP in patients treated with pancreatic prosthesis.

There was a higher incidence of PEP in women in both groups and a trend towards greater number of PEP among those treated with Diclofenac, although without statistical significance. There was also a greater number of PEP in patients under 40 years of age treated with Diclofenac compared to those not treated with 14.3% versus 7.1% (p=0.024).

No differences were found between the groups treated and not treated with Diclofenac when crossing with sphincter dysfunction of Oddi, previous PEP, number and sizes of choledocholithiasis and sizes with the appearance of PEP.

2016 vol.65;146–181.

D1 and E1 in the post-ERCP pancreatitis. Dig Dis Sci 2014
Conclusion: In this retrospective cohort study of patients undergoing ERCP that included low-risk patients, rectal diclofenac was not associated with a significant decrease in the absolute rate of pancreatitis. In our study, diclofenac decreases the impact of PEP in those patients who are cannulated the pancreas.

Introduction: The confocal laser endomicroscopy (CLE) is of two types, an endoscope-based CLE (eCLE), which is integrated in the tip of the endoscope, and a probe-based CLE (pCLE), which goes through the accessory channel of the endoscope. The biliary tract, which cannot be reached by using eCLE, is observable with pCLE by using cholangiopscopy. pCLE has the advantage of obtaining a magnification image that is like taking a biopsy tissue specimen but noninvasively, without the interference of bleeding and mucus secretion. However, it is sometimes difficult because only few gastroenterologists can achieve the required level of diagnostic accuracy.

Aims & Methods: We developed a computer-aided diagnosis (CAD) system based on pCLE imaging using deep learning technology. The purpose of this study was to determine the usefulness of this CAD system for the diagnosis of bile duct cancer. We prepared the classifier of the extracted features of the bile duct cancer pCLE images by using the deep learning framework presented by Kyocera communication system Co. Ltd. Japan. The pCLE images by Cellvisio (Mauna Kea Technologies, France) were obtained through the SpyGlass DS (Boston Scientific Corporation, USA). Learning sets were constructed by using 49 images of normal area and 25 images of cancer lesion. The test sets of the pCLE images were constructed by using 6 images of normal area and 14 images of cancer lesion separately from the learning set.

Results: The accuracy, sensitivity for cancer diagnosis, specificity, negative-predictive value, positive-predictive value of our CAD system by test set were 85.4% vs. 84.1%, p = 1.000 and diagnostic accuracy (72.0% vs. 74.4%), p = 0.860.

P1556 COMPARISON OF EUS-GUIDED FINE NEEDLE BIOPSY TECHNIQUES FOR CORE TISSUE ACQUISITION AND DIAGNOSTIC PERFORMANCES IN PANCREATIC SOLID LESIONS
C. Cho1, S.J. Yeo1, A.N. Soo2, H.I. Bae3
1Internal Medicine, Kyungpook National University Medical Center, Daegu/Korea, Republic of
2Pathology, Kyungpook National University Medical Center, Daegu/Korea, Republic of

Contact E-mail Address: cmcho@knu.ac.kr

Introduction: Acquisition of core tissue in endoscopic ultrasound-guided tissue sampling (EUS-TS) is necessary for histologic diagnosis and immunohistochemical staining in the diagnosis of some solid mass lesions. Although recent studies revealed the superiority of core biopsy needle in the specimen adequacy, core recovery still remains that which EUS-TS techniques would result in better acquisition of core tissue and diagnostic accuracy.

Aims & Methods: The aim of our study was to evaluate EUS-TS techniques with a ProCore needle using suction and slow pull suction for solid pancreatic lesions with a cytopathologist. Patients who referred to EUS-TS for pancreatitic mass were enrolled. We performed EUS-guided fine needle biopsy (EUS-FNB) using a ProCore needle (Cook Medical, Limerick, Ireland) with two needle passes and applied each pass of different techniques (suction or slow pull suction) which were randomly allocated. EUS-TS specimens were evaluated by one experienced cytopathologist who was blinded to applied techniques. The acquisition of core tissue and diagnostic performances were compared between two techniques.

Results: From Aug. 2014 to Dec. 2016, 94 patients with pancreatic mass were enrolled and 12 patients were excluded due to no final diagnosis (n = 5), cystic lesion (n = 5) and loss of follow up after EUS-TS (n = 2). Finally, 82 patients (48 males; median age, 63 years) with 164 needle passes were included without technical failure and procedure-related adverse events. The median size of the lesions was 29.4 mm (range, 11 to 80 mm). There were 68 malignant and 14 benign lesions. Overall core tissue acquisition and diagnostic accuracy was 84.8% (139/164) and 73.2% (120/164), respectively. There was no significant difference between suction and slow pull suction in the acquisition of core tissue (85.4% vs. 84.1%, p = 1.000) and diagnostic accuracy (72.0% vs. 74.4%, p = 0.860).

Conclusion: Although our study revealed no differences between EUS-TS techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions, further prospective study including variable lesions and sizes of needle is needed to validate for optimal application and sequences of EUS-FNB techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1560 EUS-GUIDED GALLBLADDER DRAINAGE FOR ACUTE CHOLECYSTITIS WITH A SILICONE-COVERED NITINOL SHORT FLARED ENDS STENT: A CASE SERIES

Introduction: Gallbladder drainage, performed by EUS-guided positioning of specially designed fully covered metal stents, may be considered a valid option in patients with cholecystitis unfit for surgery. We describe the first case series of patients with diagnosis of acute cholecystitis treated conservatively using a silicone-covered nitinol stent with bilateral anchor flanges (NAGI-stent).

Aims & Methods: Our aim was to evaluate the feasibility and clinical impact of EUS-guided drainage with NAGI-stent in patients with acute cholecystitis unfit for surgery. Sixteen consecutive patients (9 males; Mean age: 84 years) with diagnosis acute cholecystitis according to Tokyo guidelines criteria, not suitable for surgical approach, were conservatively treated and drained with EUS-guided short flared stents positioning. The procedure was performed in 2 tertiary endoscopy units by 4 experienced endoscopists. Both techniques were performed yearly, by using the NAGI-stent. Each attempt to access the gallbladder was firstly performed from the transduodenal position and resulted successful in 13 (81%) patients, whilst a transgastric approach was preferred in the remaining 3 patients. Two different approaches were performed for the EUS-guided gallbladder puncture: a) a 0.035-inch wire was advanced through a 19G-needle into the gallbladder and dilation of the access was achieved with a 10 Fr cystoenterostome; b) a 0.035-mch wire was advanced through a 10 Fr cystoenterostome directly into the gallbladder. After each attempt, the fully covered metallic stent, 12-16 mm of diameter and 20-30 mm of length with bilateral anchor flanges (NAGI-stent) was advanced on the wire by using the fluoroscopy guide. Technical success, clinical success, adverse events, and long-term outcome were assessed.

Results: Technical success was achieved in all cases, clinical success was observed in 15 (94%) patients, whilst in 1 case the procedure failed due to stones impaction into the stent but it resolved subsequently with a new stent positioning. Symptoms relief occurred in all patients, 1 day after the procedure in 12 (75%) cases and 2 days later in remaining 4 (25%) patients. A bleeding episode occurred in 2 (12.5%) patients, in one case such complication was intra-procedural and it was successfully stopped during the same endoscopic session, in the other case it was a delayed adverse events requiring arterial embolization but the patient died 10 days later. At follow-up, two patients died due to myocardial infarction at 2 and 6 months, one for acute renal failure after 6 months, two for pancreatic cancer at 7 months and one for cholangiocarcinoma after 5 months. In the remaining patients no cholecystitis recurrence or biliary obstruction were observed at median follow-up of 112 days (range 49-180 days).

Conclusion: Our data showed that EUS-guided gallbladder drainage with NAGI-stent is a feasible and successful option in patients with acute cholecystitis unfit for surgery. Since this type of stent is cheaper compared to others, the use of such device may result more attractive as a further endoscopic option for these selected patients.

P1561 EFFICIENCY COMPARISON BETWEEN 22 G VERSUS 25 G NEEDLES DURING ENDOCOSCOPIC ULTRASOUND FINE NEEDLE ASPIRATION FOR SOLID PANCREATIC MASSES: A SYSTEMATIC REVIEW AND META-ANALYSIS BASED ON RCTS
Gastrointestinal Endoscopy Unit, Clinical Hospital of Sao Paulo University Medical School, Sao Paulo/Brazil

Contact E-mail Address: ralphbdurarte@hotmail.com
Introduction: Endoscopic ultrasound-guided fine needle aspiration (EUS-FNA) is considered the gold standard method for assessing solid pancreatic masses. The needles for aspiration currently available are 19G, 22G and 25G and there is no concrete evidence to prove the benefit of one against another.

Aims & Methods: We aimed to compare the efficiency in the diagnosis of solid pancreatic lesions through the EUS-FNA with 25G and 22G needles.

Results: A total of 462 patients were evaluated (233: 25G needle/229: 22G needle). The sensitivity of the 25G needle was 93% (CI, 89–96%; I² 0.0%), and for the 22G needle was 91% (CI, 85–94%; I² 19.9%). The specificity of the 25G needle was 96% (CI, 94–98%; I² 0.0%) and for the 22G needle was 91% (CI, 87–94%). The positive likelihood ratio of the 25G needle was 4.57 (CI, 2.08–10.03, I² 0.0%), and for the 22G needle was 4.26 (CI, 0.43–41.88, I² 94.7%). The test post-od the probability of the 25G needle in the study population was 95% and for the 22G needle was 50%. The area under the ROC curve of the 25G needle was 0.9705 and for the 22G needle 0.9795, also showing no statistically significant correlation between them (p = 0.497).

Conclusion: Baseline randomized studies, this systematic review and meta-analysis did not demonstrate a significant statistical difference between the 22G and 25G needles used during EUS-FNA in the diagnosis of solid pancreatic lesions.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1563 TECHNICAL FEASIBILITY STUDY OF EUS-GUIDED HYDROGEL MICROPARTICLE INJECTION INTO THE PANCREATIC HEAD-DUODENAL WALL INTERFACE IN A CADAVERIC MODEL

S. Kim1, K. Ding2, A. Rao2, L. Rosati3, A. Narang2, E.J. Shin1
1Gastroenterology And Hepatology, Johns Hopkins University School of Medicine, Baltimore/United States of America/MD
2Department Of Radiation Oncology And Molecular Radiation Sciences, Johns Hopkins University School of Medicine, Baltimore/United States of America/MD

Introduction: Despite advances in radiotherapy for pancreatic cancer, local gastrointestinal (GI) toxicity still remains one of the major limitations to effective dose delivery and further dose escalation due to the close proximity of the GI wall to the pancreas, particularly in the head region. One potential method to reduce local GI toxicity would be to increase the physical distance between the head of the pancreas and the duodenal wall. A novel, injectable hydrogel, synthesized as iodinated polyethylene glycol microparticles, has been FDA-approved for use as a soft tissue fiducial marker. The hydrogel remains stable for 3 months and is absorbed by 7 months. To date, there has been no reports on the technical feasibility of endoscopic ultrasound (EUS)-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall to increase the peri-pancreatic space for the course of radiotherapy.

Aims & Methods: We aimed to evaluate the technical feasibility of EUS-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall in a cadaveric model. Baseline CT was performed on three unfixed cadaveric specimens. Using a linear EUS scope, the interface between the duodenal wall and the head of the pancreas was identified in a cadaveric model. A 17G EUS-FNA needle was used to inject the hydrogel into the peri-pancreatic space with creation of a visible separation between the duodenal wall and the pancreatic parenchyma. The procedure was repeated along the length of the head and uncinate of the pancreas. CT was performed post procedure to confirm location and to measure the distance created between the duodenum and pancreas. Gross dissection of the pancreas and duodenum was performed to evaluate localization of the hydrogel.

Results: All three cadavers underwent successful EUS-guided injection of the hydrogel. Cadaver 1 received a total injection volume of 9 cc with creation of peri-pancreatic space along the head of the pancreas measuring 11.77 mm in maximal diameter. Cadaver 2 received a total injection volume of 27 cc with creation of peri-pancreatic space along the head and uncinate of the pancreas measuring 13.20 mm in maximal diameter. Cadaver 3 received a total injection volume of 10 cc with creation of peri-pancreatic space along the head of the pancreas measuring 12.89 mm in maximal diameter. The hydrogel was clearly visualized during EUS with hyperechoic echogenicity and on post-procedure CT images without any artifacts in all cases.

Conclusion: EUS-guided delivery of hydrogel is feasible and results in an increase in the peri-pancreatic space in a cadaveric model. The hydrogel is clearly visualized on EUS and CT without significant artifacts. Further studies are warranted to evaluate feasibility, effectiveness and safety in a clinical model.

Introduction: Despite advances in radiotherapy for pancreatic cancer, local gastrointestinal (GI) toxicity still remains one of the major limitations to effective dose delivery and further dose escalation due to the close proximity of the GI wall to the pancreas, particularly in the head region. One potential method to reduce local GI toxicity would be to increase the physical distance between the head of the pancreas and the duodenal wall. A novel, injectable hydrogel, synthesized as iodinated polyethylene glycol microparticles, has been FDA-approved for use as a soft tissue fiducial marker. The hydrogel remains stable for 3 months and is absorbed by 7 months. To date, there has been no reports on the technical feasibility of endoscopic ultrasound (EUS)-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall to increase the peri-pancreatic space for the course of radiotherapy.

Aims & Methods: We aimed to evaluate the technical feasibility of EUS-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall in a cadaveric model. Baseline CT was performed on three unfixed cadaveric specimens. Using a linear EUS scope, the interface between the duodenal wall and the head of the pancreas was identified in a cadaveric model. A 17G EUS-FNA needle was used to inject the hydrogel into the peri-pancreatic space with creation of a visible separation between the duodenal wall and the pancreatic parenchyma. The procedure was repeated along the length of the head and uncinate of the pancreas. CT was performed post procedure to confirm location and to measure the distance created between the duodenum and pancreas. Gross dissection of the pancreas and duodenum was performed to evaluate localization of the hydrogel.

Results: All three cadavers underwent successful EUS-guided injection of the hydrogel. Cadaver 1 received a total injection volume of 9 cc with creation of peri-pancreatic space along the head of the pancreas measuring 11.77 mm in maximal diameter. Cadaver 2 received a total injection volume of 27 cc with creation of peri-pancreatic space along the head and uncinate of the pancreas measuring 13.20 mm in maximal diameter. Cadaver 3 received a total injection volume of 10 cc with creation of peri-pancreatic space along the head of the pancreas measuring 12.89 mm in maximal diameter. The hydrogel was clearly visualized during EUS with hyperechoic echogenicity and on post-procedure CT images without any artifacts in all cases.

Conclusion: EUS-guided delivery of hydrogel is feasible and results in an increase in the peri-pancreatic space in a cadaveric model. The hydrogel is clearly visualized on EUS and CT without significant artifacts. Further studies are warranted to evaluate feasibility, effectiveness and safety in a clinical model.

P1564 EX-VIVO RADIOFREQUENCY ABLATION OF PORCINE LIVER: A PRELIMINARY STUDY OF EFFICACY OF A NEW SYSTEM
L. Archibugi1, P. Magnoni1, P.G. Arcidiacono1

1Pancreato-biliary Endoscopy And Endosonography Division, Pancreas Translational & Clinical Research Center San Raffaele Scientific Institute IRCCS Vita Salute San Raffaele University, Milan/Italy
2Digestive & Liver Disease Unit, S. Andrea University - University of Rome "La Sapienza", Rome/Italy

Contact E-mail Address: rosse.gemma@hsr.it

Introduction: There are few published studies about the use of a novel radio-frequency (RF) system (EUSRA RF needle; VIVA RF generator; STARmed Co, Ltd; Koyang, Korea), with poor standardization of the procedure in terms of ablation powers and ablation times, resulting in great heterogeneity of the results.

Aims & Methods: To standardize the radiofrequency ablation (RFA) procedure under EUS, we performed ex-vivo tests on porcine liver in order to find the best ablation power and ablation time to produce the maximum size of coagulative necrosis at histological examination. The system consists in a radiofrequency generator delivering electric energy, a 19 Gauge needle (150 cm in length with a 10 mm monopolar electrode), a peristaltic pump (to perfuse the needle with chilled saline solution, maximizing the ablation volume without tissue charring), an isolating plate and a pedal to deliver RFA. Liver samples were treated at different powers: 10, 20, 30 and 40 Watts (W); each ablation power was applied for a duration of 1, 3, 5, 7 and 15 minutes, according to Fibonacci escalation dose scheme, used in phase I studies. We registered macroscopically: the size (millimeters) of the global treated area and the size of the coagulative necrosis. Histopathologically, blinded about ablation powers and times applied, we produced the report of the histological examination (millimeters of coagulative necrosis and surrounding zone).

Results: The lower ablation power (10 W) produced the maximum macroscopic ablation effect, RFA ablation time at 10 W showed a good linear correlation with the pathologist didn’t see any difference in size of coagulative necrosis among the different injured zones by thermal effect: a central small and well-demarcated coagulative necrotic area around the needle insertion point (A zone) with a maximum diameter of 4 millimeters and a surrounded larger area of “diaphanization” (B zone), showing mild signs of cellular alterations (cytoplasmic hypochromia) without cellular necrosis. A zone sizes didn’t change among different ablation times (mean size: 3.25 mm) while B zone diameter increased with the increase RF application at the fixed power of 10 W. At the microscopic analysis the pathologist didn’t see any difference in size of coagulative necrosis among the different ablation powers (R²=0.24).

Conclusion: With this new system is feasible and effective to produce very small areas of coagulative necrosis (millimeters) well-demarcated in respect to the surrounding parenchyma and could be useful, in the future, to treat, with multiple passes and higher precision, target lesions with a flexible needle. Moreover, the system can produce larger zones of mild cellular alterations at lower ablation powers (10 W), increasing with the increase ablation times, but it needs future in-vivo animal studies in order to assess the evolution of these zones (evolving into fibrosis? necrosis? recovering?).

Introduction: Malignant associated thromboembolic disease (TED) has a complex multifactorial pathogenesis. Tumor cell activators platelets and express procoagulant factors including tissue factor and thrombin; in addition, normal host tissues express procoagulant activity in response to the tumor. Thrombotic risk varies substantially according to cancer location and pancreatic cancer is one of the leading causes. The clinical spectrum includes migratory superficial thrombophlebitis, arterial thrombosis, deep venous thrombosis, portal vein thrombosis and disseminated intravascular coagulation. We report here to assess the role of endoscopic ultrasound (EUS) diagnosing TED in pancreatic cancer patients.

Aims & Methods: We performed a retrospective review of all EUS cases for pancreatic cancer in two centers and assessed all TED diagnoses.

Results: In a period of 6 months, a total of 55 EUS for pancreatic neoplasms were performed in two centers. TED was present in 5 patients (9%): 3 were male and the mean age was 70 (range, 46-81). In 1 patient the EUS indication was a large abdominal mass whose origin was not clear, in the remaining 4 the indication was the pancreatic neoplasm. In all of them was performed EUS with fine-needle aspiration (EUS identified arterial mural nodule (PE) and 1 inferior vena cava thrombus (IVCT) with right atrial extension: 2 (3.6%) had recently been diagnosed by computed tomography (CT) but 3 (5.4%) were not previously known. In all these, CT confirmed diagnosis.

Table 1: Demographic, clinical and ultrasonographic characteristics of the patients.

</tr>
</tbody>
</table>

Conclusion: To the best of our knowledge, this is the first case series of EUS-based TED diagnosis in pancreatic cancer patients. This series underlines importance of a systematic, station approach EUS technique, namely in the mediastinum regardless the clinical indication. TED is a common complication of pancreatic cancer and has major therapeutic and prognostic implications.

Introduction: Cholelithiasis is the most common cause of biliary pain, leading to cholecystitis and gallstone pancreatitis. Patients affected by cholecystolithiasis presents an incidence of cholelithiasis ranging from 8% to 20%. When the suspicion of cholecystolithiasis is confirmed, stones should be removed by ERCP, but this operative measurement is associated with high rates of adverse events such as ERCP pancreatitis, bleeding or perforation. A correct diagnosis of cholelithiasis, before ERCP, is mandatory to decrease the operative risk and health care costs. Endoscopic ultrasound (EUS) has a high sensitivity and specificity in the diagnosis of CBD stones and could substitute other imaging modalities as CT-scan or MRCP, when indicated.

Aims & Methods: The aim of our study was to assess the role of early EUS (<48 hours), in patients undergone US in emergency room for suspected biliary colic.

We retrospectively evaluated all the patients arrived at first aid for suspected biliary colic, (i.e. right upper quadrant pain and/or epigastric region, associated with an elevation in serum ALT, AST, GGT, ALP, or total bilirubin, but in absence of amylase or lipase elevation). All patients, irrespective of the finding at US, performed an EUS within 48 hours since admission. Data are presented as proportions with 95%CI and mean±standard deviation (SD). A correlation between categorical variables was evaluated by computing the “phi” coefficient. We computed the number needed to misdiagnose, i.e. the number of patients who need to be tested in order for one to be misdiagnosed by the test, as 1/(1-diagnostic accuracy).

Results: Overall, from January 2016 to December 2016, 88 patients (56% female; mean age 64 ± 17 years) were admitted to our hospital for suspected biliary colic. All of these subjects underwent abdominal ultrasound (US) at admission, which identified gallstones in 47 patients (71%). Furthermore, US documented bile duct (CBD) stones in 58 (65%) patients, CBD sludge in 4 (5%) subjects, whereas no cholecystolithiasis was found in 26 (30%) patients. At EUS examination CBD stones were found in 70 (80%) patients. Comparing US to EUS, US gave false negative results in 16 (18%) cases and false positive findings (i.e. identifying CBD stones not documented by EUS) in 8 (9%) patients. The two diagnostic procedures showed little correlation (phi = 0.289).

The number of
patients needed to be tested by US in order to provide an incorrect diagnosis was 3.7 (95% CI: 2.6–5.5).

Conclusion: US performed in the emergency room has a low diagnostic performance compared to EUS, but remains a first-step-approach in patients with right upper quadrant pain and/or in epigastric region, associated with an elevation in liver enzyme. Based on the results of our study, EUS performed within 48 hours from the admission allows an immediate correct endoscopic treatment with significant spare of unnecessary operative procedures, reducing possible related complications and costs.

P1567 BILIOPANCREATIC RADIOFREQUENCY ABLATION: COMPARISON OF THE THREE CURRENTLY AVAILABLE DEVICES IN A PIG MODEL

M. Barret1, S. Leblanc1, B. Bordaçahar1, A. Rouguette2, S. Chausseade1, F. Prat1
1Gastroenterology, Cochin Hospital, Paris/France
2Pathology, Cochin Hospital, Paris/ France

Contact E-mail Address: maximilien.barret@aphp.fr

Introduction: Three devices are currently available to perform radiofrequency ablation (RFA) of biliopancreatic lesions. Data from animal models are scarce.

Aims & Methods: Radiofrequency ablation was performed in four live pigs on the common bile duct and the liver parenchyma using an endobiliary probe (endoHBP), on the liver and pancreatic parenchyma using an RFA catheter through an echoendoscope and biopsy needle (EUS RFA) and using a needle- shaped submucosal RFA (USRFA) through an echoendoscope. Tissue ablation time and power were allowed to vary. The animals were sacrificed 2 minutes after the procedure. Histopathological assessment of the maximal depth of thermal lesions was performed on three representative slices for each RFA implantation.

Results: In the common bile duct, the depth of ablation ranged from 215 ± 47 (Power = 8 W, Time = 90 s) to 330 ± 43 μm (Power = 10 W, Time = 30 s), suggesting that power is the most important parameter in this location. Conversely, depth of ablation in the liver parenchyma using the endoHBP probe ranged from 947 ± 237 μm (Power = 10 W, Time = 30 s) to 1960 ± 20 μm (Power = 10 W, Time = 180 s), suggesting that time is the most important parameter for RFA in the liver. The EUS RFA probe in the liver parenchyma showed a tissue necrosis increasing with the power setting used, ranging from 1981 ± 451 μm (Power = 8 W, Time = 120 s) to 2457 ± 1047 μm (Power = 12 W, Time = 120 s). This was not observed in the pancreatic parenchyma, tissue damage ranged from 3108 ± 373 (Power = 8 W, Time = 120 s) to 2305 ± 78 μm (Power = 12 W, Time = 120 s). The EUSRFA ablation of the liver parenchyma resulted in tissue damage from 1573 ± 245 μm (Power = 30 W, Time = 11 s) to 1545 ± 120 μm (Power = 70 W, Time = 9 s). In the pancreas, ablation depth ranged from 3616 ± 475 μm (Power = 30 W, Time = 15 s) to 3805 ± 446 μm (Power = 70 W, Time = 15 s).

Conclusion: Power and time of ablation have different effects on the extent of tissue necrosis in the common bile duct, the hepatic and pancreatic parenchyma, depending on the type of catheter used to perform RFA. As indications for human trials tend to expand specific ablation protocols should be developed for each tumor location and device.

P1568 ENDOSCOPIC ULTRASOUND-GUIDED RENDEZVOUS FACILITATES BILIARY CANNULATION IN CASE OF INACCESSIBLE INTRA-DIVERTICULAR PAPILLA

D. Kypraios, A. Malachias, L. Theodoropoulos, S.L. Hatzinicolau, S. Stavrinos, N. Sarbeiogiu, G. Sofianidis, K. Tsamakidis, D. Dimitrakopoulos, D. Ximopoulos

Introduction: Endoscopic ultrasound (EUS)-guided rendezvous techniques facilitate common bile duct (CBD) access during subsequent endoscopic retrograde cholangio-pancreatography (ERCP) in a single session. Cases of initial ERCP failure mainly comprise malignant biliary or ampullary infiltration and altered anatomy of the papilla, the former accounting for the majority of reports in the literature.

Aims & Methods: We aimed to evaluate the efficacy and safety of EUS-guided rendezvous in a series of distal CBD obstruction with failed initial ERCP, due to inaccessible intra-diverticular papilla. Consecutive patients with distal CBD obstruction, in whom selective biliary cannulation at ERCP was unsuccessful due to large duodenal diverticula, underwent EUS-guided rendezvous. CBD puncture was performed via the transduodenal approach and the guide wire was advanced antegradely across the papilla. The echoendoscope was then exchanged for a duodenoscope and a sphincterotome was inserted through the papilla alongside or over the wire, to allow further manipulations.

Results: A total of 2480 ERCPs performed over a 4-year period, 18 cases were selected to undergo EUS-guided rendezvous due to the presence of a large ampullary diverticulum. Primary indication for ERCP was CBD stones in 15 patients, pancreatic head cancer in 2 patients and cholangiocarcinoma in 1 patient. Mean age of the patients was 77 years (range 62–91) and mean diameter of the CBD was 16 mm (range 8–21). Successful CBD puncture with antegrade passing of the wire into the duodenum and subsequent ERCP, in the same session, was achieved in 2/3 (66.6%) cases of malignant obstruction and in 13/15 (86.6%) cases of lithiasis. Retrograde biliary cannulation during ERCP was performed over the wire in 12/15 (80%) cases and alongside the wire in 12/15 (80%) cases. The mean procedural time was 80 minutes (range 55–115). A case of inadvertent CBD wall penetration by the sphincterotome, with contrast extravasation, occurred during an over-the-wire cannulation. No major complications, i.e perforation (extra-luminal air or bile leakage), bleeding and pancreatitis occurred. Three cases of amylasemia and transient fever were noted.

Conclusion: EUS-guided rendezvous is an effective salvage technique for failed CBD cannulation via standard ERCP, in cases of inaccessible papilla due to large ampullary diverticula. Along the guide-wire biliary cannulation may prevent inadvertent CBD wall trauma, compared to the over-the-wire approach.

P5170 EARLY CAPSULE ENDOSCOPY PROVIDES BETTER BLEEDING LOCALIZATION VALUE IN PATIENTS PRESENTING WITH NON-HEMATEMESIS GASTROINTESTINAL BLEEDING WHEN COMPARED TO CLINICAL SYMPTOMS ALONE

S. Jawaid1, N. Marya2, A. Foley1, C. Marshall1, K. Bhattacharya1, D. Cave1
1University of Massachusetts Medical Center, Worcester/United States of America
2UCLA, Los Angeles/United States of America

Contact E-mail Address: sajawaid@gmail.com

Introduction: Traditionally, clinical symptoms such as melena were used as strong predictors for an upper GI bleeding source with primary evaluation with an EGD (esophagogastroduodenoscopy). Little consideration was given to the small bowel. It has been known for decades that melena can originate from the nose to the right colon and hematochezia can originate from the proximal gut to the rectum. Thus, current endoscopic approaches have limited localization value and diagnostic yields. We hypothesize capsule endoscopy (CCE) provides better localization of bleeding when compared to clinical symptoms alone.

Aims & Methods: Study design was a prospective single-center randomized trial comparing the efficacy of localizing the source of bleed in early CCE versus SOC (standard of care) tests chosen based on clinical symptoms alone. This was a prospective single center randomized trial of 73 consecutive patients presenting to the University of Massachusetts Medical Center with NHGB (melena, hematochezia/anemia, or guaiac-positive stools/anemia). Exclusion criteria included presence of pacemaker, dementia, non-English speaking, hemodynamically significant bleeding. Patients were randomized to SOC arm versus early capsule (EC) deployment. The SC group received a primary diagnostic procedure based on clinical symptoms that was dictated by the gastroenterologist on service, who was at liberty to choose the procedure sequence as they felt appropriate.

Results: Patient enrolled, 73 were included. 2 patients from the initial included group were excluded (one due to technical capsule failure and one was transferred from an outside hospital). Baseline characteristics were similar and depicted in Table 1. The EC group (n = 34) had localization of presumed source of bleed (either upper GI or colon) in 57.6% (n = 20) of patients at the time of the first diagnostic procedure compared to 48.4% (n = 16) in the SOC group (p = 0.02). Active bleeding or stigmata of recent bleeding at the time of the first procedure was seen in 64.7% (n = 22) of patients in the EC groups compared to only 30% (n = 6) in the SOC group (p = 0.003). However, when melena was the only clinical symptom in the SOC (n = 26) group, EGD was the most commonly chosen primary diagnostic procedure (n = 23), but was only diagnostic 52% of the time. After complete diagnostic evaluation in the SOC group, patients presenting with symptoms suspicious for lesions located in the esophagus (3.5%), stomach/duodenum (46.2%), small bowel (11.5%), colon (11.5%), but 27% had no source identified. EC group had lesions localized to the esophagus (2.9%), stomach/duodenum (35.2%), small intestine (8.8%), colon (20.5%), and 32.3% did not have lesions identified. When bleeding was associated with SB MRI evidence of obstruction, 31% had CE diagnostic yield of 100% (n = 9) and only 2 patients had SB MRI with SB inflammation on CE (n = 2). However, when bleeding was associated with SB MRI evidence of active SB inflammation, only 1 had lesions seen on CE. The other 3 patients had insignificant or normal CE findings. Of the 10 patients with SB thickening and/or inflammation seen on MRI, 6 had corresponding CE findings; in particular, there were 2 cases with strictures on CE and 4 cases with mucosal inflammatory changes. 64 patients had normal SB MRI and 35 (54.7%) did have a normal CE. 18/64 (28.1%) patients had mucosal inflammatory changes on CE; 2 of them had strictures which were eventually traversed by the capsule. 10 patients had other non-inflammatory findings on CE. Of 18 patients with normal SB MRI, 9 had a raised FC (>150 μg/g), 5 had borderline FC levels (50–100 μg/g). None of the patients in this group had normal FC levels; the mean FC was 637.5 ± 844.4 μg/g. In the group of patients with both normal SB MRI and CE, 16/35 had raised FC. 7 patients had borderline FC levels. The overall mean FC for the 26 patients was 261.9 μg/g and the mean FC between patients with SB inflammation seen on CE and patients with normal SB MRI and CE was significantly different (p = 0.04).

Conclusion: A significant proportion (28.1%) of patients with normal SB MRI to investigate possible SB inflammation had CE findings showing SB inflammation, including 2 patients with strictures. However, no retention occurred in this group. Raised FC was significantly associated with CE findings despite normal SB MRI.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The interpretation of small bowel capsule endoscopy (SBCE) requires a high level of concentration. An abnormality may be present on just a few of the many thousands of images presented for interpretation. It is
Aims & Methods: Thirty-two participants (16 experienced SBCE readers and 16 novices) were invited to participate in this study. Each participant was asked to read 6 pre-selected SBCE studies consecutively. These studies were presented in a random order. All readings took place using the single view mode, readers were able to choose the frames per second viewed from a range of speeds. Fatigue was measured subjectively using a Likert scale and objectively using a computer-based psychomotor vigilance test. These measures were performed at prior to commencing the study and after every second capsule read. Accuracy in lesion detection was determined by comparison with a gold standard reading derived from the non-consecutive readings of two expert capsule readers. Accuracy was plotted against the order in which SBCE studies were read. The aim of this study was to determine whether fatigue influenced accuracy of SBCE interpretation and how many cases can be read before accuracy declines.

Results: In keeping with existing literature, high intra-observer variability amongst the participants was observed, with experienced readers reaching kappa values of 0.51 with the gold standard and 0.08 amongst novices. At progressive SBCE studies were read the mean speed increased for both experts and novices, with a mean reduction of 10 minutes between the first and the last study read. This was associated with faster reading speeds selected in progressive studies read. Where accuracy was analysed with respect to the reading speed chosen, a negative correlation between increasing speed and accuracy was demonstrated, with 31% of lesions detected when read at 6–10 frames per second, compared to 15% when using the 22–28 speed. There was no significant change in accuracy with progressive capsule read when the group was analyzed as a whole. The accuracy of experienced readers declined after just one study read, from 38% to 27% and plateaued thereafter. Novice readers demonstrated no significant change in accuracy at the time points, with a trend towards improvement, perhaps indicating skills acquisition during the study.

Conclusion: The accuracy of SBCE reading declines after one study reporting in a given period of time by expert SBCE readers. The optimal time interval between readings needs to be explored. This does not affect novice readers perhaps demonstrating skill acquisition.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1574 FEASIBILITY OF SAME-DAY COLON CAPSULE ENDOSCOPY (CCE) IN PATIENTS WITH INCOMPLETE COLONOSCOPY

M. Hussey1, G. Holleran2, C. Tersaruolo3, D. McNamara1
1Gastroenterology, Tallaght Hospital, Dublin/Ireland
2Trinity Academic Gastroenterology Group, Trinity College, Dublin/Ireland

Contact E-mail Address: husseyma@tcd.ie

Introduction: Rates of incomplete colonoscopies (IC) range from 2–19%, requiring repeat procedures or radiological imaging which can often lead to diagnostic delays as well as increased inconvenience for the patient. Same-day CCE may offer a more convenient and cost-effective mode of colonic examination post IC.

Aims & Methods: We aimed to determine the feasibility of same-day CCE post incomplete colonoscopy (IC). A prospective pilot study was performed with no contraindication to CCE with an IC for reasons other than poor bowel prep was offered the test following an appropriate recovery time of 1-hour post IC. Informed consent was obtained from all subjects. Upon ingestion of the capsule the time of IV metoclopramide was given to overcome the antinomity effects of fentanyl given during routine colonoscopy. Standard booster protocol for CCE was administered. Patient demographics, procedure indication, sedation studies can be read in one session. This study was performed in a given period of time by expert SBCE readers.

Results: At date, 40 same-day CCE have been completed. The mean age was 57 yrs.(22–83 yrs.) and 65% (n = 13), Iron deficiency anaemia 30% (n = 12), Inflammatory Bowel Disease Asessment 15% (n = 6), PR bleeding 5% (n = 2), abnormal pain 5% (n = 2), positive family history of CRC 5% (n = 2) and abnormal imaging 2% (n = 1). OC were incomplete due to excessive looping (40%) (n = 10), patient intolerance 30% (n = 12) and severe diverticular disease 30% (n = 12). The mean sedation used during OC was 5 mg midazolam (range 3–10 mg) and 75 mg of fentanyl (range 50–100 mcg). In all 84% (n = 34) of CCE were complete, however full colonic views were obtained in 94% (n = 37).

Mean colonic passage time was 222 minutes and overall image quality was deemed to be excellent in 16% (n = 6), good in 31% (n = 12), adequate in 44% (n = 18) and poor in 9% (n = 4) of participants. Overall findings were normal 25% (n = 10), polyps 38% (n = 15), inflammation 22% (n = 9), diverticular disease 25% (n = 10), and hypoplasia 3% (n = 1). Amongst the patients who had polyps, 8 required polypectomies and the remaining 7 were put on a surveillance programme. Based on the CCE findings, 4 of the IBD patients required treatment escalation. In terms of adverse events one patient reported abdominal pain during the procedure and one patient retained the capsule due to an inflammatory stricture.

Conclusion: CCE would appear to be feasible in the majority of patients and significantly detects colonic pathology.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1575 DEDICATED DIFFUSION WEIGHTED MR IMAGING FOR STAGING PERITONEAL METASTASES IN COLORECTAL CANCER: AN ACCURATE PREOPERATIVE SELECTION TOOL FOR CYTOREDUCTION SURGERY (CRS/HIPEC) CANDIDATES

I. Jansen1, D. M. Lambregts2, S. Chandrasegaram-Shanmuganathan3, N. Kok2, G.L. Beets3, R. G. Beets-Tan4, A. Aalbers1, M. Lahaye1
1Radiology, The Netherlands Cancer Institute, Amsterdam/Netherlands
2Surgery, The Netherlands Cancer Institute, Amsterdam/Netherlands

Contact E-mail Address: M.Lahaye@nki.nl

Introduction: Peritoneal carcinomatosis (PC) is a well-known mechanism of spread for cancer; it is the second-most frequent cause of death in colorectal cancer patients. However, the prognosis of PC patients has dramatically improved in recent years. Now, PCS can be treated with cyto-reductive surgery and hyperthermic intraperitoneal chemotherapy (CRS- HIPEC). 5-year survival rates of up to 50% are reported after CRS-HIPEC. Despite this survival gain, CRS-HIPEC has a considerable morbidity rate of 25%–30% and severe complications in 21%2. Obvious benefits are patients with a limited life expectancy to avoid pointless and costly aggressive surgical procedures. Hence, recognizing patients with a maximum risk-to-benefit ratio for the procedure is imperative. To select patients who could benefit from CRS-HIPEC the Peritoneal Cancer Index (PCI) is used. The PCI combines the location/size of peritoneal tumours found at surgery in 13 abdominal regions. Each of the 13 regions is scored for implant size on a scale of 0–3 (= no visible tumor for implants; 1 = implants ≤0.50 cm; 2 = ≤0.50–5.0 cm; 3 = ≥5 cm). The PCI is the sum of the lesion scores from all 13 areas, and thus can vary between 0–39. The PCI is widely validated and is a quantitative prognostic indicator for long-term outcome. However, with this surgical staging procedure it is not always feasible to inspect all relevant abdominal regions. The aim of this study was to determine whether the PCI can be used to preoperatively select patients who would benefit from CRS-HIPEC.

Results: In keeping with existing literature, high intra-observer variability amongst the participants was observed, with experienced readers reaching kappa values of 0.51 with the gold standard and 0.08 amongst novices.

Aims & Methods: Therefore, the aim of this study was to estimate the PCI preoperatively with diffusion weighted MRI (DW-MRI) and compare this with the PCI found at surgery to assess whether DW-MRI can be used to select CRS- HIPEC candidates. In this ongoing project, a large ongoing study twenty-four consecutively included patients (April 2016–April 2017) with histologically proven peritoneal carcinomatosis from colorectal origin were included. Patients were scheduled for exploratory laparoscopy and/or CRS-HIPEC and underwent preoperative dedicated DW-MRI (scanning time: 30 min).

Two independent readers prospectively determined the PCI on DW-MRI. Patients were categorized as low-risk (PCI 0–21) versus high-risk (PCI 22–39); in our center considered operable versus non-operable. Reference standard was PCI at CRS surgery. Furthermore the ICC between the readers evaluating the same data was measured. In this study an ICC of ≥0.70 is the accepted level of agreement.

P1576 HISTOLOGICAL PREDICTION OF COLONIC POLYS BY COMPUTER VISION, PRELIMINARY RESULTS

1Endoscopy Unit, Hospital Clinic, University of Barcelona, Barcelona/Spain
2Center Computer Vision, Universitat Autonoma de Barcelona, Barcelona/Spain

Contact E-mail Address: crsanchez@clinic.cat

Introduction: During colonoscopy, clinicians perform visual inspection of the polyps to predict histology. Kudo’s pit pattern classification is one of the most commonly used for optical diagnosis. These surface patterns present a contrast with respect to their neighboring regions and they can be considered as bright regions in the image that can attract the attention of computational methods.

Aims & Methods: We aimed to assess the accuracy of a new computational system based on the segmentation and characterization of bright regions as
cases to obtain an automatic histological classification of colonic polyps. Our automatic classification system is based on the segmentation of textural elements from polyp surface and their correlation with Kudo’s pit pattern classification. Textural elements are identified as bright regions in polyp surface and there are characterized according to their shape into tubular and circular: a high presence of tubular patterns is associated to an adenomatous histology whereas the absence of prominent tubular structures is associated to non-adenomatous. Taking this into account, we characterized segmented bright regions using a tubularity metric (Tub) designed to obtain low values for circular shapes and high values for tubular shapes of the same area. We tested our method in high definition (HD) white light polyp images which were obtained with a colonoscope Olympus CIF-H190 at Hospital Clinic in Barcelona. Neither conventional nor virtual chromoendoscopy were used. These images were selected to show as much variability in polyp appearance as possible. We used the mean of all Tub values for an image to classify it into two classes: Adenoma and Non-Adenoma. A ROC curve was constructed to select the optimal threshold value of Tub. Then, we compared the histology prediction provided by our system and the actual histology obtained after lesion removal.

**Results:** 51 polyp images were analyzed: 38 (74.5%) adenoma and 13 (25.5%) non-adenoma. Mean size of polyps was 14 ± 13 (range 1–40) and had the following morphology based on Paris classification: 5 (9.8%) 0-Ip, 27 (52.9%) 0-IIa and 19 (37.3%) 0-IIa. Mean Tub values were different for adenoma compared to Non-adenoma (19.5 ± 6.5 vs 14.1 ± 6.3; p = 0.013). An optimal threshold value of Tub = 13.14 to separate adenoma vs. non-adenoma was selected from the operating point of the ROC curve. With this value, our method was able to provide an accurate histological diagnosis in 44 out of 51 images (86%) (table) with a Sensitivity, Specificity, PPV and NPV for the diagnosis of adenoma of 95%, 61%, 88% and 80%, respectively. On the other hand, processing of a single HD image took 2.7 seconds making feasible its use in the endoscopy room.

**Conclusion:** A computer vision system based on bright regions in the image has a high accuracy for on-line prediction of polyp histology during colonoscopy. Though the use of shape characterization is promising, the inclusion of other polyp characteristics (i.e. shape, color, vessels...) as well as enlarging the validation database could improve the robustness of our methodology.

**P1577 COLORECTAL LATERALLY SPREADING TUMORS DETECTED AT CT COLONOGRAPHY**

M. Iwabuchi, M. Sugimura, S. Toda, K. Uki
Gastroenterology, Sendai Medical Center, Sendai/Japan

**Contact E-mail Address:** s7856@shh.go.jp

**Introduction:** Laterally spreading tumors (LSTs) of the colorectum are classified into the following two subtypes according to their morphology; granular type (LST-G), and non-granular type (LST-NG). Meanwhile, CT colonography (CTC) is a relatively new radiological technique for imaging the entire colorectum and its sensitivity for detecting polyps more than 1 cm has been reported to be greater than 90%. However, the detectability of LST in CTC has not been reported. CTC images were analyzed by AZE Virtual Place software. The CTC and CS were independently analyzed by endoscopist and radiologist in blind fashion. We investigated misdiagnosed lesions with CTC more than 10 mm detected by CTC. We considered the pseudo-negative lesions misdiagnosed with CTC interpretation (PNL) by radiologist or gastroenterologist and also considered the true pseudo-negative lesions misdiagnosed with CTC interpretation (true PNL) by radiologists and gastroenterologists. Because we conceived true PNL showed the limitation of CTC interpretation instead of PNL involved a human error.

**Results:** PNL was diagnosed by CS at 0-Ip (8 cases, 8 lesions), 0-Is (10 cases, 12 lesions) and 0-IIa (17 cases, 19 lesions), respectively according to the criteria of the Paris classification. True PNL was also diagnosed at 0-Ip (1 case, 1 lesion), 0-Is (5 cases, 6 lesions) and 0-IIa (11 cases, 13 lesions), respectively. True PNL/PNL ratio was 0-Ip 12.5%, 0-Is 50% and 0-IIa 68.5%, respectively. There was no PNL at 0-Iic, Type I, II and III on this study. Most of all true PNL were so called flat lesion not only 0-IIa lesion.

**Conclusion:** CTC was proven to be a reasonably useful approach to obtain the image of colon diseases without any invasiveness to the patient. On CTC interpretation, lower protruded lesion was considered less detectivity than highly protruded lesion more than 4 Ip.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
thickess of wall thickness for fibrosis was >6.3 mm (specificity 100% and sen-
sitivity 69.23% with AUC 0.89). The cut-off of ADC value for fibrosis was

\(1.1 \times 10^{-3} \text{ mm}^2 \text{s}^{-1}\) with a sensitivity of 71.79% and specificity of 94.44%
(AUC = 0.83).

Conclusion: The DWI sequence with ADC value can identify fibrosis in intestinal

Aims & Methods: We have synthesised analogues of EMI-137 where the fluoro-
escent reporter was replaced by a radionuclide chelating moiety for PET imaging.

Results: We have identified a number of promising applications within Digestive
Onco11; gastric cancer, locally-advanced rectal cancer, and bile duct cancer surgery are all life-threatening indications with urgent healthcare problems that could be improved by utilising imaging of c-Met with EMI-137. Compatible imaging systems are commercially available for these indications. There is also strong evidence for c-Met as a biomarker in stratification in Barrett’s oesophagus (BO), a potentially precancerous lesion with the risk of progression to oesopha-

gal cancer. Progression rates are low and overall survival rates in BO patients are similar to the general population. However, due to the poor prognosis of oesophageal cancer, patients with BO lesions are managed by regular endoscopic surveillance and biopsy. This means that there is arguably a disproportionate healthcare burden relative to the level of risk.

Conclusion: Gastric cancer, locally advanced rectal cancer, and bile duct cancer surgery all have strong evidence for c-Met as a valid target, and the healthcare problems are clear and widely recognized, with EMI-137 having the potential to high cost and is not always available. Fixation by clipping or sutures has similar

placement and have higher rates when fully covered stents are employed.

Covered stents prevent tumor ingrowth and can be removed easily, they can

be used in the closure of fistulas and leaks. External fixation of the stent with

Shim’s technique seems to be efficient in preventing stent migration, but has a high cost and is not always available. Fixation by clipping or sutures has similar limitations. We developed a homemade technique for external fixation of the stent using dental floss to prevent stent migration. We pull strips of dental floss into the stent mesh and use a method similar to exchange of a nasobiliary drainage catheter, the dental floss is drawn out through the nose, tied a knot into it and its loose end is fixed to the patient’s carbo13;

Results: Upper gastrointestinal endoscopy was performed after two weeks and the proximal end of the stent was evaluated. If it was embedding the esophageal mucosa and did not separate from the esophagus with air insu14; the external fixation was removed. Otherwise, the fixation was kept for another 2–4 weeks when a new endoscopic evaluation was performed. Patients were evaluated 15–30 days after stent placement. In cases of migration of the entire length of the stent into the stomach, the patient received a new stent and the same fixation method was employed. In cases of stents partially migrated through the cardia, the same stent was repositioned and fixed with dental floss strips as previously described.

Conclusion: According to the results we believe this homemade technique using dental floss for external fixation of stents is a simple and cheap method that can be applied and used to prevent stent migration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1580 MOLECULAR IMAGING OF C-MET IN THE CLINICAL MANAGEMENT OF GASTROINTESTINAL CANCERS

N. Mcnolden, C. Portal, I. Wilson

Contact E-mail Address: iwilson@edinimage.com

Introduction: The primary indication for c-Met targeted optical imaging agent EMI-137 is enhanced endoscopic detection of lesions during colorectal cancer screening, including flat lesions that are difficult to detect by normal white light endoscopy. We have evaluated the potential benefit of EMI-137 and analogues beyond colorectal cancer screening since c-Met is up-regulated in many other cancers.

Aims & Methods: We have synthesised analogues of EMI-137 where the fluoro-
escent reporter was replaced by a radionuclide chelating moiety for PET imaging.

Results: We have identified a number of promising applications within Digestive
Onco11; gastric cancer, locally-advanced rectal cancer, and bile duct cancer surgery are all life-threatening indications with urgent healthcare problems that could be improved by utilising imaging of c-Met with EMI-137. 2. Moyes LH, Mackay CK, Forshaw MJ. The use of self-expanding plastic stents to dilate oesophageal strictures: a comparison in 4 studies, where the pooled result showed, that it decreased in the intralesional steroid plus dilation group (standardized mean difference: −0.717, 95% CI: −1.191; −0.242, p-value: 0.003). The total number of repeat dilations was comparable in 5 studies, where the standardized mean difference was −0.465 as compared to the dilation alone group (95% CI: −0.777, −0.153, p-value: 0.004). The dysphagia score was comparable in 5 studies, but in this case no significant difference could observed between the two groups (standardized mean difference: 0.274, 95% CI: −1.822; 1.165, p-value: 0.510).

Conclusion: Our meta-analysis showed a significant improvement in the periodic dilation index and total number of repeated dilations in the patients treated by intralesional steroid injection as well. We recommend the use of intralesional steroid injection for benign refractory oesophageal strictures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of the analysis is to summarise the results and establish evidence in support or against the complementary treatment. A meta-analysis was performed using the preferred reporting items for systematic review and meta-analysis protocols (PRISMA-P). Two reviewers conducted a comprehensive search on databases from inception to February 2016, to identify trials, comparing the efficacy of dilation combined with intralesional steroid injection. A meta-analysis was conducted on the data using the random-effects method by DerSimonian and Laird, because of the high level of the heterogeneity. There were 45 articles found in Embase, 55 in PubMed, and 6 in the Cochrane database. Altogether 11 articles were suitable for analyses, after exclusion of duplicate articles, case reports, results from non-human and pediatric studies. These studies involved 373 patients in total. The periodic dilation index showed a significant difference compared to the dilation alone group (95% CI: −0.465 as compared to the dilation alone group (95% CI: −0.777, −0.153, p-value: 0.004). The dysphagia score was comparable in 5 studies, but in this case no significant difference could observed between the two groups (standardized mean difference: 0.274, 95% CI: −1.822; 1.165, p-value: 0.510).

Conclusion: Our meta-analysis showed a significant improvement in the periodic dilation index and total number of repeated dilations in the patients treated by intralesional steroid injection as well. We recommend the use of intralesional steroid injection for benign refractory oesophageal strictures.

Results: Between 01.01.2012 and 01.04.2016, 152 stents were inserted in 125 patients with palliative oncologic esophageal cancer; 104 patients had stent inserted once, 16 patients had twice, 4 patients had 3 times and 1 patient had 4 stent insertions. 69.6% were male and the median age at death was 79 years (SD 10.94). The reported histology for the 125 patients revealed, 85 (68%) adenocarcinoma, 30 (24%) squamous cell carcinoma, 5 (4%) Lung cancer causing external compression of the oesophagus, 2 (1.6%) mesothelioma, 1 (0.8%) externally compressing spindle cell sarcoma, 1 (0.8%) metastatic adenocarcinoma from the colon. 1 (0.8%) externally compressing signet ring adenocarcinoma. Of these stent insertions 52 (34.2%) were documented to have on going or recurrent dysphagia after the procedure, of which the causes were: tumour over- or ingrowth in 9 (5.9%); stent migration in 15 (9.9%); distal obstruction due to gastric folds 2 (1.3%); dysfunction of the anti-reflux valve in 3 (2.0%); and food bolus obstructions in 10 (6.6%). Stent occlusion occurred in 21 (13.6%) cases and stent disintegration in 1 (0.7%) case. In 13 (8.6%) cases cause for dysphagia was not found or not investigated. 100 (63.8%) stent insertions resulted in complete resolution of the dysphagia. Repeat endoscopy was necessary in 34 (27.2%) patients, who had 98 repeat gastroscopies in total, to deal with minor complications of the stent insertion or to investigate dysphagia. In total there were 13 (8.7%) significant complications caused by the stent insertion of which 7 (4.6%) were bleeding, 2 (1.3%) were tracheo-oesophageal fistula formations, 1 (0.7%) was delayed perforation, 1 (0.7%) was a too short stent, 1 (0.7%) was a disintegrating stent and 1 (0.7%) was a compression of the bronchi. Median survival of the 125 patients after stent insertion was 96 days (SD 128) and 30-day mortality was 11.2% (14 patients). It is important to note that with retrospective data analysis, some data is not available, due to variations in recording at the time and a reliance on the patient to report symptoms to a clinician. Currently 2 patients are still alive.

Conclusion: Palliative stenting at this centre continues to be an effective treatment for patients with dysphagia from oesophageal cancer. On the whole, outcomes from stenting at this unit compare favourably with published data in terms of dysphagia, other complications, and mortality. Steps to improve post-procedure monitoring in the form of a “stenet registry” with prospective collection of data by telephone or face-to-face follow-up could be useful in future service development.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1587 LONG-TERM RESULTS: WHEN RE-STENOSIS COMES AFTER ESOPHAGEAL STENTING?

D. Gusev, S. Kashin, N. Akhkapkin
Endoscopy, Yaroslavl Regional Cancer Hospital, Yaroslavl/Russian Federation

Contact E-mail Address: denis_gusev83@mail.ru

Introduction: Self-expanding metallic stents (SEMS) is a well-established form of palliative treatment for dysphagia in esophageal cancer. Progression of the tumor after stenting with re-stenosis is a serious problem in patients with better prognosis and longer survival.

Aims & Methods: The aim of this study was to assess the timing and probability of esophageal re-stenosis after stenting by tumor growth. We performed a retrospective analysis of patients with advanced esophageal cancer who was under- went stenting as definitive treatment. A series of 165 patients were included in the study. The median follow up time was 5 years in 41.6% of patients. We installed covered SEMS of one design from one manufacturer. The length of stents was 80, 100, 120, 140 mm, diameter - 20 mm. Patients with follow-up of more than 60 days were included in this study.

Results: Of the 165 patients from the database, 97 patients were selected, whose follow-up period was more than 2 months. There was a predominantly of male patients (78.5%), mean age of 72 years. To each patient was inserted a same patent. The median stent length was 4 cm. For the stent was placed 2 cm distal and 2 cm proximal of the stricture. Of 97 patients, 18 (18.5%) patients had tumor overgrowth with recurrence of dysphagia. Tumor overgrowth was verified as malignancy. Tumor localization before stenting: the upper and middle part of the esophagus - 6 patients, the lower part and the cardia - 12 patients. In 12 cases tumor growth spread out in the proximal direction, in 6 cases-in the distal. Interestingly, the distal tumor overgrowth after stenting was predominant (66.6%) in cases of localization in middle and upper part of the esophagus, while the proximal tumor spread (83.3%) was noted in cases of localization in the lower part of the esophagus or cardia. Period of re-stenosis was from 2 to 12 months, an average of 5.7 months. The period of re-stenosis in the upper and middle part of the esophagus is 4 months, while in cases of tumor localization in the lower part of the esophagus or cardia is 6 months. In almost cases palliation was successfully achieved with re-intervention. Five patients required several sessions of argon-plasma coagulation an average one time in 3-4 weeks.

Conclusion: The use of SEMS in patients with advanced esophageal cancer, with an expected long-term survival, is associated with an increased risk of re-stenosis by tumor overgrowth. Period of re-stenosis was an average of 5.7 months. The direction of spread tumor after stenting and the time of dysphagia recurrence correspond to localization of the tumor. This complication is not fatal and managed by endoscopic methods.

Disclosure of Interest: All authors have declared no conflicts of interest.
available in many centers and have revolutionized the management of iatrogenic bile duct and vascular injuries.

**Aims & Methods:** Evaluate the role of intervention radiology procedures to manage different post-cholecystectomy complications focusing on the novel techniques to improve the final outcome. From June 2014 to June 2016, 30 patients post-cholecystectomy complications were referred to interventional radiology unit in our university hospital. They were 9 males and 21 females (age range: 18–66 years). Patients presented with biliary leaks (n = 12), benign biliary strictures with intrahepatic biliary dilations (n = 21), postoperative hernia (n = 2), bleeding related to hepatic artery pseudo-aneurysm (n = 1). Different types of interventional procedures were performed, including: Percutaneous trans-hepatic drainage (PTD) (n = 16), sequential dilatation of benign stricture with increasing calibre catheters over 6 months followed by manometry studies before catheter withdrawal (n = 6), biliary stenting with plastic stent (n = 2). Insertion of pigtail catheter (n = 15), preoperative progressive pulmonary-peritoneum for their adhesiolysis effect to manage post-operative huge incisional hernias before their surgical repair (n = 1), and selective embolization of bleeding hepatic arterial pseudo-aneurysm (n = 1) using tissue adhesive (n-Buty 2 Cyanoacrylate).

**Results:** All percutaneous procedures were technically successful. No recorded complications. No major complications or death in this cohort of patients. No recorded bleeding related hepatic artery pseudo-aneurysm (n = 3), no pneumo-peritoneum for their adhesiolysis effect to manage post-operative huge incisional hernias (n = 2). Manometric studies before catheter withdrawal (n = 3), hospital acquired infection (n = 2), Insertion of pigtail catheter (n = 5), preoperative progressive pulmonary-peritoneum for their adhesiolysis effect to manage post-operative huge incisional hernias (n = 1), selective embolization of bleeding hepatic arterial pseudo-aneurysm (n = 1) using tissue adhesive (n-Buty 2 Cyanoacrylate).

**Conclusion:** Minimally invasive interventions were valuable techniques in the management of different post-cholecystectomy complications. In fully equipped centers, expert multidisciplinary teams would achieve high cure rates for iatrogenic biliary injuries.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

P1594 PROGNOSTIC SIGNIFICANCE OF CARDIORESPIRATORY FITNESS, BODY COMPOSITION ANALYSIS, AND SYSTEMIC INFLAMMATORY RESPONSE IN UPPER GASTROINTESTINAL CANCER

N. Pati1, P. Bláke2, J. Wheat1, C. Brown1, A. Powell1, T. Abdelrahman1, W. Lewis1
1General Surgery, University Hospital Wales, Cardiff/United Kingdom

Contact E-mail Address: neilrama@hotmail.com

Introduction: Malnutrition is associated with higher rates of operative morbidity and therefore represent potentially reversible prognostic risk factors. Bioelectrical Impedance Analysis (BIA) is a non-invasive, reproducible and simple means of accurately measuring body composition.

Aims & Methods: The aim of this study was to assess the prognostic value of body composition variables determined objectively by bioelectrical impedance analysis (BIA) and subjectively by assessing potentially curvilinear surgery in the patients with oesophageal (OC) and gastric cancer (GC) within an enhanced recovery programme (ERP).

Consecutive 168 OG patients [median age 65 (24–86) yr., 131 male, 105 OC, 64 GC, 157 ACA, 8 SCC, 3 Neuroendocrine] underwent preoperative measurement of systemic inflammatory response [SIR, including FBC, CRP, Albumin, and modified Glasgow Prognostic Score (mGPS)]. Patients underwent multi-frequency (0.5 kHz, 50kHz and 100kHz) BIA assessment using a Maltron Bioscan 920 (Maltron International Ltd, Essex, UK), and Cardio Pulmonary Exercise (CPEX) assessment was performed selectively (70 OC, 27 GC). Primary outcome measure was Clavien Dindo (CD) morbidity severity score (MSS) of ≥3.

Results: Oesophagectomy was performed in 106, gastrectomy in 64, and laparotomy only in 25 patients. Postoperative morbidity and mortality occurred in 75 (8.6%) patients, and GC versus OC had a significantly higher incidence of postoperative complications (P=0.002). On univariable analysis, MSS ≥3 was associated with anaerobic threshold (p=0.011), CRP (p=0.001), mGPS (p=0.011), intra-cellular water (ICW, p=0.041), and extracellular water content (p=0.015). Multivariable binary logistic regression revealed ICCW content [ICW vs. UQ CD ≥ 3, 5 vs. 3%, OR 1.22 (95% CI 1.06–1.41) p=0.006] and CRP [ICW vs. UQ CD ≥ 3, 7 vs. 37%, OR 1.03 (99-106) p=0.076] to be independently associated with MSS.

Conclusion: Seven-fold variation in morbidity severity was observed after OG cancer surgery and SIR were the only significant prognostic indicators.

Disclosure of Interest: All authors have declared no conflicts of interest.

Multivariable binary logistic regression revealed ICCW content [ICW vs. UQ CD ≥ 3, 5 vs. 3%, OR 1.22 (95% CI 1.06–1.41) p=0.006] and CRP [ICW vs. UQ CD ≥ 3, 7 vs. 37%, OR 1.03 (99-106) p=0.076] to be independently associated with MSS.

Conclusion: Seven-fold variation in morbidity severity was observed after OG cancer surgery and SIR were the only significant prognostic indicators.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results: Thirty-two patients completed the questionnaires after surgery. Mean COPE-NVI scales were: SS =22.3 (SD 9.5), AS =23.2 (SD 4.8), PA =30.8 (SD 7.9), PO =22.5 (SD 8.8), TO =22.1 (SD 6.0).

Comparison of manual counting to the computed methods showed mostly excellent accuracy of the obtained results using intraclass correlation with reliability analysis (ICC) and coefficient B with linear regression (B):

mCRC OvCa HCC PCa
ZC ICC = 0.926, B = 0.968 ICC = 0.897, B = 0.968 ICC = 0.869, B = 0.621 ICC = 0.601, B = 1.200
ISCC = 0.973, B = 0.851 ICC = 0.992, B = 0.503 ICC = 0.990, B = 1.060 ICC = 0.934, B = 0.914
IA/ICC = 0.986, B = 0.945 ICC = 0.990, B = 0.660 ICC = 0.955, B = 0.723 ICC = 0.932, B = 0.327

Results: Quantification results from 2 blinded observers for reliable detection of hot spots were 0.949 in mCRC, 0.843 in OvCa, 0.805 in HCC and 0.957 in PCa. The ICC for the ratio of CD8/CD3 in 1 hot spot compared to the average from 3 hot spots was consistent in all groups. The absolute cell count in 1 vs 3 hot spots (CD3+/CD8+) showed a percentage agreement ≥ 0.750 in all groups yielding consistencies. The results were consistent in all groups. IAC reached excellent reliability in frozen sections and HCC but not in PCa (Table). High infiltration of CD3+ lymphocytes correlated significantly with improved DFS in HCC (p =0.016) and PCa (p =0.001) as well as improved OS in PCa (p =0.046). High infiltration of CD8+ lymphocytes correlated significantly with improved DFS in HCC (p =0.028) and OS in PCa (p =0.006).

Conclusion: In this study we introduced a systematic way to count tumor stroma cells in frozen and paraffin sections. Some rules should be observed: First, subjective selection of hot spots by 1 observer is acceptable. Second, if a ratio is to be determined, quantification of 1 hot spot is sufficient. If the absolute cell count is to be determined, quantification of 3 hot spots is recommended. Third,
P1598 LIVER RESECTION IN OBESE PATIENTS WITH HEPATOCELLULAR CARCINOMA

Hepato-biliary-pancreatic Surgery, Hyogo College of Medicine, Hyogo/Japan
Contact E-mail Address: iwamasm33bb@hotmail.com

Introduction: Liver disease has been recognized as a risk factor for hepatocellular carcinoma (HCC). On the other hand, there are few reports concerning liver resection (LR) in obese patients.

Aims & Methods: We performed curative LR in 471 patients with HCC between 2006 and 2015. In this study, we defined an obesity as no less than 25 of body mass index (BMI). We compared clinicopathological findings, operation details, and surgical outcomes of the obese and non-obese patients. Furthermore, we assessed the safety and the benefit of laparoscopic partial hepatectomy and left lateral segmentectomy in the obese patients.

Results: Among 471 patients, 123 patients (26.1%) were defined as obese. Among them, 20 patients (4.2%) showed no less than 30 of BMI. Diabetes, hypertension, and hyperlipidemia were significantly more common, and the patients with hepatic steatosis were significantly more in the obese patients group than in the non-obese patients group (p < 0.05). The two groups showed no differences in the liver function tests except the indocyanine green retention rate at 15 minutes. There were no significant differences between the two patients group in the number of tumors, diameter of tumor, prevalence of cirrhosis, frequency of portal invasion, the operative procedure, operative duration, blood loss, incidence of postoperative complications, postoperative hospital stay, and in-hospital mortality (3.3% vs. 14.4%). No significant difference was found in relapse-free survival rate, or overall survival between the two groups, too. Thirteen patients underwent laparoscopic surgery, and 34 patients had open surgery. The two groups showed no difference in the background, including BMI. However the operation time (265 min vs. 397.3 min) and the postoperative hospital stay (14 days vs. 18 days) were significantly shorter, and the blood loss (50 ml vs. 600 ml) was less in the laparoscopic surgery group than in the open surgery group (p < 0.05).

Conclusion: Liver resection in the obese patients with HCC was safe, and laparoscopic liver resection might be more useful for reducing the surgical stress and reducing the hospital stay.

Disclose of Interest: All authors have declared no conflicts of interest.

P1599 TIMING OF ELECTIVE CHolecystectomy AFTER ACUTE CHolecystitis - A POPULATION-BASED STUDY

A. Popowiec, G. Sandblom
Department Of Clinical Science, Intervention And Technology, Karolinska Institute, Stockholm/Sweden
Contact E-mail Address: agnieszka.popowiec@ki.se

Introduction: Acute cholecystitis is treated as acute cholecystitis is standard of care. However, many patients are still treated conservatively and undergo elective cholecystectomy 2-12 weeks following the primary admittance is postulated as a good timing for an elective surgery but there are no studies on the optimal timing for delayed cholecystectomy.

Aims & Methods: The aim of our study was to determine when it is most advantageous to perform a delayed surgery in case of a secondary diagnosis of acute cholecystitis. All patients treated for acute cholecystitis in Sweden during the years of 2005 and 2013 were identified through the Swedish Inpatient Register. This cohort was cross-linked with the Swedish register for gallstone surgery. Comparison on surgical outcome was retrieved with definition of a new annulament of endotherapy dedicated to such complications. In cases of post laparoscopic sleeve gastrectomy leaks, a shift is ongoing between closure or diversion methods (Ovesco, clips, covered self expandable metal stents (SEMS)) and internal drainage (double pig tail stents). Two large studies have just reported a high efficiency and a low complication rate with internal drainage with double pig tail stents for post sleeve gastrectomy leaks. No data are available for such an endoscopic internal drainage in fistulas of the upper digestive tract not linked to bariatric surgery. Here we report the results of a pilot bi-centre retrospective study.

Aims & Methods: A retrospective study of all upper digestive tract leaks not linked to bariatric surgery and treated by double pig-tail stent (DPTS) in two

P1600 MIXED REALITY SURGERY USING CT-BASED PATIENT-SPECIFIC IMMERSIVE 3D Holograms ENHANCED SPATIAL AWARENESS IN HEPATO-PANCREATO-BILIARY AND GASTROINTESTINAL SURGERY

M. Sugimoto
Graduate School Of Health Welfare Science, International University of Health Welfare, Tokyo/Japan
Contact E-mail Address: sugimotomaki@mac.com

Introduction: We developed a CT-based patient-specific holographic surgical simulation navigation system of immersive mixed reality (MR).

Aims & Methods: The aim of this study is to identify its benefit of simulating, analyzing and evaluating operative surgical treatment options in gastrointestinal and hepatopancreato-biliary surgery.

We used our original immersive MR application using HoloLens, that is a pair of MR smartglasses built-in head-mounted display. By reconstructing the patient-specific 3D surface polygons of each organ out of the patient’s MDCT images, MR anatomy was displayed on the grass three-dimensionally during actual surgical navigation. Pre- and intra-operative imaging with better visualisation of the surgical anatomy and spatial awareness with visualisation of surgical instruments in relation to anatomical landmarks.

Conclusion: We report illustrative benefits of the immersive MR in surgical planning, simulation, education, and image-guided navigation. These could overcome the limitations of the conventional image-guided surgery.

Disclose of Interest: All authors have declared no conflicts of interest.

P1602 EFFICACY OF DOUBLE PIGTAIL STENT FOR POST OESO-GASTRIC SURGICAL LEAKS NON-LINKED TO BARIATRIC SURGERY: A PILOT BI-CENTRE RETROSPECTIVE STUDY

1Department of Digestive Surgery, CHU Limoges, Limoges/France
2Department of Digestive Surgery, CHU Limoges, Limoges/France

Contact E-mail Address: la.pagnon@gmail.com

Introduction: Post-surgical leaks are the first complication after non-bariatric oeso-gastric surgery in terms of frequency and morbidity. Anastomotic fistula changes the prognostic of the operated patient increasing the length of stay, increasing costs, increasing mortality and increasing risks of oncological recurrence. Surgery is still a possibility of treatment in particular in case of severe sepsis but the role of endotherapy involved with definition of a new annulament of endotherapy dedicated to such complications. In cases of post laparoscopic sleeve gastrectomy leaks, a shift is ongoing between closure or diversion methods (Ovesco, clips, covered self expandable metal stents (SEMS)) and internal drainage (double pig tail stents). Two large studies have just reported a high efficiency and a low complication rate with internal drainage with double pig tail stents for post sleeve gastrectomy leaks. No data are available for such an endoscopic internal drainage in fistulas of the upper digestive tract not linked to bariatric surgery. Here we report the results of a pilot bi-centre retrospective study.

Aims & Methods: A retrospective study of all upper digestive tract leaks not linked to bariatric surgery and treated by double pig-tail stent (DPTS) in two
Introduction: Abdominal compartment syndrome (ACS) is serious complication of big number of surgical interventions. According the data of the World Society of the Abdominal Compartment Syndrome (WSACS), rate of mortality without treatment is more than 90%, after treatment from 25% to 75% [1]. Patients with ruptured abdominal aortic aneurysms (rAAA) are the group of high risk regarding this complication. Rate of incidence ACS at these patients is between 8% to 25%[2]. According to data of various authors, from one third to one half of them have died [3]. One of the main cause of this is the absence of good monitoring of intraabdominal pressure in this group of patients[4]. Currently, we have one effective way of treatment of ACS pathology: decompressive laparotomy[5]. But prophylaxis becomes more important point, if we take to attention mortality after start the develop of abdominal compartment.

Aims & Methods: We aimed to investigate the impact of implantation polypropylene mesh in abdominal wall on rate of development ACS and it severity for patients after open repairing of ruptured abdominal aortic aneurysm. Patients with rAAA (total amount n=87 patients) were operated in standard volume. Before finish of surgery in study group (n=49, 34 males, 15 females, average age 68 years (range: 23–86)) was after start the develop of abdominal compartment syndrome (ACS, IAP more than 25 Hgmm). Decompressive laparotomy was performed in one case with satisfactory result. In general, mortality in study group was 18.4% (9 cases). In control group we fixedated 9 cases of ACS (23.7%), including 3 cases of light ACS (intraabdominal pressure (IAP) – 12–15 mmHg), 2 cases of moderate ACS (IAP 16–20 mmHg), and 3 cases of severe ACS (IAP 21–25 mmHg). Decompressive laparotomy was performed in one case with severe ACS (IAP more than 25 Hgmm). Decompressive laparotomy was performed in three cases, satisfactory result was achieved in one case, in two cases patients have died from polyorgan insufficiency. In general, mortality in control group was 28.9% (11 cases). We did not find any specific complication, related with implantation of polypropylene mesh during all three years of follow-up.

Conclusion: 1. Implantation of polypropylene mesh is a safe and effective procedure for prophylaxis of ACS for patient with rAAA. 2. Implantation of mesh allows to avoid ACS for patient with rAAA and related with it complication and outcomes. 3. It is possible to implantate polypropylene mesh for other desease, not only for rAAA, but this point requires further investigations.

1 Department of Biochemistry; 2 Department of Gastroenterology, Medical University of Lodz, Lodz, Poland

Results: Eight patients underwent surgical correction of ileostomy leak. At endoscopy, the ileostomy was closed by performing a mucosectomy with endoscopic forceps. Five patients had no signs of peritonitis and were discharged within the first 24 hours. Two patients developed abdominal infection and underwent surgery. One patient required a percutaneous drainage procedure due to an abdominal abscess.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1606 BODY COMPOSITION AS A PREDICTOR OF MORBIDITY AND MORTALITY FOLLOWING BILIPANCREATIC CANCER SURGERY

M.P.C. Santos1, S. Velloso2, C. Cunha2, F. Costa2, L. Agostinho2, R. Cruz2, R. Maio3
1 Gastroenterology Service, Hospital Beatrice Angelo, Loures/Portugal; 2 Hospital da Luz, Lisboa/Portugal

Introduction: The impact of body composition on the outcomes following pancreaticoduodenectomy is still unclear.

Aims & Methods: The aim of this study was to analyze the association between body composition parameters and postoperative complications and 90-day mortality in patients undergoing bilipancreatic cancer surgery. Retrospective study of patients with pancreatic, ampullary or bile duct carcinoma that underwent surgery between March 2012 and October 2016. Body composition (skeletal muscle mass, abdominal fat area, subcutaneous fat area and muscle radiation attenuation) was assessed in diagnostic or staging computed tomography (CT), in axial images at the level of the third lumbar vertebra.

Postoperative complications were recorded according to Clavien-Dindo classification and categorized as minor (grade I-II) and major (grade IIIb).

Results: Fifty-nine patients were analyzed and 11 were excluded due to unavailable CT scan at our institution. Forty-eight were included, 28 were men, with a mean age of 70.8 ± 8.5 years. The incidence of major complications was 25% and 90-day mortality was 8.3%. On simple logistic regression of factors associated with major complications skeletal muscle area (OR 0.97, 95% CI 0.94–1.00, P = 0.09) and index (OR 0.91, 95% CI 0.81–1.00, P = 0.09) showed a trend for a protective effect. On multivariate logistic regression skeletal muscle area index was a protective factor (OR 0.89, 95% CI 0.79–0.99, P = 0.05) and longer surgery (OR 1.01, 95% CI 0.99–1.03, P = 0.07) was associated with higher incidence of major complications. The receiver-operator characteristic (ROC) curve showed an acceptable power of discrimination major complications using a model with skeletal muscle index and surgery duration as independent variables (area under the curve of 0.736). On simple logistic regression surgery duration (OR 1.02, 95% CI 1.00–1.06, P = 0.05), visceral fat area (OR 1.02, 95% CI 1.00–1.04, P = 0.02) and visceral fat index (OR 1.05, 95% CI 1.00–1.10, P = 0.04) were associated with higher 90-day mortality whereas muscle radiation attenuation had a protective effect (OR 0.88, 95% CI 0.76–0.99, P = 0.05).

Conclusion: These results suggest that low values of skeletal muscle and muscle radiation attenuation, as well as high values of visceral fat and lower muscle radiation attenuation, are associated with worse clinical outcomes following bilipancreatic cancer surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1607 GASTROSCHISIS: A 16-YEAR STUDY

A.M. Bradeanu 1, L. Balanescu 2, I. Nenciu 3
1 Neonatal Intensive Care Unit, Emergency Children’s Clinical Hospital “G. Alexandrescu” Bucharest, Bucharest, Romania; 2 Pediatric Surgery, Emergency Children’s Clinical Hospital “G. Alexandrescu” Bucharest, Bucharest, Romania; 3 Emergency Casualty, Emergency Children’s Clinical Hospital “G. Alexandrescu” Bucharest, Bucharest, Romania

Introduction: Gastroschisis is a ventral body wall defect through which protrude mainly large and small intestines. The disease’s clinical course and prognosis depend on both surgical techniques, severity of the defect, accompanying anomalies and complications.

Aims & Methods: We performed a retrospective study based on the analysis of patients records admitted to our hospital Neonatal Intensive Care Unit between January 2000 and December 2016. The aims of this study was to evaluate defect’s incidence, management and outcome of patients with gastroschisis in our institution.

Results: During the period 2000–2016 the overall incidence of gastroschisis in our NICU was 1.25/10,000 births (95% CI 1.13–1.37). The defect was diagnosed in 140 cases (7.83%). In 124 cases (8.86%) the abdomen was closed prenatally. In 7 cases (0.3%) the diagnosis was made after birth (due to failure of skin closure). The average birth weight was 3.5 weeks and the average birth weight was 2270 g. The abdominal wall defect was identified in antenatal period only in 15.4% of cases. Also, 23 patients (16.4%) presented other associated anomalies: 12 cases with cardiac anomalies, 3 cases with major anomalies of abdominal wall and 5 cases with cardiac defects. Surgical techniques performed for abdominal defect closure were: primary closure in 35 cases (25%), staged closure in 12 cases (8.57%), complex technique in 44 cases (31.4%) and manual reduction in 49 cases (35%). The average period of surgical pause was 12.9 days and the mean length of stay in NICU was 30.4 days. Patients were mechanically ventilated for an average period of 4.6 days. The most frequent complication was late-onset sepsis (37.8%); also 26 neonates (18.5%) underwent mechanical ventilation and 20 neonates (14.3%) remained with short bowel. The average mortality in our group was 33% but it constantly decreased over the years (from 84% in 2000 to 11% in 2016). Sepsis, prematurity, low birth weight and associated defects were identified as major risk factors for the unfavorable outcome (especially small area of abdominal wall).

Conclusion: The management of neonates with gastroschisis depends on several factors including the status of herniated organs, the size of abdominal cavity, the presence of other associated congenital anomalies and last but not least on the resources and experience of the neonatal interdisciplinary team. Significant changes occurred in the management of gastroschisis in our Unit and as consequence, the outcome of patients with gastroschisis has dramatically improved during the studied period.
Disclosure of Interest: All authors have declared no conflicts of interest.

Abstract: P1608

Assessing the effect of ethnicity on urinary metabolic profiles in inflammatory bowel disease

Introduction: Urinary metabolic profiling has been shown to distinguish patients with inflammatory bowel disease (IBD) from healthy controls (HC), and also separate ulcerative colitis (UC) from Crohn’s disease (CD) in Caucasian (Cau) cohorts (1). Diet and lifestyle also have an effect on metabolic profiles (2), and clinical phenotype varies between Caucasians and South Asians (SA)(3), however discriminative metabolites have not been studied in different ethnic populations. The aim of this study was to compare the urinary metabolic profiles of IBD patients and healthy controls from Caucasian and South Asian backgrounds.

Methods: Samples from 405 IBD patients (283 Caucasian and 122 South Asian) and 137 healthy controls (98 Caucasian and 48 South Asian) were analysed by H1NMR spectroscopy. Clinical and dietary data were collected. Orthogonal partial least squares discriminant analysis (OPLSDA) was performed to examine whether there were differences in metabolic data between Cau and SA. R2 (variance), Q2 (quality assessment) and p values (validity) for each model were described.

Results: The phenotype of South Asian Crohn’s disease was not significantly different to Caucasian Crohn’s disease in this cohort. In the South Asian UC group there was more pancolitis (p = 0.051) and less proctitis (p = 0.008). There were more vegetarians in the South Asian group. OPLSDA was able to separate patients with IBD from healthy controls, and also UC from Crohn’s disease, in the Caucasian cohort, but this separation could not be replicated in South Asians (negative Q2 values).

Conclusion: The separation between Caucasian and South Asian healthy controls may reflect differing lifestyles including diet. Caucasian IBD patients could be separated from healthy controls, and Crohn’s disease from UC, replicating previous studies. South Asian IBD patients could not be separated from healthy controls which may be due to lower numbers of South Asian patients in this study, and specifically less Crohn’s disease patients where stronger discriminating models have been shown in Crohn’s disease in previous studies. In Crohn’s disease, Caucasians and South Asians could be separated, but Caucasian and South Asian patients could not be distinguished in the UC cohort, possibly suggesting the metabolic milieu in Crohn’s disease is stronger and less influenced by the impact of ethnicity.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
antibiotics (including sulfasalazine), probiotics or fiber supplements were required. A 7-day run-in, subjects were fed study meals high (11 g oligo-saccharides, 2 g resistant starch) or low (<1 g) in fermentable fiber over a 12-h period before ingesting the pH-motility capsule, subjects then crossed over to the other diet 3 days after passage of the capsule. Endpoints were diet-associated differences in overall, caecal and distal colonic pH, and colonic transit time (CTT), taken as time between the ileo-caecal junction and capsule exit. Caecal pH was defined as the minimum pH following passage through the ileo-caecal junction whereas maximum pH was arbitrarily used as distal colonic pH.

Results: 15 UC patients (aged 24–72 y; 9 males) and 9 controls (aged 22–69 years, 4 males) were studied. A decrease in overall and distal colonic pH was observed in controls with high vs low fiber diet (Table 1). In UC patients, a high fermentable fiber intake reduced caecal pH but paradoxically tended to increase distal colonic pH. A significant association was observed for UC extent and changes in overall (r = 0.81; p < 0.001, Spearman’s correlation) and caecal pH (r = 0.53; p = 0.04) after a high fermentable fiber diet (Figure 1). No differences in CTT were observed between diets in either cohorts but subgroup analysis in the UC cohort showed heterogeneous responses to a high fermentable fiber diet. 64% patients had slower CTT whilst 36% had unchanged or faster CTT. In contrast, majority (63%) of controls had no changes in CTT after a high fiber diet.

Conclusion: A high fermentable fiber diet partially increased colonic fermentative activity in patients with quiescent UC compared to controls. Moreover, contrary to controls, UC patients exhibited an increase in distal pH and heterogeneous colonic transit responses after a high fermentable fiber intake. Our findings suggest that abnormalities in motility and regional defects in the function of the colonic microbiota exist despite quiescent disease.

Introduction: Microbial dysbiosis has in the gut has been suggested to play an important role in the pathogenesis of inflammatory bowel disease (IBD).

Aims & Methods: In this study, we aimed to analyze the fecal microbiota in Chinese patients with IBD. Fecal samples from 15 patients with Crohn’s disease (CD), 14 patients with ulcerative colitis (UC) and 13 healthy individuals were subjected to 16S rDNA sequencing. The V4 hypervariable regions of 16S rDNA were sequenced by the Illumina MiSeq2500 platform. Quality control and operational taxonomic units (OTUs) were calculated with QIIME software. Bacterial communities were subjected to 16S rDNA sequencing. The V4 hypervariable regions of 16S rDNA were sequenced by the Illumina MiSeq2500 platform. Quality control and operational taxonomic units (OTUs) were calculated with QIIME software.

Disclosure of Interest: We sought to elucidate the effects of iron supplementation on hypoxia-mediated responses in the intestinal epithelium. For this purpose, serum-starved Caco-2 monolayers were subjected to normoxia (21% O2) or hypoxia (0.2% O2) in the presence and absence of ferric ammonium iron citrate (FAc) and the iron chelator deferoxamine (DFo). Total RNA was isolated and changes in the expression of tumor necrosis factor (TNF), interleukin (IL)-1β, TIMP-1, and TNF was assessed by real-time quantitative PCR. Western blot analysis was performed with antibodies against ferritin, p-NFκB-p65, HIF-1α, p-mTOR, p62 and LC3. mRNA synthesis in Caco-2 cells under hypoxia was blocked using actinomycin D. Chromatin immunoprecipitation experiments were carried using antibodies against NF-κB and primers for p-mTOR and blocked autophagy. Iron overload led to low oxygen tension are mediated through hypoxia inducible factor (HIFs), which are tightly regulated by oxygen and iron levels through the action of hydroxylases. Dietary iron is mainly absorbed by duodenal enterocytes through the divalent metal transporter (DMT)-1. Once iron is inside the enterocytes, it is either sequestered into ferritin or transported out of the enterocyte into the circulation by ferroportin (FPN). Regulation of uptake, storage and export of iron is mediated by signals reflecting oxygen and intracellular iron levels in enterocytes, and systemic iron requirements. Central to systemic iron regulation is the liver hormone hepcidin, which regulates and is regulated by systemic iron levels. Hepcidin expression is induced by cytokines and results in anemia of inflammation.

Introduction: Environmental hypoxia has been established to influence the development of inflammatory bowel disease (IBD). Adaptive responses to low oxygen tension are mediated through hypoxia inducible factor (HIFs), which are tightly regulated by oxygen and iron levels through the action of hydroxylases. Dietary iron is mainly absorbed by duodenal enterocytes through the divalent metal transporter (DMT)-1. Once iron is inside the enterocytes, it is either sequestered into ferritin or transported out of the enterocyte into the circulation by ferroportin (FPN). Regulation of uptake, storage and export of iron is mediated by signals reflecting oxygen and intracellular iron levels in enterocytes, and systemic iron requirements. Central to systemic iron regulation is the liver hormone hepcidin, which regulates and is regulated by systemic iron levels. Hepcidin expression is induced by cytokines and results in anemia of inflammation.

Results: Hypoxia induced the mRNA expression of TNF and IL-1β concomitantly with the iron transporters DMT-1 and FPN. Moreover, we found that the abundance of 8 genera in CD and 23 genera in UC, particularly the Escherichia genus, were significantly different when comparing with controls. We next surveyed the taxonomies composition distribution between different phases of disease, detecting that the abundance of the Bacteroidetes was significantly decreased in active CD group compared with inactive CD group. However, the Proteobacteria was only nominally increased in active CD relative to inactive CD, which did not hold significance after correction. Furthermore, the relative abundance of the Bacteroidetes, especially the

Bacteroides, was negatively correlated with the calculated Crohn’s disease activity index (CDAI), indicating that the Bacteroides could be related with the disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: In both forms of inflammatory bowel disease (IBD), Crohn’s disease (CD) and ulcerative colitis (UC), inflammation of the gut wall is associated with extracellular tissue acidification. Low extracellular pH stimulates the family of proctosensing G-protein coupled receptors (GPCRs); ovarian cancer G-protein coupled receptor 1 (GPR1), T-cell death-associated gene 8 (TDA8) or G-protein and G-protein coupled receptor 4 (GPR4), which activate second messenger signaling cascades. Recent studies reported a link between IBD and this family of pH-sensing receptors; in genome-wide association studies (GWAS), TDA8 has been identified as an IBD-risk gene. The mechanism behind the interaction between treatment groups (5-ASA, Azathioprine and Steroids) and disease activity; OGR1 and TDAG8 are alleged to act in opposition by regulation of the inflammatory response; enhancing or inhibiting inflammatory pathways respectively, however the interplay between OGR1 and TDA8 is unclear.

Aims & Methods: In this study we aim to investigate the role of OGR1 in IBD patients. Expression of OGR1 in surgical specimens from non-IBD (n = 5), CD (n = 10) and UC (n = 10) patients showed similar samples taken from the same time, from non-inflamed and inflamed intestinal tissue from IBD patients showed stronger OGR1 staining in the inflamed mucosa compared to the non-inflamed mucosa. Accordingly, mRNA and protein expression of OGR1 was significantly increased in IBD compared to non-IBD patients. A significant positive correlation was observed between OGR1 expression and the clinical score in both the non-inflamed (rs 0.731, p = 0.0069) and the inflamed mucosa (rs 0.7698, p = 0.0034).

Conclusions: The expression of OGR1 is significantly increased in patients with IBD. OGR1 expression correlates with IBD disease activity, suggesting an active role of OGR1 in IBD pathogenesis. OGR1 appears to be a therapeutic target among the pH-sensing receptors involved in IBD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Increased Bifidobacteria and Lactobacilli in the SA group is consistent with the previous study. A possible explanation is the consumption of fermented foods in the SA group although there was no difference between healthy SA and Caucasian controls. There is a trend towards lower diversity in the SA group and reduced Bacteroidetes which are consistent with the UC dysbiosis described in the literature. Functional analysis of this unique microbial profile through metagenomic and metabolomic techniques may explain the different disease behaviour in the SA group.
P1615 SUPPRESSION OF PHOSPHOLIPASE A2 OF INTESTINAL MICROBIOTA AMELIORATES MUCOSAL INFLAMMATION IN A GENETIC MOUSE MODEL OF ULCERATIVE COLITIS

Introduction: Bacterial phospholipase A2 activity has been implicated in the pathogenesis of IBD. We evaluated whether the inhibition of the bacterial ectolphospholipase A2, which is likely responsible for the liberation of tissue deactivating pro-inflammatory phospholipids, might have an impact on experimental colitis.

Methods: We compared two groups of 10 female C57Bl/6 mice each, with either wild-type (WT) or STAT6 (-/-) mice, receiving a high phospholipid diet (HFD). On day 21 of age, the WT mice were treated with the bacterial phospholipase A2 inhibitor UDCA-LPE and the STAT6 (-/-) mice with saline. In order to inhibit bacterial colonization, each group of mice was treated with 1 mg of 10% Vancomycin i.p. twice a day. Body weight, stool consistency, stool calprotectin and stool macroscopic morphology were evaluated until day 7. The mice were sacrificed on day 7, and their colons were analyzed histologically

Results: Stool calprotectin levels were significantly reduced in the UDCA-LPE treated WT mice compared to saline treated WT mice. Histological analysis revealed reduced inflammatory changes in the UDCA-LPE treated WT mice compared to the saline treated WT mice. The bacterial ectolphospholipase A2 activity helps to improve mucosal inflammation in a genetic mouse model of UC.

Aims & Methods: Our results confirm the findings that the inhibition of cyclooxygenase activity reduces mucosal inflammation in a genetic mouse model of UC. It is assumed that the inhibition of bacterial phospholipase A2 activity reduces mucosal inflammation in a genetic mouse model of UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1617 B2-STRUCTURING AND B3-PENETRATING PHENOTYPE IN CROHN’S DISEASE: CHANGING DIRECTION OF MACROPHAGES POPULATION AND WNT SIGNALING

Introduction: Macrophages contribute to fibrosis through the release of different mediators and the pattern of secretion may vary according to their phenotype. Recent evidences have identified Wnt pathway as an emerging modulator of fibrosis.

Aims & Methods: The aim of the present study is to analyze the pattern of expression of macrophage markers and Wnt ligands in surgical resections from Crohn’s disease (CD) patients with different disease behavior. CD patients were categorized according to Montreal classification (age at diagnosis, location and behavior). mRNA was isolated from resections presenting an strictureting (B2) or a penetrating (B3) behavior and described using qPCR variations in the levels of macrophage markers (CD68, CD163, Arginase). The expression of macrophage markers (CD206, CD68, iNOS, Arginase), Wnt ligands (Wnt1, Wnt2, Wnt3, Wnt4, Wnt5a, Wnt5b, Wnt6, Wnt7a, Wnt8a, Wnt9b, Wnt10b, Wnt16 and DKK1) and DKK1 (inhibitor of Wnt signaling) was analyzed by RT qPCR.

Results: B2-patients seem to present a higher infiltration of macrophages since increased expression of markers classically used to detect pro-inflammatory (CD68) and regulatory/pro-resolving/pro-fibrotic phenotypes (CD206, ARG1) was detected in this group. These patients also presented a generalized overexpression of Wnt ligands together with augmented DKK1 mRNA levels. B2-patients showed a more complex situation with ligands that present increased (Wnt3), reduced (Wnt2B) or unchanged expression in the absence of significant variations in the levels of macrophage markers (Table). Table. Relative Gene expression fold induction vs control group of genes with detectable levels. Data are expressed as Mean±SEM in n≥7 in all groups and analyzed by ANOVA + Kewman-Keuls test. (*P<0.05 vs control, **P<0.05 vs WT).

Conclusion: Crohn’s disease patients presenting a strictureting (B2) or a penetrating (B3) behavior undergoing surgical resection differ in the pattern of macrophage infiltration and Wnt signaling.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1616 THE IMPACT OF THE RS8005161 POLYMORPHISM ON G PROTEIN-COUPLED RECEPTOR GPR65 (TDAG8) PH-ASSOCIATED SIGNALING IN INTESTINAL INFLAMMATION

Introduction: Inflammatory bowel diseases (IBDs), Crohn’s disease (CD) and ulcerative colitis (UC), are typically associated with a decrease in local pH. This decline is likely due to decreased luminal pH (as measured in acidified stools) and increased uptake of luminal phospholipids. These two factors are known to be critical for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucosal layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity of the mucus layer which facilitates bacterial invasion. Concomitantly to phosphatidylcholine-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

Methods: PLA2 activity was inhibited by PLA2 (rs8005161) activity in isolated macrophages from UC patients while PLA2 activity improved mucosal inflammation in a genetic mouse model of UC. It is assumed that the remaining mucus PC shield is better preserved when luminal PLA2 is suppressed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1618 CD16 POSITIVE CELLS EXPRESS TGFβ AND MEDIATES MURINE INTESTINAL FIBROSIS

P. Salvador1, D. Ortiz-Masia1, D. Macias-Ceja1, L. Gisbert-Ferrándiz1, T. Delgado1, D. Ortiz-Masia1, J. Hernández1, J.V. Espallargues2, M. Gómez-Valle1

Introduction: M2 macrophages play a key role in injury repair and fibrosis. We have previously reported that STAT6 deficient murine macrophages mediate mucosal repair after TNBS-induced acute colitis in and that, in a chronic model, STAT6 deficient animals accumulate macrophages expressing the CD6 marker that promote intestinal fibrosis.

Aims & Methods: We aim to analyze whether the expression of the pro-fibrotic mediator TGFβ is related with this macrophage phenotype and the relevance of these cells in murine intestinal fibrosis. Murine peritoneal macrophages obtained from both WT or STAT6 (-/-) mice were treated with IL-4 (20 ng/ml), IL-10 (10 ng/ml) or vehicle and the mRNA expression of CD16 and TGFβ was analyzed 72h later by qPCR. IL-4 or STAT6 (-/-) mice were weekly administered with TNBS (0.5, 0.5, 0.75, 0.75, 1, and 1 mg, intrarectally) or saline and were sacrificed 7 weeks after the first TNBS administration. The mRNA expression of CD16, TGFβ, Vimentin, Coll1a1, e-SMAD, MMP2 and TIMP1 was evaluated in murine intestinal mucosa by qPCR. In all cases results were expressed as fold induction vs vehicle and the correlation between different measurements was analyzed using Pearson’s correlation coefficient (r).

Results: A positive and significant correlation between CD16 mRNA and TGFβ mRNA was observed in isolated macrophages from WT mice (r = 0.637, P = 0.03) and STAT6 (-/-) mice (r = 0.677, P = 0.002) receiving different treatments. In the mucosa of WT and STAT6 mice the expression of TGFβ showed a positive correlation with increased pH shifts and decreased with CD16 mRNA (r = -0.60, P < 0.001), and with the expression of several fibrotic markers (vimentin: r = 0.653, P < 0.0001; Coll1α: r = 0.5101, P = 0.0003; e-SMAD: r = 0.4126, P = 0.0048; MMP2: r = 0.5729, P < 0.0001; and TIMP1: r = 0.3958, P = 0.0071).

Conclusion: The expression of TGFβ is associated with CD16 positive cells and is involved in murine intestinal fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1619 GS-21, A7 NICOTINIC ACETYLCHOLINE RECEPTOR AGONIST, ATTENUATE DSS-INDUCED COLITIS BY IMPROVING INTESTINAL MUCOSAL BARRIER FUNCTION

Introduction: The intestinal inflammation is reduced by electrical stimulation of the different vagus nerves. Cholinergic neural output may be a target to minimize tissue damage in autoimmune disease. Cholinergic neural output may modulate innate immune responses through stimulation of α7 nicotinic acetylcholine receptors (α7nAChR). GS-21, a selective α7nAChR agonist, has previously demonstrated to inhibit the inflammation associated with rheumatoid arthritis (RA). In this study we investigate whether GS-21 protects against DSS-induced colitis and its potential mechanism.

Aims & Methods: Male BALB/c mice (8–10 weeks old, n = 32) were randomly divided into 4 groups: normal control group, DSS-induced group, GS-21 treatment control group (DSS-induced mice treated with GS-21), α-BGT group (DSS-induced mice treated with α-BGT and GS-21) (n = 8, each group). DSS group was given final concentration of 3.5% DSS drinking water, the treatment group was treated with GS-21 (20 mg/kg intraperitoneal injection per day, α-BGT group was pre-treated with α-BGT (0.1 mg/kg/day, intraperitoneal injection) for 30 min prior to GS-21 injection, and the control group received saline. Caco2 cells were randomly divided into 4 groups: normal control group, TNF-α-induced group, GS-21 treatment control group, α-BGT group. TNF-α group of Caco2 cells were exposed to 25 ng/ml TNF-α, GS-21 group were given 100 ng/ml GS-21 for 30 min prior to TNF-α; α-BGT group pre-treated with α-BGT (50 ng/ml) for 30 min prior to GS-21 injection. BAY 11-2058 (NF-κB inhibitor) group were given 50 ng/ml BAY-11-2058 for 30 min prior to TNF-α. Disease activity index, macroscopic scores, and colonic damage were determined. The intestinal permeability of mice was measured by fluorescent isothiocyanate-dextran (FITC-Dextran method. Western blot was used to detect the tight junction protein and NF-κB associated protein expression.

Results: Compared with DSS-induced mice, DAI score decreased and colon length improved after administration of GS-21 (9.1 ± 0.74 cm vs 6.85 ± 0.53 cm, P < 0.01). HA1 score decreased (1.25 ± 1.32 vs 10.5 ± 6.24 P < 0.05). The α7nAChR antagonist α-BGT can eliminate those protective effects (Figure 1).

2. The intestinal permeability improved after administration of GS-21 compared with DSS-induced mice (49.52 ± 28.59 μg/ml vs 157.40 ± 32.40 μg/ml P < 0.05), whereas α-BGT can block the effect (115.50 ± 10 μg/ml vs 49.52 ± 28.59 μg/ml P < 0.05) (Figure 2). The expressions and distribution of tight junction protein in DSS-induced mice were enhanced after treatment with GS-21 (p < 0.05) (Figure 4.5). GS-21 attenuated the NF-κB activation (p < 0.05) (Figure 3). α-BGT induced protein expression reversed the inhibitory effect of GS-21 (p < 0.05) (Figure 6). GS-21 improves the distribution of tight junction proteins in the intestinal epithelial cells induced by TNF-α (Figure 7). GS-21 reduces nuclear translocation of NF-κB in Caco2 cells induced by TNF-α (Figure 8).

Conclusions: These results provide proof of mechanism for the protective effects of GS-21 in mice and human Caco2 cells. The potential target for GS-21 is the tight junction protein.

Introduction: For inflammatory bowel disease (IBD), anaemia is the most frequent extra intestinal manifestation of the disease. We aimed to determine the prevalence of anaemia in IBD patients and followed up at our hospital from June 2015 to June 2016 (male: 254, female: 211, average age: 47 ± 14.4, Crohn disease (CD): 257, Ulcerative Colitis (UC): 208). According to WHO criteria, anaemia occurs when haemoglobin value is below 13 g/dL in men and 12 g/dL in women. For inflammatory bowel disease (IBD), anaemia is the most frequent extra intestinal manifestation of the disease (p < 0.001). CD involvement were as follows: 54.5% in ileal involvement, 37.1% in colonic involvement and 28.5% in ileocolonic involvement. Furthermore, 27.5% of UC patients had proctitis (E1) involvement while 41% of them had involvement in left colon (E2) and 31.5% had pancolitis involve. There was no significant relation between anemia frequency and duration of disease (p = 0.216). We specified the following types of anaemia: IDA only 32.9% (77), ACD only 7.6% (13), IDA and ACD combination 6.8% (16), anaemia stemming from B12/folic acid deficiency 6.4% (*), multiple anaemia 17.8% (**), anaemia with no etiology 30.7% (72). 50% of patients with anaemia received treatment; 23% of IBD patients had oral iron intake and 41% of them had parenteral iron treatment while 55% of patients who were suffering from megaloblastic anaemia got B12/folic acid treatment.

Results: In our study, we determined that 50.3% of total 465 patients had anaemia, which was more frequent in women than men (64% vs. 39%, p < 0.001). Anaemia frequency was higher in CH cases (57%) then in UC cases (41%) (p < 0.001). CD involvement were as follows: 54.5% in ileal involvement, 60.4% in colonic involvement and 58.5% in ileocolonic involvement. Furthermore, 27.5% of UC patients had proctitis (E1) involvement while 41% of them had involvement in left colon (E2) and 31.5% had pancolitis involve. There was no significant relation between anemia frequency and duration of disease (p = 0.216). We specified the following types of anaemia: IDA only 32.9% (77), ACD only 7.6% (13), IDA and ACD combination 6.8% (16), anaemia stemming from B12/folic acid deficiency 6.4% (*), multiple anaemia 17.8% (**), anaemia with no etiology 30.7% (72). 50% of patients with anaemia received treatment; 23% of IBD patients had oral iron intake and 41% of them had parenteral iron treatment while 55% of patients who were suffering from megaloblastic anaemia got B12/folic acid treatment.

For inflammatory bowel disease (IBD), anaemia is the most frequent extra intestinal manifestation of the disease. Conclusion: We found out that almost half of all IBD patients (50.3%), whom we followed up, had anaemia, the most frequent reason of which was IBD. Almost half of these patients received anaemia treatment. We should increase the treat-
ment rate in our IBD patients that have anaemia.

Contact E-mail Address: dulmaec@alumni.uv.es

Introduction: IBD is a chronic disorder of the gastrointestinal tract characterized by disruption of epithelial barrier function and gut inflammation. Evidence supports a role relevant of succinate, an intermediate of the tricarboxylic acid cycle, in inflammation and the succinate receptor, SUCNR1, has been recently been related with rheumatoid arthritis1.

Aims & Methods: To analyze the role of SUCNR1 in a murine model of colitis induced by TNBS. WT or SUCNR1−/− mice received TNBS (3.5 mg/20g mice, intrarectally) or vehicle (EtOH 40%) and were weighed daily (results are expressed as percentage vs the weight at day 0) and mice were sacrificed 2 and 4 days after TNBS administration. Colon length and mucosal histology were evaluated. In addition, succinate and succinate metabolites urine concentrations were also used to characterize the subpopulations of T cells (CD4+CD45RBhi vs CD4+CD45RBlow) two days after TNBS treatment.

Results: Treatment of mice with TNBS induced a loss of body weight that peaked 2 days after treatment. Subsequently, mice began to recover and, 4 days after treatment, body weight reached similar values to those of control animals. In TNBS-treated SUCNR1−/− mice compared with TNBS-treated WT mice: a) the loss of body weight was significantly (P < 0.05) attenuated (96.99 ± 0.7% vs 91.78 ± 1.1%); b) the reduction in colon length was prevented (6.6 ± 0.2 vs 5.2 ± 0.4 cm). The score was significantly reduced (3.5 ± 0.2 vs 4.8 ± 0.5) two days after TNBS treatment. d) the increase in the expression of pro-inflammatory molecules was significantly prevented (P < 0.05) (table 1) while no significant differences were detected in the expression of COX-2 (Table 2) (1) while no significant differences were detected in the expression of COX-2 (Table 2).

Table1: mRNA expression of different molecules detected in the colon of TNBS-treated mice. Results are expressed as fold induction vs the value obtained in WT mice.

P1623 ZIP7 INDUCES DISRUPTION OF THE INTESTINAL BARRIER THROUGH ACTIVATION OF ENDOPLASMIC RETICULUM STRESS IN INFAMMATORY BOWEL DISEASE
J. Sun, Q. Zhan, F. An
Wuxi People's Hospital, Nanjing Medical University, wuxi/China

Contact E-mail Address: jingdianying99@126.com

Introduction: Inflammatory bowel disease (IBD) is a chronic intestinal inflammato-
ry disease with a tendency to recurrence, and intestinal barrier disorder plays a key role in its development. The deficiency of zinc is a clinical manifestation and crohn's disease. The transport system of IEC6, Zinc Transporter Member 7 (ZIP7) is a gate keeper protein in the intracellular release of zinc in cells. Recent studies revealed that ZIP7 helps to maintain the intestinal mucosal integrity. In addition, ZIP7 can regulate endoplasmic reticulum stress.

Aims & Methods: Our aim was to investigate the role of ZIP7 in IBD initiation and progression. We investigated the expression of ZIP7 in the intestinal mucosa of IBD patients and in interleukin-10-gene-deficient (Il10−/−) mice, and assessed the relation between ZIP7 and disease activity. ZIP7 upregulated/downregulated lentivirus was used to infect IEC6 and HIEC cells, then we evaluated the expres-
sion of inflammatory factors, mucosal tight junction proteins (Occludin and ZO-
1), and proteins related with endoplasmic reticulum stress (IRE1, XBPI,-traf2, ask1 and p-JNK). In addition, we used siRNA to silence IRE1 and SP600125 to inhibit the JNK pathway respectively, then evaluated the effect of endoplasmic reticulum stress on mucosal tight junction proteins.

Results: We found that ZIP7 was downregulated both in the intestinal mucosa of IBD patients and in Il10−/− mice, which was associated with disease activity. In IEC6 and HIEC cells, the expression of mucosal tight junction proteins was consistent with the level of ZIP7, but the expression of inflammatory factors and endoplasmic reticulum stress associated proteins were on the contrary. After the silence of IRE1 and the inhibition of JNK pathway, the expression of mucosal tight junction proteins was partly resumed in ZIP7 downregulated cells.

Conclusion: ZIP7 induces disruption of the intestinal barrier, which was associ-
ated with activation of endoplasmic reticulum stress in IBD. It is expected to provide a novel mechanism of IBD and provide a new target for the treatment of IBD.

Introduction: Enteric glial cells (EGC) are located in a defined area around the enteric neural ganglia of patients affected by Crohn's disease is predictive of disease recurrence after post-operative resection. As cells of the enteric nervous system could be implicated in the formation of these myenteric and submucosal plexus in chronic inflammatory digestive diseases, inter-relationship between T cells and enteric glial cells (EGC) was investigated.

Aims & Methods: To analyse the interactions between immune and enteric neural cells, EGC isolated from the myenteric plexus of the rat digestive tract were co-
cultured with CFSE-labeled T cells. Impact of T cell activation on neuro-immune interactions was investigated by treating T cells with anti-CD3/anti-CD28 antibodies.

To determine whether inflammatory conditions favored the contacts between glial and immune cells, EGC were treated with LPS or TNF/IL1 prior their exposition to T cells. After 2 hours, non-adherent cells were removed and the T cells interacting with EGC (S100+) were counted. Immunocytochemistry were also used to characterize the subpopulations of T cells (CD4+, CD8+) that contact glial cells.

Results: Analyses reveal that non-activated T lymphocytes are capable of inter-
acting with EGC. They also show that activation of T cells with anti-CD3/anti-
CD28 antibodies increases the number of T lymphocytes interacting with EGC. Interestingly, an increased number of EGC-T cell interactions was observed after pretreatment of EGC with inflammatory stimuli. This phenomenon was also noted with activated T cells. Characterization of T cells show that both CD4 and CD8 cells are capable of contact with EGC.

Conclusion: Our present data reveal that EGC interact with T cell. These con-
tacts are favored by T cell activation but also by EGC exposure to inflammatory cytokines. Further experimental studies are required to characterize these neuro-
immune interactions but they suggest that EGC-T cell contact play a crucial role in case of inflammatory bowel diseases. This work is supported by the Association Francais Aapetil.

Introduction: Enteric glial cells (EGC) are essential to intestinal epithelial barrier (IEB) homeostasis. In healthy intestines, EGC reduce IEB permeability and promote mucosal healing. In inflammatory bowel disease (IBD) such as Crohn’s Disease (CD) and Ulcerative Colitis (UC), both EGC phenotype and IEB functions are altered, but putative involvement of EGC in IBD pathogenesis remains unknown. If the astrocyte reactivity is well studied, the reaction of EGC to chronic inflammation is not well documented. We investigated whether EGC impact on IEB permeability was altered in an inflammatory environment and in IBD patients.

Aims & Methods: Rat EGC as well as human EGC from control, CD and UC patients were stimulated with the cytokine Th2 (TNFalpha, IL1beta, 1 to 100ng/ ml) or LPS for 2 or 4 days. Reactive EGC phenotype where characterized and reactive EGC functional impact on IEB permeability was studied (i) in vitro using human intestinal epithelial cells (IEC) in a non-contact co-culture model, or (ii) in vivo by grafting the treated rat EGC in colon wall of Sprague Dawley rats.

Results: Rat and human control EGC induced a significant reduction of IEB paracellular permeability after T1 treatment when compared with untreated or LPS treated EGC. LPS or TI treatment had no significant effects on IEB permeability.

Conclusion: Our present data reveal that EGC interact with T cell. These con-
tacts are favored by T cell activation but also by EGC exposure to inflammatory cytokines. Further experimental studies are required to characterize these neuro-
immune interactions but they suggest that EGC-T cell contact play a crucial role in case of inflammatory bowel diseases. This work is supported by the Association Francais Aapetil.

Disclosure of Interest: All authors have declared no conflicts of interest.
the permeability when compared to control animals. Human EGC from control or UC patients treated with T1 induced a decrease in IEB permeability too, but EGC from CD patients did not.

Conclusion: This work is not only the first evidence showing that reactive EGC can have beneficial effects upon IEB permeability, but also shows that EGC from CD but not UC patients have lost this reactivity. This could define EGC as active players in CD pathogenesis.

Introduction: In inflammatory bowel disease (IBD) both intestinal epithelial barrier (IEB) permeability and PTGIS expression are altered. Nevertheless the role of the lipid mediator PGI2 produced by PTGIS in IEB regulation is unknown. The present study concerns the control of IEB permeability by PGI2 and its involvement in the development of colitis.

Aims & Methods: Production of PGI2 from control or IBD biopsies was established using high sensitivity liquid chromatography tandem mass spectrometry. Consequences of flolan PGI2 analogous supplementation were evaluated in a DSS-induced mice model of colitis, measuring disease activity index (DAI), inflammation (pro-inflammatory cytokine mRNA) and IEB permeability (sulfonic acid flux). Molecular mechanisms involved were assessed by quantification of junctional and pro-proliferative or pro-apoptotic protein expression (western blot and immunostaining). Eventually PGI2 impact on reversing IEB breakdown was assessed in vitro measuring permeability of mice or human mucosal explants treated with staurosporine apoptosis inducer, or permeability of IBD biopsies both treated or not with flolan.

Results: Biopsies from IBD patients had lower PGI2 production compared to both treated or not with flolan. 3 is normalized by flolan.

Conclusion: This study not only presents a role of PGI2 in controlling IEB permeability through the regulation of apoptosis mechanisms, but also reveals that increased permeability in IBD patients can be fixed by PGI2 supplementation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1627 7A-HYDROXY-4-CHOLESTEN-3-ONE FOR DIAGNOSIS AND MANAGEMENT OF BILE ACID MALABSORPTION: FIRST YEAR CLINICAL EXPERIENCE

Introduction: 7a-hydroxy-4-cholesten-3-one (7HCO) is a reliable method to diagnose bile acid malabsorption (BAM). Since 7HCO is an intermediate metabolite in the bile acid synthesis, increased levels reflect bile acid production, which is the case in BAM.

Aims & Methods: We evaluate retrospectively, prospectively collected clinical data during the first year after implementation of a new test using ultrahigh performance liquid chromatography coupled to mass spectrometry to measure 7HCO (see reference). In adult patients with clinical suspicion of BAM, unexplained diarrhea and a subgroup with obesity 7HCO was measured. Levels <30 ng/ml are considered as normal values. The decision to treat with cholestyramine was at the discretion of the treating physicians.

Results: We performed 126 7HCO analysis in 112 patients (62% female, mean age 51+/-16 years) with a mean level of 84+/- 91 ng/ml. Cholestyramin treatment was more likely initiated in patients with Crohn’s disease (RR 1.8; 95%CI 0.9-3.7) or after ileocecal resection (RR 3.1; 95%CI 1.7-5.7). Diarrhea improved in 60% of patients with a 7HCO level above 40 ng/ml. Thresholds of 60 or 100 ng/ml do not improve prediction of response to cholestyramin treatment.

7HCO measurement in subgroups

</table>

Conclusion: A 7HCO measurement above 40 ng/ml seems to be associated with a good response to cholestyramine treatment, which suggests clinical bile acid malabsorption. However, most patients have higher levels, particularly in Crohn’s disease after ileocecal resection. These preliminary results warranted confirmation on a larger scale.

Introduction: Ulcerative colitis (UC) is a clinical type of inflammatory bowel diseases. The pathogenesis of UC remains unclear. Nowadays the role of T-helpers type 17 (TH17) as well as cytokines they release is discussed in pathogenesis of autoimmune inflammation in UC.

Aims & Methods: The aim of study is to analyze the serum levels of following cytokines: interleukin (IL)-17A and F, 21, 22, 23, 10 in UC patients both in the acute stage of disease and remission.Forty eight UC patients in the acute stage and twenty patients in remission were included into the study. Serum cytokine levels were analyzed using multiplex immunoassay for TH17 cytokines (Bio-Rad, USA). Statistical analysis was performed using STATISTICA 6.0 Software Package. The control group consisted of 11 healthy volunteers.

Results: Statistically significant increase of IL-17A level (15 pg/ml [12;11;23.38]; 14.68 pg/ml [11.29;17.19] respectively) was observed in patients with UC both in acute stage and remission compared to controls (7.36 pg/ml [5;18.86]; p = 0.00007, p = 0.00029 respectively). The same trend was observed regarding IL-21, which median values were higher both in acute stage (156.51 pg/ml [133.44;233.53]) and remission (144.02 pg/ml [133.44;154.43]) compared to control group (98.31 pg/ml [89.14;124.86], however differences were not statistically significant (p = 0.172, respectively). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune inflammation in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The role of several cytokines in the pathogenesis of autoimmune inflammation in patients with ulcerative colitis.
P1629 ANP32E IS INVOLVED IN THE STEROID-REFRACTORY ULCEARTIVE COLITIS (UC) IN HUMAN PATIENTS

Introduction: The steroid-refractoriness is a common complication of ulcerative colitis (UC), which appears unpredictably. Several mechanism of action (MoA) has been implicated in corticosteroid failure. However, there are no conclusive studies on the molecular functions involved in UC steroid-refractoriness.
Aims & Methods: Therefore, we decided to know in depth the MoA related to the steroid-refractoriness of UC. So, we have analyzed unipredictable data of patients with UC treated with glucocorticoids. RNA from rectal biopsies was obtained before and on the 3rd day of glucocorticoid treatment. Then, whole-genome expression using microarrays (Illumina, USA) and profiles microRNA by sequencing (Illumina, USA) were analysed. After quality control, omics data were compared between phenotypes. The results of these comparisons were integrated into mathematical models generated by means of Systems Biology.
Results: These models reproduced the updated molecular interactions on glucocorticoids and UC, and integrating our experimental data, we identified a potential MoA that includes 64 key proteins, 18 of them capable of perfectly classifying patients with a good response to glucocorticoids and the non-responders. The biological functions of these proteins have been associated with inflammation (e.g. RelA), glucocorticoid receptor transcription (e.g. NR3C1 and NCOA3) and angiogenesis (e.g. VEGF), mainly. But among these 18 proteins, the ANP32e has never been related to either steroid-refractoriness or ulcerative colitis. ANP32e is a member (in the H2-A group) of a cohort of the homologues flanking DNA regions recognized by the glucocorticoid receptor). Additional WB and immunofluorescence assays confirm differences in the intestinal levels of ANP32e and in the nuclear localization at baseline, between patients with drug-refractory colitis.
Conclusion: In conclusion, this study has identified a new MoA related with UC steroid-refractoriness involving chromatin remodeling modifications.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1630 CO-HOUSING DSS TREATED MICE WITH HEALTHY MICE RESULTS IN FASTER NORMALIZATION OF THE INTESTINAL MICROBIOTA AND PROMOTES RECOVERY

Introduction: The intestine is populated with myriads of bacteria, which form a complex ecosystem and have tremendous impact on our health. In inflammatory bowel disease (IBD), shifts in microbiota composition and a reduction in overall diversity have been described. There are attempts to therapeutically transfer the microbiota from healthy subjects to persons suffering from intestinal disease. In case of Clostridium difficile infections, this approach proves to be very efficient; the therapeutic value of focal microbial transfer (FMT) in IBD is being elucidated. In mouse models of intestinal inflammation, the effect of FMT has been studied poorly and if so, germ-free or antibiotic-treated animals have been used-models that poorly reflect the situation in human IBD patients. Here, we aimed to restore the composition of microbiota from healthy to diseased mice affects recovery from acute colitis.
Aims & Methods: Acute colitis was induced in 12–14 week old C57Bl6 mice by administration of 2% DSS in the drinking water for 7 days. Mice with colitis were co-housed with healthy mice after removal of DSS. Due to coprophagy, this results in fast transfer of the microbiota between co-housed mice. To analyse changes in the composition of microbiota over time, stool samples were taken every second day and sequenced for the V4 hyper-variable region in the bacterial 16S rDNA.
Results: As expected, DSS treatment resulted in severe weight loss, and even 7 days after withdrawal of DSS (day 15), histology confirmed severe colitis. Intestinal inflammation was accompanied by an overall reduction of microbial diversity (decreased Shannon index, p < 0.01), and a marked shift in the composition of the microbiota (increased abundance of Verrucomicrobia, Cyanobacteria and some families of Firmicutes [mainly Clostridiaceae], although overall abundance of Firmicutes was decreased [p < 0.01 for all]). However, on day 15, these changes were less pronounced, indicating a normalization of the microbiota composition upon recovery. DSS-treated mice which were co-housed with healthy littersmates after colitis induction, showed faster recovery (earlier weight gain, reduced histological scores, reduced levels of the infiltration marker monocyte chemotactic protein-1, less pronounced shortening of the colon, p < 0.01 for all) and an earlier normalization of the microbiota composition.
Conclusion: Our results indicate that co-housing of DSS-treated mice with healthy mice results in transfer of healthy microbiota to diseased mice, and promotes recovery from colitis. This indicates that introduction of a “healthy” microbiota might have beneficial effects during intestinal inflammation and opens the possibility to systematically study the effect of genetic alterations in donor and/or recipient on the outcome of FMT.

Introduction: In Crohn’s Disease (CD), colonic phenotype of the ileum has been reported in severe lesions, but not in CD ileum with no lesions or with early post-operative recurrence (1).
Aims & Methods: In a prospective study at 5 years, we aimed to address whether colonic phenotype of the ileum might represent a subclinical marker of clinical postoperative recurrence in CD. At this purpose, clinical recurrence was assessed yearly for 5 years in a cohort of CD patients with colonic phenotype of the ileum already defined at surgery, 6 and at 12 months after ileo-colic resection (1). A different group of CD patients with ileal colonic phenotype of the ileum already defined at surgery, and reported at 6 and 12 months after ileo-colic resection (1), was clinically followed up for additional 4 years. In the 5 years follow up, indication for treatments, haematochemical, radiological and/or endoscopic assessments was given according to current European guidelines (2). Haematochemical assessments included whole blood count, ESR, serum CRP evaluation yearly for 5 years, with possible additional assessments, according to clinical indications. Clinical recurrence (CDAI > 150) was assessed yearly for 5 years. Colonic phenotype of the ileum was already reported at surgery, at 6 and 12 mos, according to the expression of sulfomucins (colon mucin-type) and sialomucins (small intestine mucin-type) (1). In the present study, correlation between the percentage of expression of sulfomucins and clinical recurrence was evaluated yearly for 5 years. Statistical analysis: results expressed as median (range), correlations were assessed by the Spearman correlation test, differences between groups by the unpaired T test.
Results: After ileo-colic resection, clinical follow up at 5 years was completed by 17/19 (89.4%) CD patients enrolled (12 males, age 41 [17–73]). The percentage of expression of sulfomucins (colon phenotype) as assessed in the ileal surgical specimens was significantly correlated with the CDAI score at 4 years (r = 0.62; p = 0.007) and at 5 years (r = 0.6; p = 0.010). Differently, in the ileal biopsies at 6 months, no correlation of colonic phenotype of the ileum, evaluated by the expression of sulfomucins was significantly correlated with the CDAI score at 6 months (r = 0.68; p = 0.003). The percentage of expression of sulfomucins in the ileal biopsies at 12 months was significantly correlated with the CDAI score at 6 months (r = 0.57; p = 0.015) and at 2 years (r = 0.53; p = 0.022). The ileal expression of sulfomucins in the surgical specimens at surgery was higher in patients with vs without clinical postoperative recurrence at 2 years (40 [10–99] vs 5 [0–50]; p = 0.044). The expression of colon mucin-type in the ileal biopsies at 12 months was higher in patients with vs without clinical recurrence, both at 12 months (30 [1–40] versus 0 [0–35]; p = 0.02) and at 2 years (30 [0–40] versus 0 [0–35]; p = 0.029). No correlations were observed between the percentage of expression of sulfomucins at surgery, at 6 or at 12 months and the haematochemical parameters considered.
Conclusion: In CD, colonic phenotype of the ileum as assessed by the expression of ileal sulfomucins, may represent a predictive marker of clinical recurrence after ileo-colic resection for CD.

A total of 132 patients with IBD were randomly assigned to single monotherapy and 20 received anti-TNF-alpha single agent therapy. Nineteen patients received combination therapy of immunosuppressant and antitNF-\(\alpha\) agents. No significant difference between the single vaccination group and booster group was observed (geometric mean titers: H1N1: \(p = 0.41\); H3N2: \(p = 0.79\); B/Phuket: \(p = 0.82\); B/Texas: \(p = 0.84\)). In patients treated with infiximab, seroprotection rate (SP\%) and seroconversion rate (SC\%) tended to be lower in Indians than in Caucasians and Pakistanis (\(p = 0.001\)). Data for disease phenotype was available for 160/219 patients with UC (24\% E1, 42\% E2 and 34\% E3). There was no significant difference in disease extent between ethnic groups.

Conclusion: The incidence rates for IBD in seven urban populations in England are similar to recent data from Western Europe (IBD 18.5/100,000, UC 9.8/100,000 CD 2.7/100,000 UC 1.01/100,000 IBDU). Collective crude incidence rates were 15.54/100,000 for IBD, 9.69/100,000 for UC, 4.80/100,000 for CD and 1.01/100,000 IBDU. (Table 1) Crude incidence rates varied between populations: lowest was 6.81/100,000 in Pennine, North Manchester and highest 26.11/100,000 in Leicester. Overall incidence of UC was higher than CD (9.69/100,000 vs 4.80/100,000) and was consistent for all populations except Pennine (3.31/100,000 for CD and 2.76/100,000 UC). Of the total number of IBD cases recruited 298/351 were coded as IBDU. Caucasian, Indian or Pakistani. IBD, UC and CD incidence was similar between Pakistani and Caucasian groups. UC incidence was significantly higher in the Indian population compared to Caucasians and Pakistanis (\(p < 0.001\)). Data for disease phenotype was available for 160/219 patients with UC (24\% E1, 42\% E2 and 34\% E3). There was no significant difference in disease extent between ethnic groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

The most frequently observed IBD-related malignancy is CRC, biological therapy was ever given for 4/10 patients with IBD-related mortality. Earlier death than in the rest and in the non-IBD population. Septic complications were the leader causes of IBD-related mortality characterized by a significantly lower in case of IBD-related mortality compared to the general population.

The aim of our nationwide registry was to prospectively collect IBD-related mortalities and all types of malignancies diagnosed in the Hungarian IBD population. Data on all death and malignancies developed between 2015 and 2016 in IBD patients were recorded. All other authors have declared no conflicts of interest.

Results: Fifty-five newly diagnosed malignancies were reported (mean age: 49.3 years old, mean disease duration was 16.9 years; male/female ratio was 34:21). 30 CD patients, mean disease duration was 19.9 years, mean male/female ratio was 22:8) one of them had 1 pouch cancer previously colectomized because of sigmoid tumor, 4 skin, 3 lung, 2 breast, 2 cervix, 2 pancreases, 2 liver, 1 gallbladder, 1 prostate, 1 esophagus, 1 salivary gland, 1 thyroid, 1 central nervous system, 1 testis, 1 ovary, 1 bladder, 1 rectum, 1 retroperitoneal sarcoma, 1 renal, 1 prostate, 1 esophageal, 1 salivary gland, 1 thyroid, 1 central nervous system, 1 pancreas, 1 tonsil, 1 laryngeal cancer, 1 B-cell lymphoma and 1 retroperitoneal sarcoma.

The incidence and prevalence of any HPV in AC; and female gender, history of sexually transmitted disease, lifetime and past year number of sexual partners, active smoking and immunosuppressive treatment (OR 5.3) with the presence of HR HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Clinical remission, whereas half of the patients with ESBL-E colonization (n = 2.84) (p = 0.0035, compared with men). Regarding medical history, HR HPV and HPV16 prevalence were significantly higher in Crohn’s disease patients (90%, p < 0.0051; 14%, p = 0.0072, compared to the rest of the study population). Eleven patients (50%) with perianal CD had an AC infection with any HPV. Multivariable analysis associated peri-anal female gender and history of sexually transmitted disease with the presence of HPV in AC; and female gender, history of sexually transmitted disease, lifetime and past year number of sexual partners, active smoking and immunosuppressive treatment (OR 5.3) with the presence of HR HPV. These findings strongly support prophylaxis with vaccination and adequate screening in our patients.

Conclusion: We demonstrated that CD patients harbor more frequent AC infection with HR HPV and that immunosuppressive treatment is an independent factor for HR HPV infection at this site. These findings strongly support prophylaxis with vaccination and adequate screening in our patients. All authors have declared no conflicts of interest.

Introduction: Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) are the most frequently found multi-drug resistant bacteria colonizing the gut of inflammatory bowel disease (IBD) patients. Changes in the microbiome may act as a trigger in IBD inflammation process.

Aims & Methods: The aim of the study was to analyze whether gut colonization with ESBL-E produces a significant increase in clinically relevant disease activity activity increase in ulcerative colitis (UC) and in Crohn’s disease (CD). All consecutive patients with confirmed UC and CD diagnosis, previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010–2016) were included in the study, interviewed, rectal swabs were collected. Enterobacteria were cultured and analyzed for ESBL presence according to EUCAST guidelines. To clinically evaluate disease activity status, patients were evaluated according to Mayo score, Montreal classification, adapted Truelove and Witt’s criteria and CD patients according to Crohn’s disease activity index (CDAI), suggested by ECCO IBD guidelines (2016). Results: A total of 101 patients with UC and 47 patients with CD were tested for gut colonization with ESBL-E. We found that 12 (11.9%) of the UC patients and 5 (10%) of the CD patients were colonized with ESBL-E. Statistically significant differences were found in all UC clinical disease activity scores between patients with and without gut colonization with ESBL-E and showed tendency towards statistical significance in CD. The mean disease activity according to Mayo score in UC patients without ESBL-E colonization was 3.44 (SD = 2.07), whereas in patients with ESBL-E colonization it was 5.08 (SD = 2.84) (p = 0.015). Most of the UC patients without ESBL-E colonization (n = 63; 70.8%) were in clinical remission, whereas half of the patients with ESBL-E colonization (n = 6;

Introduction: Smoking has a differential effect on inflammatory bowel diseases (IBD); deleterious for Crohn’s disease (CD) and protective for ulcerative colitis (UC). Thickness of the mucus layer, immune system (cytokines production), mucoviscous and intestinal microbes are potential mechanistic factors influenced by the nicotine and numerous other substances. It has been hypothesized that smoking cessation is associated with the second peak of diagnosis in UC patients after 50 years old. Our aim was to confirm this hypothesis using data on smoking status at IBD diagnosis.

Aims & Methods: Adult IBD patients included in the Swiss IBD cohort from November 2006 to November 2015 were asked about their smoking status at diagnosis. We compared the proportion of former smokers in 10-year groups of UC and CD patients.

Results: 2361 IBD patients (1366 CD, 995 UC) were included in the analysis. Among them 52% of CD ans 24% of UC patients were smokers at diagnosis (proportion of smokers in Switzerland (2014): 29%). The higher proportion (66%) of former smokers at diagnosis was in the 50 to 60 years old group of UC patients compared to only 26% in CD patients between 40 to 50 years old (p < 0.001). On a gender basis, the higher proportion of former smokers is particularly significant high among male 50-60 years old with UC (68%) and persists among them over 60 years old (52%).

Conclusion: The proportion of former smokers at diagnosis increases dramatically and significantly over years in UC patients compared to CD patients. A peak was reached over 50 years old suggesting an indirect impact of smoking on the second peak of diagnosis in ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Crohn's disease (CD) is a chronic inflammatory disease that can affect any section of the gastrointestinal tract. Malnutrition is a common sequela in these patients and many pathogenic mechanisms could be involved such as poor dietary intake, altered energy expenditure, nutrient malabsorption and/or losses.

Aims & Methods: This cross-sectional study aimed to evaluate the resting energy expenditure (REE) in CD patients, in accordance with clinical status of disease, compared to a control group.

Methods: All consecutive adult CD women were prospectively enrolled, while a group of healthy women, matched for age and weight, served as control group (C). All CD women were classified in clinically active disease (CD-A) and clinical remission (CD-R) according to Crohn's Disease Activity Index (CDAI) (> 150 and < 150, respectively). All subjects underwent REE measure by indirect calorimetry with a canopy system, while body composition variables, such as fat-free mass (FFM) and fat mass (FM), were assessed by bio-impedance analysis (BIA).

Results: Finally, forty-two women with CD, 23 with clinically active disease (CD-A; CDAI = 219 ± 53) and 19 in clinical remission (CD-R; CDAI = 83 ± 41) were recruited for the study, while 40 matched-healthy women were enrolled as control group (C). We found that body weight, FFM and phase angle (PA) differed among groups; but age, height and FM did not. Post-hoc analysis revealed that body weight was significantly lower for CD-A in comparison with C (CD-A: 61.7 ± 9.2 kg vs C: 64.5 ± 6.3 kg; p = 0.002); FFM was reduced in women with CD than C (CD-A: 39.6 ± 4.3 kg and CD-R: 39.5 ± 6.8 kg vs C: 44.4 ± 6.8 kg; p = 0.01); while PA was lower for CD-A compared to both CD-R and C (CD-A: 5.5 ± 0.6 vs CD-R: 6.0 ± 0.5 and C: 6.1 ± 0.5; p < 0.001). REE did not differ among groups; nevertheless when it was adjusted for FFM, we observed that REE/FFM increased for both CD-A and CD-R groups compared to C (CD-A: 35.9 ± 4.17 kcal/kg vs C: 35.1 ± 4.96 kcal/kg vs C: 30.2 ± 3.38 kcal/kg; p < 0.01).

Conclusion: These preliminary results show that REE, when adjusted for FFM, is increased in women with CD, unrelated to disease activity, compared to healthy subjects and this could negatively affect the energy balance and contribute to weight loss.

Introduction: Primary sclerosing cholangitis (PSC) is a rare and devastating complication of inflammatory bowel disease (IBD). There is no standard for the screening of primary sclerosing cholangitis (PSC) in patients with IBD. Magnetic resonance cholangiography (MRC) may replace liver biopsy in this clinical situation. The main objective of this prospective observational study was to assess the frequency of MRC-detected liver abnormalities, including PSC, in adult IBD patients with liver function abnormalities and to identify clinical and biological characteristics associated with these findings.

**Aims & Methods:** From June 1, 2009 to January 31, 2017, 421 patients were included and screened with MRC: cohort 1 included 206 IBD patients with liver abnormalities; cohort 2 included 28 IBD patients without liver abnormalities; and cohort 3 included 187 non-IBD patients with liver abnormalities. Two senior radiologists independently evaluated MRC findings.

**Results:** MRC abnormalities were observed in 18% of patients in the cohort 1; 3.6% in the cohort 2; and 31% in the cohort 3 (Table 1). Based on MRC, we found respectively 11.2%, 0%, and 7% of PSC in cohorts 1, 2, and 3. 29.2% of patients had infra-clinical PSC and 11.2% of cohort 1 had apparent abnormal PSC. A histological analysis of resection tissue (n = 35) revealed 38% with MRC abnormalities. MRC Total Normal Ductopenia Doubt PSC Others

| Cohort 1 | 206 | 150 (72.8%) | 28 (13.6%) | 9 (4.4%) | 23 (11.2%) |
| Cohort 2 | 28 | 27 (96.4%) | 1 (3.6%) | 0 | 0 |
| Cohort 3 | 187 | 116 (62.0%) | 0 | 13 (7.0%) | 58 (31.0%) |

Conclusion: Using MRC in patients with IBD, we found a higher prevalence of PSC than based on clinical symptoms. Systematic screening for PSC using MRC could be recommended in routine practice for IBD patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1641 TRUECOLOURS ULCERATIVE COLITIS (TCUC): WILL PATIENTS WITH UC COMPLETE DIGITAL QUESTIONNAIRES IN REAL-TIME?**

Introduction: TCUC is a comprehensive real-time web-based programme for patients with UC. It monitors multiple parameters via electronic questionnaires: symptoms, quality of life (QoL), outcomes (eg emergency department visits) and demographics. Medications are entered and personalised treatment guidance is delivered, 28%). Of 66 patients, 29 (44%) were male, median age 40.7 yrs (IQR 17.0, range 18-65), median duration of disease 5.6 years (IQR 10.7, range 0–30), distribution of disease (E1 18%, E2 38%, PSC 11%, activity of disease at entry (remission 38%, mild 35%, moderate 26%, severe 1%), tertiary education 58%, biologic use 47%. Retention rate 57/66, (86%). Main reason for withdrawal (5/9, 55%) was the need for sigmoidoscopy and monthly blood tests during the trial.

**Table 1:** Adherence to Questionnaires

<table>
<thead>
<tr>
<th>Questionnaires</th>
<th>Adherence over 6 months</th>
<th>First 3 months</th>
<th>Last 3 months</th>
</tr>
</thead>
<tbody>
<tr>
<td>Daily symptom (SCCAI) questionnaire</td>
<td>76%</td>
<td>81%</td>
<td>72%</td>
</tr>
<tr>
<td>Fortnightly QoL questionnaires (IBD-Control 8, CUCQ-8 and EQ-SD)</td>
<td>95%</td>
<td>96%</td>
<td>94%</td>
</tr>
<tr>
<td>Once only demographic and outcome questionnaires</td>
<td>100%</td>
<td>100%</td>
<td>100%</td>
</tr>
</tbody>

Introduction: Malnutrition and altered body composition can develop in patients with inflammatory bowel diseases (IBD) for a variety of reasons. Malnutrition and sarcopenia may worsen disease outcome in chronic disorders, raise the risk of infections and hospitalisation.

**Aims & Methods:** We followed 198 IBD outpatients (144 CD and 54 UC) for 3 years to indentify potential risk factors of unfavourable disease outcome. Baseline body composition were measured by bioelectrical impedance analysing (BIA) method to evaluate nutritional status. Penalized logistic regression was used for the multivariate modelling of the outcome, with two sets of - prespecified predictor variables age, sex, Cu/CD, BMI, FFMI.

**Results:** According to our results 19.2% of the patients (n = 38) were underweight (BMI < 18.5 kg/m²) and 29.8% (n = 59) had alarming low fat-free mass index (FFMI) and were at risk of sarcopenia. Overall 31.5% (n = 62) of the patients needed steroid therapy and 53.5% (n = 106) was given anti-TNF. Almost third of the participant (30.8%, n = 61) were hospitalized due to disease flare or its complication at least once during the follow-up time. The mean period of hospitalization was 19.14 ± 32.7 days. 20.2% (n = 40%) of all participants have undergone intestinal surgery. Hospitalization was positively associated with sarcopenia risk: alarming low FFMI was associated with an OR of 1.81 (95% CI: 1.55–2.10, p = 0.0406). The risk of operation was higher in patients with lower BMI: OR = 1.55 (95% CI: 1.05–2.29, p = 0.0277) for 5 units decrease; no other association was significant in the models.

**Conclusion:** Our results suggests that low BMI is a risk factor of surgery in inflammatory bowel disease patients. Furthermore alarming low FFMI is a predictor of need of hospitalization and that suggests more serious flares. Identification of malnutrition and altered body composition has notable importance in disease outcome among IBD patients.

1Department Of Gastroenterology, St. Michael's Hospital, Bratislava/Slovak Republic
2IBD Center, Bratislava/Slovak Republic
3Department Of Surgery, St. Michael's Hospital, Bratislava/Slovak Republic

Contact E-mail Address: zuzana.zelinkova@msmas.sk

Introduction: The majority of Crohn's disease (CD) patients develop structuring complications of the disease at some point. The proper selection of patients with potential benefit of therapy escalation is crucial in order to avoid unnecessary bowel damage or uptake in the affected bowel segment; at intravenous contrast-enhanced ultrasound (CEUS) has been shown to correlate with disease activity but there are no data available on the benefit of CEUS for the therapeutic decision making in this clinical setting.

Aims & Methods: The aim of the study was to evaluate the clinical outcomes of CD patients with strictureing disease managed based on the CEUS findings. CD patients with strictureing disease were recruited from two IBD centres between June 2015 and February 2017. Patients with penetrating disease complications were excluded. CEUS performed in out-patients. Patients with rapid uptake (within 20 second after injection) were indicated for therapy escalation, patients without uptake with obstructive symptoms were referred for surgery; patients with uptake and no obstructive symptoms remained at the stable medication. In patients with the minimal follow-up of one year clinical and endoscopic remission was evaluated.

Results: In total, 27 patients were included (10 men; median age 37 yrs, range 23–67; 22 pts with ileo-coecal localization, 3 pts with multiple small bowel segments involvement, 2 with colonic disease). Seventeen patients (63%) had rapid uptake at the CEUS; 13 of these patients had therapy escalation (3 pts intensification or switch to another biological; 10 pts had therapy step-up to antiTNF or immunosuppression). Remaining three pts improved subsequently on stable therapy with antiTNF and one patient with longstanding symptomatic colonic stricture was referred for surgery. Ten patients (37%) had no rapid uptake at the CEUS; seven out of these patients had symptomatic strictureing disease and were referred for surgery. Three patients had no symptoms and no therapeutic changes were made. Twenty-five patients had follow-up longer than 12 months (median 18 months, range 13–23). In the group of patients with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. In the group with no rapid uptake, patients without surgery remained in remission without any changes in the medication. Patients who underwent surgery in this time period in therapy escalation and one of these patients had recurrence at the surveillance colonoscopy at 12 months.

Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with strictureing Crohn's disease.

P1645 Diagnostic delay and predictive factors for Crohn's disease in an Algerian population

Y. Cheli1, R. Boulares1
1Constantine, Ben Badis Hospital, Constantine/Algeria

Contact E-mail Address: Yacinechelbi4@yahoo.fr

Introduction: Crohn's disease (CD) is a chronic inflammatory bowel disease whose diagnostic delay (DD) is highly variable. A delay in diagnosis of MC patients has multiple implications, affects the therapeutic approach and patient outcome. Factors Influencing SD may be a function of the country's health system, but also linked to the particular clinical and evolutionary profile of the disease. The objective of this study was to measure the DD of CD, to describe its distribution and evolution over time and to The factors associated with a long DD (>Q3).

Aims & Methods: All patients with certain or probable CD between 2004 and 2016 identified by The department's inflammatory disease hospital registry was included. The socio-demographic characteristics collected included: the patient’s residential area at the time of diagnosis in urban, rural or semi-urban, distance from the nearest hospital (CH). Clinical symptoms and phenotype of CD to diagnosis according to the Montreal classification were collected.

Results: Among 247 patients with CD; 90 had a median SD of 0 months. A DD > 7 months was considered a diagnostic delay observed in most patients is 157. In univariate and multivariate analysis at diagnosis, the female sex (54.25%), young age (37.24%), absence of emaciation (27%), presence of extra-digestive manifestations (25.91%) and Isolated lesions (L1) (34%) and penetrating phenotype (B3) (22.67%) were associated with anaplastic lesions (27.12%). Diagnostic delay (>7 months) was associated with anaplastic phenotype. The socio-demographic characteristics were not associated with delayed diagnosis.

Conclusion: This study shows that most of the patients, 63.56% have a diagnostic delay significantly associated with the female sex. The young age, the absence of weight loss and a localization of the disease limited to the bowel had the predicting phenotype of disease. No socioeconomic variables or reflective of access to care were found to influence.

P1646 Tuberculosis in inflammatory bowel disease under tumour necrosis factor alpha antagonist—the risk beyond screening

L. Carvalho, M.A. Túlio, J. Carmo, J. Rodrigues, T. Bana, E Costa, C. Chagas
1Gastroenterology, Centro Hospitalar Lisboa Ocidental, Lisboa/Portugal

Contact E-mail Address: lilipcarvalho@gmail.com

Introduction: Tumour necrosis factor alpha antagonist (anti-TNFα) has revolutionized the treatment of the inflammatory bowel disease (IBD). Considering that it plays a central role in immune-mediated modulation, there are some concern about opportunistic infections such as tuberculosis, particularly latent infection reactivation. Due to global high incidence of tuberculosis and its commonly severity in immunocompromised patients (extrapulmonary and disseminated pattern), the exclusion of latent tuberculosis infection (LTBI) infection is currently part of the screening prior to starting biologic therapy. Despite negative screening, the risk of tuberculosis infection remains active during the immunomodulation therapy. However, only a few cases of life-threatening disseminated tuberculosis have been reported in immunocompromised patients probably related to the increased use of higher accuracy screening tests, such as interferon-gamma release assays (IGRA). Negative screening cases with IGRA are not described.
Aims & Methods: We intend to know the incidence of tuberculosis in IBD patients under anti-TNFα therapy in a single tertiary referral centre, analyzing the tuberculosis screening methods and demographic characteristics. IBD patients treated with anti-TNFα therapy between January 2000 and December 2016 were retrospectively analyzed.

Results: During this period 166 patients received anti-TNFα therapy. Before anti-TNFα treatment, screening for LT was performed through medical history, chest X-ray, tuberculin skin test (TST) and/or IGRA. Forty-two patients (25%) had positive screening and received tuberculosis prophylaxis prior anti-TNFα therapy. Seventeen patients (4.2%) developed tuberculosis while under anti-TNFα treatment (four women, mean age 44 ± 7 years and mean IBD duration 10 ± 8 years). Six of them had a negative LT screening (methods: 4 TST and 2 IGRA) and one patient had positive TST screening, been treated with isoniazid before starting anti-TNFα therapy. During screening the three patients were under immune suppressive and one under corticosteroid therapy. In the IGRA negative screening patients, the diagnosis of tuberculosis occurred within the first 10 weeks after starting anti-TNFα. There were five cases of miliary tuberculosis and two of pulmonary disease. Despite difficult diagnosis, all patients were treated successfully, six of whom needed hospitalization.

Conclusion: In our centre the incidence of tuberculosis in IBD patients under anti-TNFα therapy was 4.2% and most of them presenting with a severe disease pattern. The therapeutic regime of tuberculosis was effective and no mortality was recorded. All this patient had a previously negative screening, two of them with IGRA, been considered a high sensitivity and specificity screening method.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The MediCrohn study was designed to evaluate the level of agreement between the Harvey Bradshaw Index (HBI) translated into a patient-based questionnaire completed through a mobile app, and the original HBI questionnaire assessed by the clinician (considered as reference).
Aims & Methods: Patients completed the HBI score through a mobile app designed for both Android and iPhone devices and thereafter (<48 h later), the questionnaire was completed onsite by the gastroenterologist who was blinded for the patients’ responses. We assessed agreement between HBI scores of the clinician and patient on the total sum score and per item. HBI score < 5 was considered as inactive disease.
Results: 135 patients participated in the study and completed the HBI trough a mobile app (mean age: 36 ± 8 years, 58% women). The proportion of agreement between clinician and patient assessment, both evaluating CD as active or in remission was 91.1%. Only in 12 cases (11%), the patient classified CD as active whereas the physician evaluated it as inactive. No active cases remained undetected by the patient evaluation. Sensitivity, specificity, positive and negative predictive values are shown in Table. The highest agreement was seen for the questions: “abdominal mass” and “general well-being” whereas “number of liquid stools per day” was the item with the lowest agreement.

Conclusion: The HBI score self-administered by the patient through a mobile app resulted in a high percentage of agreement with the gastroenterologist evaluation, and high negative predictive value for disease activity. Results of the MediCrohn study encourage the use of this mobile app and gives some hints on its conditions of use as a support for the involvement of patients in the management of their disease. Future studies will help to define its precise role in clinical practice.

P1648 HISTOLOGICAL ASSESSMENT OF REMISSION IN ULCERATIVE COLITIS: DISCREPANCIES BETWEEN DAILY PRACTICE AND EXPERT OPINION
P. Kranenburg1, T.E.H. Römkes1, A. Van Tilburg2, C. Bronkhorst3, J.P.H. Drenth1, I.D. Nagtegaal2, F. Hoentjen1
1Gastroenterology And Hepatology, RadboudUMC, Nijmegen/Netherlands
2Pathology, RadboudUMC, Nijmegen/Netherlands
3Pathology, Jeroen Bosch Hospital, ’s-Hertogenbosch/Netherlands

Contact Email Address: pim.kranenburg@radboudumc.nl
Introduction: Histological remission (HR) has become an important treatment target in ulcerative colitis (UC). However, limited data exist on reliability of histological scoring in daily practice, when it comes to assess minor histological abnormalities. We investigated the reproducibility and reliability of UC histological scores in colonic biopsies assessed as HR by a general pathologist in daily practice. Next, we investigated correlations between the initial histological assessment and the expert review by expert gastrointestinal (GI)-pathologists.
Aims & Methods: We performed a retrospective single-centre study in a tertiary IBD referral centre. Colonic biopsies of UC patients with mucosal healing (MH) throughout the examined colon were included. All biopsies were re-assessed by three blinded GI-pathologists using three histological scoring indexes (Geboes score (GS), Riley score (RS), Harpaz-Botula Index (HGI)) and a global visual scale (GVS). We evaluated inter- and intrasubject variation and correlations between scores and initial histological assessment using Cronbach’s alpha and Spearman’s rho analysis.
Results: We included 270 biopsies from 89 UC patients. The interobserver concordance for all histological indexes was substantial to almost perfect (GS 0.84; RS 0.91, HGI 0.61GVS 0.74). The correlation between the RS and GS was almost perfect (R = 0.86), but no correlation was found between the primary histological assessment and the GS (0.00), the RS (<0.01), the HGI (0.03) and the GVS (<0.04) as scored by expert GI-pathologists.
Conclusion: Available histological scores for UC are reliable with strong mutual correlations in case of limited histological abnormalities. However, the discrepancies between daily practice histological assessment and dedicated GI-pathologists is significant and this may have important implications for the selection process of a unified histological disease activity score in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1649 EVALUATION OF MODIFIED MAYO ENDOSCOPIC SCORE AND DUBLIN ENDOSCOPIC SCORE TO CORRELATE ULCERATIVE COLITIS EXTENSION, IN THE PREDICTION OF RELAPSE

1Gastroenterologia, CHUYNG/E, Vila Nova De Gaia/Portugal
2Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jaimepereirarodrigues@gmail.com

Introduction: Current endoscopic activity scores for Ulcerative Colitis (UC) do not take into account the extent of mucosal inflammation. Recently, two endoscopic scores that combine the assessment of severity and disease extension were developed, the Modified Mayo Endoscopic Score (MMES)1 and Degree of Ulcerative Colitis Burden of Luminal Inflammation (DUBLIN)2. MMES and DUBLIN scores presented good correlation (r = 0.54; p = 0.03). DUBLIN was also higher in patients with histological activity defined by Nancy (1.9 ± 2.1 vs. 0.5 ± 0.8; p = 0.001) and Geboes (2.0 ± 2.3 vs. 0.7 ± 1.2; p = 0.0001). There was no significant difference between both correlations and analytically activity. Relapse occurred in 36.6% (n = 30) of patients, with a cumulative risk of 9.8, 18.4, 25.9, 31.5 and 42.0% at 12, 24, 36, 48 and 60 months, respectively. Mayo Endoscopic Subscore (MES) (p < 0.001), MMES (p < 0.001), DUBLIN (p < 0.001) presented a significant association with relapse. In multivariate analysis, MES (OR = 2.32; p < 0.001), MMES (OR = 1.19; p < 0.001) and DUBLIN (OR = 1.36; p < 0.001) were predictive of relapse independently from histology. Areas under the ROC curve were 0.71 (MES, p = 0.0001), 0.75 (MMES, p < 0.0001) and 0.74 (DUBLIN, p = 0.001) for prediction of relapse, with MMES significantly higher than MES by a difference of 0.037 (0.002-0.072); p = 0.03.

Conclusion: MMES and DUBLIN scores correlate with each other and with histological activity, being independent predictors of relapse. MMES was superior to MES in the prediction of relapse.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Magnetic resonance enterography (MRE) is an imaging technique recommended to determine and confirm the extension and activity of Crohn’s disease (CD) in the small bowel and discriminate penetrating disease and complications. MRE diagnosis allows to optimize medical treatment in IBD patients.

Aims & Methods: The aim of this study is to evaluate the impact of MRE on medical decision making in IBD patients and determine the maintenance of this new treatment along the time. Consecutive MRE studies performed in patients with confirmed or suspected Crohn’s disease between January 2011 and August 2014 were included in three different centers. Medical charts were retrospectively reviewed. MRE indication, demographic and IBD data were collected at time of MRE. Three months after MRE, medical decision (conservative approach with maintenance therapy, significant change in medical therapy or surgery) was assessed. After twelve months of follow-up, the treatment decided after MRE was reviewed.

Results: A total of 474 MRE studies were performed and indications for MRE were: assessment of small bowel involvement in 40 (8.3%) patients with indeterminate colitis (IC) and 20 (4.2%) with suspected IBD patients or evaluation of severity and extension of the disease in 414 (87.5%) CD patients (232 F; mean age 37 ± 13 years). Only 4 patients with suspected-IBD (4/20.2%) had involvement of small bowel on MRE confirming the CD diagnosis. Twenty-one patients with IC (21/40.52%) changed the diagnosis to CD. In 199/474 (40.5%) MRE determined a change on medical decision and 140 (70.3%) patients modified maintenance treatment because of MRE findings. Of them, 127 (63.8%) underwent “set-up” treatment by prescribing immunosuppressants (IS) (n = 45), anti-TNF agents (n = 22), anti-TNF escalation (n = 8), adding IS to anti-TNF agents (n = 9) and changing anti-TNF agents (n = 5). In addition, 13 (9.2%) patients underwent “top-down” therapy because of disease activity (n = 7), anti-TNF (n = 3) or anti-TNF de-escalation (n = 3). Surgery was indicated on 62 (62/199,31.1%) patients after MRE. After one year of follow-up, the medical decision was maintained on 65.4% (288/440) of patients.

Conclusion: RE is a very helpful tool for the medical management of CD patients. MRE provides major information to optimize treatment in the long-term of patients with active CD.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
2. Pariente and al, Gastroenterology 2015
3. Gastroenterology Unit, Hospital Huriez, Lille University Hospital, Lille;France

Contact E-mail Address: farre.clementine@gmail.com

Introduction: Crohn’s disease (CD) is a chronic progressive destructive disease, resulting in cumulative structural bowel damage, which may predict long-term disability. The Lémann Index (LI) has been developed to measure CD-related bowel damage, including bowel surgery, presence of stricture and penetrating lesions (Pariente and al, Gastroenterology 2015). The first Inflammatory Bowel Disease - Disability Index (IBD-DI) has recently been validated (Gower- Rousseau, Gut 2015).

Aims & Methods: The aim of the present study was (1) to identify factors associated with bowel damage and with disability in CD and (2) to evaluate the correlation between the LI and the IBD-DI. We performed a prospective study in the tertiary referral center of the Claude Huriez Hospital in Lille from September 2016 to November 2016, including all consecutive CD outpatients.

Bowel damage was assessed by the LI calculated according to the published LI protocol. Abdominal and pelvic Magnetic resonance imaging (MRI)s were reviewed and red by the same couple of one gastroenterologist and one radiologist. The IBD-DI was also calculated for all patients. Factors associated with LI and IBD-DI levels were identified by means of bivariate analyses of variance.

Results: 230 patients were prospectively and consentively included. Median age was 34.0 (interquartile range [IQR]: 26.0–46.0) and median disease duration was 10.0 (IQR: 5.0–17.0) years. 65 patients (50%) underwent at least one resection surgery. The median LI was 10.8 (IQR: 0.6–17.5). Disease duration (p < 0.0001), cumulative anal location (p < 0.0001) and CD activity (p < 0.0001) were associated with higher LI scores. Median IBD-DI was 25.0 (IQR: 14.7–41.1). Female gender (p = 0.02), CD activity (p < 0.0001) and current anoperinal lesions assessed by clinical examination and pelvic MRIs (p = 0.001) were associated with higher IBD-DI scores. The correlation coefficient between the LI and the IBD-DI was 0.12 (–0.05, 0.29; p = 0.154).

Conclusion: In a large cohort of CD patients from a tertiary referral CD center, disease duration, anal location and CD activity are associated with bowel damage assessed by the LI, while female gender, disease activity and current anoperinal lesions are associated with disability assessed by the IBD-DI. Correlation between the LI and the IBD-DI was low.

Introduction: The aetiology of Crohn’s disease (CD) and ulcerative colitis (UC) is not known. Recent data suggest a different cytokine profile between CD and UC.
Aims & Methods: The aim of this study was to analyse the expression of mRNA of proinflammatory, regulatory anti-inflammatory cytokines, chemokines and their ligands (IL-6, IL-8, 10, 12, IL-23, TNFα, CCR1, CCR2, CCR5, CD206, and transcription factor Foxp3) in the inflamed and non-inflamed intestinal biopsy samples of mucosa in IBD patients. We performed a cross-sectional study. The cohort consisted of 87 consecutive IBD patients (47 CD and 40 UC) who underwent colonoscopy at the IBID centre of University Hospital Bratislava. We biopsied and froze non-inflamed and inflamed tissue samples obtained from inflamed mucosa from sigma (CD, UC) and terminal ileum (CD). mRNA was extracted from mucosal biopsy samples, isolated by a RLT buffer and reversely transcribed. We normalized the expression of the target genes to the expression of the house-keeping gene (GAPDH). Finally, we compared the expression of cytokines in inflamed and non-inflamed mucosa separately for CD and UC patients.
Results: In UC patients, we observed higher expression of IL-8 (p = 0.04), IL-23 (p = 0.019), IL-10 (p = 0.002), CCR1 (p = 0.007), CCR2 (p = 0.037), CCR5 (p ≤ 0.01), CD206 (p = 0.011), TNFα (p = 0.002) and IL-6 (p = 0.006) in the inflamed mucosa from sigma. In CD patients, we observed increased expression of IL-8 (p = 0.005) and IL-10 (p = 0.001) in the inflamed mucosa of a terminal ileum and decreased expression of CCL5. Also, in group of patients with CD we did not observe the difference of the expression of mRNA cytokines between the inflamed and non-inflamed mucosa of sigma.
Conclusion: There was a significant difference in the mRNA cytokine profiles between CD and UC patients.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1654 THE RELATIONSHIP OF NEUTROPHEILIC AND ENDOTHELIAL ACTIVITY MARKERS WITH THE DISEASE ACTIVITY IN INFLAMMATORY BOWEL DISEASE
S. Boga1, A.R. Koksal1, H. Alkim1, A. A. Ozagari1, I. Sen1, M. Sahin1, C. Akkim1

Introduction: Inflammatory Bowel Disease (IBD) is a chronic autoimmune condition affecting epithelial and endothelial cells of the gastrointestinal tract. In IBD patients, inflammation, neutrophilia and endothelial dysfunction are common. There are limited number of studies that evaluate the relationship of neutrophilic and endothelial markers with disease activity of IBD. We aimed to investigate the relationship of these markers with disease activity in patients with Crohn’s disease.
Aims & Methods: Eighty-six UC, 63 CD, 36 non-IBD (screening, irritable bowel syndrome) and 52 healthy controls who were followed up in Gastroenterology Department of Sisli Hamidiye Etfal Education and Research Hospital between years 2015-2016 were enrolled. Patients were evaluated by endoscopic (Rachmilewitz index for UC, simple endoscopic score for CD (SES-CD) for CD) clinical (colitis activity index (CCI) for UC and CD activity index (CDAI) for CD), and pathologic activity scores and immunohistochemical staining.
Results: There were no differences between UC and CD patients in terms of serum endoglin and NGAL levels. NGAL and endoglin levels were significantly higher in endoscopically active UC group (n = 59) (142.8 ± 67.8 ng/mL and 26.3 ± 13.6 pg/mL) compared to inactive UC (n = 27) (119.7 ± 26.3 ng/mL and 476.9 ± 134.2 pg/mL) to non-IBD (115.8 ± 27.2 ng/mL and 460.6 ± 103.2 pg/mL) and to controls (116.7 ± 31.7 ng/mL and 457.2 ± 114.1 pg/mL). Although there were limited number of inactive CD patients (n = 11), serum NGAL and endoglin levels were significantly higher in endoscopically active CD groups (n = 52) (153.0 ± 28.9 ng/mL and 555.6 ± 136.3 pg/mL) compared to inactive CD (115.2 ± 35.9 ng/mL and 458.7 ± 132.8 pg/mL), to non-IBD and to controls (Figure). Structuring and fistulizing CD groups had significantly higher endoglin levels compared to inflammatory CD (p < 0.001 and p = 0.001). NGAL levels were significantly increasing with the increasing disease extension in UC and CD (p = 0.012 and p < 0.001). While the clinical activity subgroups were evaluated, there were significant difference in UC and CD patients in terms of endoglin levels but not NGAL levels (Endoglin: p = 0.002 p = 0.574, NGAL: p = 0.20, p = 0.171). Endoglin levels were more strongly correlated with the pathologic activity scores in both UC and CD groups compared to NGAL levels (Endoglin: r = 0.443, p < 0.001; r = 0.453, p < 0.001; NGAL: r = 0.274, p = 0.011; r = 0.409, p = 0.001). The immunohistochemical staining index of endoglin showed positive correlation with the immunohistochemical staining of vascular endothelial growth factor (VEGF) (UC r = 0.486, p < 0.001; CD r = 0.383, p = 0.002). The immunohistochemical staining index of endoglin in the colonic mucosa was correlated with the serum levels of endoglin in both UC and CD patients (UC r = 0.641, p < 0.001; CD r = 0.437, p < 0.001).
Conclusion: The present study highlights significant associations between endoglin and NGAL and IBD presence and activity, and demonstrates elevated serum and colonic endoglin levels in patients with active IBD as a novel finding.
Disclosure of Interest: All authors have declared no conflicts of interest.
Disclosure of Interest: Although thiopurine-induced myelotoxicity and hepatotoxicity rarely occur during maintenance thiopurine therapy for inflammatory bowel disease (IBD), current guidelines advise laboratory monitoring every 3 months. This study was performed to assess the current laboratory monitoring regime in thiopurine maintenance therapy with regards to consequences of myelotoxicity and hepatotoxicity.

Aims & Methods: In this multicenter cohort study, we evaluated adult IBD patients with quiescent disease who were on maintenance thiopurine therapy between 2000–2016. Data collection started after 12 consecutive months of thiopurine treatment. The primary outcome was therapy adjustment, i.e. therapy cessation or dose reduction, due to myelotoxicity (leukocyte count < 1.5 × 10⁹/l, platelet count < 1.50 × 10⁹/l) and/or hepatotoxicity (alkaline phosphatase (AP), gamma-glutamyltransferase (γ-GT), alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) above the upper limit of normal (ULN)). The secondary outcomes were prevalence of myelotoxicity and hepatotoxicity and additional diagnostic procedures due to this toxicity.

Results: This study included 223 IBD patients (55% female, 64% with Crohn’s disease, mean age at diagnosis 27.2 years (SD 11.5)). Median follow-up was 3.2 years (IQR 1.9–4.7). The mean monitoring frequency was 3.3 assessments per treatment year (SD 1.8). Toxicity was observed in 445/2402 laboratory assessments (18.5%) in 120 patients. In total, 20 (0.8%) therapy adjustments were performed and 25 laboratory assessments (1.0%) led to additional diagnostic procedures. Myelotoxicity, observed in 244 assessments, led to 11 dose reductions and in 3 patients therapy was stopped. For hepatotoxicity, observed in 201 assessments, 2 dose reductions were performed and in 4 patients therapy was stopped. Ninety percent of observed toxicity were mild leukenopia (leukocyte count < 3.0 × 10⁹/l) or mild hepatotoxicity (< 2 ULN), primarily in the first years of treatment. Dose adjustments were more often associated with moderate leukenopia (leukocyte count < 3.0) than with mild leukenopia (p < 0.01). In total, 2 complications were recorded, 1 patient was hospitalized because of pancytopenia and received red blood cell transfusion, and 1 patient was treated for a CMV infection. Both patients presented with symptoms in clinic with preceding normal laboratory values. No mortality due to thiopurine-induced toxicity was observed.

Conclusion: Although mild toxicity is common during maintenance thiopurine therapy, adjustments based on laboratory assessments are rare. Therefore, a less intensive regime to monitor thiopurine-induced toxicity should be considered.

Ulcerative colitis (UC) generally involves the entire large intestine extending from the rectum to the ileocecal junction. However, some patients with moderate or severe UC lack any obvious rectal involvement (known as rectal-sparing (RS)-UC).

In a total of 18 patients, by evaluating 123 colonic segments, 1831 images taken by FICE were evaluated by seven endoscopists and statistical analysis was performed. Images taken by FICE separately, from each areas of normal colonic mucosa, showed that the best imaging channels are; 2, 6, 9 for normal mucosa; 3, 7, 9 for dysplasia, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique.

Aims & Methods: The purpose of this study is; to evaluate the image patterns of dysplasia in ulcerative colitis, and their histopathological correlation, by using a virtual chromoendoscopy technique, FICE and to investigate the effectiveness of this technique. Eighteen follow-up patients of our inflammatory bowel disease polyclinic, with UC at least 8 years of disease history and who are in clinical remission, were included to this study. Screening colonoscopy was performed to the patients included in the study. Entire colon and especially dysplasia suspected areas visualised with standard endoscope first, and then with FICE; random and targeted biopsies were taken. Image patterns were compared with histopathology diagnosis. Normal, colitis and polyps images acquired by FICE, were evaluated by seven endoscopists and statistical analysis was performed.

Results: In a total of 18 patients, by evaluating 123 colonic segments, 1831 images were acquired and processed. In dysplasia, differences between patients with refractory UC with or without RS. Of the 437 inpatients with refractory UC who achieved remission between April 2001 and September 2016 (follow-up period: 915 ± 53 days, mean ± SD), 57 patients were classified as RS-UC and 340 patients without RS (standard [S]-UC group). Patients of the two groups were compared for gender, age at onset, site of involvement, disease duration, pretreatment clinical activity index (CAI, Lichtiger score), Hb, C-reactive protein (CRP), total dose of pre-, and UC symptoms at UC center, and stored at –80°C in a molecular biology laboratory. Data on dysbiosis, bacteria profiles, and FCal were available in 57 CD, 80 UC, 12 IBD-U patients and 100 symptomatic non-IBD patients, and 45 healthy controls. CRP was available for 52 CD, 74 UC, 10 IBD-U patients, and 88 symptomatic non-IBD patients. HBI was available for 50 CD patients, while SCCAI was available for 77 UC patients. Disease activity: No association was found between FCal and dysbiosis in UC patients (P = 0.08), CD patients (P = 0.22), and healthy controls (P = 0.57). However, an association was found between FCal and dysbiosis in symptomatic non-IBD patients (P = 0.04) and in IBD-U patients (P = 0.005). An association was found between CRP and dysbiosis in CD patients (P = 0.02), while not for UC and symptomatic non-IBD patients. No association was found between HBI and dysbiosis in CD patients (P = 0.23), and between SCCAI and dysbiosis in UC patients (P = 0.32). Microbiota: Increasing severity in UC and non-IBD patients, and in combination with elevated levels of FCal and/or FCR in UC patients. In the healthy controls, increasing dysbiosis severity yielded higher abundance of Proteobacteria.

Conclusion: In conclusion, a relationship between faecal dysbiosis in sub-groups of IBD patients also with high FCal. Accordingly, gut bacteria profiles and abundance may potentially be used to differentiate between severity in UC and CD patients, as a non-invasive tool to monitor disease activity in IBD.
P1660 SIMPLIFIED MR ENTEROCOLONOGRAPHY CAN BE USED ON ENDOSCOPIC FINDINGS FOR ACTIVITY ASSESSMENT OF CROHN’S DISEASE

Introduction: Crohn’s disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with Crohn’s disease. MR imaging is one of the most recommended technique for detection of large and small bowel lesions, as it gives excellent information about the clinical utility of the 3-point MR enterocolonography (MREC) classification for assessing CD activity based on endoscopic findings.

Aims & Methods: A total of 120 patients (70 for derivation cohort and 50 for validation cohort) with CD and undergone MREC and ileocolonoscopy or balloon-assisted enteroscopy (BAE). MREC was evaluated for each bowel segment; rectum, sigmoid, descending, transverse, ascending colon, terminal, proximal ileum, and jejunum, according to the consensus of two observers in the derivation phase, and independently by three observers in the validation phase, using a 5-point MREC classification based on a lexicon of MR findings. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients.

Results: BAE was performed in 49 (70%) and 37 (74%) patients in the derivation and validation cohorts. The AUCs of MREC classification were 0.90% in the derivation phase and 88.5, 81.0, and 77.3% for three observers in the validation phase. The AUCs of MREC classification were statistically non-inferior to those of MaRIA (p < 0.001). The cross-validation accuracy was 81.9% in the derivation and 81.5% in the validation phase. The MREC classification showed good agreement.

Conclusion: For clinical use, radiological reporting systems should be simple and provide appropriate levels of accuracy and reproducibility. The 5-point MREC classification meets these requirements, and is useful for evaluating CD activity in the large and small bowel segments.

Introduction: Syndrome (MetS) is a combination of biological and anthropometric disturbances and a recognized risk factor for cardiovascular disease. A higher prevalence of this condition has been previously reported in IBD patients, correlating to age as in the general population.

Aims & Methods: The aim of this study was to assess the effect of individual disease activity-related putative risk factors for MetS in a group of IBD patients, as well as any protective effects of treatment on MetS or its components. Consecutive IBD patients and age- and sex-matched controls were included during a 1-year period. MetS was diagnosed according to the “harmonized” criteria as the presence of >3 criteria among elevated waist circumference, blood pressure, blood glucose, serum triglycerides, or reduced HDL cholesterol. All subjects underwent colonoscopy; endoscopic disease activity was assessed according to SES-CD and Mayo endoscopic scores. CRP, faecal calprotectin (FC), hemoglobin and ferritin levels were also measured.

Results: We enrolled 145 consecutive IBD patients (53 Crohn’s disease and 92 ulcerative colitis; 58 M/87 F; mean age 51 ± 18 years) and 250 age- and sex-matched controls. Overall MetS prevalence was 37% in IBD and 21.6% in controls (p = 2.1, 95%CI:1.32–3.39). Prevalence according to sex or disease type did not show significant differences. At multivariate analysis, age and BMI > 25 were associated to an increased probability for a positive MetS status both in IBD (OR = 3.41, and OR = 6.01) and controls (respectively OR = 3.47 and OR = 3.74). In patients under 50 years, age (OR = 1.24), CRP (OR = 1.9) and FC (OR = 1.35) positivity were associated to MetS status, while a BMI > 25 increased risk at any age (<50ys OR = 3.8, >50ys OR = 1.56). Disease activity related to MetS status at any age. Interestingly, anti-TNFα treatment was protective in both groups, but reached statistical significance only in older subjects (>50ys OR = 0.08). Regarding individual MetS components, in the <50ys subgroup, age and CRP positivity associated with an impaired glycemic (respectively, OR = 1.15 and OR = 2.28) and lipidemic status (respectively, OR = 1.23 and OR = 2.3). In older patients, CRP positivity only associated to impaired HDL status (OR = 5.41). Importantly, anti-TNFα treatment favourably associated to HDL status (OR = 0.2).

Conclusion: MetS prevalence is increased in IBD compared to healthy controls at any age. Age, age with increased BMI and/or inflammatory markers are at higher risk for MetS, while anti-TNFα agents appear to be protective. The components associated to MetS are differently distributed according to age, with the inflammatory ones prevailing in subjects <50 years and metabolic disturbances in older patients. These results indicate that with an increased age, inflammatory disease-related treatment and/or atherogenic MetS components may reduce MetS occurrence and associated risks in subjects >50 years, in younger patients more effective inflammation control measures may prevent MetS and its related long-term neoplastic and cardiovascular complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1662 C-REACTIVE PROTEIN/ALBUMIN RATIO IS A GOOD PREDICTOR OF RESPONSE TO INTRAVERSE CORTICOSTEROIDS IN ACUTE SEVERE ULCERATIVE COLITIS
S. Monteiro1, T. Cárdia Gonçalves2, F. Días De Castro2, S. Leite1, M.J. Moreira1, J. Cotter2
1Gastroenterology, Hospital Senhora do Oliveira–Guimarães, Guimarães/Portugal
2Ives/38, PF Government Associate Laboratory, Guimarães/Braga/Portugal

Contact Email Address: sara.s.monteiro@gmail.com

Introduction: Patients with acute severe ulcerative colitis (ASUC) have a high risk of adverse medical therapy or colectomy. Recently, the C-reactive protein (CRP)/albumin ratio on admission, to predict response to intravenous corticosteroids in patients with ASUC. Retrospective assessment of systematically hospitalized patients with first episode of ASUC, who required intravenous corticosteroids. Demographic, clinical, laboratory and endoscopic variables were evaluated on admission. The response to intravenous corticosteroids within 48hrs was based on the lack of response. The non-respondents, rescue medical therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve (AUC).

Results: 51 patients were included, 30 (58.8%) of them female, with a mean age 34.3 ± 14.5 years. Twelve patients (23.5%) required medical rescue therapy. No patient underwent colectomy. The presence of deep ulcers and a shorter evolution of the disease were associated with a lack of response to intravenous corticosteroids, p < 0.001 and p = 0.008, respectively. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared with patients with response, 111 vs 67.5 (mg/L), p = 0.028, 2.8 vs 3.5 (g/dl), p = 0.005, respectively. The CRP/albumin ratio was a higher in unresponsive patients 40.06 vs 22.14, p = 0.022, showing a good accuracy for predicting non-response to intravenous corticosteroids with an AUC of 0.746, p = 0.01.

Conclusion: A high value of CRP/albumin ratio was significantly associated with the lack of response to intravenous corticosteroids, at the 3rd day of treatment. This index may also better risk stratification on admission, of patients with acute severe ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1663 INSUFFICIENT VARIATION OF MEDIUM CORPOSCULAR VOLUME (ΔMCV) IN INFLAMMATORY BOWEL DISEASE UNDER THIOPURINES PREDICTS DIFFICULTY IN ACHIEVING MUCOSAL HEALING COMBINATION WITH ANTI-TNF - THE OTHER SIDE OF THE MCV FLOW STUDY
J. Roseira1, H. Tavares De Sousa2, A. Marreiros2, P. Queiros2, A.M. Vaz2, T. Gago1, L. Contente1, H. Guerreiro2
1Gastroenterology, Algarve Hospital Center, Portimão/Portugal
2Biomedical Science Department, University of the Algarve, Faro/Portugal

Contact Email Address: jsr_roseira@hotmail.com

Introduction: The MCV flow study confirmed the association ΔMCV ≥7f1 at week 26-28 of Azathioprine monotherapy (mAZA) with favourable outcomes in severe inflammatory IBD patients.

Aims & Methods: For this work, our aims were to evaluate the need for step-up therapy in those under mAZA with ΔMCV ≤7f and to identify predictors of combined deep remission outcomes (DeepRem), at the same timepoint, for the patients who subsequently began combination therapy with Anti-TNF (AzAExperienced + Anti-TNF). Evaluation of patients under mAZA with ΔVGM ≤7 at key timepoint week 26-28 treatment, included for The MCV flow study. Demographic characterization and severity of pre-treatment disease was evaluated (Montreal classification, previous surgery status, Mayo score and Crohn’s disease activity index [CDAI]). ΔMCV’s association with DeepRem [Steroid-free clinical remission (CDAI < 150, Mayo < 2) + mucosal healing (MH)] + C-reactive protein (CRP) < 10] and need for biological therapy at the 7f timepoint was verified. Evaluation of DeepRem in mAZA, as an independent predictor in patients who subsequently started combination therapy. Statistical: Chi-square test; Binary logistic regression.

Results: A total of 106 IBD patients were evaluated [56.6% women, mean age 39 ± 12.5 years; 58 ad, 14% operated] at week 26-28 of mAZA. Identified strong association between at average ΔVGM ≥7 (n = 70; 66%) with DeepRem (p < 0.05), while a ΔVGM <7 was associated with biological therapy need (p < 0.05). 45 patients were later started with Anti-TNF therapy.
with fasting hyperglycemia (only 12.5%) had elevated C-reactive protein level but not fasting insulin level - it was within normal range. The highest level of the fasting insulin (over 10^11 IU/ml) in this group was observed in 3 patients who had to undergo immediate surgical treatment - two of them because of the bowel obstruction and one of them because of the perforation.

**Conclusion:** In our opinion there is a strong connection between fasting glucose, CRP level and exacerbation of the disease in CU patients but not in case of the Crohn’s Disease. In this group the elevated fasting insulin may be a marker of severe illness.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**THE ROLE OF MR IMAGING IN ASSESSMENT OF LEMANN INDEX IN THE COURSE OF CROHN’S DISEASE**

J.M. Pienkowska, O. Kozak, T. Nowicki, E. Szurowska

**Contact E-mail Address:** oliwa@kumed.edu.pl

**Introduction:** Crohn’s disease (CD) is a progressive, chronic and destructive inflammatory bowel disease process which, during its course, can lead to complications such as strictures and penetrating lesions (fistulas and abscesses), which may consequently require operative treatment. In some patients, bowel damage is present at the moment of diagnosis. The aim of the study is to assess the initial Lemann Index (LI), which comprehensively evaluates the entire gastrointestinal tract damage in patients with newly diagnosed Crohn’s disease.

**Aims & Methods:** In 209 patients with clinical suspicions of Crohn’s disease MR examinations for digestive tract histopathology were performed. In 151 patients with confirmed active/chronic CD the Lemann Index has been calculated on the basis of radiological and clinical information for initial assessment of cumulative digestive tissue damage. To create the Lemann Index the gastrointestinal tract was divided into 4 organs: upper digestive tract, small bowel, colon, rectum and anus. Each organ was divided into segments (3 for the upper digestive tract, 6 for the colon/rectum and 1 for anus). Strictures and penetrating lesions were assessed at each segment on 4-degree scale (0–3) according to the severity of lesions.

**Results:** Based on the findings of the initial radiological examination, active inflammatory process was found in 76 patients and chronic process in 75 patients. The baseline study demonstrated such complications as strictures in 14 patients, fistulas in 15 and abscesses in 4 patients. For all patients the LI was calculated. The obtained values were within the range from 0 to 22.

**Conclusion:** Over the years, the progression of Crohn’s disease leads to an increase in the value of Lemann Index, therefore, it seems that the evaluation of the first, baseline stage of the follow-up control MR examinations will allow for a more complete assessment of patients in terms of progressive bowel damage and modification of the therapeutic process.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**OPTICAL CHARACTERIZATION OF LESIONS IN IBD COLITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS**

R. Lord1, N. Burr2, N. Mohammed3, V. Subramaniam3

**Contact E-mail Address:** richard.lord@nhs.net

**Introduction:** Optical imaging is being increasingly advocated for characterization of polyps during colonoscopy. The accuracy of these techniques during surveillance colonoscopy in colon inflammatory bowel disease (IBD-C) is unclear and with variable results reported. We aimed to perform a systematic review and meta-analysis of the diagnostic accuracy of optical imaging techniques including dye based and virtual chromoendoscopy, magnification endoscopy and confocal laser endomicroscopy.

**Aims & Methods:** We searched Medline and Embase for relevant papers. Full articles or abstracts were eligible when characterization performance of dye-based chromoendoscopy (DCE), virtual chromoendoscopy (VCE) (narrow-band imaging [NBI], i-scan, Fujinon intelligent chromoendoscopy [FICE]), magnification endoscopy and confocal laser endomicroscopy (CLE) had been compared with histopathology, as the reference standard. Enough information had to be provided for the calculation of sensitivity, specificity and diagnostic odds ratio. We pre-defined the decision-making criteria regarding the cut-off values for the analysis (in CLE NBI, FICE and VCE cut-off values were 1.2; 1.2 and 1.0, respectively). Both authors independently assessed the quality of each included paper. Disagreements were solved by consensus. Analyses were performed using RevMan software.

**Results:** After exclusion of duplicate studies, 146 relevant studies were identified. 23 studies were selected for qualitative analysis, and 12 were selected for quantitative analysis. Nine studies compared dye-based chromoendoscopy and histopathology, and 5 compared virtual chromoendoscopy and histopathology.

**Conclusion:** There is consistent evidence for the use of optical imaging techniques in detecting polyps in patients with IBD colitis, although with varying sensitivity, specificity and diagnostic accuracy. Further high-quality studies are needed and the development of high-quality standards is recommended.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1667 EVALUATION OF SEVERITY SCORE IN CROHN’S DISEASE

Introduction: The need to stratify patients with Crohn’s disease (CD) according to the risk of developing complications is essential to delineate therapeutic approaches. A score that evaluates the severity of disease (Stiegel et al. Gut 2016) has recently been developed and published, taking into account intestinal lesions, disease activity and complications during the course of the disease, ranging from 0 to 100.

Aims & Methods: We aimed to evaluate the performance of the aforementioned score at the time of diagnosis and its relation to the need for surgery and hospitalizations in patients with CD. We performed a retrospective study that included patients diagnosed with CD in our hospital between 01/2012-12/2015. The score was calculated at the time of diagnosis and information on the course of the disease was collected. Statistical analysis was performed in SPSS (v23).

Results: A total of 57 patients (52.6% women) with a mean age of 33.74 ± 15.8 years were included. The median severity score at diagnosis was 16 ± 16.5 ranging from 4 to 50. Twenty-four patients (40.7%) required surgery and 29 (49.2%) were hospitalized for reasons associated with the disease. At diagnosis, the score was higher in AI1 patients (26 vs 19.2 and 13.7, p = 0.05), with a penetrating phenotype (25.5 vs. 19 and 12, p = 0.02), and in patients requiring surgery during the course of their disease (21 vs 14, p = 0.1). There was a positive correlation between the score at diagnosis and the number of surgeries during follow-up (r = 0.43; p = 0.05). Survival analysis showed a trend towards shorter time for surgery or hospitalization in patients with a score above the median at diagnosis (p logrank = 0.09).

Conclusion: The new severity score seems to be a promising tool for stratification and prognosis of patients with CD at diagnosis, and its utility should be validated in prospective studies.

Introduction: Microscopic colitis (MC) is a clinical syndrome of severe watery diarrhoea with few or no endoscopic abnormalities. The incidence of MC is reportedly similar to that of other inflammatory bowel diseases. The need for histological confirmation of MC frequently guides reimbursement health policies. With the advent of high-definition (HD) coloscopes, the incidence of distinct endoscopic findings reported in MC has risen. This has the potential to improve diagnosis times, increase cost-effectiveness of MC management and diminish the workload and costs of busy modern endoscopy units.

Aims & Methods: Publications on distinct endoscopic findings in MC available until 31st March 2017 were searched systematically (electronic and manual) in PubMed. The following search terms/descriptors were used: collagenous colitis(CC) OR lymphocytic colitis(LC) AND endoscopy, colonscopy, findings, This search was conducted separately with macrocolonscopía, score, categories, fractures. An additional search for MC AP was made.

Results: Eighty (n = 80) articles, predominantly single case reports (n = 45), were retrieved. Overall, 1,582 (1,159 female; 61.6 ± 14.1 years) patient(pts) with MC and endoscopic findings were reported. The majority of articles (n = 62) were on CC (756 pts; 77.5% female). We identified 16 papers comprising 779 pts (68.9% female) with LC and 7 articles describing 47 pts (72.3% female) confirmed to have MC. The youngest patient was 10 and the oldest 97 years old. Aside from diarrhoea, symptoms included abdominal pain, weight loss, bloating, flatulence and oedema. In the study group we found 616 (38.9%) pts with macroscopic lesions and endoscopic findings were reported. The majority of articles (n = 45) were on CC (756 pts; 77.5% female). We identified 16 papers comprising 779 pts (68.9% female) with LC and 7 articles describing 47 pts (72.3% female) confirmed to have MC. The youngest patient was 10 and the oldest 97 years old. Aside from diarrhoea, symptoms included abdominal pain, weight loss, bloating, flatulence and oedema. In the study group we found 616 (38.9%) pts with macroscopic lesions and endoscopic findings were reported.

Conclusion: Endoscopic findings are recognized with increased frequency in pts with MC. This could improve MC diagnosis by prompting a more extensive biopsy protocol in such cases and an earlier initiation of treatment. Procedure-related perforation has been reported in this group; therefore, cautious air insufflation is advisable when endoscopic findings are recognised.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** It is well recognized that patients with inflammatory bowel disease (IBD) are at risk for nonalcoholic fatty liver disease (NAFLD). Our aim was to evaluate the prevalence and to quantify hepatic steatosis in IBD patients by using the controlled attenuation parameter (CAP).

**Aims & Methods:** We prospectively recruited all IBD patients presenting for a disease flare or follow-up visit in our clinic, during a 18 month period. Patients with alcohol intake, those with a history of viral hepatitis were excluded from analysis. Clinical characteristics and laboratory data were recorded. Hepatic steatosis was evaluated by conventional ultrasound, hepatic steatosis index (HSI) and transient elastography with CAP (Fibroscan, Echosens, Paris). Significant steatosis (S ≥ 2) was defined for a CAP value over 236 [1], and the cut-off of HSI for detecting NAFLD was set at ≥ 36 [2].

**Results:** Altogether 62 IBD patients (35 ulcerative colitis, UC and 27 Crohn’s disease, CD), mean age 45 ± 15 years, 50% female, were included in the analysis. The two groups (UC, CD) were similar regarding disease activity (remission/flare 48.5/53.1% in the UC group, 55.6/44.4% in the CD group), BMI (24.1 ± 3.9 vs. 21.5 ± 3.1 kg/m²), and Crohn’s disease severity (median HBI 21 and 21.1 mm (interquartile range 498 and 513 mg/dl). UC patients had higher mean cholesterol values (205.9 vs. 176.4 mg/dl) and 11% of them were diabetic (compared to none in the CD group). Mean CAP was higher in CD compared to UC–246 vs. 225 dB/m, while mean HSI was higher in the two groups 49.4 vs. 36.5, respectively. UC identified 18/29 (62%) patients with fatty liver, HSI detected 3 more patients (21/62, 33.9%) and CAP even more 2 (23/62, 37.1%), yielding an extra 8% detection rate. NAFLD-IBD patients were more likely to have CD phenotype, history of resection, steroid use and longer disease duration.

**Conclusion:** In our cohort, about one in three IBD patients had fatty liver disease, as quantified by CAP. Diagnostic performance of CAP was better than conventional ultrasound and HSI in detecting fatty liver in IBD patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Interruption:** Irritable Bowel Syndrome (IBS) is a common gastrointestinal disorder that affects around 11% of global population. Despite the high prevalence of IBS, the cause of this disorder remains unknown and the criteria used to diagnose IBS are still unclear. In recent years, disturbances in the intestinal microbiota have been associated to the pathophysiology of IBS. Recently, two accurate stool biomarkers (Fpra and Eco) have been shown to discriminate between Inflammatory Bowel disease (IBD) and Healthy subjects (H). Therefore, the purpose of this study was to verify the capability of Fpra and Eco abundances to distinguish among healthy subjects, IBS, and IBD patients, in order to create a non-invasive system of diagnostic support for IBS patients.

**Aims & Methods:** A cohort consisting of 33 H and 14 IBS was enrolled. IBS patients were separated by subtypes: IBS with constipation (C-IBS), IBS with diarrhea (D-IBS), alternating IBS (A-IBS). Rome IV criteria were used to diagnose IBS patients. Moreover, 29 ulcerative colitis (UC) and 15 Crohn’s disease (CD) patients were also included. All subjects were recruited by the Gastroenterology Services of the Hospital Universitari Dr. Josep Trueta (Girona, Spain) and La Fe Hospital Universitari de Bellvitge, Hospitalat del Llobregat (Spain).

**Results:** We found lower abundance values of Fpra in IBS patients when compared with H (P = 0.005). In contrast, Eco abundance was higher in IBS patients, although the differences observed were not significant (P = 0.221). When comparing among subtypes of IBS (C-IBS, D-IBS, and A-IBS) no significant differences were observed, although Fpra abundance was lower in C-IBS. We also used Fpra in combination with Eco as a complementary indicator of dysbiosis (Ratio Fpra/Eco). This ratio allows a good discrimination between H and IBS (FPR = 0.04). When it comes to discrimination between IBS and IBD patients, significant differences were observed in Fpra/Eco ratio between UC and IBS patients (P = 0.008), but not between IBS and CD patients (P = 0.775). Concerning disorders different to IBS, significant differences were also observed between UC and CD (P > 0.001), between H and UC (P = 0.037), and between CD and UC (P = 0.027).

**Conclusion:** Fpra abundance is a good biomarker to discriminate between healthy subjects and IBS patients. The use of Fpra/Eco ratio allows to distinguish IBS from H and UC patients. In contrast, none of the used biomarkers was able to differentiate IBS and CD patients. These results show that IBS and CD patients share similar dysbiosis parameters opening the need of further study to stablish any eventual pathogenic link.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inflammatory bowel disease (IBD) and irritable bowel syndrome (IBS) may present in a similar manner [1] [2]. Measuring faecal calprotectin concentration is often recommended to rule out inflammatory bowel disease, however, there are no tests to positively diagnose irritable bowel syndrome and investigative tests are still used to rule out other pathologies [3, 4]. There is a chance, therefore, for novel, non-invasive disease-specific biomarkers. Volatile organic compounds (VOCs), originating from physiological metabolic processes in the human body, are excreted as waste products through stool samples. For this reason, several biological, non-invasive, simple and low-cost biological markers of inflammation that are useful in clinical practice for both diagnostic screening and therapeutic or course response monitoring are being evaluated in recent years Evolution of the disease. In this sense, stool markers, and especially calprotectin, have become of great importance in recent years as screening to select patients requiring more diagnostic studies and as a marker of activity for therapeutic follow-up [5]. Can the VOCs from stool samples show differences between ulcerative colitis and Crohn’s disease?

**Aims & Methods:** Five healthy individuals (control group- CON) and nineteen patients diagnosed with IBD were selected for the analysis of their stool VOCs. Healthy participants Healthy control samples (Control) (n = 5) were collected from healthy volunteers in the Digestive Diseases Area and they represented controls to illnesses related to the gastrointestinal tract and had not undergone antibiotic treatment in the 3 months before sampling. Active patients were defined as a Mayo Clinical score of 3 or more for ulcerative colitis (UC) and a Harvey Bradshaw clinical index of 4 or more for Crohn’s disease (CD). In both cases, calprotectin > 300 mg/g or relevant endoscopic lesions. Patients were classified according Montreal and ECCO criterias. This preliminary study is based in a group of CD-UC-CON where was analyzed 10 CD patients, 9 UC patients and 5 controls with 455 samples. Data from stool samples was obtained using eNose MOOSY32 [6].

**Results:** Figure 1 shows the scatter 3D plot with three voltage parameters for the group CD-UC-CON. These parameters mean the voltage from the eNose’s signals on saturation slope (vB) and late saturation (vE) and the number of sensor from the MOOSY32. Table 1 shows the comparative between relative error absolute and classification.

**Conclusion:** In this preliminary research to distinguish between Ulcerative Colitis and Crohn’s disease, the best algorithm for patient’s classification was the MLP with 30% to train and 70% to test. Although the high classifications result it is hopeful is necessary continue working to understanding how the eNose’s signals affect to the relative absolute error and improving the algorithms to decrease the error.

Introduction: In patients with inflammatory bowel diseases (IBDs), comprising Crohn’s disease (CD) and Ulcerative colitis (UC), a patient-tailored therapy is an unmet need that requires accurate monitoring of the intestinal disease activity. We demonstrated recently, that the expression of microRNA (miR)-320a follows the disease activity in murine colitis models. In this prospective study we evaluated the potential of miR-320a as a biomarker to monitor the disease activity in IBD patients as well as its potential to distinguish UC/CD from infectious colitis.

Aims & Methods: The miR-320a was measured by qRT-PCR analysis in peripheral blood samples from 36 CD and 34 UC patients with acute flare of disease (n = 51) and in remission (n = 37) as well as in healthy control patients (n = 20) and in patients with infectious colitis (n = 9). Disease activity was assessed clinically applying the Crohn’s disease activity index (CDAI) and the partial Mayo score (pMayo) for UC patients as well as the simple endoscopic score Crohn’s disease (SES-CD) and the endoscopic Mayo score (eMayo) to score endoscopic disease activity.

Results: Both in CD and in UC patients, miR-320a expression in remission was significantly increased as compared to healthy controls (49 ± 8.7 vs. 17 ± 3; both p < 0.001) but distinctly lower as in CD/UC patients with acute flare (1718 ± 488; p = 0.006; 531 ± 107, p = 0.001). In CD patients with acute clinical flare (CDAI > 220), miR-320a expression level were significantly increased as compared to CD patients in clinical remission (CDAI < 15; 267.7 ± 637 vs. 57 ± 9; p < 0.001) and showed a strong correlation with endoscopic disease activity (r² = 0.70). Similarly, in UC patients, miR-320a also revealed a significant increase in patients with low (pMayo 3–4), moderate (pMayo 5–6) and severe clinical disease activity (pMayo > 6) as compared to UC patients in remission (259 ± 47; 281 ± 26, 1090 ± 24 vs. 76 ± 13, all p < 0.001). Furthermore, we detected a significantly enhanced miR-320a expression with increasing endoscopic disease activity (eMayo 1: 89 ± 14 vs. eMayo 2: 301 ± 30, p = 0.006; vs. eMayo 3: 775 ± 245; p = 0.02). Most importantly, miR-320a expression in CD and UC patients with acute flare of disease was significantly increased as compared to patients with infectious colitis (53 ± 12, p < 0.001).

Conclusion: The miR-320a expression in peripheral blood from IBD patients followed the clinical and endoscopic disease activity and may distinguish between CD and infectious colitis. Therefore, miR-320a might serve as biomarker to non-invasively assess the disease activity in IBD patients.

Introduction: Infliximab (IFX) is a monoclonal antibody used for the treatment of inflammatory bowel disease (IBD) and is nowadays the drug of choice for refractory moderate to severe ulcerative colitis. Furthermore, IFX is the most used biological drug in the treatment of Crohn’s disease. However, the optimal IFX dosage is still unknown. In this study, we aimed to compare the accuracy of an established ELISA method with a newly developed rapid test and to determine the optimal IFX dose for patients with IBD.

Material and methods: Seventy patients with IBD, 47 CD and 23 UC, have been included in the study. The monitoring of serum IFX levels was done using the rapid test and an established ELISA method. Both tests were performed at a ratio of 1:1000 dilution. The rapid test has a sensitivity of 10 ng/ml and the ELISA has a sensitivity of 1 ng/ml. The optimal dose was determined based on a complete remission criteria (CD: CDAI ≤ 150; UC: Mayo ≤ 2).

Results: The rapid test showed 60 samples with a positive result, while the ELISA test showed 70. The optimal dose was calculated based on the results of the ELISA test, which showed that the optimal dose was 2 mg/kg dose for both CD and UC patients. The rapid test showed a sensitivity of 97.1% and a specificity of 85.7%.

Conclusion: The rapid test is a promising tool for the monitoring of IFX levels in IBD patients. It provides a quick and easy way to monitor the drug levels and determine the optimal dose. The results of this study suggest that the rapid test can be used as a reliable alternative to the established ELISA method for the monitoring of IFX levels in IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Aims & Methods:

Therapeutic drug monitoring (TDM) and a treat-to-target therapeutic approach may arise as a clinical strategy to optimise infliximab efficacy, safety and cost. The IFX levels measured by the point-of-care method were stratified according to a commonly accepted therapeutic range (3–51.4 g/ml) lower than 3 and higher than 7) with a high agreement. We estimated a simplified score to convert the “point-of-care” level into “Promonitor” level and facilitate dose management: “Nivel de Promonitor = 0.793 + 0.615*Nivel QB”. This new assay is a really useful technique enabling the fast and friendly quantitative determination of IFX levels to ensure correct dosing in IBD.

P1680 CORRELATION BETWEEN EXTRA-INTESTINAL MANIFESTATIONS AND ANTI-DRUG ANTIBODIES DEVELOPMENT IN CROHN’S DISEASE PATIENTS

M. Crespi1, G. Bodin1, E.G. Giannini1, V. Savarino1, A. Jain2, E. Savarino3
1Department Of Internal Medicine, IRCCS San Martino DIMI, Genova (GE) Italy 2Prometheus Laboratories Inc., San Diego/United States of America 3University Of Padova, Padova Italy

Contact E-mail Address: mattia_crespi4@gmail.com

Introduction: Extra-Intestinal Manifestations (EIM) are frequently (up to 40%) encountered in patients with Crohn’s Disease (CD). Commonly, their presence is associated to a more severe degree of laminar disease and lower response to conventional therapy (i.e. immunosuppressants). Drug trough levels are associated with biological drug response, while the role of Anti-drug Antibodies (AAA) is still debated. Moreover, the predicting factors associated with AAA development have not been thoroughly studied yet. To the best of our knowledge, there are no studies correlating the presence of EIM and AAA development.

Aims & Methods: The aim of our prospective study was to identify an association between the presence of EIM and the development of AAA in CD patients treated with biological therapy. We prospectively enrolled 60 CD patients (32 males, mean age 46y, range 21–72) treated either with adalimumab (ADA n 39, 65%, IFX n 21, 35%) with a median follow-up of 80 (range 14–206) weeks. Blood samples were drawn at standardized time points assessed using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States).

Results: ADA were detected in 27 (45%) patients and their development has proved to be more frequent in subjects treated with IFX rather than those in therapy with ADA (n 14, 66.6% vs 13, 33.3%, P = 0.017). EIM were observed in 26 (43.3%) patients, without any significant difference between ADA and IFX patients (n 17, 51.5% vs n 9, 42.9%, P = 0.1). We found that ADA treated patients with EIM were more likely to develop AAA (n = 9, 52.9% versus n = 4, 18.2%, P = 0.039) while no statistically significant association between EIM and AAA development was observed in IFX treated patients (n = 5, 55.5% versus n = 9, 75%, P = 0.64).

Conclusion: We found that ADA-treated patients with EIM tend to develop more frequently AAA. Assuming that the presence of AAA reduces the effectiveness of biological therapy, the presence of EIM may be considered a predictive factor for loss of response to biological therapy with anti-tumor necrosis factor alpha drugs.

P1681 THE PRESENCE OF IRRITABLE BOWEL SYNDROME-TYPE SYMPTOMS IN MICROSCOPIC COLITIS IS ASSOCIATED WITH INCREASED PSYCHOLOGICAL COMORBIDITY AND IMPAIRED QUALITY OF LIFE

J. S. Kane1, A. Irvine1, Y. Derwa1, O. Rotimi2, A.C. Ford3
1Leeds Gastroenterology Institute, St James’s University Hospital, Leeds/United Kingdom 2Department Of Histopathology, St James’s University Hospital, Leeds/United Kingdom

Contact E-mail Address: jackjohnkane@gmail.com

Introduction: Patients with microscopic colitis (MC) often present with abdominal pain and diarrhoea, and small cross-sectional surveys suggest that up to one-third may meet diagnostic criteria for irritable bowel syndrome (IBS). However, the impact of IBS-type symptoms in patients with MC, in terms of their effect on psychological health and quality of life has not been assessed.

Aims & Methods: We conducted a cross-sectional survey of individuals with MC. We analysed demographic data, symptoms that met the Rome III criteria for IBS and these individuals reported higher levels of anxiety, depression, and somatoform-type behaviour (via patient health questionnaire-15 (PHQ-15)), and quality of life (QOL) (via SF-36) in order to examine risk factors for, and impact of, IBS-type symptoms in patients with MC.

Results: In total, 157 individuals with MC returned completed questionnaires, 53 (36.6%) of whom met the Rome III diagnostic criteria for IBS. The commonest clinical subtype of MC was collagenous colitis (52.9%, n = 83), followed by lymphocytic colitis (38.2%, n = 60), and MC-not otherwise specified (8.9%, n = 14). Individuals meeting the Rome III criteria for IBS had significantly higher levels of anxiety (HADS-anxiety score 8.6 vs. 5.0, P < 0.001), depression (HADS-depression score 6.1 vs. 3.5, P = 0.001), and somatoform-type behaviour (PHQ-15 score 12.5 vs. 7.9, P < 0.001) compared with individuals who did not. Individuals meeting the Rome III criteria scored significantly worse on all domains of the SF-36, except for physical functioning. There were also trends towards these individuals being younger (65 years vs. 69.2 years, P = 0.011) or taking proton-pump inhibitors (58.5%, n = 55.5) vs. 60), and MC-not otherwise specified (8.9%, P = 0.062).

Conclusion: More than one-third of individuals with MC met diagnostic criteria for IBS and these individuals reported higher levels of anxiety, depression, and somatoformisation plus impaired quality of life. Management strategies for these symptoms are required.

Introduction: Ustekinumab (UST) has been shown to be effective in refractory Crohn’s disease (CD) in phase III trials. The aim of the present study was to prospectively evaluate the association between UST trough levels and anti-ustekinumab antibodies, with the response and remission to induction and maintenance UST treatment in CD patients.

Aims & Methods: We performed a prospective study including all CD patients refractory to anti-TNF who received subcutaneous UST from September 2015 to November 2016 in the tertiary French referral center of Gastroenterology in CHRU Lille hospital in Lille. During induction patients received 90mg of SC UST at week 0, 4 and 12. During the maintenance phase patients received 90mg of SC UST every 8 weeks that could be optimized by shortening injection interval to every 4 weeks in case of loss of response. Clinical response was defined by decreased Harvey Bradshaw Index (HBI) by 3 points, clinical remission by HBI <5, loss of response by new increase of HBI. UST trough levels and anti-ustekinumab antibodies, with the response and remission to induction and maintenance UST treatment in CD patients.

Results: Forty-eight patients with active disease received at least three UST injections who were prospectively enrolled. At time of ustekinumab introduction 77% of patients received concomitant immunomodulators and 42% received corticosteroids. At the end of the induction phase (week 12) clinical response was observed in 57% patients. There was no significant difference in mean UST trough levels in patients who responded to UST induction (median 1160 ng/ml; IQR: 603–1644) as compared to patients who did not respond (median 1556 ng/ml; IQR: 494-2758, p = 0.24). Forty-three (90%) patients received at least 4 injections of UST, with 12 patients who were optimized at the time of dosages.

Clinical response was observed in 30/43 (70%) patients. Median UST concentration in clinical responder was 1359 ng/ml (IQR: 554-2086) and 2392 ng/ml in non-responder (IQR: 1496-3494), with no significant difference between the two groups of patients (p = 0.20). UST antibodies were undetectable for the 48 patients.

Conclusion: We confirmed that UST treatment is effective in the majority of CD patients refractory to anti-TNF agents. Median trough levels to UST are not correlated to response and remission to UST induction and maintenance treatment, with no antibodies developed against UST.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inflammatory bowel diseases (IBDs) are chronic conditions characterized by elevated costs (both direct and indirect). Over the last years also a significative healthcare burden associated with IBD has emerged, due to an increasing use of biological therapies and hospitalization costs. Despite the creation of local or regional databases in Italy data regarding healthcare expenditure are lacking.

Aims & Methods: The aim of this study was to evaluate costs comprehensive of biological treatments and hospitalizations in a series of patients with ulcerative colitis (UC) and Crohn’s disease (CD) and their correlation with demographic and clinical variables. Disease severity was evaluated by clinical scores (partial Mayo score for UC, Harvey Bradshaw Index for CD). We analyzed retrospectively treated patients by biologics referred to our IBD Unit between May 2015 and April 2016 who underwent at least six months follow-up (last visit October 2016). As regards biological therapies costs burdened by our Centre pharmacy for each drug (Infliximab, Adalimumab, Golimumab, vedolizumab) and for single patient were evaluated. About hospitalizations the average costs of expenditure for month of treatment was 1235.41 €.

Results: We collected clinical-econometric data of 142 patients in biological treatment with ustekinumab (UST) and their costs for month of treatment were 337.36 €. All authors have declared no conflicts of interest.

Results: Forty-eight patients with active disease received at least three UST injections who were prospectively enrolled. At time of ustekinumab introduction 77% of patients received concomitant immunomodulators and 42% received corticosteroids. At the end of the induction phase (week 12) clinical response was observed in 57% patients. There was no significant difference in mean UST trough levels in patients who responded to UST induction (median 1160 ng/ml; IQR: 603–1644) as compared to patients who did not respond (median 1556 ng/ml; IQR: 494-2758, p = 0.24). Forty-three (90%) patients received at least 4 injections of UST, with 12 patients who were optimized at the time of dosages. Clinical response was observed in 30/43 (70%) patients. Median UST concentration in clinical responder was 1359 ng/ml (IQR: 554-2086) and 2392 ng/ml in non-responder (IQR: 1496-3494), with no significant difference between the two groups of patients (p = 0.20). UST antibodies were undetectable for the 48 patients.

Conclusion: We confirmed that UST treatment is effective in the majority of CD patients refractory to anti-TNF agents. Median trough levels to UST are not correlated to response and remission to UST induction and maintenance treatment, with no antibodies developed against UST.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1685 THE SICILIAN NETWORK FOR INFLAMMATORY BOWEL DISEASE (SN-IBD): PRELIMINARY DATA ON EFFICACY OF BIOLOGICAL THERAPY

Introduction: The monitoring of appropriateness, costs, and clinical outcomes of biological therapy in inflammatory bowel disease (IBD) is a relevant need. Aims & Methods: We aimed to evaluate all these issues in Sicily through a web-based network of all prescribing centers. The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is composed of a super Hub coordinator centre and five Hub plus four spoken centres. From January 2013, all IBD patients starting a biological agent (incident cases) or already on treatment (prevalent cases) were entered in a web based software. Herein we report data of incident cases about the efficacy of biological therapy after twelve weeks and one year of treatment. As clinical end-point, we set remission (corresponding to a Mayo Partial Score (MPS) <2 for UC, and to a Harvey-Bradshaw Index <5 for CD), and response (reduction in Harv-Bradshaw Index ≥3 for CD and Mayo Partial Score ≥2 for UC compared with baseline).

Results: From January 2013 to January 2017, 1578 patients were included. Incident cases were 1151 (808 Crohn’s disease [CD], 333 ulcerative colitis [UC]). In 8% of patients, we set the diagnosis of a 22.2% of patients experienced more than one line of therapy, a total of 1407 treatments were reported. CD: there was a higher proportion of patients naïve to biologicals (incident cases) or already on treatment (prevalent cases) were in CD compared with baseline).

Conclusion: In one of the largest “real-life” series of IBD patients on biological therapy reported to date, ADA in CD had a higher success compared to IFX at both 12 and 52 weeks; however, this results could be influenced by the preference of ADA as first-line anti-TNF drug in CD. IFX in UC was superior to GOL and ADA at 52 weeks; once again, this result could be influenced by the preference of IFX as first-line anti-TNF drug in UC; no difference was found between GOL and ADA in UC. Being naïve to biologics is a relevant predictor of response in both CD and UC at any time point. No significant difference in efficacy was observed between IFX originator and biosimilars.

P1686 SINGLE-CENTRE EXPERIENCE WITH BIOLOGICAL TREATMENT IN BUESDONEFACATORY MICROSCOPIC COLITIS PATIENTS
N. Daferera1, S. Ignatova2, A. Münch2

Introduction: Microscopic colitis (MC) is a common cause of chronic watery diarrhoea which is effectively treated with budesonide. However, in rare cases patients are refractory to budesonide leading to a severely deteriorated quality of life. Data on treatment options for budesonide refractory MC patients are sparse. We retrospectively evaluated the outcome of MC patients who have received intravenous therapy at our centre.

Aims & Methods: All patients with MC treated with biological therapy at the Department of Gastroenterology, University Hospital Linköping, Sweden were selected and the outcome recorded. Patients were investigated according to sex, age, disease subtype, clinical remission (defined as < or equal to 3 and no watery stools/day/week), clinical response (defined as 50% reduction of mean stool frequency/day/week), side effects and long-term outcome.

Results: 14 patients (10 women) with mean age at diagnosis of 49 years (range 19–76), thereof 12 with collagenous colitis and 2 with lymphocytic colitis were investigated.

Conclusion: In our single-centre experience with biological treatment in budesonide refractory MC patients, the use of a third anti-TNF agent (certolizumab) showed benefit in selected patients. In the cases that failed anti-TNF, further treatment with vedolizumab (1000 mg twice) was effective in all patients tested. Further treatment with rituximab (1000 mg twice) and ustekinumab (300 mg) did not improve the clinical condition. Prospective studies with long duration are needed to evaluate the efficacy of various biological treatments in budesonide refractory MC.

Introduction: Recent studies have shown that FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols)-free diet is effective in subjects with Irritable Bowel Syndrome (IBS). Patients with Inflammatory Bowel Diseases (IBD), and celiac disease (CD) can experience functional gastrointestinal symptoms unrelated to inflammation, but data about the use of low FODMAPs diet in these settings is still scarce.

Aims & Methods: To evaluate the usefulness of a low FODMAPs diet on patients with IBS, non-active IBD, and CD on strict gluten-free diet (GFD), we performed a dietetic interventional prospective study evaluating the effect of a low FODMAPs diet on patients affected by IBS, CD following at least a 1-year-GFD and IBD who had been experiencing abdominal symptoms without signs of active infection. Each subject was put on a low FODMAP diet after being evaluated by filling out questionnaires concerning on quality of life and symptoms experienced (IBS-SSS and SF-36), and was re-evaluated twice, first after 1 month and second after 3 months.

Results: 127 subjects were enrolled: 56 with IBS, 30 with IBD and 41 with CD. The analysis of the IBS-SSS survey showed that abdominal symptoms improved after 1 month and low FODMAPs diet in all subjects, with statistically significant difference within each group at T0 (average score in IBS: 293 ± 137 SD, average score in IBD: 206 ± 86 SD, average score in CD: 222 ± 65 SD, p < 0.0001). Furthermore, by analysing the SF-36 questionnaire, while we did not observe any significant difference between the three groups in terms of response to diet (p = NS), we observed a clinical improvement from T0 to T3, after the start of the diet, for most of the questionnaire’s domains.

Conclusion: A low FODMAPs diet could be a valid option to counter abdominal symptoms in patients with IBS, non-active IBD or CD on GFD, and, thus improve their quality of life and social relations.

Introduction: Vedolizumab (VDZ) is a new biologic agent approved for the treatment of adult patients with moderately to severely active ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Methods: The Sicilian Network for Inflammatory Bowel Disease (SIN-IBD) is composed by all Sicilian centres prescribing biologics. These centres continuously enter in a web based software all real-life data about pre-scriptions and outcomes of biological therapy in patients with inflammatory bowel disease (IBD). Herein we report data on efficacy of VDZ on intestinal and articular symptoms after 10 and 24 weeks of treatment. As clinical end-point, we set steroid-free remission (corresponding to a Mayo Partial Score < 2 for UC, and to a Harvey-Bradshaw Index < 5 for CD), and clinical response (reduction of Harvey-Bradshaw Index ≥ 3 for CD and Mayo Partial Score ≥ 2 for UC compared with baseline with a concomitant reduction of steroid dosages at week 10, and complete discontinuation at week 24).

Results: From July 2016 to April 2017, 163 patients (84 with CD and 79 with UC) were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients reaching 24 weeks of follow-up, 29 (40.8%) were in steroid-free remission, and 10 (14.1%) had a clinical response. No significant difference in terms of clinical benefit (rate of remission plus clinical response) among patients with UC and CD was reported at week 10 (68.4% vs. 64.3%, respectively; p = 0.58) and at week 24 (54.3% vs. 55.6%, respectively; p = 0.91), and no difference was observed comparing naïve and non naïve patients, neither at week 10 (61.5% vs. 67.7%, respectively; p = 0.48) nor at week 24 (30.0% vs. 39.9%, respectively; p = 0.11). At multiple logistic regression analysis, a longer duration of disease (OR 0.961, 95% CI: 0.931-0.991, p = 0.033) was a predictor of reduced rates of clinical benefit at week 24, while a low serum level of C-reactive protein at baseline (OR 0.950, p = 0.031) was predictor of clinical benefit at week 24. An improvement of articular symptoms was reported in 39.5% of patients with active spondyloarthritis at baseline at week 10, and in 45.4% of patients at week 24. The only factor associated with articular response was the coexistence of clinical benefit on intestinal symptoms, both at week 10 (OR 8.471, p = 0.05) and week 24 (OR 5.600; p = 0.08). Three inductions or flares of spondyloarthritids during treatment with VDZ were reported.

Introduction: The primary drugs used for inflammatory bowel disease (IBD) treatment have some adverse effects and often are ineffective, so the need for more potent and more reliable medications is clear. A significant role at all the stages of the inflammatory process is attributed to reactive oxygen species, therefore the use of antioxidants is a promising direction of the IBD therapy.

Aims & Methods: C60 fullerene are the effective free radicals scavengers [1], therefore the evaluation of possible protective properties of water-soluble pristine C60 fullerene using the simulation of acute ulcerative colitis (UC) in rats was aimed to be discovered. The pristine C60 fullerene aqueous colloid solution (C60FAS, initial concentration 0.15 mg/ml) was prepared according to the protocols developed before [2]. UC was simulated by acetic acid intracolonic instillation. C60FAS was intraperitoneally or intrarectally applied at dose of 0.5 mg/kg C60 daily for 2 times after UC induction. The colon injury was estimated semi-quantitatively on macro- and light microscopy levels using 10- and 14-grade scale, respectively, and the grade of total injury (GTI) was calculated. Permeability of colon epithelium was estimated by phenol red dye excretion exceeded the control one 6.6 times suggesting the damage of colon epithelial barrier. Degenerative features of exocrine pancreas and liver injury were also observed in UC rats. Anemia features manifested by hemoglobin concentration and red blood cell count decreased, reticulocytes volume, hematocrit and the platelet count increase could be caused by intestinal hemorrhages and subsequent erythro- and megakaryocytes release following active release of "young" erythrocytes (reticulocytes) and platelets into the blood. The last could be confirmed with histological assay (rise of the erythroblastic islands and megakaryocytes numbers in the spleen). Increase the number of neutrophils and spleen lymphatic follicles suggested the inflammatory process in the organism. The application of C60FAS by both ways caused GTI drop down to 6 points, whereas its rectal application normalized both ALT and AST activities but didn’t affect the pancreas. Moreover, C60FAS rectally increased monocyes number, which could be explained by involving the latest in mucosa healing process.

Conclusion: C60FAS corrects local and systemic morphofunctional changes, conditioned by the induction of acute UC. The protective properties of C60 fullerene against bowel, hematopoietic system and liver due to its local application are more expressed compared to their systemic one, but their impact on pancreas is controversial. Thus, water-soluble pristine C60 fullerene could be used as efficient therapeutic agents at ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1690 EARLY CLINICAL REMISSION BY WEEK 2 PREDICTS GOOD SHORT- AND LONG-TERM EFFICACY OF TACROLIMUS THERAPY IN PATIENTS WITH MODERATE TO SEVERE STEROID-REFRACTORY UCERATIVE COLITIS

N. Oshima, S. Ishihara, K. Kawashima, N. Sonoyama, N. Fukuba, Y. Mishima, I. Moriyama, T. Yuki, Y. Kinoshita

Introduction: Tacrolimus, a calcineurin inhibitor, has been shown to be safe and effective when used as salvage therapy for steroid-refractory ulcerative colitis (UC). Its pharmacological effect has been reported to be dependent on trough level in blood, though little is known regarding predictive factors in relation to the clinical efficacy of tacrolimus in UC patients.

Aims & Methods: The aim of this study was to identify factors related to prediction of short- and long-time efficacy of tacrolimus for UC. We retrospectively reviewed the medical records of patients with moderate to severe steroid-refractory UC who were treated with tacrolimus as induction therapy at Shimane University Hospital between January 2010 and March 2016. Oral tacrolimus was administered at a whole-blood trough level of 10-15 ng/ml to induce remission and then 5-10 ng/ml to maintain remission. Following tacrolimus therapy for 3 months, patients in clinical remission were given azathioprine for maintenance at an appropriate dosage. Using the Rachmilewitz clinical activity index (CAI), clinical remission was defined as a score of ≤ 4. Predictive factors associated with short- and long-term tacrolimus efficacy were analyzed by evaluating various clinical parameters.

Results: Thirty-six patients received oral tacrolimus for induction, of whom 22 (61.1%) and 27 (75%) experienced clinical remission at 2 and 12 weeks, respectively, after starting therapy. In evaluating the short-term efficacy, the remission rate at 2 weeks was significantly associated with CAI at 12 weeks. Interestingly, of the 22 patients in clinical remission within 2 weeks, 21 (95.5%) remained in remission at 12 weeks. In contrast, only 6 of 14 (42.9%) who did not achieve clinical remission at 2 weeks were not in clinical remission at 12 weeks. For evaluating the long-term efficacy of tacrolimus induction therapy, relapse-free periods were assessed using the Kaplan-Meier method. The relapse-free rate at 48 weeks was higher in patients who achieved clinical remission within 2 weeks compared to those without remission at that time point (79.0% vs. 60.0%).

Conclusion: Tacrolimus induction therapy was effective for patients with moderate to severe steroid-refractory UC. Our results clearly indicate that clinical remission at week 2 is useful for predicting both short- and long-term outcome in UC patients treated with that therapy.

Introduction: UC is a potentially severe disease that carries an increased risk of complications and colectomy. Immunosuppressant and biological therapies are relevant tools for complex patients. The ACCENT study showed that in Crohn’s disease (CD), scheduled IFX infusions vs. episodic are associated with greater efficacy. However, historical difficulties of economic access in BDAD and IFX toxicity in BDAD had conditioned to our IBD center, to use IFX in moderate to severe UC as a bridge to thiopurines in pts 6 mp/aza naïve. In UC, the mentioned strategy was insufficiently compared with a regimen of scheduled IFX treatment, that currently we use.

Aims & Methods: Suffering from arthropathies in IBD is strongly associated with different illness perceptions, coping strategies and illness outcomes and changes of these factors over time. As a gastroenterologist, addressing the maladaptive illness perceptions, coping strategies and related poor illness outcomes in these patients may provide an important driver for health care professionals about interventional strategies including cognitive behavioural therapy (CBT) or physical exercise.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CT-P13, the first biosimilar monoclonal antibody to infliximab (IFX) has previously been confirmed to be efficacious in inducing mucosal healing in ulcerative colitis (UC) patients.

Aims & Methods: The aim of this study was to evaluate the efficacy of CT-P13 therapy in maintaining mucosal healing in UC. Patients diagnosed with UC, who were administered CT-P13 from June 2014 at 4 Hungarian and one Czech IBD Centre were prospectively enrolled. Sigmodoscopy was performed at week 14 and week 54 to assess mucosal healing. Mucosal healing was defined as Mayo endoscopic subscore of 0 or 1. Complete mucosal healing was defined as Mayo endoscopic subscore of 0. CT-P13 trough levels, antibody positivity, serum inflammatory markers as CRP level, fecal calprotectin at weeks 14 and 54, concomitant drug cell adhesion markers at the time of treatment and during weeks 14 and 54, previous use of anti TNF drug and the need of dose intensification as possible predictive factors for mucosal healing at week 54 were evaluated. Results: Seventy-five UC patients were included in the study of which 74 patients completed the induction therapy and 54 patients had already completed the 54-week treatment period. Mucosal healing was shown in 55.4% of the patients at week 14 and 61.7% at week 54 (p = 0.03). Complete mucosal healing was patient in 24.3% at week 14, but in 61% at week 54. The median values of CRP (p = 0.017), leukocytes (p < 0.001), thrombocytes (p = 0.01) and albumin (p = 0.002) showed significant difference at baseline and week 54. Mean trough level of CT-P13 was 5.02 μg/ml and 4.4 μg/ml at week 14 and 54. Serum antibody positivity was assessed in 77% and 26.2% of cases at week 14 and 54, respectively. Dose escalation was necessary in one third of patients. None of the patients need surgery who completed week 54, however 4 subjects who stopped CT-P13 therapy after induction regimen required colectomy.

Conclusion: CT-P13 is better option for the third of the patients during CT-P13 maintenance therapy. Our study confirmed the long-term efficacy of CT-P13 therapy on mucosal healing in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI603 ILLNESS PERCEPTIONS, COPING STRATEGIES, OUTCOMES AND THEIR CHANGES OVER TIME IN IBD PATIENTS WITH ARTHROPATHIES: A 12-MONTH FOLLOW-UP STUDY

Introduction: EIM (Erosive inflammatory bowel disease) provides an opportunity to study the most common extra-intestinal manifestation (EIM) in patients with inflammatory bowel disease (IBD). Psychological and behavioural factors, including illness perceptions and coping strategies, perceived by IBD patients with arthropathies may differ from patients without arthropathies and may change during follow-up. Understanding these differences and changes over time, creates knowledge for health care professionals about interventions that may be effective in IBD patients with arthropathies.

Aims & Methods: This longitudinal follow-up study evaluates the differences in illness perceptions (emotional cognitions and emotions about a disease), coping strategies (behavioural efforts and strategies to deal with a chronic disease) and illness outcomes between IBD patients with and without arthropathies, and examines the changes of these variables in IBD patients with arthropathies after 12 months.

In total, 204 IBD patients with n = 123 and without (n = 81) arthropathies completed questionnaires at baseline and after 1 year follow-up to assess illness perceptions (Revised Illness Perception Questionnaire), coping strategies (Coping with Rheumatic Stressors Questionnaire) and illness outcomes including quality of life (Short Form-36), and activity and work impairment (Work Productivity Activity Index). Linear regression analyses were used to assess the impact of arthropathies on illness perceptions, coping and illness outcomes compared with IBD patients without arthropathies. Mixed model analyses were used to evaluate the change of these variables in IBD patients with arthropathies over time.

Results: Linear regression models demonstrated that arthropathies in IBD were associated with the illness perceptions strong ‘illness identity’ (β 1.15 (95%CI 0.31-1.96), p = 0.007), strong ‘cyclical timeline’ (β 1.33 (95%CI 0.33-2.34), p = 0.024) and more ‘consequentiality’ (β 2.00 (95%CI 0.60-3.42), p = 0.006), stronger ‘emotional representations’ (β 1.58 (95%CI 0.08-3.08, p = 0.039) and a low ‘coherence’ (β −1.29 (95%CI −2.45-(-0.14)), p = 0.029). In addition, the coping strategies increased ‘diverting attention’ (β 1.54 (95%CI 0.26-2.66), p = 0.047) and increased ‘consideration’ (β 0.18 (95%CI 0.10-2.27, p = 0.033), as well as the illness outcomes low physical (β −7.22 (95%CI −9.68-(-4.77), p < 0.001) and mental (β −3.10 (95%CI −5.39-(-0.23)), p = 0.035) health and increased activity impairment (0.15 (95%CI 0.07-0.23), p < 0.001) were related with IBD with arthropathies. Two months follow-up, lower scores on the illness perception dimension ‘treatment control’ (p = 0.001) and increased scores on the coping strategy ‘pacing’ (p = 0.03) were found in IBD patients with arthropathies compared with baseline scores.

Conclusion: Suffering from arthropathies in IBD is strongly associated with different illness perceptions, coping strategies and illness outcomes and changes of these factors over time. As a gastroenterologist, addressing the maladaptive illness perceptions, coping strategies and related poor illness outcomes in these patients may provide an important driver for health care professionals about interventional strategies including cognitive behavioural therapy (CBT) or physical exercise.

PI605 THE USE OF ANTI-TNFs IN INDUCING CLINICAL RESPONSE AND REMISSION IN ULCERATIVE COLITIS: A COMPARATIVE ANALYSIS IN THE REAL-LIFE EXPERIENCE OF A SINGLE REFERRAL CENTER
B. Scrivo, M.G. Cilluffo, G. C. Morreale, V. Calvaruso, M. Mendoloro, A. Vitello, S. Peralta, M. Cappello
Gastroenterology And Hepatology, Policlinico Paolo Giaccone, Palermo/Italy

Contact E-mail Address: barbara.scrivo@gmail.com

Introduction: Anti-tumor necrosis factor (anti-TNF) agents, infliximab (IFX) and more recently adalimumab (ADA) and golimum (GOL), have been shown effective and safe in the treatment of moderate-to-severe ulcerative colitis
Aims & Methods: Our aim was to compare efficacy of IFX, ADA and GOL in inducing clinical response and remission in a prospective cohort of patients with moderate to severe UC. From June 2015 to October 2016, 61 consecutive UC patients were treated with anti-TNFs: 19 with IFX, 25 with ADA and 17 with GOL. Disease activity was assessed by Mayo Score. Clinical response and/or remission were evaluated at week 8 and at week 16. We also recorded: indications to biologic therapy, previous immunom suppressive or anti-TNF therapy and rate of anti-TNF discontinuation.

Results: Among the 61 patients, 36 were males; mean age was 43.6 ± 15; no significant difference was present in baseline characteristics (extent and disease activity); 39 patients were thiopurine failure; 38 were naïve to anti-TNFs, most were treated with IFX (p = 0.001). ADA and GOL were more often used as a second-line or third-line. The principal indication for steroid resistance patients was IFX. No significant difference was observed between IFX and ADA both at week 8 (response: IFX vs ADA p = 0.08; remission p = 0.28; at week 16 (response p = 0.5; remission p = 0.97), though there was a trend towards a higher rate of response at week 8 with IFX (79% vs 64%). IFX and ADA were more effective than GOL at week 8 (response: IFX vs GOL p = 0.02; remission: ADA vs GOL p = 0.027). At week 16 only IFX seems to be more effective than GOL in inducing clinical response (p = 0.048) but not remission. No significant difference among the three drugs was observed in patients naïve to anti-TNFs. Treatment was discontinued in 2 patient in IFX group and in 6 patients in GOL group and in 6 patients with ADA due to persistent disease activity.

Conclusion: This single-center study shows that IFX is more effective than GOL both in the induction (8 weeks) and in the maintenance of response (16 weeks). ADA is more effective than GOL in inducing remission at 8 weeks but no significant difference is observed in the medium-term. However, GOL was used mainly as a second or third-line. In naïve patients, efficacy among anti-TNFs is comparable. Our results may help clinicians in the choice of an anti-TNF in UC. IFX is preferred in steroid-resistant patients to get a faster response, ADA and GOL should be the first option in steroid-dependent patients naïve to anti-TNFs.

Disclosure of Interest: All authors have declared no conflicts of interest.

*Includes paradoxical skin manifestations, acute generalised exanthematous pustulosis, dry skin, erythema nodosum, palmar erythema. *Includes spontaneous nausea. *Includes liver test abnormalities (transient transaminases), drug-induced liver injury (not specified).*Includes severe musculoskeletal syndrome, exacerbation of pre-existing enteropathic arthritis *Includes pneumonia, lower respiratory tract infections, respiratory tract infection (not specified).

Pooled analysis of AE rates across multiple studies support the favourable, long-term benefit–risk profile of VDZ in real-world clinical practice, with low rates of infection-related reactions, serious infections and malignancies reported, and no identification of new safety signals. These results are consistent with integrated safety data reported for VDZ in six clinical trials (≥4000 patient-years), indicating the selection of complex patients failing previous immunosuppressive or biologic therapies. Limitations of incidental reporting in real-world studies include potential underestimation of AE rates and the reporting of AEs not regularly observed in clinical trials; for example, due to the variability in medication use and sub-optimal screening of prior infections.

INFLAMMATORY BOWEL DISEASE: A META-ANALYSIS

Introduction: Vedolizumab (VDZ), a gut-selective monoclonal anti-α4β7-integrin antibody, is used for treatment of Crohn’s disease (CD) and ulcerative colitis (UC). Data from large real-world cohorts can further characterise safety events not fully elucidated in a clinical trial setting, such as the risk of serious infections, as identified with anti-tumour necrosis factor-alpha (TNFα) therapy in the THAMAS [1] and ENACT-2 [2] registries.

Aims & Methods: We conducted a systematic review and meta-analysis of real-world safety outcomes reported for VDZ in UC and CD. MEDLINE-, Cochrane-, and EMBASE-indexed publications and conference abstracts (n ≥ 10) from May 1, 2014–January 10, 2017 were searched for studies reporting real-world VDZ safety outcomes. Reports for patients < 18 years of age or for off-label VDZ use were excluded. A meta-analysis was conducted using the DerSimonian-Laird random effects method to obtain a weighted mean of adverse event (AE) rates.

Results: Two hundred and eighty published studies were identified, with 33 reporting safety rates on 2857 VDZ-treated patients (CD: 1532; UC: 829; unspecified/other: 36, three studies [n=460] did not report individual UC/CD data) over a VDZ exposure/follow-up period ranging 0.5–18 months (20 studies). Among included studies, the mean age of patients ranged from 21 to 67 years, with mean disease duration ranging from 7 to 16 years. Most VDZ-treated patients (62–100%) had prior exposure to ≥1 anti-TNFα therapy and 6–64% of VDZ-treated patients were receiving concomitant corticosteroids and immunomodulators. The most common non-infectious AEs were acne or acne-like lesions (7%; 95% confidence interval [CI] 3–11%), fatigue (6%; 95% CI 3–15%) and arthralgia (5%; 95% CI 3–10%) (Table 1). The most common infections were upper respiratory tract infections (6%; 95% CI 3–11%) and sinusitis (4%; 95% CI 1–19%) (Table 1). Infection-related reactions occurred in 2% (95% CI <1–4%) of patients (n = 811), and malignancies were reported in <1% of patients (<1–4%; 2 studies). Overall, the pooled AE rate reported in VDZ-treated patients was 21% (95% CI 14–32%); 10% (95% CI 6–16%) for infections, 8% (95% CI 6–10%) for serious AEs and 7% (95% CI 3–13%) for serious infections (Table 1).

*Includes paradoxical skin manifestations, acute generalised exanthematous pustulosis, dry skin, erythema nodosum, palmar erythema. *Includes spontaneous nausea. *Includes liver test abnormalities (transient transaminases), drug-induced liver injury (not specified).
P1687 COST-UTILITY ANALYSES OF BIOLOGICS FOR REFRACTORY ULCERATIVE COLITIS

S. Campbell Davies1, C. Inserra1, R. Salerno1, A. Cassinotti2, G. Muserra2, M. Piacenza1, S. Ardizzone2

1Pharmacy, ASST Fatebenefratelli Sacco, Milan/Italy
2Gastroenterology, ASST Fatebenefratelli Sacco, Milan/Italy

Contact E-mail Address: secampbelldavies@gmail.com

Introduction: Although many biologics (Bs) have been approved for the treatment of refractory-to-severe Ulcerative Colitis (UC) in patients who have responded inadequately to conventional therapy, the selection of Bs is controversial due to the lack of head-to-head trials. Indirect economic comparisons of these costly drugs are available from National Healthcare perspectives that are not adequate to inform patients.

Aims & Methods: The objective is to evaluate cost-utility of Bs for the treatment of refractory-to-severe UC both in Italy and in the Lombardy region. A Markov model (considering 3 transition states: remission, clinical response, response lost) was used to evaluate the incremental cost-utility ratio (ICUR) of adalimumab (ADA), infliximab (IFX), vedolizumab (VED) and golimumab (GOL) in ulcerative colitis patients over a 10-year time horizon from the perspective of the Italian (N) and Lombardy Region (R) healthcare system. Clinical parameters were derived from clinical trials. Costs (actualized by –1.5%) were obtained from the National database and Regional public tender. Utility was expressed as QALY (Quality Adjusted Life Years).

Results: Costs per treatment were different from a N and R perspective (ADA = –55%; IFX = –16.7%; IFX-B = –29.6%; GOL = –9.6%; VED = –10%). Direct healthcare costs (treatment cost, visits, lab tests, hospital admissions) were calculated over 10 years of treatment per patient: ADA (N: €114,227, R: €68,314, –40.2%); IFX (N: €113,595, R: €103,081, –23%); IFX-B (N: €110,435, R: €78,852, –28.6%); GOL (N: €118,602, R: €96,922, –18.3%); VED (N: €113,852, R: €102,932, –9.6%) with associated QALY respectively of 6.68, 6.66, 6.66, 6.70, 7.02. From a N perspective, IFX-B was dominating compared to all other treatments. The ICUR of VED/IFX-B was €408,483 for 10 years of treatment (willingness to pay €408/QALY). From a R perspective, ADA was dominating compared to all other treatments. The ICUR of VED/ADA was €101,818 for 10 years (WTP €101,818/QALY).

Conclusion: National and Regional cost-utility analyses produced different results. As Regional price discounts can occur, local analysis is needed to estimate the economic impact of therapies to ensure optimal choice.

Introduction: Biological therapies are effective treatments for inflammatory bowel disease (IBD) but represent an important economic burden to the healthcare system. Adherence surveillance is necessary to optimize the treatment of IBD and its costs. This issue has been evaluated just in a few studies.

Aims & Methods: We aim to describe the adherence to infliximab in patients with IBD and identify causes and factors associated with poor adherence. We identified all IBD patients treated with infliximab in a single center since 2009. Fulfillment of the prescribed schedule was assessed for every single infliximab infusion. For every patient, we grouped infusions in “courses of treatment” defined as the administration of infliximab at the same dose and schedule for a minimum of six months. Therefore, restarting the treatment after a holiday of more than 4 months, or changing the interval of doses were considered as a new course of treatment. We defined “infusion well administered” when it was done within seven days before or after the date prescribed.

Results: We included a total of 147 courses of treatment, administered to 100 patients. Seventy-four percent of courses were Crohn disease patients, and 25% in ulcerative colitis patients. In 89% of courses combo therapy with immunosuppressants was used. The prescribed regimens were: every 8 weeks (76.2%), every 4 weeks (18.7%), every 6 weeks (5.5%), every 12 weeks (5.4%) or every 4 weeks (2%). The mean duration of the courses was 23 months (range: 6–103). Only 69 out of 1714 infusions (4%), were not properly administered. The reported causes for that included: 36 “unknown” (52%), 18 “change requested by patient” (26%), 14 “due to logistic reasons” (21%) and 4 “other” (5%). In 107 courses (73%) all the infusions were well administered; in 143 (97%) >80% of infusions were well administered and only 4 courses (2.7%) had less than <80% of adherence. In more than an half of the infusions the cause could not be identified, for that reason analysis of predictive factors could not be performed.

Conclusion: The adherence to the scheduled infliximab regimen was very high and it would contribute to maintain the drug efficacy. The reasons for changing the date of administration should be indicated in the clinical history to identify associated factors and minimize the lack of adherence.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1700 TNF-EXPRESSION OF MONOCYTES IS A PREDICTIVE MARKER FOR RESPONSE TO INFlixIMAB TREATMENT IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

D. Lissner, B. Jessen, E. Sonnenberg, F. Schmidt, A. Kuehl, B. Siegmund

Department For Gastroenterology, Infectious Diseases And Rheumatology, Charité–Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin/Germany

Contact E-mail Address: domata.lissner@charite.de

Introduction: One-third of all patients with inflammatory bowel diseases (IBD) do not respond to initial treatment with the anti-TNF-antibody Infliximab. Thus, predictive markers for response to anti-TNF-treatment are required.

Methods: The study was designed to investigate whether levels of TNF produced by peripheral blood mononuclear cells (PBMCs) can predict response to anti-TNF-treatment. Fourteen patients with proven Crohn’s disease (CD) or ulcerative colitis (UC) without treatment with biologics in the past six months were included prior to first Infliximab infusion. Disease activity was measured by the use of Harvey-Bradshaw-Index (HBI) or partial Mayo Score, C-reactive protein (CRP) and ultrasound (Limberg Score). TNF-expression of LPS-stimulated PBMCs was measured by ELISA before treatment. Additionally PBMCs’
intracellular TNF-expression was analysed by flow cytometry. According to a cut-off identified by receiver operating characteristic analysis, high TNF-producers were defined as positive and low TNF-producers as negative. Primary endpoint was clinical response, secondary endpoints were decrease in CRP and Limberg Score. Clinical response was defined as a decline in Score of ≥2 (HBI) or ≥3 (partial Mayo Score). A HBI <1 or a partial Mayo-Score <2 was defined as remission. Results were analysed using the Fisher’s exact test. Results: Nine patients reached the endpoint at week 6 and were available for further analysis (5 patients with CD, 4 patients with UC). The median TNF-expression was defined as remission. Results were analysed using the Fisher’s exact test. There was no difference in the number of prior TNF-alpha inhibitors between CS users and non-CS users. However, remission rates were significantly higher in high producers compared to low producers (high: 90% vs. low: 30% p = 0.04). Secondary endpoints showed no significant difference in the two groups. Conclusion: Quantification of TNF-expression in PBMCs and the resulting classification in low- and high-producers could be a potential predictive marker for response to anti-TNF-treatment in IBD patients.

Introduction: Corticosteroids (CS) are often used concomitantly with biologics in treatment of inflammatory bowel disease (IBD). However, their side-effect profile causes significant clinical and economic burden in long-term treatment. In this study, we investigated the impact of concomitant CS use on vedolizumab treatment persistence in patients with Crohn’s disease (CD) and ulcerative colitis (UC).

Aims & Methods: This was a nationwide (Finland), retrospective, non-interventional, multi-center chart review. From 27 centers, we included adult (≥18 years of age) IBD patients who received at least one vedolizumab infusion since 2014. Data were extracted from patients’ electronic medical records charts in a standardized case report form. The key data collection points were at baseline, week 14 and month 6 of vedolizumab treatment. The main aim of the study was to analyze vedolizumab treatment persistence among IBD patients using CS in real-world clinical setting.

Results: 247 patients (CD 108, UC 139) were included. At baseline, 47 (43.5%) CD and 84 (60.4%) UC patients were using CS. Higher percentage of patients using CS at baseline discontinued vedolizumab during the 6-month follow-up compared to CS non-users (CD, 14/47 (29.8%) vs. 13/61 (21.3%); UC, 31/84 (37.3%) vs. 16/55 (29.1%). CS users had less vedolizumab discontinuations due to primary inefficacy (p = 0.04) and more discontinuations due to adverse events (p = 0.04), than CS non-users. Over half of the patients on CS at baseline and who persisted on vedolizumab were able to discontinue CS before 6 months (CD: 18/33 (54.5%); UC, 37/53 (69.8%). Among CD patients, CS users had higher baseline disease activity than non-users. Such difference was not observed in UC. CS users had shorter disease duration in both CD and UC. There was no difference in the number of prior TNF-alpha inhibitors between CS users and non-CS users.

Conclusion: Use of CS at the time of initiating vedolizumab treatment was more common in UC than in CD. Vodelizumab treatment persistence was lower in CS users than in non-users in both CD and UC. The data suggests that CS users have less vedolizumab discontinuations due to primary inefficacy and more discontinuations due to adverse events, than CS non-users. The majority of patients on CS at baseline who persisted on vedolizumab were steroid-free by 6 months, potentially relieving the burden of CS-induced side-effects for both patients and society.

Jokelainen: JJ is employee of MedEngine Oy. S. Herrala: SH is employee of MedEngine Oy. K. Tamminen: KT is employee of Takeda Oy. All other authors have declared no conflicts of interest.
results of the context of ~77.382 patient-years of VDZ exposure and a total of 36 VDZ-treated patients (events = 13 serious, non-serious) occurred in 15 patients with pre-existing viral hepatitis B (n = 5, including 2 chronic cases) or hepatitis C (n = 10). Of the 15 patients, six had ulcerative colitis, seven had Crohn’s disease, and in two the indication was not specified (NR). Eight patients received prior/concomitant anti-TNFa therapy (anti-TNFa; NR = 2. Events were reflective of the general VDZ safety profile in patients without viral hepatitis. Liver-related events were reported in two patients with hepatitis C—one patient who was a smoker reported hepatic neoplasms; the other had a history of skin cancer, cholecystectomy, bladder tumour removal and right radical orchidectomy. Both events resulted in VDZ discontinuation. Of events with a reported outcome, 22/26 (84.6%) were resolved or resolving at the time of reporting and 4/26 (15.4%) were unresolved; NR = 2. VDZ treatment was continued in 10/14 (71.4%) patients and discontinued in 4/14 (28.6%); NR = 1.

Conclusion: In the post-marketing setting, there was no evidence of increased risk of viral reactivation in patients with hepatitis B or hepatitis C receiving VDZ. Limitations (associated with post-marketing safety reporting, nature of reporting and incomplete patient medical history) and currently limited availability of VDZ in regions with endemic hepatitis B and hepatitis C infection should be considered when interpreting these results.

P1707 AMINOSALICYLATES FOR MAINTENANCE THERAPY IN ULCERATIVE COLITIS: IS THE ADHERENCE REALLY IMPORTANT?
D. Marti, M.P. Ballester, M. Fullana, P. Navarro, M.M. Boscá, J. Tosca, F. Mora, M. Minguez
Digestive Disease, University Clinic Hospital of Valencia, Valencia/Spain
Contact E-mail Address: maphibe@gmail.com

Introduction: The goal of maintenance therapy in Ulcerative Colitis (UC) is to keep clinical and endoscopic steroid-free remission. 5-aminosalicylate (5-ASA) represents the first line maintenance therapy. Non-adherence to 5-ASA is associated with an increased risk of disease relapse, colorectal cancer and worsening of quality of life1. Adherence rate has been analysed in several studies with controversial results2-4.

Aims & Methods: The aim of this study is to quantify the prevalence of adherence to 5-ASA, to identify risk factors to non-adherence and its correlation with the clinical outcome. Observational analysis, retrospective, single tertiary centre, cohort study of all UC patients followed-up in our IBD unit, until January 2016, with 5-ASA maintenance treatment prescribed by an electronic management program. Adherence was considered when 80% of the prescribed 5-ASA was dispense at pharmacy in the one year (2016), assuming that dispensed 5-ASA is equivalent to medication intake. The study analysed, according to the existence and degree of 5-ASA adherence, UC phenotypic expression (age, sex, smoking habit, Montreal classification, extraintestinal manifestations, complications), disease course (moderate-severe relapse rate that require corticosteroid therapy), 5-ASA properties (dose, administration regime, formulation), consumption of other UC and non-UC chronic drugs. A multivariable logistic regression model was applied to discriminate the adherent patients including the risk factors of the univariate analysis. A Spearman’s rank coefficient analysis was performed to correlate percentage of adherence with relapse rate.

Results: The study cohort included 433 patients, 55% males with a median age at the first 5-ASA prescription analysed of 49 years (IQR 39-61). 17% had a proctitis, 31% a left-side colitis and 52% an extended disease. 30% of patients suffered from extraintestinal manifestations and 8 from a complication. The mean dose of 5-ASA taken was 2.6 g/day (range 0.7-4.8) distributed in a daily dosage of 14 of the patients. Adherence prevalence to 5-ASA was 63%. Adherent group had a higher median age (52 (±11) vs 43 (±13), p = 0.001) and received more non-UC chronic drugs (OR = 2.3, 95CI = 1.5-3.4, p = 0.001). The independent variables, age and intake of other non-UC drugs, included in the multivariate analysis reached a predictive capacity of 65% outcomes of adherence. There was no significant reduction in the risk of moderate-severe flares that required corticosteroid therapy when comparing both adherent and non-adherent groups and rank correlation showed no relationship between adherence to 5-ASA and relapse rate (t = 0.12, p = 0.29). Patients treated with adjuvant maintenance therapy (bithery with thiopurines or anti-TNF or triple therapy with both) presented a significant reduction of flares (OR = 0.6, 95CI = 0.7-0.9, p = 0.019).

Conclusion: Adherence to 5-ASA in our population is low. Older patients that take other non-UC chronic treatments show higher adherence. With a one year prescribed and dispensed analysis, non-adherence to 5-ASA is not related with a higher risk of flares that require corticosteroid therapy. Patients treated with adjuvant maintenance therapy, show better results throughout the course of the disease.

**Introduction:** Randomized controlled trials provide efficacy data of novel IBD drugs. The majority of patients included in these trials however, especially for novel biologics, are highly selected patients from referral centres and are included in a variety of countries with very different health care systems. Inclusion criteria and follow-up protocols are strict and do not reflect routine care. Long-term country specific effectiveness and safety data for novel drugs are therefore warranted. Development and implementation of a novel protocol and electronic case reporting registry for every new compound is however time consuming and expensive. Therefore, the Initiative on Crohn and Colitis (ICC) aimed to develop a web-based registry suitable for capturing, managing, and reporting data for all drugs and all IBD phenotypes in everyday practice in all centres. Aim & Methods: Here, we aim to test the feasibility of the web-based registry in patients starting vedolizumab. With a structured iterative process with IBD-specialist from the ICC, case report forms and lab-evaluation forms were developed to assess key elements of disease activity, safety and a PROM. Furthermore the ICC decided on a uniform follow-up protocol reflecting everyday practise. A web-based registry for capturing, managing and reporting follow-up data of IBD patients starting a new drug was developed (ICC-case series). The registry automatically reminds the treating physician or nurse prior to novel follow-up visits. Feasibility of the ICC-case series was assessed in 6 centres in the Netherlands in patients who started vedolizumab. To test data extraction and reporting, the baseline characteristics of the first cases were assessed. The characteristics were compared to baseline characteristics of subjects in the vedolizumab registration studies.

**Results:** A total of 230 IBD (4 IBD-U) patients starting vedolizumab were included. All users found the ICC-case series easy to use and received the reminder mails for follow-up visits. Baseline characteristics were successfully extracted and are reported in table 1.

**Table 1:** Baseline characteristics of ICC cohort and GEMINI trials

**Conclusion:** The ICC developed a uniform web-based registry to study post-marketing safety and effectiveness of novel IBD-drugs. A feasibility study with 230 patients starting vedolizumab showed successful data-capture, managing, and reporting with the ICC-case series in 6 centres. Table 1 shows clear differences between baseline characteristics of real-life Dutch patients and patients in the GEMINI studies underlining the importance of country specific post-marketing data.

Contact E-mail Address: claudio.cassieri@libero.it

**Introduction:** Azathioprine (AZA) and thiopurines are widely used for induction and maintenance of remission in patients steroid-resistant or dependent with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5–30% of patients due to the occurrence of adverse events.

**Aims & Methods:** Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients six year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985–2015, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg. Blood chemistry was analysed before administration of the drug, every 10–15 days for the first 3 months and then every 1–2 months following the institution of treatment.

**Results:** Out of 2722 consecutive IBD outpatients visited in the index period, AZA was prescribed to 415 patients, 227 (54.7%) were affected by Crohn’s disease (CD) and 188 (45.3%) by ulcerative colitis (UC). One hundred and fifty-eight patients with a follow-up <72 months were excluded from the study. Two hundred and fifty-seven patients were evaluated, 143 (55.6%) with CD and 114 (44.4%) with UC. One hundred and forty-two (55.2%) were male.
P1708 CLINICAL Efficacy and SAFETY OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE IN THE ELDERLY: A UK TERTIARY REFERAL CENTRE EXPERIENCE

J. Digby-Bell
Dept. Of Gastroenterology, St. Thomas’ Hospital, London/United Kingdom

Contact E-mail Address: jdigbybell@doctors.org.uk

Introduction: Many patients, especially the elderly or those with comorbidities, are excluded from clinical drug trials and little real-life data exists on the safety and efficacy of anti-TNF.

Aims & Methods: We aimed to compare the clinical efficacy and safety of anti-TNF therapy in patients over 60 years in a tertiary IBD centre in London, UK. We interrogated our IBD databases from January 2009 to November 2015 and performed retrospective data analysis until end of follow up in April 2017. Data was collected on demographics, endoscopy, calprotectin, CRP, clinical scores, serious infections, malignancy, drug levels and anti-drug antibodies. Patients with an age of ≥60 when starting anti-TNF therapy were identified and <60 comparators were selected at random in a 2:1 ratio. Primary endpoints: week 14 and week 54 steroid-free clinical remission (Harvey Bradshaw Index <5 or Simple Colitis Activity Index <3) Secondary endpoint: proportion of patients remaining on anti-TNF at the end of follow up

Results: See table.

Conclusion: Only a small number of ≥60 patients started anti-TNF (29 out of greater than 650). This may reflect our local population or that clinicians favour anti-TNF therapies in this older group. Overall there was similar clinical efficacy at weeks 14 and 54 of anti-TNF therapy between the ‘young’ and ‘old’ groups. There was a higher discontinuation rate after 1 year of therapy in the older group (p=0.043). There were more adverse events in the older group (7/29) including 3 new cancer diagnoses compared with the younger group (3/58). 4 patients had detectable anti-drug antibodies in the older group despite 2 of them having therapeutic thiopurine suggesting that the elderly may have more immunogeneity than the young. Further studies with more patients across multiple sites are required to clarify safety and efficacy in the elderly.

P1709 TACROLIMUS IN REFRACTORY ULCERATIVE COLITIS–12 MONTH OUTCOME IN A SINGLE-CENTRE UK DISTRICT HOSPITAL

N. Jayasooriya, L. Everson, S. Mann
Gastroenterology, Barnet and Chase Farm Hospital, Royal Free Trust NHS, Barnet/United Kingdom

Contact E-mail Address: nishani.jayasooriya@nhs.net

Introduction: Rescue therapy is required for patients with moderate - severe ulcerative colitis (UC) who have failed to respond to steroids and thiopurines. Anti-Tumour Necrosis Factor agents (Anti-TNFs) are widely used before considering a colectomy. Calcineurin inhibitors such as ciclosporin and Tacrolimus may be considered as alternatives to biologics. There have been some case series in assessing the use of Tacrolimus in such patients although the United Kingdom experience is limited. (1, 2)

Aims & Methods: We aimed to review the outcome of patients who received Tacrolimus as rescue and subsequent maintenance therapy for refractory symptoms of UC. This was a retrospective single-centre case review series. All patients who were refractory to standard medical therapies and being considered for a colectomy were reviewed by a Gastroenterologist with an interest in Inflammatory Bowel Disease. Demographic data, indications for treatment, clinical course and outcomes were reviewed from Electronic Patient Records (EPR).

Results: Fourteen patients (F=6; mean age of 54 years) received Tacrolimus. 8 patients (57%) had evidence of pancolitis and six patients (43%) had distal colitis. All patients had previously received thiopurines and 11 patients (78.6%) had also received anti-TNFs. Three patients declined Anti-TNF treatment. All patients were steroid-dependent prior to commencing Tacrolimus. One patient received ciclosporin before the switch. The remaining 13 patients were initiated on Tacrolimus in the out-patient setting at a starting dose of 0.1 mg/kg/day in 2 divided doses. Patients took Tacrolimus for a mean period of 18.8 months (range: 2 months to 49 months). Eight patients (57%) achieved a steroid-free remission within 6 months. An additional 3 patients (23%) had a clinical response within 6 months, but required one course of steroids during this time period. Three patients (23%) failed to respond to Tacrolimus; 1 patient remains steroid-dependent and does not wish to proceed to surgery, 1 patient was switched to infliximab and 1 patient proceeded at 10 months to have an elective subtotal colectomy. Tacrolimus was withdrawn in all 3 non-responders. Of the 11 (78.6%) initial responders, 12-month outcome included withdrawal of Tacrolimus in 7 patients (63.6%). Reasons for withdrawal included: n = 1 renal impairment; n = 1 started on infliximab; n = 3 referred for leucapharesis; n = 1 restarted on Azathioprine and n = 1 referred for proctocolectomy. Three patients (21.4%) remain in steroid-free clinical remission with a good quality of life and

and 115 (44.8%) female (average age of 35.68 ± 14.22 SD years, range 14–74 y.), Six years after the institution of treatment, 130 (50.6%) patients still were in steroid-free remission (85 CD vs 45 UC, 59.5% and 39.5%, respectively, \( p = 0.0017 \)), 71 (27.6%) had a relapse requiring retreatment with steroids (29 CD vs 24 UC, 20.3% and 36.6%, respectively, \( p = 0.0048 \), 56 (21.8%) discontinue the treatment due to side effects (29 CD vs 27 UC, 20.2% and 23.7%, respectively). Loss of response from 1st to 6th year of follow-up was low, about 20%.

Conclusion: Six years after the onset of treatment 56% of patients did not require further steroid courses. After the first year loss of response was low in five subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

Disclosure of Interest: All authors have declared no conflicts of interest.
no adverse effects on maintenance treatment with Tacrolimus. 11 patients (29.7%) of ADA and 11 patients (23.3%) of golimumab discontinued because of drug-related adverse events in the first 12-months of follow-up. Conclusion: Tacrolimus should be considered as an alternative treatment for patients with refractory UC in the out-patient setting. This is particularly useful if the patient is unwilling to consider a colectomy. With close monitoring and early intervention if needed, it is safe and it is avoiding patients an alternative immunosuppressant which may either avoid the need for a colectomy or, give some time to adjust to its implications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1710 A REAL LIFE COMPARISON OF THE EFFICACY OF ADALIMUMAB VERSUS GOLIMUMAB IN MODERATE-TO-SEVERE ULCERATIVE COLITIS: A MULTICENTER EXPERIENCE FROM THE SICILIAN NETWORK FOR INFLAMMATORY BOWEL DISEASE (SN-IBD)

S. Renna1, F. Mocciaro2, M. Ventimiglia1, F.S. Macaluso1, R. Orlando1, M. Billeci3, M. Cappello1, M. Mendolara3, A.C. Privitera1, C. Ferracane1, W. Fries1, V. Pisana7, A. Magnano8, D. Pluchino8, G. Inserra9, G. Scarpulla10, Catania/Italy, Messina/Italy

Introduction: Adalimumab (ADA) and golimumab (GOL) are effective in the induction and maintenance treatment of moderate-to-severe ulcerative colitis (UC). No comparable data between the 2 drugs are available up to now.

Aims & Methods: We reported the Sicilian Network experience on the comparative efficacy of ADA and GOL in patients (pts) with moderate-to-severe UC. From June 2015 until April 2017, 197 consecutive pts with moderate to severe UC treated with ADA or GOL. The efficacy was evaluated at 8 weeks and at the end of the follow up considering “clinical response” (reduction of at least 2 points of Partial Mayo Score with concomitant steroid reduction or discontinuation) and “clinical remission” (Partial Mayo Score ≤ 1).

Results: 118 pts were treated with ADA and 79 with GOL for a median follow up of 40.21 [20.32, 69.14] weeks for ADA and 34.00 [17.43, 54.79] weeks for GOL (p=0.08). Eighty-eight pts were naïve to anti-TNFa (59 ADA, 29 GOL, p=0.09). No difference in Mayo Score value was observed between the 2 groups at the time of first drug injection (p=0.92). After 8 weeks clinical benefit was achieved in 93/118 (78.8%) pts treated with ADA and 50/79 (63.3%) pts treated with GOL (p=0.026). Clinical remission was achieved in 48/118 (40.7%) pts treated with ADA and 20/79 (25.3%) pts treated with GOL (p=0.038). At the end of the follow up clinical benefit was achieved in 79/118 (66.9%) pts treated with ADA and 37/79 (46.8%) pts treated with GOL (p=0.008). Clinical remission was achieved in 50/118 (42.4%) pts treated with ADA and 23/79 (29.1%) pts treated with GOL (p=0.08). No difference was observed in clinical outcomes at 8 weeks and at the end of the follow up between naïve and non naïve pts (p=0.187). At the end of the follow up the median Endoscopic Mayo Score was 3.00 [0.00, 5.00] in pts treated with ADA and 4.00 [1.00, 7.00] in pts treated with GOL (p=0.025). Univariable analysis revealed that age > 40 years at the time of first drug injection and age < 40 years at the diagnosis were associated with higher remission rate in pts treated with ADA respect to pts treated with GOL at 8 weeks and at the end of the follow up (p = 0.016 respectively). Median duration ≥ 5 years was associated with a higher remission rate in pts treated with ADA respect to pts treated with GOL at 8 weeks and at the end of the follow up (p = 0.037).

Conclusion: This is the first study where the comparable efficacy of ADA and GOL was evaluated. These real life data confirmed the efficacy of subcutaneous anti-TNFα in the treatment of moderate to severe UC. ADA resulted to be more effective than GOL in inducing and maintaining clinical benefit. Larger prospective studies with longer follow up are warranted to confirm this data.

P1711 REAL-LIFE STUDY (GORE-UC) EVALUATING THE EFFECTIVENESS OF GOLIMUMAB FOR THE TREATMENT OF ULCERATIVE COLITIS: AN INTERIM ANALYSIS FROM ITALIAN GROUP FOR THE STUDY OF INFLAMMATORY BOWEL DISEASE (IG-IBD)

D. Pugliese1, A. Variola2, A. E. Privitera1, M. Allocca3, F. Bossi4, M. Cappello6, G. Lorenzo5, S. Mazzoloi6, A. Principe6, R. Sablich10, A. Armond11

Introduction: The efficacy of golimumab (GOL) and adalimumab (ADA) in the treatment of patients (pts) with moderate-to-severe ulcerative colitis (UC) has been studied in two completed clinical trials.1,2 However, patients enrolled in clinical trials are not entirely representative of those encounters in the clinical practice. GOL is not on the market for treating UC from March 2015. The aim of our study is to evaluate the durability and safety of golimumab in the context of real-life clinical practice.

Aims & Methods: An observational, multicenter, retrospective-prospective, phase IV study, enrolling all patients starting golimumab from March to December 2015, from 21 IG-IBD centers. This study consists of two different parts: 1) retrospective, regarding data until December 2016 and 2) a prospective one, still ongoing, that will be concluded at the end of 2017. The co-primary outcomes were the overall durability of treatment with golimumab, defined as persistence of golimumab therapy because of sustained clinical benefit, and safety. Results for the first 54-weeks period are reported. Results: 121 patients (47% female, 53% Mayo score < 7 at baseline, median age of 45.7 years (SD 14.3) and a median duration of disease of 8 years, (range 0–28) were included. Sixty-seven patients (55.4%) had severe endoscopic activity (Mayo 3). Clinical activity was defined as moderate (Partial Mayo Score (PMS) 5–6) in 55 patients (45.5%) and severe (PMS ≥ 7) in 66 patients (54.5%). The mean exposure to anti-TNFα-was reported in 52% of patients (38 Infliximab, 4 Adalimumab, 21 both). Steroid dependence and refractoriness were reported in 78.5% and 16.5% of patients, respectively. After 54 weeks, the cumulative persistence on golimumab therapy was 35%. Seventy-seven patients withdrew from treatment, without significant difference among anti-TNFα-naïve vs exposed patients (55.2% vs 71.4%, p = 0.11 Chi-Square test). Among 90% of patients who completed week 54, 48% of patients were still on golimumab therapy at week 54. Thirty patients (25%) were still on treatment without significant difference between weeks 24 and 54. After 54 weeks the persistence on golimumab therapy was 57.1%. Ten patients reported an adverse event, but only 6 of them withdrew from treatment. Four patients reported paradoxical skin lesions, unresponsive to topical therapies. Fifteen patients (12.4%) underwent colectomy within the first 54 weeks, with a greater percentage among anti-TNFα-exposed patients (20.6% vs 3.4%, p = 0.02 Chi-Square test).

Conclusion: This preliminary real-life data study endorses golimumab’s promising results, showing 57.1% of durability treatment at week 54 in those patients.
who completed first 14 weeks of treatment and confirming it as a safe drug. Anti TNF α more likely to avoid colonic resection.

Results: A total of 148 patients with confirmed IBD diagnosis were included in the study. In UC (47.3%) with CD. We found that 12 (12%) of the UC patients and 5 (11%) of the CD patients were colonized with ESBL-E. The isolated ESBL producing strains from UC patients included Escherichia coli (n=10), Klebsiella oxytoca (n=1) and Escherichia hermanii (n=1). The isolated ESBL producing strains from CD patients included only Escherichia coli (n=5). The isolated bacterial planktonic genes associated with ESBL production in UC included CTX-M (n=11; 92%), TEM (n = 4; 33%), SHV (n = 1; 8%), in CD; TEM–CTX-M (n = 4; 40%) and TEM (n = 3; 60%). In UC (60%) and in CD (20%) of the CD patients included only Escherichia coli. In 1 case of the ciprofloxacin resistance CTX-M, TEM and SHV gene combination was observed, in 1 case TEM-CTX-M and TEM gene combination was observed, in 4 cases only CTX-M gene was present and in 1 case only TEM gene was present.

Conclusion: The general sample of health insurance beneficiaries’ database provides a unique representative sample to analyze and describe real-life usage of anti-TNF in Crohn’s disease patients in France.

P1714 PREDICTIVE FACTORS OF RESPONSE TO ANTI-TNF A TREATMENT OF COMPLEX ANO-PERINEAL FISTULAS IN CROHN’S DISEASE

M. Hafi, D. Pugliese: Lecture fees from AbbVie and Takeda, which has received honoraria from Janssen

L. Lamarsalle: Ludovic LAMARSALLE is an employee of HEVA HEOR, which has received honoraria from Janssen

M. Allez: Matthieu Allez has received honoraria from Novo Nordisk, MSD, Abbvie, Ferring, Genentech, TCell, Janssen, Pfizer, GSK, Hospira and UCB

Introduction: Anti-TNFs are well-established in therapeutic management of Crohn’s disease (CD). Real-life data on their pattern of use in a French clinical setting are, however, limited to this day.

Aims & Methods: The objective of this study was to examine for characteristics of CD patients and anti-TNF use in a real-life setting in France through the general sample of health insurance beneficiaries (EGB database) which includes reimbursement data from a sampled 1/97th of the French population. A cohort of 1280 patients with CD in the EGB database between 01/01/2010 and 31/02/2014 was retrospectively constituted, of which 189 (14.8%) initiated an anti-TNF treatment during that period and were studied for this analysis. An additional analysis was performed based on French hospital discharge data (medical information systems program [PMSI]) from 8142 CD patients to compare results from the EGB database but only support infliximab use due to its exclusive hospital availability in France (adalimumab can be prescribed in both hospital and retail markets).

Results: 48.7% of anti-TNF treated patients were male and the mean age at the initiation of an anti-TNF treatment was 38. The mean duration between diagnosis and treatment started ranged from 1 to 7 years. A total of 12 months of follow-up at 12 months, 13.6% of patients underwent surgery. Results from the hospital discharge database confirmed some of our observations. Optimization rate for infliximab 12 months after initiation was similar (31.4% at 12 months for infliximab). Treatment discontinuation rate was also within the same range observed and stable over time, with 10% of patients discontinuing infliximab year each treatment year and a discontinuation rate after 12 months of treatment of 27.2%.

Conclusion: The general sample of health insurance beneficiaries’ database provides a unique representative sample to analyze and describe real-life usage of anti-TNF in Crohn’s disease patients in France.

Disclosure of Interest: The present study was supported by the French Society for Inflammatory Bowel Disease.

Introduction: Anti-TNFs are a common location of Crohn’s disease (CD). Their treatment is still disappointing. Identifying the predictive factors of response could guide the practitioner to adapt the anti-TNF α treatment of each patient.

Aims & Methods: We performed a descriptive, longitudinal and retrospective study over a period of 14 years. We included all patients with a definite diagnosis of complex AP of CD treated with anti-TNF α with a minimum follow-up of one year. Patients less than 16 years of age or over 70 years were excluded and non-observing patients were also excluded. A univariate and multivariate statistical analysis was then carried out using the SPSS software to identify the predictive factors of response to the treatment.

Results: A total of 49 patients had complex AP treated with anti-TNF α. 10% of the patients had also recto-vaginal fistulas. The mean age was 31 years. The sex ratio women/men was 1.35. All of the patients had an MRI at diagnosis. Patients had concomitant antibiotics and seton drainage in all cases. 76% of the patients received azathioprin. After the induction phase, 53% of the patients...
achieved clinical remission, 31% a partial clinical response and 12% a primary failure. The patients maintained a clinical remission after a year of anti-TNF therapy. After a mean time of 13 months, 42% of the patients had a loss of response. The analytical study found that the absence of recto-colic involvement, CRP negativity and normalization of platelet count under treatment and achievement of clinical remission after the induction phase were predictive factors of long term good response to anti-TNF treatment. Clinical remission after the induction phase was the only independent predictive factor of long-term remission maintenance under treatment after multivariate analysis. However, predictive factors of early treatment discontinuation as well as the presence of a recto-vaginal fistula and young age at diagnosis.

Conclusion: According to our results, the type of response obtained after the induction phase seems to be closely related to the subsequent development of outcomes. Further studies assessing early therapeutic adaptation and factors influencing outcomes could better evaluate this perspective in the event of a partial clinical response. In addition, rectal involvement and recto-vaginal fistulas are factors of poor response for which aggressive and specific treatment is essential.

Introduction: The management of chronic inflammatory bowel disease (IBD) has experienced significant advance with the development of biologic therapy. Infliximab (IFX) was the first monoclonal antibody approved for IBD. The patent expiry of biologics and their relatively high costs result that in a significant economic burden on the healthcare system, had led to the development of bio-similar agents. The biosimilar IFX has been authorised for use in all the indications as the reference IFX. The demonstration of biosimilar IFX efficacy and safety equivalence was based on two pivotal clinical trials in rheumatic diseases. As a result of the extrapolation to IBD, there is growing controversy regarding the appropriate use of biosimilar IFX. The efficacy and safety of infliximab reference in inducing and maintaining remission in IBD has been extensively proven in clinical trials. However, the role of biosimilar IFX, has not been systematically investigated in clinical practice.

Aims & Methods: We aimed to compare the safety and efficacy in inducing and maintaining remission in IBD, between the reference IFX group and biosimilar IFX group. This retrospective, multicenter study was carried out on 4 tertiary hospitals in Spain from January 2013 to December 2016. The analysis included all consecutive IBD patients. One cohort composed of patients who were started original IFX since 2013. The second cohort included patients who were treated from the introduction of biosimilar IFX. Adverse events (AEs), demographic, clinical, endoscopic and laboratory data were collected on all patients. Efficacy was assessed according to response and remission at 14th, 54th week. For CU, response was defined as a decrease in partial Mayo score of 2 or more from baseline and a partial Mayo score of 1 or less was used to was used to remission. For CD, response was defined as a decrease in Harvey-Bradshaw score of 3 or more from baseline, and a Harley-Bradshaw score of 4 or less was used to was used to remission. We used Student’s t for independent samples and Chi-square test. Time to withdrawal due to adverse effects was estimated using Kaplan-Meier survival analysis.

Results: The analysis included 346 consecutive IBD patients, 104 treated with original IFX and 242 with biosimilar IFX. 103 patients were diagnosed with CU, 238 with CD and 5 with indeterminate colitis. Overall median follow-up was 21 months. Baseline clinical activity scores were not significantly different among the 2 groups. Frequency of concomitant azathioprine and systemic steroids were not different among both groups. Patients in biosimilar infliximab group were more likely to experience previous biologic treatment failure (29.2% versus 20.2% in the original IFX, p = 0.0163). There were no significant differences in patients achieving response and remission at weeks 14 and 54. There were no significant differences in rate of withdrawals among the 2 groups (37.1% versus 38.8% for biosimilar IFX, p = 0.811). There were no significant differences in cumulative discontinuation rate due to AEs in original IFX and biosimilar IFX (42.4%, 95% CI 39.49–45.34 months versus 44.61 (95% CI 42.66–46.56 months), log-rank test p = 0.292).

Conclusion: This study experienced similar efficacy and safety profile of biosimilar IFX compared to original IFX.

Introduction: Acute severe Colitis (ASC) is a severe complication of inflammatory bowel disease (IBD), for which there is no consensus definition. Its diagnosis is often based on clinico-biological and endoscopic criteria. Low endoscopy is essential for the positive diagnosis of ASC as well as for the diagnosis of IBD.

Aims & Methods: The objective of this study is to describe the endoscopic aspect of ASC and its interest in therapeutic management in our series of 48 cases it is a prospective descriptive and analytical study of a series of 48 cases of acute severe colitis (ASC) collected during a period of 3 years (2014-2016) in the gastroenterology department.

Results: The average age of our patients is 39.8 years with extremes ranging from 14 years to 65 years, a female predominance was found with a sex ratio of 0.77. The ASC was inaugural in 20 (41.66%), while 28 cases (58.33%) are known to have IBD, with 24 cases of UC (85.7%). Initial endoscopy was performed in all patients. The average time to perform endoscopy (from the onset of symptoms) was 37 days (2 to 75 days). Severe endoscopic aspects were present in 30 patients: deep ulcer (29 cases), spontaneous bleeding (4 cases), friability (4 cases). Other endoscopic lesions found were erythema (12 cases), erosions (5 cases), superficial ulcer (25 cases), pseudo polyps (14 cases), contact bleeding (27 cases). Biopsy was performed in all patients, histology was in favor of UC in 64.58% cases. CMV viral inclusions were found in 2.08% of cases. First-line medical treatment is based mainly on parenteral corticosteroid therapy, has been established in all cases. A second-line treatment with anti-TNF therapy was used in 5 cases (10.41%) while surgical treatment was indicated in 15 cases (31.25%) of which 12 cases had severe endoscopic colitis. steroid refractory disease was associated with endoscopic severe colitis (p = 0.04). In mono-varied analysis, endoscopic disease was found in more than females (53.6 vs 43.3). With a statistically significant difference p = 0.020

Conclusion: Endoscopy in ASC occupies an important place to specify the morphological severity and thus make the positive diagnosis, the severe endoscopic colitis constitutes one of the predictive elements of steroid refractory disease requiring the use of a second therapeutic pallium.

Introduction: Response to biological drugs in ulcerative colitis (UC) is variable with induction response rates of 64.5% (vs 29.3% for placebo), 50.4% (vs 34.6% for placebo), 51.0% (vs 30.3% for placebo), 47.1% (vs 25.5% for placebo) for infliximab, adalimumab, golimumab and vedolizumab respectively. Apart from prior exposure to anti-tumour necrosis factor (anti-TNF) agents and concurrent immunomodulatory therapy, predictors of clinical response and remission to biological drugs have not been fully identified. We sought to investigate the utility of baseline faecal calprotectin (FC) and early change in FC in predicting clinical response and remission to biological therapy in UC.

Aims & Methods: Patients who were commenced on any biological therapy for UC and had a baseline FC at the time of commencement were included in this retrospective study. Disease activity was monitored semi-serially by calculation of Simple Clinical Colitis Activity Index (SCCAI) or by Physician global assessment (PGA) or by treatment persistence. Clinical response was defined as decrease in SCCAI of 3 or a decrease in PGA of 2 points or less. Remission was defined as decrease in SCCAI or PGA to 0. Ability of FC and fold change in FC to predict response and remission at 6 months was estimated using Mann-Whitney test.

Results: A total of 94 patients were commenced on biological therapy of who 70 (75%) commenced vedolizumab with a mean age of 41.8 (SD: ±18.2). Fifty-one (72%) and 39 (55%) patients commencing anti-TNF therapy were on concurrent immunomodulators (IM) and steroids respectively compared to 9 (38%) and 16 (67%) patients respectively for vedolizumab. Sixteen (67%) patients treated with vedolizumab had prior exposure to anti-TNF agents compared to 4 (6%) in the anti-TNF treated group. The 6-month response among patients treated with vedolizumab and anti-TNF agents was 77.2% and 73.5% respectively. The calprotectin values were similar for responders (428.5 (75-1359.0) [n = 50] to vedolizumab or 428.5 (75-1359.0) [n = 50] to vedolizumab (P = 0.56). Similarly, responders (909 (13, 2100) [n = 28] and non-responders (850 (240, 2000) [n = 13]) to anti-TNF agents had comparable calprotectin values at baseline, P = 0.93.

Conclusion: In a single-centre series of biologic treated UC patients, baseline FC did not predict clinical response at 6 months.

Introduction: The prevalence of Crohn’s disease is important for planning of health care and allocation of clinical resources. In 2005, a National Patient’s Registry in Poland was established to collect demographic and clinical data. To quantify efficacy of medications in real-life treatment during the study period, data regarding medical treatment were collected from Registry.

Aims & Methods: The aim of the study was assess the efficacy and tolerability of different medications in reference to demographic data and disease location and behaviour. 6030 of patients have been enrolled to the Polish National CD Patient’s Registry, conducted in 9 gastroenterology centers in Poland. Patient’s phenotype according to: Montreal classification, demographics, smoking, alcohol consumption, extraintestinal manifestation and medical treatment have been evaluated. The impact of demographic factors on the use of drugs from different groups (mesalamine, prednisone, azathioprine, methotrexate, anti-TNF), and medications efficacy and tolerance was assessed. The efficacy assessment was evaluated according to subjective 4-step scale. Similarly treatment tolerance was assessed according to 2-step scale.

Results: No gender effects were observed on the use or efficacy of individual drug classes, although greater tolerability of prednisone and azathioprine was observed in men (respectively 95.56 vs 93.82 and 93.94 vs 91.65, both p<0.05). Smoking did not affect the effectiveness and tolerability of the used medications. However surprisingly fewer smokers were treated with azathioprine, methotrexate, and anti-TNF in comparison to non-smokers (38 vs 45%, 0.5 vs 1.55%, 0.5 vs 11%, all p < 0.05) In patient’s declaring casual alcohol use, the efficacy and tolerability of prednisone was significantly better than in patients declaring abstaining (89 vs 84 and 96 vs 93%; p < 0.05).

Conclusion: This is the first study comparing efficacy and tolerability of treatment methods used in “real-life” practice in Poland during last 8 years. Most observations are in compliance with data from clinical trials. Positive effect of casual alcohol consumption on efficacy of medications requires further observation. Interestingly some unexpected relationships, concerning similar efficacy of infliximab in different disease behavior was found. This effect requires also further observations in regards to more frequent use of anti-TNF drugs in last years.

Introduction: Vedolizumab (VDZ) is the first gut-specific monoclonal antibody alternative to anti-tumor necrosis factor alpha therapy in patients with moderate-to-severe inflammatory bowel disease (IBD). It has been registered since 2016 in Hungary, but currently the high treatment costs are considerably limiting the availability of VDZ. All newly initiated VDZ therapy is individualized, it should be approved by the steering committee of five Hungarian IBD-specialists. This results in that VDZ therapy is available exclusively for patients in whom conventional treatment was ineffective or contraindicated.

Aims & Methods: The aim of our non-interventional prospective study was to assess the efficacy of induction VDZ therapy in patients with Crohn’s disease (CD) and 25 with ulcerative colitis (UC) received VDZ induction therapy between September 2016 and April 2017 in Hungary. Efficacy of induction therapy was assessed based on the changes of activity indices on week 14.

Results: 41 of 41 enrolled IBD patients were therapeutic failure or intolerant for infliximab and/or adalimumab therapy. The mean age was 38.6 years (range 18–67; median 40) and the average disease duration was 11.7 years (range 1–36; median 10). In 16 cases moderate and in 25 cases severe disease activity was observed. Extranodal manifestations occurred in 44 patients, and in 4 cases the IBZ was associated with primary sclerosing cholangitis (PSC). Rate of the therapeutic responders for VDZ induction therapy was 80.49% (N = 33). Complete clinical remission was observed in 19 cases (46.34%) 8 cases (19.51%) of which were steroid-free remission. In one case VDZ therapy had to be interrupted due to development of IBZ associated colorectal cancer and in one case due to MCV infection.

Conclusion: Our results suggest that induction VDZ therapy is effective and it is a safe therapeutic option in anti-tumor necrosis factor alpha failure or intolerant IBD patients with moderate or severe disease activity.

Introduction: Tuberculosis (TB) reactivation is of particular concern in patients with inflammatory bowel disease (IBD) treated with biologic therapies. Screening for latent tuberculosis infection (LTBI) is indicated prior to initiating treatment. Despite a reduction of TB incidence since 1990 and August 2016 only one LTBI patient diagnosed with LTBI following treatment for LTBI the risk of reactivation still exists. The efficacy of LTBI treatment in IBD patients receiving biologic therapy and the timing of biologic therapy initiation has not been extensively studied.

Aims & Methods: In order to evaluate the effectiveness of LTBI treatment in IBD patients receiving biologic therapy, we conducted a retrospective review of all IBD patients diagnosed with LTBI following a tuberculin skin test (PPD) or interferon gamma release assay (IGRA) and who received biologic therapy between January 1990 and August 2016. LTBI data included extracted included from patient demographics, TB risk factors, chest x-ray findings, biologic agent used, prior and concomitant therapies, and LTBI treatment regimen. TB reactivation after completion of LTBI treatment was the primary outcome of the study. Risk of TB reactivation was calculated using McGill University’s ‘The Online TST/IGRA Interpreter.

Results: A total of 35 IBD patients (27 Crohn’s; 8 ulcerative colitis) were included in the study. Their mean age was 38.3 ± 14.4 years and 66.8% were male (Table 1). The median time from diagnosis of IBD to LTBI was 9 years (0–48 years). Prior IBD therapies included corticosteroids (86%), aminosalicylates (83%), other immunosuppressants (69%). At least 43% of patients have been previously exposed to at least 1 biologic agent. The most common LTBI treatment regimen was isoniazid (INH) for 9 months (n = 26, 74%). Biologic therapy used were infliximab (n = 14, 40%), adalimumab (n = 10, 29%), vedolizumab (n = 7, 20%), and certolizumab pegol (n = 4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n = 20). All patients were treated for LTBI and the majority (83%) was treated prior to

A753
starting biologic therapy. The median time from initiation of LTBI treatment to biologic therapy was 43 days (range 4-3635). Additional studies with extended follow-up are warranted to further characterize the efficacy of LTBI treatment in these patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1721 CLINICAL CHARACTERISTICS AND MANAGEMENT OF CROHN'S DISEASE IN PATIENTS WITH RESIDUAL DISEASE AFTER SURGERY COMPARED WITH CURATIVE SURGERY. RESULTS FROM PRACTICROHN STUDY

Introduction: Resection in Crohn’s disease (CD) intends to be a curative surgery, but recurrence is a frequent event in these patients. Consequently, the aim of our study was to describe the characteristics and management of patients with residual disease after surgical resection (RD) and compare these patients with patients undergoing curative surgery (CS) in post operative CD patients.

Aims & Methods: PRACTICROHN was a retrospective study that included adult patients from 26 Spanish hospitals who underwent CD-related ileocolonic resection in the period 2007-2010. Clinical data was retrospectively collected from clinical charts. RD was defined when lesions were still present after surgical resection. Postoperative recurrence (POR) was defined by clinical symptoms (diarrhea, abdominal pain) and endoscopic Rutgeerts score ≥2, and/or CT or MRI confirmation of disease activity. Categorical variables were compared with the x² test or Fisher’s exact test. Kaplan-Meier method was used to estimate time to clinical recurrence and a log-rank test to obtain statistical significance.

Results: Three hundred and sixty-four patients were analyzed (mean age 40 years). There were 243 patients in RD group and 121 patients in CS group. More patients were performed an endoscopy within the first year after surgery in the RD group vs CS (59% vs 123%); p = 0.03 but no difference in prophylactic treatment were found in RD vs CS groups. POR was more frequent among patients with RD (69% vs. 29%, p = 0.001). Median time to POR was longer in patients who received prophylaxis vs those who didn’t received it (698 vs 392 days; p = 0.41, 81/275 (29%) in the CS presented POR with median time to POR being longer in patients who received prophylaxis (no median found vs 1529 days); p = 0.04. Table 1.

Table 1: Cohort Characteristics and Estimated Post-treatment Tuberculosis Reactivation Rate

| Mean Age | 38.3 (±14.4) years |
| Male Sex | 24/35 patients |
| Type of Inflammatory Bowel Disease (IBD) | Ulcerative Colitis (23%); Crohn’s Disease (77%) |
| Mean Time since IBD Diagnosis | 9 years (range: 0-48) |
| Type of Biologic Therapy | Infliximab (40%); Adalimumab (29%); Vedukizumab (20%); Certolizumab (11%); Isoniazid (INH) for 9-months |
| Therapy | (74%) INH for 6-months (11%) Rifampin 4-months (9%) INH + Rifampin for 3-months (3%) Others (3%) |
| Median time to initiate biologic therapy | 43 days (range: 4-3635) |
| Mean duration of follow-up | 2.9 ± 3.3 years |
| Mean Pre-treatment Risk of Development of Tuberculosis | 0.52%/year (range: 0.0%–1.3%/year) |
| Estimated Post-treatment Tuberculosis Reactivation Rate | 0.98 cases per 100 patient-years |

Conclusion: Treatment for LTBI in patients with IBD treated with biologics is effective, but does not eliminate the risk of reactivation, which occurred at a rate of 0.98 cases per 100 patient-years in our cohort. Additional studies with extended follow-up are warranted to further characterize the efficacy of LTBI treatment in these patients.

FECAL CHOLIC ACID CONCENTRATIONS DURING
Medical Center, Boston, MA, USA, Boston/United States of America
Sorbionne Paris Cite ´, INSERM UMR 1149, Louis Mourier Hospital, APHP,
Colombes, France, Colombes/France

Aims & Methods: 'pro-germination' primary BAs including CA in human stools B) Describe primary BAs (cholic acid and chenodeoxycholic) into secondary (deoxycholic acid). A) Assess the effects of an antibiotic therapy. Group 1 (n = 12) received AC for 7 days and SB for 14 days. Group 4 (n = 12) did not receive any treatment. Groups 1, 2, 3 had successive stool samples at D-8, 0, 3, 7, 10, 13, 21. Group 4 had stool samples at D0, 7, and 21. The fecal concentrations of 28 BAs were measured by HPLC-MS, and expressed as % of total BA concentration.

Results: AC alone (group 2) significantly reduced the rate of fecal secondary BA at day 7 compared to control (group 4) (54.8 ± 1.0 vs 83.1 ± 7.4%, p = 0.017). In group 3 (AC plus SB), the decrease in secondary BA rate was significantly less than AC (71.23 ± 7.4% vs 54.8 ± 9.5%, p = 0.04), and this difference was prolonged over time. Similarly, the AC + SB group showed a significantly lower (and sustained) increase in CA than in the AC alone group.

Conclusion: Antibiotics alter the transformation of BA by microbial enzymes into secondary BAs (deoxycholic acid) and fecal fecal secondary BAs. This may affect metabolic pathways for the carcino-gene.

Introduction: While particular imbalances in the gut microbiota have been linked to colorectal adenomas and cancers, some specific bacterium have been identified as a related factor. Recent studies have reported a high abundance of Fusobacterium nucleatum (F. nucleatum) in colorectal cancer (CRC) subjects compared to normal subjects1-3. F. nucleatum is also known as a pathogenic species of oral microbiota, but it is not known if F. nucleatum plays a role in other part of the digestive tract. F. nucleatum may affect metabolic pathways for the carcinogenesis4. We examined whether there is relationship between F. nucleatum oral cavity and CRC.

Aims & Methods: We assessed the abundance of Fusobacterium in CRC, colorectal mucosa and saliva. We extracted DNA from mucosal biopsy and measured bacterial levels by quantitative PCR of the 16S ribosomal RNA gene. We also investigated the homology of F. nucleatum in oral cavity and CRC.

Results: In 51 CRC cases, Fusobacterium positivity was significantly higher in CRC compared to controls (p < 0.05). Fusobacterium was more detected in CRC (12.9%) than in normal tissue (3.9%) respectively. The detection rate of F. nucleatum was 96% in saliva and 93% in CRC by next-generation sequencer. A total of 15 patients with CRC were included to check the homology of F. nucleatum in saliva and CRC. From the 15 patients, 9 were F. nucleatum-positive in saliva and CRC. From these patients who were F. nucleatum-positive in saliva and CRC, we next looked for the results of AP-PCR and 6 patients have shown common band patterns. Conclusion: The results support a link between the abundance of F. nucleatum in oral cavity and CRC. Our data also indicate that there may be a route from the oral cavity to the CRC in F. nucleatum positive cases. We are now identifying DNA sequences, for the objective for the strict bands.

P1727 HUMAN MILK OLIGOSACCHARIDES: A NEW STRATEGY AGAINST POST-ANTIBIOTIC CLOSTIDIUM DIFFICILE INFECTION?

L. K. Vignaes
Business Development, Glycom A/S, Horsholm/Denmark

Contact E-mail Address: louise.vignaes@glycom.com

Introduction: Human Milk Oligosaccharides (HMOs) are a family of complex carbohydrates found in high concentrations in human milk and which are now becoming commercially available. In clinical studies, in both infants and adults, HMOs powerfully and specifically modulate the gut microbiota by increasing bifidobacteria and reducing certain pathogenic bacteria (1,2). Also, HMO bacterial consumption results in the production of beneficial metabolites such as short chain fatty acids and the lowering of pH. Hence, the selective growth of bifidobacteria on HMOs can create an ecological niche that is more colonization resistant against pathogens. Bifidobacteria may also have a direct impact on microbial toxins by reducing their level and cytotoxic effect (3). Antibiotics, especially broad spectrum antibiotics, dramatically impact the microbiota and its balance, and have been implicated in the pathogenesis of many health conditions including gastrointestinal symptoms such as diarrhea (4). The most commonly cited mechanism for antibiotic-associated diarrhea is intestinal overgrowth of the pathogenic bacterium, Clostridium difficile.

Aims & Methods: The aim of this study is to investigate, in *in vitro* models of *C. difficile* infection, (i) the impact of HMOs on the microbial community and activity (e.g. bacterial metabolites and pH), and (ii) the anti-pathogenic activity of HMOs against *C. difficile*, with a focus on preventing recurrence of the infection. Two *in vitro* models, each using human faecal microbiota infected with *C. difficile*, were used to examine the impact of HMOs on bacterial metabolite production and *C. difficile* infection. One model is a 48 hour batch fermentation, while the other is a simulated gut model, run for 3 weeks post infection, which simulates the infection cycle of *C. difficile* after antibiotic treatment.

Results: The study revealed that the HMOs increase the level of bifidobacteria, important members of beneficial bacteria such as short chain fatty acids and decrease pH compared to a control with no added HMOs. Additionally, HMOs reduced the level of *C. difficile*; in some cases completely eradicating *C. difficile* below detection limits. This antimicrobial effect of HMOs on *C. difficile* was pH-independent, hence another mechanism is causing the anti-pathogenic activity of HMOs.

Conclusion: Conclusively, the results show that HMOs can impact *C. difficile* infection in an *in vitro* system, which suggests HMOs as a potential approach to reduce risk of antibiotic associated diarrhoea and post-antibiotic *C. difficile* infection.

Introduction: It has been reported that the composition of human gut microbiota changes with aging, body mass index (BMI), diet and other environmental factors. In particular, the relationship between gut microbiota and obesity has been underlined frequently because intervention in the microbiota may reduce body fat. In this study, we investigated the relationship between obesity and composition of gut microbiota in healthy Japanese population.

Aims & Methods: Participants were 1,082 healthy Japanese adults (410 males, 672 females) who participated in the Iwaki Health Promotion Project in 2014. Faecal samples were analysed by 16S rRNA gene-targeted sequencing to determine family composition of gut microbiota. They were classified into obese group (BMI ≥ 25) and normal weight group (BMI < 25) according to Japanese standard and were stratified in 7 age groups, 19–29, 30–39, 40–49, 50–59, 60–69, 70–79 and 80–90. The family composition of gut microbiota in each age group was compared between obese and normal group.

Results: There were 235 obese participants, and 847 normal ones. The proportion of Bacteroidiaceae decreased substantially, and Ruminococcaceae increased slightly with aging in obese group. The proportion of Bifidobacteriaceae, Lachnospiraceae and Porphyromonadaceae decreased gradually with aging in both groups.

Conclusion: Changes in composition of gut microbiota with aging were different between obese and normal group. Some previous researches observed differences of gut microbiota between obese and normal group, but many of the researches did not take aging into consideration. Our study indicated that different intervention stratified with age could be needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Due to its high incidence, sporadic colorectal cancer (CRC) remains one of the most frequent cancers worldwide. The exact contribution of large intestinal bacteria to the pathogenesis of CRC has not been elucidated yet, still the mucosal, not the luminal, microbiota seem to play the crucial role. Bacteriocins are small proteins, which are produced by the *Lactobacillus helveticus* D76 strains and which are resistant against pathogens. Bacteriocins are divided into more groups, colicins and microcins are the most important ones. Bacteriocins possess antibacterial, antineoplastic, proapoptotic and probiotic effect.

Aims & Methods: The aim of this prospective study was to evaluate bacteriocin production by mucosal large intestinal bacteria in colorectal neoplasia. We used an original methodology reported by our group (1). Mucosal biopsies were taken in the caecum, transverse colon and rectum within the colonscopia in patients with non-advanced colorectal adenoma, non-a-A (11 men, 10 women, mean age 63 ± 10), advanced colorectal adenoma, a-A (which was defined as neoplasia larger than 10 mm and/or containing villous component and/or containing high-grade dysplasia; 13 men, mean age 70 ± 9) and CRC (12 men, 10 women, mean age 70 ± 10) and in the controls (average risk population with normal findings on colonscopia and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 7 men, 13 women, mean age 56 ± 12).

Results: A total of 249 mucosal biopsies were taken (60 controls, 63 non-a-A, 60 a-A, 66 CRC) and samples were further investigated. Colcin producing strains were detected in 22% (13/60) controls, 59% (37/63) non-a-A, 55% (33/60) a-A and in 76% (50/66) CRC. Significantly higher production of colicins was observed in non-a-A, a-A and CRC group when compared to controls, p < 0.001. Significantly higher production of colicins was confirmed in patients with CRC compared to patients with a-A, p = 0.016. Microcin producing strains were isolated in 23% (14/60) controls, 56% (35/63) non-a-A, 78% (47/60) a-A and in 62% (41/66) CRC. Significantly higher production of microcins was observed in non-a-A compared to controls, p = 0.002, in a-A and CRC group when compared to controls, p < 0.001. Microcins were produced more frequently in patients with a-A compared to those with non-a-A, p = 0.008.

Conclusion: Strains isolated from large bowel mucosa in patients with colorectal neoplasia produce bacteriocins more frequently compared to those with normal findings on colonscopia. We presume, that mucosal large intestinal microbiota with their products including bacteriocins play an important role during the development of colorectal neoplasia.

Introduction: The production of bacteriocins is considered as the key metabolic function of gut microbiota and as the inherent property of probiotic strains. Bacteriocins and metabolites of probiotic microorganisms (metabiotics) can optimize host-specific physiological functions related to human health.

Aims & Methods: This study aims to: (a) detect the bacteriocin genes of probiotic strain *Lactobacillus helveticus* D75 (NCBI Reference Sequence NZ_CP008291.9) and *Lactobacillus helveticus* D76 (NCBI Reference Sequence NZ_CP016827.1) and (b) evaluate in vitro effects of the carboxylic and amino acids mixture identical to the metabolites of the probiotic Escherichia coli strain M17 (components of ActoFor®-S dietary supplement). The antagonistic activity of *Lactobacillus helveticus* D75 and *Lactobacillus helveticus* D76 strains was estimated by the deferred antagonism method. The identification of bacteriocin genes was performed by PCR using helveticin J gene primers. Amplified fragments were sequenced using ABI PRISM® 310 Genetic Analyzer and were analyzed using NCBI/BLASTX.

Results: The identical sequences of 537 bp homologous to gene fragment of helveticin of *Lactobacillus helveticus* DPC 4571 (hiv_1632 gene) were detected.
in DNA of both probiotic strains. Sequencing of these fragments showed differ-
ences in three nucleotides compared to the reference DNA of DPC 4571 strain (A instead of G at position 46, C instead of T at position 249 and A instead of T at position 537), but all these replacements do not lead to changes in the amino acid sequence.

**Conclusion:** Study shows that there are at least two bacteriocins in Lactobacillus helveticus D76 and one bacteriocin in Lactobacillus helveticus D75. Carboxylic acid and amino acids mixture identical to the metabolites of the probiotic Escherichia coli strain M17 probably induces bacteriocin synthesis in probiotic strains Lactobacillus helveticus D75 and Lactobacillus helveticus D76 and enhances their antimicrobial activity against test pathogens Escherichia coli O75 and Salmonella Enteritidis 209, most likely due to an increase in bacteriocin gene expression.

**Introduction:** Fecal microbiota transplantation (FMT) has been shown to be effective treatment for recurrent Clostridium difficile infection. Concern has been raised about the long-term safety of FMT.

**Aims & Methods:** The aim of this study was to determine the long-term safety of fecal microbiota transplantation (FMT), and its effect on gastrointestinal symptoms (GI) in Clostridium difficile (CDI) patients. We studied 84 patients of which 45 received an FMT treatment via colonoscopy and 39 served as controls receiving antibiotic treatment (AB) for the recurrent CDI and followed their recurrence and progression for a median period of 3.8 yrs. All together 130 patients (55 patients in the FMT group and 75 patients in the AB group were sent a 45-item questionnaire collecting information about the patient demographics, their physical and mental health, including allergies, infections, gastroenterological conditions such as IBD and IBS, diabetes, autoimmune diseases, neurological disorders, mental wellbeing and malignancies. Response rate for the questionnaire was 64.6%.

**Results:** There were no differences in the incidence of severe diseases between the groups including the incidence of IBD, diabetes, diseases of the nervous system, autoimmune disease, incidence of colon polyps and cancer. Change of weight was neither different between groups (kg/SD): FMT = 2.5 (5.6) and AB = 1.3 (5.6), p = 0.51. The AB treated subjects reported more frequently that their bowel function had become worse and more irregular after the treatment (68.9% vs. 55.8%, p = 0.001) compared to FMT group. 77.8% of the patients treated with FMT experienced GI symptoms related to IBS whereas 92.3% of antibiotic-treated patients reported these symptoms (P = 0.006). AB patients experienced more symptoms of the upper intestinal tract than the FMT group (40.9% vs. 25.5%, p = 0.015). In this cohort 97.6% of the FMT-treated patients and 60% of AB treated patients would prefer in the future that their initial treatment to be FMT instead of antibiotics.

**Conclusion:** FMT is a rational, durable, safe, and acceptable treatment option for patients with recurrent CDI. No severe diseases appeared after FMT and FMT seem to relieve GI symptoms better than antibiotic treatment. FMT and AB treated patients would prefer in the future that their initial treatment for recurrent CDI to be FMT instead of antibiotics.

**Introduction:** Clostridium difficile–associated disease (CDAD) is an infection caused by Clostridium difficile, gram-positive, anaerobic, spore-forming and toxin-producing bacteria. Infection is recognized as the leading cause of diarrhea associated with health care services in the developed countries. In Portugal epidemiological data are limited.

**Aims & Methods:** Characterize Clostridium difficile–associated disease episodes in a Portuguese Hospital Center. Retrospective analysis of 250 hospitalized patients with CDAD, in Centro Hospitalar do Algarve, between 2011 and 2015. The data was obtained from clinical processes and statistical analysis was performed with SPSS version 23.

**Results:** The patients were mostly women (52%). The mean incidence of CDAD was 0.21% and the patients had an associated mortality of 28%. The year with the highest incidence was 2015 (0.51%) but with a lower associated mortality rate. CDAD was mostly acquired at the hospital level (75.6%) and the mean length of hospital stay was 33 days. About 82.4% of the cases were first occurrences and the remaining (18.6%) were recurrences of CDAD. The majority of the patients underwent study under performed Proton Pump Inhibitors–IBP (52.8%) and antibiotic therapy (74.6%) (28.6% made a single antibiotic, and 23.6% 2 or more distinct antibiotics). Penicillin antibiotic class was the most used, followed by Cephalosporins (21.5%), Fluoroquinolones (11.4%) and Macroline (10.1%).

**Conclusion:** A significant increase in the incidence of CDAD was observed in this study. This increase may be related to several factors, such as the improvement of laboratory diagnostic methods, increased antibiotic prescription, hospital contamination with Clostridium difficile spores or with the appearance of new and more virulent Ribotypes.

**P1735 GLASGOW-BLACHFORD SCORE ACCURATELY PREDICTS THE NEED OF TRANSFUSION IN ACUTE LOWER GASTROINTESTINAL BLEEDING. A DIAGNOSTIC ACCURACY EVALUATION STUDY**

Gastroenterology, Hospital Universitari Parc Taulí, Sabadell/Spain

**Contact E-mail Address:** smachlab(at)tauli.cat

**Introduction:** The incidence of acute lower gastrointestinal bleeding (LGB) is increasing in Western countries, but the predictors of its outcome are not well studied. Blachford's score was defined.

**Aims & Methods:** The aim of this study was to compare the accuracy of Glasgow-Blachford score (GBS) with three available risk scores (State, Velayos and Newman) for predicting the need of any clinical intervention (endoscopic therapy, vascular embolization, surgery and need of transfusion) in patients admitted for acute LGB. Retrospective study from January 2013 to December 2015 in a university tertiary care hospital. Patients with acute LGB were identified using the International Classification of Diseases (9th Revision) and Clinical Modification codes for admission diagnosis. Scores were retrospectively calculated according to clinical reports data. Area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, positive and negative predictive values were calculated for four scores. Also the best cut-off of each score was chosen from using the AUROC curve values.

**Results:** A total of 298 (51% men) consecutive patients with acute LGB were identified. Median age was 76.1 years (range 25.4–96.5), 201 (67.4%) of patients were older than 70 years. Five patients (1.7%) died, 16 (6%) developed recurrent bleeding, 89 (29.9%) needed transfusion, 30 (12.1%) received endoscopic therapy, and 3 (1%) underwent transcatheter arterial embolization. No patient required any surgical intervention. AUROC of GBS score was 0.87 (95%CI:0.82–0.91) for the need of transfusion, and 0.82 (95%CI:0.76–0.87) for the need of any clinical intervention. AUROC for the need of transfusion and clinical intervention were 0.68 (95%CI:0.61–0.74) and 0.67 (95%CI:0.60–0.73) for the Strate score, 0.77 (95%CI:0.71–0.83) and 0.74 (95%CI:0.68–0.80) for the Velayos score and 0.78 (95%CI:0.72–0.85) and 0.74 (95%CI:0.68–0.81) for the Newman score, respectively. GBS was significantly more accurate than LGB risk scores for predicting the need of transfusion. Although AUROC of GBS was also numerically better for predicting the need of any clinical intervention, the difference was only significant when comparing with the Strate score. All the risk scores were more accurate for predicting the need for transfusion than for the need of clinical intervention. Sensitivity, specificity and positive and negative predictive values for each score are shown in table 1.

**Table 1:** Sensitivity (S), specificity (Sp), Positive (PPV) and negative (NPV) predictive values of the different scores for detecting the need of transfusion (TRF) or clinical intervention (CI). *Best cut-off scores for Blachford score were 6 for transfusion and 4 for clinical intervention. Values are expressed as %.

Introduction: Acute lower gastrointestinal bleeding (ALGB) occurs in patients taking anticoagulants either warfarin or non-Vitamin K oral anticoagulants (NOACs). The use of NOACs has been increasing compared with warfarin in recent years. We investigated patients with ALGB on anticoagulation therapy and we analyzed characteristics, management and clinical outcome in patients treated with NOACs versus warfarin.
Aims & Methods: All patients with ALGB on anticoagulation therapy treated in our hospital during a seven year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.
Results: Out of 587 patients with ALGB, 43 (7.3%) were on NOACs and 68 (11.6%) on warfarin with an age 75.9±10.9 years. We investigated patients with ALGB on anticoagulation therapy and we analyzed characteristics, management and clinical outcome in patients treated with NOACs versus warfarin.
Aims & Methods: All patients with ALGB on anticoagulation therapy treated in our hospital during a seven year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.

P1737 NOBLADS - THE NEW RISK SCORE TO PREDICT THE SEVERITY OF ACUTE LOWER GASTROINTESTINAL BLEEDING
M. Patita, G. Nunes, R. Barosa, L. Ramos, C. Fonseca
Gastroenterology, Hospital Garcia de Orta, Almada/Portugal
Contact E-mail Address: martapatita21@gmail.com
Aims & Methods: We aimed to evaluate the accuracy of the NOBLADS score to predict severe LGIB and the outcome of patients admitted by LGIB. We performed a retrospective, observational and unicentric study. Including patients admitted for acute LGIB and submitted to endoscopic evaluation between January/2015 and March/2016. LGIB was classified as severe if ≥ 2 units of erythrocyte concentrate (UCE) were required and/or if hematocrit drop ≥ 20%. Total score ranges from 0-8; when total score is ≥ 2, it is considered high risk for severe LGIB.

Introduction: A new risk score for acute lower gastrointestinal bleeding (LGIB) has recently been validated, based on 8 admission criteria–nonsteroidal anti-inflammatory drugs use, absence of diarrhea, absence of abdominal tenderness, white blood cell count ≥ 15,000, hemoglobin ≤ 9, platelet count ≤ 100,000, age ≥ 65 alike, and disease score ≥ 2 (Charlson comorbidity index) and syncope (NOBLADS). Results: 173 patients were included (male: 50.3%, mean age: 69 ± 17 years), with LGIB manifested by hematochezia (91.9%) or melena. Endoscopic evaluation was performed 1.7 ± 2 days after admission, with the most frequent findings being diverticular hemorrhage (n = 53) and ischemic colitis (n = 29); no lesions were found in 8.3% of cases. Thirty-three patients required intervention (endo- scopic n = 27, radiological n = 2, surgical n = 4) and 36 (20.8%) repeated endo- scopic intervention. 28.9% of the patients presented severe LGIB and NOBLADS score determined the severity of LGIB with an area under the curve value of 0.92 ± 0.018. Overall, higher score values were associated with a requirement for transfusion support, intervention and longer hospitalization (p < 0.001 for trend test). Patients at high risk for severe LGIB (score ≥ 2, n = 59) presented a significantly higher number of transfused UCEs (3.6 vs 0.08, p < 0.001), intervention (38% vs 13%, p < 0.001) and days of hospitalization (12.8 vs 3 days, p < 0.001).
Conclusion: The NOBLADS score is simple and quick to apply. It predicts with high accuracy the risk of severe LGIB and allows to identify patients that are more likely to require transfusion support, intervention and prolonged hospitalization. In clinical practice, NOBLADS score may be useful to select on admission patients who will benefit from hospitalization or from earlier intervention.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1739 ENDOCOSPIC MUCOSAL RESECTION OF COLORECTAL POLYS IN ANTICOAGULATED PATIENTS
S. Kohayashib, T. Nowa, K. Harada2, H. Seki2, Y. Noma1, T. Ueki1, H. Okada2
1Fukayama City Hospital, Fukayama/Japan
2Okayama University Hospital, Okayama/Japan
Contact E-mail Address: sayo44@hotmail.co.jp
Introduction: The management of antithrombotic agents during the peri-endoscopic period concerns the risks of bleeding and thromboembolism. The Japan Gastroenterological Endoscopy Society (JGES) guidelines revised in 2012 emphasizes the risk of thromboembolism rather than bleeding. So heparin bridge of anticoagulants is recommended at high-bleeding-risk procedure such as endoscopic mucosal resection (EMR). However heparin bridge in colorectal EMR raises the bleeding rate to approximately 20%, that is very high-rate incident compared with the bleeding rate of 0.3-6.1% generally. It is doubtful whether heparin bridge is appropriate.
Aims & Methods: The aim of this study to clarify the safeness of colorectal EMR under taking anticoagulants without a heparin bridge in anticoagulated patients. We performed a prospective study in our hospital JGES and NOBLADS centers (UMIN00002146). The subjects are colorectal polyps resectable by EMR. Inclusion criteria of patient is good performance status (ECOG) 0–1, without organ failure. Warfarin is continued as usual if PT-INR is less than 2.6, and direct oral anticoagulants (DOAC) is continued until an evening of the day before and is discontinued on only the day. Primary endpoint is post-EMR bleeding required any interventions (major bleeding). Major bleeding is defined as active bleeding or adherent clot on the resection site by emergent colonoscopy, or conservative treatment required blood transfusion. Conservative bleeding with no intervention (minor bleeding), thromboembolism, and comparison between warfarin and DOAC are clarified as secondary endpoint.
Results: 41 patients (154 lesions) were performed EMR from February 2015 to March 2017. Patients’ characteristics were as follow, the median age was 74 years old (range 68–94) and the average polyp size was 11.6 (range 5–22) mm in diameter. Anticoagulants were divided into 19 cases of warfarin and 22 cases of DOAC. The incidence of major bleeding was none in all cases. On the other hand, minor bleeding which did not require any intervention was recognized at 14.6% (6/41), but there was no case to interrupt anticoagulants. The rate of minor bleeding is no difference between warfarin and DOAC. There was no correlation between minor bleeding and PT-INR value in three cases of warfarin. All three cases of DOAC were medicate once a day. Thromboembolism was not observed.
Conclusion: In colorectal EMR, we clarify the safeness with continuation of warfarin and short discontinuation of DOAC on that day, compared with heparin bridge. We expect to lead to reconsideration of current guideline for safer treatment.
Disclosure of Interest: All authors have declared no conflicts of interest.

P1740 RISK OF COLORECTAL CANCER IN ASYMPTOMATIC INDIVIDUALS WHOSE FIRST DEGREE RELATIVES WERE AFFECTED BY CRC AT DIFFERENT AGES OF ONSET: A SYSTEMATIC REVIEW AND META-ANALYSIS OF 9.28 MILLION SUBJECTS
J.L. Huang, M.C. Wong, C. Chan, J. Lin, W.W. Cheung, M. Liang, Y. Fang, C. Yu, D. Fung

Contact E-mail Address: martin_wong@cuhk.edu.hk

Introduction: The current literature is mixed regarding whether first-degree relatives (FDRs) of patients who suffered from colorectal cancer (CRC) at much earlier age are at substantially increased risk of CRC.

Aims & Methods: The present systematic review and meta-analysis examined the CRC risk conferred by family history of CRC in FDRs according to their age of onset. We searched Ovid Medline, EMBASE and grey literature from their inception to December 2016, and all selected studies that met the selection criteria were included. Two reviewers independently worked on selection, assessment and data extraction of eligible articles. A random effects meta-analysis was employed to pool relative risks (RR) and odds ratios. Subgroup analyses were performed according to the age of onset of CRC in FDRs of asymptomatic subjects (<40 vs. ≥40; <50 vs. ≥50; <60 vs. ≥60 years). Statistical heterogeneity was assessed by the I² statistics. Publication bias was evaluated by an inverted funnel plot analysis with Begg’s regression model.

Results: Fifty-six case-control and seven cohort studies involving 9.28 million subjects were included in the analysis. A family history of CRC in FDRs of asymptomatic subjects conferred a significantly higher risk of CRC (RR=1.76, 95% CI=1.57–1.97; p < .001, I²=95.7%). Earlier age of onset of CRC in FDRs was associated with significantly higher risk of CRC in index subjects (RR=3.29, 95% CI=1.67–6.49 for <40 vs. RR=1.42, 95% CI=1.24–1.62 for ≥40 years, p = 0.017; RR=2.81, 95% CI=1.94–4.07 for <50 vs. RR=1.47, 95% CI=1.26–1.69 for ≥50 years, p = 0.001). The Begg’s regression test did not identify any publication bias (Kendall’s taum=0.122, p = 0.159).

Conclusion: A family history of CRC in FDRs whose age of onset is earlier than 40 or 50 years conferred a significantly higher risk of CRC to asymptomatic individuals, implying that age of onset could potentially enhance the discriminatory capability of CRC prediction scores.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1741 IS THERE ANY DIFFERENCE IN RISK OF COLORECTAL CANCER AMONG ASYMPTOMATIC SUBJECTS WHOSE SIBLINGS VS. PARENTS WERE AFFECTED? A SYSTEMATIC REVIEW AND META-ANALYSIS
J.L. Huang, M.C. Wong, C. Chan, J. Lin, W.W. Cheung, M. Liang, Y. Fang, D. Fung, C. Yu
Chinese University of Hong Kong, Hong Kong/Hong Kong Prc
Contact E-mail Address: martin_wong@cuhk.edu.hk

Introduction: Few studies compared the risk of colorectal cancer (CRC) among individuals with probands who were parents, siblings, and those with two or more probands.

Aims & Methods: This systematic review and meta-analysis tested the hypothesis that the risk of CRC conferred by family history of CRC in parents vs. siblings vs. ≥2 first-degree relatives (FDRs) was similar. The Ovid Medline, EMBASE and grey literature were searched from their inception to December 2016, and all screening studies that met the selection criteria were included. Two reviewers independently searched, assessed and extracted data from eligible studies. The relative risks (RR) and odds ratios were pooled based on a random effects meta-analysis. We conducted subgroup analyses according to the identity of FDRs affected (parents vs. siblings vs. ≥2 FDRs), and examined statistical heterogeneity by the I² statistics. Potential publication bias was explored by funnel plot analysis with Begg’s regression test.

Results: We identified 56 case-control and 7 cohort studies, consisting of 9.28 million subjects who were finally included in the meta-analysis. Asymptomatic individuals with siblings affected (RR=2.44, 95% CI=1.90–3.13); parents affected (RR=2.18, 95% CI=1.95–2.45) and ≥2 FDRs affected (RR=2.68, 95% CI=1.62–4.43) had statistically similar risk of CRC. We did not identify any publication bias based on the Begg’s regression test (p = 0.159).

Conclusion: The risk of CRC was similar among subjects whose siblings; parents or ≥2 FDRs were affected by CRC. Information on the identity of the FDRs affected does not seem to be necessary when the risk of CRC in asymptomatic individuals is predicted.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1742 GILBERT SYNDROME IS NOT THAT INNOCENT?
N. Arber1, N. Menachem1, L. Ari2, G. Lion1, B. Ezra1, H. Gilt1, H.G. Amir2, J. Mazoyer3, S. Shapira1
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel

Contact E-mail Address: nadira@tlvmc.gov.il

Introduction: Gilbert’s syndrome is considered to be entirely benign. Some studies have shown a reduced risk for cardiovascular disease (CVD). There is conflicting data regarding cancer risk among Gilbert’s syndrome patients.

Aims & Methods: We aimed to evaluate the association of Gilbert syndrome with CVD and cancer. Clinical and epidemiological data was obtained from consecutive healthy subjects undergoing annual screening at the Integrated Cancer Prevention Center in Tel Aviv. The annual check-up includes: thorough examination by specialists in internal medicine, surgery, dermatology/plastic surgery, OB/GYN, urology, oncology, oral surgery, gastroenterology. Blood work (smac 24; blood count, TSH, CRP, PSA), vaginal papa, PSA and mammography (≥40yrs), LDCT in heavy smokers and all needed imaging when clinically indicated. Peripheral blood DNA was extracted from all subjects. Gilbert syndrome was determined by clinical criteria (normal liver function tests but to mild elevation in unconjugated bilirubin <3 mg/dl without any hemolysis. In the majority of the cases the diagnosis was confirmed genetically by the homozygous mutation (TA)7TA in the promoter region of UGT1A1 enzyme. Prevalence of CVD and cancer were compared between subjects with/without Gilbert syndrome. Mortality data was obtained from the Israeli ministry of health and cancer incidence from the Israeli registry.

Results: A total of 6258 (49%) men and 6461 (51%) women, median age 47.0 ± 11.5 years, were included of which 1.019 had clinical Gilbert. Gilbert was significantly more common among men (11.5% versus 4.6% P < 0.001). The rate of Gilbert syndrome was equal in Sephardic and Ashkenazi Jews. Malignancy and CVD were diagnosed in 678 (5.3%) and 1.837 (14.4%) subjects respectively. The prevalence of any CVD was significantly higher in the Gilbert group (OR 2.04, 95% CI=1.04–4.16 p=0.017), as well as hypertension (OR 1.37 95% CI 1.12–1.68 p=0.003) and CVA (1.1% versus 0.6% p=0.06). Higher rate of kidney and bladder cancers (2.6.4, 1.22–5.70, p=0.019) was also observed in the Gilbert group. In contrast, the prevalence of breast cancer was much lower among patients with Gilberts (OR 0.36, 95% CI=0.13–0.97, P = 0.034).

Conclusion: In Israel Gilbert syndrome is not that innocent. In a large cohort it seems to be associated with increased risk of hypertension, CVD and CVA. Bladder cancer is higher but females are protected from breast cancer. Further studies are mandated in order to better understand these findings and determine proper screening and surveillance practices in Gilbert disease.

Introduction: Interval colorectal cancer is largely related to a poor endoscopic performance (missed lesions), incomplete and/or non-responsive surveillance and/or different detection capabilities. The interval cancer is largely related to the development of the polyp (accelerated growth). Thus, quality endoscopic measures and Lynch syndrome were highly investigated for their association with interval cancer. However, most reports came from the Western world and not the Middle East, and differences in ethnicity or environmental factors might potentially have impact on the biology of tumor progression. In addition, patient-related factors were less investigated for their association with interval cancer. The aim of this study was thus to assess tumor and patient characteristics and predictors of interval cancer in a population from Israel.

Aims & Methods: This retrospective cohort study included all patients that were diagnosed with colon cancer in our institution between 2005-2014. Cases included patients with a previous colonoscopy within 1–10 years before the diagnosis of cancer, with either negative 13 indents or benign polyps. Only full colonoscopies with at fair or good preparation were included. Interval cancer was defined on an individual basis, when cancer occurred within the recommended surveillance interval according to accepted guidelines. Cases were further stratified according to time since index colonoscopy (<3 years, 3-10 years). Positive controls were cancer patients without previous colonoscopy, and “negative” controls were sex- and age-matched patients with two negative colonoscopies within the study period who were randomly selected on a 1:1 ratio. Tumor characteristics (location, staging) and patient-related features (age, gender, positive family history of colon cancer, aspirin use, diabetes, diverticulosis) were compared between cases and control groups.

United European Gastroenterology Journal 5(5S) A760
Results: 845 patients were diagnosed with a colon cancer within the study period, and 83 cases (9.8%) were found to have interval cancer. Among them, 51 patients (61.5%) had negative findings at index colonoscopy, while 22 (28.5%) had either non-advanced adenomas (12%) or advanced adenoma (26.5%). Compared to "positive" controls with primary cancer (575 patients with full data), patients with interval cancer were older (84% above 60y vs. 65%, p = 0.03) and had proximal (cecal to splenic flexure) tumor location (57% vs. 34%, p = 0.0001), but gender (47% vs. 53% males) and tumor staging (78% vs. 70% in stage 0–2, p = 0.12) were not different. Compared to "negative" healthy controls (255 patients), interval cancer and negative findings at index colonoscopy (51 patients) had higher prevalence of diabetes (33% vs. 15%, p = 0.002) but the same rate of family history, aspirin use and diverticulosis. There were no significant differences in all these characteristics between patients with interval cancer and controls.

Conclusion: Patients with interval cancer tend to be older and have proximal tumor location than patients with primary colon cancer, and have higher prevalence of diabetes. A close surveillance or the use of better endoscopic techniques (e.g., use of NBI, longer retrieval time) should be considered for patients with these characteristics.

P1745 THE RELATIONSHIP BETWEEN QUANTITATIVE FIT RESULTS AND NEOPLASTIC FINDINGS

J. S. McGrath, M. Bergaonkar, D. Pace, S. Antile, S. Stone, E. Randall, J. Quinlan
Dept. Of Gastroenterology, Memorial University, St. John’s/Canada

Contact E-mail Address: jm McGrath@mun.ca

Introduction: Fecal Immunochemical Testing (FIT) is currently used in most Canadian provinces to screen for colorectal cancer. Newfoundland and Labrador is a provincial population-based colorectal cancer screening program over the past five years. Newfoundland and Labrador selects patients for colonoscopy if one of two FIT values ≥100ng/mL.

Aims & Methods: The goal of this study is to assess the effectiveness of different FIT cut-offs and number of FIT tests for detecting adenomas and colorectal cancer.

Results: Data for this study were obtained in a prospective fashion using the Newfoundland and Labrador Colon Cancer Screening Program. 21,371 patients enrolled in the study between the ages of 50–74 and at average risk for colorectal cancer between July 1, 2012 and June 30, 2016. 16,152 participants returned their FIT tests. 1831 were positive on at least one FIT kit and underwent colonoscopy. The positive FIT values ranged from 100.0 to 54,017. The mean FIT was 942.3 (25th percentile: 145, 50th percentile: 260, 75th percentile: 576). Of the 1831 participants who had a colonoscopy 73 (4.0%) were found to have colorectal cancer and 1092 (59.6%) were found to have an adenoma. By using only one FIT test at a cut-off of 100, our program would have missed 8.2% of cancers. An additional 541 colonoscopies were required to detect these cancers. If we stratified patients according to number of FIT tests we found that 83.5% of colon cancers detected were positive on both FIT kits at a quantitative cut off of 100. If a FIT cut off of 200 was used and applied to our patients our program would have missed 17% of cancers based on both FIT tests being positive. 24.7% of cancers is only one FIT kit were supplied to patients and 38.4% of cancers based on both FIT kits being positive. An additional 1133 colonoscopies were required to detect the additional cancers by using two FIT kits as opposed to one. There was no difference in the detection of cancer, advanced adenoma or colorectal adenoma as FIT cut off was increased and with a reduction in FIT kits compiled from two to one. The positive predictive value for cancer increased as the quantitative cut off was increased but this increase was not at the expense of case detected.

Conclusion: Two FIT tests are more effective than one at screening. Patients with two FIT positive results are more likely to have: colon cancer, an advanced adenoma and a simple adenoma. Further triaging of colonoscopy wait lists could be considered based on quantitative FIT values and number of positive tests. Provinces and health authorities need to be cautious when determining the number of FIT kits a patient should complete as well as setting the quantitative cut off. Increasing the FIT cut-off results in a higher probability of colon cancer or adenoma, but there are overall less case detection.

P1746 PREVALENCE OF SERRATED POLYPSYNDROME IN AVERAGE-RISK SCREENING COLONOSCOPY IN GERMANY

C. Schramm1, K. J. Hanssen2, J. Dinter1, F. Kueutting1, T. Goeser1, H. Steffen1
1University Hospital Cologne, Cologne/Germany
2St. Katharinen-Hospital, Prechen/Germany

Contact E-mail Address: christoph.schramm@uk-koeln.de

Introduction: Serrated polyps (SPs) have been recognized as precursors of colorectal cancer (CRC), accounting for up to 30% of CRCs via the serrated neoplasia pathway. SPs are classified into hyperplastic polyps (HPs), sessile serrated polyps (SSPs) with or without dysplasia and traditional serrated adenomas (TSA). The serrated polyps syndrome (SPS) is characterised by multiple SPs throughout the colon. SPS is associated with a lifetime risk of CRC of 6.6% and an increased cancer risk during follow-up in patients with hyperplastic disease. One large case-control study on the prevalence of SPS in average-risk individuals under-going screening colonoscopy was 6.6%. Detection rates for SPs, HPs, SSAs and TSAs were 21%, 18%, 4%, and 33.9%, Detection rates for SPs, HPs, SSAs and TSAs were 21%, 18%, 4%, and 20% respectively. Of all individuals with detected SPs none fulfilled the diagnostic criteria for SPS. Hence, we determined a prevalence of SPS of 0% in our cohort.

Conclusion: The aim of the study was to determine the prevalence of SPS in average-risk individuals participating in the German CRC screening programme. We retrospectively analyzed screening colonoscopies performed by 11 gastroenterologists in 4 medical practices and 1 tertiary academic hospital between 01/01/2011 and 14/12/2016. Individuals <50 years, with an increased risk for CRC (i.e. family history of CRC, cancers in first-degree relatives with SPS) from medical records of individuals with SPS in Germany. Hence, we determined a prevalence of SPS of 0% in our cohort.

Background: Screening: colorectal cancer is focused on the population with average risk of this disease. Individuals with metabolic syndrome represent a population with a higher risk of developing colorectal cancer, but they are not included in colorectal cancer screening standards.

Methods: Two FIT tests are more effective than one at screening. Patients with interval cancer tend to be older and have proximal tumor location than patients with primary colon cancer, and have higher prevalence of diabetes. A close surveillance or the use of better endoscopic techniques (e.g., use of NBI, longer retrieval time) should be considered for patients with these characteristics.

Disclosure of Interest: All authors have declared no conflicts of interest.
Results: Using optical imaging, we detected a significant increase of luminescent and tumor areas in the gut of the infected group suggesting an increase of oxidative stress and inflammation. Histological analyses showed no difference about intratumoral immune infiltrate density on 11G5 and K12-infected mice. However, using our specific algorithm, we observed a significant increase of lymphoid follicle size in the gut of mice infected with the 11G5 strain compared to mice feeding with non-pathogenic K12 strain. Interestingly, follicle size was positively correlated with tumor volume, on the 11G5 infected group suggesting an association between pro-carcinogenic proprieties of this strain and gut immune response. In addition, we observed an increase of neutrophils (Ly6G+ cells) in mucosa and lymphoid follicle of mice infected with 11G5 compared to K12 and non-infected mice. These results can be linked with our in vivo optical imaging observations and our results about the increase of neutrophils chemo-attractants CXCL1 and CCL20 measured by qRT-PCR after infection. Analyses of T cells, macrophages, B cells and myeloid suppressive cells are in progress.

Conclusion: Here we can observe an increase of lymphoid follicle associated with tumor volume after colibactin-producing E. coli infection. Our first results suggest that neutrophils can be one of the immune cells implicated in this process. This work shows a link between immune microenvironment, pathogenic E. coli and tumor development.

Introduction: Early onset gastrointestinal cancers lacking a positive family history are an increasingly worrisome entity. On one hand, early onset is the cornerstone of genetically determined oncological problems, but on the other negative family history does not support the suspect of familial syndromes.

Aims & Methods: We addressed the contribution of germline mutations to non-familial early onset cancers. Patients with pancreatic, gastric, esophageal, duodenal and colorectal cancers were enrolled from 2015 to 2017 at the Gastrointestinal Personalized Medicine unit. Eligibility criteria were the juvenile onset and the negativity for clinical criteria of hereditary cancer syndromes. Early onset colorectal cancer was defined as <45 yrs. For the other cancers, the threshold was defined at 50. Eligible patients provided informed consent. Genes were sequenced by means of a validated Next Generation Sequencing panel of oncological susceptibility genes and confirmed by means of Sanger sequencing.

Results: Among 12 colorectal cancer patients (7F, 5M), NGS analysis showed that: 2: mosaic mutations in the ApcMin (clone1) gene, given the absence of family history; 3: variants of unknown significance (VUS) (2 MSH2 and 1 MLH1); and 7 were negative. Age-stratification revealed that, among those <35 years (n = 4), 1 had MSH2 gene mutation and 3 were negative. In the 36-40 age group (n = 3), 1 had MSH2 VUS, 1 had VUS and 2 were negative. In the age group 41-45 (n = 5), MSH6 mutation and 2 VUS were found, alongside 2 negative results. Among the colorectal cancers, 17% of patients had a de novo mutation of Lynch Syndrome, 25% had a VUS, and 58% were negative. 2 gastric diffuse cancer underwent NGS analysis (40 and 45 yrs, 1M and 1F), both negative.

Among 2 pancreatic cancer patients (<50 yrs, 2F), one tested negative and the other had a VUS on PMS2.

NGS analyses performed on 1 esophageal cancer (46 yrs, M) was negative.

1 duodenal cancer (46 yrs, F) has a MSH2 mutation and 2 VUS (MSH6 and PMS2).

Conclusion: A significant percentage (17%) of early onset colorectal cancers resulted in Lynch Syndrome even when family history is not suggestive of hereditary cancer. We reliably infer the determinant role of genetics, even when the family history does not support the hypothesis. Elsewhere, our results suggest that the already known susceptibility genes seldom contribute to sporadic early onset cancers. Other genes and mechanisms may explain the early onset phenotype. Our data show that NGS is often non conclusive in early onset GI cancers, and further development is needed to better classify VUS (25%).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1750 YM155 AS AN INHIBITOR OF CANCER STEMNESS SIMULTANEOUSLY INHIBITS AUTO-PHOSPHORYLATION OF EGFR AND G9A-MEDIATED STEMNESS IN EGFR-POSITIVE CANCER CELLS

C. Cheng, A. Ho
1Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan
2Division Of Gastroenterology, Cheng Hsin General Hospital, Taipei/Taiwan

Contact E-mail Address: aisheng49@gmail.com

Introduction: Cancer stem cells survive as the leading reason to tumor recurrence after tumor repressive treatments. Therefore, it is worth discovering specific and efficient inhibitors against cancer stemness for applications in reducing tumor recurrence. Previously, literature has indicated that YM155 can significantly reduce the numbers of tumor spheres derived from gastric carcinoma and suppress EGFR activity. However, the pharmaceutical mechanism of YM155 is not completely clear.

Aims & Methods: The aim of this study attempted to investigate the potential mechanism of YM155 against cancer stemness in EGFR-positive cancers. The tumorspheres derived from EGFR-mutant HCC827 and EGFR-wild-type HCT116 and A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models.

Results: We found that higher EGFR autophosphorylation (Y1068) in HCC827-, A549-, and HCT116-derived tumorspheres compared to the parental cells, which induced tumorsphere formation through activating G9α-mediated stemness property. YM155 was demonstrated to inhibit the tumorsphere formation by unexpectedly blocking the autophosphorylation of EGFR and G9α-mediated stemness pathway. The chemical and genetic inhibitions of EGFR and G9α revealed the significant role of EGFR-G9α pathway in maintaining the cancer stemness property.

Conclusion: In conclusion, this study not only revealed that EGFR triggered the formation of tumorspheres through elevating the G9α-mediated stemness, but also demonstrated that YM155 inhibited the formation of tumorspheres by simultaneously inhibiting EGFR autophosphorylation and activity of G9α as a potent anti-stemness agent against EGFR-positive cancers.

Introduction: Promoter hypermethylation-induced epigenetic silencing of tumor related genes played a key role in the initiation and development of colorectal cancer (CRC). Using Methylation DNA Immunoprecipitation (MeDIP), we identified that Fibroblast Growth Factor 14 (FGF14) was preferentially methylated in CRC.

Aims & Methods: We aimed to investigate the epigenetic regulation and biological function of FGF14 in CRC. The expression of FGF14 in 10 CRC cell lines and 24 pairs of CRC tissues and paired adjacent normal tissues by real-time PCR. CRC cells were treated with DNA demethylating agent 5-aza-2′-deoxycytidinetriphosphate (5-Aza). The methylationspecific status of FGF14 in CRC cell lines and CRC tissues were determined by real-time MSP. The biological function of FGF14 in CRC was interrogated by cell viability assay, colony formation, immunofluorescence and flow cytometry, as well as in vivo study.

Conclusions: FGF14 was downregulated or silenced in all (10/10) CRC cell lines, while it was readily expressed in normal colonic tissues. The expression of FGF14 was significantly lower in primary CRCs as compared to their adjacent normal tissues (P < 0.01). The loss of FGF14 gene expression was restored by treatment with DNA demethylating agent 5-Aza. Overexpression of FGF14 in CRC cell lines inhibited colony formation, suppressed cell viability, and induced cell apoptosis via AMPK/mTOR pathway, accompanied with enhanced protein expression of cleaved caspase-3, cleaved caspase-7, cleaved caspase-9 and PARP. In xenograft mouse model, overexpression of FGF14 significantly reduced tumor growth (P < 0.001). Conclusion: FGF14, which induces cell apoptosis via AMPK/mTOR pathway, is a novel tumor suppressor down-regulated by epigenetic inactivation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A cancer with a number of somatic mutations is defined as “hypermutator,” and shows therapeutic features, such as high sensitivity to immune checkpoint inhibitor. However, to date, analyses of hypermutator have not been done with a large number of cases.

Aims & Methods: The aim of this study is to analyze the incidences and characteristics of hypermutator in digestive system cancers. We analyzed somatic mutations in digestive system cancers in 1145 cases (age: 67.4±11.3 yrs, M:F = 755:390), those underwent surgery after full informed consent during 2014 to 2015. Genomic sequencing was performed on 47 inherited cancer-associated genes and 411 cancer-associated genes using next-generation sequencer (Illumina NextSeq500). The results were compared with the cases of normal colonoscopy, 14 first degree healthy relatives from Lynch families.

Results: The 1145 subjects included 583 colorectal cancers (CRC), 229 gastric cancers (GC), 103 metastatic liver tumors, 100 hepatocellular carcinomas (HCC), 45 pancreatic cancers, 23 GISTs, 15 esophageal cancers and 14 neuroendocrine cancers. Hypermutator was defined when a tumor having >500 mutations in the somatic DNA.

Conclusion: The incidence of hypermutator in digestive system cancers developed in 13.9% of CRC patients and 25.9% of GC patients. It was also detected in 33.3% of small intestinal cancers. Moreover, the result of this study suggests that the significant loss of the transcriptional regulator CtBP2 contributes to intestinal epithelial stem cell differentiation.

P1757 MICROBIOTA A NEW INDICATOR OF COLORECTAL CANCER (CRC) HETEROGENEITY

I. Sobhani1, B. Bergstein2, A. Gholizade2, S. Kennedy2

Introduction: Location and somatic gene signature of CRCs may impact prognosis and response to therapy. A relative specific CRC-related dysbiosis has been characterized.

Aims & Methods: The aim was to characterize colon microbiota in CRC patients regarding location, gene markers and outcome. Patients (N = 173) signed consent forms. Microbiota was sequenced from Illumina HiSeq2500. Analysis of stool DNA: 72 CRC (35 sporadic-S, 19 Lynch-L), 87 asymptomatic subjects (normal colonoscopy), 14 first degree healthy relatives from Lynch families.

Conclusion: Microbiota was sequenced from 72 CRCs (35 sporadic-S, 19 Lynch-L) and compared to control and an increase in differentiation markers were seen. Interestingly, in mouse small intestine, CtBP2 is expressed in the proliferative compartment. The specific taxonomic composition of the control and CRC groups was subjected to random analysis (Caret’s R package) with two optimization parameters (precision and kappa) in the model.

Introduction: Colorectal serrated lesions (SLS) include hyperplastic poly (HP), traditional serrated adenoma (TSA) and sessile serrated adenoma/polyp (SSA/P). SSA/Ps are well-known precursors of colorectal cancer (CRC) characterized by BRAF mutation and microsatellite instability (MSI), whereas the molecular characteristics of TSAs are not fully understood.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

Aims & Methods: We aimed to identify epigenetic alterations associated with the development of TSAs and to clarify the associations between clinical, pathological and molecular characteristics in colorectal lesions. The genome-wide DNA methylation status in TSAs consisting of protruding and flat components were analyzed using an Infinium HumanMethylation450 BeadChip, and changes in DNA methylation within the development of TSAs were identified. Identification of methylated genes and CIMP markers (MINT1, -2, -12, -31, -p16 and MLH1) and BRAF/KRAS mutations were analyzed in 847 colorectal lesions and 61 samples of normal colonic tissue. Effects of epidermal growth factor on CRC cell growth in a preclinical setting were identified. Methylation of identified genes and CIMP markers were significantly downregulated in TSAs. Immunohistochemical analysis showed that SMOC1 was expressed in the epithelium of normal colonic tissues and SSA/Ps, but that expression is significantly reduced in TSAs. Immunohistochemical analysis of SMOC1 in SSA/Ps was associated with higher metastasis rate. Immunohistochemical analysis of SMOC1 in TSAs were assessed in vitro and in vivo.

Results: BeadChip analysis revealed 11 genes in which methylation levels were progressively increased during development of TSAs. Among them, SMOC1 was prevalently methylated in TSAs, but was rarely methylated in SSA/Ps (p = 0.001). RT-PCR revealed that SMOC1 is abundantly expressed in SSA/Ps, colon formation and in vivo tumor formation by CRC cells. Analysis of colorectal lesions revealed that SMOC1 is frequently methylated in TSAs and CRCs, and that SMOC1 methylation is strongly associated with KRAS mutation and CIMP-low.

Conclusion: Methylation of SMOC1 is associated with TSA development but is rarely observed in SSA/Ps. Immunohistochemical analysis of SMOC1 may be a useful marker to discriminate between SSA/Ps and TSAs. Our data suggests SMOC1 methylation may play a role in the neoplastic pathways arising in TSAs.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to improve a simple, noninvasive blood test that would easily identify individuals with different types of cancer. Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer, PC, gastric cancer (GC), sarcoma and HM), that was confirmed by histology. Age, gender and ethnic matched healthy individuals served as controls. Hemoglobin levels were determined by HemoCue (Hemofilcro, Sweden). All tests were repeated at least three times. A total of 684 healthy controls, and 20,000 leukocytes were analyzed by flow cytometry using the method outlined above. An initial template data has been generated using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition has been completed. The template file contains a template data in order to minimize fluorescence overlap among detection channels.

Results: The novel assay was improved significantly, distinguished healthy from CRC (Fig 1a) (P < 0.013), PC (Fig 1b) (P < 0.018), biliary tract (P < 0.4E-12), Lung cancer (Fig 2a) (P < 0.001), and MDS (P < 0.01) and Lymphoma (P < 2.1E-07) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity and specificity for CRC were 72.9% and 77.4%, and for PC 70.6% and 75.9%, respectively. The positive (PPV) and negative predictive (NPV) values of CD24 for the detection of CRC was 38% and 94.8%, and for PC 17.1% and 97.3%, respectively. Specificity and sensitivity for HM were also statistically significant (data not shown). The CD24 test could not discriminate between patients with cervical, stomach and lung cancers and healthy subjects.

Conclusion: Conclusions: CD24 expression in PBLS is a promising blood test for the early detection of CRC, PC, and HM.

P1760 CD24 PREDICTIVE LEVELS - A SIMPLE NOVEL BLOOD TEST FOR IDENTIFICATION OF VARIOUS CANCER ALTERNATIVE VACCINE PATHWAYS

Aims & Methods: We aimed to improve a simple, noninvasive blood test that would easily identify individuals with different types of cancer. Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer, PC, gastric cancer (GC), sarcoma and HM), that was confirmed by histology. Age, gender and ethnic matched healthy individuals served as controls. Hemoglobin levels were determined by HemoCue (Hemofilcro, Sweden). All tests were repeated at least three times. A total of 684 healthy controls, and 20,000 leukocytes were analyzed by flow cytometry using the method outlined above. An initial template data has been generated using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition has been completed. The template file contains a template data in order to minimize fluorescence overlap among detection channels.

Results: The novel assay was improved significantly, distinguished healthy from CRC (Fig 1a) (P < 0.013), PC (Fig 1b) (P < 0.018), biliary tract (P < 0.4E-12), Lung cancer (Fig 2a) (P < 0.001), and MDS (P < 0.01) and Lymphoma (P < 2.1E-07) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity and specificity for CRC were 72.9% and 77.4%, and for PC 70.6% and 75.9%, respectively. The positive (PPV) and negative predictive (NPV) values of CD24 for the detection of CRC was 38% and 94.8%, and for PC 17.1% and 97.3%, respectively. Specificity and sensitivity for HM were also statistically significant (data not shown). The CD24 test could not discriminate between patients with cervical, stomach and lung cancers and healthy subjects.

Conclusion: Conclusions: CD24 expression in PBLS is a promising blood test for the early detection of CRC, PC, and HM.

Introduction: Background: CD24, a mucin-like cell surface molecule, highly expressed on solid tumors and hematological malignancies (HM) (Gastro 2006, Clin Am Rev Cancer 2007, Can Rev 2008). mAb to CD24 were found to inhibit the growth CD24 cancer cells (Kraus et al., 2009). We have shown that a simple non-invasive blood test evaluating CD24 levels on PBL had good sensitivity and specificity for detecting colorectal neoplasia in subjects undergoing screening colonoscopy (Kraus et al., 2009).

Conclusion: Diabetics require a more intense bowel preparation aided by budesonide to help others. This suggests that both doses of budesonide 8 and 8 hours and preparation should end no later than 8 hours prior to colonoscopy. Patients should be instructed to drink a minimum of 8 glasses of water with each dose of picoxol.

Introduction: Colonoscopy is the gold standard method of colorectal cancer and polyp screening, but polyps are missed during a colonoscopic examination at a rate that varies from 6% to 27%. Improved adenoma detection rates can be achieved with optimized endoscopic visualization methods. A recently developed new Fujinon endoscope system, Eluxeo carries a new function of electronic chromoendoscopy, Linked Color Imaging (LCI), that enhances the coloring and contrast of mucous membranes and blood vessels which are difficult to see with the conventional endoscopes. In our prospective randomized study, we evaluated the effectiveness of LCI, a new endoscopic visualization technique that may enhance image quality to improve colonic adenoma detection.

Aims & Methods: Up till now 247 eligible patients, elder than 45 years, admitted for screening outpatient colonoscopy were randomly enrolled to undergo high-definition white-light colonoscopy (WLC) or LCI colonoscopy during instrument withdrawal. The colonoscopic procedures were performed by three experienced endoscopists on the 7000 processor endoscopes, whether the conventional high-definition Fujinon EC 590z or a new EC 760z VS Eluxeo colonoscope. All of the colonoscopic procedures were made under Propofol deep sedation guided by an anesthesiologist team. The minimum withdrawal time was defined as no more than 6 minutes. All colonoscopies were routinely assisted with pure CO2 insufflation. The primary outcome parameter of our study was to assess and compare the polyp and adenoma detection rate with the two endoscopic techniques.

Results: A total of 247 patients were randomized (mean age 58.7 years), 101 patients enrolled in the WLC group and 146 patients in the LCI group. No significant differences have been observed in the patient demographics and colonoscopy withdrawal time between the two groups. Patients having both colorectal polyps and adenomas were detected more frequently in the LCI group than in the control group: 60.9% and 43.8% versus 55.4% and 33.6% respectively, however, this was not statistically significant (p=0.32 and 0.16). In contrast, the total number of adenomas relative to the total number of polyps detected with LCI withdrawal were significantly higher than with conventional WLC: 105 vs. 63.2 adenomas, respectively (p<0.005).

Conclusion: The LCI enhancement of the Fujinon Eluxeo colonoscopy system was superior to the conventional HD-WLC in detecting patients with colorectal adenomas, which was mainly due to the ability of the more sensitive detection of minute (<5 mm) adenomas.(Study was supported by ECT grant GINOP-2.1.1-15-201500128.)

Contact E-mail Address: alexandra.kalmar@gmail.com

Introduction: Long non-coding RNAs (lncRNAs) play a role in colorectal cancer (CRC) development, however, lncRNA expression profile in CRC and its relation to the epigenetic regulatory system still remain incomplete.

Aims & Methods: We aimed the perform whole genomic lncRNA expression profiling and the analysis of underlying functional interactions of aberrantly expressed lncRNAs. lncRNA expression levels were analyzed on 60 colorectal biopsy samples (20 CRCs, 20 adenomas, 20 normals) by Human Transcriptome v3.0 A 2.0. Expression alteration of certain candidates was verified by qPCR. Furthermore, in silico validation was performed on HGU133 Plus 2.0 array data and also on TCGA COAD dataset. mRNA targets of lncRNAs were predicted with the miRCODE algorithm and miRNA expression was analyzed with miRNA 3.0. Arca, Transcriptome-wide lncRNA-miRNA coexpression pattern analysis was also performed.

Results: According to HTA results in adenomas 12 lncRNAs (e.g. LINC00278) were upregulated and 6 lncRNAs (e.g. RP17.479D18.1) were downregulated compared to normals, while in CRCs 1 lncRNA (UCA1) was overexpressed and 8 lncRNAs (e.g. LINC00350) were underexpressed compared to adenomas (p<0.05; 2≥FDR ≥2). In CRC samples 8 lncRNAs (e.g. AC123023.1) were overexpressed and 9 lncRNAs (e.g. RP13-497K6.1) were downregulated compared to normals. 42% of lncRNAs upregulated in CRC samples showed high AUC in their expression in adenomas (p<0.05). Of the 8 lncRNAs (e.g. overexpressed CCAT1, downregulated LINCO1313). In line with aberrant expression of certain lncRNAs in tumors, mRNA and mRNA targets expression showed systematic alterations, e.g. UCAP1 upregulation in CRC samples in parallel with miR-1 down-regulation accompanied by CMET target mRNA overexpression (p<0.05).

Conclusion: The defined lncRNA sets (e.g. CCAT1, UCA1) may have a regulatory role in adenoma and CRC development and in tumor cell growth pathways. A subset of CRC-associated lncRNAs showed significant differential expression in colorectal precancerous samples, which raise the possibility to develop potential adenoma specific markers and achieve early detection of colon lesions.

Introduction: Serine protease inhibitors (Serpins) play an important role in the regulation of enzymes involved in proteolytic cascades. Members of the family are: alpha-1-antitrypsin, alpha-1-antichymotrypsin, C1 inhibitor, antithrombin and neuroserpin. Kallikrein-related peptides (KLKs) are involved in proteolytic cascades of different tissues. KLK14, acting via PAR-2, represents an auto- crine/paracrine regulator of colon tumorigenesis and alpha-1-antitrypsin is a natural inhibitor of KLK14. Therefore its role in regulating the proteolytic cascade in colorectal tumorigenesis is of great importance.

Aims & Methods: The aim of this study was to analyze A1-antitrypsin (AAT) expression in tissue samples at different stages in the process of colorectal cancer development. We examined a total of 245 colon samples. Of those, there were 101 colorectal carcinoma tissues, for 70 of which paired normal mucosa was also examined. A total of 74 colorectal adenomas were examined. Quantitative real time PCR was used to measure AAT expression. Clinical evaluation of AAT levels was determined in terms of disease-free survival (DFS) and overall survival (OS).

Results: Alpha-1-antitrypsin expression was found to be significantly associated with longer DFS (p=0.028). Cox proportional hazard regression model using univariate analysis revealed that high status alpha-1-antitrypsin expression is a significant factor for disease-free survival (DFS) (p=0.002) and overall survival (OS) (p=0.026) in patients with colorectal cancer. Kaplan-Meier survival curves demonstrate that low alpha-1-antitrypsin expression is significantly associated with longer DFS (p=0.001) as well as OS (p=0.021).

Conclusion: Our data suggests that alpha-1-antitrypsin expression could be considered as a potential biomarker of unfavorable prognosis for colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Real-time differentiation between neoplastic and non-neoplastic colorectal lesions may be crucial during colonoscopy. While adenomas are
neoplastic, and therefore should be resected, hyperplastic polyps never turn malignant and do not require specific endoscopic therapy. The aim of our prospective, randomized study was to distinguish subcentimeter hyperplastic and adenomatous polyps based on Fujinon FICE versus Eluxeo BLI electronic chromoendoscopy technology with high-definition colonoscopy with and without optical magnification.

Aims & Methods: In order to create a video and digital picture library of polyps, patients undergoing screening or diagnostic colonoscopy were considered for inclusion. Patients with at least one histologically verified <10 mm polyp were included. Video clips of each polyp were digitized and stored for subsequent analysis without and with 50x optical zoom at standard white-light (WLI), and with FICE-light or BLI-light were recorded with Fujinon EC 590Z and EC760Z endoscopes and stored in an anonymized database. The video-library was comprised of each of our 5 colonoscopic experts (ML, SZM, OL, DZS, and SZA) independently and randomly reviewed all of the cases with a standardized electronic questionnaire. In each cases, all of the observers had to assess the color, the vascularization and the surface of the polyps, and the pit pattern was also assessed. The Kudo classification was used. Finally, with the definitive histological confirmation (low/medium/high on VAS), the histological prediction and the final decision has been clarified on each lesion as neoplastic or non-neoplastic (hyperplastic).

Results: Up till now 115 polyps were enrolled and recorded into our digital web-based library, 59 were assigned into the FICE and 56 into the BLI group. All of the detected 115 polyps were endoscopically removed and histologically analyzed and this was regarded as gold standard. The overall accuracy with WLI versus FICE versus BLI endoscopy technology of the 5 experts without zoom and with 50x magnification to differentiate between hyperplastic and adenomatous lesions were 77.62% and 84.51%, vs. 74.58% and 83.90% vs. 89.84%, respectively. There was an excellent correlation between the histopathological results and our KUDO classification with both FICE and BLI technology. Both 50x times optical zoom and BLI technology were independently and significantly improved our confidence rate that was associated with a more precise histopathological prediction as compared to non-zoom, WLI or FICE endoscopic polyp assessment.

Conclusion: The new electronic chromoendoscopy technology with Eluxeo BLI significantly improved the reliability of the histology prediction as compared to FICE and WLI endoscopy technology. High-confidence predictions for the differentiation of neoplastic and non-neoplastic polyps with Eluxeo BLI electronic chromoendoscopy provide a potential for real-time endoscopic diagnosis of hyperplastic polyps to support reset and discharge strategy. (Study was supported by ECT grant G1/155/2015-04128)

Disclosure of Interest: All authors have declared no conflicts of interest.
symptomatic condition (lumbago): lesion site (Rs/Ra/Rb), 1/2/19 cases; mean temperature of biopsied cervical enzymes: biopsy positive rate, 11/14 (78.5%); presence/absence of endoscopic ultrasonography, 11/11 cases; and M/SM/MP, 1/19/1 cases. The TNM classification of the cases was as follows: T1a, 16 cases; T1b, 5 cases; T2, 1 case; N1, 1 case; and M1, 1 case. The treatment was primarily chemotherapy/endoscopic mucosal resection with ligation/endoscopic mucosal resection/endoscopic submucosal dissection/surgery/drug therapy in 5/7/2/1/1 case. Of 19 endoscopic treatment cases, 15 corresponded to a tumor diameter of ≤10 mm, with negative resection margin and vascular invasion as criteria for curative resection, and 3 cases of unknown stumps were recognised. In the EMRL group, all cases were negative. In all the cases except the case of other-disease death, it elapsed without recurrence. Both surgical cases showed a positive vascular invasion, and one case was a confirmed N1, but neither of the patients survived without a relapse. In the case with hepatitis and bone metastases, medication was administered, and the effect was temporarily effective, but the patient died a year and a half later.

**Conclusion:** Endoscopic treatments are considered appropriate for rectal NETs with a diameter ≤10 mm or with a diameter >10 mm in diameter. Among the treatment options, EMRL is considered useful and well tolerated. However, follow-up observation and case accumulation seem necessary to determine the long-term prognosis in NET, which may recur after year two.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Inactivation of TP53 is the most frequent genetic damage in human cancer. In addition, hyperactivation of the RAS pathway is common in many human malignancies (Lung (LC)--40%, pancreatic (PC)--95%) and colorectal cancer (CRC)--50%). Despite multiple attempts, targeting these pathways for the treatment of cancer, for example through the development of RAS pathway inhibitors has not proven to be effective thus far. Herein, we propose to exploit the hyperactive RAS pathway and TP53 mutation status of human cancer to deliver targeted antitumor therapy. We have previously reported that a recombinant adenovirus, carrying a pro-apoptotic gene (PUMA) under the regulation of RAS (Rasmut/p53wt and HCT116-/-;Rasmut/p53 mut CRC cell lines, expressing the anti-toxin under p53 responsive elements (RGC) specifically in cancer cells harboring hyperactive RAS (Giladi et al. 2007). Furthermore, we have shown, both in vitro and in vivo, that replacing the pro-apoptotic gene with a bacterial toxin can improve the efficacy of this system (Shapira et al. 2015).

**Aims & Methods:** We aimed to establish a tight regulated dual system by expressing a toxin under PTX4 elements in cancer cells, while sparing normal cells by expressing the anti-toxin under p53 responsive elements (RGC) specifically in non-malignant cells. Adenoviral vectors carrying the toxin (P4-Maf-Mcherry) and anti-toxin (Maf-Mcherry) were engineered and fused to the lentivirus envelope. Cell death was measured qualitatively by the MTT assay. Human colorectal, pancreatic, lung and triple negative breast cancer cell lines, A549, H1650, DU145, and A549 EGFR-positive cancer cells. We demonstrated that ILF3 stabilized and activated EGFR-mediated G9A in EGFR-positive cancers.

**Results:** In conclusion, this study demonstrated that ILF3 was an oncogene property in the EGFR-positive cancers. In conclusion, this study demonstrated that ILF3 was an oncogene property in the EGFR-positive cancers. In conclusion, this study demonstrated that ILF3 was an oncogene property in the EGFR-positive cancers.

P1772 Efficacy and safety of twelve chemopreventive regimens for the recurrence of colorectal adenomas: A network Meta-analysis

H. Chen
Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: chenhant68@hotmail.com

Introduction: Although various pharmacological agents have been trialed for recurrent colorectal adenomas, their comparative effectiveness remains unclear. We conducted both direct and indirect comparisons of twelve chemopreventive agents for recurrent colorectal adenomas.

Aims & Methods: MEDLINE, EMBASE, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials, and ClinicalTrials.gov were searched up to May 1, 2016.RCTs were assessed by a random-effects model within a Bayesian framework. Agents for each outcomes were ranked by surface under the cumulative ranking area (SUCRA). This study is registered with PROSPERO, number CRD42016041923.

Results: 33 RCTs were eligible, enrolling 44,447 participants treated by twelve preventive agents for recurrent colorectal adenomas. Aspirin (95/%) and other NSAIIDs, 11 antioxidants, 4 dietary supplements, 3 calcium, 4 folate acid, 2 calcium plus antioxidants, 2 aspirin plus folate acid and 1 5-aminosalicylic acid were the most efficacious on COX1 and COX2 protein expression in EPA-resistant MC38r compared to EPA alone. A similar pattern of response was measured in vivo. We measured EPA incorporation in these cells and observed an increased accumulation of EPA in CT26wt cells treated with both EPA and aspirin compared to EPA alone. This correlation was confirmed both in primary operable and metastatic CRC patients with elevated GPS was associated with poor OS (HR = 0.01). This correlation was confirmed both in primary operable and metastatic CRC patients with the GPS system was wide and accounts for 10% of all newly diagnosed cancers1. Although the therapeutic options have dramatically developed, the long-term survival rate of patients with CRC remains low. In recent years, great efforts have been made to identify inflammation-related factors for precise prediction of disease progression. Prognostic ratio of inflammation is increased by the combination of the level of serum C-reactive protein (CRP) and albumin, which are indicators of systematic inflammatory response and nutritional status respectively. Growing evidence suggested that GPS was served as an independent prognostic index in a variety of malignancies. For patients with CRC, the GPS system was also widely studied, but the results were controversial.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancer (CRC) is the third most common cancer worldwide. The overall 5-year survival rates for patients with CRC have dramatically improved. The 5-year survival rate of patients with CRC remains low. In recent years, great efforts have been made to identify inflammation-related factors for precise prediction of disease progression. Prognostic ratio of inflammation is increased by the combination of the level of serum C-reactive protein (CRP) and albumin, which are indicators of systematic inflammatory response and nutritional status respectively. Growing evidence suggested that GPS was served as an independent prognostic index in a variety of malignancies. For patients with CRC, the GPS system was also widely studied, but the results were controversial.

Aims & Methods: To investigate the correlation between GPS and prognosis of patients with CRC to further clarify its clinical significance. A comprehensive search was carried out on PubMed, Embase, Chinese, and National Knowledge Infrastructure was performed to identify eligible studies, from which the risk of overall survival (OS) and cancer-specific survival (CSS) were extracted. A random-effect model was adopted to combine hazard ratio (HR) and 95% confidence interval (CI). Heterogeneity and publication bias among studies were assessed.

Results: 25 articles with a total of 5660 participants were included. The pooled results indicated that elevated GPS was associated with poor OS (HR = 2.83, 95%CI: 2.00–4.00, P < 0.01) and CSS (HR = 1.94, 95%CI: 1.51–2.49, P < 0.01). This correlation was confirmed both in primary operable and advanced inoperable patients. Increased GPS was also closely related to advanced tumour-node-metastasis (TNM) stage (odds ratio [OR] = 1.44, 95%

Introduction: The implementation of the CRC screening program has generated an increase in surveillance colonoscopies. However, the intermediate-high risk group that included advanced lesions (size ≥10 mm, villous component or high grade dysplasia) or the presence of 3 or more polyps, has a low incidence of metachronous risk lesions when performing colonoscopy at 3 years according to the current recommendations. Identifying predictors of metachronous lesions would provide a better risk stratification and improve the efficiency of surveillance programs.

Aims & Methods: We aimed to identify the cost effectiveness of the first surveillance colonoscopy and the predictive factors of metachronous lesions at 3 years in individuals with advanced lesions or ≥3 polyps detected at baseline screening colonoscopy. This was an analysis of all cases with advanced polyps and/or multiplicity from CRC screening program population of Barcelona detected at baseline colonoscopy during the years 2010–2011 and with a performed colonoscopy after 3 years. Epidemiological and clinical data of all individuals were collected as well as the morphological data of all polyps. For the statistical study, a bivariate analysis and logistic regression were performed.

Results: 638 cases were identified, with mean age of 64 years. 342 were men (62.2%). 23.8% required more than one colonoscopy for the complete removal of all polyps. A complete surveillance colonoscopy at 3 years was performed in 518 cases (82%) with an average surveillance time of 38 months [15–75]. Mean fecal hemoglobin was 440 ng/mL. 51.8% suffered from hyperinsulinemia, 15% from diabetes mellitus, 45.5% from dyslipidemia and 12.3% from chronic obstructive pulmonary disease. 43.8% of individuals were overweight (BMI ≥25) and 34.7% were obese (BMI ≥30). Surveillance colonoscopy was normal or with low-risk polyps in 420 cases (80.1%); and advanced polyps or multiplicity were identified in 98 cases (19.8%) 73 advanced adenomas in 59 cases (11.4%), ≥3 adenomas in 62 cases and ≥3 adenomas and/or serrated polyps in 71 cases (13.7%). The presence of ≥3 adenomas and/or serrated polyps was the only variable that was associated with increased risk of the diagnosis of advanced adenomatous or serrated lesions in surveillance colonoscopy (p < 0.0001).

Conclusion: In individuals with advanced polyps and/or multiplicity the incidence of metachronous risk lesions at 3 years is low. Assessment a baseline colonoscopy with complete removal of all the polyps could allow to increase the interval of surveillance, maintaining and ensuring the compliance of the surveillance at 3 years in the cases with multiplicity in the baseline colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal Endoscopic Submucosal Dissection (ESD) is recommended for superficial neoplastic lesions at high risk of submucosal invasion. ESD allows an en-bloc resection but ESD experience is still limited in Western countries.

Aims & Methods: The aim of this retrospective study was to evaluate technical and clinical outcomes of colorectal ESD, in a single tertiary European center. We retrospectively analyzed all consecutive patients treated by ESD for colorectal lesion at Humanitas Research Hospital (Milan, Italy) from January 2011 to September 2016. The primary outcomes were technical success, defined as en-bloc resection and clinical success, defined as curative resection (R0) without need for surgery. Secondary study outcomes were complication rate and adenoma/carcinoma recurrence. Complications were divided in early (<24 hours) and delayed (>24 hours) and included bleeding and perforation. Recurrences were identified as the presence of adenoma or carcinoma at the endoscopic follow-up performed at 6 months, 1, 3 and 5 years. Data were analyzed by STATA 14 statistical software.

Results: A total of 185 lesions in 185 patients (M: F 97:89, mean age 66.7 ± 11.5). Lesions were located in the rectum (63.4%), left colon (9.7%), transverse (11.9%) and right colon (14%). Mean size of lesions was 39.3 ± 24.3 mm. Mean Glasgow Prognostic Score was 1.3 ± 0.7. Recurrences were found in 24 out of 185 lesions (12.9%). At 3 years follow-up, 57 lesions (30.3%) were classified as curative resection (R0). Recurrences were identified as the presence of adenoma or carcinoma at the endoscopic follow-up performed at 6 months, 1, 3 and 5 years. Data were analyzed by STATA 14 statistical software.

Conclusion: ESD is a feasible strategy to manage superficial colorectal tumors. This study demonstrates favorable technical and short-term clinical outcome of colorectal ESD, but further studies are needed to confirm the long-term efficacy.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: The transition to population-based program resulted in the improvement of target population participation followed by increase in colorectal neoplasm detection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1778 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY CANCER AND HIGH GRADE DYSPLASIA IN COLORECTUM

P. Zhou1, T. Chen1

1Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

Contact E-mail Address: chentao666@yahoo.com

Introduction: Although endoscopic submucosal dissection (ESD) is a widely accepted treatment for colorectal neoplasm, little is known about large consecutive studies evaluating long-term outcomes of early cancer and high grade dysplasia. We investigated the efficacy and safety of ESD for early cancer and high grade dysplasia in colorectum and evaluated the long-term outcomes, including local recurrence and metastasis.

Aims & Methods: We performed a retrospective analysis of data collected from 514 consecutive patients with 520 colorectal early cancer and high-grade dysplasia treated with ESD between January 2007 and December 2013. Histology and patient data were collected during an average follow-up time of more than 5 years to determine tumor stage and type, resection status, complications, tumor recurrence, and distant metastasis.

Results: The overall rates of en bloc resection, complete resection, R0 resection, major complications were 94.4%, 91.3%, 89.2% and 2.1%, respectively. Large tumors and snare-assisted ESD were independent factors of piecemeal resection. ESD of colon tumors increased the risk for complications. During the follow-up period, all patients remained free from metastasis. However, local recurrence occurred in 4 patients (0.8%); large tumors and piecemeal resection were risk factors.

Conclusion: ESD is effective and safe for resection of early cancer and high grade dysplasia in colorectum and long-term outcomes are favorable. ESD is indicated for the treatment of colorectal early cancer and high grade dysplasia to obtain curative resection and prevent the local recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1779 LOW UPTAKE OF PSYCHOLOGICAL THERAPIES AMONG PATIENTS WITH IRRITABLE BOWEL SYNDROME IN SECONDARY CARE

O. Craig1, C. Black1, L. Houghton2, A.C. Ford1

Introduction: Patients with irritable bowel syndrome (IBS) often have co-existent intestinal disorders (FGID). Recent studies demonstrated that an impairment in psychological factors.

Conclusion: Despite high levels of psychological comorbidity and NICE recommendations, patients with IBS in a specialist clinic were generally reluctant to consider psychological therapies such as CBT or hypnotherapy. Those with anxiety, depression, somatof orm-type behaviour, or severe symptoms were no more willing to consider these therapies than those without.

P1780 GUT SYMPTOMS AND TRANSIT DISTURBANCE IN PARKINSON’S DISEASE ARE PAN-ENTERIC BUT NOT UBQUITOUS: A WIRELESS MOTILITY CAPSULE STUDY

V. Passananti, N. Zarate Lopez, R. Sweis, A. V. Emmanuel

GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Symptoms of gastrointestinal dysfunction are among the most common non-motor complaints in Parkinson’s patients. These may involve muscles from the oropharynx to the anorectum, and the autonomic and enteric nervous system are often involved, resulting in secondary bowel motility.

Aims & Methods: The objectives of this study were to evaluate a technology measuring the spectrum of gut dysfunction, the Wireless Motility Capsule (WMC), in Parkinson’s disease. We also wanted to correlate transit measures with gastrointestinal symptoms. Fifteen PD patients and 7 controls (table1) were included. PD severity was scored with the modified Hoehn and Yahr (H&Y) staging scale. GI symptom burden was identified by Wexner constipation score and Gastroparesis Cardiac Syndrome Index (GCSI). Acidity, motility and transit data were obtained, as standard, by WMC. All medications affecting pH and motility, including L-dopa, were discontinued for 5 days before and for the duration of the WMC study. Were analyzed data about gastric emptying time (GET), small bowel transit time (SBTT), colonic transit time (CTT) and whole gut transit time (WGTT).

Results: One patient could not swallow the capsule, and of the 14 patients completing the study, 8 reported GI symptoms. Compared to non-symptomatic PD patients, those with GI symptoms showed significant delayed transit in the stomach, colon and whole gut (table 1). However, small bowel transit did not significantly differ. GI dysfunction was not correlated with H&Y score in this small study, used the risk lower constipation scores were correlated, suggesting a pan-enteric problem in symptomatic individuals. There was a significant correlation between the Wexner constipation score and CTT in all patients (p < 0.01) but not GCSI and GET (p > 0.10). The results of Wireless Motility Capsule did not differ between non-symptomatic PD and controls.

P1781 OUTLET DYSFUNCTION IS PREVALENT IN SEVERE FUNCTIONAL BLOATING: PRELIMINARY REPORT FROM A MULTICENTER ITALIAN STUDY

Introduction: Bloating and abdominal distension are common and bothersome symptoms and a frequent complaint of patients affected by functional gastrointestinal disorders (FGID). Recent studies demonstrated that an impairment in psychological therapies as their first-choice treatment option than those with mild or moderate symptoms (7.7% versus 21.7%, P = 0.10).

Conclusion: We have shown that Parkinson’s patients with gut symptoms have both upper and lower complaints. Symptomatic PD patients also have markedly delayed transit times throughout the whole gut compared to asymptomatic PD patients and controls. Whilst severity of constipation is related to delayed colonic transit no such relationship was present between gastroparesis symptoms and gastric emptying. The implication is that treating symptomatic Parkinson’s patients should address the whole gut, whether with prokinetics or dual therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.
the handling of gas is a relevant underlying mechanism in FGID patients with bloating. A subset of patients with severe abdominal bloating and gas directional defects are lacking in these patients.

Aims & Methods: Our aim is to study the relationship between the defecation pattern, the severity of bloating and the abdominal girth measurements in FGID patients consulting for bloating as primary complaint with/without visible abdominal distension. In addition, we propose a prospective, multi-center study of patients with severe abdominal bloating (VAS score ≥ 24 on a 100-mm scale) as primary complain with/without visible abdominal distension. Patients were recruited at 4 gastroenterology outpatient clinics in Italy. Clinical examination, demographic data, Rome III criteria. All patients were prescribed a lactose-free diet supplemented by dietary advice according to the NICE guidelines for two weeks. A belt around the abdomen at standardized sites provided assessment of abdominal girth measurements. During the 2-week run-in period patients completed a daily diary log including abdominal bloating and pain/discomfort scores (100-mm VAS), Bristol Stool Form and stool frequency. At randomization visit, all patients filled in a questionnaire on adequate relief of bloating on a Likert scale and a further abdominal bloating 100-mm VAS. All patients underwent an anorectal manometry and electromyography.

Conclusion: In this prospective, multicenter trial simple diet advise was of benefit in approximately 30% of FGID patients consulting for severe bloating. In the non-responders outlet dysfunction was prevalent and correlated with subjective bloating perception. The study is ongoing, but our data may support bowel retraining as potential treatment option for functional bloating.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: emanuela.ribichini@gmail.com

Introduction: Faecal Incontinence (FI) is a common and socially disabling condition, more prevalent among females over 50 years old. Detailed anatomical and physiological assessment of each patient is important to determine the correct cause of FI and selection the most appropriate therapy. Conventional and High Resolution (HR) Anorectal Manometry (ARM) is a useful tool to categorize anal and/or rectal dysfunction in addition to provide physiological assessment of both anal sphincters and rectum.

Aims & Methods: To evaluate symptoms and anorectal function of patients affected by FI, we included 358 patients with FI (77% female (F) and 23% male (M), mean age 63 range (22–92) years in 2016) were divided into two groups: 67 patients with severe abdominal bloating and gas directional defects and also severe FI and 67% of these patients had also severe FI. After excluding organic disorders, the cases of abdominal bloating and gas directional defects were further divided into two groups: 67 patients with severe abdominal bloating and gas directional defects and also urinary incontinence (UI) (44%); 70 patients with severe abdominal bloating and gas directional defects and also severe FI (47%). Proctological and urological conditions were: 47% of patients had history of previous pelvic surgery (34, 23%) and pelvic surgery was: 77% (21%); 40% (47%) of patients were diagnosed with UI. The FI may be confused with dyschezia and the defecation maneuver.

Conclusion: In our study, in accordance with the literature, we observed a female prevalence in FI. FI is significantly associated with previous proctological/pelvic surgery and traumatic anal/vaginal delivery. Furthermore, patients with FI referred difficulty evacuating stools, too. In fact in patients with dyschezia-type constipation, the FI may be confused with an encopresis. Finally we observed these prevalent manometric alterations: combined dysfunction IAS and EAS, and rectal hypersensitivity. Manometric findings could help physicians to identify appropriated patients for a biofeedback therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bile acid malabsorption (BAM) is a common and frequently under-investigated cause of chronic diarrhea. Most of the cases of chronic diarrhea after excluding organic disorders are labelled as functional diarrhea or irritable bowel syndrome (IBS). The most commonly used diagnostic test is Seleno-humidic acid taursine (SeHCAT) scan due to its sensitivity, specificity, safety and low cost. However this test is not frequently used in the algorithm for the diagnosis of chronic diarrhea.

Aims & Methods: We aimed to evaluate the usefulness of SeHCAT scan in evaluating patients with chronic diarrhea and identify potential risk factors associated to BAM. We retrospectively reviewed all patients who had SeHCAT scan between June 2014 and October 2016 in a University Hospital. BAM was defined as SeHCAT retraction of less than 15%. We collected the following variables: demographic characteristics, IBS-D Rome III criteria, duration of diarrhoea (months), stool culture, parasitic investigation of stool specimens, background of comorbid gastrointestinal and other comorbid conditions, positive HLA-DQ2 and DQ8 haplotype.

Results: 137 patients referred to clinic for chronic diarrhea underwent SeHCAT testing over the reviewed period. 42M; 95F, median age 46 y (95% CI: 44.0–50.1), median BMI 25.34 kg/m2 (95% CI: 24.8–27.0), 70.4% of patients met IBS-D Rome III criteria, median duration of diarrhoea 48 months (95% CI: 43.0–59.24). Background of co-morbid gastrointestinal conditions 45.3% (62/136), other co morbid conditions 55.3% (75/136). History of previous positive stool culture for parasites and parasitological associations of stool specimens 13.1% (17/136). Percentage of positive HLA-DQ2 and DQ8 haplotypes were 27.8% (35/126) and 10.2% (13/127), respectively. SeHCAT test was positive for BAM in 48.9% (67/137): 25.4% (mild 10–15%); 31.3% (moderate 5–10%); and 43.3% (severe < 5%). Patient characteristics between positive and negative SeHCAT test were similar (Table 1). Interestingly, patients with SeHCAT test exhibited longer periods of diarrhoea.

Table 1

Sex (M:F) 30:37 12.58
Age (median; 95% C.I) 48.00 (44.52–53.54) 40.50 (40.06–49.49)
BMI (median; 95% C.I) 26.84 (25.56–28.78) 23.64 (23.31–25.98)
Duration of diarrhoea (months; median; 95% C.I) 60.00 (43.51–66.95) 24.00 (23.55–38.34)

Positive SeHCAT Negative SeHCAT

Bile acid malabsorption (%) 34.3%(23/67) 14.3%(10/70) 0.031
IBS-D Rome III criteria 67.2%(45/67) 71.4%(53/70)

P1784 INTAKE OF FERMENTABLE OLIGO-, DI- AND MONO-SACCHARIDES AND POLYOLS (FODMAPS) INCREASES THE RISK OF IRRITABLE BOWEL SYNDROME (IBS) IN INDIVIDUALS EXPOSED TO PSYCHOSOCIAL STRESS IN THE COMMUNITY: RESULTS OF A LARGE, PROSPECTIVE, POPULATION BASED STUDY

Introduction: The cause of IBS is uncertain; however, food intolerance shares many features with this condition. Consumption of FODMAPs has been shown to induce IBS-type symptoms (Shephard 2008) and clinical trials have shown that a low FODMAP diet can improve symptoms in this patient group (Halmos 2014). However, FODMAP intake is not higher in IBS than in health (Bohn 2013) and it is not proven that the outcome of low FODMAP diet is better than standard dietary advice in this condition (Bohn 2015). Recent, experimental research has shown that psychological factors are associated with increased postprandial symptoms in IBS patients (Zhu 2013, Van Oudenhove 2016). This study was designed to assess the relative importance of, and interaction between, psychiatric disease, social stress and diet in the aetiology of IBS in the general community.

Aims & Methods: This population based study tested the hypothesis that high FODMAP intake increases the risk of IBS more in individuals with psychiatric disease and/or life event stress than other members of the community.

Subjects aged 16-74 were randomly selected from five South-Chinese communities. All subjects completed questionnaires by face-to-face inquiry with investigators including demographic information, gastrointestinal symptoms (Rome III), dietary intake (food frequency chart validated in Chinese community), psychiatric disease (HADS), life event stress (LES) and quality of life (SF-8).

Results: From 1999/2115 (94.7%) members of the community that completed study questionnaires, 117 (5.9%) had IBS by Rome III criteria. The IBS group also had lower quality of life (p = 0.03) or medical and/or surgical co-morbidity (OR = 2.84 (1.84–4.39), p < 0.001), recent life event stress (1.5(1.03–2.20); P = 0.03) or medical and/or surgical co-morbidity (OR = 2.90 (1.30–5.45), P = 0.001). The IBS group also had lower quality of life (p < 0.001). Joint risk analysis identified high intake of total FODMAP intake as a risk factor for IBS only in subjects with psychiatric disease and/or life event stress (table). Similar effects were seen for individual symptoms, in particular bloating (OR 2.4(1.25–4.60), p < 0.008). Increased risk of IBS was identified with ingestion of high intake of individual FODMAPs (e.g. fructose, lactose) in combination with psychosocial factors, but not with sucrose (control) in any group.

Conclusion: FODMAP intake was similar in IBS and No-IBS groups in the community (lactose intake was lower in IBS subjects, likely due to avoidance of dairy products (Long 2017)). However, as expected, IBS patients in the community had a greater likelihood of psychiatric disease, life event stress and clinical co-morbidity. Joint effects analysis demonstrated that high FODMAP intake alone was not associated with abdominal symptoms; however, IBS was more common in those with a high FODMAP intake and concomitant psychosocial factors known to increase visceral sensitivity to digestive function (Zhu 2013). (ClinicalTrials: NCT0126597)

Disclosure of Interest: All authors have declared no conflicts of interest.

P1785 CHARACTERIZING IBS PATIENTS WITH ANXIETY OR DEPRESSION

I. Pontien1, M. Simrén1, H. Törnblom1

1Department Of Internal Medicine And Clinical Nutrition, Sahlgrenska Academy, University of Gothenburg, Gothenburg/Sweden

Contact E-mail Address: irina.pontien@gu.se

Introduction: A large proportion of patients with irritable bowel syndrome (IBS) suffer from anxiety or depression, but the associations with pathophysiological findings and overall symptom reporting are not clear.

Aims & Methods: We included 772 patients with IBS (Rome III criteria) who attended a university hospital-based outpatient clinic specialized in functional GI disorders between 2005 and 2015. The patients underwent examinations to investigate oro-anal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to investigate oro-anal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to investigate abdominal symptoms (IBS-SSS), bowel habits (BSF), quality of life (IBSQOL), extraintestinal somatic symptoms (PHQ-12), sense of coherence (SOC), fatigue (MFI), GI-specific anxiety (VSI) and physical and sexual abuse.

Results: Based on validated HAD cut-off levels (≥8), anxiety and depression were present in 55% and 26% of the IBS patients, respectively. More women were affected (p < 0.001, but for depression no gender differences were detected (p = 0.76). IBS patients with anxiety or depression were younger (p < 0.001, p = 0.01), and more commonly reported sexual and/or physical abuse (p < 0.001) than IBS patients without anxiety or depression. The presence of anxiety or depression did not differ between IBS subgroups based on the predominant bowel habit (p = 0.41, p = 0.18). For an overview of comparisons of data from questionnaires and pathophysiological examinations, see table 1. Both the presence of anxiety and of depression were associated with reports of more severe GI and extraintestinal symptoms, GI-specific anxiety, fatigue, and lower sense of coherence. Regarding pathophysiological examinations, the findings were more inconsistent. OATT was similar between groups, as was stool form and frequency. Visceral sensitivity tended to be higher in patients with anxiety, and depressed patients reported more severe pain during the lactulose challenge.

Conclusion: The presence of anxiety and depression seems to clearly potentiate the already substantial disease burden in IBS patients. However, the association with other pathophysiological findings is less distinct. This group of patients with complex and severe symptoms will benefit from a holistic management approach.

Introduction: Irritable bowel syndrome (IBS) and lactose intolerance may co-exist and readily cause diagnostic confusion due to similar symptomatology (1,2).

Aims & Methods: This study aim to examine the incidence of lactose intolerance in healthy controls and in subjects diagnosed with IBS based on Rome III criteria, as an effort to investigate the association between IBS and lactase intolerance. The patient population consisted of individuals between 18 and 80 years of age who attended between June-December 2013. Patients diagnosed with IBS based on Rome III criteria comprised the IBS group, and subtypes of IBS. Control subjects were healthy volunteers over 18 years of age with no IBS-like symptoms. All participants ingested 25 g of lactose dissolved in 250 ml of water within 5 minutes after 8 hours of fasting, in order to evaluate the lactase intolerance via hydrogen breath test (0, 15, 30, 60, 90, and 120 minutes). Additionally, symptoms arising during the test were assessed.

Results: Of the total 200 participants, 100 (50%) were in IBS and 100 (50.0%) were in control group. There were 133 females (66.5%), and the mean age was 40.5±12.3 years. Of the total 70 patients (35.0%) with lactose intolerance, 47 (47.0%) were in IBS and 23 (23.0%) were in control groups (p = 0.001). Symptoms related to IBS were more common in participants with lactase intolerance in both groups (p = 0.001, p = 0.001 respectively). A comparison of the two groups with regard to symptomatology after the test showed the presence of complaints in 35 (35.0%) patients in IBS group as compared to 24 (24.0%) subjects among controls (p = 0.092). The incidence of lactase intolerance in patients with IBS subtypes of diarrhea-predominant IBS, constipation-predominant IBS, mixed IBS, and unspecified IBS were 27 (57.4%), 7 (4.9%), 10 (21.3%), and 3 (6.4%), respectively, with no significant differences (p = 0.161, p = 0.124, p = 1.000, and p = 0.661 respectively).

Conclusion: A significantly increased frequency of lactose intolerance was found among IBS patients than in controls. In additional, symptoms associated with lactose intake occurred at a higher frequency in IBS patient, although the difference was insignificant.

Introduction: The population prevalence of Rome IV functional gastrointestinal disorders (FGIDs) and their cumulative effect on health impairment is unknown. We sought to address this issue.

Aims & Methods: An Internet-based health survey was completed by 5931 of 6300 general population adults from three English-speaking countries (2100 each from US, Canada, and UK). The survey included questions on demographics, medication, surgical history, somatisation, quality of life, doctor-diagnosed organic GI disease, and criteria for the Rome IV FGIDs. Comparisons were made between those with Rome IV FGID diagnoses against non-GI and organic GI disease controls.

Results: The number of subjects having symptoms compatible with a FGID was 2083 (35%) compared to 3421 (57.7%) non-GI and 427 (7.2%) organic GI disease controls. The most frequently met diagnostic criteria for FGIDs was bowel disorders (n = 1665, 28.1%), followed by gastroduodenal (n = 627, 10.6%), anorectal (n = 440, 7.4%), oesophageal (n = 414, 7%), and gallbladder disorders (n = 10, 0.2%). On average, the 2083 individuals who met FGID criteria qualified for 1.5 FGID diagnoses, and 742 of them (36%) qualified for FGID diagnoses in more than one anatomic region. The presence of FGIDs in multiple regions was associated with increasing somatisation, worse mental and physical quality of life, greater use of medical therapies, and a higher prevalence of abdominal surgeries; all p < 0.001, see table. Notably, individuals with FGIDs in multiple regions had worse somatisation and quality of life scores than organic GI disease controls.

Conclusion: Roughly a third of the general adult population fulfils diagnostic criteria for a Rome IV FGID. Beside a third of this subset have FGID diagnoses in multiple GI regions and this overlap is associated with increased health impairment. Study Support: The Rome Foundation

Introduction: Although correlations between features of irritable bowel syndrome (IBS) and HRQoL have been reported, these were based on between-person rather than within-person variation. We investigated the longitudinal within-person correlations between features of IBS.

Aims & Methods: We used a longitudinal cohort of 276 IBS patients, who filled out questionnaires one annually over five years. On the following features: gastrointestinal (GI) symptom severity (GSSR), quality of life (QOL), GI specific anxiety (VSI), general anxiety and depression (HADS), coping resources (CRI), and sense of coherence (KASICM). For each participant, scores were centered on their own mean, and within-person correlations were computed for all pairs of features.

Results: Aggregate within-person correlations are shown in figure 1. Within-person correlations were strong for the triad GI symptom severity, GI specific anxiety, and QOL (r: 0.37 to 0.5). Within-person correlations between the two sets were weak (r: 0.00 to 0.37). However, within-person correlations tended towards bimodal distributions across the population, especially for GI symptom severity and depression (r = 0.6 for half of participants, and r = 0.4 for the other half).

Conclusion: Here we show that, within individual IBS patients, GI symptom severity is strongly updated with GI specific anxiety and QOL, but not with four other psychological features. The presence of negative within-person correlations in some individuals may imply a lack of relation, but could also signal long-term causative processes.

Conclusion: Among this patient population, IBS-C patients with higher symptom severity reported greater impairments in HRQoL. These results indicate that symptom severity may be an important consideration for disease management and emphasise the need for IBS-C treatments that improve both symptom burden and quality of life.
symptoms, IBS subjects also reported more somatic symptoms; 103 (34%) had abdominal pain at least 3 times/month, 232 (76%) subjects reported sensation of bloating at least 3 times/month, and 232 (76%) scored > 7 on PHQ-12, indicating high somatic symptom burden (p < 0.001 for all). They also had poorer self-rated overall health, more general body pain, and more health-related impairment of social activities (p < 0.001 for all). See table 1 for details. IBS subjects also reported more frequent visits to the doctor compared to the non-IBS population, both subscribed and over the counter, GI related symptoms, depression and anxiety was increased amongst subjects with IBS, as was the rate of abdominal surgery (p < 0.001 for all), appendectomy excluded. See table 1 for details.

</table>

Results: Significant differences were recorded in the levels of PT (median: 14.5 vs 13.1 sec, p = .0005) and aPTT (median: 28.7 vs 26.4 sec, p = .0005) between patients and controls, respectively. Prolongation over the upper limit of normal of PT (>14 sec) was most common in IC patients, 67.9% vs 18.2% (p = .0005) as well as the prolongation of aPTT (>35 sec), 12.7% vs 6.2% (p = .469). The presence of LA was characterized as weakly present in 5 of 6 patients with the aPTT prolongation (9.6%, normalized LAC ratio: 1.2-1.5) and moderately present in 1 patient (1.9%, normalized LAC ratio: 1.5-2.0).

Conclusion: Prolongation of PT and aPTT, possibly indicating a chronic Vitamin K deficiency state, may be implicated in the pathophysiological mechanisms of IC.

Contact E-mail Address: magnavitorp@gmail.com

Introduction: Ischaemic colitis (IC) encompasses a number of clinical entities resulting in insufficient blood supply to the colon. The incidence of adverse outcome in patients with IC remains high.

Aims & Methods: We conducted a multicenter retrospective cohort study including consecutive patients with IC diagnosed between January 2013 and December 2016, according to the Modified Brandt and Boles criteria (clinical, colonoscopy, pathology consistent with IC and negative culture). The following data were collected: age, sex, clinical exacerbation of IC, organ failure, laboratory results (hemoglobin, platelet number, leucocytes, C-reactive protein, creatinine, sodium, potassium, arterial pH and arterial lactate and LDH), endoscopic and CT findings, surgery and death. Logistic regression was used to study association with poor outcomes - surgery and overall mortality.

Results: In this study, 349 patients were registered and 193 fulfilled the predefined criteria: 121 (62.7%) were females and mean age was 72-years-old (IQ: 23–94). At admission a total of 165 (85.5%) patients presented with hematoxia, 112 (58%) with abdominal pain, 82 (42.5%) with diarrhea, 27 (11.9%) with shock and 7 (3.6%) with occlusion. Twenty three (11%) required surgery. In-hospital, 30-day and overall follow-up mortality rates (up to 205 weeks) were 7.3%, 6.7% and 14%, respectively. On multivariate analysis, surgery was independently associated with shock (OR: 4.8; p = 0.011) (internal occlusion OR: 3.5; p = 0.046), and arterial lactate (OR: 1.3; p = 0.012). On univariate analysis, hemoglobin, hematocrit, C-reactive protein, LDH, the number of risk factors, arterial pH, and the need of red blood support were significantly (p < 0.05) associated with in-hospital and 30-day mortality. Creatinine was also associated with intra-hospital mortality. The variables that correlated independently in the multivariate analysis with in-hospital mortality were male gender (OR:4.3; p = 0.03), and arterial pH (OR: 0.001; p = 0.036) and with 30-day mortality was the need of blood cells support (OR: 2.1; p = 0.006).

Conclusion: In our cohort of predominant elderly patients, arterial pH, shock and lactate were significantly associated with need of surgery. Arterial pH on admission was also independently associated with in-hospital mortality. Early identification of these factors can aid in the decision making in this context and select the best care level for each patient.

P1795 THE RISK PREDICTIVE VALUES OF ACG CLASSIFICATION IN A COHORT OF ISCHEMIC COLITIS—REFINING THE DEFINITION OF MILD DISEASE

Introduction: Although most cases of colon ischemia (IC) are mild and self-limiting, when severe it implies high mortality rates. We aimed to evaluate the risk predictive value of classification of disease severity proposed by American College of Gastroenterology (ACG) guidelines (2015), to create a management algorithm for these patients and select the level of care.
Aims & Methods: A retrospective multicenter study was conducted on adult patients with definite CI (clinical, colonoscopic, pathologic and culture criteria), between 2013 and 2016. Data was collected on clinical presentation, comorbidities, organ failure, management and outcome. Each case was classified according to ACG guidelines after assessment of the number of risk factors (gender, systolic blood pressure <90 mmHg, heart rate >100 beats per min, abdominal pain without rectal bleeding, BUN >20 mg/dl, Hgb <12 g/dl, LDH >350 U/l, serum sodium <136 meq/l, WBC >15 x 10^9/cmm). Patients were then classified as mild (0 risk factors (RF)), moderate (1–3 risk factors), and severe (3 or more risk factors) or any of the following: peritonial signs, pneumatosis or portal venous gas, gangrene on colonoscopy examination and pan-colonic or isolated right-colon ischemia involving by colonoscopy or computed tomography.
Results: 349 cases with the clinical diagnosis of IC were analyzed. 193 patients met the inclusion criteria of definitive diagnosis of CI (62.7% females; mean age 72 years (+13). ACG classification of mild, moderate and severe disease was attributed respectively to 21% of patients (0 intrahospital deaths), 45% (2 deaths) and 34% (12 deaths). The number of ACG RF was: 40% with 0 RF, 8% with 1, 9% with 2, 15% with 3, 16% with 4, 8% with 5, 4% with 6 and 1% with 7. No patient with 0 or 1 RF died. Only 1 patient with 2 RF died. The remaining 13 deaths were verified to be due to 3 RF. The univariate analysis revealed a statistical correlation between RF and intra-hospital or 30-day mortality as well as the need for surgery (mean = 4.06, sd = 1.85). ACG classification presented high predictive accuracy for in-hospital and 1-month mortality with an AUROC of 0.80 (95% CI 0.78–0.83). For a cutoff of 3 ACG RF, the sensibility (SE) for death was 100%, specificity (SP) 52%, with a positive predictive value (PPV) 1%, negative predictive value (NPV) 99%. 3 or more risk factors had an odds ratio of 20.2 (confidence interval (CI) 2.59–158) for intra-hospital mortality and 18.42 for 1-month mortality (CI 2.34–144).
Conclusion: No patient in this cohort with less than 2 ACG RF died, suggesting that the ACG classification as mild disease may include 0 and 1 risk factor without changing the prognosis. Short-term mortality risk increases significantly in patients with at least 3 ACG RF.

P1796 HOW COST AFFECTS THE TREATMENT CHOICE FOR IRREVERSIBLE BOWEL SYNDROME WITH DIARRHEA PATIENTS: A COST-EFFECTIVENESS ANALYSIS OF TRICYCLIC AGENTS AND RIFAXIMIN
E. D. Shah, E. Andraska, J. Li, S. Zhang, W.D. Chey
Division Of Gastroenterology, University of Michigan, Ann Arbor/United States of America
Contact E-mail Address: ershah@med.umich.edu
Introduction: Drug pricing and third party payer coverage exert a profound effect on access to prescription therapies in patients with irritable bowel syndrome with diarrhea (IBS-D). We performed a cost-effectiveness analysis to assess the trade-offs associated with treating IBS-D patients with a tricyclic agent (TCA) or rifaximin.
Aims & Methods: We constructed a decision analytic model evaluating three treatment strategies for IBS-D in the United States healthcare system: first-line therapy with TCA-only, first-line rifaximin followed by second-line TCA for nonresponders, and first-line TCA followed by second-line rifaximin for nonresponders. This model accounted for direct and indirect costs of therapy (Medicaid NADAC database and Healthcare Blue Book) and work-productivity loss (published literature and US Bureau of Labor) with a 3% per annum discount rate. Rifaximin was administered in 4-month treatment cycles based on past clinical experience. Responder and discontinuation rates were derived from clinical trial data, and validated health utility values were assigned to terminal health states. Base-case analysis was performed to determine incremental cost-effectiveness ratios (ICER) for both rifaximin strategies. Threshold analysis assessed rifaximin pricing at contemporary willingness-to-pay (WTP) levels per quality adjusted life year (QALY). Appropriate sensitivity analyses were conducted. Analysis was performed with a 1-year time horizon from societal and payer perspectives.
Results: Based on the average acquisition cost of rifaximin (USD $29.78/pill), second-line rifaximin could be cost-effective from a societal perspective (Table 1). However, at contemporary WTP thresholds neither rifaximin strategy was cost-effective from a payer perspective despite greater effectiveness than TCA alone. Dependent on WTP, a 12-62% price reduction (USD $18.46-$26.34/pill) would enable the first-line TCA followed by second-line rifaximin to be more cost-effective than a TCA-only strategy (Table 1). An 84-88% price reduction (USD $5.53-$4.71/pill) would enable first-line rifaximin followed by second-line TCA to be more cost-effective than TCA-only, though first-line TCA followed by second-line rifaximin would remain the most cost-effective strategy. Our model was robust in tornado analysis and most influenced by rifaximin treatment interval. Sensitivity analysis on rifaximin retreatment interval suggests that current pricing may be based on longer retreatment intervals than those found in clinical literature (Fig 1a). Sensitivity analysis with a lower TCA responder rate could enable first-line rifaximin to be the preferred strategy, albeit at a reduced price (Fig 1b).
Conclusion: Rifaximin is an effective therapy for IBS but is less cost-effective than TCA as currently priced. We propose an evidence-based pricing strategy which would maximize the cost-effectiveness of rifaximin in IBS-D patients.

Results: Diagnostic cases in purpose, sigmoid colon in location and non-clipping status were significantly more common in surgery group than conservative group (Table). Endoscopic clipping was performed in 31 cases (immediate; 23, delayed; 8), and immediate clipping group had significantly lower rate of operation (p = 0.013) and better clinical outcome (duration of antibiotics: p = 0.006, hospital stay: p = 0.001). Among 18 surgical cases, 13 patients had primary closure and 5 patients had complex surgery (2; segmental resection, 3; Hartmann’s procedure). The early (<24hr) surgical management significantly decreased the possibility of complex surgery (p = 0.002), as well as had better clinical outcomes such as duration of antibiotic use, fasting time and length of hospital stay (p = 0.003, p = 0.001, p = 0.005, respectively). In therapeutic cases, all five perforated patients who had surgery within 1 day could be managed by simple primary closure, but all four patients who had surgery after 1 day required complex surgery.
Aims & Methods: We aimed to explore and describe the patient and primary healthcare provider (PHCP) experience of a novel non-specialist-dependent algorithm (ADAM-FGID). Consecutive patients triaged to the ‘routine waitlist’ of an Australian public hospital Gastroenterology Department over 2 years, with non-specific gastrointestinal symptoms (no alarms) were randomised to waitlist control or algorithm (2:1). Algorithm patients were screened for organic disease with the algorithm (2:1). Algorithm patients were screened for organic disease with an alarms-based questionnaire and panel of routine blood/stool tests. When patients had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist and, if appropriate, prompt gastroenterologist appointment offered. All other patients were screened using the Rome III criteria, and received a letter explaining their FGID diagnosis and dietary/psychological management options. Waitlist control patients were not screened. All participants completed follow-up surveys at 6, 26, and 52 weeks. Referring doctors of the algorithm group were sent a feedback survey at study completion.

Results: 89 participants were screened (42 years [SD 14], 62% female). 35 had clinical alarms warranting gastroenterologist review and 45 were diagnosed with FGID (9 excluded). At 6 week follow up: 35/36 FGID respondents had read the diagnostic/management letter, and most (n = 22) of patients saw their FGID diagnosis and dietary/psychological management options. Waitlist control patients had clinical alarms or abnormal tests, data were reviewed by a gastroenterologist and, if appropriate, prompt gastroenterologist appointment offered. All other patients were classified using Rome III criteria, and received a letter explaining their FGID diagnosis and dietary/psychological management options. Waitlist control patients were not screened. All participants completed follow-up surveys at 6, 26, and 52 weeks. Referring doctors of the algorithm group were sent a feedback survey at study completion.

Conclusion: In colonoscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, and early surgical approach decreases complex operation rate. Especially, early operation need be considered in diagnostic perforation regardless of endoscopic clipping.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1799 ANNUAL FECAL IMMUNOLOGICAL TESTING IS LESS COSTLY THAN COLONOSCOPY EVERY 5 YEARS AND REDUCES MORTALITY IN FAMILIAL COLORECTAL CANCER SCREENING

Conclusion: In colonoscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, and early surgical approach decreases complex operation rate. Especially, early operation need be considered in diagnostic perforation regardless of endoscopic clipping.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1798 PATIENTS’ AND CLINICIANS’ VIEWS OF AND EXPERIENCE WITH A NOVEL CLINICAL PATHWAY FOR FUNCTIONAL GASTROINTESTINAL DISORDERS

Conclusion: In colonoscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, and early surgical approach decreases complex operation rate. Especially, early operation need be considered in diagnostic perforation regardless of endoscopic clipping.

At 6 week follow up: 35/36 FGID respondents had read the diagnostic/management letter, and most (n = 25) found it useful (17 useful, 8 partially useful). Few discussed it with their PHCP (n = 13), yet most (n = 28) commenced management (n = 33 by 12 months). Dietary management options were preferred over psychological therapies (n = 30 vs n = 16) (p = 0.001), as were do-it-yourself options above therapist consultation. 61% (n = 22) of patients saw symptom improvement at 6 weeks, (18/21 at 12 months). 2 did not accept the diagnosis, and 3 consulted a specialist privately. 19/36 participants had no concerns at 6-week follow-up (19/21 at 12 months). Common concerns included symptom persistence (6-week n = 10, 12-month n = 10) and fear of missed pathology (6-week n = 4, 12-month n = 4). Most respondents (74%, 46/62) found the approach acceptable (FGID group: acceptable 12/36, moderately acceptable 10/36; Screen Fail Group: acceptable 20/26, moderately acceptable 4/26). Others expressed dissatisfaction with the healthcare system (n = 4), diagnosis (n = 3), screening questionnaire (n = 1) and lack of improvement in symptoms (n = 1). All responding PHCPs (23/30, 14 FGID group, 9 screen-fail group) found the approach acceptable (13 acceptable, 12 moderately acceptable).

Conclusion: An algorithm-based approach to the diagnosis and management of FGIDs, which does not rely on specialist input is feasible, acceptable and effective. A larger scale randomised controlled trial of this new clinical pathway for the diagnosis and management of FGIDs in primary care is warranted.
previously unscreened FDR, starting at age 40 years and ending at age 75. A 5-g FIT was used in all trials, except for one, where a 10-g FIT was used. The model was adjusted to the incidence of CRC in Spain and real prevalence of advanced adenoma and CRC in the familial-risk population (http://dx.doi.org/10.1371/journal.pmed.1002008.g001). The main outcomes were quality-life-year (QALY) gained compared to no screening, lifetime burden of colorectal cancer, lifetime cost of colonoscopy complications, and the incremental cost-effectiveness ratio (ICER). We applied a willingness-to-pay threshold of €25,000 per QALY gained. Data from a prospective EuroQol survey carried out on 920 Spanish patients at different disease stages were used for QALY measurement. Sensitivity analysis was performed to evaluate the robustness of the model.

**Results:** In a hypothetical cohort of 10,000 asymptomatic FDR, annual FIT and colonoscopy every 5 years were cost-effective over no screening. Taking no screening as the reference, FIT was cost-effective for all CRC and colonoscopy every 5 years was 1989 and 4472 euros/QALY, respectively. Compared to no screening, annual FIT and colonoscopy every 5 years reduced CRC mortality by 59% and 81%, respectively. The annual FIT strategy saved 33% of colonoscopies and was associated with a number of complications compared to colonoscopy every 5 years. The results were robust in sensitivity analyses.

**Conclusion:** Assuming a 50% adherence, annual FIT is less costly than colonoscopy every 5 years for CRC screening and reduces mortality in the familial-risk population. These data suggest that FDR of patients with CRC could be included in organized nationwide FIT-based screening programs.

**Contact E-mail Address:** carlos@sostres@gmail.com

**Introduction:** Fecal occult blood test (FOBT) is a non-invasive and easily performed test which has demonstrated to reduce CRC incidence and mortality in the populations. Fecal calprotectin (FCP) has good evidence for detecting inflammatory bowel disease but its value in CRC and adenoma detection in the populations. Faecal calprotectin (FCP) has good evidence for detecting a formed test which has demonstrated to reduce CRC incidence and mortality in the populations. These data suggest that FDR of patients with CRC could be included in organized nationwide FIT-based screening programs.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**References**

Results: Thirty-two subjects (41% males), aged 31–74 years and with a mean BMI of 26.9 (SD 4.9), were included in the analysis. Indications for colonoscopy included family history of CRC (56%) and polyposis surveillance (44%). No serious adverse events were reported. The Pure-Vu significantly increased the number of subjects with an adequate cleansing level (BBPS ≥ 2 for all 3 colon segments) from 25% at baseline (CI 95% [11%, 43%]) to almost 100% (CI 95% [89%, 100%]) after Pure-Vu and the cecum was reached and visualized in all study cases (i.e., 100%; CI 95% [89%, 100%] after Pure-Vu and the cecum was reached and visualized in all study cases (i.e., 100%; CI 95% [89%, 100%]).

Seventy-nine percent of patients who had a previous colonoscopy procedure reported that the Pure-Vu bowel preparation was more tolerable as compared to their previous colonoscopy preparation and 14% of the patients reported it to be about the same.

Conclusion: The Pure-Vu System was found to be safe and effective in cleaning inadequately prepared colons to an adequate level for a thorough exam. Based upon these early results it is expected that the device may play a role in patients with an inadequately prepared colon which may help to improve the overall quality of colonoscopy.

Contact E-mail Address: marek.bugajski@gmail.com

Introduction: Recently, the European Society of Gastrointestinal Endoscopy (ESGE) published guidelines on key performance measures for colonoscopy (1). We analyzed feasibility of monitoring these measures and whether the proposed standards were met in the Polish Colonoscopy Screening Program (PCSP).

Aims & Methods: We analyzed database records for 40,644 participants aged 55 to 64 years, who between 2014 and 2015, underwent screening colonoscopy in 24 centers of population-based PCSP. We used the ESGE guideline definitions to calculate values of all seven key performance measures. We compared key performance measures within the PCSP against proposed standards on the program and center level. Data on adequacy of bowel preparation was routinely assessed with the Boston Bowel Preparation Scale, whereas data on patient experience with the validated GastroQuo-NOM questionnaire (2). Data on complication rates were collected from the National Health Fund database and Personal Identification Number Registry.

Results: Overall, on the program level, all minimum standards for colonoscopy key performance measures were met. Rate of adequate bowel preparation was 92.1% for the whole program, ranging 80.9–99.2% per individual center, with 7 centers (29.2%) not reaching minimum standard of 90% and 9 centers (37.5%) reaching the target standard of 95%. Cecal intubation rate was 97.4% (range 93.4–99.4%), with all centers reaching minimum standard of 90% and only one center not reaching target standard of 95%. Adenoma detection rate was 29.9% (range 19.1–39.1%), with 7 centers (29.2%) not reaching minimum standard of 25%. Appropriate polypectomy technique was applied in case of 90.9% 6 to 9 mm polyps (range 64.3–100%) with only 2 centers not reaching minimum standard of 80% and 48.2% of 4 to 5 mm polyps (range 0–100%) with only 6 centers reaching minimum standard of 80%. Target standard of 90% was reached in 15 centers for polyps 6 to 9 mm in diameter and only 2 centers for polyps 4 to 5 mm in diameter. For the whole program, 7-day hospitalization rate after screening colonoscopy was 0.3% (122 cases) and 30-day all-cause mortality was 0.02% (9 cases). Gastrotet questionnaire coverage is assumed to be 100%, however the response rate was 65.3% (range 7.6–81.8%), with painful colonoscopy rate of 19.2%. No minimum standard is set, however target standard of 90% of procedures with measured patient’s experience was not met. Appropriate post-polypectomy surveillance, based on the European guidelines, was proposed in 95.4% of cases (range 84.9–99.7%). Target standard of 95% was met in 15 centers, the minimum standard is not set.

Conclusion: Monitoring ESGE performance measures for colonoscopy is feasible in colonoscopy programmatic screening setting. 6 of 7 performance measures were easy to monitor with PCSP database, however monitoring complications needs further development to avoid extracting data from external registries. PCSP meets proposed minimum standards on program level, however some centers need additional interventions to meet the quality standards. Applying appropriate polypectomy technique for polyps ranging 4 to 5 mm in diameter
is currently the biggest issue in PCSP and further training is needed to reach minimum standards for this performance.

P1805 VALIDATION OF THE "FAILURE TO PROVIDE ADEQUATE RELIEF" (F-PAR) SCALE IN A SPECIALIST CLINIC SETTING
V. Passananti, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Treatment of chronic idiopathic constipation is somewhat empiric, but based on step-wise approach[1]. If first-line conservative treatment (lifestyle advice and laxatives) do not relieve symptoms sufficiently, secondary approaches with prokinetic or secretagogue drugs are used before considering hospital-based (biofeedback, psychosocial support, transanal irrigation (TAI), surgery). Nevertheless, patients are often dissatisfied with care[2] and fail to progress to adequate levels of therapy. The 5-point Failure to Provide Adequate Relief (F-PAR) scale[3] was developed to facilitate the recognition of when to move from one step to the next.

Aims & Methods: The aim of this study was to validate F-PAR in a tertiary clinic setting. We studied 403 consecutive consultations of 331 patients (262 women, mean age 41) in our specialist clinic. All fulfilled Rome III/IV diagnostic criteria for chronic constipation. Immediately prior to each face-to-face clinical assessment by one of 2 experienced physicians, participants completed the F-PAR scale: patients were blind to the F-PAR result. Standard clinical assessment was undertaken to identify efficacy of the current management as the gold standard.

Results: Of the 403 consultations, clinical assessment identified inadequate relief with current therapy was identified in 200. Neither duration nor type of treatment were correlated with relief. The table stratifies, by clinical gold standard, with current therapy was identified in 200. Neither duration nor type of treatment was identified to be a significant factor in relief. The use of prokinetic or secretagogue drugs are used before considering hospital-based treatment. A common cause of treatment cessation is impaired hand[1]. Training in TAI therapy was undertaken by the same experienced nurse, with weekly follow up until a stable regime was established. Adherence with therapy at 12 weeks was identified.

Results: At 12 weeks, 16/28 (57%) of patients were still using Navina TAI, similar proportions with SCI (11/19) and MS (5/9). There was no difference in baseline scores for HAD-anxiety (6.4 vs 5.9; p = 0.37) and HAD-depression (8.6 vs 8.4; p = 0.46) and were similar in both those who were and were not still using TAI (mean ± SD respectively). The Rotter score for non-adherers was significantly greater than adherers (14.2 ± 6.7 vs 10.6 ± 5.9 respectively; p = 0.0080). There was no difference in any of the anorectal parameters between those who did or did not adhere with TAI.

Conclusion: Navina Smart TAI is an effective therapy in 57% of NBD patients with significant hand dysfunction. Anorectal physiology, anxiety and depression scores did not predict likelihood of treatment adherence. An external locus of control, reflecting a belief that health events occur because of outside forces (such as fate, chance, or powerful others), is associated with reduced treatment success. The results suggest that future studies of TAI should consider locus of control as an important potential predictor of outcome.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1806 ADHERENCE WITH TRANSDUAL IRRIGATION USING THE NAVINATM SYSTEM IS ASSOCIATED WITH PERSONALITY TRAITS EVEN WHEN THERE IS IMPAIRED HAND FUNCTION
V. Passananti, J. Storrie, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Transanal irrigation has become a key therapeutic modality in managing patients with neurological diseases who experience constipation and/or faecal incontinence. Such neurogenic bowel dysfunction (NBD) complicates over three quarters of patients with spinal cord injury (SCI) and multiple sclerosis (MS). Approximately 60% of patients who start TAI continue with long-term treatment. A common cause of treatment cessation is impaired hand[1]. Training of the patient is a key aspect of TAI therapy and requires patients to be willing to manage their health themselves: self-efficacy.

Aims & Methods: We wished to study whether use of a novel TAI system, Navina Smart, which has an electronic pump component allows patients with impaired levels of hand function to adhere to TAI therapy. We also wished to identify if there were physiological or psychological correlates of adherence. Twenty-eight consecutive patients (19 SCI and 9 MS; 17 male, mean age 42) were studied. All patients scored greater than 18 on the Cochin Hand Function Questionnaires were completed to assess anxiety/depression and locus of control respectively. Anorectal physiology (manometry, sensation and rectal compliance) was undertaken at baseline. Training in TAI was undertaken by the same experienced nurse, with weekly follow up until a stable regime was established. Adherence with therapy at 12 weeks was identified.

Results: At 12 weeks, 16/28 (57%) of patients were still using Navina TAI, similar proportions with SCI (11/19) and MS (5/9). There was no difference in baseline scores for HAD-anxiety (6.4 vs 5.9; p = 0.37) and HAD-depression (8.6 vs 8.4; p = 0.46) and were similar in both those who were and were not still using TAI (mean ± SD respectively). The Rotter score for non-adherers was significantly greater than adherers (14.2 ± 6.7 vs 10.6 ± 5.9 respectively; p = 0.0080). There was no difference in any of the anorectal parameters between those who did or did not adhere with TAI.

Conclusion: Navina Smart TAI is an effective therapy in 57% of NBD patients with significant hand dysfunction. Anorectal physiology, anxiety and depression scores did not predict likelihood of treatment adherence. An external locus of control, reflecting a belief that health events occur because of outside forces (such as fate, chance, or powerful others), is associated with reduced treatment success. The results suggest that future studies of TAI should consider locus of control as an important potential predictor of outcome.

non-duodenal sequences. Bioinformatics and statistics were performed in QIIME and Calypso.

Results: A diverse microbiota was observed in duodenal mucosal samples from all subjects, following overnight fasting or bowel preparation. Overall the duodenal microbiota was dominated by the genus Streptococcus, followed by Prevotella, Veillonella and Nisseria. Microbial diversity within samples was not significantly different with and without bowel preparation (Chao1 metric). Principal coordinates analysis (weighted UniFrac) revealed substantial overlap between the two groups, and no significant clustering was observed (ADONIS) based on whether patients had undergone overnight fasting or bowel preparation. Similar findings were obtained when these analyses were repeated with exclusion of the Crohn’s disease population.

Conclusion: This study reveals a diverse duodenal MAM is retained following bowel preparation. The comparison of overnight fasting and bowel preparation indicates these differences in patient preparation do not substantially alter the duodenal MAM. Thus patients undergoing concurrent upper GI endoscopy and colonoscopy can be included in study cohorts investigating the upper GI MAM without risk of a substantial confounding effect.

P1808 PERFORMANCE OF GLASGOW-BLATCHFORD, ROCKALL, AND AIMS65 SCORES TO PREDICT OUTCOMES AND TO IDENTIFY THE LOW-RISK GROUP AFTER UPPER GI BLEEDING IN PATIENTS WITH CANCER

M. C. Franco1, S. Jang2, B. D. C. Martins3, T. Stevens4, V. Jairath5, R. Lopez2, J. J. Vargo6, A. Barkun4, F. Maluf-Filho1
1Gastrointestinal Endoscopy Unity, Cancer Institute of University of Sao Paulo, Sao Paulo/Brasil 2Department Of Gastroenterology And Hepatology, Cleveland Clinic, Cleveland, United States of America 3Western University, London/Canada 4Gastroenterology, McGill University and the McGill University Health Centre, Montreal/Canada

Contact E-mail Address: mcavalcantefranco@gmail.com

Introduction: Upper gastrointestinal bleeding (UGIB) in patients with cancer presents a unique and difficult challenge as these patients are at higher risk for rebleeding and mortality. Currently available prognostic scoring systems for UGIB for the general population have produced variable accuracy in their validation studies. An effective method of stratification for cancer patients to identify the high-risk group for early hospital-based intervention and death could enhance the outcomes of this specific population.

Aims & Methods: The primary aim of this study was to compare the Glasgow-Blatchford score (GBS), Rockall score (RS) and AIMS65 score for predicting ICU admission, blood transfusion, hemostatic therapy, rebleeding, and in-hospital mortality in cancer patients with UGIB. The secondary aim was to assess the above cited scores in correctly identifying low-risk patients that can be effectively managed as an outpatient. An IRB-approved prospective study was conducted at the Cancer Institute Sao Paulo, Brazil. Consecutive patients with known cancer admitted with UGIB were enrolled. Pre-endoscopic clinical parameters pertinent to the scoring systems, hemostasis techniques, and outcomes were collected into a prospective registry. Patients were followed for at least 30 days or until the day of discharge, whichever was longer. The low-risk group was defined as those without blood transfusion, hemostatic therapy (by endoscopy, radiotherapy, angiographic or surgical intervention), rebleeding or mortality in 30 days. Multiple logistic regression with receiver operating characteristics analysis was done to assess the predictive ability of each scoring system for the above outcomes.

Results: From April 2015 to May 2016, 394 consecutive patients were screened, while 259 patients met the inclusion criteria. A total of 243 patients were considered for the final analysis, after excluding 16 patients due to missing data or lost to follow up (Table 1). Predicting outcomes: The AIMS65 score (area under curve) was significantly better than both the predicting ICU admission than GBS (AUC 0.79; p = 0.04) and AIMS65 score (p < 0.001) for predicting both the clinical RS (p < 0.001) and AIMS65 (p = 0.001) in correctly identifying low-risk patients.

</tr>
</tbody>
</table>

Conclusion: The AIMS65 score was superior to other scoring systems in predicting in-hospital mortality and ICU admission in patients with cancer and UGIB, whereas the GBS was superior for predicting the need for blood transfusion. All scores performed poorly in prediction of hemostatic therapy and rebleeding. The GBS was superior in accurately identifying low-risk patients. Furthermore, the cut-off ≥2 in GBS score displays increased sensitivity without compromising specificity, effectively increasing the number of patients who can be safely managed as an outpatient.

1Gastroenterology, Cancer Institute Hospital Ariake, Tokyo/Japan 2Gastroenterology, Ehime Medical Center Hospital, Matsuyama/Japan 3Gastroenterology, Cancer Institute Hospital JFCR, Tokyo/Japan 4Gastroenterology, JFCR, Tokyo/Japan

Contact E-mail Address: ken.namikawa@jfcr.or.jp

Introduction: Endoscopists are more frequently performing endoscopic resection (ER) in patients on antplatelet or anticoagulant therapy and nowadays patients have increasingly started taking direct oral anticoagulant (DOAC) therapies, including direct anti-Xa and thrombin inhibitors. Major guidelines recommend the cessation of anticoagulants before ER and heparin bridging therapy (HBT) for high thrombotic risk cases, although these are still controversial. A recent study has suggested that HBT may be associated with a higher post-endoscopic resection bleeding (PEB) rate in patients on anticoagulants.

Aims & Methods: This study aimed to evaluate the effect of anticoagulants on PEB rate. This was a retrospective study based on medical records from three日本 hospitals between October 2013 and September 2016. PEB was defined as bleeding that occurred 6 h to 10 days after ER, which required endoscopic hemostasis. We reviewed 108 gastric tumors including adenoma and early cancer in 97 patients on anticoagulant therapy who underwent endoscopic submucosal dissection (ESD) in our hospitals between June 2008 and February 2016. Further, we reviewed 69 colorectal polyps including adenoma and early cancer in 69 patients on anticoagulant therapy who underwent ER in our hospitals between October 2013 and September 2016. ER included endoscopic mucosal resection (EMR), and ESD. Patients were divided into two groups: those prescribed warfarin and patients prescribed DOAC. The main management of antithrombotics was based on the Japanese Gastroenterological Endoscopy Society guidelines published in 2005 and 2012. The anticoagulants used during the study period were warfarin, dabigatran, rivaroxaban, apixaban, and edoxaban. Warfarin was discontinued 4-5 days before ER, whereas the others were stopped 24-48 h prior to the procedure. For patients at a high thrombotic risk, intravenous unfractioned heparin was administered after ceasing anticoagulants.

Results: Warfarin and DOAC were prescribed to 73 (75%) and 24 (25%) patients, respectively. Apixaban was administered to 1 (1%), dabigatran to 12 (12%), rivaroxaban to 11 (11%) patients. There were no significant differences between the DOAC and warfarin groups in terms of clinical characteristics or...
P1801 CLINICAL FEATURES OF DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS IN HIGH-RISK AND LOW-RISK PATIENTS
Gastroenterology, Osaka General Medical Center, Osaka/Japan
Contact E-mail Address: taktakakkun@gmail.com
Introduction: Antithrombotic drugs are administered to patients undergoing endoscopic treatment at high risk for thromboembolism. However, antithrombotic drugs have been also known as a cause of delayed bleeding associated with endoscopic treatment, including endoscopic submucosal dissection (ESD). We previously reported the clinical features of post-polypectomy bleeding associated with heparin bridge therapy (1), and then various risk factors of delayed bleeding after endoscopic treatment have been reported.
Aims & Methods: The aims of the present study are to investigate the risk factors of delayed bleeding after gastric ESD and to clarify the clinical features of delayed bleeding associated with antiplatelet or anticoagulant using data of gastric ESD procedures performed in Osaka General Medical Center between January 2009 and December 2016 were retrospectively investigated. Independent risk factors of delayed bleeding were analyzed by using a multivariate analysis by logistic regression model, and three predictors of delayed bleeding were selected. Patients were categorized into a high-risk group or low-risk group for bleeding, and the clinical features of post-procedural bleeding in each group were investigated.
Results: A total of 717 patients with 781 gastric neoplasms were identified. Mean age was 74.6, and 71.6% was male. With regard to comorbidity, the proportion of hypertension, diabetes, chronic liver disease, and hemodialysis was 50.2%, 19.2%, 2.7%, and 6.1%, respectively. Totally 118 patients had past cardiovascular history, and 50 patients treated by heparin ESD treatment may be achieved by physical barrier of mucoadhesive and physical barrier when this powder immediately forms mucoadhesive hydrogel after contacting blood or water. It shows high adhesiveness and persistency of gel on mucosal barrier.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Department of Internal Medicine, SoonChungHyang University School of Medicine, Bucheon/Korea, Republic of

Contact E-mail Address: bangbyoung@naver.com
Introduction: Although endoscopic hemostasis is usually effective in controlling gastrointestinal (GI) hemorrhage, some have difficulty in achieving successful hemostasis depending on the location and severity of hemorrhage. NEXPOWDER® (Next Biomedical, Incheon, South Korea) is a biocompatible and biodegradable powder and the hemostatic effects are accomplished by physical barrier when this powder immediately forms mucoadhesive hydrogel after contacting blood or water. It shows high adhesiveness and persistency of gel on ulcer base.

Aims & Methods: The aims of this study were to confirm 1) success rate of hemostasis using NEXPOWDER® in acute GI bleeding from post-endoscopic procedure or various causes, 2) re-bleeding rate on second-look endoscopy at 1 or 3 days after the procedure, 3) persistent rate of hydrogel on ulcer base at follow-up endoscopy, and 4) clogging rate of catheter during spraying powder. The NEXPOWDER® was delivered by newly developed spraying device through catheter clogging during endoscopic application.

Results: A total of 57 patients were enrolled. The bleeding developed in 46 patients with post-endoscopic resection ulcers (41 ESD induced ulcers and 5 EMR induced ulcers), 8 patients with peptic ulcers and 3 patients with other causes. 1) Success rates of hemostasis in acute bleeding were 96.5% (55/57) of NEXPOWDER® group, 2) Re-bleeding rates were 5.3% (3/57) of NEXPOWDER® group; 3) Persistent rate of NEXPOWDER® on ulcer base was 70.3% (26/37) day after the procedure, and 38.5% (15/38) 3 days after the procedure; 4) Clogging rate of spraying catheter was 3.5% (2/57).

Conclusion: The endoscopic application of NEXPOWDER® is effective for the several types of acute GI bleeding. This effective hemostatic action of NEXPOWDER® might be achieved by physical barrier of mucoadhesive and persistent hydrogel on ulcer base. And new powder delivering device shows low rate of catheter clogging. In addition, a newly developed powder delivering device was delivered by newly developed spraying device through catheter clogging.

Introduction: There are few studies of the efficacy of parenteral ferric carboxymaltose (FCM) treatment in acute gastrointestinal bleeding (GIB) of different origins. Few data are available on its use to treat anaemia post-acute haemorrhage.

Aims & Methods: To determine the efficacy and safety of FCM treatment in patients with acute GIB not associated with portal hypertension. A retrospective descriptive 3-year study of patients with acute GIB (anaemia with evident bleeding and/or hemodynamic instability) treated with FCM as part of our hospital’s habitual clinical practice.

Results: Analysis of 84 patients admitted with acute GIB (69.0% male, mean age 68.0 years [SD 6.9]), with a Charlson index ≥ 3 in 67.1% of cases (≥ 5 in 31.6%). 5.5% had previously suffered acute GIB due to peptic ulcer. There were 86 hospital admissions for acute GIB; 93.8% were upper GIB (above the angle of Treitz). The most frequent clinical presentation was menemia, in 76.7% of cases. 25.0% presented hemodynamic instability at admission. The mean Glasgow-Blatchford index score was 16.1 (SD 2.7) and the mean Rockall score post-endoscopy was 4.2 (SD 1.7). The most common causes of bleeding were: 36.0% duodenal ulcer, 29% gastric ulcer, 9.3% gastritis/erosions, and 7.3% angiodysplasia of the colon. The mean Hb at admission was 9.0 g/dL (SD 2.2)

United European Gastroenterology Journal 5(5S) A783
and the mean of the lowest Hb during admission was 7.6 g/dL (SD 1.3). The most common total dose of FCM administered was 1000 mg. During admission, a mean Hb increase of 0.8 g/dL (SD 2.3) was observed in a mean period of 5.7 days (median: 4.0) after treatment with FCM, with an increase of 4.2 g/dL (SD 2.6) 30 days after acute GIB. After FCM administration, the mean Hb increased significantly (p < 0.001) in patients ≥75 years (2.1 g/dL [SD 1.7]), in patients with Charlson index ≥3 (1.9 g/dL [SD 1.6]), and when Hb level during admission was <10 g/dL (2.0 g/dL [SD 1.7]). No adverse reactions were observed.

Conclusion: In patients with acute GI bleeding the administration of ferric carboxymaltose increases Hb levels promptly and safely, especially in patients of advanced age and with associated comorbidities.

Disclosure of Interest: M. Cucala-Ramos: Mercedes Cucala is employee of Vifor Pharma. J.M. Reñé-Espinet: Reñé-Espinet, Josep Maria received research grant from Vifor Pharma. All other authors have declared no conflicts of interest.

Results: 431 patients have been included in this study. 24.8% of patients were ≥75 years old. The following differences have been observed by comparing the two groups of patients (over and below 75 years old): female 47.7% vs 25.3% (p < 0.001); antiplatelets use 40.2% vs 20.1% (p < 0.001); oral anticoagulants use 20.6% vs 7.7% (p < 0.001); NSAIDs use 25.2% vs 33.6% (p = 0.133); smoking use 35.2% (p = 0.099); alcohol consumption 17.8% vs 45.3% (p < 0.001); one or more comorbidities 77.6% vs 62% (p = 0.005); high risk endoscopic stigmata 61.7% vs 64.4% (p = 0.724); multiple ulcers 41.1% vs 31.8% (p = 0.099); need for blood transfused 59.8% vs 58% (p = 0.832); hospitalization duration 8.4 ± 6.1 vs 7.8 ± 6.0 days (p = 0.382); rebleeding 10.3% vs 11.4% (p = 0.745); need for surgery 2.8% vs 4.6% (p = 0.589) and in-hospital mortality 13.1% vs 6.2% (p = 0.021). In most of the cases (88.2%), the cause of death was other than hemorrhagic shock (92.9% vs 85.0%, p = 0.484). Using multivariate analysis, three out of these factors were identified as independent factors significantly associated with the age over 75 years old: oral anticoagulants use (OR = 2.40, 95%CI:1.24–4.62, p = 0.009), antiplatelet use (OR = 2.33, 95%CI:1.43–3.81, p = 0.001) and in-hospital mortality (OR = 2.09, 95%CI:1.27–4.47, p = 0.048).

Conclusion: The use of oral anticoagulants and antiplatelet was significantly higher in older patients, compared to the younger group. Elderly patients with peptic ulcer bleeding do not have a different rebleeding, need for surgery, need of transfusion or hospitalization mortality compared to younger patients. Mortality was higher in elderly patients due to more frequent association of comorbidities.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
Aims & Methods: 

Patient data over a period of up to 12 months post discharge was collected to monitor their anaemia. A Student's T-Test was used to compare the average blood pressure testing. Dysfunction was considered to exist if at least two tests were positive. Gastric emptying time was evaluated by a standard 2-hour scintigraphic test using a solid meal. A half-time of longer than 110 minutes was chosen in the present study to further investigate patients with delayed gastric emptying. Serum ghrelin and motilin levels were tested by ELISA and circulating antimyenteric antibodies were tested by IFA.

Results: Forty-one patients (27 women), mean age 56.61 ± 11.79 years with AIG were included in the study. Overall, 22 (53.6%) patients showed delayed GE and 19 patients showed normal GE (GET ½: 241.19 ± 90 ± 19 mins, p = 0.001). Serum ghrelin and motilin levels of patients with delayed GE were significantly decreased compared to patients with normal GE, respectively (67.55 ± 8.81 vs 126.79 ± 25.81 pg/mL, p = 0.001 and 279.59 ± 111.12 vs 500.42 ± 155.95 pg/mL, p = 0.001). In all, 26 (63.4%) patients showed autonomic nervous system dysfunction and, 15 (35.5%) patients had normal autonomic nervous system test findings (total autonomic test score: 0.8 ± 0.25 vs 5.65 ± 1.74, p < 0.001). Serum ghrelin and motilin levels of patients with deranged autonomic nervous system function were significantly decreased compared to patients with normal autonomic nervous system function, respectively (78.03 ± 28.46 vs 127.79 ± 28.06 pg/mL, p < 0.001 and 316.92 ± 160.47 vs 490.20 ± 141.02 pg/mL, p = 0.001). In multivariate analysis, plasma motilin level was found as an independent factor that affected serum ghrelin level (β = 0.623, p = 0.019). However, serum ghrelin (r = 0.70, p < 0.001) levels were found as independent factors that affected plasma motilin level. We also investigated the presence of antimyenteric antibodies, however all the patients were negative by means of antimyenteric antibodies therefore, no further relationship was sought.

Conclusion: Mean fasting serum ghrelin and plasma motilin levels in autoimmune gastritis patients with delayed GE and deranged autonomic nerve function were significantly decreased. Nondiet-related factors and altered gut microbiota and circulating antimyenteric antibodies. These decreased serum ghrelin and plasma motilin levels in patients with autoimmune gastritis suggest a potential role for ghrelin and motilin in explaining the finding of the delayed gastric emptying in patients with autoimmune gastritis patients. We believe that these new observations supply more insight in the pathophysiology of autoimmune gastritis.

Introduction: The interaction between gut microbiota and enteric nervous cells alterations is believed to play an important role in the pathophysiology of irritable bowel syndrome (IBS). The densities of the duodenal enteroendocrine cells are abnormal in IBS patients, which appears to be caused by a reduced stem cells density and their differentiation into endocrine cells (1).

Aims & Methods: The aim is to investigate the effects of faecal microbiota transplantation (FMT) on the differentiation of the stem cells into endocrine cells as detected by neurogenin 3, the stem cells as detected by Musashi 1 and the enteroendocrine cells in the duodenum of patients with IBS. The study included 16 IBS patients according to Rome III criteria and four patients were excluded. The remaining patients (n = 12, 4 females and 8 males, age range 20-44 years) were divided according to the cause of IBS into PI-IBS patients (n = 6) and idiopathic IBS (n = 6) and received FMT donated from their relatives. The patients completed the IBS-symptom severity scoring system (IBS-SSS) before and 3 weeks after FMT. The patients underwent gastrosopies with biopsies taken from the descending part of the duodenum at baseline and 3 weeks after FMT. The biopsies were immunostained for neurogenin 3, Musashi 1 and all types of duodenal enteroendocrine cells, and quantified by computerized image analysis.

Results: The score of IBS symptoms as assessed by IBS-SSS was significantly reduced 3 weeks after (240.2 ± 33.60) compared to before (326.6 ± 22.3) receiving FMT, P = 0.0009. The scores of IBS-SSS before and 3 weeks after FMT for PI-IBS (n = 6) patients were 343.2 ± 27.5 and 220.4 ± 41, respectively (P = 0.025), and for idiopathic IBS are 352 ± 34 and 270.3 ± 54, respectively (P = 0.043). The densities of neurogenin 3, Musashi 1 and enteroendocrine cells in the duodenum of IBS patients before and 3 weeks after receiving FMT are presented in Table 1.

Conclusion: Fecal microbiota transplantation improved the symptoms in IBS patients, both PI and idiopathic. This improvement was associated with a change in the enteric nervous cells density. The changes in the enteroendocrine cell density does not appear to be caused by changes in the stem cells or their early progenitors, but rather by changes in the differentiation progeny as detected by changes in neurogenin 3.

P1817 THE RELATIONS AMONG SERUM GHERELIN, MOTILIN, CIRCULATING ANTIMYENTERIC ANTIBODES AND GASTRIC EMPTYING IN AUTOINMUNE NERVOUS SYSTEM FUNCTION IN PATIENTS WITH AUTOIMMUNE GASTRITIS

C. Kalkan, F. Karakaya, I. Soykan

Introduction: Autoimmune gastritis (AIG) is an organ-specific autoimmune disease of the stomach marked by autoantibodies directed to hydrogen/potassium-ATPase and intrinsic factor. Gastric emptying of solids is delayed and autonomic nerve dysfunction is detected in patients with autoimmune gastritis. This may be a cause of symptoms and also there is a close relation between autonomic nerve dysfunction and delayed gastric emptying. As ghrelin and motilin are putative regulators of gastric emptying and, some autoimmune gastritis patients may have delayed gastric emptying, leading up autonomic gastrointestinal symptoms.

Aims & Methods: The aim of this study was to: (i) compare serum levels of ghrelin and motilin in patients with delayed normal gastric emptying and (ii) investigate whether circulating antimyenteric antibodies, serum levels of ghrelin and motilin are related on autonomic nervous system function and gastric emptying. Forty-one patients with AIG were included into this study. Autoimmune gastritis was diagnosed depending upon histopathological findings in gastric biopsy specimens. Non-invasive cardiovascular reflex tests were used in order to evaluate autonomic nervous system function. Sympathetic nerve function was evaluated with two tests: blood pressure response to standing and handgrip test. Parasympathetic nerve function was evaluated with three tests: valsava manoeuvre, heart rate response to deep breathing (E/I ratio) and orthostatic blood
P1819 THE EFFECT OF ESOPHAGEAL ACID EXPOSURE ON NMDA RECEPTOR SUBUNITS EXPRESSION AND D-SERINE IN PREFRONTAL CORTEX AND HIPPOCAMPUS

Introduction: Neuronal plasticity has been reported to develop following nociceptive emotional experience in prefrontal cortex (PFC) and hippocampus. The N-methyl-D-aspartate receptor (NMDAR) and D-serine, the endogenous co-agonist of NMDAR1, may mediate the neural plasticity. However, whether the neural plasticity participates in the mechanism of esophageal visceral hypersensitivity is little known.

Aims & Methods: This study aims to investigate the expression of NMDAR and the alteration of D-serine after neonatal and adult esophageal acid exposure. All rats were exposed to esophageal acid or saline at postnatal days 7-15 (P7-P15), and most rats underwent acute acid or saline exposure again at adult time (P60). All rats were randomly distributed to 5 groups, including P7S, P7H, P60H, P7H + P60H, P7 + P60H (P7-postnatal 7-15 days; P60-adult at postnatal 60 days; H: 0.1N HCL infusion; S: saline control). The tissue harvest was conducted at P60. We examined the expression of subunits of NMDAR (including NR1, NR2A and NR2B), and c-fos, and serum racemase in PFC, dorsal hippocampus (DH) and ventral hippocampus (VH). We also determined the D-serine and L-serine in PFC and hippocampus by LC-MS analysis. Statistical comparisons were performed by General Linear Model and one way ANOVA in SPSS.

Results: In PFC, compared with adult saline treatment (AS, including P7H + P60H and P7S + P60H group) and without adult treatment (A-, including P7H and P7H group), adult acid exposure (AH) increased the expression of NR1 (P = 0.052, P = 0.298), NR2B (P = 0.035, P = 0.045), and serum racemase (P = 0.022, P = 0.017) significantly. In ventral hippocampus, compared with adult treatment absence, adult acid exposure caused increasing expression of NR2B (P = 0.012) and NR1 (P = 0.024) significantly. In PFC, the expression of serum racemase in the P7S + P60H group was obviously higher than that of other groups (P = 0.008). See Table 1. In dorsal hippocampus, there was statistical significance on the level of c-fos between the P7S + P60H group and other groups (P = 0.008). Table 1. In PFC, the LC-MS analysis results that D-serine (AH vs A-: P = 0.000, AS vs A-: P = 0.042, AH vs AS: P = 0.081) and L-serine (AH vs A-: P = 0.000, AS vs A-: P = 0.015, AH vs AS: P = 0.082) decreased in the AH and AS group, comparing with A- group.

The expression of serine racemase in PFC and c-fos in VH

(continued)

Conclusion: Acute esophageal acid exposure may increase the expression of NMDAR in PFC and ventral hippocampus. We also found the first acid exposure at adult stage may enhance the expression of serine racemase in PFC and c-fos in ventral hippocampus, but this phenomenon may be absent in those rats having the experience of acid exposure in early life. Those long-term and transitory molecular alterations may mediate the development of acid exposure related esophageal visceral hypersensitivity.

Introduction: Globus pharyngeus, a sensation of a lump or tightness in the throat, is a well-defined clinical symptom that is usually long-lasting, difficult to treat, and has a tendency to recur. More than half of globus patients suffered from probable psychological disorders, such as anxiety and depression. Antidepressants are used in the treatment of functional gastrointestinal disorders (FIGIDs) and showed a promising efficacy. Our study manifested that low-dose amantadine may be well tolerated and effective for general globus pharyngeus patients. Our anterior study had ever speculated that AMT could modify brain-gut axis function, up-regulating brain-gut peptides, reducing the visceral sensitivity and regulating the secretory and motor functions of the gastrointestinal tract, so that gastrointestinal symptoms as well as emotional well-being could be significantly improved. As we known, serotonin (5-hydroxtryptamine, 5-HT) is an important factor in gut function, playing key role in intestinal peristalsis, secretion, and sensory signaling in the brain-gut axis. Several studies have investigated the association between SLC6A4 and functional gastrointestinal disorders, including IBS and FD. Besides, the association between various complex behavioral traits and disorders were also studied, including anxiety, major depression, suicide, smoking behavior, alcohol dependence. A single gene (SLC6A4), located on the human chromosome 17q11.2, 17q12, is coded by serotonin transporter (5-HTT). The polymorphism of this gene is characterized by the insertion or deletion of the 44-bp sequence and this is related to the different transcriptional activity of the gene. Allele with 44-bp deletion (short allele) is characterized by a three times lower transcriptional activity than allele with 44-bp insertion (long allele). Compared to other FIGIDs, the researches about globus are rare. The pathogenesis of globus pharyngeus is still unknown.

Introduction: Multiple rapid swallows (MRS) and rapid drink challenge (RDC) are provocative tests that can enhance the diagnostic value of esophageal HRM. The discriminatory characteristics of these provocative tests were evaluated in symptomatic patients referred for esophageal HRM.

Aims & Methods: Consecutive patients presenting for esophageal HRM were divided into a 2-month ‘pre-test’ population for provocative testing with MRS and RDC in addition to the standard manometric protocol. Integrated relaxation pressure (>15 mmHg) identified outflow obstruction; those without outflow obstruction were further analyzed utilizing software tools (IRP, distal contractile integral, DCI; intrabolus pressure, IBP) for peristaltic reserve (MRS or RDC DCI > mean DCI from wet swallows), and obstruction (IBP > 30 mmHg during MRS or RDC). All patients completed symptom questionnaires addressing reflux symptoms (GERD-Q), dysphagia (Vigo Dysphagia Questionnaire), and global symptom severity (GSS) on a 100 mm visual analog scale (VAS). Univariate and multivariate analyses were performed to evaluate overall yield (proportions with MRS/RDC findings not seen with the standard HRM protocol) and to assess association of presenting symptoms with results of MRS and RDC in patients without outflow obstruction.

Results: 149 patients (55.4 ± 1.2yr, 68% F) fulfilled inclusion criteria and had no outflow obstruction on HRM. Of these, 91 (61%) had peristaltic reserve on MRS, and 17 (12%) on RDC (p < 0.001), only 10 were concordant. Obstruction was noted in 16 (9.8%) on MRS, 8 (4.9%) on RDC (p = 0.09), and 5 were concordant; of these, only 2 patients had panesophageal compartmentalization of pressure, and only 1 had elevated IRP during provocative measures. Within inclusive esophageal motility, peristaltic reserve was noted in 59.3%. Within dysphagia presentations, obstruction was noted in 7.7%, and absent peristaltic reserve in 50%. Thus, the overall yield of MRS was 80.5%, and RDC 19.8% (p < 0.001). 131 patients had adequate questionnaire data. Findings on provocative tests did not predict presenting symptoms (GERD-Q or MDQ). Obstruction on RDC predicted higher GSS (odds ratio 5.56, 95% CI 1.04–29.72).

Conclusion: MRS identifies peristaltic reserve better than RDC and has higher overall clinical value. While both MRS and RDC identify outflow obstruction, only RDC obstruction predicts higher symptom burden. Neither MRS nor RDC findings correlate with presenting symptoms.

Introduction: Achalasia is an uncommon condition of failed lower oesophageal sphincter relaxation. Data regarding the incidence and prevalence are limited. The aim of this study was to provide accurate, contemporary epidemiological data utilising two national databases.

Aims & Methods: Hospital Episode Statistics (HES) includes demographic and diagnostic data for all English hospital admissions. The Health Improvement Network (THIN) database includes primary care records of 7% of the UK population, representative of national demographics. Both were searched for incident cases and THIN for prevalent cases of achalasia.

Results: There were 10,509 and 711 new achalasia subjects in HES and THIN respectively. The incidence per 100,000 population in HES was 1.99 (95% CI 1.87–2.11) and 1.53 (1.42–1.64) per 100,000 person years in THIN. The prevalence measured in THIN was 27.1 (25.4–28.9) per 100,000 population.

Conclusion: The incidence of oesophageal achalasia was approximately 15 to 20 per 100,000 population. There were approximately 17,500 patients with achalasia in UK. In 2015 the above data represents the largest published epidemiological investigation of achalasia. The variation of findings between the databases likely results from differences in coding practice and marginally different population structures.

Introduction: Residual flow to bolus flow across the lower esophageal sphincter (LES) is a hallmark of achalasia. Presently the gold standard of diagnosis is by high-resolution manometry (HRM) demonstration of raised integrated relaxation pressure (IRP) following ten 5ml water swallows; however, this does not rule out normal swallowing behavior. It has been demonstrated that the addition of adjunctive tests improves sensitivity of identifying relevant dysmotility. Such tests include multiple water swallows (MWS: 200 ml water drunk freely) and solid swallows. In addition, the timed barium esophagram (TBE) measures esophageal emptying. This study describes a cohort of patients who have been treated as having achalasia based on resistance to flow not exhibited with single water swallows.

Aims & Methods: Inclusion criteria were all patients between October 2014–2016 with normal mean and median IRP with 5ml water swallows but considered to have achalasia due to resistance to flow demonstrated by pan-esophageal pressurization (PEP) during MWS or solid swallows and/or a persistent column at 5 minutes during TBE. Outcome following treatment was based on the Eckardt symptom score (ES).
Results: 14 patients (9 male) fulfilled inclusion criteria. 7 were treatment-naïve and 7 had undergone therapy (3 myotomy, 3 pneumatic dilatations, 1 balloon dilation). Mean resting LES pressure was 4.6 ± 7.4 mmHg. In all patients, mean and median IRP values for ten 5 mL water swallows were non-raised (mean 9.1 ± 4.3 and 8.7 ± 4.5 mmHg respectively). Of the 7 treatment-naïve patients, 5 demonstrated PEP on MWS, 3 on solid swallows and 6 had a positive TBE at 5 minutes. In treatment-experi- enced patients, 5 had PEP on MWS, 1 on solid swallows and all had a positive TBE. Of the 13 who had resistance to flow on TBE, 10 (77%) also had resistance demonstrated during MWS and/or solid swallows. Mean height of the 5-minute contraction in SA in patients with ulcerative colitis was 16.5 ± 8.9 cm. 8 patients had (so far) under- gone therapy based on these findings; one per-oral endoscopic myotomy and 7 pneumatic dilatations. The median baseline ES was 7.5 (IQR 5–8). The median ES at minimum 3 months (range 3–15 months) following treatment was 1 (IQR 0–1); (P < 0.001 cf. baseline). Similarly, there was significant improvement in TBE findings post-therapy (mean 5-minute column height 3.5 ± 4.1 cm; P = 0.04 cf. baseline).

Conclusion: A normal IRP for water swallows does not preclude a diagnosis of achalasia. The addition of free drinking/solids during HRM or the TBE can identify pathology that might have been missed with standard 5 mL water swallows alone as normal, clinically relevant swallowing behavior is reproduced. Patients treated based on this algorithm exhibit excellent treatment outcomes, validating this approach. Further, the close correlation of TBE adjunctive test- ing with TBE supports its routine inclusion in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The timed barium esophagram (TBE) is an objective measurement of esophageal emptying used in the assessment of achalasia. Post-therapy reduc- tion of the maximum height of the residual barium column has been found to correlate imperfectly with short-term symptomatic outcomes, but carries long- term prognostic implications. We hypothesize that the shape of Achalasia (SA) of the barium column may be more accurate than height, firstly, by looking for improvement in esophageal width that often occurs post-therapy, but also by correcting for artificially higher height values due to esophageal (longitudinal) contraction occurring during a single image. We aimed to compare the correla- tion of TBE outcome measures of height and SA with symptom improvement post-therapy.

Aims & Methods: Inclusion criteria were achalasia patients who underwent ther- apy between August 2015–6 and had TBE and Eckardt score (ES) performed at baseline and at least as well as within 6 months post-therapy. With TBE upright single images were acquired at 1.2 and 5 minutes following infusion of 100–200 mL of low-density barium sulfate. Barium height was measured between the gastro-esopha- geal junction and the superior extent of any residual barium column. After manually defining the column boundaries, software was used to calculate SA (AGFA IMPAX surface area tool (Figure)). Adequate symptom relief was defined as reduction in ES to ≤3. On TBE, metrics of adequate emptying evaluated were i) post-therapy column height <5 cm, ii) >50% reduction in column height from pre to post-therapy and iii) >50% reduction in column SA from pre to post-therapy. Associations between symptom improvement and TBE measures of emptying were assessed using Pearson’s correlation (R). Paired t-tests com- pared TBE measures before and after therapy.

Results: 18 patients (9 male; 6 Type I, 11 Type II, 1 Type III) were included. 11 had dilatation and 7 endoscopic myotomy. Reductions with therapy of both mean 5-minute barium column height (14.7 ± 8.7 to 7.9 ± 6.0 cm; P = 0.01) and mean 10 cm (52.7 ± 43.5 to 24.5 ± 26.8 cm2; P = 0.02) were noted. Symptoms also improved with treatment; median baseline ES of 7 (IQR 5.25–8) improved to 0 (IQR 0–1) post-therapy. Only 2 patients had inadequate symptom relief and are awaiting further treatment. However there was poor concordance between post- therapy barium column height and symptomatic relief (i.e. post-therapy column height >5 cm despite ES ≤ 3 or vice versa), and the correlation (R) between these two variables was poor (Table). Similar poor concordance was seen when adequate emptying was defined by >50% reduction in column height, but >50% reduc- tion in SA paralleled symptoms.

Conclusion: In TBE performed on achalasia patients post-therapy, reduction in SA of the residual barium column compared with baseline values parallels symptomatic relief more closely than reduction of column height.

STOP. Gastric nutrients reduced significantly rectal gas evacuation (90 vs 100 Kcal/saline), increased the number of defecations (3.3±0.3 vs 2.3±0.3), and reduced the number of peristaltic waves by 0.3±0.1 vs 0.0±0.0 (p=0.001), which is equivalent to a 30% reduction in postprandial rectal motor activity. These findings are consistent with the hypothesis that nutrients can modulate intestinal motor activity, which may have implications for the management of chronic constipation and other gastrointestinal disorders.

Introduction: Well-verified treatment options for the therapy of functional gastrointestinal disorders are rare and therefore gain high attention. One of the first to be considered as an alternative to standard treatments is STW 5 (Iberogast), for which more than five decades of therapeutic experience in human medicine have been collected. In clinical trials with STW 5 have proven compliance to modern standards for a proof of efficacy, now sub-group analyses were conducted. The analyses (ANOVA) were based on the original single patient data from the trials, including demographics and endpoints.

Results: As the primary outcome variable, the validated gastrointestinal symptom score (GIS) [1], as well as the therapeutic dose (3 × 20 drops/day) were identical in all trials, a uniform evaluation was possible. The full analysis set (FAS) included 557 patients (272 resp. 285 for placebo resp. verum). The mean age (45 yrs) was in both groups 68.7 cm, BMI (27.0 resp. 22.2 kg/m²), the BMI (25.35 resp. 25.54), the gender distribution (67.5% vs 69.5%) females, the duration of the disease at the time of inclusion and the baseline of the GIS (11.6 resp. 11.5 points) were very comparable between both groups. For the primary variable GIS the difference between placebo and verum after 28 days of treatment showed a highly significant (p < 0.001) difference between placebo and verum (6.7 resp. 4.7 points). The analyses in different age groups (up to 30, 30–40, 40–50, 50–60, above 60) and in male and female patients did show a comparable efficacy in all these groups.

Introduction: Achalasia is a chronic condition presenting with dysphagia, regurgitation, chest pain and/or weight loss. Management options include Heller’s myotomy, Botox, pneumatic dilation and Per-Oral Endoscopic Myotomy (POEM). Treatments carry risks of bleeding and perforation. Concomitant portal hypertension with varices is very rare and achalasia treatment in this context has only been described in single case reports.

Aims & Method: Experience from physicians/surgeons treating these disorders was sought through the International Manometry Working Group.

Results: 13 patients with portal hypertension from 6 international centres have been collected; mean age 61 ±9 years. The median pre-therapy Eckardt score was 7 (IQR 6–9). 9/13 (69%) patients had a barium swallow and 12/13 (92%) had oesophageal physiology studies performed. There were 3 Type I, 6 Type II, 2 Type III achalasia and 2 with oesophage-gastric outflow obstruction. Varices were identified endoscopically in 7 patients, radiologically in 5 and in 1 patient varices were first noted during surgical myotomy. 2 patients had grade 3 varices, 3 grade 2 and 3 had grade 1 varices (grading not provided for the rest). Cirrhosis was due to alcohol in 7 patients, non-alcoholic steatohepatitis in 3, cryptogenic in 2 and 1 had hepatitis C cirrhosis. 75% were Child-Pugh A and 25% were Child-Pugh B. Patients had diverse treatments for their achalasia. 4 were treated with Botox injections (1 with EUS), 4 had dilation alone, 3 received a POEM, another had POEM then dilation and 1 patient had Botox followed by Heller’s myotomy. 3 patients underwent variceal eradication in advance; all had banding first but in 2 patients superficial eradication was followed by a transjugular intrahepatic portosystemic shunt (TIPSS). POEM before endoscopic dilation. All patients had symptomatic improvement with median Eckardt score post intervention = 1 (IQR 0–2) < 0.0001 compared to baseline. A matched group of 20 patients who underwent treatment for achalasia (all subtypes) but without varices had recurrent dysphagia and 2 patients had erosive complications of bleeding or perforation; however both patients who had TIPSS had temporary hepatic decompenation.

Conclusion: This reports 13 patients from international centres who have had interventions for achalasia on the background of oesophageal varices. None had bleeding complications despite only 3 having had variceal eradication. Symptom response mirrored those who undergone standard achalasia therapy,
**P1830 THE NATURAL HISTORY OF ACHALASIA: EVIDENCE OF A CONTINUUM—THE PATTERN-EVOLUTIVE STAGING THEORY**

Dept. Of Surgical, Oncological And Gastroenterological Sciences, University Hospital of Padova, Padova/Italy

Contact E-mail Address: m.costantini@unipd.it

**Introduction:** Esophageal achalasia is classified into three clinically relevant patterns at High Resolution Manometry (HRM) and according to Chicago Classification. Currently, it is unclear whether they represent distinct entities or are part of a disease continuum.

**Aims & Methods:** The aims of this study were: a) to test the hypothesis that the three manometric patterns represent different stages in the evolution of esophageal achalasia and b) to investigate whether manometric patterns change after Laparoscopic Heller-Dor (LHD). We evaluated the patients who had a diagnosis of achalasia and underwent LHD as first treatment from 1992 to May 2016. Symptoms were scored using a detailed questionnaire for dysphagia, food-regurgitation, and chest pain; barium swallow, endoscopy, and esophageal manometry (conventional or High Resolution technique) were performed, before and after 6 months after surgical treatment. All conventional manometric tracings, before 2010, were reviewed and re-classified according to the manometric-pattern classification, whereas after 2010 the HRM data were prospectively collected.

**Results:** Five-hundred and eleven consecutive achalasia patients (M:F 283:238) represented the study population. Based on their manometric findings, 231 patients (45.2%) were classified as having pattern I, 241 (47.2%) had pattern II, and 39 (7.6%) had pattern III. Demographic and clinical data showed that pattern III cases had a shorter duration of symptoms, a more incidence of chest pain, and a less dilated gullet (p < 0.001). Further, all patients with a sigmoid-shaped mega-esophagus (radiological grade IV) had pattern I achalasia. One patient with diagnosis of pattern III achalasia, who refused any treatment ever evolved to pattern II at a follow-up manometry performed for a progressive worsening dysphagia after 36 months. At a median follow-up of 30 months (IQR 12–56), the outcome of surgery was positive in 479 patients (91.7%). The only predictor of final outcome was the preoperative manometric pattern (IQR 12–56), the outcome of surgery was positive in 479 patients (91.7%). All patients (42) whose surgical treatment failed underwent one or more endoscopic pneumatic dilations using Rigiflex balloons (30, 35 or 40 mm). The overall success rate of the combined treatment (LHD plus endoscopic dilations where necessary) was 98%. All patients with pattern I preoperatively had the same pattern after LHD, whereas more than 50% of patients with pre-treatment pattern III had patterns I or II after surgery. There were no cases showing the same pattern after LHD, whereas more than 50% of patients with pre-treatment pattern II had patterns I or II after surgery. Conclusion: The data of this study strongly support the hypothesis/theory that the different manometric patterns of achalasia could represent different evolutionary stages of the disease - where pattern III is the earlier stage, pattern II an intermediate-stage, and pattern I the end stage.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The development of non-invasive methods to detect the presence of H. pylori, and to estimate the extent and severity of gastritis, has reduced the need for diagnostic endoscopy in asymptomatic individuals. However, it is not known whether the use of non-invasive diagnostic methods is effective in dyspepsia patients.

**Aims & Methods:** To use a non-invasive blood test with four stomach-specific biomarkers to assess the prevalence of different stomach conditions: gastroesophageal reflux disease (GERD), H. pylori (HP) infection, chronic atrophic gastritis (CAG), and the efficacy of proton pump inhibitor (PPI) therapy in a primary care population. A cohort of 2583 dyspeptic patients (male 36%, mean age 44.0 yrs, range 6–95) was selected in a primary care population and examined with a panel of biomarkers [Pepinogen-I (PG-I) and -II (PG-II), amidated gastrin-17 (G-17), and HP IgG (Biohit, Finland)]. A standard questionnaire, including upper gastrointestinal symptoms and PPI use, was administered. Exclusion criteria were dysphagia, anemia, weight loss and vomiting. CAG patients underwent to endoscopy and histological examination.

**Results:** Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p = 0.0001). Table 1 shows the serum biomarkers values divided according to five manometric categories: healthy achalasia (H), GER, HP, CAG, and PPI therapy. Conclusion: The combination of data on the levels of PG-I, PG-II, G-17, and HP IgG allow to diagnose different pathological conditions such as HP- and non HP-related gastritis, the appropriateness of PPI administration, GERD and CAG, a precancerous condition.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

abdomen, ‘discomfort in upper abdomen’, ‘cramps in upper abdomen’ and ‘burning in upper abdomen’ and ‘fullness after eating or slow digestion’) and for QoL by NDI total score were compared and descriptively tested by means of Wilcoxon-Mann-Whitney U-tests.

Results: After the initial 4 weeks, 54/114 patients opted for an extension of therapy. Interestingly, 34 out of 52 patients had been on active therapy while during placebo treatment. 1 Menthacarin and placebo, respectively (p = 0.0014). Overall QoL improvement was better for active medication for 4 and 12 weeks as compared to placebo.

Conclusion: After 4 weeks of randomised double-blind, placebo-controlled treatment with either Menhacarin or placebo, patients who received active medication are more likely to opt for a continuation of therapy as compared to patients on placebo. The gain over placebo remained significant even after 12 weeks of treatment.

Introduction: The introduction of proton pump inhibitors (PPIs) into clinical practice has revolutionized the management of acid-related diseases. Studies in primary care and emergency settings suggest that PPIs are frequently inappropriately prescribed or used in clinical conditions with little benefit.

Aims & Methods: To evaluate the role of GastroPanel in relation to the appropriateness of PPI-therapy prescription. 2583 dyspeptic patients (male 36%, mean age of 44.0 yrs, range 6–95) with no alarm symptom (i.e., dysphagia, anemia, weight loss and vomiting) from a primary care population were included in the study. For each patient a blood sample was collected for serum Pepsinogen I (PG-I) and II (PG-II), Gastrin 17 (G-17) and IgG HP (Biohit, Oyj, Finland); urea breath test and bacterial overgrowth were performed. All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.

increasing. Pepsinogen I (PGI) <30 μg/L, PGI/PGII <3 and gastrin-17 (G17) >10 μmol/L are non-invasive serological markers to surrogate to explore gastric function, with a negative predictive value for chronic atrophic gastritis (CAG) of 96%.

Aims & Methods: Aim of the study was to evaluate gastric function by means of serology (PGI, PGII, G17 and IgG-antibodies against Helicobacter pylori) in very elderly patients, including centenarians. A total of 379 patients were progressively enrolled (M = 126, F = 253, mean age = 83.6 ± 8.7, range 70-106). They were divided in four groups: 132 subjects with an age between 70 and 79 years old (first group), 97 subjects between 80 and 89 (second group), 76 subjects between 90 and 99 (third group) and 25 subjects between 100 and 106 (fourth group). Demographics and drug intake, particularly the PPI intake, were collected. For all patients, serological markers were determined in fasting blood by using Gastropanel® (Biohit Oyj, Finland; normal values: PGI: 30-120 μg/L; PGII: 2-15 μg/L; PGI/PGII ratio: > 3; G17: 1.9 ± 1 μmol/L; IgG: < 30 EU).

Results: In the first group (age 70-79), 18.2% of the subjects showed H. pylori infection (PGI >30 μg/L, G17 against H.p. > 30 EU), 22.7% had CAG (PGI < 30 μg/L and PGII < 3) and 53.8% were under PPI therapy. 16.9% of the patients on PPI therapy had CAG. In the second group (age 80-89), 32.9% of the subjects showed H. pylori infection, 8.9% had CAG and 48.6% were under PPI therapy. 8.5% of the patients on PPI therapy had CAG. In the third group (age 90-99), 22.4% of the subjects showed H. pylori infection, 10.5% had CAG and 48.7% were under PPI therapy. 8.1% of the patients on PPI therapy had CAG. In the fourth group (age 100-106), 44.0% of the subjects showed H. pylori infection, 16.0% had CAG and 72.0% were under PPI therapy. 16.7% of the patients on PPI therapy had CAG.

Conclusion: Acid secretion is preserved in most of the elderly and very elderly subjects, even in centenarians. Serological markers may be helpful to identify patients affected by CAG in which the administration of PPI is inappropriate, especially in the elderly.

Introduction: Reflux hyper sensitivity (RHV) was lately defined as a functional esophageal disorder by the Rome IV workshop. The clinical and psychological characteristics are still unknown.

Aims & Methods: The aim of this study was to assess the reflux and psychological characteristics of RHV. Patients who underwent 24 h pH-impedance monitoring were screened from Jan 1st 2011 to Nov 31st 2015. The patients with heartburn or chest pain ≥2 days/week for more than 6 months were enrolled. Healthy volunteers (HV) were enrolled too. All subjects fulfilled the SCL-90 questionnaire, underwent gastroscopy to exclude upper gut organic diseases and underwent HRM test to exclude manometric disorders. The patients for esophageal manometry was evaluated in 12/15 volunteers. The patients with normal esophageal mucosal and normal reflux but positive symptom index (SI) or symptom association probability (SAP) were diagnosed as RHV. The patients with normal mucosal, normal reflux, normal SI or SAP and negative PPI test results were enrolled in functional heartburn (FH) group. The reflux and psychological characteristics were compared among NERD, RHV and FH.

Results: Total 231 patients were enrolled. 107 were NERD (48.25 ± 8.0, M:F = 55:52), 92 were FH (48.30 ± 8.7, M:F = 90:4), 28 HVs (47.21 ± 9.0, M:F = 10:18) were enrolled. Healthy volunteers (HV) were enrolled too. All subjects fulfilled the SCL-90 questionnaire, underwent gastroscopy to exclude upper gut organic diseases and underwent HRM test to exclude manometric disorders. The patients with normal esophageal mucosal and normal reflux but positive symptom index (SI) or symptom association probability (SAP) were diagnosed as RHV. The patients with normal mucosal, normal reflux, normal SI or SAP and negative PPI test results were enrolled in functional heartburn (FH) group. The reflux and psychological characteristics were compared among NERD, RHV and FH.

Conclusion: Reflux hyper sensitivity (RHV) is a distinct functional esophageal disorder. The role of psychological factors in the pathogenesis of RHV needs to be studied furtherly.

Introduction: High-Resolution Manometry (HRM) has recently become the gold standard for the evaluation of esophageal motility. A new classification of esophageal motility disorders (Chicago Classification, v. 3.0) has been developed, based on the findings from a given hardware and software. Different systems for HRM and new features of the existing ones have recently been developed.

Aims & Methods: In this study we aimed to evaluate a new solid-state HRM system and a new 3-D catheter and system for the study of lower esophageal sphincter (LES). Fifteen healthy volunteers (7 m, 8 f, median age 27) underwent two consecutive Esophageal HRM studies by using two different solid state systems (ManoScan, Medtronic, Minneapolis, USA and Medica SpA, Italy with Unisensor AG, Atikon, Switzerland catheter). The studies were performed in a random order using the standard protocol. Furthermore, a new 3-D catheter for the study of sphincters was evaluated in 12/15 volunteers.

Results: Table 1 reports the findings obtained with the Medica system compared to the consolidated Medtronic system. The data of the 3-D evaluation are also reported. The data are expressed as medians (and 5th-95th percentiles).

Conclusion: Significant differences were recorded in most of the considered parameters obtained by the two HRM systems. This is particularly relevant in the evaluation of the LES relaxation, the cardinal point in the hierarchical approach of the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCl and DL) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new motility disorders manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

Introduction: Proton pump inhibition-response esophageal eosinophilia (PPI-REE) is a condition characterised by symptoms of esophageal dysfunction in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of 5 weeks of PPI therapy. Recent data collected by using esophageal high resolution manometry (HRM) documented that patients with PPI-REE present frequently motility abnormalities, mostly weak peristalsis and hypotensive esophagegastic junction (EGJ). Data on the effect of PPIs in improving these motor abnormalities are lacking.

Aims & Methods: The aim of this study was to assess the diagnostic and therapeutic management of patients diagnosed with eosinophilic esophagitis (EoE). In this study we measured systemic eosinophilia and, then, were treated with twice-daily PPI for at least 8 weeks. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Patients with PPI-REE underwent HRM at the time of the diagnosis (off-PPI) and after the course of PPIs (on-PPI). Patients with achalasia and absent peristalsis were excluded (Chicago Classification v.3).

Results: Twenty-eight patients [23M:5F; mean age 33] reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. After a median diagnostic delay of 6.5 years (IQR, 2-14 years). The incidence of patients newly diagnosed with EoE increased steadily over a period of 11 years. Criteria for the microscopic diagnosis of EoE varied between pathologists in each hospital. Initial treatment included topical corticosteroids (30.3%), proton pump inhibitors (PPIs) (29.4%) or a combination of both (10.1%). A follow-up endoscopy was performed in 40.3% of patients. Remarkably, the diagnostic entity PPI-responsive EoE was only used in one center, follow-up endoscopy was performed in less than half of patients and all pathologists used different criteria for the microscopic diagnosis of EoE. Moreover, varying therapeutic strategies were utilized in the participating centers.

Conclusions: In most PPI-REE patients, PPI therapy restores the impairment of esophageal peristalsis, thus favouring the return to a normal motility pattern. This finding, paralleled with the presence of at least 15 eos/hpf on oesophageal biopsies at mid/proximal esophagus, which is presented by esophageal dysfunction und histologically characterized by a predominant eosinophilic inflammation. EoE is mainly found in children and adults: a systematic review and consensus recommendations for diagnosis and treatment. Gastroenterology 2007;133: 1342-63.

Results: In total, 119 patients were diagnosed with EoE and included in this study. The median age at onset of symptoms was 29 years (IQR, 15-42) and the median age at diagnosis was 38 years (IQR, 23-51 years), leading to a median diagnostic delay of 6.5 years (IQR, 2-14 years). The incidence of patients newly diagnosed with EoE increased steadily over a period of 11 years. Criteria for the microscopic diagnosis of EoE varied between pathologists in each hospital. Initial treatment included topical corticosteroids (30.3%), proton pump inhibitors (PPIs) (29.4%) or a combination of both (10.1%). A follow-up endoscopy was performed in 40.3% of patients. Remarkably, the diagnostic entity PPI-responsive EoE was only used in one center, follow-up endoscopy was performed in less than half of patients and all pathologists used different criteria for the microscopic diagnosis of EoE. Moreover, varying therapeutic strategies were utilized in the participating centers.

Conclusions: Diagnostic and therapeutic discrepancies between daily clinical practice and recommendations for diagnosis and treatment include a need for prospective studies to further improve the diagnostic and therapeutic management of EoE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Eosinophilic Esophagitis (EoE) is a chronic immune disease of the esophageal mucosa with histologically characterized by a predominant eosinophilic inflammation. EoE is mainly found in patients with atopic conditions. However, recently an association with IgG4 but not with IgE has been reported. Gastroesophageal reflux disease (GERD) is the most important differential diagnosis of EoE. In this study we measured systemic serum IgG4 and IgE levels of EoE patients before and after a topic steroid therapy, correlated them to esophageal IgG4-positive plasma cells and compared them to GERD patients.

Cases and Methods: The aim of this study was to compare the diagnostic and therapeutic management of patients diagnosed with eosinophilic esophagitis (EoE) in daily clinical practice and whether this was according to guidelines and recommendations. A population-based, retrospective cohort study was conducted using data from the Dutch national pathology registry (PALGA), medical records, and telephone interviews of patients diagnosed with EoE in two academic and two non-academic hospitals in the period 2004–2014. Data regarding demographics, clinical manifestations, endoscopic results, histologic samples and therapeutic strategies were collected. Standard statistical analyses were performed to summarize the patient characteristics.

P1841 SYSTEMATIC REVIEW: HEALTH-RELATED QUALITY OF LIFE IN CHILDREN AND ADULTS WITH EOSINOPHILIC ESOPHAGITIS: MEASURE INSTRUMENTS AND DETERMINANT FACTORS
A. J. Lucendo Villarín, L. Arias-González, J. Molina-Infante, A. Arias
Dept. De Gastroenterología, Hospital General de Tomelloso Dept. of Digestive Health Dept. of Gastroenterology, Tomelloso/Spain

Contact E-mail Address: alucendo@vodafone.es

Introduction: Measurement of Health-related quality of life (HRQoL) with generic or specific instruments has been increasingly used in patients suffering from Esophagus to support both research and clinical care. Generic instruments aim at measuring the overall HRQoL of patients across several conditions, being useful for comparisons across different countries and evaluating health economics outcomes. Disease-specific instruments assess domains specific to a given disease and are considered more sensitive to changes in the patient’s health state. An up-to-date systematic review will provide a useful resource for researchers and HRQoL specialists to ensure they can select an appropriate HRQoL measure for patients in their practice in order to identify correctable factors determining an impaired perception and to improve treatment outcomes.

Aims & Methods: We aim to systematically review the current HRQoL measures for patients with Esophagus and to appraise their measurement properties using a robust evaluation methodology checklist. We also sought to identify disease-specific determinant factors for HRQoL in children and adults with Esophagus, and the effect of interventions and treatments on HRQoL. A search strategy was used to identify and retrieve relevant studies on the relationship between HRQoL and Esophagus in children and adults. This systematic literature search was performed in 5 major databases (PubMed, EMBASE, Scopus, PsycINFO and Web of Science) for the period up to March 2017. The measurement properties of each specific Esophagus instrument identified and their performance properties were assessed using the quality properties checklist proposed by Terwee et al. Levels of the HRQoL measure establishment or use in literature: we used Cohen’s criteria. Cohort studies, case series and case reports were evaluated for the risk of bias with the aid of the Joanna Briggs Institute critical appraisal checklist. A descriptive summary with data tables was produced to summarize the literature. Quantitative pooling of data was not meaningful so a narrative synthesis was used.

Results: Of the 596 references identified, data was collected from 34 studies including 1,182 individual patients. Three disease-specific HRQoL measures in Esophagus covering different aspects of patients’ lives and developed in English were scored positive regarding measurement properties. Respectively, the PedsQL inventory (including parent and child report forms) and the Peds-QoL Esophagus module were the generic and specific instruments respectively used in children, while the SF-36 and EuroQoL-5D were the most used questionnaires in adults. Esophagus affect children and adolescents, which manifests in the normal development of their daily activities, their physical health and their mental status, with parents generally underestimating the impact of the disease regarding children declared HRQoL. Regarding determinant factors, age was not associated with HRQoL. Number and severity of symptoms negatively correlated with child-reported and Parent proxy-reported PedsQL score and family impact score. Disease duration was identified as a risk factor for a low SF-36 score. Esophagus impact on a number of domains including frustration levels did not show a significant difference in the overall PedsQL score were found in adult patients managed with dietary or pharmaceutical therapy, with specific treatment modalities having a negligible influence on overall Esophagus specific QoL. Symptoms scores determined exercised an increased impact on swallowing anxiety and emotional impact subscales. Female gender negatively influenced QoL scores. Disease activity, as expressed by endoscopic findings, were also significant determinants of QoL. A higher educational level was also found to be a strong determinant for a worse QoL.

Aims & Methods: Serum levels of IgG4 and IgE of 19 Esophagus patients were measured before and after therapy, showing a trend towards a decrease. Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with Esophagus without histological proof of eosinophilic granulocyte infiltration were taken as a control group. Serum levels of IgG4 of Esophagus patients were measured before and after eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with Esophagus without histological proof of eosinophilic granulocyte infiltration were taken as control group. Results: Serum IgG4 levels of Esophagus patients were significantly higher than in GERD patients (mean: 121.0 mg/dL vs. 71.2 mg/dL, p = 0.034). In contrast, no significant difference of IgG4 levels in Esophagus and GERD patients was observed. In Esophagus patients with eosinophilic granulocyte infiltration in histology was decreased at a significant level after topic steroid therapy (mean: 51.9 eosinophils/high power field (hpf) vs. 6.4 eosinophils/hpf < 0.001). After therapy lower levels of IgG4 serum levels could be measured (mean: 121.0 mg/dL vs. 104.2 mg/dL). PPI therapy did not show a significant difference. The eosinophi- geal biopsies of Esophagus patients showed a high number of IgG4-positive plasma cells (mean expression of 27.4 IgG4-positive plasma cells of 46.4 stomal plasma cells hpf).

Conclusion: Esophagus patients show higher systemic IgG4- but not IgE serum levels compared to GERD patients. These elevated levels normalize under effective topic steroid therapy. Additionally high local expression of IgG4-positive plasma cells can be seen in Esophagus patients. These findings might be further evidence for a possible IgG4-association of Esophagus.

Introduction: Available treatment options for adult Esophagus patients include drugs (proton-pump inhibitors [PPI], swallowed topical corticosteroids [STC]), food elimination diets, and esophageal dilation. Knowledge about patients’ view regarding the different therapeutic options is very limited.

Aims & Methods: We aimed to systematically assess adult Esophagus patients’ satisfaction with different Esophagus-specific treatment modalities. We first created a questionnaire that included items that queried general demographic characteristics (7 items), Esophagus-specific patient history and presence of atopic disease (8 items), past and present Esophagus-specific therapy (9 items), concomitant medication use (7 items), important considerations for choice of therapy (2 items), as well as treatment satisfaction with various therapies recalled over a period of 12 months (assessed using the validated “Treatment Satisfaction Questionnaire for Medication” [TSQM], 52 items). The TSQM consists of 14 items falling into 4 scales: effectiveness (3 items), side effects (5 items), convenience (3 items), and overall satisfaction (3 items). The score for each TSQM scale ranges from 0 (dissatisfied) to 100 (satisfied). In analogy with other conditions, a score above 66.8 and 83.3 identifies patients that are ‘satisfied’ and ‘very satisfied’ with therapy, respectiv- 1

Results: Patient response rate was 73.5% (108/147). Mean patient age at inclu- sion was 54±15.9 years, 85/108 (78.8%) of patients were male, and mean disease duration (from the time of diagnosis to the time of enrollment) was 6.8±5.1 years. In the last 12 months, 11.1%, 48.1%, 10.2%, and 28.7% of patients reported to have suffered from symptoms of asthma, rhinoconjunctivitis, eczema, and food allergy, respectively. In the last 12 months, 25.0%, 3.7%, 77.8%, 1.9%, 19.4%, and 13.0% were treated with PPI, STC in the form of a syrup, STC in the form of a powder, STC in a form of a spray, diet, and esophageal dilation, respectively (37.0% patients received more than one treat- ment). EoE patients appear to be ‘satisfied’ with PPI, STC, and dietary therapy and are considered more sensitive to changes in the patient’s health state. The TSQM scales scores as well average TSQM values for patients on PPI, STC, and diet are shown in Table 1.

Conclusion: Adult Esophagus patients consider both effect of medication on symptoms as well as inflammation as most important criteria, when choosing EoE therapy. Esophagus patients appear to be ‘satisfied’ with PPI, STC, and dietary therapy and are considered more sensitive to changes in the patient’s health state. The TSQM scales scores as well average TSQM values for patients on PPI, STC, and diet are shown in Table 1.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: For technical reasons, the histologic characterization of eosinophilic (EoE)-specific alterations is almost exclusively based on those found in the esophageal epithelium, whereas little is known about subepithelial abnormalities.

Aims & Methods: In this study, we aimed to systematically assess the nature of subepithelial histologic alterations, analyze their relationship with epithelial histologic findings, endemic features, and symptoms, and evaluate the diagnostic impact of subepithelial eosinophilic counts in patients with an epithelial peak eosinophil count of <15/hpf. We prospectively included in this cohort study adult EoE patients who underwent assessment of clinical, endoscopic, and histologic disease activity using scores.

Results: We included 200 EoE patients (mean age 43.5±15.7 years, 74% males) with a median peak count of 36 intraepithelial eosinophils/hpf [IQR 14–84]. The following histologic features were identified in the subepithelial layer: eosinophilic infiltration (median peak count of 20 eosinophils/hpf [IQR 10–51]), eosinophil degranulation (43%), fibrosis (82%), and lymphoid follicles (56%). Peak intraepithelial eosinophil counts were higher, identical, and lower when compared to 0.75%, 5%, and 30.5% of patients, respectively. Subepithelial histologic activity correlated with epithelial histologic activity (rho 0.331, p < 0.001), endoscopic severity (rho 0.208, p < 0.003), and symptom severity (rho 0.179, p < 0.011). Forty percent (21/52) of patients with <15 intraepithelial eosinophils/hpf had subepithelial peak counts of ≤15/hpf.

Conclusion: In one third of patients subepithelial peak eosinophil counts are higher than epithelial eosinophil counts. Systematic assessment of subepithelial eosinophilic counts can aid in diagnosing EoE in additional 40% of all patients with epithelial eosinophils <15/hpf.

Introduction: The modern understanding of gastroesophageal reflux disease (GERD) pathogenesis includes identification in the subepithelial layer of eosinophilic infiltration (median peak count of 20 eosinophils/hpf [IQR 10–51]), eosinophil degranulation (43%), fibrosis (82%), and lymphoid follicles (56%). The peak intraepithelial eosinophil counts were higher, identical, and lower when compared to 0.75%, 5%, and 30.5% of patients, respectively. Subepithelial histologic activity correlated with epithelial histologic activity (rho 0.331, p < 0.001), endoscopic severity (rho 0.208, p < 0.003), and symptom severity (rho 0.179, p < 0.011). Forty percent (21/52) of patients with <15 intraepithelial eosinophils/hpf had subepithelial peak counts of ≤15/hpf.

Conclusion: In one third of patients subepithelial peak eosinophil counts are higher than epithelial eosinophil counts. Systematic assessment of subepithelial eosinophilic counts can aid in diagnosing EoE in additional 40% of all patients with epithelial eosinophils <15/hpf.

Introduction: The pathophysiology of heartburn perception in gastro-esophageal reflux disease (GERD) remains unclear. The degree of reflux-induced epithelial change seldom predicts symptom severity, as evidenced by the greater symptom burden seen in non-erosive reflux disease (NERD) compared to patients with Barrett’s esophagus (BE). Existing models of acid hypersensitivity are inadequate to explain this discordance.

Aims & Methods: To test the hypothesis that differences in epithelial nasal nerve fiber densities in patients with NERD and BE and compared the results with that of healthy subjects. 13 patients with NERD undergoing reflux testing and 16 patients with BE undergoing endoscopic surveillance were prospectively recruited. Biopsies were obtained from the proximal and distal esophageal mucosa in NERD patients and the distalmost squamous epithelium in BE patients, then examined immunohistochemically for presence and location of calcitonin gene-related peptide (CGRP)-immunoreactive nerve fibers. The results were compared with those from 10 healthy volunteers (HV) previously studied by our group.

Results: The distribution of mucosal CGRP-immunoreactive nerves is equidistant from the distal esophageal lumen in HV and BE (median 25.5 cell layers to surface [IQR 21.4–28.8] vs 21.5 [16.1–27.5] respectively, p = 0.015). Mucosal innervation is significantly more superficial in NERD both distally (9.5 cell layers [1.5–13.3], p < 0.0001 vs both BE and HV) and proximally (5.0 [2.5–9.3], p = 0.0008 vs HV).

Conclusion: The acid hypersensitivity seen in NERD may be partially explained by the increased proximity of mucosal afferents to the esophageal lumen, and therefore greater exposure to noxious substances in reflux. Conversely, the relative acid hypo-sensitiveness in BE may be attributed to the deeper location of mucosal sensory receptors.
Belching is a commonly occurring symptom in patients with gastroesophageal reflux disease (GERD). Belching may reflect reflux. It is unknown whether GERD patients with isolated pathological upright reflux (UP) have belching patterns that are different from GERD patients with pathological bisphosphonate reflux.

**Aims & Methods:** Aim of this study was therefore to examine the belching patterns of UP reflux patients as compared with BIP reflux patients. We included 50 consecutive patients with pathological reflux and typical symptoms who underwent 24-h pH-impedance monitoring at the Maastricht University Medical Centre from 2015 to 2017. Patients referred for excessive belching were excluded. A group of 25 UP reflux patients (10 male, mean age 52.9 years (range 22–77)) and 25 BIP reflux patients (11 male, mean age 47.9 years (range 18–77)) were examined. pH-impedance tracings were analysed manually. We classified belches according to: a) physiological mechanism: supragastric vs. gastric; and b) their temporal relationship with a liquid reflux episode: isolated belch, preceding or during a liquid reflux episode. Symptom-association analysis was performed to assess a relationship between reported symptoms and reflux episodes.

**Results:** BIP patients showed higher acid reflux time (17% ± 2.4% vs. 7.3% ± 0.6%, p < 0.001) and higher number of total reflux episodes (121 ± 9 vs. 97 ± 8, p = 0.05) than UP patients. Notably, both the proportion of reflux episodes with belches of any type and the proportion of belches preceding liquid reflux were higher in UP patients than in BIP patients (51.7 ± 3.6% vs. 32.1 ± 3.7%, p < 0.001 and 27.3 ± 3.1% vs. 17.8 ± 2.9%, p = 0.03, respectively). No difference was found in the proportion of both supragastric and gastric belches between groups. During 24-h pH-impedance monitoring UP patients reported more symptoms (21.6 ± 6 vs. 12.4 ± 3, p = 0.16) and had more positive symptoms with belches (60.2 ± 7.1% vs. 39.0 ± 6.6%, p = 0.03) than BIP patients. Of the total number of belches that were detected using 24-h pH-impedance, more belches were reported in UP patients than in BIP patients (24.8 ± 6.4% vs. 11.1 ± 2.5%, p = 0.06).

**Conclusion:** In our study, GERD patients with isolated pathological upright reflux had more often (symptomatic) belches than GERD patients with pathological bisphosphonate reflux. Therefore, examination of belching patterns can assist diagnostic and therapeutic strategic planning in GERD patients who are refractory to medical therapy.

Introduction: Menthol is widely used as a food flavourant. In general, it is considered safe, but some reports indicate a possible pro-inflammatory effect on the upper respiratory tract.

Aims & Methods: The aim of the study was to evaluate the effect of the menthol infusion into the esophagus on the esophageal peristalsis and lower esophageal sphincter pressure in healthy volunteers. High-resolution manometry and the parameters of esophageal pressure topography were used to quantitatively evaluate the contractile components of esophageal motility. 13 healthy volunteers without out esophageal symptoms were enrolled. High-resolution manometry, with a thin silicon tube attached, was placed transnasally so that the distal end of the tube was 5 cm above the LES. After a 5 min. adaptation period the measurement was performed in the supine position according to the protocol as follows: water swallows of 5 ml and 3 water swallows of 10 and 15 ml after that a 20 min. infusion challenge with 3 mM menthol 8 ml/min. was carried out and subsequently the water swallows in order described above were repeated. HRM tracings were manually analyzed using ManoScan software and parameters used in the Chicago classification (v3.0) were evaluated. Integrated relaxation pressure (IRP), nadir LES pressure and distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows were evaluated. Integrated relaxation pressure (IRP), nadir LES pressure and distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows were obtained. These were compared before and after the menthol infusion. Paired t-test was used for statistical analysis.

Results: None of the subjects had any motility disorder defined by the Chicago Classification v3.0. Few volunteers reported only mild cold sensation during infusion presumed to be of the esophageal origin. The nadir LES pressure before and after menthol infusion was 7.5 ± 0.5 mmHg vs. 7.3 ± 0.7 mmHg, respectively (p > 0.7). IRP of 5 ml swallows was 2.8 ± 0.6 mmHg vs.2.1 ± 0.5 mmHg showed significance (p < 0.01). However, difference of IRP of 10 ml and 15 ml swallows was not significant (p > 0.1, p > 0.5, respectively). Averages of 5 ml (swallows 5 [1.8-0.3], respectively, p = NS, or for the pharyngeal acid exposure time (45 ± 14 s vs. 88 ± 42 s, respectively, p = NS). We speculate that more acidic LPR events (pH drop to < 5.5) might be of greater relevance. However, no significant difference was found between the benign positive and negative patients either in the number of LPR events (10–2 vs. 1–1, respectively, p = NS), or the pharyngeal acid exposure time (16 ± 6 s vs. 42 ± 36 s, respectively, p = NS).

Conclusion: We found no significant difference in the reflux burden in the distal esophagus/hypopharynx between the groups of symptomatic LPR patients with and without using during 24 h dual channel pH-impedance. Other factors, e.g. visceral hypersensitivity might play a role in the development of globus symptoms, even in patients with objectively established LPR.

Introduction: Globus is considered to be related to the gastroesophageal reflux disease/laryngopharyngeal reflux (LPR). However, a substantial part of subjectiveness and self-perception of globus sensation which is impossible to measure objectively makes this symptom difficult to study. Visceral hypersensitivity and/or altered functional state of the afferent nerve endings in the hypopharynx resulting from reflux have been suggested responsible for the development of globus. We hypothesized differences in the reflux burden and esophageal/pharyngeal pH/impedance monitoring between the patients with LPR symptoms with globus compared to the patients with LPR symptoms without globus.

Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux symptom index (RSI > 13) and at least one acidic LPR episode during 24 h pH/impedance study were enrolled. We recruited patients that were at least 30 days without PPI treatment. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor was positioned 4–6 cm above LES. For each LPR event we determined the maximum level of pH on the pH drop to < 5.5 and < 5.0. For these pH levels we determined pharyngeal acid exposure time calculated as cumulative time of pharyngeal reflux below that pH level during 24 h. According to the question 8 (sensations of sticking/lump in the throat) of self-evaluated RSI questionnaire those were divided into globus positive (tick 4–5 in the RSI) or globus negative (tick 0–1 in the RSI).

Results: 19 (13M/6F) completed the study. The number of globus positive and negative patients was 11 and 8, respectively. There were no major differences between groups. Disregarding the question about globus in the RSI there was a significant difference of the RSI between the globus positive and negative group (25 ± 2 vs. 21 ± 2, respectively, p = NS). As for the reflux in distal esophagus, we observed no difference in the acid exposure time between the globus positive and negative patients (11.1%, respectively, p = NS). Therefore, we assumed differences in the results from the hypopharyngeal pH sensor. However, the number of LPR events with pH drop to < 5.5 showed no significant difference between the globus positive and negative patients, either for the number of the LPR events (92±6–5.5 vs. 88±4.2, respectively, p = NS) or for the pharyngeal acid exposure time (45±14 s vs. 88±42 s, respectively, p = NS). We speculated that more acidic LPR events (pH drop to < 5) might be of greater relevance. However, no significant difference was found between the globus positive and negative patients either in the number of these LPR events (10–2 vs. 1–1, respectively, p = NS), or the pharyngeal acid exposure time (16 ± 6 s vs. 42 ± 36 s, respectively, p = NS).

Conclusion: We found no significant difference in the reflux burden in the distal esophagus/hypopharynx between the groups of symptomatic LPR patients with and without using during 24 h dual channel pH-impedance. Other factors, e.g. visceral hypersensitivity might play a role in the development of globus symptoms, even in patients with objectively established LPR.

Introduction: Due to a negative feed-back mechanism, gastrin-17 (G17) can be considered a marker of acid secretion: the lower G17 values, the higher gastric acid secretion. Some studies suggest serum G17 low levels as a marker of acid-related conditions, like Gastroesophageal Reflux Disease (GERD). Aim of the study was to evaluate the property of low levels of G17 in GERD diagnosis, compared in clinical and instrumental GERD gold-standards (typical symptoms, esophagitis at endoscopy, a positive Demeester score at pH-metry).

Aims & Methods: We enrolled 777 consecutive patients (M 369; mean age 55.3 ± 11.2 years) affected by upper gastrointestinal (GI) troubles, showing low levels of serum G17 (BioHit Oyj, Finland; mean values: 1–9 pmol/l). Exclusion criteria included: current Proton Pump Inhibitors, previous history of surgery, neoplasms, current Helicobacter Pylori infection. Both typical, atypical and extra esophageal GERD symptoms, according with Montreal Classification were collected. All patients underwent upper GI endoscopy and esophagitis was classified according with Los Angeles criteria. In a subgroup of 221 patients (M 103; mean age = 55.2 ± 11.2 years) with Non Erosive Reflux Disease (NERD) a 24 h hours pH-metry was performed using the Demeester score of 14 to establish a condition of acid reflux.

Results: Typical symptoms (heartburn and/or regurgitation) have been detected in 243 patients, being in 479 one heartburn the prevalent symptom and in 68 ones regurgitation. Extra-esophageal symptoms (mainly chronic cough) were present in 303 patients. At the endoscopic evaluation, 349 subjects showed a picture of esophagitis with different degrees of severity of Los Angeles score. One hundred and seventy out 221 patients which underwent 24 h pH-metry showed a positive Demeester score for acid gastroesophageal reflux. Summarizing, 700 out of the 777 subjects included in the study showed at least one of the criteria (clinical, endoscopical or functional) accepted to support the diagnosis of GERD.

Conclusion: By using low levels of G17 as a non-invasive marker of GERD, in more than 90% (700 out of 777 pts) the diagnosis of reflux disease was confirmed, according with the current clinical or instrumental gold standard criteria, suggesting the use of this simple method to identify subjects with suspected GERD almost when typical symptoms are lacking or a NERD picture is find.

6Dept Internal Medicine, Universita di Genova, Genova/Italy

Introduction: Sliding hiatal hernia (HH) is a frequent diagnosis during upper endoscopy (UE) in patients with GERD-related symptoms. Recently, high resolution manometry (HRM) allowed an accurate evaluation of the esophago-gastric junction (EGJ) and its sub-types (Chicago Classification V3.0; CCv3). Few data are available comparing the diagnostic accuracy of HRM and UE to detect HH.

Aims & Methods: The aim of this study was to compare the prevalence of HH obtained with UE and HRM and to determine the role of this finding by diagnosing gastroesophageal reflux disease (GERD) on the basis of impedance and pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH diagnosed with UE. After UE, all patients underwent HRM and MII-pH to investigate GERD. All tests were performed previous a 20-day wash-out from pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH.

Methodology: The aim of this study was to compare the prevalence of HH obtained with UE and HRM and to determine the role of this finding by diagnosing gastroesophageal reflux disease (GERD) on the basis of impedance and pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH diagnosed with UE. After UE, all patients underwent HRM and MII-pH to investigate GERD. All tests were performed previous a 20-day wash-out from pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH.

Results: We evaluated 151 patients (94 females) with mean age of 56.2 yrs. EE was diagnosed in 34 patients (22.5%). MII-pH allowed to subgroup patients in: 48 (31.8%) NERD, 43 (28.3%) HE, and 26 (17.2%) HH. As expected, MII-pH showed a higher AET in HRM and NERD group (p < 0.001). HH was normal in 131/151 (86.6%) and 20/151 (13.2%) had ineffective motility. HH was confirmed in 95% (HRM 55%, p < 0.05) with HRM and in 88/151 patients (barium 58.3% vs UE 100%; p < 0.05) with barium X-ray. The mean length of HH during endoscopy (5.4 cm) was reported greater than that during HRM (3.9 cm) and Barium X-ray (4 cm) (p < 0.05). All details are reported in Table 1.

Contact E-mail Address: j.labenz@t-online.de

Introduction: Randomized controlled trials report about 30% of GORD patients complain of bothersome remaining symptoms (heartburn, regurgitation) despite PPI. The LOPA (Lost Patients) 1 Study of 333 GORD patients seen in general practice revealed 46% of patients experienced heartburn or regurgitation symp- toms at least twice per week despite PPI. A total of 20% were dissatisfied with their treatment. Few patients had received specific GORD diagnostics or recom- mended other options (<10%).

Aims & Methods: The LOPA II study is a prospective, multicenter, observational study conducted in 17 general practice clinics. Patients with chronic GORD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire. Patients were asked the duration of their PPI therapy, satisfaction with their current condition, frequency of symp- toms in the last week, whether they had previously received diagnostic evaluation or surgical consult related to GORD, whether they plan to consult a reflux specialist for further diagnostics, and reasons for dissatisfaction with their cur- rent medication treatment. “Lost Patients” were defined as those with a satisfac- tion score of 1 or 2 on a 5-point Likert scale (1: very dissatisfied; 2: dissatisfied), GerdQ score at least 8, and have not previously received specialized GORD diagnostics.

Results: 510 consecutive patient responses were collected within one year. Patients suffered from GORD an average of 9.6 years and prescribed PPI therapy for an average duration of 7.9 years. 70% were dissatisfied or very dissatisfied on their current medication (GerdQ score of 1 or 2). 83% reported heartburn or regurgita- tion at least 2 days in the prior week (53% 4-7 days), 49% reported using additional medication other than their prescribed PPI at least 2 days per week (34% 4-7 days). In patients dissatisfied on PPI, most cited insufficient symptom control for dissatisfaction. In addition, 31% cited concerns about long-term use of drugs and 27% the need for daily medication. 92% of patients had received an upper endoscopy, 12% had a prior pH-metry, 7% manometry, and 9% received prior surgical consult for GORD. Of patients who never received a surgical consult, 48% were not aware of any surgical anti-reflux meth- ods, 25% were concerned about possible complications, 18% felt their condition is not serious enough, 6% were recommended against anti-reflux procedure by their doctor.

Conclusion: Chronic GORD patients who are dissatisfied with their PPI therapy are rarely offered specialized GORD diagnostic procedures or treatment alter- natives. Half of the patients took medication in addition to PPI to control their reflux. In addition to persistent symptoms, concerns of long-term PPI use and burden of daily medication play a role in patient dissatisfaction with PPI therapy.

Introduction: Gastroesophageal reflux disease (GERD) is a common disorder commonly regarded as a gut disorder and a result of overactivity of the lower esophageal sphincter (LES), whose symptoms are related to food intake. Awareness of health care costs and potential side effects of long-term acid suppression has increased the attention in non-pharmacologic treatment for alleviating reflux symptoms.

Aims & Methods: The aim of our prospective study was to evaluate the non- inferiority of a controlled diet compared to antacid compounds in relieving reflux symptoms in patients suffering from mild GERD. We considered 500 consecutive patients referred to the Division of Allergy and Clinical Immunology of Azienda-ISTITUZIONE IRCCS San Martino di Genova for gastrointestinal symptoms associated to food intake. Patients with a clinical and instrumental diagnosis of food allergy, food intolerance, Irritable Bowel Syndrome (IBS) and Small intestinal Bacterial Overgrowth (SIBO) were excluded. Patients with a diagnosis of GERD based on clinical history represented our study population. Basal metabolic rate and cal- ories needs of patients was assessed by means of Harry-Benedict equation cor- rected for their physical activity. Patients were asked to take antacids for one month. Subsequently patients discontinued medication consumption and fol- lowed an elimination diet of food commonly associated to eliciting reflux symp- toms, based on their calories need. Efficacy of the two treatments was evaluated by means of a validated symptomatic questionnaire (RDQ administered at base- line, after antacids course (1 month) and after diet (1 month)). A treatment was considered effective if a 50% improvement in the symptom score was recorded.

Results: After investigations 261 patients out of 500 (52.2%) were excluded because of IBS (140), celiac disease (6), nickel allergy (25, lactose intolerance (60), SIBO (10), and allergy to other foods (20). The remaining 239 patients were diagnosed as affected by mild GERD (median age 47; BMI 24; 132/F:107M; no erosive reflux disease) and were included in our interventional prospective study. Among them, 10 patients (4.2%) were excluded for protocol violation. Basal metabolic rate and calories needs of patients was assessed by means of Harry-Benedict equation corrected for their physical activity. Patients were asked to take antacids for one month. Subsequently patients discontinued medication consumption and fol- lowed an elimination diet of food commonly associated to eliciting reflux symp- toms, based on their calories need. Efficacy of the two treatments was evaluated by means of a validated symptomatic questionnaire (RDQ administered at base- line, after antacids course (1 month) and after diet (1 month)). A treatment was considered effective if a 50% improvement in the symptom score was recorded.

Conclusion: A structured diet regimen, tailored on the metabolic need of the patients, appears more effective than antacids alone in relieving reflux symptoms in patients with mild GERD. Further controlled studies are mandatory to con- firm these preliminary data.

Introduction: Safety and efficacy of electrical stimulation of the lower oesophageal sphincter (LOS) using the EndoStim® LOS Stimulation System (Nijmegen, The Netherlands) has been demonstrated in clinical trials up to >5 years. Data on outcomes in routine clinical practice is growing.

Aims & Methods: An ongoing, prospective international multicenter web-based registry is collecting data in patients with disruptive GORD symptoms, treated with ES-LOS in clinical practice. Data is collected at baseline and at routine follow-ups for 5 years. Demographics, adverse events, GORD symptoms, GORD health related quality of life (GORD-HRQL) scores, use of proton pump inhibitors (PPIs) and physiological data (oesophageal pH/manometry) are collected when available.

Results: 180 patients at 13 sites in Europe and Latin America have been enrolled. Follow-up data up to 2 years is available. Median (IQR) age at the time of implant was 51 (41–60), 57% were male. All patients were taking prescription PPI at baseline. At their last follow-up between 6 and 24 months post op, 70% (84/121) were completely off PPI (p < 0.001). Median (IQR) composite GORD-HRQL score improved from 23 (17–29) preoperatively to 8 (4–15) at 6 months, 7 (2–12) at 12 months, and 5 (4–15) at 24 months (p < 0.001 at all time points, n = 154, 121, 66, 33 at baseline, M6, M12, M24, respectively). Oesophageal pH testing post-op was performed by a few sites either as standard of care or in in patient populations. Median (IQR) 24% hour oesophageal acid exposure improved from 8.2% (4.6–18.4) at baseline to 4.7% (1.4–14.5) at 6 months (p = 0.26) and 3.6% (1.0–5.8) at 12 months (p = 0.04) (n = 120, 39, 10 at baseline, M6, M12, respectively). The proportion of patients with moderate to severe regurgitation decreased from 64% at baseline to 22.5% after 6 and 13.4% after 12 months. Extra-oesophageal symptoms (recurrent cough, pneumonia, shortness of breath) and sleep disturbances also decreased substantially. Overall, dysphagia and gas were less common at 12 months than preoperatively. Four severe adverse events were reported in one patient. One myocardial infarction related sudden death at 11-month post-op, not related to the device or procedure; 1 event of asymptomatic electro erosion into the oesophagus detected during routine endoscopy and the device safely removed during laparoscopic fundoplication; and 2 events of gas intolerance in 1 patient requiring hospitalization, possibly related to the device, were reported.

Conclusion: ES-LOS is safe and effective in treating patients with disruptive GORD symptoms despite PPI in routine clinical practice. ES-LOS should be considered as a potential treatment option for this patient group.

Contact E-mail Address: anmolbapaye@gmail.com

Introduction: ARMS remains the mainstay for treatment of gastroesophageal reflux disease (GERD), however laparoscopic fundoplication is recommended in refractory patients. Various endoscopic methods have been attempted with variable success. Anti-reflux mucosectomy (ARMS) is a recently introduced option for refractory GERD patients.

Aims & Methods: The current study describes initial clinical experience of ARMS. Data from a prospectively maintained database of consecutive patients undergoing ARMS for refractory GERD was abstracted. Inclusion criteria- GERD symptoms persisting under a PPI for >6 months; absence of hiatus hernia >3cm on EGD and normal esophageal body motility on high-resolution manometry (HRM). Exclusions-hiatus hernia >3cm, poor or absent esophageal body motility, poor-risk candidates for anesthesia or invasive procedure. Pre-ARMS evaluation—EGD to assess Hill’s grade of flap valve, esophageal manometry, 24-hour ambulatory esophageal pH studies, PPI requirement and GERD-HRQL questionnaire. ARMS performed using cap EMR technique. Follow up protocol—EGD at 2-4 weeks, GERD-HRQL questionnaire, pH studies and HRM at 4-6 weeks. Parameters for data analysis—pre and post-ARMS GERD-HRQL questionnaire and Deemster scores, Hill’s grading of gastroesophageal valve on EGD, PPI requirement and procedure-related adverse events (AE).

Results: N = 15, duration—12 months. Mean age 40.8 years (Range 22–69); M: F = 11: 4. HRM-normal esophageal body motility in all. Mean GERD-HRQL score improved significantly from pre-ARMS 40.4 to post-ARMS 7.6 (p < 0.05). Mean Deemster score decreased from 85.8 pre-ARMS to 5.9 post-ARMS (p < 0.001). Mean Hill’s valve grade decreased post-ARMS = 2.8: post-ARMS = 1.6 (p < 0.05). Three AE’s—muscle injury—2 (treated by endoclip), grade I dysphagia—1. At 4 weeks follow up, 11/15 patients (73.3%) had discontinued PPI. 4/11 (36.3%) had > 50% reduction in PPI dosage.

Conclusion: Current study shows impressive short-term results for ARMS. Significant symptom resolution and acid exposure reduction occurred in all patients. 100% patients could discontinue or reduce PPI usage. AE’s were minor. Larger randomized studies with longer term follow up are recommended.

P1859 EFFECTIVENESS OF SELECTIVE SEROTONIN REUPTAKE INHIBITORS IN PATIENTS WITH NON-EROSIVE REFLUX DISEASE: A RANDOMIZED TRIAL

I. Birichenko 1, N. Bondarenko, A. Svintsitsky 1

1 National Medical University, Kyiv/Ukraine

Contact E-mail Address: doctor.gastro@yahoo.com

Introduction: To date a large quantity of 5-HT3 receptors were found in esophageal mucosa that indicates on an important role of this neuromediator in pathogenesis of non-erosive reflux disease (NERD) and gastroesophageal reflux disease (GERD). Antidepressants with 5-HT3 receptor antagonist and analgesic effect, reduce chemical and mechanical sensitivity and have local effect on gastrointestinal tract.

Aims & Methods: Our aim was to assess the superiority of combined treatment using proton pump inhibitor (PPI) plus antidepressant by comparison with PPI for patients with NERD. Methods: In this randomized superiority study adult patients (18-65 years) with confirmed diagnosis of NERD were eligible to participate. Exclusion criteria: the presence of any other neuromediatory, psychological or cardiac conditions. Patients were assessed in clinically and psychologically. Psychological testing was done using validated short-form version of the depression anxiety stress scales (DASS-21) and Toronto alexithymia scale (TAS). All the patients used were randomly divided into two arms: patients of the first arm received PPI (pantoprazole) 40 mg once a day plus escitalopram as follows: initial dose - 5 mg/day for the first two weeks of treatment; depending on individual response the dose was increased to 10 mg/day. The second arm received only PPI 40 mg once a day. Patients were assessed on the 4th and 8th week of treatment. The superiority was shown if there was more last decreasing in heartburn severity, reduced anxiety (A), depression (D) and alexithymia levels.

Results: Of 75 randomized patients 39 were allocated to the first arm and 36 to the second one. The groups were statistically comparable in age and sex. Treatment results showed reduction of heartburn severity in both groups on the 8th week, however more significant in the first group (1group-89.7%, 2group-61.1%, P < 0.001). Also both A and D levels were much lower in the first group compared to the second one (P < 0.001). Comparing the levels alexithymia between two arms on the 8th week after the initiation of treatment we found that alexithymia type of personality prevailed in patients that received PPI only (P < 0.001).

Conclusion: The combination of PPI plus antidepressant demonstrates superiority to PPI therapy alone, showing more lasting symptoms regression and improved psychological and emotional condition of patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1860 QUALITY OF ESOPHAGEAL MUCOSAL HEALING IN EROSI VE REFLUX DISEASE: A RANDOMIZED COMPARATIVE TRIAL WITH LANSOPRAZOLE ALONE OR COMBINED WITH REBAMIPIDE

Introduction: The quality of histologic healing or inflammatory cytokine-related change in erosive reflux disease (ERD) had been verified in few studies. However, it is not clear if combined therapy is better than monotherapy in ERD.

Aims & Methods: We conducted double-blinded comparative study to assess endoscopic, histologic quality of mucosal healing in ERD, following 4-week medical treatment with lansoprazole combined with rebamipide or not. The patients with ERD in modified LA classification grade A-D were enrolled via four referral institutes, regardless of GERD related symptoms. The enrolled subjects were randomly allocated to ingest 30 mg lansoprazole alone or ingest lansoprazole 30 mg with rebamipide 100 mg three times in a day for 4 weeks. Biopsies were performed to assess endoscopic healing (regressed into minimal change or normal), and to obtain esophageal biopsy specimens (at 3 o’clock direction, 3 cm proximal area from squamocolumnar junction). Additional tissue samples were obtained to measure tissue inflammatory cytokines (IL-8, PAF, at 9 o’clock direction, 3 cm proximal area from squamocolumnar junction).

Results: Overall 109 patients were enrolled and randomly allocated to lansoprazole group (N = 54) or combination group (N = 55). Demographic data, smoking or drinking habits were not significantly different between both groups. The endoscopic healing rate at 4-week was not different significantly (75.0% vs 78.9%; P = 0.686. Difference 3.95%, 95%CI [-15.24, 23.13]). The histologic changes of basal layer thickness, intraepithelial infiltration of inflammatory cells (eosinophils, neutrophils) were normalized in subsets of patients regardless of the fate of endoscopic healing, and were not different in both groups. In contrast, papillary length, intraepithelial infiltration of T lymphocyte and the dilated intercellular space (DIS) was normalized significantly in endoscopically
healed combination group. When both group were pooled in a group (proton pump inhibitor administration), the papillary length and DIS was significantly improved in endoscopically healed patients. Tissue level of IL-8, but not Lyso-PAF, was significantly decreased in lansoprazole alone group.

**Conclusion:** Adjuvant therapy of rehampibide to lansoprazole failed to reveal additional esophageal healing effect by endoscopic or histologic evaluation. Papillary length and DIS was more evident parameter of quality of mucosal healing in patient of erosive reflux disease treated with proton pump inhibitor. Long term follow-up data are needed on whether these histologic parameters of mucosal healing can help predict the prognosis of gastroesophageal reflux disease.

**P1861 LONG-TERM RESULTS OF RADIOFREQUENCY ABLATION (RFA) IN PATIENTS WITH BARRETT’S ESOPHAGUS RELATED NEOPLASIA**

J. Krajcová1, J. Malaskova2, M. Kollár2, Z. Vackova1, J. Spicař1, J. Martinek1, J. Benes2, T. Heger1, M. Ruzicka3, K. Rehacek1, J. Frantl1, 2Department of Gastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

**Introduction:** Radiofrequency ablation (RFA) with or without endoscopic resection (ER) is an established endoscopic treatment of early Barrett’s esophagus (BE) related neoplasia (BORN). After successful treatment, follow-up is still required as recurrences may occur. The aim of this prospective single-center case series was to assess the long-term efficacy of endoscopic treatment (RFA with or without ER) for BORN. Main outcomes were complete remission of neoplasia (CR-N) and intestinal metaplasia (CR-IM) and recurrence of IM (R-IM) and neoplasia (R-N).

**Aims & Methods:** A total of 99 consecutive patients with BORN have been treated with endoscopic ablation. Nineteen patients were referred for RFA alone, 75 patients (75 cm, mean age 64, range 22-91) completed the treatment and were included into this analysis. The patients had been followed up during 296 patient-years (mean 3.4 years, range 0.5-6). Thirty-three patients were diagnosed with adenocarcinoma (58%), 24 patients with high-grade dysplasia (28%) and 30 patients with low-grade dysplasia (34%). Prior to RFA, ER for visible lesions was performed in 57 patients (66%). Mean length of the Barrett’s esophagus (BE) was 4.6 cm (range 1-13 cm). After treatment, the patients have undergone regular endoscopic surveillance with multiple biopsies. Recurrence: Complete remission of IM (CR-IM) and complete remission of neoplasia (CR-N) were achieved in 54 patients (54/31 pts, 65.1%; 95% CI 54.3-74.5) and 82 patients (98.8%; 95% CI 92.8-99.9), respectively. All patients who did not achieve CR-IM had macroscopically normal neo-Z-line without visible abnormality. For one patient where macroscopic eradication of BE was not achieved due to giant hiatal hernia and who was referred for anti-reflux surgery. During the follow-up, 18 patients (13.3%, 18/134 pts) experienced a recurrence of IM and 3 patients (2.4%) had a recurrence of neoplasia (LGD 2x, HGD 1x). We did not encounter any patient with a submucous neoplasia. All recurrences occurred at the level of neo-Z-line and 6 patients with recurrent IM had also macroscopic recurrence of BE. A total of 13 patients underwent endoscopic retreatment: 7x probe-based re-RFA, 5x esophageal argon plasma coagulation (APC) and 1x ER. After retreatment, we achieved 100% CR-N and 54% (713 pts) CR-IM. Treatment-related adverse events occurred in 22 patients (25%); 12x chest pain and 10x stricture. Two patients with a stricture had to undergo surgical resection - first patient due to perforation during balloon dilatation of a post-RFA stricture, the second because of refractory post-RFA stricture after 20 sessions of dilatation.

**Conclusion:** RFA combined with ER for patients with BORN achieves a high success rate of CR-N with durable results. Recurrence of IM occurs in approxi- mately one-third of patients and supports continuous endoscopic surveillance even after complete eradication. Nonetheless, the majority of recurrent IM occurs within a normally appearing neo-Z-line with questionable clinical relevance.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Barrett’s Esophagus (BE) is a premalignant condition, in which prolonged gastroesophageal reflux results in intestinal metaplasia, leading to an annual risk of adenocarcinoma 0.12%/year1. The current standard of treatment is Endoscopic Resection (ER) of visible nodular lesions and Radiofrequency Ablation (RFA) at Barrett’s, which has a success rate of 92%2. For refractory cases, wide field ER, cryotherapy and other methods are used, but may have higher adverse events. We hypothesize that thicker Barrett’s tissue is less likely to respond to RFA and have developed methods to precisely measure tissue thickness with Volumetric Laser Endomicroscopy (VLE). These methods may facilitate future studies, correlating tissue thickness with response to therapy and prediction of optimal treatment.

**Aims & Methods:** We performed a nested cohort study from the U.S. VLE Registry (which comprises 1000 patients) of patients with BE who had a baseline VLE scan, followed by RFA ablation and had at least one follow up exam. We excluded patients who had any ablative therapy prior to baseline VLE. The primary outcome was the percentage reduction of Prague length after the first treatment. Secondary outcomes were: 1. complete remission of intestinal metaplasia (CRIM) during 12 months after baseline procedure, 2. complete remission of dysplasia (CRD) during 12 months after baseline procedure, 3. number of RFA treatments necessary for complete response of intestinal metaplasia. We estimated the thickness of BE mucosal layers, by measuring the distance between the esophageal surface to the deepest edge of the lamina propria. In order to do so, we developed an algorithm (ImageJ software; imagej.nih.gov/ij/) that automatically adjusts every clockwise image into a high-resolution vertical scan with enhanced contrast. We used two measurement protocols: subjective, by drawing a line from the surface to the edge of the lamina propria (LP) and by plotting a grayscale density plot at the same location, using the sharp drop off in density to infer the thickness. The measurements were done by Levink, I. S. Schlachter: Schlachter, S is an employee at Ninepoint Medical and manages the data of the Ninepoint registry. Schlachter, S had no influence on the outcomes themselves were done by Iris Levink. S. Schlachter: Schlachter, S is an employee at Ninepoint Medical and manages the data of the Ninepoint registry. Schlachter, S had no influence on the outcomes of the measurements. The measurements were done by Levink, I. All other authors have declared no conflicts of interest.

Barrett’s esophagus (BE), with or without prior endoscopic resection (ER) of focal lesions, results in complete eradication of intestinal metaplasia (CE-IM) and complete eradication of neoplastic mucosa (NE-SCJ) in 93–100% of patients. The aims of our study were to evaluate recurrence of endoscopically visible Barrett’s mucosa. Secondary outcomes: Buried Barrett’s glands; IM in biopsies obtained distal to a normal appearance neo squamous columnar junction (neo-SCJ); need for retreatment; sustained CE-IM and NE-SCJ at last FU.

**Results:** 68 patients were included (55 men, median 64 yrs, median BE C5M6). In 53/68 patients ER was performed (worst pathology: low-grade dysplasia (LGD) n = 32, high-grade dysplasia (HGD) n = 27). Worst pathology pre-RFA (after ER): non-dysplastic IM (n = 9), LGD (n = 27), HGD (n = 32). Median FU was 85 months (IQR 58–96) with a median of 7 FU endoscopies per patient. Recurrence of endoscopically visible Barrett’s mucosa was seen in 32% of patients, however it was not reproduced in 84%. In 3 patients LGD without IM was found in the neo-SCJ. Eleven patients required retreatment: APC for small areas of visible BE was found in 32% of patients, however it was confined to small islands or tongues ≤1 cm in the vast majority of patients.

**Conclusion:** With 7-years of follow-up, this study presents the longest published follow-up data on RFA for BE with HGD/EC to date. Our long-term outcomes show that after successful RFA recurrence of HGD/EC is rare (3%). Recurrence of endoscopically visible BE was found in 32% of patients, however it was confined to small islands or tongues ≤1 cm in the vast majority of patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1864 ACTION IS REQUIRED TO IMPROVE UNDERSTANDING AND REDUCE ANXIETY LEVELS AMONGST PATIENTS IN THE BARRETT’S SURVEILLANCE PROGRAMME**

**Introduction:** Barrett’s oesophagus (BE) is the only identifiable pre-cursor condition for oesophageal adenocarcinoma. Endoscopic surveillance is performed in BE to detect dysplasia as it likely to be amenable to curative therapy. There is data suggesting that a diagnosis of BE has a negative impact on the quality of life of patients. To our knowledge, no guidance exists on the counselling of patients with BE. To our knowledge, no guidance exists on the counselling of patients with BE to detect dysplasia as it likely to be amenable to curative therapy. There is data suggesting that a diagnosis of BE has a negative impact on the quality of life of patients.

**Aims and Methods:** The aim of this study was to assess if the excellent results after successful RFA for BE with high-grade dysplasia (HGD) or early cancer (EC) are sustained on the long term. We screened all patients treated with RFA, and ER, for recurrence of visible HGD/EC, which were previously enrolled in 5 consecutive cohort studies in a tertiary referral center in the Netherlands. All patients who had reached endoscopic and histologically confirmed CE-NEO and CE-IM after RFA were included for evaluation of long-term follow-up (FU). Primary outcome: recurrence of HGD/EC; recurrence of endoscopically visible Barrett’s mucosa. Secondary outcomes: Buried Barrett’s glands; IM in biopsies obtained distal to a normal appearance neo squamous columnar junction (neo-SCJ); need for retreatment; sustained CE-IM and NE-SCJ at last FU.

**Results:** 68 patients were included (55 men, median 64 yrs, median BE C5M6). In 53/68 patients ER was performed (worst pathology: low-grade dysplasia (LGD) n = 32, high-grade dysplasia (HGD) n = 27). Worst pathology pre-RFA (after ER): non-dysplastic IM (n = 9), LGD (n = 27), HGD (n = 32). Median FU was 85 months (IQR 58–96) with a median of 7 FU endoscopies per patient. **Introduction:** Data on the association between inflammatory and metabolic biomarkers and Barrett’s oesophagus (BE) are scant and conflicting.

**Aims and Methods:** We aimed to study the association between circulating inflammatory biomarkers (interleukin-6 [IL-6], high-resolution C-reactive protein [hsCRP], intra-cellular adhesion molecule [ICAM], tumor necrosis factor receptor-2 [TNF-R2]) and metabolic biomarkers (leptin, adiponectin, C-peptide, insulin-like growth factor 1 [IGF-1], and insulin-like grow factor binding proteins -1, -2 and -3 [IGFBP-1, -2 and -3]) with BE. This was a case-control study, nested within two female-only prospective cohort studies (Nurses’ Health Study 1 and 2) and one male-only prospective cohort (Health Professional Follow-up Study). Participants of provided biennial detailed information on demographic, lifestyle, dietary and medical factors, including endoscopy use. Overall, 80,437 participants enrolled in these cohorts provided a prediagnostic blood specimen between 1989 and 1995. Among these participants, through 2012, we identified 283 cases of BE (163 females and 120 males). Two study physicians, blinded to biomarkers results, reviewed the medical records of patients reporting BE. We matched BE cases with controls in a 1:1 ratio. Controls underwent upper endoscopy during the same time period and did not have BE (361 females and 265 males) on year of birth, year of blood collection, month of blood collection, fasting status and “am or pm” blood draw. We used multivariable conditional logistic regression models, adjusted for known and putative risk factors for BE, to assess the association between each biomarker and the risk of BE. We used the lowest quintile as reference, and assessed linear trend across exposure categories using the median of each quintile as a continuous variable.

**Conclusion:** We have demonstrated that patients with BE have a relatively poor understanding of their diagnosis and the treatment options that are available to them. Further efforts need to be made to address this and help empower a group of patients who are understandably anxious about their diagnosis.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

LET NOT LEPTIN AFFECT DIFFERENT SUBGROUPS DEFINED BY BMI (N=196). AN ASPIN ASK (P=0.82). ASK (P=0.82).

We observed an OR of 0.41; 95% CI 0.17, 0.99 comparing extreme quintiles of IGF-BP-3 (p-trend = 0.11). Among both women and men, we did not observe any other significant associations between inflammatory biomarkers and metabolic biomarkers were associated with a decreased risk of BE in women but not in men. These findings may serve to guide future risk assessment for BE and shed light on potential mechanisms of its pathogenesis.

P1866 OUTCOMES OF TREATMENT OF PATIENTS WITH EARLY-STAGE ADENOCARCINOMA OF THE ESOPHAGUS WITH INCIPIENT SUBMUCOSAL INVASION, RETROSPECTIVE ANALYSIS OF 19 CASES FROM A TERTIARY REFERRAL CENTER IN THE UK

B. Eross1, C. Clisby2, C. Gordon3
1Gastroenterology, Royal Bournemouth Hospital, Bournemouth/United Kingdom
2Endoscopy, Royal Bournemouth Hospital, Bournemouth/United Kingdom

Contact E-mail Address: xerobal@yahoo.it

Introduction: Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early neoplasia and not enough data and research on the outcomes in the patients, in whom the EMR’s histologic assessment identifies early-stage adenocarcinoma of the esophagus with incipient submucosal invasion (pT1b sm1).

Aims & Methods: We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR from October 2010 to December 2016. We investigated the size of the EMRs, the complication rates of the EMRs, the histological features and the resection margins of the EMR specimens and also the outcomes with the mortality.

Results: A total of 99 patients underwent 134 EMR procedures, and the histology identified early adenocarcinoma with incipient invasion of the submucosa in 25 patients. 23 (92%) were male, the mean age at the EMR was 71 years (SD: 8.1). In all 25 EMR 9 (36%) patients had a single piece, 7 (28%) patients 3 pieces and 4 (16%) patients 4 pieces EMR. The median length of the circumferential and maximum extent of the BO segments were 2 and 5 cm respectively (interquartile range (IQR) 2–4). We observed 6 (24%) intra-procedural bleedings and 2 (8%) patient needed admissions with post procedural bleeding and 1 (4%) of them required transfusion. Stricture was endoscopically detectable but not causing any symptoms in 1 (4%) patient and another patient (4%) had slight dysphagia post EMR, but did not need dilation. Histology showed lymphovascular invasion in 6 (28%) patients and vascular invasion in 1 (4%) patient. Of all 25 early adenocarcinomas 7 (28%) were reported as poorly differentiated, 11 (44%) as moderately differentiated and 3 (12%) as well differentiated. In 4 (16%) cases differentiation was not reported. All resection margins were reported as being clear from dysplasia or cancer. There were 9 (36%) patients with clear margins on the radial and/or deep margin of the EMR specimen, of these patients 9 (60%) cases showed residual cancer in 3 (33.3%) of the surgical specimens and also the outcomes with the mortality.

Conclusion: The median survival of all 21 (84%) patients currently alive is 25 months (range: 0.5–180). Of the 25 patients 5 (20%) met the criteria and had radio frequency ablation of the residual Barrett’s oesophagus. Of the 13 (52%) patients who have had oesophagectomy 1 (7.7%) patient died of the deterioration precipitated by the operation and in 9 (69%) patients the surgery was performed for clinical reasons. There were 10 (40%) patients without cancer invasion of the submucosa. Clinical decision making remains very challenging and has to be individualised for all patient, until further in depth studies gives us more useful prognostic factors.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1867 THE USE OF ENDOCYSTOSCOPY FOR THE EARLY DETECTION OF ESOPHAGEAL NEOPLASM

S. M. Chan1, P. W. Y. Chiu2, A. Y. B. Teo2, H. C. Yip2, V. Wong1, E. Ng1, J. Y. Lau2

Contact E-mail Address: shannomechan@surgery.cuhk.edu.hk

Results: From July 2015 to March 2017, forty-four patients were included in the study. Seventeen of the forty-four (38.6%) patients had histological confirmed cancer of the esophagus. There were sixteen patients who had normal finding and nine patients with esophagitis. The positive predictive value for malignancy (ECA 4 and 5) was 89.5%; the negative predictive value was 100%. Sensitivity was 100% and specificity was 92.6%. Similar findings were noted with IPCL on magnifying NBI. The positive predictive value for malignancy (IPCL 4 and 5) was 100%; the negative predictive value was 100%. Sensitivity was also similar at 100% and specificity 92.6% respectively. To compare the diagnostic accuracy of endocystoscopy and magnifying NBI, the McNemar test was performed. The McNemar chi-squared statistic is NaN, and the McNemar chi-squared statistics with continuity correction 0.5 is infinity, meaning that the two tests have the same diagnostic accuracy.

Conclusion: Endocystoscopy had a high positive predictive value and sensitivity for esophageal malignancy. Its diagnostic accuracy was comparable to magnifying NBI. It may be helpful as an adjunct for better characterization of esophageal lesions. However, further studies on interobserver variability is required.

P1868 CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION FOR ACHALASIA-ASSOCIATED SUPERFICIAL ESOPHAGEAL CANCER

Gastroenterology, Showa University Koto-Toyosu Hospital, Tokyo/Japan

Contact E-mail Address: nishikawak@med.showa-u.ac.jp

Introduction: Esophageal achalasia is considered to be a high-risk factor for superficial esophageal cancer. But there are few reports of endoscopic resection for this cancer, and the outcome is unclear. In our hospital, we have performed over 1300 Per-Oral Endoscopic Myotomy procedures for esophageal achalasia and related upper aerodigestive diseases. In the present study, we report the clinical outcomes of endoscopic resection (ESD/EMR) for superficial esophageal cancer in patients with achalasia. We performed endoscopic resection for all cases and report relatively long-term outcome.

Aims & Methods: We aimed to evaluate clinicopathological findings and outcomes of endoscopic resection for 10 achalasia-associated superficial esophageal cancer. This is a case series study at our hospital. Between August 2010 and February 2017, 10 achalasia patients with superficial esophageal cancer underwent endoscopic resection. We performed in all cases upper gastrointestinal endoscopy with narrow band imaging and endocystoscopy were performed in these patients. During the procedure, the esophageal mucosa was stained with 0.5% methylene blue and then with crystal violet. The endoscopic findings were graded from 1 to 5 according to the Inoue et al’s ECA classification. The esophageal mucosa was also evaluated with narrow band imaging (NBI) and the findings were classified according to the Intrapapillary capillary loop (IPLC) pattern classification. These findings were compared against the gold standard of histopathological examination which was based on the Vienna classification.

Disclosure of Interest: All authors have declared no conflicts of interest.

was followed up without additional therapy, and free from LNM for one year. 5. The rate of lymph-duct involvement of EP and SEP were 0% and 5.7% (2/35), respectively. LNM was found in one of two patients who had inflammation. 4. The rate of lymph-duct involvement of EP and SEP were 0% and 5.7% (2/35), respectively. LNM was found in one of two patients who had inflammation. 5. The rate of lymph-duct involvement of EP and SEP were 0% and 5.7% (2/35), respectively. LNM was found in one of two patients who had inflammation.

Aims & Methods: The aim of this study is to clarify the usefulness of triamcinolone injection to prevent stricture after circumferential ESD. A total of forty-four patients treated by circumferential esophageal ESD from 2004 to 2016 in Saku Central Hospital Advanced Care Center were enrolled to this retrospective study. The patients treated from 2004 to 2009 were followed up without TA injection (Non-TA group), and injection of TA was performed for the patients after 2009 (TA group). The number of patient in Non-TA and TA group was 16 and 28, respectively. Age of both groups was 65 (30–83) and 61 (42–82) years old. The length of circumferential resection was 75 (50–10) and 76 (55–11) mm, respectively. There was no significant difference in the background of both groups. Fifty mg TA was injected into submucosal layer just after ESD, and TA injection was repeated in two-week intervals by the ESD ulcer. When the length of circumferential ESD was 50 mm or longer, 100 mg Triamcinolone was injected just after TA injection was repeated in two-week intervals. Fifteen mm endoscopic balloon dilation (EBD) was performed when the scope couldn’t pass the ESD ulcer. The primary endpoint was the number of balloon dilation. The secondary endpoints were duration from ESD to ulcer healing, and the difference between Barrett’s esophagus adenocarcinoma (EAC) and squamous cell carcinoma (SCC).

Results: 1. Number of EBD in Non-TA and TA group were 20 (13–33) and 5 (1–23), respectively (p = 0.01). Duration from ESD to ulcer healing were 10 (3–23) and 7 (4–12) months, respectively. Complications (p = 0.47) and postoperative bleeding rate due to EBD was 6.3% (1/16) and 3.6% (1/28). Both patients were treated by conservative therapy. 4. Difference between EAC and SCC: There were four EAC and 24 SCC patients in TA group. The number of EBD were 5.3 (1–11) and 26.8 (5–65) mm, respectively. Duration of ulcer healing were 10 (4–14) and 6.5 (1–24), respectively. There was no significant difference between two groups.

Conclusion: Triamcinolone injection is safe and effective treatment to prevent stricture after circumferential ESD, not only for SCC but also for EAC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1870 OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL PHARYNGEAL SQUAMOUS CELL CARCINOMA

T. Oyama1, A. Takahashi1
1Endoscopy, Saku Central Hospital Advanced Care Center, Nagano/Japan

Contact E-mail Address: aurenvoiroueurope@yahoo.co.jp

Introduction: Superficial pharyngeal squamous cell carcinoma (SCC) has been increasing in Japan. And, such SCC could be treated by endoscopic submucosal dissection (ESD). However, the outcome of pharyngeal ESD is unknown.

Aim of this study is to clarify the outcome and prognosis of pharyngeal SCC treated by ESD. 89 pharyngeal SCC in 68 patients treated by ESD from Jan. 2006 to Jan. 2017 in Saku Central Hospital Advanced Care Center were enrolled to this retrospective study. CT and neck US were performed for preoperative staging. All ESD were performed using an IT knife with a Histoacule under general anesthesia with tracheal intubation. Clip with line or forceps was used for traction during ESD. Annual endoscopy, CT scan and neck US were performed as surveillance after ESD, and these examinations were recommended twice a year for the patients who had subepithelial (SEP) SCC. Male:Female was 75:25 and 25:75 years), sex, body mass index (BMI), treatment for synchronous multiple ESCNs, previous radiation therapy, antithrombotic agents, lesion location (upper or middle or lower), lesion size (≤2 cm or >2 cm), lesion circumferential lesion size (≤120 sec or >120 sec), lesion depth (d2 cm or >2 cm), lesion circumference (≤25 or >25), treatment for synchronous multiple ESCNs, previous radiation therapy, antithrombotic agents, lesion location (upper or middle or lower), lesion size (≤2 cm or >2 cm), lesion circumferential lesion size (≤120 sec or >120 sec), and the endoscopist’s experience of esophageal ESD (>40 or ≥40 procedures).

Results: Twenty-nine ESCNs (6%) were treated by ESD without discontinuation of antithrombotic agents. Hemostatic forces were used for 116 lesions (25%), median forceps use time was 73 secs (range: 8–1200 secs), and the median number of antithrombotic agents may therefore not be necessary prior to esophageal ESD. Continuous use of antithrombotic agents may therefore not be necessary prior to esophageal ESD.

Conclusion: Our results suggest that continuous use of antithrombotic agents does not increase the risk of bleeding during esophageal ESD, and that postoperative bleeding was a rare occurrence. Discontinuation of antithrombotic agents may therefore not be necessary prior to esophageal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1871 SHOULD ANTITHROMBOTIC AGENTS BE DISCONTINUED PRIOR TO ESOPHAGEAL SUBMUCOSAL DISSECTION?

Division Of Endoscopy, Shizuoka Cancer Center, Shizuoka/Japan

Contact E-mail Address: n.kawata@scchr.jp

Introduction: Endoscopic submucosal dissection (ESD) has been widely performed as a minimally invasive treatment for superficial esophageal neoplasms (ESCsNs) in Japan and Asian countries. According to the current guideline[1], ESD is classified as a high bleeding risk procedure. However, these guidelines have not been fully validated.

Aims & Methods: The aim of this study was to identify the risk factors of bleeding associated with esophageal ESD, and to clarify whether antithrombotic agents must be discontinued prior to esophageal ESD. A forward stepwise multivariate logistic regression analysis was performed using an IT knife nano (Olympus, Tokyo, Japan). Hemostatic forces (Coagrasper, Olympus, Tokyo, Japan) were used when hemostasis during ESD proved difficult with the IT knife nano. Longer hemostatic time during ESD was defined as more than 120 seconds for hemostasis with hemostatic forceps. We analyzed the relationship between risk factors for longer hemostatic time during ESD and the following factors using univariate and multivariate analyses: age (<75 or ≥75 years), sex, body mass index (<25 or ≥25), treatment for synchronous multiple ESCNs, previous radiation therapy, antithrombotic agents, lesion location (upper or middle or lower), lesion size (≤2 cm or >2 cm), lesion circumferential lesion size (≤120 sec or >120 sec), and the endoscopist’s experience of esophageal ESD (>40 or ≥40 procedures).

Results: Twenty-nine ESCNs (6%) were treated by ESD without discontinuation of antithrombotic agents. Hemostatic forces were used for 116 lesions (25%), median forceps use time was 73 secs (range: 8–1200 secs), and the median number of antithrombotic agents may therefore not be necessary prior to esophageal ESD.

Conclusion: Our results suggest that continuous use of antithrombotic agents does not increase the risk of bleeding during esophageal ESD, and that postoperative bleeding was a rare occurrence. Discontinuation of antithrombotic agents may therefore not be necessary prior to esophageal ESD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: While definitive chemoradiotherapy (CRT) showed high efficacy for esophageal squamous cell carcinoma (ESCC), approximately 40% of patients develop local failure, resulting in poor long-term survival. However, there is no definitive biomarker which is useful to predict survival outcome after CRT for ESCC. Several studies have investigated the correlation of expression of CD24, cytokeratin 4 (CK4), and podoplanin (PDPN) with prognosis for various malignant tumors who underwent surgical resection. However, it remains unclear whether the expression of these proteins can predict the outcome of CRT for patients with ESCC.

Aims & Methods: The purpose of this study was to clarify the predictive values of expression of CD24, CK4, and PDPN for ESCC patients who received CRT. Among patients with ESCC who received CRT or curative esophagectomy with extended lymph node dissection (OPE) as an initial treatment between 2005 and 2009 at our institution, cohorts were selected based on the following criteria: clinical stage II, III (UICC-TNM classification 6th edition), age of 75 years old or younger, ECOG Performance Status 0–1, and no prior or concurrent other cancers. The method of immunohistochemistry (IHC) was utilized to examine the protein expression of CD24, CK4, and PDPN in pretreatment biopsy specimens of ESCC. The cut-off values for CD24, CK4, and PDPN expression were used hazard ratio for overall survival (OS). The prognostic factor of CD24, CK4, and PDPN expression were statistically analyzed. OS was calculated from the date of CRT or OPE to the date of death or last follow-up, using the Kaplan-Meier method. The survival predictors identified by univariate analysis was assessed by multivariate analysis using a Cox’s proportional hazards model.

Results: 148 ESCC patients (CRT group, n=83; OPE group, n=65) were analyzed. In the CRT group, 40 patients had stage II and 43 patients had stage III, and the 5-year OS was 52%. In the OPE group, 32 patients had stage II and 33 patients had stage III, and the 5-year OS was 66%. By univariate analysis, there were no statistical variables for OS in differences between CRT and OPE group. The cut off value for CD24, CK4, and PDPN expression were 20%, 10%, and 20%, respectively. While the expression equal to the cut off value or more was defined as strong, the expression less than the cut off value was defined as weak. The frequency of strong protein expression was 50% for CD24, 12% for CK4, 65% for PDPN, respectively. In the CRT group, the OS of patients with strong CD24 expression was significantly better than that of patients with weak CD24 expression (P=0.015; strong/weak 5-year OS: 65%/43%). On the other hand, for the strong CD24 expression was poorer OS comparing with patients with weak expression in the OPE group, however there was no significant difference (P=0.286; strong/weak 5-year OS: 57%/74%). As for patients with strong CD24 expression, there was no significant difference between CRT group (P=0.445), however there was significant difference between CRT and OPE group in patients with weak CD24 expression (P=0.009). There were also no significant differences of the OS based on expression of CK4 or PDPN between the CRT and OPE group, respectively. Multivariate analysis showed the strong CD24 expression in CRT group (P=0.012; HR=2.787; 95%CI: 1.253–6.200) as an independent variable for favorable outcome.

Conclusion: CD24 expression was significantly associated with the survival outcome in ESCC patients when treated with CRT. Furthermore, weak CD24 expression might be a useful predictive biomarker of poor outcome for CRT in ESCC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

4. P1874 DIAGNOSTIC ACCURACY OF ENDOSCOPIC ULTRASONOGRAPHY FOR ESOPHAGEAL SUBMUCOSAL GLAND DUCT INVOLVEMENT ACCOMPANIED BY EARLY ESOPHAGEAL CANCER

Y. Jie, L. Ying

Digestive Department, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, Jiangsu Province, Ch, Nanjing/China

Contact E-mail Address: 13770755008@126.com

Introduction: Normally, resided within the submucosal layer of esophagus, each esophageal submucosal gland duct (ESMGDs) have respective glandular tissue and muscularis mucosa, and deliver the acinar secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement (ESMGDI) and its precursor lesion have not been comprehensively evaluated so far, and the series study focusing on endoscopic features of this lesions has not been reported widely. During the last 1990s, the esophageal lesions presumed to originate from ESMGDs had been described constantly in various case reports. Currently, in addition to the gold standard of histology, almost no useful modalities could be applied to this lesion. In our study, we considered that the ESMGD had a correlation with early esophageal cancer, and we noted that the ESMGD had special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnose ESMGD.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing ESMGD accompanied by early esophageal cancer, which were suggested by combined esophagitis or endoscopy or histology, we undertook a retrospective analysis on consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2016. The clinical data of 519 patients were included in this study, and all of them had already undergone EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.

Results: According to the pathological results, all patients (371 males and 148 females, with a mean age of 67.5±4.5 years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESMGD by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESMGD, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESMGD were diagnosed exactly by EUS. Another six cases were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intranepithelial neoplasia. One case was diagnosed as ESMGD by endoscopy, however confirmed not by pathology. Consequently, the EUS values for sensitivity and specificity for the diagnosis of ESMGD were 85.0% (34/40) and 99.8% (478/478) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/478).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lesion performed as a hypoechoic sonographic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESMGD as well as the clinicopathological features and sensitivity and specificity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1873 ENDOSCOPIC TREATMENT OF PATIENTS WITH HIGH-RISK EARLY ESOPHAGEAL CANCER

Introduction: Endoscopic treatment is a standard therapeutic approach for patients with T1a early esophageal cancer (EEC). In patients with ‘high-risk’ T1a (T1a grade 3b or 4b grading or invasion of blood/lymphatic vessels) and in patients with any submucosal (sm) invasion (T1b), surgery is recommended as a standard of care. However, recent data suggest, that endoscopic treatment might be curative in selected patients with ‘high-risk’ EEC.

Aims & Methods: The aim of this study was to assess outcomes of endoscopic treatment in patients with ‘high-risk’ EEC. ‘High-risk’ cancer was defined as any cancer with sm invasion or mucosal cancer with at least one of the following: poor differentiation (G3/G4), invasion to blood (A+) or lymphatic vessels (L+)) and high tumor cell dissociation (TC3D). The main outcome measurement was tumor-free survival.

A single-center, retrospective analysis of prospectively collected data. Patients with EEC underwent endoscopic resection (ER) or endoscopic submucosal dissection (ESD). Based on histopathological staging, patients with ‘high-risk’ EEC were referred for ER or ESD. All patients continued in endoscopic treatment consisting of further sessions of ER and/or radiofrequency ablation if necessary. The patients have been followed up for a median of 39 months (range 2–156).

Results: A total of 56 patients with ‘high-risk’ EEC underwent endoscopic treatment: 21 patients (41%) had T1a cancer with ‘high-risk’ features and 35 patients (59%) had T1b cancer with sm invasion (sm: 15; sm: 2; 9, sm: 3; 11); 45 patients had adenocarcinoma (EAC), 11 patients had squamous carcinoma (SCC); 19 (40%) were referred for ER, 37 patients (66%) referred for ESD. All patients were referred for surgery. A total of 37 patients (66%) continued in endoscopic treatment. Complete local remission (CLR) of neoplasia was achieved in 35/37 patients (95%). Two patients without CLR continued endoscopic therapy with palliative intent. Tumor generalization occurred in 2 patients (one of them achieved CLR) 24 months after endoscopic treatment (both patients had sm3 invasion, A+, L+) and these patients are undergoing oncological treatment. All remaining patients with CLR (n = 33) have experienced neither local relapse nor generalization. One patient had to undergo surgery due to endoscopy related perforation. Tumor-free survival was 89% (CI 79–99%) in patients treated endoscopically and endoscopic related mortality was 0% (0/37). Among 19 patients who were referred for esophagectomy, one patient presented with tumor generalization revealed during the operation. The remaining 18 patients underwent esophagectomy, local residua of malignancy were present in 5/18 patients (28%). Lymph node (LN) metastases have not been detected in any patient among the 337 examined LNs. Surgery related mortality was 6% (1/18).

Conclusion: Endoscopic treatment provides long-term remission or cure in a considerable number of patients with ‘high-risk’ EEC and it may thus represent a valid alternative to surgery. Broadening of indications for radical endoscopic treatment of early EEC should be reconsidered.

P1875 PRETREATMENT NEUTROPHIL TO LYMPHOCYTE RATIO IS NOT A PREDICTOR OF RESPONSE TO NEOADJUVANT THERAPY IN ESOPHAGEAL CANCER

G. Pirozolo1, S.S. Gisbertz2, O. De Simone1, A. Slaman2, C. Castoro1, M. Scarpè1, M.I. Van Berge Henegouwen2
1Esophageal And Digestive Tract Surgical Unit, Regional Centre For Esophageal Disease, Venesto Institute of Oncology, Padova/Italy

Contact E-mail Address: giovanni.pirozolo@gmail.com

Introduction: Preoperative Neutrophil to Lymphocyte Ratio (NLR) has been proposed as a prognostic marker in several solid tumors (Templeton et al. 2014). A retrospective prospective study of 60 patients showed the prognostic relevance of NLR as a predictor of response in esophageal cancer patients treated with chemoradiotherapy. The aim of this study is to assess the NLR prognostic strength in a retrospective series of two high-volume centers.

Aims & Methods: A retrospective review of two prospective esophageal cancer database was conducted. Neutrophil to lymphocyte ratio was defined as the prechemoradiotherapy serum neutrophil count divided by lymphocyte count. We dichotomized the NLR data using as cut-off values 2.5 and 3 respectively. Univariable logistic regressions were performed to determine the effect of NLR on response after neoadjuvant treatment. Survival curves were constructed with Kaplan Meier method and compared with the long rank test.

Results: We included 280 patients. The analysis of NLR as predictor of pathologic complete response (pCR) showed a OR of 0.963 (95% CI 0.531–1.746, \(p = 0.901\)) and 1.161 (95% CI 0.647–2.081, \(p = 0.617\)) considering as cut-off values 2.5 and 3 respectively. In our large series, NLR did not result as a predictive marker neither in terms of Overall Survival nor in terms of Disease Free Survival (\(p = 0.997\) and \(p = 0.672\) respectively).

Conclusion: Our results did not confirm NLR as a significant marker of pCR. Moreover, the survival analysis did not reveal significant differences using NLR as a stratification risk marker. The heterogeneity of treatments, the complexity of the disease, the absence of a validated and pre-defined NLR cut-off value in the available literature are the main limits to our analysis. Further studies are needed to assess the clinical relevance of NLR as a predictive marker of response to neoadjuvant treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Background consumption of non-steroidal-anti-inflammatory-drugs (NSAID) and Aspirin is high in Denmark and the majority of these drugs are prescribed in General Practice. Risk factors for complicated ulcer are well established and include NSAID, Aspirin, age, prior ulcer, Helicobacter pylori, anticoagulants, selective-serotonin-reuptake-inhibitors (SSRIs), Adenosine-Diphosphate (ADP)inhibitors and glucocorticoids. Proton Pump Inhibitors (PPIs) reduce the risk of complication but preventative treatment with PPI is only given to a third of the people at risk. The mortality from an ulcer complication is 10% and above.

Aims & Methods: The aim was first in a randomised cluster design to test if a Computer Decision Support System (CDDS) - based on a risk profile for the individual patient - reduced the frequency of ulcer complications. Second to investigate if the use of the CDDS changed the prescription pattern in general practice with regard to prescriptions of NSAID, Aspirin and PPI.

Results: Ninety-six GP’s responsible for the treatment of 52,649 patients were randomised to the CDDS-group and 90 GP’s responsible for the treatment of 43,861 patients to the control group. No significant differences were found between the two groups with regard to prescriptions of NSAID, Aspirin and PPI. In addition a significantly higher co-prescription of NSAID and PPI was found in the CDDS group particularly in high-risk patients. No significant difference was found in co-prescription of Aspirin and PPI when comparing CDDS-group to the control group.

Conclusion: Conclusion: A CDDS based on a risk profile for the individual patient had no impact on the main outcomes ulcer complications, uncomplicated ulcer, reflux or endoscopies. Usage of CDDS increased the amount of co-prescription of anti-inflammatory drugs in medium and high-risk patients. A CDDS was not found for Aspirin. Triggering and the timing of the CDDS and its implementation in the Electronic Health Record should be optimized.

P1877 ACCELERATION OF HEALING OF PREEXISTING GASTRIC ULCERS BY CARBON MONOXIDE RELEASING MOLECULE -2 (CORM-2), INVOLVEMENT OF HEME OXYGENASE, OXIDATIVE STRESS AND PROINFLAMMATORY MARKERS

Physiology, Jagiellonian University Medical College, Cracow/Poland

Contact E-mail Address: katarzyna.magierowska@uj.edu.pl

Introduction: Carbon monoxide (CO) is produced endogenously in the body as a by-product of heme degradation via activity of the enzyme heme oxygenase (HO-1). This gaseous mediator with multidirectional biological activity exerts anti-inflammatory, anti-fibrotic, and immunomodulatory properties; notably new discovered class of compounds, named CO-releasing molecules (CORMs), is capable of liberating CO gaseous molecule that can be useful as pharmacological tool to assess the physiological role of CO under experimental conditions. CORM-2 was implicated in gastroprotection against formation of acute gastric lesions but the contribution of CO to the mechanism of gastric ulcer healing has not been fully elucidated.

Aims & Methods: We determined the effect of daily treatment with vehicle or CORM-2, on healing of preexisting gastric ulcers induced by serosal application of acetic acid (ulcer area = 28 mm²) in rats. Our second goal was to examine the mechanism of CO released from its donor by the determination of the CORM-2-induced alterations in gastric blood flow (GBF) at ulcer margin, the parameters of oxidative stress and the gastric mucosal expression of pro-inflammatory and anti-inflammatory factors. Groups of seventy rats with gastric ulcers (A-D) received daily treatment with A) vehicle (saline), B) CORM-2 in doses from 1 to 10 mg/kg i.p. or C) the HO-1 inducer, hemin (5 mg/kg i.p.), D) the HO-1 activity inhibitor, zinoporfin IX (ZnP(IX) (5 mg/kg i.p.). After 9 days of treatment, the ulcer area was measured by planimetry, the gastric blood flow (GBF) at ulcer margin was determined by Laser Doppler technique, plasma TNF-α and IL-1β levels were measured by ELISA and TNF-α, HO-1, COX-1, COX-2, iNOS, eNOS mRNAs were analyzed by RT-PCR and Western blot. Gastric mucosal samples were collected for the assessment of MPO activity, level of reduced glutathione (GSH) and lipid peroxidation products (MDA + 4HENE) by spectrophotometric methods.

Results: Treatment with CORM-2 significantly reduced the area of gastric ulcers and significantly raised GBF at ulcer margin. The dose accelerating ulcer healing was 5% (D50) and significantly raising GBF was 10 mg/kg as compared with vehicle and NSAID. The HO-1 inducer, hemin, found in the CORM group, significantly reduced the area of gastric ulcers and raised GBF at ulcer margin but the treatment with ZnP(IX) significantly increased the area of gastric ulcers and significantly decreased the GBF at ulcer margin. The decrease in gastric ulcer healing by
The theoretical risk of FGP seems to be very low for clinical consequence in the development of fundic gland polyps (FGP). The trend of change in the upper gastrointestinal endoscopy between years 2015–2016 was performed. The mucosal content of MDA increased by treatment with CORM-2. The gastric mucosal MPO activity and the increased mucosal expression of mRNA for HO-1 were attenuated in CORM-treated animals. The increased mucosal expression of markers IL-1ß, TNF-alpha, COX-2 and iNOS as well as by antioxidative properties of CORM-2 releasing CO limiting lipid peroxidation.

P1879 PROTON PUMP INHIBITORS INAPPROPRIATE USE IN PATIENTS ADMITTED IN A TERTIARY GREEK HOSPITAL CREATES SIGNIFICANT DIRECT COSTS BURDEN AND EXPOSURE OF PATIENTS TO THE RISK OF UPPER GASTROINTESTINAL COMPLICATIONS

Contact E-mail Address: kiriati@med.uoa.gr
Introduction: There is evidence of proton pump inhibitors (PPIs) misuse in the community and in the hospitals causing significant direct and indirect costs burden for the health care system.

Aims & Methods: We aimed to evaluate the frequency of inappropriate PPIs administration in hospitalized patients, to measure the direct in-hosptial costs of PPIs misuse and to calculate the number of patients exposed to the risk of upper gastrointestinal (UGI) complications due to medication underuse. This was a prospective, cross-sectional, prescription-indication drug-utilization, chart-review study in hospitalized patients with follow-up until discharge, in a tertiary hospital in Athens, Greece. We recorded data of all patients admitted (intensive care, psychiatric, pediatrics and day clinic admission were excluded) during three consecutive on-call days of the hospital in March 2017 regarding PPIs utilization before admission, during hospitalization and at discharge. We calculated the direct hospital costs of PPIs overuse and the number of patients at risk of UGI complications due to PPIs underuse for 1 year period, using a simulation model.

Results: We included data from 470 patients aged 67 ± 19 yrs; 32.5% were perioperative admission, 65.9% during hospitalization and 72.8% at discharge. PPIs overutilization was detected in 15.7%, 41.3% and 12.6% of the patients before, during and after the admission, while medications underutilization was detected in 10.2%, 8.1% and 9.5% of them, respectively. Adenocarcinogenic and orthotopic carcinogenic risks was assessed and found to be the highest unadjusted ORs (1.68 [95% CI 1.63–1.72] and 1.68 [1.59–1.78]) for PPIs misuse, 80% of the 193 over treated patients received PPIs iv (80% of them od, 20% bid) while the rest were treated with PPIs per os (80% of them od, 10% bid) during hospitalization. This accounts for 1460 PPI iv and 344 PPI per os doses inappropriately given during the observation period. Taking into account in our simulation model that there are 90 on-call days of our hospital in a year, the cost of each PPI iv dose is 3.455 and 0.235 euros for iv and per os preparations and assuming a similar to that of our sample case distribution for the next 12 months, we calculated the direct hospital costs burden of inappropriate PPIs use at 154940 euros per year. Using the same model, 1200 patients would be at risk of UGI complications annually, due to under prescription of PPIs at discharge.

Conclusion: Hospitalization does not represent an opportunity for optimization of PPIs utilization. On the contrary, the frequency of PPIs inappropriate use during hospital stay is higher than that during in-hospital admission, causing significant direct costs for the hospital and exposing patients to the risks of UGI complications.

P1880 ENDOSCOPIC RESECTION OF ADVANCED AMPULLARY ADENOMAS: A SINGLE-CENTER 14-YEAR RETROSPECTIVE COHORT STUDY

Contact E-mail Address: s.e.vanderwiel@erasmusmc.nl
Introduction: Adenomas of the ampulla of Vater are rare. Endoscopic ampullectomy has been recognized as a safe and reliable treatment of selective tumors of the ampulla of Vater and is associated with lower morbidity and mortality rates than surgical resection. However, the success rates for endoscopic ampullectomy range from 61 to 92 percent, with recurrence described in up to 33 percent of patients. Despite the increasing number of studies concerning endoscopic resection of ampullary tumors, data evaluating endoscopic resection of the more advanced ampullary adenomas are limited.

Aims & Methods: The aim of our study was to evaluate the technical success, complications and recurrence of endoscopic resection for treating patients with ampullary adenomas with intraductal extension (IAE), and patients with lateral spreading adenomas (LSA). Between January 2002 and November 2016, all patients referred to the Erasmus University Medical Center, Rotterdam, for endoscopic resection of an ampullary lesion were retrospectively identified. Cases were selected by using ENDOWEB and we provided a search in the our local PALGA database. We included patients with a histological diagnosis of adenoma. Endoscopic resection was performed by 5 experienced endoscopists. Endoscopic success was defined as complete excision of the adenoma, irrespective of the number of attempts, and in the absence of recurrence. All patients underwent endoscopic follow-up. Early and late complications were registered.

Results: We included 84 patients, 56 patients (67%) had an adenoma confined to the ampulla (ACA), 17 patients (20%) had a LSA and 11 patients (13%) were treated for adenomas that demonstrated growth pattern with intraductal extension. Fifty-five percent of the patients were men and the median age was 65.4 years (range 32–89). The median lesion size was 24.6mm (range 5–80) for patients with ACA, 34.8 mm (range 23–50) for LSA and 16.3 mm (range 10–20) for patients with an IAE (P = 0.039). Complications occurred in 26 patients (30.9%), of which hemorrhage was most seen in 17.9%, followed by perforation in 5.9% of the patients. Complications were equally divided over these three groups (P = 0.775). The mean follow-up duration was 31.1 months (range 0–129) for ACA, 23.1 months (range 0–127) for LSA and 11.9 months (range 0–137) for IEA (P = 0.136). Endoscopic resection was curative in 87.5% of patients with a localized adenoma, 82.3% in patients with a lateral spreading adenoma and in only 9.1% of patients with an intraductal extended tumor (P < 0.000). Recurrence occurred in 9 patients (10.7%), 5 of them had a localized adenoma, 3 patients with a lateral spreading adenoma and 1 patient with an intraductal extended adenoma (P = 0.875).

Conclusion: Endoscopic ampullectomy is a safe and successful treatment in patients with an adenoma with or without a lateral spreading growth pattern. Furthermore, an intraductal extended adenoma endoscopic success rates are significantly lower.

P1883 A COMPARISON OF SUBMUCOSAL TUNNELING ENDOSCOPIC RESECTION AND ENDOSCOPIC FULL-THICKNESS RESECTION FOR GASTRIC FUNDUS SUBMUCOSAL TUMORS

T. Duan, Y. Tan, X. Wang, L. Liang, D. Liu
Department Of Gastroenterology, The second Xiangya Hospital of Central South University, Changsha/China

Contact E-mail Address: tianyingduan@163.com

Introduction: Endoscopic submucosal tumors (SMT) refer to protuberant lesion covered with intact mucosa, and those from small and asymptomatic. While a half of these gastric SMTs are considered to be gastrointestinal stromal tumors (GIST) with malignant potential, especially for those with large diameter. One of the strategies for SMTs < 2 cm is surveillance by endoscopic ultrasonography (EUS) and endoscopic ultrasound guided fine needle aspiration (EUSFNA), but it involves issues related to the patient’s compliance and stress, cost-effectiveness, and the risk associated with repeated endoscopic procedures and accurate diagnosis of malignancy. Therefore, it is necessary to remove these SMTs and endoscopic resection could be considered as an alternative method. Endoscopic full-thickness resection (EFR) is a safe and effective endoscopic method for gastric fundus SMT originating from the muscularis propria (MP) layer with a high rate of complete resection. Submucosal tunneling endoscopic resection (STER) is a novel endoscopic technique and has been demonstrated to be safe and effective for the treatment of gastric SMTs. However, little is known about the comparison between STER and EFR for treating SMTs in gastric fundus. In this retrospective study, we aimed to compare both endoscopic techniques for treating gastric fundus SMTs.

Aims & Methods: Both submucosal tunneling endoscopic resection (STER) and endoscopic full-thickness resection (EFR) are effective methods for gastric fundus submucosal tumors (SMTs), however, little is known about the comparison between these two resections. The aim of this study was to compare the safety and efficacy of STER and EFR for treating SMTs in gastric fundus. We retrospectively collected the clinical data about patients with gastric fundus submucosal tumors who received submucosal tunneling endoscopic resection or endoscopic full-thickness resection at our hospital from April 2011 to May 2016. Epidemiological data (gender, age), tumor size, procedure-related parameters, complications, length of stay, cost and follow-up data were compared.

Results: A total of 43 patients were enrolled, and 15 of them received submucosal tunneling endoscopic resection, while the other 28 cases received endoscopic full-thickness resection. There was no significant difference between the two groups in terms of gender, age, tumor size, en bloc resection rate, operation time, pathohistological results, hospital stay and cost (p > 0.05). However, patients who received endoscopic full-thickness resection had a longer suture time and needed more clips to close the gastric wall defect (p < 0.05). No recurrence was found in the submucosal tunneling endoscopic resection and endoscopic full-thickness resection groups during a mean follow-up of 12.1 and 22.8 months, respectively.

P1888 COMPARATIVE EFFECTIVENESS OF NOVEL FINE-NEEDLE BIOPSY DEVICE VS CONVENTIONAL FINE-NEEDLE ASPIRATION FOR ENDOSCOPIC ULTRASOUND DIAGNOSIS OF GASTRIC SUBMUCOSAL LESIONS

Contact E-mail Address: mmirzali@bidmc.harvard.edu

Introduction: Endoscopic ultrasound with fine-needle aspiration (EUS-FNA) is commonly used for the diagnosis of various gastrointestinal lesions. Recently, a novel fine-needle biopsy (FNB) system (SharkCore, Medtronic) was developed to acquire cohesive units of tissue to increase the diagnostic yield of EUS. Aims & Methods: Our study objective was to compare the diagnostic yield of EUS-FNA using a conventional needle vs. EUS-FNB using the novel needle for gastric submucosal lesions. We conducted a prospective analysis of patients undergoing diagnostic EUS from November 2014 to October 2015. Each patient underwent 3 FNA passes followed by 3 FNB passes, without onsite cytologic evaluation. Data gathered included demographics, size and location of the lesion, needle size, and complications. Pathology and cytology were reviewed separately by two blinded, expert gastrointestinal pathologists. Diagnostic yield was defined as the ratio between the number of significant findings detected by EUS tissue acquisition and the total number of EUS examinations performed for a given indication.

Results: During the study period 1487 EUS procedures were performed in our clinic. Thirty patients with gastric submucosal lesions were enrolled to participate in the study. 66% were female, mean age was 62 years (range 31–88). Mean lesion size was 27 mm (range 12–60 mm). Twenty-two-gauge needles were used in 14 cases (55%) and twenty-five-gauge needles were used in 12 cases (45%). Overall diagnostic yield for 3 needle passes was higher for FNB vs. FNA for gastric submucosal lesions (78% [95% CI 66.2–88.4] vs. 44% [95% CI 12.1–75.9], P < 0.04). Among the different sites of the different passes, the diagnostic yield was: 61%, 67% and 78% with the first, second, and third FNB pass, respectively. In evaluation of tissue quantity and quality of FNB specimens, the mean tissue length was 7.3 ± 5.2 mm, with a median endoscopist tissue proportion between 5% and 75% of the total tissue processed (determined as the percent of the surface are occupied by lesion over the surface area of the entire tissue on one slide). No complications occurred during the study period.

Conclusion: FNB using a novel core needle system is effective and preferential for diagnostic submucosal lesions. When performed without on-site cytologic evaluation, EUS-FNB has a higher diagnostic yield than FNA and may represent an advance for endoscopic ultrasound guided gastrointestinal biopsies.

P1885 SHORT-TERM OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER IN ELDERLY PATIENTS AND LONG-TERM OUTCOME AFTER NON-CURATIVE RESECTION

H. Sakaguchi1, Y. Obara2, T. Toyonaga2, H. Haku1, K. Matsuoka1, T. Sako1, R. Aiyoshi2, H. Abe3, F. Kawara4, S. Tanaka1, T. Ishida1, Y. Morita1, E. Utagaki1

2 Endoscopy, Kobe University Hospital, Kobe/Japan

Contact E-mail Address: valencia.0001@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is widely used as a standard treatment for superficial tumors in the GI tract and its safety has been established. Opportunities for elderly patients to undergo ESD for gastric cancer is increasing due to the continued improvement in life expectancy. However, short-term and long-term outcome of ESD for elderly patients is still unclear because of the high incidence of comorbidities and possible increased risk of complications related to ESD in this population.

Aims & Methods: Therefore, we investigated the safety, efficacy and short-term outcome of gastric ESD for patients over 80 years old. Additionally, we evaluated the long-term outcome of non-curative resections according to both age groups.

Results: 1056 lesions in 886 patients treated with ESD between January 2011 and December 2015 in our hospital were retrospectively reviewed. They were classified into two groups; elderly group > 80 years old (246 lesions in 201 patients) and non-elderly group - 79 years old and younger (810 lesions in 685 patients). The patient demographics, lesion characteristics, short-term ESD outcome, complications (perforation, postoperative bleeding, postoperative delirium), and recurrence were compared and between the two groups.

Concerning the long-term outcome of non-curative ESD, cases performed between 2011 and 2013 were assessed.

Results: The median age was 83 years old (range: 80–92) in the elderly group and 69 years old (range: 36–78) in the non-elderly group. The rate of female patients was significantly higher in the elderly group (30.9% vs. 17.0%: p < 0.0001). Comorbidities were significantly higher in the elderly group including heart disease (24.8% vs. 10.5%: p < 0.0001), lung disease (13.6% vs. 7.4%: p = 0.002) and diabetes mellitus (3.5% vs. 1.0%: p = 0.049). Tumor location was not significantly different between the two groups. Median specimen and tumor size were the same in both groups with no significant difference: 43 mm and 15 mm, respectively. The en bloc resection rates (96.3% and 97.8%) and the curative resection rates (82.5% and 84.6%) were not significantly different. The perforation rate was not significantly different (2.44% and 3.21%). However, the postoperative bleeding rate (5.28% vs. 2.72%: p = 0.05), postoperative delirium (2.0% vs. 0.25%; p = 0.009) and pneumonia (2.0% vs. 0.25%; p = 0.009) were significantly higher in the elderly group.

Multivariate analysis, age over 80 was not an independent risk factor for postoperative bleeding, however it was the independent risk factor for postoperative delirium and postoperative pneumonia. Nineteen elderly patients and 54 non-elderly patients with non-curative resections were followed up for 3 years after ESD for the long-term outcome analysis. The percentage of patients who underwent additional surgery after ESD was 26.3% (5/19) and 51.8% (28/54) respectively (p = 0.05). Neither disease specific death nor progression to advanced gastric cancer was found in each age group. Overall survival rate 3 years after ESD was 84.6% and 82.7% respectively (p = 0.01).

Conclusion: ESD is a safe and effective treatment for early gastric neoplasia even in patients over 80 years old. However, because postoperative delirium and postoperative pneumonia were observed more often in the elderly patients, more careful attention to these conditions during perioperative care may be necessary. Elderly patients over 80 years old, with non-curative resections, underwent less frequent additional surgery without any impact on the disease specific death and global mortality.

Introduction: Gastric adenocarcinoma and proximal polyposis of the stomach (GAPPS) has been described recently only in a few families worldwide (only one in Europe so far). Three different point mutations in promoter IB of the APC gene were identified as causal (c.-191T>C, c.-192A>G, and c.-195A>C). We diagnosed GAPPS in the second Czech white family (not related to that one published previously–ref. 1).

Aims & Methods: We diagnosed GAPPS across 3 generations in a new Czech white family. A genetic analysis of the family was performed.

Results: The Proband (a 43-year-old male) was endoscopically regularly surveyed from his 34 years of age because of fundic-gland polyposis with predominant involvement of the gastric fundus and body (with relative sparing of the lesser curve) and microcytic anemia. Polyposis slowly progressed with the intestinal differentiated low-grade dysplasia in polypectomy specimens 10 years after the diagnosis. As the GAPPS criteria were fulfilled (ref. 2), he and his family underwent genetic testing and bi-directional Sanger sequencing of promoter IB revealed a point mutation (c.-191T>C). The same type of mutation was described in his father (63 years old), sister (41 years old), nephew (son of his sister, 6 years old), uncle (father’s brother, 51 years old) and 2 cousins (uncle’s daughters, 23 and 27 years old), all have been asymptomatic. No gastric cancer in the family history was mentioned. The Proband underwent preventive total gastrectomy, histology of the surgical specimen confirmed severe involvement of gastric body with fundic gland polyposis, low-grade and focal high-grade dysplasia. The microcytic anemia improved rapidly after surgery. The rest of family is scheduled for gastroscopy. The fundic-gland polyposis of similar distribution (with significantly lower number of polypos, without any dysplastic changes) was recently diagnosed in a 23-year-old cousin.

Conclusion: The second European family with GAPPS is presented. The recently described mutations in promoter IB of the APC gene does not automatically mean a faster progression of the disease as suggested earlier. GAPPS can be presented with various phenotypes with a different course of disease, the prevalence can be higher than previously reported. Acknowledgement: The study was supported by the Research Project PROGRES Q40–15.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: ESD is the one of the options of treatment even for lateral spreading (LSE) of esophageal squamous cell carcinoma (ESCC). Endoscopic diagnosis is developed by magnified endoscopy, however accuracy of diagnosis for lateral spreading ESCC is not high. Some patients have to undergo additional treatment because tumor is invaded to submucosal layer or lymphvascular invasion. On the other hand, wide resection by ESD could cause the delay of additional treatment because of the treatment for esophageal stricture after ESD. Thus, treatment strategy for lateral spreading ESCC has to include additional treatment after ESD. Aim of this study is to evaluate our treatment strategy for lateral spreading superficial ESCC.
Aims & Methods: From January 2010 to December 2014, 49 cases of lateral spreading superficial ESCC were resected by surgery or ESD. Diagnosis, treatment methods and outcomes are evaluated. Our indications for additional treatment after ESD are the cases of over pT1b (SM2) or lymphvascular invasion.
Results: In 49 cases of lateral spreading superficial ESCC, 32 cases were treated by ESD and 17 case were treated by surgery. All lesions of 32 cases are completely resected by ESD. Average size of tumor treated by ESD is 59.4 mm (50–85.0%). Accuracy of estimated depth of invasion by ESD for ESCC cases is 65.7%. Four of 32 cases of ESD underwent additional therapy (3 for surgery and 1 for CRT) because of pT1b (SM2) or lymphvascular invasion, and one case has lymph-node metastasis. Rate of stricture after ESD is 20.0% for sub-circumferential ESD and 77.8% for circumferential ESD instead of steroid injection. Average time and duration for control of esophageal stricture by Baloon Bougie is 13.5 times and 18 weeks. In 17 surgical cases, all cases are treated by thoracoschoposcopic esophagectomy. Average size of tumor treated by surgery is 76.6 mm (50–120 mm). Accuracy of estimated depth of invasion by endoscopy for surgical cases is 47.1%. Seven cases in 17 (41.2%) have lymph node metastasis. Rate of lymph node metastasis is 42.9% for pT1a-MM, 100% for pT1b-SM1 and 42.9% for pT1b-SM2. One case died by recurrence after surgery and 48 cases were not affected any recurrence.
Conclusion: Accuracy of estimated depth of invasion by endoscopy for lateral spreading superficial ESCC is quite low compared to normal superficial ESCC. Most of strictures after sub-circumferential ESD could be prevented by steroid injection. However control of strictures after circumferential ESD is difficult. Thus, diagnostic ESD should not be performed for circumferential lesions of lateral spreading superficial ESCC for the patients who will select CRT for circumferential lesions of lateral spreading superficial ESCC by our treatment strategy.

Introduction: Few major international guidelines consider pepsinogen tests as the best available non-invasive tests to detect precancerous lesions (in particular, - corpus atrophy) in the stomach mucosa. Gastrin-17 (G-17) has been suggested as a possible additional marker for antral atrophy, and different tests are used in Europe and Asia. Recommendations from the European Commission expert group consider the need for additional studies before any screening with biomarkers can be recommended for implementation.
Aims & Methods: Generally healthy 40-65 years aged participants of the GISTAR pilot study referred for upper endoscopy according to the pilot study recommendations from the European Commission expert group were included in this study, and all of them had already underwent EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperational diagnosis were compared with the results of postoperative pathology from ESD. Results according to the pathological diagnosis were divided into three groups: patients with early esophageal cancer and four high-grade intraepithelial neoplasia. One case was regarded as ESMGD by EUS while confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESMGD were 85.0% (34/40) and 99.8% (478/479) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/478).
Conclusion: The esophageal submucosal gland duct involvement is a kind of histopathological sign, and the endoscopic ultrasonography shows the same finding. The EUS and pathology diagnosis are consistent. EUS can be helpful, especially when the pathology cannot be performed.

P1891 ULTRASONOGRAPHY FOR ESOPHAGEAL SUBMUCOSAL GLAND DUCT INVOLVEMENT ACCOMPANIED BY EARLY ESOPHAGEAL CARCINOMA
Y. Jie, L. Ying
Digestive Department, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, Jiangsu Province, China, Nanjing/China
Contact E-mail Address: 13770755008@126.com
Introduction:Normally, resided within the submucosal layer of esophagus, each esophageal submucosal gland will culminate in a single duct. The esophageal submucosal gland ducts (ESMGDs) can traverse the subepithelial connective tissue of esophageal squamous mucosa, and deliver the various secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement (ESMGD) and its precursor lesion have not been comprehensively evaluated so far, and the series study focusing on endoscopic features of this lesion has not been reported widely. While since the 1990s, the lesions presumed to originate from ESMGDs had been described constantly in various case reports. Currently, in addition to the gold standard of histopathology, almost no more useful modality could be applied to this lesion. In our study, we considered that the ESMGD had a correlation with early esophageal cancer, and we noted that the ESMGD had special features under the endoscopic ultrasonography (EUS). The typical ultrasonic images of EUS could help diagnose ESMGD.
Aims & Methods: In order to investigate the clinical value of EUS for diagnosing Gastro-oesophageal squamous cell carcinoma, which were suggested by conventional endoscopy or biopsy, this study retrospectively analyzed the consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2015. The clinical data of 519 patients were included in this study, and all of them had already underwent EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.
Results: According to the pathological evaluation, the endoscopic ultrasonography showed that the ESMGDs were found in 519 cases (73.7%) of 719 patients, and 318 cases (61.2%) of 519 patients were already underwent EUS combined with Endoscopic Submucosal Dissection (ESD). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD. Results according to the pathological diagnosis were divided into three groups: patients with early esophageal cancer and four high-grade intraepithelial neoplasia. One case was regarded as ESMGD by EUS while confirmed not by pathology. Therefore, the EUS values for sensitivity and specificity for the diagnosis of ESMGD were 85.0% (34/40) and 99.8% (478/479) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (478/478).
Conclusion: The endoscopic ultrasonography shows the same finding. The EUS and pathology diagnosis are consistent. EUS can be helpful, especially when the pathology cannot be performed.
The expression levels of miR-211-5p were significantly decreased in vitro. miR-211 in the development of gastric cancer. The expression level of miR-211-gene in non-small cell lung cancer by targeting SRCIN [5]. Therefore, the functional role of miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines in vitro. Results: The expression levels of miR-211-5p were significantly decreased in gastric cancer and low expression of miR-211-5p correlates with poor prognosis in gastric cancer patients. Ectopic expression of miR-211-5p suppressed proliferation, migration and induced apoptosis in gastric cancer cells in vitro. Bioinformatics and quantitative analysis revealed that FoxC1 might be a target of miR-211-5p. Downregulation of FoxC1 inhibited proliferation and migration of gastric cancer cells and Overexpression of FoxC1 partly abrogated the inhibitory effects of miR-211-5p on gastric cancer cell proliferation and motility. Conclusion: We believe that miR-211-5p acted as a tumor suppressor by targeting FoxC1 in gastric cancer and miR-211-5p might be a potential target for the treatment of gastric cancer.

P1893 CONGENITAL OR METAPLASTIC: EVALUATION OF GASTROESOPHAGEAL NEO-JUNCTIONS TO ASSESS CARDIAC TYPE EPITHELION
Núcleo Regional do Sul da Liga Portuguesa Contra o Cancro, Lisboa/Portugal

Contact E-mail Address: joanarocaste@gmail.com

Introduction: The dramatic rise in the incidence of gastroesophageal junction (GEJ) adenocarcinoma in the Western countries, has promoted an increased interest about the etiopathogenesis and natural history of GEJ. The cardiac epithelium (CE), which integrates the morphological spectrum of Barrett’s esophagus, is frequent to find in endoscopic biopsies in children and adults. Its congenital versus metaplastic origin still needs to be clarified. The gastroesophageal neo-junction after esophagectomy seems the ideal model to study the development of GEJ epithelium, reproducing “in-vivo” its natural history.

Aims & Methods: The aim of this study was to evaluate the prevalence of metaplastic CE in the gastroesophageal neo-junction. Prospective study of patients undergoing esophagectomy due to esophageal/GEJ neoplasia between November 2012 and November 2016. Upper gastrointestinal endoscopy (UGIE) (Olympus, GIF-HQ 190) was performed 3 months after surgery; the neo-junction was evaluated with white light and Narrow band imaging (NBI); protocolocated biopsies were made (suspected areas of CE, randomized in the anastomotic site or in the remnant esophagus after cardia resection, and 3 cm above and below the anastomosis). Endoscopic CE defined by the presence of circular pattern with NBI in the anastomosis. Histological evaluation performed by 3 pathologists with gastro-intestinal expertise. A questionnaire for gastroesophageal reflux (GER) symptoms evaluation was applied.

Results: 20 patients were included (9 adenocarcinomas), 19 men, mean age 60 ±11 years, 9 under proton-pump inhibitor and 10 with GER symptoms. UGIE: unable to pass a standard scope in anastomosis due to stenosis: 3/20; esophagitis: 5/20; columnar epithelium of the esophagus: 1/20. Endoscopy suggested of CE: present in 17/20, suspect in 2/20 and absent in 1/20. Histologically: CE confirmed in 18/20 patients; additionally identified oxyntocarcina epithelium in 12/20 and intestinal metaplasia in 2/20. The endoscopic diagnosis of CE revealed a sensitivity, specificity, positive and negative predictive value of 94.4%, 100%, 100% and 66.7%, respectively.

Conclusion: The identification of metaplastic CE in neo-junctions is a very frequent and early event and its presence corroborates the hypothesis of metaplasia, to the detriment of a congenital origin. The good endoscopic and histological correlation observed for CE will allow the definition of endoscopic patterns, essential for its recognition.

Introduction: Duodenal adenomas are rare epithelial tumors and represent 25% of the benign lesions diagnosed in the small bowel. Non-ampullary sporadic duodenal adenomas (NASDA) are usually asymptomatic and their diagnosis is mostly incidental. NASDA are benign epithelial tumors with a potential for malignant transformation via the adenoma– carcinoma sequence; nevertheless this risk is lower compared to ampullary or duodenal adenomas in the context of genetic syndromes. Results of Endoscopic Mucosal Resection (EMR) of NASDA are rarely assessed in a large series.

Aims & Methods: Consecutive patients undergoing EMR of NASDA between May 2002 and December 2016 were identified from an electronic database. Patients with a genetic polyposis syndrome (FAP or Peutz-Jeghers) and/or adenomas of the major or minor duodenal papilla were excluded. Preoperative biopsy were performed at operator discretion, considering that the majority of the patients were referred from other centers. In case of doubt for a possible involvement of the ampulla of Vater, duodenoscopy with a side-viewing endoscope was also performed. EUS was not systematically done before duodenal EMR. Size, site of the lesion, pre- and post-EMR histology, adverse events, local recurrence and survival rates were retrospectively analysed. En-bloc resection was preferred, when possible, for lesions > 20 mm; bigger lesions were removed piecemeal. Blended “endocut” current was used in all the cases. All resected specimens were retrieved for histological examination. CO2 insufflation was routinely used during duodenal EMR after 2013. Argon plasma coagulation was used to eradicate residual adenomatous tissue at discretion of the operator. Endoscopic follow-up was scheduled after 3, 6 and 12 months for the first year, and then yearly for up to 5 years.

Results: EMR of 75 NASDA was performed in 68 patients (56% en-bloc resection, 44% piecemeal). The mean size was 14.4 mm and 28.9 mm for lesions resected en-bloc and piecemeal, respectively. Histopathological findings were: low-grade dysplasia (n = 27, 36%), high-grade dysplasia (n = 34, 45.4%), high-grade dysplasia with focal adenocarcinoma (n = 12, 16%), intramucosal adeno- carcinoma (n = 2, 2.6%). Pre-EMR biopsy tended to downgrade the lesion in 44.4% (16/36). Retroperitoneal perforations occurred in 3/75 (4.0%) procedures and were treated by surgical (n = 2) or percutaneous (n = 1) drainage; delayed bleeding was reported in 13/75 (17.3%) resections and was successfully managed by endoscopic hemostatis (n = 12) or radiological embolization (n = 1). There was no procedure-related mortality. Follow-up was available in 61/68 patients (89.7%) after a median time of 39 months (range 3–147) from resection. Residual and recurrent adenoma were diagnosed in 9 and 6 cases, respectively; all but one were successfully retrorectively endoscopically.

Conclusion: The present series reports the results of duodenal EMR for NASDA after more than 4-year median follow-up. When biopsies had been performed before duodenal EMR for NASDA, the lesion was recorded more than 40% cases in our series, suggesting that biopsies are not routinely necessary before EMR. EMR for NASDA is effective for favorable long-term outcomes. The main limitation of duodenal EMR is the high incidence of residual/recurrent adenoma which was 27.3% in our series. Piecemeal EMR was
associated, in our series, with a higher incidence of residual/recurrent adenoma, when compared to other hospitals; these results are similar to those reported in the literature. Residual and recurrent duodenal adenomas were successfully retreated by EMR in all of them but one. Mortality related to NASDA was absent in our series after a median follow-up of 59 months (range = 1–147). Management of these events after EMR for NASDA requires the availability of interventional radiologists and surgeons with experience in retroperitoneal surgery. In our experience colorectal adenomas was correlated to NASDA (33.3%), colonooscopy is considered part of the pre-EMR assessment when NASDA is diagnosed. A recall system and patient’s compliance to endoscopic follow-up are mandatory to detect recurrences and their prompt treatment.

Introduction: Obestatin is a bioactive peptide with a well-defined function on cell proliferation mediated by the GPR39 receptor. Our data involve this system in several processes located in the stomach: from pepsinogen secretion in healthy individuals to the differentiation of the tumour.

Aims & Methods: The aim of the present study is to elucidate the detailed activation regulation mechanism of GPR39-RTK crosstalk triggered by obestatin.

Results: Obestatin triggers phosphorylation of RTKs that belong mainly to the family of EGFR (EGFR, 126.7±1.1%; insulin (InsulinR, 128.6±1.3%)), Trk (TrkA, 170.9±4.0%; VEGF (VEGF-R3, 114.9±3.1%)), and the ephrin receptors ( EphA1, 135.8±5.2%; EphB4, 138.4±4.5%)), both in AGS and KATO-III cell lines. Furthermore, we observed an augment in the expression of proteases in lysates and secretomes after obestatin treatment both in AGS and KATO-III cell lines. The most outstanding increments were located in the families of: ADAMs (ADAM9, 133.9±3.7%; ADAM17, 158.9±9.6%), CTSS (CTSS, 193.4±3.9%; CTSV, 189.2±4.9%), KLKS (KLK3, 358.4±12.6%; KLK13, 365.1±7.1%) and MMPs (MMP1, 690.6±10.0%; MMP3, 273.1±0.2%). In human tissues, the overexpression of KLKs is especially abundant. However, it was observed an overexpression for EphA1 and InsulinR in adenocarcinomas when compared to healthy stomach, which was observed a decrease for Axl. Regarding the proteases, ADAMTS13 and PSEN1 were found overexpressed in healthy tissue compared to gastric adenocarcinomas. Besides, CTSX/ZP expression augmented with the differentiation of the tumour.

Conclusion: These data corroborated obestatin involvement in proliferation, migration and apoptosis and in diverse oncopgenic processes. Besides, the GPR39-RTK crossstalk is not only limited to the EGFR, but instead depends on the existing RTKs present in the tissues, and regulated the expression of proteases involved in processes and pathways already described for obestatin.

P1897 HOXD10 METHYLATION IN PLASMA WAS POTENTIALLY SERVED AS BIOMARKER OF GASTRIC CANCER AND PRECANCEROUS LESIONS

L. Wang, L. Wang, M. Luo
The Second Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou/China

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastric cancer (GC) is the fifth most common cancer and the third leading cause of cancer-related deaths worldwide. Our previous studies have demonstrated that HoxD10 functions as a candidate tumor suppressor in GC, which is silenced through promoter hypermethylation. The diagnostic value of HoxD10 methylation in the plasma of GC patients was not determined.

Aims & Methods: We aim to evaluate whether HoxD10 promoter methylation in plasma could serve as noninvasive biomarker of GC. Methylated specific PCR (MSP) assays were used to measure HoxD10 promoter methylation in plasma of 38 healthy volunteers, 55 patients with gastric intramucosal neoplasia (GIN), 123 GC patients and 17 GC after surgery patients.

Results: We demonstrated that the rate of HoxD10 methylation was 0% in healthy controls, 34.55% in GIN, 46.34% in GC and 17.65% in GC after surgery group, respectively. The methylation rate was significantly higher in GC in or GC than in the normal control group (p < 0.01). The methylation rate of the post-treatment group was significantly lower than that in the GC group (p < 0.05). In GC patients, HoxD10 promoter methylation was correlated to tumor invasion depth (p < 0.05), which was associated in found sex, age, tumor size, TNM stage, CEAS level and H. pylori infection (p < 0.05).

Conclusion: It demonstrated that the HoxD10 promoter methylation rate in plasma dissociated DNA was increased with the progression from precancerous lesion to GC. Combined testing of HoxD10 methylation and CEA may be a great significant method for the early diagnosis of GC in high-risk populations.

Cells of diffuse type via activation of muscarinic and nicotinic pathways. It also shows that ACh induces CSC properties of gastric cancer and in particular its capacity to induce the stem cell phenotype, and to study the mechanisms involved. Adenocarcinoma gastric epithelial cells MKN-45 were first cultured in adherent conditions in the presence of ACh (0.1–10 μM), before being cultured in non-adherent condition in order to favour expansion of CSC and formation of tumorspheres (T). The effect of ACh on T formation was evaluated under microscope by counting the number and size of T using the System snapshot file in INCell analyzer 2200/6000. The involvement of different cholinergic (muscarinic and nicotinic) receptors in ACh-induced responses was studied by pharmacological approach using selective agonists and antagonists. The experiment was carried out by SNP (NO donor) and L-NAME (nitric oxide synthesis inhibitor). Finally, the effect of ACh on the expression of CSC and epithelial-mesenchymal transition (EMT) markers was studied by fluorescence microscopy, RT-qPCR and flow cytometry. Statistical analysis was performed using one-way ANOVA test, Kruskal-Wallis test, or two-way non-parametric ANOVA test using SPSS16.0 software.

Results: ACh at concentrations of 0.1 and 1 μM significantly increased the number and size of T as compared to control conditions (p < 0.001). Bethanecol, a selective muscarinic receptor agonist, increased the number and size of T, while the stimulatory effect of ACh on T was significantly reduced by atropine, a selective muscarinic receptor antagonist, atropine. Similarly, DMPP, a selective nicotinic receptor agonist, increased the number and size of T, while hexamethonium, a selective nicotinic receptor antagonist, decreased it. Finally, ACh induced CSC properties of gastric cancer cells.

Conclusion: This study shows that ACh induces CSC properties of gastric cancer cells of diffuse type via activation of muscarinic and nicotinic pathways. It also shows that ACh effects are, at least in part, mediated by nitric pathway. These results suggest that ENS may be a new actor in gastric carcinogenesis.

P1903 SEROLOGICAL CHANGES AFTER EQUIVOCAL HELICOBACTER PYLORI- SEROLOGY TEST FINDINGS DEPEND ON THE GASTRIC SECRETING ABILITY
Internal Medicine, Gastroenterology, Konkuk University Hospital, Seoul, Korea, Republic of

Contact E-mail Address: kjhces@gmail.com

Introduction: The serum anti-Helicobacter pylori (Hp) IgG and serum pep-
sinogen (PG) assays are widely used for gastric cancer screening. An equivocal
serology test finding indicates IgG titer between the positive and negative test
findings.

Aims & Methods: The study aim was to evaluate the long-term, follow-up result
after an equivocal test finding on the serum anti-H. pylori IgG assay. Koreans
above 18-years-old with an equivocal serum anti-H. pylori IgG assay finding were
included. Subjects were excluded if they did not undergo H. pylori serology test,
serum PG assay, and upper gastrointestinal (UGI) endoscopy on the same day at
our center. Annual test findings were followed up using the same methods.

Results: Of the 7,178 subjects who underwent the serum assays and UGI endo-
scopy on the same day, 274 (3.8%) subjects showed an equivocal Hp serology test
and Hp infection was diagnosed in 37 subjects. Of the 7,178 subjects who underwent the serum assay and Hp serology test, 7 (0.1%) subjects showed sero-
positive test finding at the mean follow-up period of 30.6±12.4 months. Subjects
with seroconversion showed a higher initial serum PG I (p=0.023) and PG II
(p=0.036) levels than the subjects without seroconversion.

Conclusion: The equivocal Hp pylori serology test finding is not rare (3.8%) in
Korean adults, and 60% of the equivocal subjects show seroconversion within 3
years. Higher seroconversion rates in the subjects with high PG I and PG II levels
suggest that intact gastric secreting ability play a role for the survival of Hp pylori.
Therefore, equivocal subjects with increased serum PG levels should be consid-
ered as a potential seropositive subjects.

Introduction: Several H. pylori (HP) infection related gastric findings (mucosal atrophy, metaplastic change, diffuse redness, spotted redness and nodular change of the antrum etc.) are so important sign of HP infection on endoscopic examination. On the other hand, we have confused with various newly endoscopic findings (patchy redness and map-like redness etc.) were seen on all atrophic eradicated stomach. On this time, we have found out a new other ultimate useful finding showing HP infection related gastritis at gastric cardia (EG junction) including present and post HP infection. The endoscopic image of gastric cardia is the first gastric view through the esophagus on each endoscopic examination.

Aims & Methods: Our aim of this study is to elucidate possibility of judgement with only this cardiac endoscopic view about presence or absence with HP infection. We have found out so useful and specific cardiac image (We call Whale Shark Sign: WSS) closely related to HP infection. We have examined the presence of WSS on 4, 268 cases that have been able to overviewed on their endoscopic examination. We have judged the presence of HP infection with serum HP antibody titers on each case. The 3,233 cases their serum HP antibody titer were measured were found from Jan. 2012 to Oct. 2016. A total of 2,810 patients (HP positive) were enrolled. Fisher’s exact test was used in all statistical analyses. The judgement of HP present or past infection was done more than serum HP antibody 3 U/ml to avoid false negative results.

Results: Mean age of patients was 52.4 years old. In case of WSS positive, all their serum HP antibody titer showed more than cut-off level (3 U/ml). This means that the presence of WSS closely related to HP related gastritis. The positive predictive value (PPV) of WSS was surprisingly high (95%). According to this high PPV, we can think WSS positive cases are high risk of gastric carcinoma. This WSS mean that the presence of irregular gastric mucosal surface pattern and the presence of lymphoid hyperplasia, that showing HP infection in stomach. Especially presence of lymphoid hyperplasia at gastric cardia is most important specific sign of HP related gastritis. This lymphoid hyperplasia at gastric cardia were recognized small round whitish nodules on white light endoscopy. And this was more emphasized with image-enhanced endoscopy (Narrow Band Imaging; NBI), it looks like Whale Shark Sign. This WSS sign is very simple and easy for every gastroenterologist. It is so useful to know gastric cancer risk at gastric entrance (cardia) with the presence of very easy simple sign.

Conclusion: We have been able to judge the presence of HP infection with only cardiac endoscopic images (WSS), we should take care of seeing the presence of WSS sign. Since this sign is very easy and simple, everyone will be able to judge the presence of HP infection by gastric cancer risk.

Introduction: The diagnosis of Helicobacter pylori (H.p.) infection is currently made by means of non-invasive (Urea Breath Test or HpSA) or invasive (gastric biopsy or culture) methods. Serological assessment of H.p. infection by using levels of IgG is not recommended. Pepsinogen II (PGII) is validated in the literature as a non-invasive marker of gastric inflammation. The aim of the study was to assess in a population of dyspeptic patients the clinical availability of PGII determination in singling out subjects infected by H.p. in comparison with non-infected ones.

Aims & Methods: A cohort of 880 consecutive dyspeptic patients (F 439; mean age 55.5 yrs; range: 29.83 yrs) were enrolled in the study. Exclusion criteria: previous surgery, previous H.p. eradication therapy, concomitant PPI. In all patients the diagnosis of H.p. infection was made by means of upper GI endoscopy and at least one of these two methods: UBT, HpSa. All patients underwent blood sample for determination of serum levels of PGII (Biohit Oyj; Finland; normal values: 2-15µg/l). In a group of 670 pts a course of antibiotics (triple, concomitant or sequential therapy) to cure H.p. infection was performed and PGII levels were measured at baseline (T0) and after two months (T1) from the end of the antibiotic therapy. The search for the most appropriate cut-off of PGII in diagnosis of H.p. infection was assessed by using the ROC curve method.

Results: 430 out of 660 dyspeptic patients (F 245;mean age 52.3 yrs; range 32-69 yrs) showed an H.p.-related gastritis (group 1) in comparison with 430 (F 261; mean age 57.3 yrs; range 38-74 yrs) resulted negative for H.p infection (group 2). The mean value of PGII in group 1 was 20.9±6.1 opposite to 7.2±1.7 in group 2; p<0.0001. 415 out of 670 patients treated with antibiotics schedules showed a course of antibiotics (triple, concomitant or sequential therapy) to cure H.p. infection was performed and PGII levels were measured at baseline (T0) and after two months (T1) from the end of the antibiotic therapy. The search for the most appropriate cut-off of PGII in diagnosis of H.p. infection was assessed by using the ROC curve method.

Conclusion: serum PGII levels seem able to perform diagnosis of H.p. infection in dyspeptic patients, as well as the efficacy of antibiotics treatment for H.p eradication, being 10.6µg/l the best cut-off in singling out infected from non-infected subjects.

Introduction: The Urea Breath Test (UBT) is considered the gold standard non-invasive test for detection of Helicobacter pylori infection in Ireland. In Ireland, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. With this in mind, it is important to optimise management of H. pylori infection. It has been suggested that the DOB value is reflective of the amount of bacteria present in the stomach and could predict whether the infection is eradicated.

Aims & Methods: The aim of this study was to determine whether there is an association between DOB and eradication of H. pylori infection in an Irish cohort. Treatment naïve adult patients undergoing UBT were included. Patients were deemed to be H. pylori positive if a Delta Over Baseline (DOB) value of > 2.0 % was obtained. Positive patients were categorised into low (< 16 %), intermediate (16-35 %), and high (> 35 %) DOB groups. A random subset of positive patients was given clarithromycin-based triple therapy for 7 days. A follow-up breath test was performed at least 6 weeks post-treatment to confirm eradication of H. pylori in all patients. The three DOB groups were compared with respect to age, gender and eradication rates.

Results: Out of 860 of UBTs assessed (mean age 43.1 ± 15.2 years, 39% male), 24% were positive (mean age 43.1 ± 14.9 years, 41.9% male). Of the total positive patients, 91 (31.5%) returned for a follow-up UBT to confirm eradication of H. pylori. When patients were categorised into low, intermediate and high UBT groups, there was no significant difference in age and gender between these groups (p = 0.06 for age and 0.3 for gender). Eradication rates in the low, intermediate and high UBT groups were 70.5%, 63.0% and 50.0% respectively (p = 0.3). Patients were then categorised according to eradication status. When eradication was successful, the average DOB value was significantly lower (29.1 ± 28.1 %) compared to eradication failure (29.8 ± 29.8 %). When eradication was unsuccessful (p = 0.03, 95% CI 0.69 to 17.5), 46 (50.5%) patients were given clarithromycin-based triple therapy for 7 days. When this subset of patients was categorised into low, intermediate and high UBT groups, eradication rates were 75.0%, 46.2% and 50.0% respectively. When these rates were compared to respective rates in those whose treatment was not known, no difference was observed. The subset was also categorised according to eradication status. When eradication was successful, the average DOB value was lower, at 22.0% compared to 32.9% (p = 0.06). Similarly, when these DOB values were compared to respective values in those whose treatment was not known, no difference was observed.

Conclusion: As the DOB value increases in the UBT, the eradication rate of H. pylori decreases, regardless of treatment regimen. When categorised according to eradication status, the DOB value was significantly lower when eradication was successful (20.6 % vs 29.8%, p = 0.03). The DOB value could be a useful value in stratifying patients with H. pylori infection; especially as histology and antimicrobial resistance information is unavailable in patients undergoing non-invasive testing for H. pylori infection.

P1908 COMPARISON OF THE EFFICACY BETWEEN BISMUTH AND ALTERNATING RIFAXIMIN ON SECOND-LINE QUADRUPLE REGIMES OF HELICOBACTER PYLOРИ ERADICATION
Dietetic Disease Center, Institute For Digestive Research, Soonchunhyang University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: junspark@schmc.ac

Introduction: Bismuth is a heavy metal which has antimicrobial activity through inhibition of bacterial protein synthesis. Bismuth is also highly susceptible to bismuth. So the Korean guideline preferably recommends the regimen contains bismuth for the patients who failed on H. pylori eradication with the primary regimen consists of proton pump inhibitors, amoxicillin, and clarithromycin therapy. Rifaximin is one of derivatives of rifamycin with antimicrobial activity against H. pylori. It can achieve high concentrations within the gastrointestinal tract and remains active in acidic condition. So rifaximin has been studied as a treatment for persistent H. pylori infection. Rifaximin has been prescribed for replacing the bismuth of the regimen concurrently uses PPI, metronidazole, and tetracycline in Soonchunhyang University Hospital, Seoul for a while. So we reviewed the clinical outcomes of the 2 different regimens.

Aims & Methods: From May 1st 2003 to October 31st 2015, six thousand and five hundred ninety-five patients were treated their H. pylori infection in Soonchunhyang University Hospital, Seoul. And their prescriptions and result of eradication were retrospectively reviewed on the medical records. The patients who had clarified pre-ant eradication result, which can be assured by the rapid urease test performed within the first 2 to 5 days of eradication were enrolled. And statistical analyses were performed to the patients who had second-line treatment to compare the efficacy of the bismuth containing regimen and the rifaximin containing one.

Results: During the periods over 12 years, two thousand and seven hundred patients were prescribed the standard triple eradication regimen and 2,109 (78.11%) patients showed the successful treatment result. One hundred twenty-six treatment failure group patients were consecutively treated with second-line regimens. Thirty-five patients were prescribed the bismuth-containing regimen and 34 (97.14%) of them showed successful eradication result. Other 91 patients were treated with the rifaximin-containing regimen and showed 92.31% of eradication rates. The treatment success rates are not different significantly in statistics. (Fisher’s exact test, p-value = 0.442)

Conclusion: Alternative rifaximin containing regimen of second-line H. pylori treatment didn’t show inferiority on standard bismuth-containing one. This suggests that the use of rifaximin is possible in the patients who are not suitable to bismuth use and failed with primary eradication.

Introduction: Standard triple therapy (STT) has been widely used in Helicobacter pylori infection, but eradication rate is decreasing because of clarithromycin resistance. Recently, Levofoxacin-based therapy (LBT) has been evaluated to overcome the low eradication rate of standard triple therapy and reported eradication rate over 80%. Aims & Methods: We compared the efficacy and safety of STT group and LBT group for Koreans. Between April 2014 and April 2016, 49 patients in the STT group (amoxicillin 1 g bid, clarithromycin 500 mg bid and omeprazole 20 mg bid for 10 days) and 48 in the LBT group(levofloxacin 500 mg bid, amoxicillin 1 g bid, AMX (1,500 mg/day) b.i.d., AMX (1,500 mg/day) b.i.d. for 7 days. Regimen of RAC (400 or 800) was RPZ (20 mg/day) b.i.d., AMX (1,500 mg/day) b.i.d. plus CAM (400 or 800mg/day) b.i.d. for 7 days. The judgement of success or failure on eradication was done with UBT breath test on 3 months later after eradication therapy to avoid false negative results.

Results: Success rate of VAC 400 showed significantly high (416/428 = 97.2%, PPS) rather than VAC 400 (373/423 = 88.2%, PPS) (p < 0.001). The average success rate of VAC regimen was 91.7% (789/851, PPS). On the other hand, success rate of RAC 400 (190/245 = 77.6%, PPS) rather than RAC 400 (140/198 = 70.7%, PPS) (p = 0.125). The average success rate of RAC regimen was 74.5% (330/443, PPS). The average success rate of VAC regimens were 92.7% (789/851, PPS). On the other hand, average success rate of RAC regimens (330/443 = 74.5%) (p < 0.001). These results suggest that using high dose CAM with VPZ (P-CAB) plus AMX regimen might be the strongest H. pylori eradication triple therapy regimen to overcome CAM resistance.

Conclusion: High-dose CAM with Vonoprazan (P-CAB) plus AMX triple therapy regimen is the strongest H. pylori eradication therapy even if CAM resistance. We will be able to expect significantly high success rate (more than 97%) with low dose VPZ for HP 1st eradication therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.
bid and esomeprazole 20 mg bid for 10 days) were enrolled, prospectively. H. pylori eradication rate as the primary endpoint and serious adverse effects as the secondary endpoint were defined. 

**Results:** H. pylori eradication rate as the primary endpoint was higher in the LBT group than in the STT group, but there was no statistically significant difference between the two groups (82.0% vs 75%, P = 0.927). Serious adverse effects as the secondary endpoint tended to be more frequent in the LBT group, but there was no significant difference (6.1% vs. 15.2%, P = 0.267). The overall rates of adverse effects were not different between two groups.

**Conclusion:** In comparison of H. pylori eradication rate of our study, LBT was not significantly higher than STT, but it may be an alternative treatment if STT eradication rate is lowered in Korea.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1910 TREATMENT OF HELICOBACTER PYLORI INFECTION: WILL TAILORING THERAPY FIRST TIME OVERCOME INCREASING FAILURE OF STANDARD TRIPLE THERAPY? 

**D. Brennan, M. Hussey, D. Tighe, C. O’Morain, S. Smith, D. Menamara**

**Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland**

**Contact E-mail Address:** dbrennan9@tcd.ie

**Introduction:** In Ireland, Helicobacter pylori infection has become increasingly resistant to commonly used antibiotics, such as clarithromycin. Concurrently, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment.

Aims & Methods: Of this study was to compare eradication rates of standard clarithromycin-based triple therapy with those of tailored therapy based on antimicrobial susceptibility as a first-line treatment for H. pylori infection. Treatment-naive adult patients undergoing endoscopy were prospectively recruited. Biopsies from H. pylori-positive patients (assessed by CLO test) were processed for sensitivity testing by E-testing and genotyping by the GenoType HelicoDR assay (Hain). Patients randomly received either clarithromycin-based standard triple therapy or tailored treatment based on antibiotic sensitivities, for 7/14 days. A follow-up breath test was performed at least 8 weeks post-treatment.

**Results:** To date 889 patients have undergone endoscopy and 186 (21%) were H. pylori positive. Infected patients were significantly younger (mean age 53 vs 49 years, p = 0.002) and tended to be male (43% vs 53%, p = 0.02). Of 186 H. pylori-positive patients, 112 (60%) were treatment-naive. Culture of H. pylori was successful in 57% (64/112) of samples and primary clarithromycin resistance was 47% (30/64) by E-test. Genotypic resistance data was available for 93% (75/81) of resistant strains.

The eradication rate of our study, LBT was 81% (30/37) for standard therapy (p<0.05) versus 70% (25/36) for standard therapy (p<0.05). In those who are sensitive to clarithromycin, standard clarithromycin-based triple therapy achieved an acceptable eradication rate of approximately 81%. However, a high primary clarithromycin resistance rate was observed in this study (47%). In those who are resistant to clarithromycin, prescribing a regimen based antibiotic susceptibilities increases eradication rates to 83%, compared to those treated with standard triple therapy (75%, p = 0.09).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

### P1912 ARE PROBIOTICS USEFUL AS ADJUVANTS IN ERADICATION THERAPY OF HELICOBACTER PYLORI INFECTION?

**Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland**

**Contact E-mail Address:** dbrennan9@tcd.ie

**Introduction:** Helicobacter pylori (Hp) successful eradication has been considered since it contributes to several gastrointestinal disorders. Sequential therapy has been used widely as the first approach in Hp eradication therapy (HpET). However, its failure is 10-45%. The addition of probiotics has been considered because of potential benefit in the improvement of efficacy and reduction of side effects during HpET.

Aims & Methods: We aimed to evaluate the effect of probiotics, as adjuvant to sequential HpET on treatment efficacy, side effects and patient compliance. This was a prospective study of total of 1159 patients followed in a gastroenterology outpatient clinic. Selected patients underwent Hp screening for unexplained gastrointestinal symptoms or disorders with HpET indication. Comparison was done between sequential therapy (10-day treatment of 5 days of pantoprazole + amoxicillin followed by further 5 days of pantoprazole + clarithromycin + metronidazole) and HpET (Hp-positive patients) with an additional supplement of Lactobacillus reuteri (2 tablets/day in previous HpET treatment).

**Results:** Of 265/229 (92.5%) patients who participated in this study (47%). In those who are resistant to clarithromycin, prescribing a regimen based antibiotic susceptibilities increases eradication rates to 83%, compared to those treated with standard triple therapy (75%, p = 0.09).

**Disclosure of Interest:** All authors have declared no conflicts of interest.
0.0% (p = 0.106). However, significantly higher rates of diarrhea were noted in treatment with bismuth quadruple therapy (51.3% vs 35.6%; p = 0.031; 96.9% CI). Of G2 patients, 19.24% (55.5%) performed sequential therapy first, with eradication rate improvement of 78.9% (15.1%). The remaining cases that did not respond were submitted to 14-day of quadruple therapy with PPI + amoxicillin + metronidazole + levofloxacin with success.

Conclusion: Concomitant sequential therapy with probiotic Lactobacillus reuteri protectis, within previous two weeks to final of treatment, is associated with higher HpET rate, initially or after sequential therapy failure, and lower rate of diarrhoeal side effects.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1913 THE IMPACT OF CLOSTRIDIUM BUTYRICUM MIYAIRI-588 ON HELICOBACTER PYLORI ERADICATION THERAPY

Department Of Gastroenterology And Hepatology, Kyoto Prefecture University of Medicine, Kyoto Japan

Contact E-mail Address: shunt02@koto.kpu-u.ac.jp

Introduction: As a country with high incidence of gastric cancer, the elimination of Helicobacter pylori (HP) is useful strategy for the prevention of gastric cancer in Japan. And the eradication therapy for HP-infected gastritis was approved as an insurance indication since 2013, and virtually all HP-infected patients were submitted to eradication therapy using proton pump inhibitor (PPI)/amoxicillin (AMPC)/clarithromycin (CAM) has been used as a regimen for the primary eradication therapy. Since HP has rapidly acquired the resistant character against CAM, the eradication rate has gradually been decreasing. Recently, vonoprazan (VPZ), a novel potassium competitive acid blocker, has been approved for HP eradication therapy. Recently, higher HP-eradication rate by VPZ+AMPC+CAM than PPI based triple therapy has been reported. However, there might be some concern for the use of VPZ, higher serum gastrin, decrease in the diversity of intestinal microbiota and increase in colitis. Therefore, PPI-based triple therapy is still used, and additive effect of probiotics has been reported in this therapy.

Aims & Methods: The aim of this study is to investigate the effect of probiotics, Clostridium butyricum Miyairi-588 (Miya-BM) on PPI-based triple therapy comparing the eradication rate and side effect with VPZ-based triple therapy. From January 2015 to December 2016, patients who received HP primary eradication therapy in our hospital were retrospectively evaluated. They were divided into three groups; 1) patients who received PPI+AMPC+CAM therapy (PPI group), and 2) patients who received VPZ+AMPC+CAM therapy (VPZ group), 3) patients who received PPI+AMPC+CAM+MBM therapy (PPI+MBM group), and the eradication rate and side effects were evaluated.

Results: The number of patients enrolled in this study were 468: 150 cases in the PPI group, 271 cases in the VPZ group and 47 cases in the PPI+MBM group. Successful rate of HP eradication was 81.7% in the PPI group, 89.8% in the VPZ group and 89.1% in the PPI+MBM group. The eradication rate in VPZ group was significantly higher than that of PPI+MBM group. The rate of side effect was 14.7% in the PPI group, 10.0% in the VPZ group and 19.1% in the PPI+MBM group, and there was no significant difference between 3 groups. Comparison shows that Clostridium butyricum Miyairi-588 can have additive effects in PPI-based triple therapy for HP.

P1915 “CONCOMITANT” OR “SEQUENTIAL” THERAPY FOR THE ERADICATION OF HELICOBACTER PYLORI: WHICH REGIMEN COMES FIRST IN MOROCCO?

A. Ait Errami, Z. Samlani, S. Ouabba, K. Krati

Repepato-gastroenterology, CHU Mohamed 6th V, Marrakech/Morocco

Contact E-mail Address: adil.ae@hotmail.com

Introduction: Morocco, an African country, the efficacy rates of the concomitant versus the sequential H. pylori eradication therapy. Our prospective randomized study included 164 patients with newly diagnosed H. pylori infection, randomized to receive a 14-day concomitant or 10-day sequential therapy. Treatment outcome was assessed by 13-cure breath test at 14 weeks after therapy. Intention to treat (ITT) and per protocol (PP) analysis of the eradication rates were performed.

Secondary end points included patient compliance and safety. Results: The concomitant therapy group achieved statistically significant higher eradication rates when compared with the sequential treatment group, both in the ITT and in the PP analysis (86.6% versus 79.9%, p<0.002, and 90.6% versus 72.1%, p<0.001, respectively), after adjusting for age, gender, smoking status, and the presence or not of concomitant eradication in whom showed played excellent compliance rates (99.5% for the concomitant therapy group and 96.2% for the sequential therapy group, p<0.007). Regarding treatment safety, major adverse events that led to the discontinuation of both regimens were few, with no statistical difference between the two groups (6.2% for the concomitant therapy group and 3.1% for the sequential therapy group).

Conclusion: Concomitant therapy led to statistically significant higher eradication rates over sequential therapy. Both therapies showed excellent compliance and an acceptable safety profile. The concomitant quadruple therapy scheme should be the adopted for first-line H. pylori eradication in Morocco.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1916 PROSPECTIVE COMPARATIVE STUDY OF TWO FIRST-LINE REGIMENS FOR HELICOBACTER PYLORI ERADICATION: 14-DAYS NON-BISMUTH QUADRUPLE OPTIMIZED CONCOMITANT THERAPY VERSUS 10-DAYS BISMUTH-CONTAINING QUADRUPLE THERAPY USING A THREE-IN-ONE CAPSULE

Department Of Digestive Diseases, Miguel Servet University Hospital, Saragossa/Spain

Contact E-mail Address: jalcedo@telefonica.net

Introduction: The Maastricht V/Florence Consensus Report recommends bismuth quadruple or non-bismuth quadruple concomitant therapies as first-line treatments for H pylori infection, in areas where clarithromycin resistance is high (>15%). Head-to-head studies between both therapies are needed.

Aims & Methods: We aimed to compare compliance, efficacy and adverse effects of two first-line H pylori eradication therapies in a high clarithromycin resistance rate.
area, and in clinical practice. A prospective study was performed in a Spanish center recruiting consecutive naive adult patients, candidates to H pylori eradication. Omeprazole 40mg, Clarithromycin 500mg, Amoxicillin 1g and Metronidazole 500mg, all drugs b.i.d, for 14 days (OCAM); or Omeprazole 20mg b.i.d and 3-in-1 capsule with Bismuth 140mg + Tetracycline 125mg + Metronidazole 125mg. 3 capsules q.i.d, for 10 days (3–1-OBMT) were prescribed according to physician criteria. Compliance was assessed by striking the consumed doses in a patient filled template, and adverse effects using a specific questionnaire with a 1–3 intensity scale. Efficacy was determined by 13C-urea breath test. A descriptive study and analysis of efficacy by intention to treat (ITT) were performed. Cases with poor therapeutic compliance (< 80%) or no available data were excluded in per-protocol (PP) analysis. Chi2, Student’s t, and Mann-Whitney U tests with significance level p < 0.05 were applied. The protocol was approved by the Ethics Committee. Results: 216 patients (63.43% women; mean age 51.53 ± 19.89 years) were included. OCAM were prescribed in 103 and 3–1-OBMT in 113. No differences in sex, age and functional dyspepsia as indication to eradicate were observed between groups. Main indications for treatment were functional dyspepsia (39.35%), gastroduodenal ulcer (19.44%) and non-investigated dyspepsia (13.89%). Compliance was < 80% in 11 patients and unknown in 7. The efficacy outcome was unavailable in 9 subjects. Compliance > 80% was maintained in 95% with OCAM and in 93.53% with 3–1-OBMT (p=0.064). The ITT rates were 82.52% vs 85.84% (p=0.63), and PP 89.47% vs 96.04% (p=0.13), for OCAM and 3–1-OBMT respectively. The outcomes of adverse effects (frequency, number, duration and intensity) are shown in the Table. Conclusion: In a high clarithromycin resistance area, 14-days OCAM and 10-days 3–1-OBMT regimens achieve high and similar compliance and efficacy rates, but 3–1-OBMT provides a superior safety profile. Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: Hp infection management at primary care level is inappropriate with low eradication rates. The introduction of a specific counselling to PCP has significantly improved these outcomes. These data should encourage the implementation of interventional strategies in order to reduce the actual increase in antibiotic resistance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1918 VALPROATE AND CHIR 99021 AMELIORATES RADIATION-INDUCED INTESTINAL EPITHELIAL INJURY IN MOUSE MODEL
Y. Kim, J.S. Shin
Internal Medicine, Division Of Gastroenterology, Korea Cancer Center Hospital, Seoul, Korea, Republic of

Contact E-mail Address: younjoo282@gmail.com

Introduction: Radiation-induced gastrointestinal syndrome (RIGS) stems from the clonogenic loss of crypt cells and villi depopulation and results in mucosal barrier disruption, bacterial invasion, inflammation and sepsis. Valproate (VPA) is the one of the popular anti-convulsants, recently its Notch signal modulatory effect has been reported. Notch signalling pathway is highly conserved, to maintain intestinal stem cells and to differentiate to secretory cells such as goblet cell. Moreover, it has been reported that combination of VPA and CHIR 99021 (GSK3β inhibitor) has powerful proliferative effect for intestinal stem cells, such as Lgr 5+ cells. One of the major difficulties for RIGS studies is the fact that crypts are not easily accessed and cultured with traditional means. Ex-vivo culture techniques for single crypt or a stem cell derived enteroid, with essential features of the in vivo tissue architecture, have been recently developed. Thus, we have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS.

Aims & Methods: We have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS. To culture enteroid, ten centimeters segments of jejunum were procured from 9–13 week-old C57BL6 mice. Crypts were isolated by EDTA chelation, suspended in Matrigel and grown in culture media containing epidermal growth factor, noggin, R-spondin 1. After 1 day in culture, the enteroids were treated (or not) 3 mM CHIR 99021 (GSK3β inhibitor) and 1 mM VPA. On day 3, the enteroids were irradiated as a dose dependent manner. The evaluation of irradiated enteroids was performed by measuring MTT assay, budding efficiency of enteroid, and EdU staining. On post-irradiation Day 2 and Day 7, RT-PCR was performed.

Results: Enteroid from mouse had multiple crypts (‘budding’) with well-differentiated goblet, Paneth cells, + stem cells (quiescence stem cells, BM1 is expressed), Lgr5+ stem cells. In the response of radiation, irradiated enteroid decreased proliferation rate in a dose dependent manner, as measured by MTT assay, and budding efficiency of enteroids. Irradiated enteroids with VPA +CHIR 99021 could maintain their + stem cells even in 10 Gy of irradiation, lethal dose of mouse intestinal epithelium, and they were able to proliferation. Combination of VPA = CHIR 99021 did not have an effect on paneth cells, enteroid differentiating goblet cells and stem cells.

Conclusion: VPA and CHIR 99021 may ameliorate RIGS in ex-vivo mouse enteroid, through +reservoir stem cell reservation and stimulatory action for epithelial proliferation. Considering their clinical application such as safety, they could be possible strategy for prevention and treatment of RIGS.

2 School Of Medicine, University of Tampere, Tampere/Finland
3Faculty Of Social Sciences, University of Tampere, Tampere/Finland

Contact E-mail Address: laura.kivel@utu.fi

Introduction: Celiac disease affects 1–2% of population, but due to diverse presentation many patients remain unrecognized. Diagnostic efficiency could be improved by screening of at-risk groups, but long-term benefits of this approach are unclear. To shed light to this issue, we compared a variety of celiac disease-related and other parameters in large cohorts of adult patients diagnosed in childhood either because of clinical suspicion or by screening.

Aims & Methods: A questionnaire about current health and lifestyle, adherence to gluten-free diet (GFD) and follow-up of celiac disease was sent to 654 adults with childhood diagnosis. Further, the participants fulfilled validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for symptoms and quality of life. Clinical and histological presentation at diagnosis and other relevant medical data were confirmed from patient records. All variables were compared between screen-detected and clinically detected patients.

Results: Altogether 235 (42%) adults completed the questionnaires. At diagnosis, screen-detected patients (n = 49) were older (11.3 vs 8.8 yr, p = 0.016) and had lower BMI (19.0 vs 20.8, p = 0.005). They also had a trend to have less symptoms (44% vs 85%, p = 0.001) than clinically detected patients (n = 186). They also had a trend to have less total vitrual alopecia (18% vs 32%, p = 0.075) and anemia (18% vs 32%, p = 0.072). The groups did not differ in gender, current age (median 26.5 vs 27.0 yr, p = 0.95) or education (41.5% vs 40.0%, p = 0.70). They had a trend to less from the diagnosis till current health or concern about health, clinical symptoms, strict GFD (74% vs 80%, p = 0.16), lifestyle restrictions caused by GFD, presence of celiac disease-related complications, physical activity, fertility or GSRS and PGWB scores. However, screen-detected patients smoked less (4% vs 15%, p = 0.037) and had more often celiac disease in relatives (78% vs 58%, p = 0.011).

Conclusion: Diagnostic approach and presentation of celiac disease in childhood do not seem to affect the long-term health outcomes or attitude towards the disease in adulthood. Lack of difference in the dietary adherence and lifestyle recommendations gives further support for active screening and early diagnosis of celiac disease.

P1924 CIRCULATING EXTRACELLULAR VESICLES, A NOVEL MECHANISM OF ENDOCINE CELLULAR CROSS-TALK, ARE INCREASED IN NEWLY DIAGNOSED CELIAC DISEASE PATIENTS

Department Of Medicine And Ageing Sciences And Center For Excellence On Ageing And Translational Medicine (cesi-met), “G. D’Annunzio” University and Chieti/Italy

Contact E-mail Address: effa78@gmail.com

Introduction: Extracellular vesicles (EVs) have been recently hypothesized to represent a major peripheral mechanism of cellular cross-talk. EVs carry surface receptors and proteins characteristic of their cells of origin and shuttle molecules (proteins, RNAs, microRNAs) potentially controlling physiological and pathologic systemic processes. Recent studies have demonstrated an increased number of circulating EVs in a variety of conditions characterized by multi-organ impairment and/or damage such as insulin-resistance, atherosclerosis and obesity. Celiac disease (CD) is an immune-mediated inflammatory enteropathy, triggered by gluten ingestion in genetically susceptible individuals. It is frequently associated with a variety of systemic conditions both autoimmune and potentially immune-mediated in nature.

Aims & Methods: The aim of this study was to assess and characterize patterns of circulating EVs in newly diagnosed CD patients. We enrolled consecutive adult anti-tTG positive, biopsy proven CD patients. Circulating EVs were identified untouched on whole blood samples by a no-lyse/no-wash method, combined with EVs volumetric count (FACSVerse, BD), based on a novel six-colour flow cytometry panel, in order to identify and enumerate both the whole EV compartment and different EV subpopulations. Data are expressed as mean ± SD and statistical differences were evaluated by means of T-test.

Results: We evaluated 12 CD patients (mean age 42.4 ± 19.1 vs. 40.8 ± 15.9 years, F/M = 4:1) at diagnosis and 12 age- and sex-matched healthy controls. Histology was considered positive for lesions of grade ≥B1 according to the Corazzi-Villanacci classification. Mean anti-tTG levels at diagnosis were 6.9 ± ± 3 times ULN. Mean number of total circulating EVs was significantly higher in CD than in controls (59895 ± 72482 vs 14383 ± 1008 EV/microL, p = 0.035). Subgroup analysis showed that EpCAM+ EVs, of epithelial origin, and CD41+ platelet-derived EVs were not significantly different between CD and controls (894 ± 1004 vs. 548 ± 1237 and 3052 ± 1563 vs. 1734 ± 1810 respectively, p = ns). On the contrary, CD45 + EVs, of leukocyte origin, showed a significantly higher number on the contrary patients vs. controls (460 ± 492 vs. 119 ± 150 p = 0.026).

Abstract No: P1923

Data on levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to treatment.

Data on levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to treatment.
Conclusion: Celiac disease patients at diagnosis show higher numbers of circulating CD8+ T cells, with a bias towards IFN-γ+ T cells, compared to the control group, which suggests that the presence of gluten induces a Th1 lymphocyte bias. Moreover, gluten-free diet can lead to a decrease in the number of IFN-γ+ T cells, which indicates the potential of gluten-free diet to modulate the immune response in celiac disease.

P1925 COELIAC DISEASE AND REPRODUCTIVE DISORDERS: IS THERE ANY CORRELATION

H. Boutallaka, I. Benbelharbadi, F.Z. Ajana
Medecine C, Ibn Sina University Hospital, Rabat-Morocco

Contact E-mail Address: hanaeboutallaka@gmail.com

Introduction: The coeliac disease is an autoimmune enteropathy induced by the ingestion of gliadin, which is a ubiquitous protein (Corn, barley, rye), that in genetically predisposed individuals, triggers the immune system leading to atrophic lesions of the small intestine, which can be accompanied by extraintestinal manifestations.

Aims & Methods: The aim of our study was to compare the two groups of patients with and without CD to evaluate the frequency of reproductive disorders in the two groups.

Results: About 241 patients suffering from coeliac disease, 58 patients presented reproductive disorders, either 28.9%. Recruiting 53 women and 5 men, with a sex ratio M/F of 10/6. The mean age was 32.2±5.2 years ranging from 13 to 59 years old. The diagnosis of coeliac disease was based on: Histology (severe or partial villous atrophy with intraepithelial lymphocytosis exceeding 30%), the antidiomysial antibodies and/or antitransglutaminase antibodies positive. The reproductive disorders were never isolated but always associated with digestive or extradigestive signs at the time of the diagnosis of coeliac disease. These disorders were divided into two groups: 1/11 cases (19%), secondary amenorrhea and/or IUGR in 6 cases (10.3%), premature labour one case, and one case was delivered a baby in term after a repeated premature deliveries. The evolution was good in 3 cases as regard missed abortion four years after the gluten-free diet in 1 patient, and amenorrhea continued in 2 cases.

Conclusion: Reproductive disorders related to the coeliac disease were frequent and variable. In our study, these disorders well responded to the gluten-free diet in 90% of cases, and these disorders were reversible under gluten-free diet.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1926 SEVERITY OF MUCOSAL DAMAGE AND TISSUE TRANSGLUTAMINASE ANTIBODY LEVELS CORRELATE WELL IN ADULT CELIAC DISEASE IRRESPECTIVE OF CLINICAL FEATURES

R. Maxim1, A. Trifan2, A. Pleas3, S. C. Oana Cristina1, I. Ciortescu3, I. Girlea2, C. Stanciu1

Contact E-mail Address: ancatrifan@yahoo.com

Introduction: Celiac disease (CD) is a chronic imune-mediated enteropathy that occurs in genetically predisposed individuals. The clinical phenotypes ranges from classical gastrointestinal manifestations to only atypical signs, thus making the clinical diagnosis a challenge. The aim of the study was to investigate the relationship between duodenal histology, specific antibody levels and clinical presentation in adult CD Romanian patients.

Aims & Methods: The study group included 81 adult patients with a female: male ratio of 38yrs/ 47yrs, mean age 40.0±2.12 years. A total of 46.1% patients presented with gastrointestinal (GI) complaints and 51.9% of patients presented mostly with non-GI manifestations, and advanced age of symptom onset in the latter category (38yrs ≥ 47yrs). Marb-Oberhuber classification was used to assess mucosal injury and Marsh 3c lesions were found in 25 (30.9%) cases. When assessing the serological parameters, IgA anti-tissue transglutaminase (IgA-tTG) antibody (61.45±1.67.458 u/mL vs 162.02±10.167 u/mL, P = 0.001) and IgA anti-gliadin antibodies (IgA-AGA) levels (61.83±6.941 u/mL vs 77.15±71.02 u/mL, P = 0.001) correlated with intestinal villous atrophy (Marsh 3b-3c) in CD patients by Spearman rank correlation. Among symptomatic, abdominal distention and diarrhea were associated with abnormal histology. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients among patients with elevated IgA-tTG levels (r = 0.516, P = 0.004), IgA-AGA (r = -0.301, P = 0.006) and Marsh 3b-3c lesions (P = 0.0048). Among biological markers included in the statistical analysis, low iron levels (cut off 30 mg/dl), hypocholesterolemia and low protein levels were associated with Marsh 3b lesions (P = 0.008) and elevated IgT-AGA titers (r = -0.384, P = 0.001). Correlation between IgA-tTG and AGA levels correlate with duodenal villous atrophy in adult CD patients. An IgA-tTG titer >160 was nearly always associated with severe CD histopathology. GI and non-GI symptoms are not reliable predictors of CD.

Disclosure of Interest: All authors have declared no conflicts of interest.
recommendations. Paraffin embedded biopsy samples were assessed for villous height (VH), crypt depth (CD) and VH:CD ratio. The corre-
sponding frozen duodenal samples were assessed for duodenal IgA deposits tar-
getting transglutaminase 2 (TG2-IgA), density of CD3 (cut-off 37 cells/mm epithelium) and γδ T cell receptor bearing intraepithelial lymphocytes (IELs (cut-off: 4.3 cells/mm epithelium). The study was approved by the Local Ethical Committee.

Results: Altogether 41 patients, mean age 45 ± 14 years, 61% female, were recruited. Among these, 21 were finally diagnosed as adult CD (mean TG 156 ± 50, CD 50 ± 26, and VH:CD ratio critically low). As expected or newly-diagnosed coeliac disease of whom 76 (89%) were referred with positive coeliac serology and would be subject to the 6-week target. Six patients declined or delayed endoscopy, and endoscopy or referral information were not available for 4 patients. For the remaining 66 patients, median time from referral to diagnosis was 12 weeks (SD 37 days), with up to 59 patients (80%) within 18 weeks, but only 11 patients (17%) within 6 weeks (Figure 1). Duodenal bulb biopsies were taken at endoscopy in 31 patients (44%). A diagnosis of coeliac disease was made in 74 (87%) of all patients referred, of whom 67 (90%) were referred to a specialist dietitian. Haematomics (iron studies, vitamin B12 and folate) were measured in 67 patients (90%), bone densitometry was measured in 51 patients (69%) and all patients were offered a follow-up appointment in the coeliac clinic. Iron deficiency was found in 31 patients (45%) of patients tested, folate deficiency in 12 patients (18%), vitamin B12 deficiency in 5 patients (7%) and vitamin D deficiency in 23 patients (38%). Osteoporosis was diagnosed in 5 patients (10%) and osteopenia in 10 patients (20%).

Conclusion: Appropriate dietitian referral, specialist follow-up and screening for nutritional deficiency and bone disease occur within the Oxford coeliac disease service. Compliance with recommended biopsy protocols was only 44%. Whilst most referrals met the previous 18-week RRT pathway, few would have met the new quality standards.

Introduction: We previously reported that small-bowel capsule endoscopy (CE) is effective in diagnosing small-bowel lesions with occult obscure gastrointestinal bleeding (OGIB) (Gastroenterol Rex Pract. 2013). However, there is no consensus regarding the management of occult OGIB patients without bleeding source revealed by CE.

Aims & Methods: We aimed to consider management of occult OGIB patients based on the long-term outcomes. A total of 357 consecutive occult OGIB patients (203 men; mean age: 59.7 years) who underwent CE at Hiroshima University Hospital before March 2016 and whose entire small-bowel could be observed and followed-up by CE for at least 12 months, were enrolled. We examined each patient to confirm the positive CE findings rate, the detection rate of bleeding source lesions, the details of bleeding source lesions, the overt

Introduction: Quality standards in coeliac disease management were recently published by the National Institute for Health and Care Excellence2. These specify a new 6-week target for the time from referral to endoscopy, which was previously covered by the 18-week referral to treatment (RTT) pathway1. They also state that all newly-diagnosed patients should discuss a gluten-free diet with a specialist dietitian. We retrospectively evaluated practice in the Oxford University Hospitals NHS Foundation Trust coeliac clinic against these criteria, and against national guidelines (duodenal bulb sampling at endoscopy and screening for nutritional deficiency1).

Aims & Methods: The medical records of 110 patients referred to our clinic between September 2015 and September 2016 were examined. The date of referral and endoscopy were recorded, along with relevant demographic, clinical and laboratory information. Data were collected and analysed in Microsoft Excel.

Results: Eighty-five patients (68% female, median age 34) were seen with suspected or newly-diagnosed coeliac disease of whom 76 (89%) were referred with positive coeliac serology and would be subject to the 6-week target. Six patients declined or delayed endoscopy, and endoscopy or referral information were not available for 4 patients. For the remaining 66 patients, median time from referral to diagnosis was 12 weeks (SD 37 days), with up to 59 patients (80%) within 18 weeks, but only 11 patients (17%) within 6 weeks (Figure 1). Duodenal bulb biopsies were taken at endoscopy in 31 patients (44%). A diagnosis of coeliac disease was made in 74 (87%) of all patients referred, of whom 67 (90%) were referred to a specialist dietitian. Haematomics (iron studies, vitamin B12 and folate) were measured in 67 patients (90%), bone densitometry was measured in 51 patients (69%) and all patients were offered a follow-up appointment in the coeliac clinic. Iron deficiency was found in 31 patients (45%) of patients tested, folate deficiency in 12 patients (18%), vitamin B12 deficiency in 5 patients (7%) and vitamin D deficiency in 23 patients (38%). Osteoporosis was diagnosed in 5 patients (10%) and osteopenia in 10 patients (20%).

Conclusion: Appropriate dietitian referral, specialist follow-up and screening for nutritional deficiency and bone disease occur within the Oxford coeliac disease service. Compliance with recommended biopsy protocols was only 44%. Whilst most referrals met the previous 18-week RRT pathway, few would have met the new quality standards.

References
bleeding rate with or without treatment, the rate of anaemia exacerbation (hemo-
globin <10 g/dl), 5 year overall survival rate (OS), and 5 year disease specific survival rate (DSS). Occult OGIB was defined as recurrent or persistent iron deficiency anaemia with or without a positive faecal occult blood test and no bleeding findings by esophagogastroduodenoscopy and colonoscopy. Result: Results: The positive CE findings rate was 44% (157/357) and the detection rate of bleeding source lesions was 27% (98/357). All of the treated recurrent bleeding source lesions (Group A) were as follows: angioectasia 61 patients (Yano-Yamamoto classification Type 1a 37 patients, Type Ib 24 patients), non-specific ulcers, gastrointestinal anti-inflammatory drugs-independent ulcer, 3 patients, hemangioma 5 patients, Crohn’s disease 3 patients, primary cancer 2 patients, metastatic cancer 2 patients, gastrointestinal stromal tumour 2 patients, malignant lymphoma 2 patients, others 3 patients. Lesions that were not regarded as bleeding source lesions (Group B) were as follows: angioectasia 25 patients (Type 1a without oozing 25 patients), erythema 31 patients, others 3 patients. There were no patients with overt bleeding in Group B. Although 6 patients (10%) had anaemia exacerbation in Group B (Type 1a), this was not a bleeding source lesion. On the other hand in both Group A and Group B was 90%. DSS in Group A was 99% and in Group B was 100%. One patient in Group A died of a primary small-bowel cancer.

Conclusion: Conclusion: Long-term outcomes with occult OGIB patients were good except malignant tumor, because overt bleeding and/or anaemia exacerbation did not occur within the follow-up period. Thus, occult OGIB patients without bleeding source lesions, including Type 1a angioectasia without oozing, and erythema, are unnecessary to follow-up with CE in occult OGIB patients.

2Department Of Clinical Chemistry, AMNCH Tallaght, Dublin/Ireland

Contact E-mail Address: donal.tighe83@gmail.com

Introduction: Small bowel capsule endoscopy (SBCE) is a very useful method of investigating iron-deficient anaemia, or occult gastrointestinal (GI) bleeding. It can detect lesions of anaemia or bleeding, such as angiodysplasia, small bowel Crohn’s disease, polyps, lymphoma, and malignant lesions. There is however a need to improve the diagnostic yield, particularly where resources and access to capsule endoscopy are restricted. Faecal immunochromatographic test (FIT) has an established role, in investigating large bowel bleeding, and is incorporated into a number of bowel cancer screening programmes.

Aims & Methods: The aim of our study was to investigate whether FIT could help predict likelihood of small bowel bleeding or other significant pathology at time of small bowel capsule endoscopy. This was a prospective pilot study, performed at our centre from September 2016-April 2017. Indications for enrolment were referred for SBCE with the indication of anaemia or occult GI bleeding. Baseline patient characteristics were obtained including age, gender, history of radiation therapy, disease, transfusion requirements and use of anti-coagulants/anti-platelets. Patient haemoglobin (Hb) level was checked on the day of SBCE where possible. Patients were asked to return one completed FIT for further analysis. A cut of 50 ng/ml was used in this standard cut-off used, in the Irish National Bowel Cancer Screening programme.

Results: A total of 40 patients were enrolled, mean age 55.4 years (range 18–77), 64% were female. A total of 27.6% of patients were on anti-platelet agents or anti-coagulants. 34% of patients had a blood transfusion within the last year. Mean Hb for the cohort was 12.8 g/dl (range 7.8-15.9 g/dl). The average FIT reading was 459 ng/ml (range 0-4426 ng/ml). 30% of patients had a FIT level >50ng/ml. 46% of patients, had positive findings at SBCE. 9/12 (75%) of patients with a FIT level >50ng/ml had positive findings at capsule endoscopy compared to 5/28 (17.8%) for FIT <50 ng/ml, p value = 0.02, 95% C.I 0.29–0.86 O.R. 0.16. These included 4/12 (33%) new cases of Crohns, 3/12 (25%) angiodysplasia, 3/12 (33%) non-HB enteritis, 1/12 (16.7%) small bowel tumour, 1/12 (16.7%) melanoma, with no clear source. In addition there was a good correlation between FIT and Haemoglobin levels. 60% of patients with FIT >90ng/ml were anaemic (Hb <11.5 g/dl), compared to 17% with FIT <90ng/ml, p value = 0.02 95% C.I 0.09–0.76 O.R. 0.14. Combining Hb and FIT levels, was also informative and predictive of small bowel pathology.

83% of patients, who were anaemic and had a FIT >50 ng/ml had clinically significant findings at SBCE compared to 21% pick up rate in patients with normal Hb and FIT levels, p value = 0.05 95% C.I 0.22–1.03 O.R. 0.05. Overall the sensitivity for a FIT >50 ng/ml for detecting small bowel pathology was 83% with a specificity of 92%, giving a positive predictive value of 83.3% (95% C.I. 56%-95%). Antiplatelet use was not predictive of a positive FIT, as 16.7% of patients with a FIT >50 ng/ml were on anti-platelet agents, compared to 83.3% who weren’t.

Conclusion: FIT is useful at predicting clinically significant small bowel pathology at the time of capsule endoscopy. It may help better identify and prioritise patients who would benefit from referral.

Introduction: The features of the portal hypertension enteropathy (PHE) vary from mucosal to submucosal ulceration. The prevalence and the correlation of factors that predict the development of PHE are not fully understood.

Aims & Methods: Our aim in this study is to examine the prevalence of the different manifestations portal hypertensive enteropathy and its correlation with the Child-Pugh score (CTP) in cirrhosis using video capsule endoscopy (VCE). At a single center, we performed a retrospective chart review study of patients between the age of 18 and 80 with cirrhosis, who had VCE study between January 2010 and January 2016. Based on the published literature, we divided the portal hypertensive enteropathy lesions in our study into vascular lesions (arteriovenous malformation (AVM), red spots, bleeding or varices) and mucosal lesions (mild inflammatory changes or severe inflammatory changes which are a mosaic, congested and friable mucosa).

Results: 100 patients with cirrhosis had a VCE study. The mean age was 62.82 years. Male gender was predominant with a 64%, while the Caucasians represented 82% of the cohort. The most common etiologies of the cirrhosis were chronic alcohol abuse followed by chronic hepatitis C virus (HCV) and non-alcoholic steatohepatitis (NASH)(table 1A. The average MELD score was 13.86(±6.66). VCE detected small bowel lesions in 71% of the patients while the features of portal hypertensive enteropathy were found in 5% from the total cohort. AVMs and Inflammatory changes were the most common findings, followed by bleeding. 13 patients found to have two or more lesions by VCE. More than 50% of the lesions were vascular in nature (table A1). The percentage of the CTP A, CTP B and CTP C was 46%, 42% and 12% respectively. The odds of finding portal hypertensive enteropathy in decompensated cirrhosis is twice that in compensated cirrhosis (odd ratio of 2.0) table 1B. 45 patients had negative EGD exam for any active bleeding, esophagael varices (EV), portal hypertensive gastropathy(PHG) or gastric varices(GV). 31 of them (69%) had features of portal hypertensive enteropathy in their VCE. table 1B.

(continued)
Results: Data were collected from 1052 patients with obscure gastrointestinal bleeding associated with overt SBB using a case-crossover design. The Japanese Association for Capsule Endoscopy (JACE) has recommended examining patients with overt SBB who have previously undergone DBE using endoscopy including DBE (within less than 48 hours) and/or contrast-enhanced computed tomography (CECT) was performed in all patients. The bleeding source was identified in 17 of 19 patients (89.4%). The bleeding source were diverticula, and polyps. Loxoprofen-associated SBB was caused by mostly loxoprofen-induced injuries. The aim of this study is to evaluate long-term outcomes in patients with negative balloon assisted enteroscopy for suspected overt small bowel bleeding (obscure-overt gastrointestinal bleeding). The results were published among Western and Eastern studies.

Conclusion: VCE detected small bowel lesions in 71% in our cohort. There is a high prevalence of PHE in patients with decompensated cirrhosis. Vascular lesions are the most common finding in the small bowel of this population. Disclosure of Interest: All authors have declared no conflicts of interest.

References

Conclusion: Enteric-coated aspirin, clopidogrel, and loxoprofen were identified as risk factors causing overt SBB during a relatively short period after administration. Disclosure of Interest: All authors have declared no conflicts of interest.

P1937 DOES DISCONTINUATION OF ANTITHROMBOTIC AGENTS AFFECT DIAGNOSTIC YIELD OF SMALL BOWEL CAPSULE ENDOSCOPY IN PATIENTS WITH OBSURE GASTROINTESTINAL BLEEDING?

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy (CE) is a useful and noninvasive modality for investigation of the small intestine, and currently, it has become the first-line method for the diagnosis of obscure gastrointestinal bleeding (OGBB). Use of antithrombotic agents including antiplatelets and anticoagulants is associated with gastrointestinal bleeding. Antithrombotic users account for a large portion of patients with OGBB, and those with OGBB often undergo CE. It should be noted that some patient with over OGBB discontinue antithrombotic agents at the time of CE, which may affect endoscopic findings.

Aims & Methods: To examine the effect of discontinuation of antithrombotic agents on the diagnostic yield of CE, and to assess the predictive factors associated with positive CE findings in patients using antithrombotics who developed overt OGBB. Between March 2004 and December 2015, 130 consecutive patients (75 male; mean age, 71.9 years) taking antithrombotics who underwent CE for overt OGBB were enrolled, whereas patients who underwent double-balloon endoscopy prior to CE were excluded. Findings were considered positive if the observed lesions could explain the bleeding, while findings including isolated red spots and a single small polyp were considered negative. The primary endpoint was the difference in the rate of positive CE findings between patients who continued and those who discontinued antithrombotic agents. Furthermore, a propensity score analysis was performed to reduce the effects of selection bias and potential confounding factors. The secondary endpoint was to assess the predictive factors for the positive CE findings by using multiple logistic regression.

Results: Of the 73 patients who continued antithrombotic agents, 36 (49.3%) patients had positive findings in the small intestine (ulcer/erosion [n = 24], angioectasia [n = 7], tumor [n = 4], and blood pooling [n = 1]), while of the 57 patients who discontinued these agents, 35 (61.4%) patients had positive findings (ulcer/erosion [n = 17], angioectasia [n = 11], tumor [n = 3], and blood pooling [n = 4]). The rates of positive CE findings did not differ between the two groups. Even after propensity score matching, discontinuation of antithrombotic agents did not affect the positive CE finding. In multivariate analysis, the lowest hemoglobin level before CE examination was an independent predictive factor associated with positive CE findings. The odds ratio per 1 g/dL increase in the lowest hemoglobin level was 1.04 (95% confidence interval, 0.97-1.08). However, other factors, including sex, age, and discontinuation of antithrombotic agents, were not associated with positive CE findings.

Conclusion: Discontinuation of antithrombotic agents did not affect the diagnostic yield of CE with overt OGBB, and lowest hemoglobin level was associated with positive CE findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1938 EFFICACY OF REBAMIPIDE TO PREVENT LOW-DOSE ASPIRIN-INDUCED SMALL INTESTINAL INJURY

S. S. Vylow
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: ssvylow@mail.ru

Introduction: Long-term use of low-dose aspirin (LDA) is associated with development of peptic ulcers, gastrointestinal bleeding, enteropathy. For prevention of LDA-induced small intestinal mucosal injury, there is no established prophylactic agent (PPI) that are the first-line therapy according to several guidelines. However, gastric acid suppressants, like PPI, do not prevent small intestinal mucosal injury. The latest clinical trials showed that rebamipide stimulates the production of prostaglandins, thereby preventing mucosal injury. This could improve mucosal breaks in small intestine in patients receive LDA.

Aims & Methods: We aimed to investigate the protective role and efficacy of rebamipide for prevention low-dose aspirin-induced small intestinal mucosal injury and enteropathy. Subjects comprised patients undergoing longlife low-dose aspirin therapy prescribed by cardiologist. Patients with a high-risk of gastrointestinal bleeding were excluded. This trial was performed as a randomised open-labelled clinical study with the permission of an institutional review board. The trial was included 100 patients (50 cases in each group) received enteric-coated low-dose aspirin 100 mg. The Group PPI received LDA plus pantoprazole 40 mg, the Group RBD received plus rebamipide 300 mg. Before starting therapy, we checked the background characteristics of each patient (H.pylori, use of LDA, NSAID, bismuth, PPI; and endoscopic findings). Gastric endoscopy and capsule endoscopy were performed, and the fecal occult blood reaction and fecal calprotectin levels were measured before, two and four weeks after drug administration. After the therapy, we asked physicians and patients about medication compliance and side effects. Capsule endoscopy was then repeated. The primary endpoint was the change in the number of mucosal breaks from baseline to 4 weeks. The secondary endpoints were the rates of side effects.

Results: The fecal calprotectin levels increased significantly in Group PPI, they did not increase in Group RBD. The mean number of small intestinal injuries by capsule endoscopy in Group PPI increased significantly up to 3.9 after 4 weeks of LDA treatment. There was not detected new small intestinal injuries in Group RBD. Stomach ulcer, bleeding or stenosis were not found in any subject. There were no significant differences in the presence of fecal occult blood in both groups. There were no significant side effects in Group RBD.

Conclusion: In conclusion, rebamipide is effective and sufficient for preventing mucosal injury of the small intestine induced by low-dose aspirin. These results show the gastroprotective and enteroprotective effects of rebamipide, suggesting that it may be a good choice in low-dose aspirin users with gastrointestinal toxicity that is not suppressed by acid suppressants alone.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Patients suspected of CMI referred were included consecutively from January 2014 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography or MR-angiography, and a mucosal ischemia test (visible light spectroscopy or tonometry), all patients were discussed in a specialized CMI multidisciplinary meeting resulting in an expert based consensus diagnosis. All patients with a CMI consensus diagnosis were planned for treatment (revascularization or endovascular therapy). Treatment was performed if successful treatment resulted in durable symptom relief. The definitive diagnosis of CMI was made if successful treatment resulted in durable symptom relief. The score chart to predict the risk of CMI was computed for each patient.

Results: A total of 246 patients were included and consensus diagnosis of CMI was made in 108 (44%) patients, which resulted in 96 (39%) patients with a definitive diagnosis of CMI after a positive response therapy. A definitive diagnosis of CMI was made in 9% of the patients with low risk, in 40% of the patients with intermediate risk and in 94% of the patients with high risk of CMI. Diagnosis of CMI was more frequent in patients with abdominal symptoms (70/92) compared to patients with only gastrointestinal symptoms (55/104). In 20% of the patients with abdominal symptoms no CMI consensus diagnosis was obtained. A definitive diagnosis of CMI after a positive response therapy was achieved in 108 (44%) patients, which resulted in 96 (39%) patients with a CMI consensus diagnosis were planned for treatment (revascularization or endovascular therapy).

Conclusion: The score chart for CMI based on patient characteristics and anatomy is a reliable tool to discriminate the risk of CMI and useful for clinical decision-making, for example to adopt a wait-and-see policy in patients with a low risk and immediate vascular intervention in patients with high risk of CMI.

Disclosure of Interest: All authors have declared no conflicts of interest.

BACKGROUND:

Endoscopists may need to perform repeat endoscopy with argon plasma coagulation (APC) in patients with angiodysplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding. The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodysplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodysplasias.

METHODS:

The study included 197 patients with proven angiodysplasia as cause for anaemia (mean age 43.6 years; 58% male). Median follow-up was 40 years old [13,79]. The following chart summarizes the digestive manifestations (%):

Patients symptoms and clinical findings were: Abdominal pain in 32 cases (22.9%), nausea and vomiting in 7 cases (5%), stool modification in 15 cases (10.7%), jaundice in 4 cases (2.9%), dysphagia in cases (7.1%), hematemegaly in 4 cases (2.9%), splenomegaly in 8 cases (5.7%), ascitis in 13 cases (9.3%), digestive bleeding in 17 cases (12.1%). Laboratory findings: elevated liver enzymes in 18 cases (15.9%), alkaline phosphatase elevation in 15 cases (19.2%). Radiological findings: 17 ascitis (14.4%), 12 digestive thickening (10.16%), 6 hematemegaly (5.08%), 14 splenomegaly (11.86%), 2 portal cavernoma (1.6%), 3 portal thrombosis (2.5%), 4 esophageal distension (3.4%), acalculous cholecystitis in 2 cases (1.6%), 2 portal hypertension (1.6%), steatosis in cases (2.5%), 3 hepatic angioma (2.5%), acute pancreatitis in 2 cases (1.6%), 2 mesenteric ischemia (1.6%), 1 Budd Chiari (0.8%), 1 hepatic carcinoma (1.8%). Upper gastrointestinal Endoscopy findings: hiatus hernia in 3 cases (8.6%), esophagitis in 11 cases (31.4%), esophageal varices in 2 cases (5.7%), Gastritis in 14 cases (37.8%), duodenitis in 14 cases (37.8%), ulcers in 3 cases (8.6%), 4 celiac disease (11.42%). Lower GI endoscopy: Crohn’s disease in 1 case (8.3%), ulcerative colitis in 1 case (8.3%), 1 hyperplastic polyp (8.3%), 2 colitis (16.6%). Esophageal manometry: motility disorder in 4 cases. The most used drugs were immunosuppressive drugs, steroids and hydrochloroquine, all causing digestive side effects mainly abdominal pain.

Conclusion: The digestive involvement is around 10% of cases in the most representative systemic diseases, the main symptom is abdominal pain probably related to medication, endoscopic modifications are mainly non-specific but we found some association with celiac disease and IBD. Liver involvement was noticed in 15% of cases.

P1944 CHANGES IN LEVELS OF VITAMIN D IN OBESE PATIENTS SUBMITTED TO BARIATRIC SURGERY

A. Vaz, R. Guerreiro, D. Sousa, P. Queiroz, T. Gago, J. Roseira, H. Guerreiro

Introduction: An association between obesity and vitamin D deficiency has been reported in several studies. This may be explained, among other things by the sequestration of the fat-soluble vitamin D in the adipose tissue. Bariatric surgery, including Roux-en-Y gastric bypass (RYGB) is an effective treatment for more extreme cases of obesity, promoting significant weight loss and consequently reduction in some obesity-related health problems. However, the problem of vitamin D deficiency doesn’t seem to be solved after RYGB and can even be exacerbated by the changes in digestion and absorption of this nutrient after the surgery.

Aims & Methods: The aim of this study was to analyze the prevalence of vitamin D deficiency (VDD) and vitamin D insufficiency (VDI) in a population of obese patients, before and after being submitted to RYGB. We included patients submitted to RYGB for obesity. We measured anthropometric variables and the levels of 25-hydroxyvitamin D (25(OH)D) before and 1 year after the procedure. VDD was defined as serum 25(OH)D <20ng/mL and VDI as serum 25(OH)D concentrations between 20-30ng/mL. Levels of 25(OH)D >30ng/mL were considered normal.

Results: We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6±13.1 years. The mean BMI before surgery was 41.6±kg/m². There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before
bariatric surgery, 52.3% of patients had VDD and 36.8% had VDI. After surgery, the number of VDD increased to 71.1% (p = 0.0079). The mean levels of 25(OH)D decreased significantly from 19.8 ng/mL before surgery to 16.6 ng/mL after surgery (p < 0.05). There was no correlation between the amount of weight loss and the changes in the levels of 25(OH)D in our study.

Conclusion: There is a high prevalence of vitamin D deficiency in obese patients eligible for bariatric surgery. The level of deficiency tends to increase after RYGB. This population of patients should, therefore, be offered an adequate level of vitamin D supplementation, especially after the procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1946 INTRAGASTRIC BALLOON: A CRITICAL VIEW IN NON ELECTIVE BARIATRIC SURGERY PATIENTS

R.J.F. Fernandes1, E. Usuy2, C.F. Dietel3, S. Barrichello1, A. F. Teixeira3, M. Galvao Neto3

3 Bariatric Endoscopy, Gastro Obeso Center, São Paulo/Brazil

Contact E-mail Address: ricfittipaldi@hotmail.com

Introduction: Bariatric surgery is established as an excellent therapy for obesity. However, lower degrees of overweight without surgical indication also impact on patients’ health and quality of life, and the intragastric balloon (IGB) may be a treatment option.

Aims & Methods: We aimed to assess the efficacy of excess weight treatment with an IGB in patients with overweight and grade I obesity at EndogastroRio Clinic. A total of 717 patients were analyzed. A liquid filled IGB was used. The patients had initial body mass index (BMI) between 27 and 34.9 kg/m². The level of significance was set at p < 0.05.

Results: 615 patients were women. 131 patients had overweight and 586 had grade I obesity. Mean age was 37.97 years (17-75). Weight loss results and treatment success rates are shown on table 1. Percent excess weight loss (%EWL) was higher in overweight group (p < 0.0001) and percent total body weight loss (%TWBL) was higher in the grade I obesity group (p = 0.0009). 96 (73.28%) overweight patients and 132 (22.52%) grade I obesity patients reached a normal BMI (< 25 kg/m²).

*p < 0.0001 for all comparisons between values at baseline and at the end of the study. IGB = intragastric balloon; BMI = body mass index; TWBL = total body weight loss; EWL = excess weight loss. Success rates (criteria: ≥10% TWBL or ≥25% EWL).

Conclusion: Endoscopic treatment of obesity with an IGB shows to be an excellent therapeutic option to non elective patients for bariatric surgery according to BMI criterion.

Introduction: Intragastric balloons (IGB) are already used worldwide in the treatment of overweight and obesity, with established success. The Spatz3® adjustable balloon brings the possibility of balloon volume control during all the treatment, possibly reducing the risk of early removal due to intolerance and greater weight loss compared to traditional IGBs.

Aims & Methods: We aimed to analyze the initial 25 months results regarding weight loss and complications with Spatz3® adjustable intragastric balloon in Brazil. In this retrospective longitudinal study were included patients submitted to Spatz3® adjustable IGB treatment between October 2014 to April 2017 in four private clinics in Brazil. The IGB Spatz3® was filled with a standard volume of 600 ml that was downward or upward adjusted when necessary. The patients presented a minimum body mass index (BMI) of 27 kg/m². Were analyzed the complications of Spatz3® treatment and BMI reduction, percent total body weight loss (%TWBL) and percent excess weight loss (%EWL). Data were analyzed using descriptive statistic and the Student t test. The level of significance was set at p < 0.05.

Results: 422 patients underwent implant Spatz3® balloon in the period. The complications (14.28%) at the present study were: early balloon removal (6.89%), gastric ulcer (3.94%), spontaneous deflation (1.48%), gas production inside the balloon (0.98%), gastric perforation (0.23%) and Malory Weiss Syndrome (0.23%). There was no death at the present study. Twenty-eight patients underwent downward adjustment due to intolerance (mean volume reduction: 162.86 mL) and all of then kept in the treatment (no early removals). 180 patients have completed the treatment (minimum 9 months of gastric balloon stay). The BMI decreased from 37.69 to 31.51 kg/m² (p < 0.0001), body weight decreased from 107.67 to 90.16 kg (p < 0.0001) and excess weight diminished from 36.79 to 19.27 kg (p < 0.0001). Eighty-six patients underwent upward adjustment. The adjustment resulted in a further mean weight loss of 4.2 kg (p < 0.0001) and excess weight diminished from 107.67 to 90.16 kg (p = 0.079). The mean levels of 25(OH)D decreased significantly from 19.8 ng/mL before surgery to 16.6 ng/mL after surgery (p < 0.05). There was no correlation between the amount of weight loss and the changes in the levels of 25(OH)D in our study.

Conclusion: This study shows that Spatz3® IGB treatment is an effective procedure for weight reduction, without mortality but with higher morbidity rates when compared to traditional IGBs. Even more, the downward adjustment treatment seems to be effective in preventing the early balloon removal. Although the upward adjustment does not show to be able in providing a greater weight loss.

**P1948 VOMITING FREQUENCY AFTER INTRAGASTRIC BALLOON PLACEMENT AND INTRAVENOUS HYDRATION REQUIREMENT**

T. F. Souza1, R.J.F. Fernandez2, E. Usuy3, T. F. Teixeira4, M. Galvao Neto5, A. F. Teixeira1, E. Grecco6

**Introduction:** The endoscopic treatment of obesity and over weight with intragastric balloon (IGB), is a safe and effective option. Nausea and Vomiting are the most common side effects after IGB implant.

According to A. Scaduto Sanches, 71.1% of patients experience nausea and 57.9% have vomiting requiring treatment. 65.61% of patients showed that nausea and vomiting are the fifth leading cause of early accessory expellation. The reported symptoms are more common in first 3 days post implant.

**Aims & Methods:** Evaluation of frequency of vomiting and number of patients requiring intravenous hydration (HEV) after gastric balloon placement. This was a retrospective analysis of medical records of 340 obese and overweight patients treated with intragastric balloon, between November 2013 to December 2016 in the Department of Digestive Endoscopy of the Hospital Mario Covas. The implant was performed by 3 endoscopists with experience in bariatric endoscopy, all procedures were performed under moderate sedation and anesthetist’s care.

All other authors have declared no conflicts of interest.

**Results:** There were 340 patients treated with intragastric balloon between 2015 and 2016. The present study showed 74.41% vomiting until the third day after placement of the IGB, and it is in accordance with literature. Those 252 patients who had vomiting, 67.58% presents frequency of 0 to 5 times per day and 32.42% of the patients showed that nausea and vomiting were about the numbers and frequency of vomiting and if there was need for intravenous hydration during the first three days after intragastric balloon implant.

**Conclusion:** Gastric balloon causes vomiting in the early days post implant in 74.41% of patients and cause dehydration requiring Intravenous fluid therapy in 74.41% of patients and cause dehydration requiring IVF therapy in 74.41%

**Aim & Methods:** To evaluate the efficacy and complications of excess weight treatment with an IGB has been shown to be effective for the treatment of excess weight.

**Aims & Methods:** We aimed to assess the efficacy and complications of excess weight treatment with a non adjustable IGB. A liquid-filled IGB with a volume of 600 to 700 ml was used. The patients had a minimum initial body mass index (BMI) of 27 kg/m² and were followed up by a multidisciplinary team consisting of a nutritionist, a doctor and a psychologist.

For statistical analysis, the patients were divided into groups according to sex and degree of excess weight (overweight and grade I, II and III obesity). Data was analyzed using descriptive statistical methods, the Student’s t-test and analysis of variance followed by the Tukey post-test. The level of significance was set at p < 0.05.

**Results:** A total of 5874 patients were analyzed. The incidence of complications was 7.32% (n=430), as listed below: 299 (5.09%) early IGB removal, 58 (0.98%) absence of weight loss or weight gain. The incidence of gas production inside the balloon was 0.20% (n=12) and the incidence of leakage was 0.54% (n=32); pregnancy was 0.32% (n=19); gastric perforation was 0.006% (n=4); upper gastrointestinal bleeding was 0.05% (n=3); Wernicke Korsakov syndrome due to excessive vomiting was 0.01% (n=1); pancreatitis and esophageal perforation was 0.01% each (n=1). Of the 5444 remaining patients, 4081 (74.9%) were women and 1363 (25.1%) were men. Mean age was 38.38 years. The patients showed a significant weight loss, with a significantly lower final BMI (mean: 30.08 ± 5.06 kg/m²) than the initial BMI (mean: 36.94 ± 5.67 kg/m²) (p < 0.0001). Mean BMI reduction was 6.85 ± 3.06 kg/m² (range: 0.25–29.79). Mean percent total body weight loss (TBWL) was 18.42 ± 7.25% and mean percent excess weight loss (EWL) was 65.66 ± 36.24% (range: 3.99–336.14). The weight loss in kilograms was 19.13 ± 8.86. The treatment success rate (%EWL > 25) was 93.0%, as follow: overweight was 99.0%, grade I obesity was 95.83%, grade II obesity 93.65% and grade III obesity was 86.09%. Percent EWL was higher in the overweight group (OW) (131.54% EWL), followed by grade I obesity (G1O) (76.67%), grade II obesity (G2O) (50.61%) and grade III obesity (G3O) (45.45%) sequentially (p < 0.0001). Percent EWL was also higher in women (69.71% EWL) than in men (53.39% EWL) (p < 0.0001).

Results are better shown in table 01.

**Conclusion:** Endoscopic treatment of excess weight with an IGB has been established as an excellent therapeutic option.

2Institute of Clinical Medicine, University of Chinese Academy of Sciences, Beijing/China

Contact E-mail Address: binnai@zju.edu.cn

Introduction: Main factors contributing to the development of irritable bowel syndrome (IBS) includes the altered visceral perception, intestinal low-grade inflammation and psychosocial factors. Recent research has revealed a relationship between intake of FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols) and abdominal complaints. A diet low in FODMAPs can reduce symptoms in patients with IBS but mechan- isms were poorly understood.

Aims & Methods: We aim to explore the role of FODMAPs in triggering IBS symptoms by investigating visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) in stress induced IBS mice model. Fructo-oligosaccharide (FOS) as one of the most frequently exposed FODMAPs in daily life was used in this study. Mice were subjected to water avoidance stress (WAS condition; 1 h/day for 10 days) or sham stress (basal condition; 1 h/day for 10 days) with an oral gavage of saline or saline solution containing FOS (8 g/kg) for 2 weeks. Then visceral sensitivity was measured by abdominal withdrawal reflex (AWR) in response to colorectal distension (CRD) and histological analyses were used to evaluate mucosal inflammation. Immunohistochemistry, reverse trans- scriptase, and gas chromatography were used to estimate mucosal mast cell, levels of cytokines (IL-6, IL-23, TNF-α, IL-10, IL-1β) and SCFA, respectively.

Results: Visceral hypersensitivity, mucosal mast cell (12.3 ± 2.61 vs. 8.33 ± 3.55, P < 0.01) were observed in WAS-administered mice compared with saline-administered mice. In WAS condition, cytokine expression were mediated by FOS with increased IL-23 (3.17 ± 2.11-fold, P < 0.05) in ileum and IL-1β (2.45 ± 1.55-fold, P < 0.05) in colon compared with saline. In addition, the average concentrations of acetic (2.48 ± 0.62 vs. 1.04 ± 1.0, P < 0.01), propionic (0.48 ± 0.09 vs. 0.33 ± 0.0, P < 0.01) and butyric (0.50 ± 0.03 vs. 0.39 ± 0.03, P < 0.05) SCFA were significantly increased in FOS-administered mice compared with saline-administered mice in WAS condition. In basal condition, no difference of visceral sensitivity, intestinal inflammation and SCFA were observed between mice treated with FOS or saline.

Conclusion: Oral gavage of FOS leads to both an increase in visceral sensitivity and gut inflammation in stress induced IBS mice. These effects are linked with the production of SCFA in the gut which involved in the regulation of sensitivity and intestinal immunity activation. These findings support the hypothesis that visceral hypersensitivity and intestinal inflammation aggravated by certain FODMAPs may be responsible for IBS symptom generation, and indicate an alternative mechanism of the efficacy of the low-FODMAP diet for IBS patients.

P1952 GENOMIC ANALYSIS OF THE MULTISPECIES PROBIOTIC PRODUCT VSL#3

D. Mora1, W. M. De Vos2, F. P. Douillard2
1Department Of Food Environmental And Nutritional Sciences, University of Milan, Milan/Italy
2Ruij Immunobiology And Dept Of Food Hygiene, University of Helsinki, Helsinki/Finland

Introduction: Several formulations consisting of live lactic acid bacteria, including bifidobacteria, are marketed as probiotic products. However, these products are often poorly defined and insight into their mode of action is lacking. This hampers further application in treating diseases, limits comparative studies, and pre- vents predicting their efficacy. We have previously addressed this by providing genomic and functional characterization of single commercial strains (Kainkainen et al 2009, Douillard et al 2013, Tytgat et al 2016). The multispecies product VSL#3 is marketed globally for treating colitis ulcerosa, pouchitis, and irritable bowel syndrome. To provide a rational basis for understanding the function of VSL#3 and generate a baseline for future studies, the genomes of all 8 strains that make up this multispecies product were determined and used to predict their function. The strains were provided by the facility which is currently producing both the single strains and the blend mix (CDSL-SACCO System, Zelo Buon Persico - Lodi/ITALY).

Aims & Methods: The individual strains of multispecies product VSL#3 were extracted from their DNA samples by ethanol precipitation. The DNA was subjected to paired-end Illumina sequencing using a HiSeq2000 platform, assembled and annotated as previously described (Douillard et al 2013). The next generation sequencing provided high quality genomes of all 8 strains that are components of the multispecies product VSL#3. Detailed phylo- genetic and genomic analysis confirmed the species composition to be as indi- cated in the VSL#3 product specification and showed the 8 strains of this multispecies product to be highly related and in need for further official taxonomic resolution. The anno- tated genes of the assembled genomes were used to identify genes involved in potential probiotic functions. Full sets of genes for the production of tight adher- ence pili were observed in the Bifidobacterium spp. and are known to produce biofilms that we recently found to mediate mucosal adhesion and promote intestinal integrity, and influence host cell development (O’Connell Motherway et al 2011). Moreover, a series of signaling proteins were identified in the genomes of the Lactobacillus spp., including surface layer proteins and surface-dependent pili proteins that we showed to interact with the mucosal surfaces and dendritic cells (Konstantinov et al 2008; Kankainen et al 2008; Tytgat et al 2016). The genomic analysis of the VSL#3 strains confirmed the product specifications, defined the baseline genetic coding capacity, and predicted a number of probiotic mechanisms that could explain the efficacy of this multi- species product.

Introduction: Disease prevention and public health awareness are fundamental to reduce morbidity, mortality and health-related costs. Extensive research led to identification of causes of gastrointestinal (GI) disorders, but despite the advancements, still difficult to get population involved. The goals of our pilot campaign are: (a) to raise awareness about GI diseases, risk factors, signs, symptoms, in order to convince people to change behavior and to prompt them with concerns to visit doctors as early as possible; (b) to facilitate communication between healthcare providers and population; (c) to determine the knowledge of health personnel about the appropriate diagnostic investigations. Any information we can share may also benefit patients and their families, in recognition of the many people who suffer with the pain and discomfort caused by GI disorders.

Aims & Methods: We organized population-based events, out of health facilities during which: (a) giant inflatable anatomical models of GI organs that can be visited inside, were installed; (b) educational panels and brochures were set and exhibited both inside and outside the models; (c) videos illustrating endoscopy exams and histopathology examinations were projected and discussed; (d) clinical cases, also mimicking patient encounter, were simulated.

Results: We started an innovative strategy focused on the keywords: multidiscipli- nary team, scientific rigor but simple words, people attraction, cuiding communciation, in Parma and neighbouring Cities. Specialists in Gastroenterology, Anatomic Pathology, Radiology, Surgery, Biochemistry, Nutrition, together with pre- and post-graduated Students, discussed various aspects of gastrointestinal diseases. Selected people were examined by ultrasound, Municipality and civil society were also involved to ensure organiza- tional efficiency. The most discussed topics regarded dyspepsia, gastritis, helicobacter pylor infection, gastrointestinal reflux disease, alcohol abuse, cir- rhosis, hepatitis, intestinal bowel disease and polyposis, GI cancer, food allergy and intolerance, optimal nutrition in health and disease. The event performed in the main square of Parma lasted two consecutive days and was attended by about 3,000 people, most of which also filled a ques- tionnaire. A total of 120 ultrasound examinations were performed. In neighbour- ing Cities the events were organized for one day; as a consequence, the number of participants was lower in proportion, but very satisfactory.
Conclusion: The events were educational and enjoyable for all age groups. The interactive approach and the environment out of health-care centres facilitated the population to feel comfortable and eager to learn, as well as clinical cases simulation provided a valuable entertaining experience. This strategy of raising public awareness of GI diseases seems promising, we are refining the model for a national campaign.

Introduction: Amino acids are essential metabolites which play a role as protein constituents. Moreover, amino acids and their metabolites feature in regulation of anabolic and catabolic metabolism, detoxification processes, and act as neurotransmitters. Concentration of circulating amino acids reflects about dietary protein intake and can be an indicative of malnutrition. Changes in the amino acid homeostasis are observed in coeliac disease (CD) [1] due to malabsorption caused by enteropathy but also because of the treatment with gluten-free diet (GFD) shown to be low in the important nutrients.

Aims & Methods: A randomized, placebo-controlled interventional trial was designed to assess the influence of an oligofructose-enriched inulin (OEI) as a supplement of GFD on plasma profile and urine excretion of amino acids in CD children strictly following GFD at least 1 year. We randomized 34 children diagnosed with CD into a group receiving 10g of OEI daily and a placebo (maltodextrin) group during a 12-week nutritional intervention. Amino acid profiles in urine and plasma was analysed via EZ:Fast®1-2 derivatisation method followed by gas chromatography/mass spectrometry detection.

Results: At the baseline and after supplementation, 22 and 27 amino acids were identified in plasma and urine, respectively in both groups of children. Significantly higher levels (p < 0.05) of alanine, serine, asparagine, glutamine, threonine, arginine, lysine, histidine, leucine, aspartic acid, alanine, citrulline, hydroxylysine and cystine were determined in urine of OEI group after intervention as compared to the baseline and placebo group. The analysis of amino acid profiles in plasma samples showed a significant increase (p < 0.05) of many amino acids in both OEI and placebo groups after intervention. However, the concentrations of glutamine and glutamic acid were significantly higher (p < 0.05) in the OEI supplemented group.

Conclusion: Our study showed that supplementation of GFD with OEI impacts the amino acid homeostasis in CD children. OEI in GFD increased a total concentration of amino acids in both urine and plasma. Higher excretion of amino acids in urine accompanied with increased amino acid content in plasma may indicate the improved absorption or/and stimulated de novo synthesis of proteins. Increase in the concentration of glutamic acid can stimulate growth of the intestinal mucosa by itself or by the involvement in the synthesis of citrulline known as negatively correlated with intestinal mucosal damage [1], therefore we can suspect that OEI added to GFD can help in restoring of the intestinal barrier integrity.

P1955 LONG-TERM TRENDS IN HEMATOLOGICAL AND NUTRITIONAL STATUS AFTER GASTRECTOMY FOR GASTRIC CANCER

J. Kim

General Surgery, The Catholic University of Korea, Seoul/Korea, Republic of

Contact E-mail Address: doctor2003@catholic.ac.kr

Introduction: The quality of life and nutritional management after gastrectomy are major issues for gastric cancer patients, as is oncological surveillance. Weight loss usually follows gastric resection, with reported losses ranging from 10% to 30% of the preoperative weight. This loss has been attributed to inadequate oral intake, malnutrition, rapid intestinal transit time, and bacterial overgrowth. Timely, appropriate nutritional intervention can minimize diet intolerance, weight loss, and micrometabolic deficiencies that often follow surgery.

Aims & Methods: This study investigated long-term trends in hematological and nutritional parameters after gastrectomy for gastric cancer and evaluated the influence of the reconstruction type on these trends. The medical records of 558 patients who underwent curative gastrectomy with standard lymph node dissection for stage I gastric cancer between January 2006 and December 2013 were reviewed. The hematological and nutritional parameters evaluated included preoperative hemoglobin, ferritin, vitamin B12, total protein, albumin, total cholesterol, triglyceride, and calcium. The patients were followed up for 6 months postoperatively and then annually until death, cancer recurrence, or follow-up loss.

Results: In the long term, ferritin and triglyceride gradually decreased after gastrectomy, while the other parameters decreased slightly or were stable. In the comparisons according to reconstruction type, the Roux-en-Y group had the lowest levels of hemoglobin, ferritin, vitamin B12, total protein, albumin, and total cholesterol beginning 6 months postoperatively compared with the Billroth I and II groups. However, only ferritin and vitamin B12 had significant differences in the 5-year cumulative incidences of deficiency according to the reconstruction type, whereas albumin, triglyceride, total cholesterol and calcium did not.

Conclusion: Although malabsorption and malnutrition are common in patients after a gastrectomy, most nutritional parameters were stable or decreased slightly in the long-term and were not markedly influenced by the reconstruction type or extent of gastrectomy. Therefore, for more accurate nutritional assessment after gastrectomy, multidirectional nutritional intervention should be considered rather than simply measuring biochemical parameters.

Introduction: Celiac disease is an autoimmune enteropathy induced by the ingestion of gluten. The classical form has become very common in the majority. Currently, the most frequent forms of presentation are extraintestinal with various manifestations, among others, reproductive disorders. The aim of our study is to assess the frequency of these disorders in celiac disease and their evolution under gluten-free diet.

Aims & Methods: Descriptive retrospective study of 173 patients with celiac disease followed in the department of diseases of the digestive tract of the Ibn Sina Hospital in Rabat, over a period of 18 years.

Results: In 173 patients with celiac disease, 58 patients had reproductive disorders. There are 53 women and 5 men. The average age was 32.25 years; the diagnosis of celiac disease followed in the departement of diseases of the digestive tract of the Ibn Sina Hospital in Rabat, over a period of 18 years.

In 173 patients with celiac disease, 58 patients had reproductive disorders. 15 Patients lost to follow-up, 2 patients died, and 12 patients undergoing follow-up. The remaining 29 patients, the evolution of reproductive disorders under gluten-free diet was favorable in 26 cases (90%), with the normalization of cycles in 15 cases, resumption of amenorrhea in 6 cases development of secondary sex characteristics in 8 cases, spontaneous abortions in 7 cases, menometrorrhagia in 4 cases, primary sterility in 5 cases early menopause in 6 cases, premature delivery in 3 cases primary amenorrhoea in 2 cases and intrauterine fetal death in 1 case. All our patients have had a gluten-free diet. 15 Patients lost to follow-up, 2 patients died, and 12 patients undergoing follow-up. The following 29 patients, the evolution of reproductive disorders under gluten-free diet was favorable in 26 cases (90%), with the normalization of cycles in 15 cases, resumption of 4 cases development of 6 cases development of secondary sex characteristics in 2 cases, fertility resumption in one case, initiation of cycles after primary amenorrhoea in one case and delivery of a newborn at term after premature deliveries in one case. The evolution was unfavorable in 3 cases with the notion of miscarriage in 2 cases and intrauterine fetal death in 1 case. All our patients have had a gluten-free diet. 15 Patients lost to follow-up, 2 patients died, and 12 patients undergoing follow-up. The remaining 29 patients, the evolution of reproductive disorders under gluten-free diet was favorable in 26 cases (90%), with the normalization of cycles in 15 cases, resumption of amenorrhea in 6 cases development of secondary sex characteristics in 8 cases, spontaneous abortions in 7 cases, menometrorrhagia in 4 cases, primary sterility in 5 cases early menopause in 6 cases, premature delivery in 3 cases primary amenorrhoea in 2 cases and intrauterine fetal death in 1 case. All our patients have had a gluten-free diet.

Conclusion: The reproductive disorders associated with celiac disease are frequent and varied. In our study, these disorders responded very well under a gluten-free diet and constituted in 90% of the case. These disorders are thus reversible under this diet.

Introduction: Total gastrectomy can profoundly influence patients’ nutritional status and dietary patterns. This review aims to summarize the various nutritional options available post-operatively, namely total parenteral nutrition (TPN), or enteral nutrition (EN) either via the nasojejunal (NJ) or feeding jejunostomy (JEJ) route. The aim of this review was to determine the optimal nutritional route after total gastrectomy for patients with or without a jejunal feeding jejunostomy.

Aims & Methods: PubMed, MEDLINE and the Cochrane Library (January 1985 to January 2017) were systematically searched for randomized controlled trials comparing various nutritional routes after total gastrectomy. The primary outcome measure was morbidity. The Cochrane risk of bias tool was used to assess methodological quality of included trials.

Results: Six studies involving 353 patients (median age 62 years, 217 males, 170 TPN, 96 NJ, 87 JEJ) who underwent total gastrectomy were analysed. Overall morbidity was significantly greater in patients who received TPN compared with EN or NJ (OR 4.59, 95%CI 1.74–12.10, p = 0.002). There was a trend towards greater mortality in patients who received TPN compared with EN (OR 1.90, 95%CI 0.64–5.70, p = 0.25). When EN was sub-analysed according to NJ or JEJ, morbidity was significantly greater in patients who received EN compared with TPN (OR 5.1, 95%CI 1.74–14.20, p = 0.01). There was no difference in mortality between the two groups. Exit-site infection was more common in patients who received EN compared with TPN (OR 3.9, 95%CI 1.02–16, p = 0.31). In general, patients who received EN had a lower incidence of exit-site infections compared with TPN.

Introduction: Patients on home parenteral nutrition (HPN) are exposed to a lifelong risk of catheter-related bloodstream infections (CRBSI), which threaten catheter and patient survival. Both taurodiline 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurodiline as CLS is superior to saline in preventing CRBSI in HPN patients.

Aims & Methods: We hypothesized that taurodiline 2% as CLS is superior to saline 0.9% in preventing CRBSI in HPN patients. This multicenter double blind trial randomly assigned HPN patients to use either the CLS taurodiline 2% or saline 0.9% solution after the catheter and patient survival. Both taurodiline 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurodiline as CLS is superior to saline in preventing CRBSI in HPN patients.

Aim & Methods: We hypothesized that taurodiline 2% as CLS is superior to saline 0.9% in preventing CRBSI in HPN patients. This multicenter double blind trial randomly assigned HPN patients to use either the CLS taurodiline 2% or saline 0.9% solution after the catheter and patient survival. Both taurodiline 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurodiline as CLS is superior to saline in preventing CRBSI in HPN patients.

Aim & Methods: We hypothesized that taurodiline 2% as CLS is superior to saline 0.9% in preventing CRBSI in HPN patients. This multicenter double blind trial randomly assigned HPN patients to use either the CLS taurodiline 2% or saline 0.9% solution after the catheter and patient survival. Both taurodiline 2% and saline 0.9% solution are used as catheter lock solutions (CLS) to prevent CRBSI. The optimal agent however, remains unclear. We hypothesized that taurodiline as CLS is superior to saline in preventing CRBSI in HPN patients.

Conclusion: Taurolidine 2% decreased the risk for CRBSI by more than four fold in HPN patients compared to saline 0.9%. Given its favorable safety profile and lack of evidence for altering microbial susceptibility, taurolidine lock- ing therefore seems a key strategy to prevent CRBSI.

Introduction: Patients with severe intestinal failure depend on lifelong home parenteral nutrition (HPN) support. Repeated central venous catheter (CVC) loss due to complications, including mechanical damage, compromises vascular access. It remains unclear whether repair of damaged CVCs is an effective strategy to extend catheter life, avoid surgical replacement and maintain venous access.

Aims & Methods: The objective of this study was to characterize patients who underwent catheter repair and to evaluate effects on catheter survival and describe complications. This study concerns a retrospective analysis of all catheter repairs that were performed in HPN patients in the Radboud Medical Center between January 2000 and May 2017. Primary endpoint was the difference in catheter survival in the presence or absence of catheter repair. To this end, a non-parametric survival analysis was performed. Secondary outcomes included localization of catheter damage and frequency of repair-related complications within 1 month after catheter repair.

Results: A total of 50 repairs in 38 CVCs of 32 HPN patients were included in the analysis. 16 CVCs (32%) were damaged at the distal end, near the screw thread of the catheter, 25 CVCs (50%) at the junction between the rigid and flexible part of the catheter, and 9 CVCs (18%) at the flexible part of the catheter. The mean time to catheter repair after failure was 2.2 years (95% CI = 1.55–2.89). The mean catheter survival after repair was extended by 1.4 years to 3.6 years (95% CI = 2.69–4.46; p < 0.01). No repair-related complications occurred within 1 month after catheter repair.

Conclusion: Repair of damaged CVCs significantly extends catheter life in HPN patients with compromised vascular access. Catheter repair is a safe procedure.

Introduction: Catheter-related complications (CRCS) in home parenteral nutrition (HPN) patients are a threat to both catheter and patient survival. Taurolidine 2%, an antimicrobial catheter lock solution (CLS), is aneffective agent for the prevention of catheter-related bloodstream infections (CRBSIs). Aim of the study was to evaluate the role of taurolidine in preventing long-term clinical outcomes of our HPN patient cohort that uses the CLS taurolidine. Between 2008 and 2016, all adult HPN patients requiring a central venous catheter (CVC) were included. The incidence rates/1000 catheter days were described. Kaplan-Meier analysis was used to determine the time until a first CRC. Cox proportional hazard analysis was performed to identify risk factors for a first CRC.

Results: In 221 HPN patients, 658 CVCs (418 Hickmans, 172 PACs, and 28 non-tunneled CVCs) were inserted, comprising 261252 catheter days. Median survival for Hickmans, PACs and non-tunneled catheters was 175 (43–544), 310 (61–827) and 14 (7–19) days, respectively. During eight years of follow-up, 17 CRBSI occurred and 80 catheter-related occlusions (CRO). CRBSI and CRO rates/1000 catheter days were 0.74 and 0.34, respectively. In 47% and 32% of patients, at least one CRBSI or CRO occurred, respectively. Median time to a first CRBSI or CRO was 246 (58–817) and 215 catheter days (5–2070). Numerically, but not significantly, CRBSI and CRO rates decreased over time. The sole use of intravenous fluids was associated with a significantly lower risk for CRBSI (RR 0.32). Twenty patients reported adverse events (5 grade 1, 13 grade 2 and 2 grade 3) which were possibly related to the use of taurolidine.

Conclusion: This study describes the largest cohort of HPN patients to date on long-term taurolidine 2% as CLS. Overall, CRC incidence rates were low when compared with the literature. We found no evidence for a decreased effect of long-term taurolidine 2% as CLS. Overall, CRC incidence rates were low when compared with the literature. We found no evidence for a decreased effect of long-term taurolidine 2% as CLS.
patients required blood transfusion for the peristomal bleeding. In a univariate analysis, age, the rate of aspiration pneumonia as the reason for the PEG placement were higher in patients encountering adverse events (p < 0.05) (table 1). Also, serum platelet level, serum albumin and the rate of nutrition supports for cancer as the reason of the PEG placement was lower in patients encountering adverse events (p < 0.05). In a multivariate analysis, lower serum platelet level was solely recognized as a relevant predictive factor for adverse events (p < 0.05). The types of the technique used were not relevant to risks of adverse events.

Clinical backgrounds of patients with and without adverse events.

Conclusion: There was no significant difference in overall risks of adverse events between the modified introducer technique group and the overtube assisted pull technique group. However, the modified introducer technique may be associated with higher risks of severer adverse events. Especially, special care should be taken in patients with lower serum platelet level.
