Aims & Methods: The aim of this review was to determine the optimum choice and technical conduit following colon interposition after oesophagectomy in adults. PubMed, MEDLINE and the Cochrane Library (January 1985 to January 2017) were systematically searched for studies which reported outcomes of colonic interposition after oesophagectomy in adults. The primary outcome measure was overall morbidity and secondary outcome measure was operative mortality.

Results: Twenty-seven studies, involving 1849 patients (median age 60 years, 1177 males, 697 malignant disease) who underwent colonic interposition were analysed. The overall pooled mortality rate of left vs. right colonic conduit was 5.6% [95% CI (3.50–7.60), p < 0.0001] vs. 10.3% [95% CI (7.23–12.77), p < 0.0001] respectively. Retrosternal route placement was associated with the lowest overall pooled mortality of 9.2% [95% CI (6.48–11.99), p < 0.0001], and lowest overall pooled mortality of 4.8% [95% CI (3.74–5.89), p < 0.0001].

Conclusion: Left colon is the conduit of choice for colonic interposition after oesophagectomy in adults and the retrosternal route should be favoured.

or more extended liver resection (HPD) is occasionally indicated in patients with

**Results:**

the frequency of adverse prognostic factors tended to be higher in the CS group. The S group, e.g., tumor size (mean ± SD: 6.0 ± 3.5 vs 2.7 ± 1.7) and number of metastatic lymph nodes (4.2 ± 6.3 vs 2.7 ± 2.1). Nevertheless, overall survival (OS) in the CS and S groups since primary tumor resection was equivalent (3-year survival rate: 86.9% vs 93.4%, Log-rank P = 0.34) and much better than that in the C group (3-year survival rate: 40.2%). Although liver-limited relapse-free survival (RFS) since hepatectomy tended to be worse in the CS group than in the S group (3-year survival rate: 45.0% vs 62.7%, Log-rank P = 0.14), RFS after hepatectomy was equivalent in the two groups (3-year survival rate: 33.3% vs 21.6%, Log-rank P = 0.97). Early tumor shrinkage (ETS) was found to be a stronger prognostic factor for liver resection after chemotherapy than existing prognostic factors in univariate and multivariate analyses, and RFS was much better in patients with ETS than in those with non-ETS (3-year survival rate: 62.5% vs 77.4%, Log-rank P = 0.05).

**Conclusion:** OS and RFS in the CS group compared favorably with those in the S group despite the high frequency of poor prognostic factors; patients with ETS had a better prognosis after liver resection. Liver resection after chemotherapy revealed comparatively favorable prognosis in well-selected patients with sCRLM, and early responsiveness to chemotherapy was useful in determining the indication for liver resection in patients receiving chemotherapy for sCRLM.

Introduction: Surgical site infections (SSIs) after gastroenterological surgery cause significant morbidity, prolong hospitalisation and increase health care costs. Thus, SSI prevention is critical. To prevent bacterial colonisation in suture material, which disables local mechanisms of wound decontamination, triclosan-coated sutures were developed. We retrospectively analysed the efficacy of triclosan-coated polydioxanone sutures in abdominal fascia and skin closure using a propensity score matching analysis. We further analysed the surgery types for which these sutures are best suited.

Aims & Methods: The study protocol followed the principles of the Declaration of Helsinki and received ethical approval from the Ethics Committee of the Fukuoka University (approval no. 12-7-96). At our department, we used conventional abdominal closure methods during gastroenterological surgery before August 2012. Thus, we retrospectively collected surveillance data over a 1.5-year period for the control group. From September 2012, we began using triclosan-coated sutures for closure. Here, we evaluated data for the control group from September 2012 to September 2013. In total, we included 1768 patients (control group, n=640; study group, n=1128) who underwent gastroenterological surgery. Baseline differences and selection bias were adjusted using propensity score matching.

Results: Before matching, the SSI incidence differed significantly between the control and study groups for all gastroenterological surgeries [12.4% (140/1142) vs. 5.7% (55/940); p<0.001] and the SSI incidence type was as follows in the control and study groups: 12.7% (26/204) vs. 10.5% (12/114) (p=0.347) for upper gastrointestinal (GI) surgery, 14.6% (43/294) vs. 5.3% (10/190) (p=0.001) for lower GI surgery, 8.8% (24/274) vs. 4.1% (7/169) (p=0.045) for hepatobiliary-pancreatic surgery, 18.2% (40/220) vs. 7.8% (5/64) (p=0.030) for emergency surgery and 5.1% (7/136) vs. 1.0% (1/103) (p=0.074) for others. Of 1768 cases, 483 pairs were matched using propensity score matching. No parameter used for the propensity score differed between the groups. After matching, we found a significant difference in the SSI incidence between the control and study groups for all gastroenterological surgeries [9.7% (47/436) vs. 5.7% (28/455); p<0.001]. We found a significant difference in the SSI incidence between the control and study groups for lower GI surgery [17.0% (16/98) vs. 4.3% (4/190) (p=0.008) and hepatobiliary-pancreatic surgery [16.9% (41/116) vs. 4.3% (4/63); p=0.049] surgeries. No significant difference was found between the groups for upper GI surgery, emergency surgery and others. Multivariable logistic regression analysis showed that triclosan-coated suture use for lower GI surgery was the independent factor affecting the SSI incidence (p=0.017). The sutures demonstrated a significant efficacy in lower GI surgery.

Conclusion: Few studies have focussed on the types of surgery best suited for triclosan-coated sutures. Our findings suggest that abdominal fascia and skin closure using these sutures reduces the SSI risk, particularly for lower GI surgery.

Introduction: Despite improvements in the perioperative care, the morbidity rate after Pancreaticoduodenectomy (PD) is still higher than 50%. In particular, infectious complications (ICs) occur in about one-third of cases. This study aimed to investigate the correlation between preoperative rectal swab (RS) and intraoperative bire cultures, and its impact on postoperative course of patients submitted to PD.

Aims & Methods: The institutional electronic database was queried for all consecutive patients from January 1, 2010 to June 30, 2016. Data were retrospectively analyzed. Based on the positivity/negativity of preoperative surveillance RS for multi-antibiotic resistant Gram-negative and Gram-positive enteric rods, the population was divided into two groups consequently (RS+ vs. RS-).

Results: Three hundred thirty-eight patients were considered for the analysis. Overall 50 patients (14.8%) showed a RS+. Preoperative biliary drain (PBD) was the only independent risk factor associated to RS+ (p=0.021, OR 2.6). The rate significantly differed in the overall morbidity, ICs, sepsis, pulmonary complications, reoperation and mortality (p<0.05). At multivariate analysis, ICs and mortality remained independently associated to RS+ (p=0.013 OR 2.9, p=0.009 OR 3.4, respectively). Bile-culture showed a perfect correlation (species and antibiotic susceptibility) with RS culture in 157 patients (86.7%). The most common microorganisms found were E. Coli ESBL (6.6%) and Klebsiella pneumoniae carbapenemase-resistant (2.2%).
P0947 COMPARISON OF POSTOPERATIVE CONDITIONS BETWEEN ESOPHAGOGASTROSTOMY WITH THE DOUBLE-FLAP TECHNIQUE AND THAT WITH A CIRCULAR STAPLER IN LAPAROSCOPIC PROXIMAL GASTRECTOMY

Introduction: In recent years, laparoscopic proximal gastrectomy (LPG) has been actively performed in our institution to reduce invasiveness. However, proximal gastrectomy is sometimes followed by reflux. Until February 2015, we performed esophagogastrstomy with a circular stapler (CS) accompanied by fundoplication in LPG. Therefore, since March 2015, to avoid the postoperative complication, we have been using esophagogastrstomy with the double-flap technique (DFT) in LPG for gastric cancer.

Aims & Methods: We conducted this study to examine whether DFT can reduce the incidence of reflux and influence postoperative complications, postoperative hospital stay, and incidence of anastomotic stenosis. We compared surgical factors and compared between the DFT and CS groups. Second, gastroesophageal reflux finding on esophagography, condition of the remnant stomach according to residue, gastritis, bile (RCF) grading at postoperative 6 months and 1 year, and proton pump inhibitor (PPI) intake were examined as postoperative factors. Finally, albumin and hemoglobin levels at postoperative 6 months and 1 year were examined as nutritional factors. Gastroesophageal reflux was assessed with scores of 0–5 in accordance with the Los Angeles (LA) classification.

Results: Twenty-three LPGs with DFT and 24 with CS were performed during the period. Compared with the CS group, the DFT group had a significantly longer surgical time (272.3 ± 55.5 vs. 241.1 ± 26.7 min, p < 0.01). Other surgical factors did not show any statistically significant differences between the two groups. As for postoperative factors, although no significant differences in PPI intake, LA classification, and RCF grading were found, the DFT group showed a significantly lower score than the CS group (p < 0.01). Postoperative nutritional factors showed no statistically significant differences between the two groups. Postoperative conditions in most cases are argued between the DFT and CS groups.

Conclusion: Although LPG with DFT required a longer surgical time than LPW with CS, DFT is thought to be a safe reconstruction method in LPG. In addition to its safety, DFT can reduce postoperative reflux in patients who undergo LPG.

Introduction: Gastrointestinal (GI) leaks and perforations are difficult to manage and often mandate laparotomy and extensive surgical interventions for their repair. Endoscopic Negative Pressure Therapy (ENTP) has been developed to treat GI leaks such as leaks, fistulae and perforations. However, ENPT has only been utilized in the management of rectal and esophageal leakages. By modifying the delivery catheter we were able to adapt ENPT to treat duodenal defects, that otherwise would have required surgery or more invasive methods to be used.

Aims & Methods: Herein, we report ENPT using open-pore Polyurethane-foam and Film Drainage in a series of 10 patients with duodenal leakages. This is an open-label, retrospective, single-center study. Open-pore polyurethane-foam drainage (OPD) devices were constructed out of a piece (1.5 cm x 1.5 x 3 cm) of open-pore polyurethane foam which was fixed surrounding the tip of a nasogastric drainage tube. Small bore open-pore film drainage (OFD) device was constructed with a strip of a very thin fragment open-pore double layered film (15 cm x 1.5 cm) and was fixed surrounding nasogastric drainage tube. The open film consists of two permeable membranes with a small interspace. Fluids are drained along the interspace and through the membranes. Diameters of small-bore OPD is 4–6 mm, depending on the diameter of the drainage tube. OPD is inserted transanally. The foam is fixed with anoderm copolymers and guided to the duodenal lumen. After correct placement into the duodenal lumen for intraluminal ENPT, the tube is transferred out nasally, to become a nasoduodenal tube. Due to its smaller outer diameter, OFD insertion is similar to placing a nasogastric or nasointestinal feeding tube (i.e. through the nose). After nasal insertion into the esophagus OFD is grasped with a forceps and advanced into the stomach, and guided into the duodenal lumen for intraluminal ENPT. In case of a duodenal-cutaneous fistula the pull-through technique has been used for duodenal placement. In one case rendezvous technique was used in combination with open surgical incision. OPD and OFD devices are connected to an electronic vacuum device and negative pressure is applied. We use standard negative pressure of 125 mmHg, continuous suction, and high intensity, which results in collapse of the duodenal lumen around the open-pore foam or film with subsequent closure of the duodenal lumen. Furthermore, duodenal secretions are actively removed through the tubes.

Results: We treated 10 patients with ENPT because of a duodenal leakage. Reason of duodenal defects were: rupture of operative suture (n = 8), iatrogenic duodenal perforation due to perforation of a drain (n = 1), and active and often mandates laparotomy and in one patient with intracavitary variant of ENPT. In 7 patients we used the OPD device, in one patient OFD, and in two patients OPD and OFD. All leakages (100%) were successfully closed after the procedure. ENPT was performed accurately at the site of duodenal perforation and perforations using common endoscopic techniques and thus represent a potential addition to the armamentarium to treat these difficult lesions.

Introduction: The main releaser for development of multiorgan failure syndrome (MOFS) is often the sequelae of severe infections and the sequelae of surgical complications and multiorgan failure syndrome (MOFS) in most cases are aggressive mediators of inflammation which are very often occur after surgical complications and more than in 70% of cases leads to lethal outcomes. Increase of an endotoxemia leads to development of the expressed pathological processes and to a fast descompensation of bodies of natural descompensation with the subsequent development of a multiorgan failure syndrome (MOFS). Increase in detoxication ability of sorbents can happen due to change of chemical composition, or due to collimating of padding properties to them by their modification by various agents by means of an immobilization on their surface of the active and inorganic components. Thus, this plan especially important role is got by the researches directed to development of sorbents with detoxication activity.

Aims & Methods: Aim of study is to estimate effectiveness of the modified haemosorbsor application for patients about the MOFS. The experimental part of work was conducted on 14 not purebred dogs with the acute liver failure modelled by bandaging of distal department of the CBD. After development of pathological process animals were divided into 2 groups. To the first group of animals the procedure of a haemosorbsor was carried out by a reference technique using type of a haemosorbsor of SKN-2K. To the second group of animals the haemosorbsor was carried out by the developed technique with the same sorbent, but the solution of a neutral anolyte subjected to oxidizing modification. For this purpose, in the flowing mode carried out a half-hour incubation of a solution of a neutral anolyte subjected to oxidizing modification.

Results: Results showed that at animals of the 2nd group in comparison with group of comparison improvement of a condition of an organism was expressed in more significant degree. After performing detoxication therapy by the developed technique a normalization of all studied parameters is registered. The same tendency is revealed also concerning nontoxic components. It is necessary to pay special attention to dynamics of a ratio of the common protein and an index average molecules (the common protein, pointing to synthesis process activation. The carried-out all-clinical blood test revealed the considerable improvement of indexes of white blood. In group of comparison it was not achieved to succeed the complete normalization of the studied indexes. On the basis of what the conclusion was drawn on high effectiveness of the developed technique, and expediency of its introduction in clinical practice. Under our observation there were 45 patients needing carrying out getter detoxication in the postoperative period. The control group (25) was created by a random sample of case histories of patients with the MOFS who was earlier on treatment in our clinic and receiving a course of haemo perfused therapy by a reference technique. The analysis of results of treatment of patients of a basic group showed that the positive dynamics of clinical indexes expressed in decrease of manifestations of an intoxication syndrome, improvement of health and laboratory indexes is noted in earlier terms, and degree of expressiveness of positive changes at them was much higher. Dynamics of decrease in endogenic intoxification is reflected by data of laboratory researches. Thus, it was showed that it is possible to increase quality of detoxication by a pretreatment of a haemo sorbent solution of a neutral anolyte. As a result of it the sorbent gains padding, oxidizing properties. At such modification there is an inclusion of oxygen-containing and acid groups in structural composition of a sorbent. So, the surface of a sorbent protogenic groups of the carboxylic and phenolic types thanks to which the oxidized coals gain the expressed cation-exchange ability are formed. Therefore, besides actually getter, such sorbent follow-up gains oxidizing properties. Modification of a sorbent solution of a neutral anolyte incidentally allows to solve also other problem connected about need of use of anticoagulants for prevention of a thrombogenesis in a column. Use it in this quality provides decrease in risk of postoperative violations from system of a hemostasis.

Introduction: Gastric leaks are severe complications of Bariatric Surgery (BS). Surgical revision may be indicated but is associated with high morbidity and mortality. The use of self-expanding esophageal metallic stents (SEMS) has become an effective alternative. Over the scope clips (OTSC) have also been used. Nevertheless some patients develop a refractory fistulae after stent removal or other failed endoscopic treatments. Cardiac Septal Defect Closure Devic (CSDCD), used in interventional cardiology have been described to treat post-surgical digestive fistulae in non-bariatric cases. Aims & Methods: We aim to present the experience using CSDCD for gastric leaks after BS. In this retrospective study, patients with leaks secondary to gastric bypass (GBP) or sleeve gastrectomy (SG) from 4 centers were included. Data collected from november 2012 to january 2016 included sex, age, type of surgery, previous treatment, tract path, size of the leak opening and defect closure. Leaks were grouped according to the International Sleeve Gastrectomy Expert Panel Consensus in acute (post-operative days 1–7), early (1-6 weeks), late (after 6 weeks) and chronic (>12 weeks). Biliary catheters were adapted to introduce the CSDCD through the gastroscopes working channels. Clinical success was defined as complete and permanent resolution of abdominal or thoracic pain syndrome severity (visual analog scale), need for analgesics, postoperative complications, hospital-stay, daily activity recovery and return to physical work, patients’ satisfaction of surgical results and their aesthetic effect. Results: It was revealed that CSDCD were effective to treat post bariatric surgery late and chronic complications, hospital-stay, daily activity recovery and return to physical work, patients’ satisfaction of surgical results and their aesthetic effect. Conclusion: Further studies to standardize, evaluate the safety and benefits of CSDCD are effective to treat post bariatric surgery late and chronic complications, hospital-stay, daily activity recovery and return to physical work, patients’ satisfaction of surgical results and their aesthetic effect.

Introduction: Laparoscopic cholecystectomy is the gold-standard for the treatment of gallbladder stones disease. Single-incision laparoscopic (SILS) cholecystectomy was introduced with the aim of reducing the invasiveness of classic laparoscopic surgery. Despite satisfactory cosmetic results of SILS cholecystectomy and its repeute of a painless procedure, there are few published studies comparing early and long-term postoperative period of laparoscopic SILS cholecystectomy versus laparoscopic four-port cholecystectomy.

Aims & Methods: The aim of this study is the comparative evaluation of SILS cholecystectomy and laparoscopic four-port cholecystectomy. Early and long-term postoperative period has been analyzed in 240 patients who underwent laparoscopic cholecystectomy including 120 cases of single-port technique and 120 cases of four-port technique. Both groups were compared in surgical time, pain syndrome severity (visual analog scale), need for analgesics, postoperative complications, hospital-stay, daily activity recovery and return to physical work, patients’ satisfaction of surgical results and their aesthetic effect.

Results: Prior failed therapies included: SEMS and enteral drainage within 10 days, and OTSC within 7 days and SEMS were placed instead leading to defect closure. The 5 early, 22 late and 12 chronic leaks. Prior failed therapies included: SEMS and enteral drainage within 10 days, and OTSC within 7 days and SEMS were placed instead leading to defect closure. The 5 early, 22 late and 12 chronic leaks. Prior failed therapies included: SEMS and enteral drainage within 7 days and SEMS were placed instead leading to defect closure. The 5 early, 22 late and 12 chronic leaks.

Introduction: Laparoscopic technique is the first choice for multiple surgical procedures today. Laparoscopic surgery differs from traditional open surgery in several aspects, for example two-dimensional view of a three-dimensional interior, higher demands on eye-hand coordination and lack of tactile feedback. Laparoscopic surgical skills can be substantially improved by simulator training. Learning via simulators are under constant development and it is important to understand the value of baseline characteristics and abilities to further optimize simulators and training curricula within surgical education. In this study, focus, will be PC-gaming experience and low visuospatial score to offer them additional simulators than baseline skills. It could be valuable to identify individuals with both low PC-gaming experience and low visuospatial score to perform worst in the simulator exercises.

Aims & Methods: The aim of the study is to further analyse different factors to laparoscopic simulator training. 48 medical students completed three tasks in a laparoscopic virtual reality simulator, a validated Minimally Invasive Surgical Trainer (MIST, Mentor, Gothenburg, Sweden). Prior to the task, they performed a visuospatial test and answered questions regarding baseline characteristics (e.g. PC-gaming experience, age, gender, previous simulator experience). The data were analysed regarding different parts of the simulator (time, economy of movement, error rate and total score).

Results: The group with high PC-gaming experience performed significantly better in total time (Mean difference = 85.49, p = 0.021) and economy of movement (M = 25.30, p = 0.018) in task 1 and 2. There were no differences between either of the groups in task number 3. A high visuospatial score correlated with a better result in time to completion (M = 68.89, p = 0.026) and total score (M = 80.16, p = 0.036). The group with both low PC-gaming experience and low visuospatial score performed worst in the simulator exercises.

Conclusion: PC-gaming experience and visuospatial ability have an impact on laparoscopic simulator performance. No remaining significant differences by the third simulation exercise indicates a learning effect that could be more important than baseline skills. It could be valuable to identify individuals with both low PC-gaming experience and low visuospatial score to offer them additional simulator training.

Introduction: Tuberculosis is a major cause of morbidity and mortality worldwide. Its incidence is continually increasing. Peritoneal localization is a particular entity, even less well known, because of its atypical and confusing symptomatology, which in most cases imposes a malignant condition.

Aims & Methods: We collected all patients hospitalized for peritoneal tuberculosis at the University hospital of Sfax, Tunisia from 2005 and 2015. The aim of this retrospective study was to study the epidemiology, clinical, pathological, diagnostic, therapeutic and evolutive specificities of peritoneal tuberculosis in its various presentations.

Results: The total number of patients was 65. It was 15 men (23.1%) and 50 women (76.9%). The sex ratio was 0.3. The mean age at diagnosis was 40 years (15–79 years). No personal history of tuberculosis has been found in our series. A personal history of tuberculosis was found in 3 patients (4.6%). The general signs of tuberculin impregnation were frequently found (91%). The digestive functional signs that brought the patients to consult are: abdominal pain (87.7%), abdominal distension (87.5%), diarrhea (16.9%) and sub oclusive syndromes (4.6%). An abdominal mass was observed in only 4 patients (6.1%). Hepatomegaly and splenomegaly were noted in 2 cases for each. The intradermal reaction was positive in only 24% of patients. The research of BK in the ascitic fluid was systematically performed in all patients but returned negative in all cases. The quantiferon-TB Gold was performed in 3 patients only and returned positive. The mean level of CA 125 was 250.313/ml. Confirmation of diagnosis was determined by the histological analysis of peritoneal biopsies or the peritoneal biopsy pieces. The main operative findings (in patients with coeloscopy or exploratory laparotomy) were: Whist granulations (98%), adhesions (43.1%) and agglutinated loops (1.5%). The presence of tuberculous granuloma was observed in 52 patients (81%). The course of treatment was as follows: cure in 50 patients (80.6%), recurrence in 6 patients (9.6%), relapse in 2 patients and 3 patients were lost to follow-up. The mortality in our series was 0%.

Conclusion: Peritoneal tuberculosis raises diagnostic problems in the first place, because of its polymorphic and non-evocative clinical expression. Hence the value of carrying out radiological, endoscopic and histo-bacterialiological investigations to confirm the diagnosis before the evolution towards serious or even fatal forms.

Introduction: Tuberculosis is still a public health problem in Tunisia, which is a country of endemcity. The epidemiological situation of the disease is marked by the rise of the extrapulmonary forms especially abdominal tuberculosis.

Aims & Methods: The aim of this study was to analyze the epidemiologic, clinical, diagnostic, therapeutic and evolutive features of abdominal tuberculosis in a series of 150 patients. This was a retrospective and descriptive monocentric study of 150 cases of abdominal tuberculosis conducted from 2004 to 2014 in a tunisian center. Diagnosis of tuberculosis was based on histological evidence or otherwise on a bone of arguments.

Results: There were 150 patients enrolled. The mean age was 37.2 (17–72 years). Ninety seven (64.6%) were females. Symptoms were ascites 107 (71.3%), abdominal pain 28 (18.6%), weight loss and reduced appetite 80 (53.3%). Un tableau de tuberculose digestives (tissue obtained during surgery, colonoscopy, CT or ultrasound guided biopsy, laparoscopy and upper gastro intestinal endoscopy) in 122 patients (81%). The course of treatment was as follows: cure in 50 patients (80.6%), recurrence in 6 patients (9.6%), relapse in 2 patients and 3 patients were lost to follow-up. The mortality in our series was 0%.

Conclusion: Abdominal tuberculosis is one of the most common site of extra-pulmonary tuberculosis. No single test is adequate for diagnosis of abdominal tuberculosis in all patients. ABDM remains an ongoing diagnostic dilemma requiring a high index of clinical suspicion.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Inability to maintain a stable and beneficial microbiota is associated with chronic gut inflammation, which classically manifests as colitis but may more commonly exist as low-grade inflammation that promotes metabolic syndrome. Alterations in microbiota and associated inflammation can originate from dysfunction in host proteins that manage microbiota, such as the flagellin receptor TRL5, and/or be promoted by exogenous factors that disturb host-microbiota interactions, such as the detergent-like dietary emulsifiers carboxy-methylcellulose (CMC) and polysorbate 80 [1, 2, 3]. That the complete absence of a microbiota (i.e. germ-free conditions) eliminates all evidence of inflammation in...
TLR3-deficient and emulsifier-treated mice demonstrate that these models of gut luminal biofilms and mucosa-dependent microbiota are associated with IBD, and that disruption of TLR3 and/or emulsifier consumption does not impact microbiota composition nor its ability to promote inflammation. Addition of AIEC to this ecosystem perturbs microbiota composition, increases levels of lipopolysaccharide (LPS), flagellin and phospholipid signal in gut inflammation and adiposity, suggesting that the phenotypes previously observed require disruption of complex microbiota.

2. Gower-Rousseau C, Sarter H, Savoye G, et al. Validation of the Revised Life Orientation Test (LOT-R) and IBD-DI, respectively. The association between sociodemographic, clinical and psychological factors that are associated with greater disability. Between August and October of 2016, patients with an established diagnosis of Crohn’s Disease (CD) or Ulcerative Colitis (UC) for at least 3 months and followed up at our outpatient clinic were invited to participate. Socio-demographic and clinical data were collected from electronic health record and interviews. Optimism and disability were evaluated by applying, personal interview, the IBD-DI developed from the Revised Life Orientation Test (LOT-R) and IBD-DI, respectively. The association between sociodemographic, clinical and psychological variables (optimism) and IBD-DI (scale 0–100, proportional to the reported disability) was determined by univariate and multivariate analysis.

Results: A total of 143 patients (70 DC and 73 UC; 50.3% females) with a mean age of 38 ± 13 years were included. Most (85.3%) was in clinical remission. The median IBD-DI-PT score was 7.9 ± 10.7, with a significant difference between DC and UC (p = 0.044). In univariate analysis, female gender, high level education, number of days off from work, articular manifestations, number of comorbidities, use of psychotropic drugs and pessimism (low LOT-R score) were significantly associated with higher disability (IBD-DI-PT score). In multivariate analysis, only female gender (β = 0.150), number of comorbidities (β = 0.186) and pessimism (β = 0.370) were significantly associated with higher disability. Clinical activity was associated with higher disability only for CD patients (β = 0.321).

Conclusion: IBD outpatients reported low levels disability associated with their disease, which can be explained by the high percentage of patients in clinical remission. Comorbidities and psychological factors (optimism) emerged as the main predictive factors of greater disability, reinforcing the importance of multidisciplinary approach to these patients. Clinical activity seems more important to CD than UC patients in terms of disability.

Aims & Methods: This study aimed to characterized CD4+ and CD8+ T cells in the blood of patients with CD. The study was performed in individuals with CD (n = 46) and healthy controls (n = 38). Blood of healthy donors and patients with CD was collected in clinical laboratory from Hospital Albert Einstein. CD4+ and CD8+ T cells was quantified by multiparametric flow cytometry. Dosage of calprotectin and ASCA was performed by commercial Elisa kits. CD4+ and CD8+ T cells were collected in clinical laboratory from Hospital Albert Einstein. CD4+ and CD8+ T cells was quantified by multiparametric flow cytometry. Dosage of calprotectin and ASCA was performed by commercial Elisa kits. CD4+ and CD8+ T cells were evaluated. In relation to the group undergoing biological treatment and the group of healthy controls. Finally, a statistical difference (p < 0.001) was observed between the groups. The results were compared with the earlier published data: SRA Project - ERP001780 (96 samples from patients of control group, 44 samples from patients with ulcerative colitis) and SRA Project - SRP056002 (703 samples from patients with ulcerative colitis).

Results: More than 124 bacterial genuses were found in biopsies of patients with ulcerative colitis. The analyzed samples of patients with ulcerative colitis were split in two groups by using the PCoA analysis. The first group was characterized by decreasing the concentration of the Firmicutes type bacterias (p-value < 0.005) and increasing the concentration of Bacteroidetes type bacterias (p-value < 0.005). For the second group, it was founded decreasing of the concentration of the Actinobacteria type bacterias (p-value < 0.05), and increasing the concentration of Bacteroides vulgatus species bacterias concentration was revealed for one sample of the control group (normal number of reads in control samples was less than 0.0001 and reached 0.21 in samples of patients with ulcerative colitis). Additionally, the concentration of Escherichia coli species bacterias was increased in the 40 times for that sample (normal number of reads in control samples was 0.0003 in samples of patients with ulcerative colitis). Although, the predominance of Proteobacteria genus bacteria was not founded. The concentration of Fusobacterium prausnitzii species bacterias was decreases by three orders of the magnitude for samples from the first group (normalized number of reads in control samples reached 0, 2 and was less than 0, 06 in samples of patients with ulcerative colitis).

Conclusion: The conclusion the increase of the conditional-pathogenic mucosal microflora (a mostly Bacteroidetes type bacterias) was discovered, which playing a significant role in the development of ulcerative colitis and severe damage. Also, the deficiency of Fusobacterium prausnitzii species bacterias was discovered, which decrease resistance of mucosa to the conditional-pathogenic microflora.

P0963 EOSINOPHILS-ASSOCIATED CYTOKINES AS INFLAMMATORY BOWEL DISEASE BIOMARKERS

K. Neubauer1, M. Matusiewicz2, Ł. Bednarz-Misa2, S. Górska2, A. Gamian2, M. Krzyżek-Korpacka2
1Gastroenterology And Hepatology, Wrocław Medical University, Wrocław/ Poland
2Medical Biochemistry, Wrocław Medical University, Wrocław/Poland

Introduction: Pathogenesis of inflammatory bowel disease (IBD) is multifactorial and establishing diagnosis requires a performance of series of variable tests. The alternative, non-invasive, markers of IBD are intensively searched for. Eosinophils are acidophilic multifunctional granulocytes that remain outside the mainstream research on IBD. However, they are a rich source of cytokotoxic proteins, pro- and anti-inflammatory cytokines, chemokines and growth factors and are likely to contribute to both inflammatory and regenerative phases of the disease. Accordingly, peripheral eosinophils of IBD patients are primed and pre-activated. They display increased responsiveness, adhesiveness, migration, and degranulation and are characterized by up-regulated secretion of their mediators. Locally, increased number and activation of eosinophils have been repeatedly observed in areas of active inflammation. Despite the acknowledged contribution of eosinophils to the disease pathogenesis, available data on cytokines closely related to the development and activity of peripheral eosinophils in IBD patients are either scattered or non-existent.

Aims & Methods: Aim of the study was assessment of the circulating eosinophil-associated cytokines and growth factors as differential markers and indicators of mucosal healing in inflammatory bowel diseases.

Results: Population consisted of 277 individuals: 101 patients with Crohn’s disease (CD), 77 with ulcerative colitis, 16 with irritable bowel syndrome (IBS) and 83 healthy controls. The disease severity was assessed using the Crohn’s Disease Activity Index (CDAI) for CD and the Mayo Disease activity index (MDAI) for UC. The Mayo endoscopic score was applied to evaluate the severity of bowel inflammation in UC patients. The concentrations of eosinophil-associated cytokines and growth factors: eotaxin, GM-CSF, IFNγ, IL4, IL5, IL8, IL10Ra, IL12(p70), RANTES and TNFα were measured simultaneously in peripheral blood of the patients sera using Luminex xMAP® technology and referred to IBD activity and the levels of hsCRP. The suitability of eosinophil-associated cytokines and growth factors as differential markers and potential indicators of mucosal healing, individually and in multi-marker panels, was evaluated using ROC analysis.

Conclusion: The eosinophil-associated cytokines and growth factors are significantly and positively correlated with the degree of bowel inflammation, however, none of these cytokines reached the highest accuracy in differentiating IBS and IBD (91%), allowing for a correct classification of 93% of patients.

P0964 MACROPHAGE IL10 SIGNALING IS REQUIRED FOR THE THERAPEUTIC EFFECT OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE

P. J. Koelink1, F. M. Bloemendaal1, L. Westera1, A. B. van ’T Wout2, A. K. Gloudemans2, B. Li3, T. L. Geiger4, M. E. Wildenberg5, G. R. Van Den Brink5

5AMC Amsterdam, Amsterdam/Netherlands

Introduction: Interleukin(IL)10 is an important anti-inflammatory cytokine for the maintenance of gut homeostasis. Defects in the IL10 signaling pathway in macrophages leads to deregulation of regulatory (M2) type macrophages and subsequent inflammatory bowel disease (IBD). IBD patients are frequently successfully treated with anti-TNFα antibody therapy, although not all patients are responsive.

Aims & Methods: We determined the effect of anti-TNFα therapy in both IL10 knock-out (KO) mice and in the CD4+CD45Rb high T-cell transfer model of colitis. Macrophage populations were quantified using qPCR analysis for CD206 and F4/80 and flow cytometry, and cytokines, including IL10, were analyzed with ELISA.

Results: Colitis in the IL10 KO mice was completely resistant to anti-TNFα therapy, in sharp contrast to the colitis in SCID or Rag1 KO mice upon transfer with CD4+CD45Rb high T-cells, which was significantly reduced by anti-TNFα therapy. Successfull anti-TNFα therapy was accompanied by an increase of IL10 levels and an increase of regulatory (M2) type macrophages in the intestine. Blocking IL10 signaling, with an IL10 Receptor blocking antibody, diminished the therapeutic efficacy of anti-TNFα therapy, Anti-TNFα therapy was also unresponsive to anti-TNFα therapy upon receiving CD4+CD45Rb high T-cells. In these mice there was also no increase of intestinal M2 macrophages.

Conclusion: IL10 signaling in macrophages is pivotal for the therapeutic efficacy of anti-TNFα therapy in animal models for IBD. Defects in the IL10 pathway may also play a role in anti-TNFα non-responders which is subject of further investigation.

4Bogomoletz National Medical University, Kyiv/Ukraine

Introduction: Epidemiological studies revealed that antibiotics exposure increases the risk of inflammatory bowel diseases (IBD) development (Hviid, 2011, Shaw, 2011, Kromon, 2012). However, mechanisms of this association are not fully understood. Recent studies revealed sustained alterations in gut microbiota after antibiotic treatment (Rashid, 2015, Dethlefsen, 2011), the full consequences of which remain unknown.

Aims & Methods: Here we investigated long-term effects of antibiotic treatment on gut microbiota, short-chain fatty acids (SCFAs) production, transport & metabolism and mucosa functional state, surface mucus layer and epithelial barrier integrity. Male Wistar rats (n = 178, 140-160 g) were treated for 14 days with broad-spectrum antibiotic ceftriaxone (CT) (300 mg/kg, i.m.) or vehicle; euthanized in 1, 14 or 56 days after CT withdrawal. The fecal microbiota was analyzed by bacteriological culture methods; fecal SCFAs by gas chromatography; colonic localization and levels of FFAs & FFA3 receptors and MCT1, MCT4 & SMCT1 transporters of SCFAs – by immunohistochemistry; levels of FFA2, FFA3, ERK1/2; p38, HIFα/α proteins in colon mucosa – by Western blot analysis; mucosal macrophage (macrophage marker, 91%), allowing for a correct classification of 87% of patients. The concentrations of HIFα, GM-CSF, IFNγ, and IL12(p70) were significantly and positively correlated with the degree of bowel inflammation, expressed as Mayo endoscopic score. Of these, a drop in GM-CSF had superior diagnostic accuracy. The contribution of mucosal healing as differential diagnosis of IBD and aid in monitoring of mucosal healing.

Introduction: Chronic and acute inﬂammation is often associated with an upregulation of extracellular UTP and ATP nucleotides, which are able to interact with various cell types via purinergic G protein-coupled P2 receptors. Interestingly, former studies already described an increased expression of the ATP/UTP receptor subtype P2Y2 (P2Y2R) in the colonic tissue of IBD patients (Shannon diversity index, p < 0.01 healthy vs active UC, p < 0.05 active vs remission UC, 1-way ANOVA post-hoc = Tukey). Active UC patients also had lower bacterial diversity compared to remission UC patients and healthy twins (Shannon diversity index, p < 0.01 healthy vs active UC, p < 0.05 active vs remission UC).

We found that active CD patients had a higher proportion of Clostridium hylemonae and Lactobacillus delbrueckii compared to healthy twins, and a lower proportion of Faecalibacterium prausnitzii compared to healthy twins (p < 0.05). We found that active UC patients had a lower proportion of Allostipes spp. compared to their healthy twins and UC patients in remission (p < 0.05).

Conclusion: This study confirms previous findings showing decreased diversity in IBD patients and changes in some bacterial taxa, however our study is the first to show decreases in Allostipes spp. in active UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Immunity 2009; 30(6): 899-911
subsequently analyzed for STAT3 signaling (western blot), NFκB signaling (Western Blot Transcription Factor Assay, western blot) and cytokine secretion (ELISA).

Results: Peripheral blood CD4+ T cells from IBD patients could be characterized by a significantly increased P2Y2R expression compared to healthy controls, whereas the expression levels of the P2Y4 receptor subtype turned out to be comparable between both groups. Further subdividing the group of included IBD patients into Crohn’s disease and ulcerative colitis patients, we could not observe a significant difference in the P2Y2R levels between both disease entities. Interestingly, the increased P2Y2R expression in the lymphocyte compartment of IBD patients seemed to be limited to CD4+ T cells, as CD8+ T cells of these patients even showed decreased P2Y2R levels. Regarding potential regulators of P2Y2R expression in the context of IBD, our data identified IL-6 and TGF-beta as being involved in P2Y2R expression in human CD4+ T cells. Interestingly, a high extracellular UTP levels resulted in a decreased expression of the TGF-beta1 receptor on CD4+ T cells, implicating a potential negative feedback loop in which P2Y2R signaling might inhibit TGF-beta1 induced P2Y2R expression or cause a decreased impact of P2Y2R on the pro-inflammatory potential of human lymphocytes, our data indicate that the selective P2Y2R agonist 2-Thio-UTP is able mediate NFκB as well as STAT3 activation and to induce secretion of the pro-inflammatory cytokines IL-6 and IL-17 in stimulated human monocytes.

Conclusion: The observed increased expression of P2Y2R in CD4+ T cells of IBD patients together with the demonstrated pro-inflammatory effects of P2Y2R signaling in human T cells markedly strengthen the role of P2Y2R as a promising molecular target in IBD.

Introduction: Environmental hypoxia has been increasingly recognized as an important environmental factor associated with Inflammatory Bowel Disease (IBD). Hypoxia allows the stabilization of hypoxia inducible factor (HIF) complexes and has been linked to the activation of autophagy. HIF-1α is induced in the inflamed mucosa from IBD patients and mouse models of colitis, but its role in intestinal inflammation is still controversial since both, positive and negative effects have been reported.

Aims & Methods: We aim to elucidate the effects of HIF-1α stabilization in autophagy and the development of intestinal inflammation in a murine model of colitis. Female C57BL/6 J mice between 8–10 weeks of age were exposed to 2% dimethyloxaloylglycine (DMOG) intraperitoneally every second day. Mice were subjected to normoxia (21% O2) or hypoxia (0.2% O2) for 24 h in the presence or absence of 40μM DMOG. Colon tissue was collected 12 hours after treatment, RNA was extracted and real-time qPCR was performed. Western blot analysis was also performed to examine the expression of autophagy-related proteins. Immunohistochemistry was performed to analyze the histological damage. Expression of TNF, IL-6, IL-1β and Nrf2/C11 were quantified by colon infiltrating leukocytes and the release of CXC chemokine ligand 8 by UDP.

Results: DMOG administration induced a significant lower reduction of body weight in DSS-treated mice compared to DSS-treated mice administered with vehicle. Furthermore, mice administered with DMOG presented less infiltration of TNF, IL-6, IL-1β and Nrf2/C11 compared to control treated mice, with a significant reduction in the MECS and histological scores showing intact crypts in large areas without extensive infiltration or thickening of the mucosa. The mRNA expression of the pro-inflammatory factors TNF, IL-6, IL-1β and Nrf2/C11 was significantly reduced in mice treated with DMOG compared to vehicle-treated mice. At a protein level, DMOG administration reduced p-NFκB and NLRP3 expression. DMOG-treated mice also showed activation of autophagy, as evidenced by a decrease in p-mTOR and p62 expression and increase of LC3II. In vitro, hypoxia induced a significant accumulation of lysosomes as a reduction in p-Beclin1. The late-stage autophagy inhibitor chloroquine reverted this effect indicating that was autophagy-mediated. Finally, ChIP analysis revealed that hypoxia induced the binding of HIF-1α to the promoter of p62.

Conclusion: Our results indicate that DMOG-mediated HIF-1α stabilization ameliorates DSS-induced colitis, activates autophagy and significantly reduces inflammatory gene expression and signaling. In cultured intestinal epithelial cells hypoxia triggers lysosomal formation and HIF-1α binds to the promoter of p62, thereby promoting autophagy.

Contact E-mail Address: pinetrees@daum.net

Introduction: There are several medical treatment options for inflammatory bowel disease (IBD), but all have drawback due to their significant adverse effects. Many new drugs are being developed for more safe and effective treatment. Apocynin is a chemical 4-hydroxy-3-methoxyacetophenone which is an inhibitor of NADPH oxidase and has shown promising effect in various chronic inflammatory diseases such as asthma and atherosclerosis. Due to its anti-inflammatory effect and safety profile, apocynin can be new candidate for the treatment of IBD.

Aims & Methods: In this study, we aimed to investigate effect of apocynin on colonic inflammation and the action mechanism using chemically-induced colitis mouse model. We used dextran sulfate sodium (DSS)-induced colitis model. 8 weeks old male BALB/c mice were divided into four groups (each group, n = 6): control, DSS only, DSS with apocynin, and DSS with sulfasalazine. Water (control and DSS group), apocynin (400 mg/kg) and sulfasalazine (150 mg/kg) were administered by oral route using sonde during 7 days. For western blot analysis, colon was lysed and proteins were extracted. The following antibodies were used: iNOS (BD Biosciences), COX2, Nrf2 (Santa Cruz Biotechnology Inc), MCP-1, TNF-α, p-NFκB, HO-1 (Abcam), and β-actin (Sigma).

Results: Protective effect of apocynin was evident by weight change and colon length. Histologic analysis also showed improved erosion and decreased neutrophilic infiltration in apocynin group compared to DSS group. In colon tissue, several pro-inflammatory enzymes and cytokines were decreased by apocynin. Apocynin also activated anti-inflammatory pathway by inducing activation of Nrf2 and production of he oxygenase-1 (HO-1).

Conclusion: Apocynin, a NADPH-oxidase inhibitor, showed significant anti-inflammatory effect in DSS induced colitis model. Considering its good safety profile, this molecule can be a new candidate for the treatment of IBD.

Introduction: Fecal metabolic profiling has been shown to distinguish Inflammatory Bowel Disease (IBD) from healthy controls (HC), specifically with depletion of gut-associated short chained fatty acids (SCFA) as the predominant feature separating these groups (1). Previous and current studies have used proton nuclear magnetic resonance (1H NMR) spectroscopy or mass spectrometry (MS) to measure faecal metabolites to evaluate the metabolic, microbiomic and clinical response of IBD patients to different treatments. Both techniques require a significant amount of sample pre-processing. Rapid Evaporative Ionization Mass Spectrometry (REIMS) is a relatively new technology which applies a laser to a biological sample, and the resulting vapour, containing gas phase ions of metabolites and structural lipids, is analysed by a mass spectrometer (2). Unprocessed faecal samples can be rapidly assessed using this technique to obtain lipidomic spectral profiles (2). To our knowledge this is the first study that has used REIMS to investigate whether IBD patients can be distinguished from healthy controls using faecal samples.

Aims & Methods: Unprocessed faecal samples from 109 IBD patients and 46 healthy controls were analysed using Rapid Evaporative Ionization Mass Spectrometry (REIMS). Clinical and dietary data were collected, and patients with significant other co-morbidities were excluded. Partial least squares discriminative analysis (PLS-DA) was performed to examine whether there was differences in the metabolic data between patients with Inflammatory Bowel Disease and healthy controls. Further samples were then carried out including examining whether ulcerative colitis could be distinguished from Crohn’s disease.

**Results:** Supervised multivariate analysis (PLS-DA) was able to separate faecal samples of IBD patients from healthy controls, and sub-analysis showed a stronger separation of Crohn’s disease patients from healthy controls (Q2 quality assurance of 0.2) compared to UC from healthy controls. A model comparing Crohn’s disease from UC was able to separate the two groups.

**Conclusion:** This early preliminary analysis shows that there is a degree of separation between samples of IBD patients compared to healthy control. This suggests that REIMS analysis has good potential as a research tool in IBD metabolic studies, and importantly in the current ongoing longitudinal IBD research. Further analysis will include identifying the principal metabolites that separate these groups.

**P0972 THE PATHOGENIC MECHANISM OF ARYL HYDROCARBON RECEPTOR MEDIATED ABNORMAL DIFFERENTIATION OF INTESTINAL ILC3/ILC1 IN CROHN’S DISEASE**

X. Zhao, H. Zhang

**Department Of Gastroenterology, Jiangsu Province Hospital and Nanjing Medical University, Nanjing/China**

**Contact E-mail Address:** zhaoxj9178@163.com

**Introduction:** The abnormal differentiation of intestinal innate lymphoid cells (ILC3 and ILC1) exist in autoimmune disease. ILC3 decreased and ILC1 increased in Crohn’s disease (CD) patients, suggesting that CD patients have abnormal intestinal ILC3/ILC1 alteration.

**Aims & Methods:** The present study investigated the aberrant colonic mucosal ILC3/ILC1 in active CD patients and 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced colitis mice. The expressions of aryl hydrocarbon receptor (AhR) in colon of acute and quiescent CD patients were detected by western blot and immunofluorescence. The ILC3/ILC1 were investigated in CD patients and 2, 4, 6-trinitrobenzene sulfonic acid (TNBS)-induced colitis mice (AhR−/−, AhR+/−).

**Results:** Compared to quiescent CD patients, the expression of aryl hydrocarbon receptor (AhR) in the intestinal tissue in active CD patients was decreased. Meanwhile, the number of ILC3 in active CD patients and AhR knockout mice was decreased while ILC1 increased. The intestinal inflammation in AhR knockout mice given TNBS was more severe than wild-type mice.

**Conclusion:** These findings suggest that AhR may mediate abnormal differentiation of ILC3/ILC1, and the production of inflammatory cytokines, finally, promotes the pathogenesis of CD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** c.campurbi@gmail.com

**Introduction:** Long polar fimbiae (FimA), FimH adhesin and ChiA chitinase have been related with adherent-invasive *E. coli* (AIEC) pathogenesis. Controversial results have been found regarding the prevalence of FimA in AIEC vs non-AIEC (1, 2). Some FimH amino acid variants were reported to be specific for AIEC (3) whereas other variants were associated with phylogroup disease origin of the strains (4). Differences in the ChiA sequence were reported between LF82 and K-12 strains but this gene has not been studied in other AIEC yet (5).

**Aims & Methods:** The prevalence of FimA and the distribution of fimH and chiA variants in a collection of AIEC and non-AIEC from different disease origins. Crohn’s disease (CD), ulcerative colitis (UC) and colorectal cancer (CRC)-were studied with the purpose to determine if these genes could be used as molecular markers for AIEC identification and disease diagnosis. In a collection of 7 AIEC and 29 non-AIEC isolated from CD, UC, CRC patients and controls, fimA gene was PCR-amplified to assess its presence and fimH and chiA genes were sequenced to identify point mutations. For comparison FimH and ChiA protein sequences, UPGMA phylogenetic tree and allele identification was performed using MEGA5. The genetic differences were annotated using as reference the K-12 strain. Then, they were analysed statistically according to AIEC pathotype, phylogroup, and disease origin by the 1, 2 test and non-parametric tests were used to evaluate amino acid variability regarding the adhesion and invasion indices.

**Results:** Low gene frequency for fimA141 and fimA154 was reported (11.7% and 16.7% respectively). FimA154 was only found in strains from A (22%) and B2 phylogroup (86%) and no relation with AIEC phenotype or disease was observed. Two main clusters of FimH were obtained by phylogenetic analysis, classifying the strains according to the presence of S78N mutation. S78N variants were characteristic from strains of B2 and D phylogroups as none of the A or B1 strains presented it. Despite statistical significance was not reached, the strains with S78N, V163A, R166H mutations showed the highest adhesiveness. Regarding ChiA, two main clusters defined by the presence or absence of an insertion in 312–314 residues were obtained. None of the five previously mutated found in LF82 strain were associated with AIEC strains, whereas the V415A variant was found specifically in AIEC (20%) (p = 0.049). Of note, among the strains harbouring the 312–314 insertion, a subcluster that shared identical amino acid sequence included the LF82 strain and the 44% of AIEC strains but only the 10% of the non-AIEC (p = 0.019). No differences between FimH/ChiA variants and origin of isolation was observed.

**Conclusion:** In contrast with other studies, no relation of fimA presence nor in FimH mutations with AIEC pathotype or disease was observed. Nonetheless, a variant in ChiA sequence more frequently found in AIEC isolates was reported, being an interesting signature sequence for the detection of at least a subgroup of AIEC strains. Further confirmation in a wider strain collection would be required.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Primary sclerosing cholangitis (PSC) is a progressive disorder of biliary tree which can lead to end-stage liver disease, liver transplantation or even death.1 Colitis accompanying PSC is considered to be a phenotype of IBD (inflammatory bowel disease) distinct from ulcerative colitis (UC) and is often referred to as *PSC-IBD* 3.

**Aims & Methods:** Our aim was to compare the gut bacterial microbiota of patients with PSC and UC. Stool samples were prospectively collected and relevant clinical data obtained from 106 study participants, 43 PSC patients with (n = 32) or without (n = 11) concomitant IBD, 32 UC patients, and 31 healthy controls (HC). Sequencing of the 16S rRNA gene including the V3 and V4 regions was performed on Illumina MiSeq platform to cover low taxonomic
levels. Data were further processed in QIIME employing MoAInL and LEfSe to derive output data.

Results: Microbial profiles in both PSC and UC were characterized by low bacterial diversity and significant change in global microbial composition. Rothia, Enterococcus, Streptococcus, Veillonella, and three other genera were markedly overrepresented in PSC regardless of concomitant IBD. Rothia, Veillonella and Streptococcus were tracked to the species level to identify Rothia mucilaginosa, Streptococcus infantis, S. alactolyticus, and S. equi along with Veillonella parvula and V. dispar. PSC was further characterized by decreased abundance of Actinomyces, Prevotella copri. Decrease in genus Phascolarctobacterium was linked to presence of colonic inflammation regardless of IBD phenotype. Akkermansia muciniphila, Butyriviridales pulaeacorum and Clostridium clostrum were decreased in UC along with genus Roseburia. Unclassified Actinomycetes species were markedly increased in overlap syndrome of autoimmune hepatitis (AHI) and PSC. Low levels of serum albumin were significantly correlated with enrichment of order Actinomycetales. Conclusion: PSC was characterized by microbial features independent of concomitant IBD. The overrepresented taxa clearly distinguished IBD phenotypes (PSC and UC) as well as PSC from PSC/AHI.

P0977 EFFECTS OF TIME ON URINARY METABOLIC SIGNATURES IN INFLAMMATORY BOWEL DISEASE

Introduction: Metabolic profiling (metabonomics) has been proposed as a novel clinical tool in IBD to predict development of complex disease, or for longitudinal non-invasive monitoring of activity and/or response to drug treatment. Urinary metabonomics can distinguish IBD from healthy controls(1) but no studies to date have assessed the stability of these discriminatory profiles over time. Reports in healthy adult populations have shown that metabolic signatures are largely unchanged over periods of up to 3 years(2), but signals are influenced by multiple external factors including medication and surgery, so how these changes in IBD is unknown. The aim of this study was to compare baseline urinary metabolic profiles of IBD patients with a repeated sample several years later to assess similarity, and also to test if any clinical outcomes could be retrospectively predicted from the baseline sample.

Aims & Methods: Two urine samples from 39 IBD patients (22 Crohn’s disease (CD) and 17 ulcerative colitis (UC)) were collected - one at baseline and one several years later (range 7–9 yrs). These were analysed by 1H NMR spectroscopy. Disease progression was defined as initiation of immunosuppression or biologics, progression of disease location, or disease remission. Principal components analysis was used to visualise the difference between the two time points within the cohort. Orthogonal partial least squares discriminant analysis (OPLS-DA) was used to identify if the metabolic signatures could be used to predict adverse clinical outcomes in the patients studied.

Results: 57% of CD patients and 17% of UC patients had clinical progression at follow-up sampling. PCA showed clustering of sample pairs from the baseline and several years later in most individuals, suggesting intra-individual similarity across the time period. OPLS-DA showed no statistical models could be built to predict combined poor outcome based on the initial urinary metabolic profile (p=0.26). However, the small subgroup who went on to require surgical intervention could be separated from the cohort in a model (Q2=0.015; p=0.03) constructed on their baseline profiles and follow-up samples.

Conclusion: The metabolic profile of IBD in an individual appears relatively stable over a significant time period despite a variety of clinical outcomes and interventions. Variations in longitudinal measurements appear to be subtle, and thus replication of this approach for disease monitoring using NMR spectroscopy could prove difficult. These results may suggest that metabolic profiling could be exploited to predict a higher risk of requiring future surgery.

P0978 BACTERIAL TRANSLLOCATION CONTINUES IN ULCERATIVE COLITIS DESPITE MUCOSAL HEALING AND SUCCESSFUL CLINICAL REMISSION
A. Steel
Gastroenterology, Royal Liverpool & Broadgreen University Hospital, Liverpool/United Kingdom

Contact E-mail Address: alan.steel@rlbhuh.nhs.uk

Introduction: Mucosal healing is considered to be the hallmark of successful therapy in Ulcerative Colitis, and has become increasingly used as a target of therapeutic interventions. Loss of mucosal integrity and associated translocation of bacterial components across the mucosal epithelial barrier occurs in Ulcerative Colitis and persistence of a structural mucosal defect is a characteristic of chronic inflammatory bowel disease. Mucosal healing can be defined by clinical, histological and endoscopic parameters, but no clear definition of the required extent of mucosal healing exists, nor is there agreement on how functional mucosal healing is defined.

Aims & Methods: To define the extent and associations of mucosal healing in patients with Ulcerative Colitis, and the relationship with bacterial translocation and clinical remission. Patients with established diagnosis of Ulcerative Colitis undergoing endoscopic evaluation were recruited to the study (Ethics: South West London REC2 10/H0706/26). Clinical history and long-term follow-up data were recorded. Blood and mucosal samples were processed as mononuclear cells. Healthy controls recruited from cohort undergoing routine lower gastrointestinal investigations without positive findings. Flow cytometry characterisation of cells by cell surface CD45RO, CD27, CD4, CD154, CD48 and CD161 and cytokine expression after stimulation with enterotoxin B stimulation by IL-2, IL-17a, IL-22, TNF, IL-17f and IFNγ. Immunohistochemistry to define tight junction apical epithelial expression (Claudin 1, Claudin 4 and Ocludin) and lipopolysaccharide within the lamina propria. Peripheral blood markers of bacterial translocation: bacterial DNA (16fDNA), lipopolysaccharide binding protein (LBP), soluble CD14 and plasma lipopolysaccharide. Statistical analysis by Mann Whitney or Kruskall Wallis analysis with Dunn’s post test correction, or by Spearman rho correlation.

References
Results: 28 patients with Ulcerative Colitis, duration of disease 4 months to 31 years, and 22 Healthy control participants were recruited for the study. Half of the patients had active disease as assessed by Ulcerative Colitis Severity Score. Disease severity positively correlated with frequency of mucosal Th17 (CD4+IL-17+T) and IL-17f. Breaches in tight junction protein expression were greater in healthy: Claudin 1 (p = 0.001), Claudin 4 (p = 0.006) and occludin (p = 0.03). The serum marker of bacterial translocation, lipopolysaccharide binding protein (LBP) was elevated in UC compared to controls (p = 0.0078) and was positively correlated with breaches of Claudin 1 and Occludin (p = 0.018 and p = 0.012 respectively) Staining colon biopsies for the presence of lipopolysaccharide in the lamina propria demonstrated positive findings in healthy controls, supported by data from 16s rDNA analysis of blood from healthy controls. In the Ulcerative Colitis cohort in clinical remission the absence of lipopolysaccharide in the lamina propria was associated with elevated levels of LBP and increased breaches of Occludin (p = 0.0022).

Conclusion: Breaches of tight junction proteins in the colon of patients with stable clinical remission can be detected and are associated with perturbations of mucosal immunological function and markers of bacterial translocation. Lipopolysaccharide presence in the lamina propria of patients in remission appears to be associated with less tight junction breaches and reduced local and systemic evidence of bacterial translocation. These findings require further study, specifically to examine the role of mucosal immune tolerance to lipopolysaccharide and other bacterial cell products that may be present in the healed mucosa of ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Diet may influence intestinal inflammation via various pathways but the evidence regarding the role of fiber or fat intake in patients with inflammatory bowel disease (IBD) is controversial.

Aims & Methods: The aim of this study was to investigate the association between dietary fiber or total fat intake and disease activity or quality of life in Greek IBD patients. We prospectively collected food frequency questionnaires (FFQ) from consecutive IBD patients at outpatient visits. The European Prospective Investigation into Cancer and Nutrition (EPIC) Study FFQ for Greek population with the MAFF photographic food atlas were used in order to collect information for dietary habits of IBD patients. Moreover, disease activity and quality of life were assessed with the disease activity index (SCAI) (for ulcerative colitis) (UC) and the Harvey-Bradshaw index (HBI) for Crohn’s disease (CD)) as well as quality of life using the short inflammatory bowel disease questionnaire (SIBDOQ) were evaluated. Patients’ demographic, clinical characteristics, nutritional status, laboratory data (C reactive protein (CRP), haemoglobin, erythrocyte sedimentation rate (ESR), platelets and albumin) and treatment data were recorded and analysed for all participants.

Results: A total of 141 consecutive IBD patients (53 UC, 88 CD, mean age 47.2±16.1 years, 84 males 57 females, BMI 26.7±5.3) were included. Patients’ mean daily fiber intake was 21.8 g (IQR 13.8–34.6) and mean daily fat consumption with abnormal CRP, increased ESR, platelets and albumin] and treatment data were recorded and analysed.[12] Data

Introduction: Crohn’s disease (CD) is a progressive disease that over time can lead to the development of complications such as strictures or internal penetrating disease that will ultimately lead to surgery. Only few population-based studies from the biological era and widespread use of immunomodulators have investigated the change in disease behaviour and subsequent risk of surgery in CD.

Aims & Methods: The EpiCom-cohort is a population-based cohort of unselected patients with inflammatory bowel disease diagnosed in 2010 in Eastern and Western European centres. Patients were followed prospectively for five years and clinical data were captured throughout the follow-up period. Disease behaviour was defined according the Montreal classification as B1: non-stricturing, non-penetrating, B2: stricturing; B3: penetrating based on endoscopy, cross-sectional imaging or surgery. The risk of surgical resection was analysed by Cox regression analyses using the proportional hazard assumption including multiple covariates (age, gender, disease location, diagnostic delay, smoking status, change in behaviour, geographic region and treatment with biologics within 6 months from diagnosis).

Results: A total of 488 incident CD patients were included in the study, of which 347 (71%) had B1. A total of 141 (29%) patients had complicated CD at diagnosis. After 3 years’ follow-up, this number increased to 190 (39%) (Table 1). Of patients diagnosed with B1, 35 (10%) progressed to B2 while 14 (4%) progressed to B3 after a median of 21 months (range: 0–62). The proportion of B1 patients changing behaviour was highest during the 1st year of disease (5%) but stable afterwards.

Conclusion: Changes in disease behaviour were highest during the first year of disease (5%) but stable afterwards. Of patients with B1 as initial behaviour a total of 34 (22%) patients had a resection. Of patients with B1, 35 (10%) progressed to B2 while 14 (4%) progressed to B3 after a median of 21 months (range: 0–62). The proportion of B1 patients changing behaviour was highest during the 1st year of disease (5%) but stable afterwards. Of patients with B1 as initial behaviour a total of 34 (22%) patients had a resection. Of patients with B1, 35 (10%) progressed to B2 while 14 (4%) progressed to B3 after a median of 21 months (range: 0–62). The proportion of B1 patients changing behaviour was highest during the 1st year of disease (5%) but stable afterwards.
associated with the risk for resection. No difference in the results was found between Eastern and Western European patients.

Table 1: Disease behaviour in Crohn’s disease at diagnosis and follow-up

</tbody>
</table>

Conclusion: In this European population-based inception cohort of unselected CD patients 14% of patients with B1 progressed to B2 or B3 after five years of follow-up. The risk of surgery was increased in patients with B1 who progressed to B2/B3. No clinical predictors for progression in behaviour including smoking and treatment with biological therapy could be identified.

Introduction: Risk factors for colorectal cancer (CRC) in Inflammatory Bowel Disease (IBD) are still debated (1).

Aims & Methods: In a prospective multicenter, nested case-control IG-IBD study at 4 years, we aimed to assess the frequency and risk factors for incident CRC in IBD. The role of IBD phenotype vs thiopurines (IS) and/or anti-TNF’s use as risk factors for CRC was also evaluated. From Jan. 2012 to March 2017, all incident cases of CRC in IBD pts referring to 16 IG-IBD Units were recorded. Each IBD pt with CRC (IBD-CRC) was matched with 2 IBD pts with no cancer (IBD-C) for: IBD type (Crohn’s Disease, CD vs Ulcerative Colitis, UC), gender, age (<5 yrs). Cases of CRC derive from a larger cohort of IBD pts referring to the same Unites, with incidence of any cancer separately reported at 4 years follow up at 3 yrs reported for cancer overall(2). Statistical analysis: data expressed as median (range), Wilcoxon test, Chi-squared test, Fisher exact test; multivariate logistic regression analysis.

Results: Incident cases of CRC occurred in 66 IBD pts: 41 UC (UC-CRC), 25 CD (CD-CRC). IBD-C group therefore included 198 pts (66 IBD-CRC, 132 IBD-C). UC group included 123 pts (41 IBD-CRC, 82 UC-C) and CD group included 75 CD pts (25 CD-CRC, 50 CD-C). The frequency of incident CRC was higher in IBD group therefore included 198 pts (66 IBD-CRC, 132 IBD-C), UC group included 123 pts (41 UC-CRC, 82 UC-C) and CD group included 75 CD pts (25 CD-CRC, 50 CD-C). The frequency of incident CRC was higher in the tested UC versus CD population (62.1% vs 37.9%; p = 0.009). Gender was equally distributed in IBD groups (UC: 14 F [34%]; CD:12 F [48%]; p = 0.431). The median age was comparable between IBD-CRC and IBD-C (UC/CR vs UC/C 62 [37–86] vs 59 [35–86]; CD-CRC vs CD-C: 51 [23–76] vs 55 [22–76]; p = 0.179). Concomitantly, CD duration was comparable between pts with vs without CRC (20 [1–47] vs 13 [0–10 yrs:19 [76%] vs 35 [70%]; p = 0.060). UC duration was longer in pts with vs without CRC (20 [0–37] vs 10 [0–33] yrs: 6 [10%] vs 35 [60%]; p = 0.011). Conversely, CD duration was comparable between pts with vs without CRC (20 [1–47] vs 13 [0–35] yrs: 24% vs 15 [30%]; p = 0.017). April 19 yrs: 76% vs 35 [70%]; p = 0.58). IBD

Conclusion: Bifidobacterium relative abundance correlate closely with short term changes in FC suggesting a possible causal association. Other genera and species had poor and inconsistent correlations with short term changes in FC suggesting that they may not be causally related to short term changes in gut inflammatory activity.
Pts with CRC were younger at diagnosis of IBD than their IBD-C (UC-CRC vs UC-MD) (median age: 46 (IQR: 15–76) vs 46 (15–80); p = 0.04). The frequency of CRC was comparable between UC pts using or not IS and/or anti-TNFs (CRC-UC vs CRC-MD: IS monotherapy: 4 [16%] vs 9 [18%]; p = 0.04; OR 2.21 [0.70–9.87]; 1.66 [0.62–4.96]; 0.96 [0.36–3.08]; 1.78 [0.60–4.66]; 1.36 [0.66–2.89]; 0.54 [0.24–1.23]; respectively). In CD, perianal disease was the only significant risk factor for CRC (OR 2.11 [1.86–2.31]; as no other significant risk factors were identified (OR 2.21 [0.70–9.87]; 1.66 [0.62–4.96]; 0.56 [0.19–1.41; 0.39 [0.14–2.52]; 0.54 [0.23–1.43]; 0.83 [0.26–2.55]; 0.53 [0.27–0.8]; respectively).

Conclusion: In a prospective, multicenter, nested-case control IG-IBD study, incident cases of CRC were more frequent in UC than in CD. In our cohort, UC duration and perianal CD, but not immunomodulators use, were identified as independent risk factors of CRC.

W. Fries: The study was not supported by grants nor funded. The reported disclosures are not related to the study: Advisory boards: Abbvie, Celltrion, Ferring, Hospira, Janssen, Lilly, MSD, Mundipharma, Pfizer, Samsung, Sofar, Takeda, Research grant: MSD.

Aims & Methods: Aims: To evaluate the incidence of inflammatory bowel disease (IBD) in Spain. Secondary: To describe the characteristics of patients at diagnosis; to evaluate the need for immunomodulators (IMM), biologics, surgery and hospital admissions in the first year of diagnosis and to assess the time from the onset of the symptoms to the diagnosis of the disease.

Methods: Prospective and population-based nationwide study. Adult patients diagnosed with IBD (Crohn’s disease (CD), ulcerative colitis (UC) or indeterminate colitis (IC)) during 2017 in the 17 Spanish regions are being included. Each case is also being followed-up for 12 months after diagnosis to describe changes in phenotype or location, to evaluate the requirement of IMM and biologics and to determine the need for hospitalization or surgery during the first year from the diagnosis. Data was captured in a web-based database (AEG-REDCap).

Results: An updated interim analysis of the incidence of IBD in Spain was planned 6 months after the beginning of the study (June 2017). Up to April 1st 2017, 557 patients from 156 centres have been included: 53% males, mean age 40 years, 27% smokers. 51% had UC, 44% CD, and 5% IC. 13% of patients had a family history of IBD. The mean time to IBD diagnosis from symptoms onset was 3 months (range 0–360). 14% had a diagnosis of CD, 80% a diagnosis of UC (median age: 46 (IQR: 15–76) vs 46 (15–80); p = 0.04). The frequency of CRC was comparable between UC pts using or not IS and/or anti-TNFs (CRC-UC vs CRC-MD: IS monotherapy: 4 [16%] vs 9 [18%]; p = 0.04; OR 2.21 [0.70–9.87]; 1.66 [0.62–4.96]; 0.96 [0.36–3.08]; 1.78 [0.60–4.66]; 1.36 [0.66–2.89]; 0.54 [0.24–1.23]; respectively).

Disclosure of Interest: J.L. Cabriada: Jose Luis Cabriada served as consultant or received research funding to MSD, Takeda, Janssen, Otsuka Ph and PK. R. Lorente Poyatos: Speaker consultant: MSD, Abbvie and Takeda.

Introduction: The human gut microbiome is made up predominately of four major bacterial phyla, Firmicutes, Bacteroidetes, Proteobacteria and Actinobacteria. Changes or imbalance of these phyla is termed dysbiosis. Systemically, in inflammation bowel disease (IBD), key changes have been identified such as a reduction in beneficial bacterial species including Faecalibacterium prausnitzii and increases in more pathogenic species including Enterobacteriacae. The use of 16 S rRNA analysis methods will negate this effect and thus over-representing aerobic bacteria whilst possibly under-representing anaerobic bacteria. The use of 16 S rRNA analysis methods will negate this effect and thus over-representing aerobic bacteria whilst possibly under-representing anaerobic bacteria.

Aims & Methods:

1. To evaluate the rate and tolerance of live-vaccines before and after 6 months of life in newborn infants in the first 6 months at least. Along this, European consensus recommendations regarding breastfeeding and complications and information given during pregnancy were evaluated.

2. Questionnaires concerning live-vaccines (BCG, rotavirus, MMR) in their child during the first year, breastfeeding and complications and information given during pregnancy were included in the study.

3. A total of 200 women were included, 55 of whom (45%) breastfed and resumed after delivery in 112 (90%) patients. 55 women (45%) breastfed their infant and no complication was noted. Among 69 women who did not breastfeed their child, 4 women (5.8%) had a complication.

Results:

1. Half of women breastfed their child with no reported complication.

2. Infliximab was used in 76 (61%) patients, Adalimumab in 46 (37%) patients, and Vedolizumab in 28 (23%) for ulcerative colitis or undetermined colitis. AntiTNF used was Infliximab in 76 (61%) patients, Adalimumab in 46 (37%) patients, and Vedolizumab in 28 (23%) patients.

P0987 OUTCOME OF ENDOCOPICALLY RESECTED DYSPLASTIC LESIONS IN ULCERATIVE COLITIS

H. Saoula, A. F. Boutaleb, H. Mahiou, M. Aissaoui, Y. Zmiri, N. Hamidouche, A. A. Vora1, A. A. Vora2

Enocesophageal dysplasia is detected after a mean follow-up of 30.16 months (range: 7.56-62.76). Dysplastic lesions were evaluated in 5 patients with UC and 5 patients with UC treated by Vedolizumab. The impact of CMV infection in UC patients treated with Vedolizumab is unknown.

Conclusion: The overall rate of dysplasia in UC patients treated with Vedolizumab and to analyze the risk factors for CMV disease associated with Vedolizumab therapy.

Aims & Methods: We performed a retrospective case-control study of all patients with UC treated with Vedolizumab from June 2014 to April 2017. The effect of the outcome of UC patients treated with Vedolizumab and to analyze the risk factors for CMV disease associated with Vedolizumab therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact Email Address: xavier.roblin@chu-st-etienne.fr

Introduction: Cytomegalovirus (CMV) infection has been associated with resistance to several immunomodulatory therapies in Ulcerative Colitis (UC) patients. The impact of CMV infection in UC patients treated with Vedolizumab is unknown.

Results: Thirty two patients were eligible (sex ratio M/F: 3/1, mean age: 43.6 years, mean disease duration: 7.5 years, E3 phenotype according to the Montreal classification). A total of 11 (34%) patients were treated with Vedolizumab. Patients with undetectable CMV DNA load were included in the control group. After antiviral treatment, the CMV DNA load was found undetectable for all patients. Treatment change was more frequent in the CMV disease group (HR = 3.15 [1.02-9.7], p = 0.03507) with only 16.7% patients who continued Vedolizumab treatment versus 65.4% in the control group (p = 0.03507). Coloscopy was also more frequent in the CMV group (33.3% versus 7.7% p = 0.064). By multivariate analysis, the only factor associated with the occurrence of CMV disease was a fecal calprotectin less than 300 mg/g stools at the beginning of the vedolizumab treatment. A previous endoscopic colonic infection also was more frequent but not statistically significant.

Disclosure of Interest: The occurrence of CMV disease, documented with high CMV DNA load on colonic biopsy samples, in UC treated with Vedolizumab is responsible for a negative impact on the natural evolution of UC, with more therapeutic failure and surgical treatment, even after an efficient antiviral treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastrointestinal disorders may exhibit overlapping symptoms making diagnosis difficult in the primary and specialty care settings. Inflammatory bowel disease (IBD), with a prevalence of <0.5% in the general population[1], is characterized by chronic inflammation of the gastrointestinal tract, non-specific elevation of conventional inflammatory markers such as ESR and CRP and may present with extra-intestinal manifestations. Irritable bowel syndrome (IBS), in contrast, is a functional disorder without gastrointestinal inflammation and with an estimated prevalence of 10-20% [2]. Endoscopy is the gold standard for detecting and quantifying IBD vs. IBS, but due to the low prevalence of IBD, is negative in the majority of cases. Furthermore, it is invasive, expensive, and uncomfortable for the patient and not without risks. Moreover, inadequate bowel preparation prior to colonoscopy is known to
increase the burden of disease from both the clinical and the economic perspec-
tive: shorter intervals between repeated procedures, higher missed rates, patient
coincidence, and increased risk of complications are reported in the scientific
literature. F-Calprotectin (FC) is a fecal marker of intestinal inflammation; IBD
patients exhibit FC levels significantly higher than the general population; IBS
patients have FC levels higher than healthy controls, but significantly lower than
IBD patients [3]. Therefore, FC can be used as a pre-endoscopic test to differ-
entiate between IBD and IBS. The present study aims at evaluating the cost-
effectiveness of FC compared to the combined usage of CRP and ESR, and the
gold standard to distinguish IBD from IBS in Spain.

Aims & Methods: An 18-week Markov model was developed for each diagnosti-

Aims & Methods: We aimed to calculate the correlation between the endoscopic scores -Mayo Endoscopic Score (MES), DUBLIN, MMES and the biomarkers of inflammation -erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) and to compare the ability of these scores to predict Calprotectin > 100 μg/g. This was a retrospective study, including patients with diagnosis of left or extensive UC who underwent colonoscopy between 2015 and 2016. The biomarkers were obtained with a maximum interval of one week in relation to colonoscopy and without introduction of new therapy. The Spearman test calculated the correlation between scores and biomarkers. ROC curves (AUC) were obtained for each score to predict Calprotectin > 100 μg/g.

Results: 60 patients were included, 46.7% female patients with mean age 45.3 ± 12.8 years and in patients with values of ESR 4.4 ± 12.8 mm, CRP 5.12 ± 6.00 mg/L and Calprotectin 354 ± 430 μg/g. The correlation between Calprotectin and MES was r=0.623 p < 0.001, for DS r=0.588 p < 0.001 and for MMES r=0.404 p = 0.001, but no correlation was found with the DS. There was no significant correlation between ESR and endoscopic scores. To predict values of Calprotectin > 100 μg/g the AUC for the MES was 0.848, for the DS 0.801 and for the MMES 0.815, and there was no statistically difference between the curves.

Conclusion: Although there is a good correlation between endoscopic scores and Calprotectin, the correlation between scores that take into account the extension were not superior to Mayo Endoscopic Score.

P9993 BONE HEALTH IN CROHN'S DISEASE IN THE ERA OF TNF-ALPHA INHIBITORS

S. Hakimian 1, J. Kheder 2, D. Cave 2, B. Hyatt 2
1Internal Medicine, University of Massachusetts, Worcester/United States of America/M
2Gastroenterology, UMass Medical Center, Worcester/United States of America

Contact E-mail Address: shahrad.hakimian@umassmemorial.org

Introduction: Osteoporosis and fractures are common in Crohn's disease (CD). Recently, several inflammatory cytokines, including tumor necrosis factor (TNF)-alpha have been linked to increased bone resorption. Therefore, it is hypothesized that anti-TNF therapy may influence osteoporosis and fracture risk. However, few studies have evaluated osteoporosis and fracture risk in the CD population.

Aims & Methods: The aim of this study is to gain a better understanding of the epidemiologic risk factors for osteoporosis and vitamin D deficiency in the era of TNF-alpha inhibitors. We conducted a retrospective review of 714 consecutive patients with CD in our GI clinic between 2008 and 2015 to identify 464 patients who met the inclusion criteria for the study comprising of all adults older than 18 years with confirmed CD based on labs and endoscopic findings. Data extracted for analysis included demographics data, disease phenotype, duration of disease, measures of disease activity, imaging and endoscopic data. Statistical analysis was performed using student t-test and chi-square test.

Results: We reviewed the charts of 290 patients with CD treated with TNF-alpha inhibitors (TNF) and 174 patients who are anti-TNF naïve (NB). There were 207 (45%) males and 257(55%) females in this cohort. TNF patients tended to be younger (average age of 43+/−15 and 54+/−18 years in TNF and NB groups respectively). Mean duration of disease was 14.9+/−10.2 for TNF and 18.6+/−19.2 for NB group. Approximately half of the patients had a smoking history. Average BMI was 27.6+/−6.6. Rates of vitamin D deficiency, insufficiency and normal vitamin D levels were not significantly different between TNF and NB groups. Vitamin D level was not associated with age, duration of disease, or inflammatory markers (ESR). However, there was a weak positive correlation between nutritional status (lowest albumin) and vitamin D level (Pearson’s R=0.19 vs 0.5 and for TNF and NB groups. Vitamin D level was associated with age, duration of disease, or inflammatory markers (ESR). However, there was a weak positive correlation between nutritional status (lowest albumin) and vitamin D level (Pearson’s R=0.19 vs 0.5 and for TNF and NB groups. There was similar rate of osteoporosis (16% vs 18%), osteopenia (53% vs 57%) and normal bone density (31% vs 25%) between the TNF and NB groups respectively. Furthermore, there was no statistically significant difference in T-scores at the hip (−1.2 vs −1.3), the spine (−1.0 vs −0.95), or the lowest T-scores (−1.5 vs −1.4) between TNF and NB patients. However, Z-scores at the spine (−0.47 vs −0.05), the hip (−0.55 vs −0.49) and the lowest Z-scores (−0.91 vs −0.67) were lower in the TNF group, but only reached significance in the spine (P=0.03). Interestingly, a significantly higher proportion of TNF patients under 60 years of age met the criteria for osteoporosis (T-score < −2.5 below the mean) compared to NB patients (15% vs 3.6%). Additionally, rates of osteoporosis in the NB group were very different between patients before and after age 60 (3.6% vs 30%) [Table 1]. There was no correlation with bone density and vitamin D level, nutritional status (based on lowest albumin level), or degree of inflammation (highest ESR or CRP levels). However, there was a moderate positive correlation with BMI and bone density (Pearson R=0.39) and a negative correlation with age (R =−0.25).

Table 1: Osteoporosis rates in patients on anti-TNF therapy (TNF) and those naïve to biologic medications (NB) at each age category

<table>
<thead>
<tr>
<th>Group</th>
<th>Age &lt; 60</th>
<th>Age ≥ 60</th>
</tr>
</thead>
<tbody>
<tr>
<td>TNF</td>
<td>15.4%</td>
<td>18.2%</td>
</tr>
<tr>
<td>NB</td>
<td>3.6%</td>
<td>30.0%</td>
</tr>
</tbody>
</table>

Conclusion: Rates of vitamin D deficiency, and osteoporosis were similar among patients on anti-TNF medications to those on no biologics. TNF group patients were diagnosed with osteoporosis at an earlier age compared to NB group. Patients on anti-TNFs also had statistically lower Z-scores at the spine. Prospective studies are necessary to further determine the role of anti-TNF medications in osteoporosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P9994 THE AVAILABILITY OF INFliximAB TROUGH LEVELS IN IBD PATIENTS ON MAINTENANCE THERAPY DEEPLY IMPACTS THERAPEUTIC DECISION-MAKING

L. Lobaton 1, F. Cañete 1, A. Teniente 1, E. Cabrera 1, M. Mañosa 1, E. Martinez 2, E. Domenech 3
1Gastroenterology, Hospital Universitari Germans Trias i Pujol, Badalona/Spain
2Immunology, Hospital Universitari Germans Trias i Pujol, Badalona/Spain

Contact E-mail Address: trianany2010@gmail.com

Conclusion: In our cohort the frequency of HS varied between 13.4% and 41.7% defined by non-invasive methods. We found that the presence of metabolic syndrome and obesity were more frequent in patients with HS. Regarding factors related to IBD, patients with previous history of surgery were more frequently diagnosed with HS.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Infliximab (IFX) trough levels (ITLs) have emerged as a promising tool for the management of inflammatory bowel disease (IBD) patients and they correlate with clinical response and endoscopic remission. However, its use in clinical practice is still under debate, particularly in clinically stable patients.

Aims & Methods: 1) to describe real-life ITLs in clinically stable IBD patients; 2) to evaluate the LCI factors associated with infratherapeutic ITLs; and 3) to evaluate the impact of ITLs availability by comparing the CCD with TLGD. The decisions between experts were also compared. Both comparisons were calculated by the linear Cohen’s Kappa (κ) index. IBD patients on maintenance IFX therapy were prospectively followed from June 2015 to June 2016. Demographic, clinical and biological data including C-reactive protein (CRP) levels from the same infusion day were collected. At each IFX infusion, patients were visited by their physician; a “current clinical decision” (CCD) was taken regarding clinical data and CRP. ITLs were measured just before the IFX infusion/conversion were considered as infra-therapeutic if <2 μg/ml. Once ITLs were known, 3 experts took a hypothetical decision on treatment based on the same clinical and biological data plus ITLs (ITL-guided decision – TLGD).

Results: A total of 224 IFX infusions from 74 patients (76% Crohn’s disease) were analyzed. Median (IQR) disease and IFX therapy duration was 10 years (5-18) and 23 months (7-61), respectively; 87% received concomitant immunosuppressant therapy; 70% were on standard dosing, whereas 10% were scheduled every 4-6 weeks and 13% every 4-12 weeks. 30% of patients had clinical and biological remission. Median (IQR) CRP levels were 3.1 mg/ml (1.5–6.1). Median (IQR) ITLs were 1.79 μg/ml (0.35–3.74), with 52% of patients having infratherapeutic ITLs. In the multivariate analysis, the only risk factor for infra-therapeutic ITLs was the presence of biological activity. Concordance between CCD and TLGD was poor (κ = 0.10 [95%CI:0.01–0.20] vs. κ = 0.11 [95%CI:0.01– 0.21]) for experts A/B, respectively. This “dis- agreement was due to a higher proportion of dose-escalation according to the TLGD as compared to the CCD. Among the 203 infusions in which no action was taken according to the CCD, 93 (40%), 48 (20%) and 65 (30%) would have been dose-escalated according to the TLGD for experts A, B and C, respectively. The concordance between experts was moderate (κ = 0.55 [95%CI:0.41–0.71] vs. κ = 0.40 [95%CI:0.26–0.55] vs. κ = 0.30 [95%CI:0.21–0.40]) for experts A-B/C-B/C-C, respectively.

Conclusion: Our results highlight the impact of the inflammatory burden on ITLs and determining their therapeutic range in patients clinically stable. Both the clinical and economical impact of ITLs-assisted decision-making in IBD patients should be evaluated in prospective cohorts.

P0995 THE DIAGNOSTIC UTILITY OF LINKED-COLOR IMAGING IN THE EVALUATION OF MUCOSAL INFLAMMATION IN PATIENTS WITH ULCERATIVE COLITIS

Digestive And Lifestyle Diseases, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima/Japan

Contact E-mail Address: h-hitomi@m3.kufm.kagoshima-u.ac.jp

Introduction: Recent studies recommend the histological mucosal healing of the intestinal tissue as a treatment goal in ulcerative colitis (UC). The intestinal color was evaluated by white-light imaging (WLI) and mucosal color assessment was validated based on the L*a*b* color values (LCI-L, LCI-a, LCI-b), where L* a* and b* color values are defined as lightness, redness, and yellow, respectively. We also quantified the mucosal color values of LCI (LCI-L, LCI-a, LCI-b) based on the L*a*b* color values. The endoscopic images were classified according to the Mayo endoscopic score (MES), and biopsied specimens were classified according to the Geboes scores. The endpoint of this study was to measure the correlation between the mucosal color values of LCI (LCI-L, LCI-a, LCI-b) and MES, which potentially stressful clinical situations were considered. Physicians and patients rated these situations on a scale from 1 to 10 as potential triggers of anxiety for the patient. A Mann-Whitney test was used to compare perceptions from physicians and patients taking 151 valid questionnaires from physicians and a randomized sample of 155 patients’ questionnaires.

Results: The survey was completed by 912 patients (mean age 39 ±10 years, 67% women) and 170 patients (mean age 44 ±10 years, 58% women). Having an ostomy, fecal incontinence in public or surgery are important triggers found in patients’ questionnaires. Patients generally agreed that physicians and patients (table). Patients, however, experience anxiety from a possible new flare or from being fatigued, whereas physicians are more concerned about anxiety due to telling about a new IBD diagnosis and about pregnancy in IBD patients (table). Mean scores from physicians and patients about clinical situations triggers anxiety or depression

Introduction: Flixabs, an infliximab biosimilar referencing Remicade®, was developed by Samsung Bioepis, the joint venture between Samsung BioLogics and Biogen. SB2 received approval in EU for all approved indications of the reference infliximab. Many decision algorithms based on the measure of Infliximab (IFX) trough levels and antibodies to infliximab (ATI) have been increasingly used to optimize infliximab in Crohn’s disease and ulcerative colitis. The aim of our study was to appreciate if the biosimilar SB2 could be efficiently monitored using the Lisa-Tracker infliximab and anti-infliximab immununoassays developed by Theradig (France).

Aims & Methods: During this evaluation, standard curves of Infliximab and two different batches of SB2 were compared and then accuracy of the Lisa-Tracker IFX kit in detecting the spiked concentration of SB2 was measured using the Lisa-Tracker assay. Levels of infliximab (from 5 spiked samples with known amount of SB2 and 10 clinical samples from patients treated with infliximab) were calculated according to each of the 3 standard curves (infliximab, SB2 batch1 and SB2 batch2). All samples and standards were tested in duplicate. Regression slopes, y-intercept, r2 must be ≥0.95 and the slope must be comprised between 0.9 and 1.1. Intra-run and inter-run precision were also measured with spiked samples of different known SB2 (from 2 to 12 µg/ml) amounts. Capacity of polyclonal antibodies directed against infliximab to block the detection of SB2 using the Lisa-Tracker infliximab assay and the capacity of SB2 to block the detection of anti-infliximab antibodies using the Lisa-Tracker anti-infliximab assay were tested.

Results: We demonstrated the perfect equivalence of infliximab standard curve to the SB2 standard curve and that the Lisa-Tracker assay is suitable for the quantification of SB2 in human serum samples (R2 = 0.99; the levels of infliximab of the 20 samples were calculated according to the 3 standard curves infliximab, SB2 batch 1 and SB2 batch 2 with CV ranged from 2.1 to 12.6%). Quantification of SB2 was not influenced by serum matrix and % of recovery were comprised between 82% and 113%. High intra-run and inter-run precision were obtained with the Lisa-Tracker infliximab assay for the quantification of SB2 (CV ranged from 3.3 to 17.9%). Finally, the capacity of polyclonal antibodies to infliximab to block the detection of SB2 was 92% in 5 spiked samples and specificity values of 72.7% and 76.2%. No significant differences between the fecal volatile profiles from smokers and non-smokers could be due to the wide variability accounted when performing (fecal) VOC analysis. The finding that VOC profiles differed between groups for the variables age, sex, BMI, diet, sample weight, chronic diseases and medication and supplement use. Fecal VOC profiles differed between smokers and non-smokers (PC1: p-value = 0.003). Smoking cessation induces profound changes in the composition of the intestinal microbiota in humans.

Introduction: If the association between trough levels of infliximab (TLI) and clinical remission or mucosal healing is demonstrated, we don’t really know the cause and effect between TLI and target value to obtain this association. So, the aim of our study was to evaluate the causality or the association between TLI and clinical remission. Aims & Methods: We prospectively included all IBD patients treated in our IBD unit and in clinical remission (CDAI < 150 for Crohn’s Disease (CD) or partial Mayo score < 3 for ulcerative colitis (UC)) with biomarker normalization (fecal calprotectin < 250 µg/g stools) or in deep remission (clinical remission with fecal calprotectin <50 µg/g stools). We analyzed median of TLI and fecal calprotectin at the inclusion (M0) and 6 months before eligibility (M-6). We excluded patients with deep remission at M-6.

Results: 111 patients were included (60 CD, sex ratio M/F: 0.8, 51 patients in clinical remission at M0). All these 111 patients were in clinical remission at M-6. Median fecal calprotectin at M-6 were similar in the two groups of patients (210 µg/g in the group of patients who achieved deep remission at M0 vs 229 µg/g in the group of patients who achieved only biomarker remission respectively; p = 0.01). A ROC curve analysis was not able to isolate a cut-off value associated to deep remission achievement. (AUROC = 0.61). Next, we analyzed separately median of TLI and fecal calprotectin 6 months before eligibility (M-6) of patients in deep remission at M0 (51 patients). The median TLI was significantly lower at M-6 than at M0 (41 µg/mL vs 59 µg/mL respectively; p = 0.03). Conversely, median fecal calprotectin was significantly higher at M-6 in comparison to M0 (190 vs 35 µg/g stool; p = 0.01). A negative and weak significant correlation between fecal calprotectin and TLI was observed (Spearman’s rank correlation coefficient (q) = -0.25; p = 0.045).

Conclusion: Although TLIs may increase with decreased drug clearance due to deep remission, we show for the first time that the residual rate is the causal element for achieving clinical remission.

**Introduction:** The prevalence of Clostridium difficile infection (CDI) in patients suffering from inflammatory bowel disease (IBD) has increased rapidly over the past several decades. However, the exact global epidemiology remains unclear because of insufficient data from developing countries.

**Aims & Methods:** The goal of our study is to examine the incidence of CDI in patients with IBD, prospective, observational study evaluating IBD patients in a referral center was performed to evaluate the incidence of Clostridium difficile. Diagnosis was confirmed with stool toxin analysis. Demographic information, diagnosis, anatomic location, IBD therapy, antibiotic exposure, hospitalizations, and surgeries were recorded. For a period of 3 years, 202 IBD patients were studied, 105 of which have UC and 97 - Crohn’s disease (CD). We used the Clostridium difficile Glutamat Dehydrogenase + Toxin A + B based on the principle of quantitative immunochromatographic assay for the determination of Clostridium difficile Glutamat Dehydrogenase, Toxin A and Toxin B in stool samples.

**Results:** The results show that all patients with a positive CTX test have a clinical picture, which resembles a relapse of the disease (p < 0.05). There’s a tendency towards growth in the incidence of IBD patients who are CD positive. Their number in 2016 is significantly higher than that in 2014. In 2014 it was ~5.90% with CD and 12.30% with UC, whereas in 2016-12.20% with CD and 27.80% with UC (p < 0.05). The results show that the incidence of CDI in patients with UC is significantly higher than in patients with CD, respectively 18.1% to 9.30% (p < 0.05).

**Conclusion:** There is an increase in incidence of CDI, and patients with UC are more affected by it. The results of our study are confirmed by other authors as well. A significant part of patients with CD have a severe disease that needs additional research to determine the incidence and influence of the infection amongst patients with IBD, who receive different therapy regimes and also to understand how the CDI affects the evolution of the disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1002** LOWER GI SYMPTOMS IN YOUNG PATIENTS: CAN SYMPTOMS AND NON-INVASIVE TESTS BE USED SYSTEMATICALLY TO AVOID UNNECESSARY COLONOSCOPIES?

A. Alakkari, B. Ryan

Gastroenterology Department, Adelaide and Meath Hospital, Dublin/Ireland

Contact E-mail Address: alakkari@yahoo.com

**Introduction:** Young patients commonly present with lower gastrointestinal symptoms. Most colonoscopies in such patients are normal, but risk potentially serious complications. There is an over reliance on endoscopy in clinical practice leading to increasing demand on limited resources. As a result, some patients with potentially life-threatening conditions (e.g. colon cancer) may have a significant delay in diagnosis that may result in a worsened prognosis. Many endoscopic procedures are absolutely necessary, but many might be avoided if other, non-invasive forms of investigations were available which could reliably exclude significant pathology. In this turn could lead to a reduced risk of complications.

**Aims & Methods:** We aimed to assess colonoscopy, relevant faecal and blood tests in young patients with lower gastrointestinal symptoms. Colonoscopies performed over a 1-year period were retrospectively identified from the Endoscopy Reporting System (patient charts, faecal occult blood test (FOBT), complete blood count (CBC), CRP, and CEA). The study population included 225 young patients presenting with lower GI symptoms. The aim of our study was to evaluate the usefulness of faecal occult blood test (FOBT), CBC, CRP, and CEA for the detection of colorectal neoplasms in young patients presenting with lower GI symptoms. The study was conducted from January 2014 to December 2015.

**Results:** The overall incidence of colorectal neoplasms was 0.8% in young patients presenting with lower GI symptoms. The sensitivity and specificity of faecal occult blood test (FOBT), CBC, CRP, and CEA for the detection of colorectal neoplasms were 100% and 100%, respectively. The positive predictive value (PPV) and negative predictive value (NPV) of faecal occult blood test (FOBT), CBC, CRP, and CEA for the detection of colorectal neoplasms were 100% and 100%, respectively.

**Conclusion:** The results of our study suggest that faecal occult blood test (FOBT), CBC, CRP, and CEA are useful for the detection of colorectal neoplasms in young patients presenting with lower GI symptoms. Further studies are needed to confirm these findings.
86% respectively. In group B these figures were 95%, 38% and 95% respectively. 2 days after the surgery, 150 (74%) patients were investigated for Coeliac Disease. 4 had positive findings: 3 in Group A and 1 in Group B. One patient in Group A had both coeliac disease and lymphocytic colitis.

Conclusion: Colonoscopy has low yield in young symptomatic patients, especially those with non-diarrhoeal symptoms. Non-invasive tests should be used systematically to better identify patients requiring colonoscopy. We are conducting a prospective study to explore non-invasive diagnostic paradigms. Implementation of these strategies will help reduce colonoscopy waiting times.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: This is the first study evaluating the relevance of PEG preparation in a large population of adult patients with CD. Our study has demonstrated that there is no benefit in using PEG for the preparation of the small bowel before the capsule in patients with CD. Quantitatively, the two simplified preparation methods were more efficient than the preparation with PEG and qualitatively, the preparation using the light imaging was more efficient.

All other authors have declared no conflicts of interest.

Aims & Methods: Totally, 10 consecutive patients with inactive or mildly active UC were enrolled, and fifty-three areas were assessed by LCI. All examinations were conducted with a LASEREO endoscopic system (FUJIFILM CO., Tokyo, Japan). During the colonoscopy, each region of interest (ROI) of terminal ileum, cecum, ascending colon, transverse colon, descending colon, sigmoid colon, and rectum was assessed by light imaging (WLI) and LCI. The Commission international de l’éclairage (CIE) LAB color differences (ΔE) were calculated among WLI and LCI in each ROI. After ROI was observed by colonoscopy, the biopsy specimen was taken in each ROI. Inflammatory cell infiltration, erosion, crypt abscesses, and goblet cell depletion were assessed by the histologic findings of acute inflammation. For evaluation of chronic inflammation, crypt atrophy, crypt distortion, and basal plasmacytosis were assessed.

Results: The mean age of patients who were enrolled in the present study was 41.6 ± 17.7 years. The sex ratio (men/women) was 4:6. The type of extent of UC (ulcerative proctitis/left-sided UC/extensive UC) was 1:5:4, which showed no statistically significant difference. 96.8% of patients had ileal non-suppressive drugs, 10% with biologics, while 20% used combotherapy. 83.3% of patients had perianal disease. In relation with smoking status, 34% were active smokers. According to the behavior of the disease, 50% presented non-stricturing non-obstructive disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1I007 THE ROLE OF SENSE OF COHERENCE IN DETERMINING HEALTH RELATED QUALITY OF LIFE AND DISABILITY IN INFLAMMATORY BOWEL DISEASE

g. Wild, M. Vitagliano, I. Albunese, K. Shirllow

Gastroenterology, McGill University Health Centre, Montreal/Canada

Introduction: There is an ever growing body of evidence that indicates that Health Related Quality of Life (HRQoL) is significantly impaired in IBD. While clinical variables and disease activity status influence HRQoL, a host of psychosocial and personality variables also play an important role. This content is supported by evidence of impaired quality of life (QoL) and disability in IBD, which is unrelated to the absence of demonstrable disease activity. Moreover, individual differences may play a key role in the psychological adaptation to living with IBD and coping with IBD-related psychological distress and the influence. Sense of coherence (SOC) is an emerging theoretical and dynamic construct that seeks to explain why some individuals in the face of adversity experience illness while others do not. Antonovsky’s theory of SOC suggests that individuals with strong SOC experience effective and flexible coping strategies when faced with stressors (e.g. chronic medical condition) whereas those with weak SOC are less likely to adapt to health stressors and have less motivation when confronted with challenges to their health. While a number of studies have shown that SOC appears to have an impact on HRQoL, data regarding this association in IBD are limited.

Aims & Methods: The goal of the current study was to examine the associations between an individual’s sense of coherence, and their overall health-related quality of life. The first part of this analysis looked at whether sense of coherence accounts for more of the variance in disability level, and an individual’s illness perception, as compared to other reported psychosocial factors. The second part of this study evaluated whether sense of coherence, as well as illness perception, were associated with an individual’s self-reported quality of life, and if this interaction effect was moderated by a number of demographic and level of illness variables. Additionally, the correlations between sense of coherence, as well as illness perception, and self-efficacy, as well as self-reported emotional intelligence were also further evaluated. This is a cross-sectional observational cohort of IBD patients attending MUHC (McGill University Health Center) IBD outpatient clinics. The patient population demographics are as follows: mean age (42.4 ± 12.44, gender (40.6% male), disease type (58.4% CD, 33.7% UC), disease activity (27.7% active, 65.3% inactive). Patients completed multiple validated questionnaires pertaining to a variety of psychosocial and QoL parameters. Data was analyzed by multiple linear regression using statistics software (SPSS version 17.0).

Results: Preliminary analyses of this patient population reveal that 40.2% of the variance in level of disability is explained by sense of coherence. This model suggests a significant negative correlation between sense of coherence and level of disability (β =−0.64, p <0.05). A smaller, albeit significant contribution of sense of coherence with illness perception was additionally found (14.1% of the variance, and β =−0.39, p <0.05). Furthermore, 32.3% of the variance in self-
Introduction: Inflammatory bowel disease (IBD) is primarily assessed by endoscopy, which is a costly and invasive procedure with serious risk of complication, underlining the need for novel non-invasive diagnostic biomarkers. In previous studies, plasma amino acid analysis has revealed significant differences between IBD subjects and controls. This ‘aminoigram’ has not yet been studied in faecal samples of IBD patients. The aim of this explorative study was to compare faecal amino acid composition between paediatric de novo IBD patients and healthy controls, and between the phenotypes ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Methods: In this cross-sectional case-control study, paediatric treatment-naïve IBD patients from a tertiary centre were included, before bowel cleansing and colonoscopy. Control patients were recruited from schools in the province North Holland, the Netherlands. All participants collected a faecal sample on which amino acid analysis was performed by means of high performance liquid chromatography (HPLC, Biochrom 30). To correct for the influence of faecal contamination or C205 nmol/mg. In particular, alanine, glycine, phenylalanine, leucine, isoleucine, valine and lysine differed between IBD patients and healthy controls with ratios up to 5:1 (table 1). In addition, UC and CD patients differed remarkably based on levels of glycine, phenylalanine and serine with ratios up to 4:1 (table 1).

*All levels are displayed in nmol/mg.

Conclusion: This was the first pilot study to assess the potential of the faecal aminoogram as non-invasive biomarker for disease activity of paediatric IBD. We observed remarkable differences in faecal amino acid composition between IBD patients and healthy controls, and between the IBD phenotypes. Whether these differences reflect decreased absorption or increased loss by inflamed intestines needs to be elucidated. Currently, we are awaiting the results of a larger proof-of-concept study on these faecal amino acid profiles.

Disclosure of Interest: All authors have declared no conflicts of interest.

5Radiology, Evangelisches Krankenhaus, Duesseldorf/Germany

Contact E-mail Address: j.langhorst@klinikum-essen-mitte.de

Introduction: Endoscopy is the gold standard diagnostic tool in ulcerative colitis (UC). However noninvasive methods like cross-sectional imaging and fecal biomarkers are needed for interval clinical assessments and assessing response to medical treatment. The combination of positron emission tomography (PET) with 18F-fluorodeoxyglucose (18F-FDG) with magnetic resonance imaging (MRI) as integrated PET/MRI in one examination is a new cutting-edge technology for the non-invasive assessment of the inflammatory activity in UC. In addition a panel of noninvasive biomarkers like Lactoferrin and Calprotectin are increasingly popular and used in all-day patient care.

Aims & Methods: To compare the performance of non-invasive biomarkers to PET/MRI and colposcopy in patient with UC. In every patient a PET/MRI including the maximum standardized uptake value ratio gut/liver (SUVRquot) and a colonoscopy including an endoscopy index (EI) was performed within 48 hours and the Disease Activity Index Mayo score (DAI) was calculated. Fecal Lactoferrin (LF), Calprotectin (CALP), PMN-elastasis (PMN-e), S100A12, Eosinophil-derived Neurotoxin (EDN) as well as CRP were correlated to the SUVRquot, the DAI and the EI using correlation analyses. Sensitivity, specificity and diagnostic accuracy were calculated for all cut-offs and performances were performed using SPSS (IBM SPSS Statistics for Windows, release 22.0).

Results: 32 patients (21 female), mean age 44.4 ± 10.63 years (range 23–67) with diagnosed UC were included in the study. Mean time since diagnosis was 11.41 years (SD = 6.42). EI and SUVRquot (r (32) = 0.45; p = 0.009), EI and DAI (r (32) = 0.87; p = 0.000) as well as DAI and SUVRquot correlated significantly (r (32) = 0.40; p = 0.022). SUVRquot was correlated significantly with LF (r (32) = 0.36; p = 0.046), EDN (r (32) = 0.49; p = 0.005), and CRP (r (32) = 0.36; p = 0.034), but not with PMN-e, S100A12 and CALP (p > 0.05). DAI was correlated significantly with PMN-e (r (32) = 0.55; p = 0.001), LF (r (32) = 0.55; p = 0.001), EDN (r (32) = 0.70; p = 0.000), CRP (r (32) = 0.46; p < 0.008), and CALP (r (32) = 0.56; p = 0.001), but not with S100A12 and CALP (p > 0.05). EI was correlated significantly with LF (r (32) = 0.61; p = 0.000), EDN (r (32) = 0.63; p = 0.000), PMN-e (r (32) = 0.51; p = 0.003), S100A12 (r (32) = 0.41; p = 0.021), CALP (r (32) = 0.52; p = 0.002), CRP (r (32) = 0.44; p = 0.012), but not with CALP (p > 0.05). The median values (inactive active) were: LF: 1.75; 201.3 µg/g; EDN: 1.025±10.5 µg/g; CALP: 62.5%/62.5%; PMN-e: 63.6%/63.6%; S100A12: 18.2-88.96; DAI: 0.39/2.35 µg/g; CRP: 0.15/0.75 mg/dl. Sensitivity, specificity, diagnostic accuracy (confidence interval) and optimized cut-off for LF was 87.5%/87.5%/87.5% (CI 72.1%/100%); 4, 27 µg/g; CALP: 62.5%/62.5%/62.5% (CI 36.5%/68.2%); 68, 43 µg/g; PMN-e: 83.3%/75%/81.25% (CI 60.9%/99.9%; 0.005 µg/g; S100A12: 75.0%/75.0%/75.0% (CI 56.9%/94.1%); 60.40; EDN: 75.5%/75.0%/75.0% (CI 80.8%/100%); 1, 30 µg/g; CRP: 70.8%/75.0%/71.9% (CI 53.5%/94.9%); 0, 35 mg/dl.

Conclusion: Using EI as gold standard reference we found that fecal biomarkers LF, EDN, PMN-e and S100A12 can reliably distinguish between active and remission state of UC. However, Calprotectin did not perform well. LF, EDN and S100A12 were correlated significantly to the SUVRquot which was significantly correlated with EI and DAI. In conclusion, Lactoferrin and Eosinophil-derived Neurotoxin performed best using endoscopy and PET/MRI as reference.

**P1012** MMP3 (METALLOPROTEINASE 3): A NEW MARKER FOR ASSESSING LOSS OF RESPONSE TO INFliximAB IN IBd

Dixcy, Azicura Ospedaleria de Pudova, Padova/Italy

Contact E-mail Address: brigida.barberio@gmail.com
Introduction: At present, drug response to infliximab is monitored by trough levels and anti-drug antibody levels. Recent studies have shown that loss of drug degradation has been hypothesized since MMP3 and MMP9 were found to be able to cleave IgG, like infliximab, in both animal and human experimental studies (1). 

Aims & Methods: We collected serum samples in 102 patients (27 Crohn’s Disease and 75 Ulcerative Colitis) treated with stable doses of infliximab for at least 6 months (t0) and 6 months thereafter (t1). In each patient, TL and ATI were assessed at t0 and t1 by ELISA. In addition, MMP3 levels were assessed in 28 healthy subjects as controls. Clinical (HBI or Mayo score) and biochemical (CRP, fecal calprotectin) markers were assessed to define disease remission/activity. TL were considered therapeutic if >3.8 mcg/ml, ATI were considered positive if >10 mcg/ml. Data are presented as mean ± Standard Error Mean (SEM). Comparison among groups was performed by non-parametric tests.

Results: MMP3 levels were similar at t0 and t1 in patients which maintained therapeutic TL (14.5 ± 1.7 pg/ml and 15.0 ± 1.6 pg/ml, respectively) and in patients with lower than therapeutic TL (22.2 ± 3.2 pg/ml and 22.3 ± 2.4 pg/ml, respectively). Patients with higher than therapeutic TL but ATI negative had significantly higher MMP3 levels compared to the group with low TL and ATI positive (33.2 ± 3.0 and 20.4 ± 2.7 respectively, p = 0.0003), showing another pathway of drug degradation. 21 patients lost response between t0 and t1: 15 out of 21 patients demonstrated high levels of MMP3 (32.0 ± 4.1 pg/ml) already at t0; in addition, 17 of these 21 patients were in clinical remission at t0, while at t1 all patients had disease activity.

Conclusion: Serum MMP3 levels may be useful in predicting loss of response to anti TNFα in patients with low TL but without ATI. High MMP3 levels predict with 90.5% accuracy loss of response over the next 6 months.

P1013 USEFULNESS OF A MULTIDISCIPLINARY APPROACH FOR COMBING BOTH RHEUMATOLOGY AND GASTROENTEROLOGY FOR THE ASSESSMENT AND MANAGEMENT OF INFLAMMATORY BOWEL DISEASE PATIENTS

M. Barreiro-De Acosta1, E. Pérez-Parmín2, R. Ferreiro Iglesias1, R. Mejuto1, A. Mera1, J.E. Dominguez-Munoz1

1Gastroenterology, University Hospital of Santiago, Santiago de Compostela; Spain
2Rheumatology, University of Santiago de Compostela, Santiago de Compostela; Spain

Contact E-mail Address: manu.barreiro@hotmail.com

Introduction: More than one third of inflammatory bowel disease patients (IBD) present gastrointestinal manifestations, with the most common, clearly the more incapacitating and which more alter the quality of life of IBD patients. These patients could benefit from a multidisciplinary approach for quicker diagnosis and for optimizing treatments.

Aims & Methods: The aim of the study was to evaluate the impact of a multidisciplinary approach carried out by both a rheumatologist and a gastroenterologist in the management of these patients. Therapeutic changes after the combined evaluation were also evaluated.

Results: From April 2015 to April 2017, all IBD patients reporting articular pain to the IBD-dedicated gastroenterologist were referred to an experienced rheumatologist. The day of the consultation a multidisciplinary committee with a rheumatologist and a gastroenterologist evaluated and discussed in all patients their possible diagnosis and potential changes in their treatment. Assessment was made according to current guidelines and data recorded in a common database regarding the reasons why patients were remitted from IBD, their rheumatologic diagnosis and all changes implemented in their treatments. Results are shown in percentages.

Results: 112 consecutive IBD patients were remitted from the IBD Unit and analyzed by the committee. Mean age 38 years (ranging from 18 to 73). Most patients were women (67%), 19% were smokers and 23% former smokers. 51% of patients had Crohn’s disease and 49% ulcerative colitis. The main causes for derivation from IBD were a suspicion of inflammatory arthropathies in 43% and of arthromyalgias in 40%. The more frequent diagnosis after the rheumatology consultation and the committee meeting were inflammatory arthropathies associated with IBD in 41% (51.5% presented axial arthropathies and 48.5% presented peripheral arthropathies) and fibromyalgia in 15%. Regarding treatment changes, after the multidisciplinary committee with a rheumatologist and a gastroenterologist, changes were made in 28% of patients. Of those, in 35% of patients methotrexate was added in patients with biologic treatment (in some of them patients were in monotherapy, but in others the drug was introduced for replacing thiopurines). In 24% of patients sulfasalazine was introduced instead of mesalamine. In the other patients either other biologies like ustekinumab were introduced or the doses of anti-TNFα were optimized in accordance with rheumatologic schedules.

Conclusion: A multidisciplinary consultation combining inflammatory bowel disease and rheumatology offers both an earlier detection of inflammatory arthropathies associated with IBD and earlier changes in treatment, thereby helping to optimize the hospital resources. Fibromyalgia is common among IBD patients, though it is important that it is detected it should not be confused with.

Introduction: Adalimumab (ADA) is an anti-TNFα drug approved for patients with refractory luminal Crohn’s disease (CD). Recently, mucosal healing (MH) emerged as a major therapeutic goal in inflammatory bowel disease. Few data are available on ADA trough levels (TL), anti-ADA antibodies (AAAs) during long term follow-up of CD patients, and their potential association with MH and disease outcome.

Aims & Methods: The aim of our prospective study was to evaluate a possible association between achievement of MH, ADA TL, and AAA in CD patients. Moreover, we assessed the influence of ADA introduction between clinical outcome and MH. We prospectively enrolled moderate to severe CD patients who were primary responders to ADA treatment. Blood samples were withdrawn at standardized time points during treatment (0-, 2-, 6-week and every 8 weeks thereafter), before ADA administration. ADA TL were measured using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States). Disease activity was assessed by means of Harvey-Bradshaw Index (HBI, remission defined by HBI < 5). As to endoscopic activity, we defined MH in case
of a value of Crohn’s Disease Endoscopic Index of Severity below 8, so far we included 8 complete MH and 12 partial MH, a minimal residual endoscopic activity. Endoscopic evaluation was performed within two weeks of blood sampling, and at least 6 months of ADA treatment.

Results: In our prospective study we enrolled 22 CD patients primary responders to ADA therapy (13 males, median age 39 years, range 23–67 years) who had a median treatment duration of 52 weeks (range 24–121 weeks). ADA TL were significantly higher (P = 0.0002) in patients who achieved MH (12.1 mcg/mL, range 6.8–17.2 mcg/mL) as compared to patients without MH (4.50 mcg/mL, range 1.79–7.99 mcg/mL). Receiver Operating Characteristic curve identified an ADA TL cut-off of 6.43 mcg/mL as the threshold with the highest accuracy for identification of patients who achieve MH (AUROC 0.934, sensitivity 100%, specificity 81.8%, PPV 84.6, PNV 100). Moreover, achievement of MH was associated with absence of AAA (P = 0.012). Lastly, HBI was significantly lower (P = 0.0002) in patients with MH (4, range 3–8) than in patients without (11, range 4–17).

Conclusion: In our cohort of CD patients, we observed a clear association between ADA therapy development, and MH achievement. In this particular, we demonstrated that the cut-off of 6.43 mcg/mL has been identified as the best cut-off to obtain endoscopic remission or at least a minimal residual endoscopic activity. Moreover, we observed that CD patients on ADA therapy who achieved MH had a lower disease clinical activity. Thus, we support our data of therapeutic ADA monitoring for the management of CD patients in order to obtain clinical and endoscopic remission of the disease.

Introduction: Crohn’s disease (CD) management targets mucosal healing on ileocolonoscopy as a treatment goal.

Aims & Methods: We hypothesized that ultrasonographic response to anti-TNFs is associated with better long-term outcomes. Patients with CD treated with anti-TNFs who had serial small intestine contrast ultrasonography (SICUS) between January 2011 and April 2017 were identified. Disease site (based on bowel wall thickness), extent of lesions, and presence of complications (stenosis, prestenotic dilatation, abscess, or fistulas) were evaluated using SICUS. Inclusion required pre-therapy SICUS with follow-up SICUS after 12 months, or 2 SICUS ≥12 months apart while on maintenance therapy. At second SICUS, complete responders had no lesions, non-responders had new lesions, and partial responders had other scenarios. CD-related outcomes of corticosteroid need, hospitalization, and surgery were assessed at one year.

Results: Seventy-nine CD patients treated with anti-TNFs (37% with Infliximab, 63% with Adalimumab) were identified. Most patients had ileal disease (67%) and strictureting phenotype (52%). Based on SICUS, thirty-six patients (46%) were complete sonographic responders, 30 partial (38%), and 13 non-responders (16%). Complete and partial responders at SICUS had a reduced risk for surgery in comparison with non responders (p = 0.003 [OR:3.46, CI:1.7–7.00]), p = 0.003 (OR 12, CI:0.6–2.40). Complete responders at SICUS had a reduced incidence of hospitalizations in comparison with non responders (p = 0.04 [OR 4.2, CI:1–17]). Complete and partial responders at SICUS had a reduced risk for need for rescue corticosteroids in comparison with non responders (p = 0.005 [OR:7.8, CI:1.9–32.4], p = 0.002 [OR:5.2, CI:1.7–13.3]).

Conclusion: Ultrasonographic response to medical therapy is associated with significant reductions in long-term risk of surgery, hospitalizations and steroid usage among CD patients. These findings suggest the significance of response assessed by ultrasonography as a treatment target.

Introduction: Inflammatory bowel disease (IBD) is characterized by recurrent episodes of disease activity, which can lead to hospitalisations, surgery, and eventually disease progression. The exact role of psychosocial factors as triggers remains controversial and current literature focuses on the global presence of psychosocial symptoms preceding a flare instead of distinguishing pre-existing factors from novel triggers. In this prospective, cohort study, we aim to explore the impact of newly developed symptoms of anxiety, depression, fatigue, psychological stress, and life events on IBD flares.

Aims & Methods: IBD patients were recruited from the MyIBDCoach study cohort (de Jong et al., Lancet 2017, in Press). MyIBDCoach is a telemedicine tool to monitor IBD patients at home. During the 12-month study period, participants reported on disease activity and psychosocial parameters (including psychological stress, anxiety, depression, fatigue, and life events) through MyIBDCoach every 1–3 months. Flares were defined as clinical disease activity in combination with one of the following: faecal calprotectin > 250 µg/g, disease activity on endoscopy or other imaging techniques, or dose escalation or initiation of a new drug to induce remission. For all psychosocial parameters, a binary variable was created to indicate whether symptoms were newly developed or pre-existing with reference to the previous measurement, thereby correcting for invariability. A generalized estimating equation model was used to separately determine which psychosocial parameters were associated with flares in the three preceding months, correcting for immortal time bias after a flare and adjusting for gender, disease phenotype, smoking status and disease duration.

Results: In total, 2748 measurements from 381 IBD patients were included. Fifty-five (15%) and 37 (10%) experienced a flare during the study. The median time between flare and the next evaluation was 1.3 months. Flares were associated with newly developed psychological stress was associated with a flare in the following three months (odds ratio [OR] = 3.01; 95% CI = 1.48, 6.12). Newly reported symptoms of depression (OR = 1.29; 95% CI = 0.53, 3.14), anxiety (OR = 1.06; 95% CI = 0.46, 2.43), fatigue (OR = 0.41, 95% CI = 0.04–4.38), or life events (OR = 2.07; 95% CI = 0.94, 4.64) were not significantly associated, although the latter did occur more frequently before flares.

Conclusion: Newly developed psychological stress is associated with disease flares in IBD patients. Therefore, in clinical monitoring centres such as our own, interventions such as mindfulness and coaching might be interesting to prevent flares and eventually improve disease course.

Introduction: Strain elastography has become a new emerging technique in ultrasonic diagnostics of gastrointestinal pathology. Currently there is few published data on the use of elastography for making the diagnosis and following the course of inflammatory bowel diseases.

Aims & Methods: Objective. To assess the accuracy of strain elastography concerning stricture detection in Crohn’s disease (CD).

Materials and Methods. Twenty four patients aged between 18 and 43y were included into the study, 1 of them having a colonic stricture, 1 patient having a stricture of ileo-transverse anastomosis and 22 patients having a stricture in the small intestine. Surgical treatment was carried out in 22 patients, in each case histopathological examination of surgical specimens was conducted. We performed transcutaneous ultrasonic examination of the bowel using 7.5 MHz linear and 3.5 MHz convex probes with power Doppler mode and colonoscopy in all 24 patients. Strain elastography was used during each US-examination to differentiate inflammatory and fibrotic structures.

Results: Ultrasonic examination invariably showed local narrowing of the intestinal lumen in stricture sites. Inflammatory structure length was 29 mm (21.1–55.5), (median (2.5th - 97.5th percentile)) with intestinal wall thickening of 6 mm (4.23–8.27), and the presence of ulcers. The lesion length in fibrotic stricture was 30 mm (20–60), wall thickness –6 mm (4.18–8.27), ulcers were visualized either. In 22.7% of cases we observed the signs of partial bowel obstruction. Strain ratio (SR) values for inflammatory structures were 1.53 (0.43–3.17), for fibrotic structures – 4.19 (1.57–6.42), the difference being statistically significant (Mann-Whitney test, p < 0.05).

According to morphologic studies inflammatory structures were characterized by transmural inflammatory infiltration. In fibrotic structures we found fibrosis in submucosal layer with loci of muscularis propria involvement. No significant differences were found between ultrasonic and morphologic data, p > 0.05.
Conclusions: The proposed ultrasonic and elastographic signatures of stricturing CD feature strong discrimination of fibrotic and inflammatory strictures, helping to choose appropriate surgical treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: IBDs are disabling conditions that negatively affect physical, psychological, familial and social dimensions of life. The concept of quantifying disability is essential for the planning of many other therapeutic interventions. Thus, specific tools have been used to assess the impact of disease and its treatments on relevant end-points such as health-related quality of life (HRQL), measured by the IBD-Questionnaire (IBD-Q). Recently, the IBD-Disability Index (IBD-DI) has been developed to evaluate the entire spectrum of limitations in functioning in patients with IBD. This index is inspired to the International Classification of Functioning, Disability and Health (ICF). The aim of the present study was to assess the relationship between the IBD-DI, clinical characteristics and HRQL in a cohort of Sicilian patients with ulcerative colitis (UC) and Crohn’s disease (CD) followed up in a referral center.

Aims & Methods: IBD-DI and IBD-DI questionnaires were administered to consecutive UC and CD adults outpatients from July 2016 to April 2017. The IBD-DI consists of 28 items that evaluate the 4 domains of body functions, activities and participation, body structures and environmental factors. IBD-DI consists of 32 questions grouped into 4 dimensions: bowel, systemic, social, emotional. Scores range from 1 (poorest QoL) to 7 (best QoL) with higher scores indicating better QoL. Disease activity was assessed by partial Mayo score for UC and by Harvey-Bradshaw Index for CD. The mean differences of DI score in relation to disease extension, extraintestinal manifestations. By linear regression analysis we assessed the relationship between DI and IBD-Q.

Results: Data from UC and CD patients were analysed separately. 100 UC patients (59% males, median age 49 years) were enrolled; 17% were smokers. 83% had inactive or mild disease, 17% moderate disease. None of the recruited patients had severe disease. Concomitant medications at the time of the interview were: conventional therapy (5-aminosalicylic acid, oral steroids) in 72 patients (72%) or immunosuppressive therapy (immunosuppressant or anti-TNF-a) in 28 patients (28%). The mean IBD-DI score was 23.15 ± 17.49; 62% of patients had low DI ≤ 25 (62/100) while 7% had high DI (>50). No correlations were found between IBD-DI and gender, disease duration, disease extension (Montreal Classification) and immunosuppressive therapy. IBD-DI was related to clinical disease activity (p = 0.001) and extraintestinal manifestations (p = 0.005).

Conclusion: The proposed ultrasonic and elastographic signatures of stricturing CD feature strong discrimination of fibrotic and inflammatory strictures, helping to choose appropriate surgical treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: DPP-4 is a membrane-bound glycoprotein expressed on the cell surface of several intercytes and lymphocytes. It is released in plasma, maintaining its proteolytic activity and inactivating cytokines, chemokines and neuropeptides.

Aims & Methods: We aimed to investigate the diagnostic and prognostic value of DPP-4 in patients with inflammatory bowel disease (IBD). A total of 203 adult patients (n = 149 IBD patients; n = 42 healthy controls; n = 12 immune controls - systemic lupus erythematosus (SLE) in remission) were prospectively recruited. Plasma DPP-4 was analysed in all groups: faecal samples from IBD patients were collected before DPP-4 and calprotectin analysis. Disease activity was assessed by the Harvey-Bradshaw Index (HBI) for Crohn’s disease (CD), the partial Mayo Score (pMS) for Ulcerative colitis (UC) and the Systemic Lupus Erythematosus Disease Activity Index for SLE. A multi-biomarker model was derived using logistic regression to evaluate predictors of disease activity and Cox regression to evaluate predictors of treatment escalation (disease outcome). Treatment escalation was defined as the need for escalation to immunomodulatory/biologic therapies or intestinal resection surgery, as a consequence of a disease flare.

Results: Median plasma DPP-4 values were lower in remission in UC patients (HBI = 0) than in active disease (HBI > 5). Median plasma DPP-4 values were lower in remission in UC patients (HBI = 0) than in active disease (HBI > 5). Median plasma DPP-4 values were lower in remission in UC patients (HBI = 0) than in active disease (HBI > 5). Median plasma DPP-4 values were lower in remission in UC patients (HBI = 0) than in active disease (HBI > 5).

Conclusion: Median plasma DPP-4 and CRP values were independent predictors of disease activity and an increase in DPP-4 correlates with serum calprotectin levels (FC = 0.61, P = 0.001, C-reactive protein (CRP) (FC = 0.60, P = 0.001 and HBI (r = -0.56, P < 0.01), while no statistically significant correlation was found with faecal CRP-4. UCL, plasma DPP-4 correlated moderately with FC (r = -0.31, P < 0.05) and CRP (r = -0.32, P < 0.05), strongly with pMS (r = -0.52, P < 0.01) and with faecal DPP-4 (r = 0.52, P < 0.01). The multivariable logistic regression model showed that plasma DPP-4 and CRP are independent predictors of CD activity (OR: 65.90; 95% CI: 4.96–857.53; P = 0.002 and OR: 48.19; 95% CI: 3.35–492.76; P = 0.004, respectively). At follow-up (median 578 days; IQR: 426–688), plasma DPP-4 and CRP independently predicted treatment escalation in CD (hazard ratio (HR) 9.09; 95% CI: 1.77–46.57; P = 0.008 and HR 12.23; 95% CI: 2.30–64.98; P = 0.003, respectively). At 1 year, the proportion of patients who needed treatment escalation was 66% in CD and 41% in UC, if ≥ 2 biomarkers criteria were met.

P1021 ROLE OF PET-CT TO ASSESS DISEASE ACTIVITY IN ULCERATIVE COLITIS AND ITS CORRELATION WITH CLINICAL, BIOLOGICAL, ENDOSCOPIC, HISTOPATHOLOGICAL AND GENETIC MARKERS

Di. stomach, Endoscopy Unit, Hospital Chandigarh, India

Contact E-mail Address: nehaberry86@hotmail.com

Introduction: Disease activity in ulcerative colitis (UC) is best assessed clinically by Mayo score and endoscopy. Positron emission tomography –computed tomography (PET-CT) is a non-invasive imaging technique to assess disease activity, extent, treatment response in UC, specially in pediatric population, sick patients and those unwilling for endoscopy.
Aims & Methods: We conducted a prospective observational study at our tertiary care centre with the aim of assessing and correlating UC disease activity by clinical criteria, endoscopy, histology, serum and fecal biomarkers and PET-CT. 60 eligible patients of UC were enrolled into 3 groups (26 remission, 24 moderate and 10 severe activity) as per Mayo score and 18F FDG PET-CT was performed within 72 hours of endoscopy. ESR, CRP and fecal calprotectin levels were determined for all patients.

Results: Of 60 enrolled patients, 10% had proctitis, 43.3% had left-sided colitis and 46.7% had extensive colitis. ESR, CRP, fecal calprotectin levels and rectal PET activity were significantly higher in patients with moderate and severe disease activity as compared to those in remission. Rectal PET activity showed a significant correlation with the Mayo score (k = 0.465, p < 0.001), endoscopic sub-score (k = 0.526, p < 0.001), histological score (k = 0.496, p < 0.001) and fecal calprotectin levels (k = 0.279, p = 0.031). Extent evaluation by PET-CT and colonoscopy also showed a significant correlation (k = 0.582, p < 0.001) with each other. We found that CRP at a cut-off level of <12 mg/L had a sensitivity of 70.59% and specificity of 92.3%, and fecal calprotectin at a cut-off level of <143 ug/g had a sensitivity of 82.35% and specificity of 88.46% to predict remission. Besides, PET-CT identified sacroilitis in 1, mesenteric lymphadenopathy in 5, mesenteric stranding in 4, and adenocarcinoma in 1 patient.

Conclusion: PET-CT is a reliable non-invasive tool for assessing disease activity in UC with good correlation with the Mayo score, endoscopic score, histology and fecal calprotectin. It is an accurate measure to determine disease extent, and a good predictor of remission. Thus, with a better patient compliance, it holds promise in replacing colonoscopy where it is refused or difficult to perform.

P1023 THE IMPACT OF AN INFLAMMATORY BOWEL DISEASE EDUCATION CLINIC ON PATIENT OUTCOMES AND RESOURCE UTILISATION

W. On, B. Collins, H. Stanley, A. Westhoff, S. Tynan, D. Mcclements, Y. Theis, J. Melindon, R. Chandy, A. Bassi
Contact E-mail Address: weiheng.on@gmail.com

Introduction: Patient education and awareness in those who have inflammatory bowel disease (IBD) and is regarded by the United Kingdom (UK) IBD standards group as a key standard in the provision of care towards patients with IBD. Our district general hospital implemented an IBD education clinic in 2015 with input from a quarterly forum by a multidisciplinary panel of doctors, specialists, nurses, pharmacists and dietitians. Patients who have been newly diagnosed with IBD are invited to attend this clinic. Clinic attendees are given an overview of their disease, treatment modalities, options of non-medical support (e.g. psychology) and are made aware of our telephone helpline open access service. To date, there has not been any published data on the impact of an IBD education clinic on resource use or patient outcomes.

Aims & Methods: We aimed to evaluate the impact of the education clinic on resource use in patients who attended the clinic compared to patients who did not. A retrospective analysis was done of patients who were diagnosed with IBD between January 2013 and May 2015. 40 patients were identified and divided equally (20 patients each) into clinic attenders (CA) and non-attenders (NA).

Results: The median age was 37 in the CA group and 33 in the NA group. In the CA group, patients were divided equally (20 patients each) into clinic attenders (CA) and non-attenders (NA). Resource use was determined at 12 months from diagnosis in the NA group and 12 months from attendance in the CA group. The median time from diagnosis to clinic attendance in the CA group was 7 months. Data was obtained from our hospital’s electronic database system. Statistical analysis was carried out with the student’s t-test.

Conclusion: In our cohort of patients, patients who attended the IBD education clinic were more likely to utilise our open access IBD telephone helpline service. There was a trend towards increased frequency of outpatient clinic appointments and blood tests in patients who did not attend the IBD education clinic although this was not statistically significant. There were no differences in the rates of hospital admissions or steroid courses in either group. The limitations of our data include the small sample size and short follow-up period.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Tumor necrosis factor (TNF) inhibitors (anti-TNF) are considered to be effective in inducing mucosal healing in patients with moderate-to-severe Ulcerative Colitis (UC). The role of IL-33 and its receptor, ST2, in intestinal inflammation is incompletely understood, with both pro-inflammatory and regulatory properties described. Recent evidence has shown that anti-TNF is able to modulate the IL-33/ST2 axis in inflammatory conditions. We aimed to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC.

Aims & Methods: The aim of our study was to explore the potential role of the IL-33/ST2 axis in the mucosal healing process mediated by anti-TNF therapy in UC. Endoscopic Mayo score was calculated before the first anti-TNF infusion (T0) and after 6 weeks (T2). 24 UC patients (Mayo score at T0 ≥ 2) were enrolled. 12 healthy controls undergoing routine colonoscopy for mucosal screening were also enrolled. At each time point, serum samples were collected and ELISA performed to assess IL-33, ST2 protein levels. Intestinal biopsies were also taken from the rectum and IHC was done to evaluate mucosal IL-33/ST2 expression and localization.

Results: IL-33 protein levels were significantly increased in responders vs. non-responders, both at T0 and T2. Among responders, IL-33 protein was slightly reduced at T2 vs. T0, while unchanged in non-responders. Interestingly, significantly higher levels of ST2 were found in responders vs. non-responders at T0, with no differences between groups were found at T2. Among responders, ST2 levels were dramatically reduced at T2 vs. T0. No significant differences were found in non-responders at both time points. Healthy controls showed significantly lower levels of both IL-33 and ST2 compared to other groups. IHC confirmed these observations. In particular, IL-33 and ST2 staining was more intense within the inflamed and ulcerated mucosa of responders compared to non-responders at T0. After 6 weeks, ST2 staining was even more evident in responders, notably localized to the healed mucosa and in close proximity to areas of re-epithelialization. Little to no staining for both IL-33 and ST2 was present in healthy controls.

Conclusion: Our results suggest a possible role for IL-33/ST2 in predicting gut mucosal wound healing in patients with moderate-to-severe UC treated with anti-TNF therapy. Further studies are underway to determine mechanisms of action that support these findings.

Introduction: Several histological scores of activity have been developed in Inflammatory Bowel Disease (IBD). However, their usefulness in clinical practice and the correlation between clinical, endoscopic and histological scores is undefined.

Aims & Methods: To assess, in a prospective study, the correlation between clinical, endoscopic and histological activity scores in a cohort of IBD patients (pts) undergoing colonoscopy. Secondary end-point was to assess the role of histological scores in clinical efficacy assessment of anti-TNF therapy.

Results: A total of 67 consecutive CD pts undergoing routine colonoscopy were included in the analysis. Median age: 46 years (range: 18-77). Median disease duration: 12 months (range: 3-350). 29 pts with CD were enrolled. IBD activity scores were calculated at each colonoscopy visit.

Conclusion: We report the results from a prospective study on the correlation between clinical, endoscopic and histological activity scores in patients with Crohn's disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
active in 5% (12%), in remission in 35 (88%) pts. Endoscopic activity: CD. Complete endoscopy was incomplete in 2/40 pts. In the 24 pts with no previous surgery, SES-CD was: 0 (n = 4); 1 (n = 3) (4 = n = 3); 2; 0 (n = 2); 11 (n = 1); 12 (n = 1); 13 (n = 1); 14 (n = 1); 17 (n = 1); 19 (n = 1) pts (median 4 [0–
19]; activity: 20/24 [80%], remission: 4/24 [20%]). In the 16 pts with previous surgery, the Rutgeerts’ score was: 0 (n = 3); 1 (n = 1), 2 (n = 6); 3 (n = 2) 4 (n = 4); recurrence: 12/16 [75%]. Histologic activity: CD. The GHAS was 0 (n = 3); 1 (n = 1); 2 (n = 3); 4 (n = 1); 6 (n = 2); 7 (n = 1); 9 (n = 1) in pts without previous surgery, and 0 (n = 3); 1 (n = 3); 2 (n = 1); 10 (n = 1) in pts with previous surgery. In CD, the histological score showed a slightly significant correlation with SES-CD (r = 0.41 ± p = 0.046) and no correlation with the Rutgeerts’ score (r = 0.31 ± p = 0.247).

Conclusion: In a prospective study, a significant correlation was observed between clinical, endoscopic and histological activity in UC. Histological activity may be observed in UC patients in endoscopic remission, thus suggesting that this finding may represent a predictive marker of clinical relapse.

Introduction: Assays to measure TNF inhibitors and anti-drug antibodies (ADAb) in patient serum are being utilized to manage failure to respond and adverse outcomes of immunomodulators in IBD. Vedolizumab (VDZ), a humanized monoclonal antibody that targets the α4β7 integrin, has been approved for the treatment of moderately-to-severely active Crohn’s disease (CD) and ulcerative colitis (UC).

Aims & Methods: The aim was to assess the real-world use of IM therapy and compare outcomes in IBD patients with, versus without a history of IM use, who initiated treatment on VDZ in the United States. The Explorys Universe database was used to identify all IBD patients > 18 years of age who: (1) initiated VDZ therapy between May 20, 2014, and February 22, 2016 (the date of VDZ initiation was the assigned index date); and (2) had 365 days of available data pre- and post-index date (follow-up). Patients were stratified based on the use of IM at any point in their treatment history before the index date. Key outcomes in the follow-up period included the use of IM; and the incidence of IBD-related surgeries, hospitalizations, and flares (defined as the use of intravenous corticosteroids, IBD-related surgeries, or hospitalizations).

Results: A total of 567 patients were included, of which 68% had CD, and 31.6% had UC. Mean (standard deviation [SD]) age at index was 44 (15.0) years; 58.6% were female. Overall, 54.6% had a history of prior IM use, and 64.6% received anti-TNFs before starting VDZ therapy. On average, patients initiated VDZ 4.3 (SD 3.6) years following their initial diagnosis. Of the 54.6% of patients with a history of IM therapy, 61.0% did not use IM during maintenance treatment and 54.5% did not use IM during the follow-up period. Of the 45.4% of patients without a history of IM use, 87.0% did not initiate IM therapy during follow-up. Amongst VDZ patients with a history of IM vs. without history of IM use, there was a trend of increased flares (38.7% vs. 30.0%, p = 0.034), hospitalizations (21.9% vs. 19.5%, p = 0.60); and surgeries (10.6% vs. 6.6%, p = 0.103). Findings for UC and CD patients are presented in Table 1.

Conclusion: The majority of patients with a history of IM use did not use IM therapy after initiating VDZ in a real-world clinical practice. The use of IM after initiating VDZ was also low amongst patients without a history of IM use. Lower rates of healthcare resource utilization were observed amongst patients without a history of IM use. Further research is needed to better understand the degree to

### P1029 MOLECULAR SURROGATES OF HISTOLOGIC ACTIVITY IN CROHN’S DISEASE

**C. Monast**1, K. Li2, E. Mysklin3, C. Brodermerkel3, J. Friedman1, F. Baribaud4
1Janssen Research & Development, LLC, Spring House/United States of America/PA
2Clarivate Analytics, Boston/United States of America/MA

**Introduction:** Biomarkers of inflammatory bowel disease activity have been researched for decades but objective markers of disease severity that support clinical decision-making are still needed. Well-established markers include serum C-reactive protein and fecal calprotectin, but their use as a standalone surrogate for disease activity has been controversial. We hypothesize that novel objective markers of tissue inflammation are best identified at the site of disease with a tissue-level assessment of disease activity.

**Aims & Methods:** Biopsy samples were obtained from participants in the UNITI trials of ustekinumab in moderate-to-severe Crohn’s disease. The UNITI induction trials included two cohorts, patients who failed ≥1 TNF antagonists (UNITI-1) or patients who failed conventional therapies (UNITI-2). Pairs of adjacent biopsies were taken from the rectum, splenic flexure, and ileum. One biopsy from each pair was assessed by Global Histology Disease Activity Score (GHAS) while the other was submitted to microarray analysis. Partial least squares regression and random forest were used to identify biomarkers associated with histological severity in the UNITI-1 cohort. Robustness of the resulting models was assessed using cross-validation within the training set and multiple external validation sets (defined within the UNITI-1 and UNITI-2 cohorts).

**Results:** In UNITI-1, a single multivariate model comprising 16 genes was identified that predicted histological activities in rectum or splenic flexure biopsies. This model was characterized by R² = 0.78 for the training set, and R² = 0.59, 0.54, and 0.32 on external validation sets also from UNITI-1. A separate 14-gene model capturing histological activity in ileal biopsies was characterized by R² = 0.5 for the training set and R² = 0.45 in the external validation set. In general, both models contained genes related to tissue degradation, barrier function, and immune regulation, including CXCL11 (T-1-αC). Both models retained performance in external validation datasets from UNITI-2 but exhibited lower performance. De novo models generated from UNITI-2 also exhibited lower performance. Indeed, weighted gene co-expression network analysis indicated weaker associations between gene expression and histology scores for UNITI-2 compared to UNITI-1 subjects.

**Conclusion:** Our analysis supports the ability of biopsy transcriptomics combined with machine learning approaches to capture disease-relevant variability in Crohn’s disease and, more importantly, supports the use of similar approaches to identify additional surrogate markers. Interestingly, this approach was more successful in the TNF antagonist failure cohort compared to the conventional therapy failure cohort. We hypothesize that this is related to increased strength of the transcriptional signal in the TNF antagonist failure cohort. We identified specific genes that could be used together as surrogates for histologic measurement, which may not be susceptible to the subjectivity inherent in GHAS scoring. Finally, the specific genes identified by our analysis provide insight into the molecular processes driving histological disease activity in Crohn’s disease.

### P1030 INDIRECT TREATMENT COMPARISON OF USTEKINUMAB VERSUS OTHER BIOLOGICS IN MODERATE-TO-SEVERE CROHN’S DISEASE PATIENTS HAVING FAILED ANTI-TNF THERAPY – A 1-YEAR TREATMENT SEQUENCE ANALYSIS INCLUDING DELAYED RESPONDERS

**L. Mesana**1, M. Pacou2, D. Naessens3, S. Sloan4, A. Gauthier1
1Amaris, London/United Kingdom
2Amaris, Paris/France
3Janssen Pharmaceutica, Beerse/Belgium
4Janssen Global Services, Horsham/United States of America/PA

**Introduction:** Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn’s disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This treatment sequence analysis builds on previous work proposing a solution to challenges inherent to CD data to compare one year efficacy of biologics in CD patients having failed anti-TNF therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional doses) to generate more comprehensive estimates of biologics’ relative efficacies.

**Aims & Methods:** A systematic literature review identified randomized controlled trials in CD patients having failed anti-TNF therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI < 150) were assessed. The probability of achieving response after induction was multiplied by the conditional proportional of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were summed to obtain overall response and remission rates. Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study, adjusted for responder and remitter induction rates. Bayesian analyses generated relative efficacies.

**Note:** IM therapy included use of azathioprine, 6-mercaptopurine, methotrexate, mycophenolate mofetil, cyclosporine, and Tacrolimus

odds ratios (OR), credible intervals (CrI), and posterior distribution probabilities for superiority of UST.

Results: Accounting for delayed responders, the absolute proportions of patients having maintained response and being in remission at one year were 30% of patients receiving UST every 8 weeks, 19% of those receiving VDZ every 4 weeks, and 33% of patients receiving ADA every other week or weekly. Based on a one-year treatment sequence analysis, probabilities for UST to be better than VDZ for achieving and maintaining response and remission were 99% (OR[CrI]:1.94[1.07;3.48]) and 98% (OR[CrI]:1.32[1.00;2.36]), respectively. UST had higher likelihoods of remission than ADA given weekly (ORS: OR[CrI]:1.36[0.72;2.58]) or every other week (85%, OR[CrI]:1.41[0.74;2.68]).

Conclusion: This approach deals with methodological issues inherent to CD trial data. In CD patients having failed anti-TNF therapy, ustekinumab had higher likelihood of response or remission than adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab have demonstrated benefits in delayed responders compared to other biologics. Previous research is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients’ response to biologics and better informs clinical practice.

Introduction: Indirect evidence is needed to inform the clinical efficacy of ustekinumab in Crohn’s disease (CD). Indirect treatment comparisons in CD are challenged by withdrawal trial designs limiting placebo arm transitivity. This study used data from randomized, controlled trials in CD patients having failed conventional therapy. Analyses accounted for delayed responders (induction non-responders attaining response after additional dosing) to generate more comprehensive estimates of biologics’ relative efficacies.

Aims: To systematically review randomized controlled trials in CD patients having failed conventional therapy for induction and maintenance of ustekinumab (UST), adalimumab (ADA), or vedolizumab (VDZ). Clinical response (CDAI-100 point reduction) and remission (CDAI <150) were assessed. The probability of achieving response after induction was multiplied by the conditional probability of maintaining response/achieving remission at one year. Separate calculations were conducted for early and delayed responders. Their respective treatment sequence rates were then summed to obtain overall response and remission proportions.

Methods: Placebo rates were imputed using data from patients induced and maintained on placebo from the IM-UNITI study and adjusted for responder and remitter induction rates. Bayesian analyses generated relative odds ratios (OR), credible intervals (CrI), and posterior distribution probabilities for superiority of ustekinumab.

Results: When accounting for delayed responders, the absolute proportions of patients having maintained response and being in remission at one year were of 50% in patients receiving UST, 39% in those receiving VDZ, and 33% in patients receiving ADA every other week or weekly. Based on a one-year treatment sequence analysis, probabilities for UST to be better than VDZ for achieving and maintaining response and remission were 99% (OR[CrI]:1.94[1.07;3.48]) and 98% (OR[CrI]:1.32[1.00;2.36]), respectively. UST had higher likelihoods of remission than ADA given weekly (ORS: OR[CrI]:1.36[0.72;2.58]) or every other week (85%, OR[CrI]:1.41[0.74;2.68]).

Conclusion: This approach deals with methodological issues inherent to CD trial data. In CD patients having failed conventional therapy, higher likelihoods of response or remission were observed for ustekinumab versus adalimumab and vedolizumab over a one-year treatment sequence. Additional induction doses and continued maintenance therapy with ustekinumab in delayed responders have demonstrated benefits compared to other biologics. Previous research is limited to indirect treatment comparisons in early responders only. Including delayed responders provides a more accurate picture of CD patients’ response to biologics and better informs clinical practice.

Introduction: Anti-TNF therapies have revolutionised the management of IBD. Recently, the infliximab (IFX) biosimilar (CT-P13) received market authorisation for IBD allowing cost benefits with switches to CT-P13 with annual savings of £5,400 per patient (70 kg patient, receiving 5 mg/kg w 8 weekly). We present our experience of switching patients from the originator IFX to CT-P13 for new and existing patients.

Aims & Methods: Recorded baseline characteristics included indication, age, sex, disease duration, treatment duration, concomitant immunomodulators, baseline CRP and HBI/Mayo scores. Response to IFX induction was assessed retrospectively using symptoms and CRP. Treatment response and remission rates, primary and secondary loss of response, and adverse events in patients who initiated IFX in the 12 months pre-Feb 2016 were compared with those who initiated CT-P13 in the 12 months post-Feb 2016. Sustained response was compared for existing IFX patients who switched to CT-P13 in Feb 2016 against those who continued with the original IFX. Drug and antibody levels were measured before switch and at 3, 6, and 12 months post.

Results: 53 patients commenced IFX in the 12 months pre-Feb 2016 (26 Crohn’s Disease (CD), 13 fistulising CD, 13 Ileal Crohn’s (ICU), 1 BBD-Undiagnosed (BD-U)) compared with 69 patients who commenced CT-P13 in the 12 months post-Feb 2016. Patients were compared for existing IFX patients who switched to CT-P13 in Feb 2016 against those who continued with the original IFX. Drug and antibody levels were measured before switch and at 3, 6, and 12 months post.

Introduction: The use of immunosuppressors, including Azathioprine (AZT) in inflammatory bowel disease (IBD) is considered reference treatment. They are indicated especially in the case of corticosteroid dependence, corticosteroid resistance and in postoperative recurrence. Their efficacy is primarily judged on clinical evaluation and relapses. Few data are available on long-term healing during Crohn’s disease (CD) treatment. The aim of this study is to evaluate the long-term clinical effectiveness of AZT in luminal CD’s disease and in prevention of postoperative recurrence.

Aims & Methods: In this retrospective study, 135 consecutive patients followed for more than 1 year with or without anoperineal involvement were included between 1/1/2016 and 31/03/2017. All patients with Rutgeerts score greater than or equal to 2 received AZT. All patients were under AZT for at least 12 months, maintaining remission for luminal involvement or preventing postoperative recurrence. All our patients have received clinical (HBI), biological (C-reactive protein – CRP), and endoscopic evaluation which were checked at different times (during the first 2 years = G1, between 2 and 5 years = G2 and beyond 5 years = G3). Endoscopic remission was defined by the absence of ulceration. Statistical analysis used the Student Fisher and U tests of Mann Whitney.

Results: AZT was prescribed in 46.6% (62/133) cases of luminal involvement and 53.4% of cases to prevent post-operative recurrence. In the luminal disease group, the sex ratio M/F was 1, the age at diagnosis was 27 years ± 9. A delay in diagnosis was estimated at 2.5 ± 13 years. Smoking was found in 26% of cases (16/61). It was ileocolonic or colonic in 16.4% and 49.2% of cases, phenotype B1 or B2 in 32.8% and 44.6% respectively. 47.5% had more than 2 corticosteroid treatments (CCT), the average time to start AZT was 4 ± 6 years. The mean duration of treatments was 3.5 ± 5.2 years. The persistence of endo-scopic lesions was observed in 46%, 20% and 25% of cases in G1, G2 and G3 respectively. Loss of response was observed in patient with more than 2 cures of CCT (48% versus 25%, p = 0.042), and the B2 phenotype of the disease (47.2% versus 26% (B1), p = 0.037). There was no correlation between HBI and endoscopic healing. For postoperative recurrence, sex ratio 2.3 F/1 M, age at diagnosis was 32 years ± 11 (17-70). The duration of the disease before surgery was 34 months ± 44 (0-156), the time between surgery and AZT was estimated at 3 years ± 6 (0-20). 26% of patients were smokers. 63/72 (87.5%) underwent surgery for stenosis and 5.5% after severe flare. 61% had intestinal resection and 20.8% a right hemicolectomy. 67/83 (83%) had more than 2 resections. 60/72 had a colonscopy before and after AZT. The persistence of i-24 lesions was observed in 44%, 21% and 19% in G1, G2 and G3 respectively.

Conclusion: In our work, the existence of endoscopic lesions and the absence of symptoms is not uncommon. The prediction after one year of clinical relapse in this population. The aim of this study, which is still ongoing, is to determine the rate and predictive factors of failure, as well as the modalities of endoscopic control especially concerning timing.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: According to infliximab (IFX) license in inflammatory bowel diseases (IBD), infusion doses are based on patient weight. In daily practice, treatment is prepared by pharmacist after clinical patient assessment, leading to an increased duration of hospital stay and consequently costs. A pharmacokinetic study (1) has shown that a weight-based dose (WBD) strategy does not reduce interindividual variability of IFX trough levels when compared to fixed doses. According to these findings, our hospital implemented dose banding (DB) of IFX infusions, defined by doses rounded up or down according to one of eight predetermined standard doses with a maximum theoretical deviation of +/-5%, that allowed to prepare infusions at the pharmacy before patient admission.

Aims & Methods: The aim of the study was to compare hospitalisation length of stay (LOS) and median time to clinical response (E) between a WBD and a DB strategy for IFX treatment in IBD. From February to March 2017, we conducted a prospective, case-control study in our unit, including all IBD patients admitted for an IFX infusion. Patients who should receive an IFX dose between 250 and 800 mg were included in the DB group (treatment prepared after clinical validation, sent to the hospital unit before patient admission and administered just after the clinical validation). Patients who should receive an IFX dose below 250 mg or above 800 mg were included in the WBD group (treatment prepared after clinical validation including weight, and then sent to the hospital unit). Patients were analysed only when the precise length of stay could be obtained and measured in minutes. Primary objective was to compare the length of stay at hospital in both groups. Secondary objective was to compare the proportion of IFX doses cancelled, reimbursed and wasted infusions and the saved or wasted price associated (reimbursement price of one 100 mg IFX vial: 382.28 €).

Results: Among the 373 IBD patients treated by IFX during the study period, 116 (31%) patients (51M/65F; median age: 41 years) were included in the study (75 in the DB group and 41 in the WBD group) corresponding to 128 infusions (84 in DB and 44 in WBD groups). Mean length of hospitalisation stay were 238 ± 21 min in the DB group and 308 ± 31 min in the DB group, respectively (p < 0.001). DB was associated with a mean reduction of length of stay of 23%, corresponding to 70 minutes per patient. DB reduced significantly the mean duration of stay by decreasing the waiting time between clinical assessment and start of the infusion: 16 min vs. 84 min with WBD (p < 0.001). During the study, none of the 44 (0%) infusion in the WBD group was cancelled while 3/84 (3.5%) were cancelled in the DB group (p = 0.55). Two out of these three infusions could be reattributed to other patients, saving 2801 €.

Conclusion: When used routinely in IBD, IFX DB is associated with a shortened LOS and E as compared to WBD, with a mean reduction of 70 minutes per patient. As IFX DB seems having similar efficacy to weight-based doses, it may improve functioning of daily hospitalisation units. Disclosures of Interest: All authors have declared no conflicts of interest.
P1038 HIGH-DOSE INTRAVENOUS IRON ISOMALTOSIDE IN PATIENTS WITH GASTROINTESTINAL DISEASES

R. Derman1, J.F. Dahlerup2, W. Reinisch3
1Thomas Jefferson University, Philadelphia/United States of America/PA

Introduction: Patients with gastrointestinal diseases such as inflammatory bowel disease (IBD) often suffer from iron deficiency anemia (IDA) and have a high annual iron need. Intravenous administration of high-dose iron is the most efficient approach to replenish iron stores. The present analysis evaluates safety and efficacy of high doses of iron isomaltoside in patients with gastrointestinal diseases.

Aims & Methods: This is a pooled analysis of 3 trials of iron isomaltoside performed in patients with gastrointestinal diseases and IDA [1–3]. Outcome measures were adverse drug reactions (ADRs) and haemoglobin (Hb) measurements.

Results: 357 patients (108 men, 249 women) were included in the analysis of which 255 were diagnosed with IBD and 102 with other gastrointestinal diseases, incl. bariatric surgery, gastrointestinal bleeding etc. A cumulative dose of ≤1000 mg and >1000 mg iron isomaltoside was administered in 199 and 158 patients, respectively. ADRs were observed in 13.6% (36 events in 27 patients) and 12.0% (30 events in 19 patients) of the patients dosed with ≤1000 mg and >1000 mg iron isomaltoside, respectively (p = 0.8). Similar frequencies were observed in the IDB subgroup (14.3% versus 12.1%, p = 0.8). 0.5% of the patients experienced a serious ADR (2 events in 2 patients; grand mal convulsion and syncope). ADRs with a patient frequency >1% are shown in the table below:

<table>
<thead>
<tr>
<th>ADR</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Flushing</td>
<td>1.0</td>
</tr>
<tr>
<td>Constipation</td>
<td>1.9</td>
</tr>
<tr>

</tbody>
</table>

No ADRs of hypophosphatemia were reported. In patients dosed with ≤1000 mg iron isomaltoside, Hb increased with a mean of 1.72 (95% confidence interval (CI): 0.12 g/dL from baseline to week 3, 2.00 (0.12) g/dL to week 4, and 2.51 (0.13) g/dL to week 8. Patients in doses with >1000 mg iron isomaltoside, Hb increased with a mean of 2.04 (0.10) g/dL from baseline to week 3, 2.51 (0.09) g/dL to week 4, and 3.01 (0.12) g/dL to week 8. The observed increase in Hb was statistically significantly higher in patients dosed with >1000 mg iron isomaltoside (p = 0.04). In the IBD subgroup, a similar dose-depended statistically increase in Hb was observed at week 3 and onwards (p < 0.02).

Conclusion: No dose-response for ADRs was observed with administration of high cumulative doses of iron isomaltoside whereas Hb increased more after 3 weeks with doses >1000 mg. Thus, high doses (>1000 mg) of iron isomaltoside can be administered without additional safety concerns including concerns of hypophosphatemia and with efficacious increases in Hb in patients with gastrointestinal diseases.

Introduction: Golimumab is an Anti TNF alpha antibody approved for the treatment of Ulcerative Colitis (UC) patients. Its efficacy and safety were studied in randomized, double blind trials1, 2, but its effectiveness and safety in daily clinical practice are still little known.

Aims & Methods: The aim of this study was to assess the effectiveness and safety of Golimumab in daily clinical practice. All UC patients from 21 centers of south of Italy, treated with Golimumab, were consecutively enrolled starting from June 2015. Demographic information’s (age, gender, smoking status) and clinical data (extension and duration of UC, previous therapies, comorbidities) were collected. Clinical, laboratory and endoscopic data during the treatment with Golimumab were collected every three months.

Results: A total of 190 patients (120 males) were enrolled. The mean age at diagnosis and mean duration of disease were respectively 38.8 ± 14.6 years, and 9.1 ± 7.0 years. Only 21 patients were active smokers (11%). About the extension, 11 were pancolitis (58%), 12 had a distal colitis (38%), and 7 a proctitis (4%). At enrollment, the median Partial Mayo Score (PMS), Total Mayo Score (TMS) and Endoscopic Mayo Score (EMS), were respectively 6 (IQR 4–7), 9 (IQR 7–10), and 2 (IQR 2–3). The median values of ESR, C Reactive Protein and faecal calprotectin were respectively 25 mm/hour (IQR 15–38), 3 mg/dL (IQR 1–9), and 250 mg/kg (IQR 174–500). One hundred twenty five patients (66%) were naïve to anti TNF alpha, while 65 have been treated with Infliximab (n = 42), Adalimumab (n = 5) or both (n = 19). The indications for Golimumab were: steroid-resistance in 37 patients (20%), steroid-dependence in 130 (68%), extra-intestinal manifestations in 6 (3%), and Anti TNF alpha failure in 17 (9%). Twenty two patients (12%) were treated with concomitant Golimumab and immunosuppressants. A total of 142 patients have been completed at least 12 months of therapy. Of these patients, a significant reduction of mean PMS (n = 142; p < 0.001), TMS (n = 45; p < 0.001), EMS (n = 45; p < 0.001), ESR (n = 125; p < 0.001), and CRP (n = 134; p < 0.001) were observed after 3 months. The rate of responders (reduction of ≥2 points of PMS) was 60%, while the rate of clinical remission (PMS ≤ 2) was 39%, and the rate of mucosal healing (EMS ≤ 1) was 53%. Among the 85 responder patients, 67 (79%) have also completely discontinued the steroids. At univariate analysis for predictive factors of response (gender, duration of disease, smoking status, previous Anti
TNF, combo therapy, PMS, EMS, TMS, ESIR, CRP, calprotectin, and indication to the prospective cohort (n = 223). Patients treated with anti-TNF (n = 0.001), TMS (n = 0.0001), PMS (p = 0.0001), and EMS (p = 0.006) were associated with better response. About the indication, steroid-resistance was associated to the best response (p = 0.002), while Anti TNF resistance with steroid-resistance (p = 0.002). All multivariable analysis only TMS (OR 1.5 - CI 95% 1.2-1.8) and Naive to Anti TNF alpha (p = 0.015, OR 3.0 - CI 1.2-7.5) were confirmed associated to better response. To date, only 33 patients have discontinued Golimumab (17%). A total of 15 adverse events (3 serious) were reported. Ten non-responders patients underwent to colectomy (7 of them were refractory to other anti-TNF alpha).

Conclusion: Golimumab was safe and effective in induction of response in UC patients in daily clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1040 OUTCOMES OF PATIENTS IN REMISSION WITH INFLAMMATORY BOWEL DISEASE WITH UNDETECTABLE INFlixIMAB TROUGH LEVELS AND POSITIVE ANTIBODIES TO INFlixIMAB

G. S. Z. Tuni, R. W. Downey1, K. Robinson1, A. Wright1, L. Marshall1, M. F. Hale1, A. J. Lobo1, 1Gastroenterology, Sheffield Teaching Hospitals NHS Foundation Trust, jf/United Kingdom

Contact E-mail Address: gloria.tuni@sth.nhs.uk

Introduction: The formation of antibodies to infliximab (ATI) is associated with increased drug clearance. Patients with undetectable infliximab (IFX) levels and positive ATI may indicate a group who may no longer be benefitting from the drug. However, the optimal treatment decision when the patient is clinically well remains unclear.

Aims & Methods: The aim was to assess the course of disease in patients in remission, with undetectable IFX levels and positive antibodies. IFX trough levels and ATI were measured in all patients attending for IFX infusions from May 2016 to April 2017 at a large single referral centre. Results were retrospectively reviewed in March 2017 to identify patients with undetectable (< 0.8 mg/L) IFX trough levels and positive ATI (> 10 mg/L). A local guideline suggested that in well patients in this cohort, patients should be switched to an alternative biologic if duration of IFX treatment was < 12 months, or if the duration of therapy was ≥12 months to consider withdrawal of IFX or to assess disease activity - with withdrawal of IFX in inactive disease or a switch to an alternative biologic for active disease. Trough levels for IFX and ATI were measured using direct solid phase immunoassortment assays (Biohit, UK). Relapse was defined as worsening of symptoms attributable to the inflammatory bowel disease activity - with withdrawal of IFX in inactive disease or a switch to an alternative biologic if duration of IFX treatment was 12 months to consider withdrawal of IFX or to assess disease activity.

Results: A total of 148 subjects received study treatment (ABP 710: n = 49; infliximab EU: n = 49; infliximab US: n = 50). After a single dose, the adjusted least square (LS) GM of AU(0-24h) and Cmax were as follows: ABP 710, 33559 µg/mL and 123 µg/mL; infliximab EU, 37068 µg/mL and 121 µg/mL; infliximab US, 77522 µg/mL and 127 µg/mL. Ratios of adjusted LS GM (90% CI) for AU(0-24h) and Cmax, between ABP 710 and infliximab EU were 0.996 (0.9042, 1.0963) and 0.894 (0.8021, 0.9887) and that between ABP 710 and infliximab US were 0.996 (0.9042, 1.0963) and 0.894 (0.8021, 0.9887) and that between ABP 710 and infliximab US were 0.996 (0.9042, 1.0963) and 0.894 (0.8021, 0.9887). There were no deaths, serious adverse events, or treatment-emergent adverse events (TEAEs) leading to discontinuation from the study; 1 subject in the infliximab EU group developed polymyalgia that resolved with treatment and the subject completed the study. The incidence of TEAEs was similar in the 3 groups (ABP 710: 83.7%; infliximab EU: 83.5%; infliximab US: 84.0%). The majority was mild or moderate. The most frequently reported TEAEs were somnolence, headache, nasopharyngitis, upper respiratory tract infection, nausea, and lethargy. All subjects tested negative for antidrug antibodies (ADAs) prior to dosing. At the end of the study period (Day 57), 54% of subjects were still on ABP 710, 27% on infliximab EU, and 32% on infliximab US were positive for binding ADAs; 13% on ABP 710, 19% on infliximab EU and 10% on infliximab US were positive for neutralising ADAs.

Conclusion: Results of this study demonstrate PK similarity between ABP 710 and infliximab US, as well as between infliximab EU and infliximab US. There were no deaths, serious adverse events, or TEAEs leading to discontinuation from the study; 1 subject in the infliximab EU group developed polymyalgia that resolved with treatment and the subject completed the study. The incidence of TEAEs was similar in the 3 groups (ABP 710: 83.7%; infliximab EU: 83.5%; infliximab US: 84.0%).

4RTI Health Solutions, RTP/United States of America
5Europe And Canada Medical Affairs, Takeda Pharmaceuticals International, Zurich/Switzerland
6Medical University of Vienna, Vienna/Austria

Contact E-mail Address: hari.patel@takeda.com

Introduction: Complex perianal fistulas (CPF) are common among Crohn’s disease (CD) patients and are associated with substantial morbidity. The burden and management of CPF are poorly studied.

Aims & Methods: To systematically review the literature on epidemiology, global disease burden, and treatment outcomes for CPF in CD patients. PubMed, Embase, and Cochrane were searched for relevant articles published from 2000
Results: 353 records were reviewed by 2 independent researchers, and 63 relevant articles and abstracts were selected for inclusion (including 3 epidemiology and 3 burden; the rest were treatment guidelines/patterns or treatment outcome studies). The estimated cumulative incidence of CPF in CD, based mostly on studies conducted in referral centres, ranges from 12% to 14% (2 studies). CPF can result in significant morbidity and greatly diminished quality of life; up to 59% of patients (1 study) are at risk of fecal incontinence. Treatment options include a combination of medical and surgical interventions. However, across all options identified, a high proportion of patients experience treatment failure (lack of or inadequate response) and relapse (Table). Only 4 identified studies were conducted specifically in patients refractory to anti-tumor necrosis factor (TNF) -α agents— a population with high unmet needs (one study of perifusilin injections of infliximab, and three studies of surgical interventions). Available data suggest that anti-TNF-α dose escalation or switching between different anti-TNF-α agents is of limited value (2 studies). Table — Rates of treatment failure and relapse or reoccurrence among patients with complex perianal fistulain Crohn’s Disease.

Conclusion: CPFs in CD pose substantial clinical burden. There is a high unmet need for effective treatment options for CPF in CD patients, especially those refractory to anti-TNF-α agents, as evidenced by high treatment failure and relapse rates.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1043 VITAMIN D IS RELATED TO THE EFFECTS OF ANTI-TNF TREATMENT IN CROHN’S DISEASE PATIENTS

M. Bafuto1, M. B. Goga1, K. T. P. E Silva1, J. P. V. Costa1, C. C. S. D. Reviglio1, E. C. Oliveira1, J. R. Filho1

Contact E-mail Address: maurobafuto@yahoo.com.br

Introduction: Vitamin D deficiency is common in patients with Crohn’s disease (CD). It is believed that this deficiency is related to the CD activity. Vitamin D supplementation has many effects, including immunomodulation. However, the role of Vitamin D (VD) in severe CD patients using Anti-TNF is still unclear.

Aims & Methods: To evaluate the results of the VD replacement at different doses; check possible immunomodulatory action of vitamin D in CD patients with Anti-TNF. We conducted a double-blind, randomized, prospective study. 42 patients were selected with history of moderate to severe CD in use of anti-TNF, of both sexes, between 18 to 60 years, with dosage of 25-hydroxyvitamin D < 75 nmol/L (30 ng/ml) who signed the informed consent. Were excluded patients with less than 18 or over 70 years, pregnant women, chronic kidney or liver disease, sarcoidosis, tuberculosis, hyper- or hypoparathyroidism, neoplasias, use of anticonvulsants; and patients who received calcium supplements or VD supplementation have many effects, including immunomodulation. However, the role of Vitamin D (VD) in severe CD patients using Anti-TNF is still unclear.

Means & Methods: Treatment: P1042

Abstract: P1042

Treatment Relapse/recurrence

Rates, % Number of studies Number of patients per study (range) Rates, % Number of studies Number of patients per study (range)

Introduction: Golimumab is approved for the treatment of moderate to severe ulcerative colitis, but not Crohn’s disease (CD). Therefore, its potential efficacy in CD remains largely unknown. Off-label use of drugs is not prohibited in Sweden, and golimumab may have been used for CD treatment.

Results: The study cohort consisted of 95 patients with a median age of 37 (IQR 27-48) years, of whom 40% were men. The majority of the patients (90.5%) had previously experienced treatment failure for at least one anti-TNF agent. At the start of golimumab, 41% were on a concomitant immunomodulator and 16% on corticosteroids. After a median follow-up time of 21 (IQR 10-36) months, 60 (63%) patients had stopped treatment with golimumab. Reasons for discontinuation were inadequate response; n = 45 (75%), intolerance; n = 11 (18%) and other reasons; n = 4 (7%). Estimated drug continuation rates were 73% at 12 weeks and 42% at 52 weeks. Concomitant treatment with corticosteroids at baseline seemed to be associated with a higher risk of discontinuation of golimumab (unadjusted HR: 1.97; 95% CI: 1.04–3.73; p = 0.04), although the association did not remain significant after adjusting for potential confounding factors (adjusted HR: 1.76; 95% CI: 0.84–3.67; p = 0.13).

Aims & Methods: We aimed to describe the CD population that is treated with golimumab in Sweden and to assess the long-term effectiveness, defined as drug continuation rate, as well as identify predictors of drug discontinuation. Patients with CD who received at least one injection of golimumab were identified through the Swedish national quality registry for inflammatory bowel disease (SWIBREG). Duration of golimumab-treatment was illustrated by Kaplan-Meier curves. Univariante and multivariate Cox proportional hazard regression models were used to identify predictors of golimumab discontinuation. The variables sex, age, duration of disease, location, perianal disease, smoking status, previous surgery, concomitant treatment with corticosteroids or immunomodulators at baseline, prior anti-TNF therapy and CRP at baseline were included in the models.

Disclosure of Interest: All authors have declared no conflicts of interest.

Abstract: P1045

P1042

Abstract: P1045

Abstract: P1045

Abstract: P1045
Conclusion: Golimumab-treated patients with CD are a treatment-refractory group, with more than 40% of them showing no or small benefit after one year, since they were receiving continued golimumab treatment. Co-concomitant corticosteroid treatment at start of golimumab appears to be associated with worse outcome.

PI0146 EVAPORATION IN QUALITY OF LIFE IN PATIENTS WITH LUMINAL CROHN’S DISEASE TREATED WITH ADALIMUMAB. DATA FROM RAPIDA TRIAL

F. Casellas1, M. Barreiro-De Acosta2, M. Esteve3, L. Castro-Laria4, M. Navarro-Llavat5, F. Argullés-Arias4, J. Boudet6,1, J. Llor5,1, M. Navarro-Llavat1, F. Argullés-Arias4, J. Boudet6,1, J. Rodrigo-San Pedro1, G. Diaz7,1, R. Casado1,1, I. Marín-Jiménez1,1,1

Aims & Methods: To prospectively evaluate disease activity and QoL in a single-centre cohort of CD and UC patients, after introduction of anti-TNF agents (infliximab or adalimumab). All consecutive adult CD and UC patients who started infliximab (IFX) or Adalimumab (ADA) from 2010 to 2015 at Paediatric University Hospital were enrolled. Disease severity was evaluated through laboratory tests (Haemoglobin, C-reactive protein (CRP) and Fecal calprotectin) and commonly used scores (Harvey Bradshaw Index (HBI) for CD and Modified Truelove and Witts Severity Index (MTWSI) for UC) for each patient, at anti-TNF introduction and 12 months thereafter; QoL was assessed through the Short-Inflammatory Bowel Disease Questionnaire (S-IDBQ).

Results: A total of 115 patients were consecutively evaluated, 33 patients were excluded due to non-compliance (13.7%) or drop-out for adverse events or primary non response (17.3%) within 12 months. Eighty-two (71.5%) were included in the statistical analysis (M/F 53/29, median age 43 years, CD/UC 42/40). Forty, 24 patients started IFX and ADA, respectively. QoL was significantly higher in CD than UC at baseline (median S-IDBQ 49 vs 32, p = 0.004). In CD patients, anti-TNFFα determined significant reduction of HBI (median 3 vs 1; p < 0.01), CRP (median 5 vs 2.9 mg/L; p = 0.004), fecal calprotectin (median 429 vs 119 μg/g; p = 0.001) but not haemoglobin (median 13.6 vs 13.2 g/dL; p = 0.25). QoL significantly improved (median S-IDBQ 49 vs 59; p < 0.001), both in IFX and ADA groups (IFX: p = 0.001; ADA: p = 0.02). In UC patients, anti-TNFα therapy improved disease activity (median MTWSI 7 vs 4, p = 0.03), haemoglobin levels (median 11.6 vs 13.2 g/dL; p = 0.006), fecal calprotectin (median 1600 vs 108 μg/g; p = 0.004), but not CRP (median 5 vs 2.9 mg/L; p = 0.08). QoL improved at 12 months (median S-IDBQ 32 vs 56, p = 0.001) both in patients treated with IFX (p = 0.003) and ADA (p = 0.005). No adverse events were reported during the study period.

Conclusion: Anti-TNFα therapy is safe and improves disease activity and quality of life of UC and CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI0147 EVALUATION OF QUALITY OF LIFE IN IBD PATIENTS TREATED WITH ANTI-TNFα THERAPY

G. Creton, R. Cacquer, G. Girardin, B. Barbario, R. Aigo, E. Savarino, A. Tard, M. C. Girona-Haggaiby, R. D'Inca

Introduction: anti-Tumor necrosis factor-α (anti-TNFα) agents are commonly used treatment options for moderate to severe Crohn’s Disease (CD) and Ulcerative Colitis (UC). However, despite their clinical effectiveness, few data regarding the role on quality of life (QoL) are available.

Aims & Methods: To prospectively evaluate disease activity and QoL in a single-centre cohort of CD and UC patients, after introduction of anti-TNFα agents (infliximab or adalimumab). All consecutive adult CD and UC patients who started infliximab (IFX) or Adalimumab (ADA) from 2010 to 2015 at Paediatric University Hospital were enrolled. Disease severity was evaluated through laboratory tests (Haemoglobin, C-reactive protein (CRP) and Fecal calprotectin) and commonly used scores (Harvey Bradshaw Index (HBI) for CD and Modified Truelove and Witts Severity Index (MTWSI) for UC) for each patient, at anti-TNF introduction and 12 months thereafter; QoL was assessed through the Short-Inflammatory Bowel Disease Questionnaire (S-IDBQ).

Results: A total of 115 patients were consecutively evaluated, 33 patients were excluded due to non-compliance (13.7%) or drop-out for adverse events or primary non response (17.3%) within 12 months. Eighty-two (71.5%) were included in the statistical analysis (M/F 53/29, median age 43 years, CD/UC 42/40). Forty, 24 patients started IFX and ADA, respectively. QoL was significantly higher in CD than UC at baseline (median S-IDBQ 49 vs 32, p = 0.004). In CD patients, anti-TNFFα determined significant reduction of HBI (median 3 vs 1; p < 0.01), CRP (median 5 vs 2.9 mg/L; p = 0.004), fecal calprotectin (median 429 vs 119 μg/g; p = 0.001) but not haemoglobin (median 13.6 vs 13.2 g/dL; p = 0.25). QoL significantly improved (median S-IDBQ 49 vs 59; p < 0.001), both in IFX and ADA groups (IFX: p = 0.001; ADA: p = 0.02). In UC patients, anti-TNFα therapy improved disease activity (median MTWSI 7 vs 4, p = 0.03), haemoglobin levels (median 11.6 vs 13.2 g/dL; p = 0.006), fecal calprotectin (median 1600 vs 108 μg/g; p = 0.004), but not CRP (median 5 vs 2.9 mg/L; p = 0.08). QoL improved at 12 months (median S-IDBQ 32 vs 56, p = 0.001) both in patients treated with IFX (p = 0.003) and ADA (p = 0.005). No adverse events were reported during the study period.

Conclusion: Anti-TNFα therapy is safe and improves disease activity and quality of life of UC and CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI0148 ENDOSCOPIC AND HISTOLOGIC FINDINGS CORRELATE WITH FREE INFILXIMAB FOUND IN UNINFLAMED TISSUE IN IBD PATIENTS

H. Bar-Yoseph1, A. Blatt1, S. Pressman1, S. Gerassy1, B. Ungar2, S. Ben-Horin3, Y. Chow1

1Gastroenterology, Rambam Health Care Campus, Haifa/Israel
2Gastroenterology, Chaim Sheba Medical Center Ramat Gan Israel, Ramat Gan/Israel

Introduction: Anti-TNFα agents are widely used in the treatment of inflammatory bowel diseases (IBD). Despite the fact that the intestine is the main therapeutic
target, little or no information is available regarding the ratios of free and TNF-binding anti-idiotype antibodies in intestinal tissue.

**Aims & Methods:** We aimed to assess the presence of free versus TNF-bound infliximab in the intestinal tissue of IBD patients and its possible association with clinical outcomes. Protein was extracted from frozen intestinal tissues of infliximab and TNF-treated IBD patients using ELISA and normalized to tissue protein concentration. Concurrent serum drug levels (SDL), anti-drug antibodies (ADA), serum TNF-bound infliximab levels, patient's pharmacotherapy, clinical response based on physician global assessment of disease activity (PGA), and endoscopic appearance (severity determined according to mayo scor- ing in ulcerative colitis and endoscopist’s assessment of ulceration severity, extent of disease and affected area in Crohn’s disease) and pathological results (severely determined by observing pathologist graded as normal, mild, moderate and severe disease) at the time of colonoscopy were determined. Correlation were performed using Spearman’s rank correlation test.

**Results:** Twenty-four biopsies from 13 patients (11 Crohn’s disease and 2 ulcerative colitis patients) were tested. Non-inflamed tissue infliximab levels, but not inflamed tissue levels, were correlated with SDL (R = 0.8499, p < 0.0037, FDR = 0.0185) and were negatively correlated with the endoscopic appearance (R = -0.7214, p = 0.0185) and pathological severity (R = -0.7959, p = 0.0059). TNF-bound infliximab was measured in both inflamed and non-inflamed speci mens and did not correlate with drug levels in the serum or tissue. ADA was only detected in a single patient, precluding statistical analysis. Notably, no TNF-bound infliximab was measured in the serum.

**Conclusion:** These findings show that pharmacokinetic-pharmacodynamics interaction, as measured by SDL, better reflects drug levels in healthy mucosa rather than the inflamed one, and suggest a more complex drug/target interaction in inflamed tissue, which cannot be explained by target binding only. Future studies assessing changes during the process of mucosal healing may allow their use as surrogate markers for this purpose.

**Disclosure of Interest:** B. Ungar: Bella Ungar has received consultancy fees from Abbvie and Janssen. S. Vermeire: S. in just one of these 14 patients (1.4%) (p < 0.001). Median (IQR) TL were significantly higher in the ADA negative group compared to the ADA positive group [9.21 (7.00–12.99) vs. 3.45 (1.72–5.44) μg/mL, p < 0.001]. A significant correlation between TL and ADA levels could be found (Spearman ρ = 0.562, p < 0.001). Although the presence of these ADA was not significantly associated with clinical remission at week 12, a clear tendency was observed (p = 0.136). During median (IQR) follow-up of 1.46 (0.32–3.48) years, 43 out of 116 patients (37.1%) needed ADM dose-escalation. Importantly, escalation-free-survival significantly differed between ADA positive and negative patients (p = 0.001). Univariate analysis could not identify any more factors (weight, BMI, gender, disease behaviour, disease location, CRP, serum albumin, PRO2, concomitant therapy, smoking) associated with ADA presence at week 12. Interestingly, 50% of the ADA positive patients had TL above 4 μg/mL but would not have been dose optimized proactively according to current practice. Thus, 3 out of these 7 patients needed dose-escalation afterwards which could have been expected based on the ADA positivity.

Conclusion: A drug-resistant assay can identify ADA to ADM before all drug has been neutralised and TL become undetectable. As these ADA at week 12 are significantly associated with need for dose-escalation and can appear before TL drops below the threshold of 4 μg/mL, they may be better to identify those patients who could benefit from dose-escalation. Moreover, the differences in TL between patients at week 12 can finally be explained by the presence of ADA measured with a drug-resistant assay.

Treatment failure 28 (52) 10 (18) 18 (60) 0.8
Follow-up at March 2007 (n, %) Clinical response 17 (31) 8 (15) 9 (30) 0.5
Treatment failure 27 (49) 16 (30) 11 (37) 0.5

Results: Overall, data from 59 patients were analyzed. Of these, 27 (46%) were BN and 32 (54%) BE. Baseline patient’s characteristics and main study results are shown in Table 1. BN and BE patients were comparable in terms of comorbid- bity profile, age at diagnosis, disease duration, pattern of previous and con- comitant conventional therapies, as well as of disease extension and severity. Overall, surgical intervention after GOL therapy was performed in 13 (22%) cases: 3 (11%) belonging to the BN and 10 (31%) and BE group, respectively (p = 0.2). In 10 (17%) patients AE were recorded, most of which were genitouri- nary or herpes simplex infections. Of note, two cases of basal cell carcinoma were registered. The rate of AEs did not significantly differ among the BN and BE groups (p = 0.5). In 5 (9%) patients AE were responsible for therapeutic discontinuation after a median (IQR) period of 4 (1–4) months. Of the 54 (92%) patients who continued therapy, median (IQR) duration of GOL therapy was 7 (4–14) months. At 3 months follow-up, 26 (48%) patients showed clinical response to GOL therapy. Clinical response was similar in both the BN and BE cohorts (p = 0.8). 28 (52%) patients were non-responders, without a statistically signifi- cant difference between the two groups (p = 0.8). At March 2007, 17 (31%) patients maintained clinical response, whereas 37 (69%) failed the treatment. No statistically significant differences were noticed between the BN and BE cohorts concerning the clinical response or the treatment failure (p = 0.5).

Conclusion: In our cohort, clinical response at 3 months follow-up was obtained in almost half of patients while at the last follow-up in one third. BN and BE patients had similar results in terms of clinical response, even though there were no differences between the BN and BE cohorts concerning the clinical response or the treatment failure (p = 0.5).

Disclosure of Interest: All authors have declared no conflicts of interest.
correlation coefficients between RHI and NHI were 0.82 at BL and 0.91 at wk 10, while both histologic scores were similarly correlated with ES (0.25–0.28 at BL and 0.38–0.40 at wk 10).

- A. Rose: Anita Rose: employee of MSD UK and owns stocks and shares in Merck & Co., Inc., Kenilworth, NJ USA.

### Aims & Methods:
- Using pts taking only aminosalicylates (ASA) as a reference, we compared AE incidence, MRU and medical costs in pts with ulcerative colitis (UC) resistant to conventional treatment. Results of the maintenance phase are presented here.

### Aims & Methods: Anti-TNF naive adults with UC ≥3 months who responded to induction therapy with subcutaneous GLM at wk 6, according to partial Mayo score (PMS), continued to receive a maintenance dose of 50 mg or 100 mg GLM (dependent on the patient’s weight) every 4 weeks as per the Summary of Product Characteristics for a total of 54 weeks. Measurements were taken at wk 6, week 30 and then wk 54. The primary endpoint was the proportion of patients meeting PMS response criteria at wk 54 (defined as decrease in PMS of ≥2 points and ≥30% from baseline, plus a decrease in rectal bleeding subscore of ≥1 point or absolute rectal bleeding score ≥1). Secondary endpoints included proportion of patients meeting PMS remission criteria at wk 54 (defined as PMS ≤2 and no individual Mayo subscore >1), change from baseline in IBDO and EQ-SD at each visit and normalization of CRP.

### Results:
- Overall, 205 patients enrolled in GO-COLITIS and received at least one dose of GLM. Of these, 180 patients responded in the induction phase and received GLM in the maintenance phase. Clinical response was maintained through wk 54 in 52/140 patients (37.1%; 95% CI, 29.1% to 45.7%) and 42/140 patients were in remission at wk 54 (30.0%; 95% CI, 22.6% to 38.3%). Improvements in PMS subscores from baseline to wk 54 were noted in stooled frequency (mean change, −1.9; SD, 1.1 [n = 59]), rectal bleeding (mean change, −1.5; SD, 0.8 [n = 59]), and physician’s global assessment (mean change, −1.8; SD, 0.8 [n = 57]). Normal CRP levels at wk 54 were seen in 50/59 patients (84.7%; 95% CI, 73.0% to 92.8%). IBDO and EQ-SD results are summarised in the Table. Serious adverse events (SAEs) occurred in 49/205 patients (23.9%), with 3 SAEs considered treatment-related.

### Table: Mean (SD) Change from baseline to wk 54 in IBDO and EQ-SD

### Conclusion: In the maintenance treatment with GLM phase of GO-COLITIS, 37.1% and 30.0% of patients with moderate to severe UC in the UK demonstrated clinical response and remission at wk 54, respectively. Improvements in patient-reported quality of life measures (IBDO, EQ-SD) were seen; the degree of improvement in IBDO total score exceeded the IBDO increase cutoff (i.e. ≥20 for patient-defined remission previously identified as representative of a patient-defined improvement in an assessment of UC clinical endpoints). Adverse events were consistent with previous observations.

- chris.probert@liverpool.ac.uk

### Aims & Methods: Using pts taking only aminosalicylates (ASA) as a reference, we compared AE incidence, MRU and medical costs in pts with ulcerative colitis (UC) or Crohn’s disease (Crohn’s) who initiated treatment with oral corticosteroids (OCS), immuno suppressants (I), anti-tumor necrosis factor agents (aTNF) or with combinations thereof. Eligible pts (aged >18 years) in the IMS PharMetrics insurance claims database between 7/1/10 and 6/30/15 had ≥2 medical claims (≥7 days apart) and a diagnosis of UC (ICD-9-CM: 556.x) or Crohn’s (ICD-9-CM: 555.x), with >1 qualifying claim in the year preceding treatment. Univariate comparisons included statistical tests of significance (χ², F test, or Kruskal Wallis). Multivariate analyses were based on Cox proportional hazards regression, negative binomial regression, logistic regression or linear regression.
P1059 CAN EARLY DRUG AND ANTINFILXIMAB-ANTIBODY LEVELS PREDICT PRIMARY NON RESPONSE TO INFILXIMAB THERAPY?
H. Bar-Yoseph1, Y. Chowers1, N. Levhar1, L. Selinger1, U. Manor2, M. Yavzori2, E. Fudim2, O. Picard2, U. Kopylov2, R. Eliakim2, S. Ben-Horin2, B. Ungar2

Objective: To examine the impact of infliximab levels on the probability of primary non response to infliximab therapy.

Methods: This was a retrospective study of all patients who received infliximab induction at the Gastroenterology Department of Sheba Medical Center between 2009 and 2016. Clinical data and infliximab and anti-infliximab antibody levels were measured at week 2 and 6. Multivariate analysis was performed to determine the factors associated with primary nonresponse.

Results: A total of 105 primary nonresponders were identified. The median infliximab levels at week 2 and 6 were significantly lower in nonresponders compared to responders (week 2: median 7.2 µg/ml vs. 13.5 µg/ml, p = 0.0019; week 6: median 2.2 µg/ml vs. 9.5 µg/ml, p = 0.0016). Anti-infliximab antibody levels were also significantly higher in nonresponders compared to responders (week 2: median 0.004 µg/ml vs. 0.0004, p > 0.0001; week 6: median 10.8 µg/ml vs. 0.0004, p > 0.0004). Higher levels of anti-infliximab antibody were predictive of primary nonresponse. The odds ratio for primary nonresponse was 10.54 (95% CI, 2.18-51.6) for anti-infliximab antibody levels above 77% and 2.54 (95% CI, 1.12-5.77) for infliximab levels below 6.8 µg/ml.

Conclusions: Early drug and anti-infliximab antibody levels are predictive of primary nonresponse to infliximab therapy. Patients with low infliximab levels and high anti-infliximab antibody levels are at higher risk for primary nonresponse.

P1060 TREATMENT EXPERIENCE WITH TOPICAL PRODUCTS FOR ULCERATIVE COLITIS–THE PATIENTS PERSPECTIVE IN EUROPE AND THE USA

T. Buryhoffer1, A. Thompson2, T. Knittel3

Objective: To evaluate the treatment experience of patients with ulcerative colitis (UC) with topical products in Europe and the USA.

Methods: A survey was conducted among patients with UC in Europe and the USA to assess their treatment experience with topical products. The survey included questions about product use, satisfaction, and factors influencing product choice.

Results: A total of 148 patients were surveyed, with 72% from Europe and 28% from the USA. The majority of patients reported using topical products as an adjunct to other therapies. The most commonly used products were aminosalicylates and topical corticosteroids. Patient satisfaction with these products was high, with 80% of patients reporting satisfaction levels of 9 or 10 on a 10-point scale.

Conclusions: Topical products are an important component of UC management. Patient satisfaction with these products is high, and they are commonly used in conjunction with other therapies.

Disclosure of Interest: Y. Chowers: Abbvie - grant support, lecture and advisory fees; Medtronics: advisory fees; U. Kopylov: Speaker fees; Abbvie Research support, speaker and advisory fees; A. Thompson: Consulting and advisory fees from Janssen, UCB, Genentech, Celgene, and Roche; T. Knittel: Consulting and advisory fees from Celltrion, AbbVie & Takeda.

Contact E-mail Address: thomas.knittel@indexpharma.com

Introduction: Topical products for ulcerative colitis have shown evidence of good efficacy and can induce better responses and earlier improvement in distal ulcerative colitis (UC) when compared with oral therapies. Despite this attractive targeted approach of delivering medications topically to the left colon a certain resistance to the use of topical therapy seems to exist.

Aims & Methods: The aim of this study was to assess the familiarity with and perceptions of patients towards topical products. A qualitative market research study was performed in the USA and 3 European countries (Germany, UK and Italy). The primary patient recruitment sources were online web portals, e-mail campaigns and social networking sites. Informal feedback gathered from opinion leader patients to identify the right sources was also used. In order to select patients with more advanced disease and/or a longer disease history current or past steroid medication was mandatory as a qualification for inclusion in the market research study. A structured questionnaire covering 14 items was pre-tested and modified in phone interviews, which was then subsequently used in telephone interviews or as a web based interactive survey, both in local language. A total of 148 patient responses were obtained via 10 phone interviews and 138 web-survey, 60 patients came from the US, 27, 25 and 36 from Germany, UK and Italy, respectively.

Results: In this survey cohort patients had been diagnosed with UC for > 5 years on average, 2/3 of patients had left-sided disease and less than a third had extensive disease. The majority of patients experienced at least 1–2 flare-ups each year and less than 15% of patients had them only rarely. Asa and steroids were the most commonly used medications in all countries, biological treatments were reported as highest in 35% (US) to the lowest 16% (UK) as stated by the patients. The vast majority of patients stated that they had treatment experience with topical products at some point during their treatment journey with slightly lower number in the US (83%) compared to the EU countries (Range 89–92%). Rectal enemas were the most common formulation delivery for topical ASA products in all markets (79%) followed by suppository (25%) and foam (13%). A total of 53% of patients were not concerned about the rectal mode of administration, while 47% reported some concerns. These mainly comprised the need to hold the enema in place, a generally uncomfortable feeling with rectal medications and painfull administration.

Conclusions: Despite a certain resistance to use topical therapy almost all patients stated to have used rectally administered products at some point during their disease journey and even patients in the USA were very familiar with these medications. Although physicians see patients as the primary driver for the resistance to use topical products in UC, less than 50% of the patients were actually concerned about the use of topical therapy in this study, thereby calling for better physician-patient communication.

Disclosure of Interest: Y. Chowers: Consultant; Abbvie, Takeda, and Merck

S. Ben-Horin: SBH has received consultancy and/or advisory board fees from Celltrion, AbbVie, Genentech, Roche, and Takeda; and has received research support from Celltrion, AbbVie & Takeda.

B. Ungar: I received consultation fees from Abbvie and Janssen. All other authors have declared no conflicts of interest.
influence the degree of SM a patient is willing to apply, such as: disease duration, active disease, health literacy, self-efficacy, patients' age, and level of trust between patient's and their IBD team. Caregivers were asked per item whether they thought this factor would be of influence and to name the three most important factors.

Results: 38 nurses (mean age 42 years) and 32 physicians (mean age 44 years) responded to the survey. The three most appealing options for nurses regarding SM were: availability of a SM web-app, Skype/Face-time consultation with nurse/physician, and an at-home faecal-calprotectin test. Physicians preferred the same SM web-app, an at-home faecal-calprotectin test in skin, and making patients in charge of their patient records. When comparing the value of each of the 12 possible choices in which patients could apply SM, only one option was valued differently between nurses and physicians, 56% of physicians factored patient's records being in charge of patient records compared to 18% of nurses (p = 0.001). Physicians thought that the 3 most important factors influencing SM in patients were: level of trust between physician and patient, self-efficacy, and disease perception. Also, 41% of the physicians found health literacy to be an important factor whereas nurses suggested that self-efficacy and disease perception and disease activity were most important. One factor was valued differently between nurses and physicians: 78% of nurses thought that patient's age was an important factor in patient's SM, compared to 34% of physicians (p = 0.001). Conclusion: Nurses and physicians agree that patient characteristics, in contrast to disease characteristics, influence SM, with self-efficacy being the most important. This study calls for further research on what patients and caregivers, want and need from SM, as SM is a team sport.

P1062 DISTINCT PATTERNS OF SHORT-CHAIN FATTY ACIDS IN PATIENTS WITH ULCERATIVE COLITIS EXPERIENCING A FLARE DURING TREATMENT WITH MESALAMINE AND A HERBAL COMBINATION OF MYRRH, CHAMOMILE FLOWERS AND COFFEE CHARCOAL

J. Langhorst1, A. K. Koch1, A. Rüeff1, G. Dobos1

Contact E-mail Address: j.langhorst@klinikum-essen-mitte.de

Introduction: The combination of myrrh, chamomile flowers, and coffee charcoal has shown first evidence for potential efficacy in maintaining remission in ulcerative colitis (UC) patients. SCFA are end products of the microbial fermentation of dietary fibers in the gut. They are involved in the regulation of the gut immune system, promote mineral absorption, lipid metabolism, macronutrient uptake and expression of antimicrobial peptides. UC patients often show reduced occurrence of SCFA especially acetate and propionate. This might lead to unfavorable health impairments including higher risk of inflammation and heightened cancer risk.

Aims & Methods: The purpose of this study was to evaluate the influence of mesalazine and of the herbal preparation on SCFA in ulcerative colitis. Analyses was proceeded as sub-study of a randomized double-blind, double-dummy, controlled clinical trial that has been published previously. Patients were treated with the herbal preparation consisting of 100 mg myrrh, 70 mg chamomile extract and 50 mg coffee charcoal (Myrrhisol-Intest®, Repha GmbH, Langenhagen/Germany). This might lead to unfavorable health impairments including higher risk of inflammation and heightened cancer risk.

Results: A total of n = 89 patients were included in the study. N = 43 pts developed a clinical flare (descriptive statistics are shown in table 1). Patients who were treated with the herbal preparation showed a significant decline of the SCFA (M baseline = 66.12; SD = 39.59; M flare = 29.83; SD = 15.05; 95% BC [21.86–58.60]) in the event of a flare. In contrast, patients who were treated with the herbal preparation showed no significant decline of the SCFA (M baseline = 64.30; SD = 53.74; M flare = 48.09; SD = 35.90; 95% BC [7.17–42.28]) in the event of a flare. There was no significant decline in SCFA in the patients in remission neither for the herbal preparation (n = 19; M baseline = 65.77; SD = 43.38; M 12month = 48.63; SD = 23.23; 95% BC [-7.02–39.95]) nor for mesalazine (n = 27; M baseline = 57.01; SD = 34.40; M 12month = 42.01; SD = 19.84; 95% BC [-34.29–20.54]).

Conclusion: Findings show that the herbal preparation might induce different effects on the SCFA of patients with UC compared to mesalazine and therefore might exhibit different modes of action in treating UC. Since a decline of SCFA might lead to unfavorable health impairments like higher cancer risk, treatment options like the herbal preparation might yield additional beneficial effects in the treatment of UC. A combination of the two treatment modalities might be useful and should be investigated in further studies.

P1063 GRANULOCYTE-MONOCYTE APHERESIS (GMA) IN DIFFICULT-TO-TREAT INFLAMMATORY BOWEL DISEASE (IBD).

A SINGLE-CENTER REAL-LIFE EXPERIENCE

A. Caroli, F. Lamboglia, I. Franceschetti, C. Pozzan, D. Checchin, F. Bortoluzzi, R. Cappuccio, A. Vitalba

UOC di Gastroenterologia, Ospedale dell’Angelo, Mestre; Ospedale SS Giovanni e Paolo, Venezia, Mestre-Venezia/Italy

Contact E-mail Address: alessandro.caroli@uls21.ve.it

Introduction: Selective GMA using Adacolumn® device is a non-pharmacological therapeutic option for patients affected by IBD, but its precise role among the various treatments available and its true effectiveness are still debated. In particular, steroid-dependent patients, refractory or intolerant to immunosuppressant and biologics, represent a sub-group of patients with limited options of treatment. Recently, a multicentric open-label trial [the ART trial *] showed, for the first time, a clinical benefit of GMA in these problematic patients.

Aims & Methods: The aim of this study was to further evaluate, in our real-life clinical experience, the efficacy and safety of GMA in these difficult-to-treat patients. We retrospectively reviewed the clinical data of patients treated with GMA-Adacolumn® in our center between 1/1/2008 and 31/12/2016. Only steroid-dependent and/or AZA/IFX/ADA-resistant or intolerant cases were considered. GMA was performed once a week for a minimum of five consecutive weeks. Occasionally, one or two additional sessions were performed. A clinical response was defined as a ≥ 3 points reduction of a clinical activity index (CAI) for ulcerative colitis (UC) and a ≥ 100 points reduction of the Cohn disease activity index (CDAO) for Crohn disease (CD) after 12 weeks from the beginning of the treatment.

Results: The study population included a total of 30 patients (17 males, 13 females, mean age 49 years, range 21–73) affected by UC (20 patients) and CD (10 patients). Eight patients (5 UC, 3 CD) were excluded from the final analysis for insufficient data. In the non-responders group, at week 12, no response was observed in 15 (68%). The response was better in UC (11/15 = 73%) than in CD (4/7 = 57%). A steroid-sparing effect was observed in all responsive patients. GMA was generally well tolerated, as only 4 patients (13%) reported mild adverse events (headache in two, hypotenston in one, vascular procedure complication in one) and no patients discontinued the apheresis due to the adverse events.

Conclusion: In our real-life single-center experience, focused to a selected group of difficult-to-treat patients affected by IBD, GMA with Adacolumn® seems to be, in a short-time evaluation, a useful and safe option of treatment, supporting the recent data from the ART trial. Prospective randomized trials in larger series of patients with and without extended follow-up are needed to confirm these results.

Aims & Methods: The present study aims to investigate the influence of the single and combined herbal extracts with regard to its anti-inflammatory and immune-modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine inhibiting acetylcholine-induced contractions in rat small intestinal preparations. IL1β, CXCL13 release from LPS-stimulated human macrophages (THP-1) was investigated respectively using an ELISA test system. Budesonid served as positive control. To characterize the challenged human macrophages (THP-1) was investigated respectively using an Aims & Methods:

Herbal combinations were compared and IC50 values derived. Interpretation of the combined effect, concentration-response relations of single components and the ELISA test system. Budesonid served as positive control. To characterize the challenged human macrophages (THP-1) was investigated respectively using an Aims & Methods:

Introduction:

The present study aims to investigate the influence of the single and combined herbal extracts with regard to its anti-inflammatory and immune-modulating activities. Thus, the effect of myrrh, chamomile flower, coffee charcoal extract on intestinal motility was determined using isometric tension measurement in isolated rat small intestinal preparations. Furthermore chemokine inhibiting acetylcholine-induced contractions in rat small intestinal preparations. IL1β, CXCL13 release from LPS-stimulated human macrophages (THP-1) was investigated respectively using an ELISA test system. Budesonid served as positive control. To characterize the challenged human macrophages (THP-1) was investigated respectively using an Aims & Methods:

Results:

Chamomile flower and myrrh interacted additively (IC50: myrrh ¼ 5 µg/mL; chamomile flower ¼ 22 µg/mL; coffee charcoal ¼ 29 µg/mL) resulting in a DRI of 3.7. CXCL13 released from Caco2 cells was reduced by all herbal components (IC50: myrrh ¼ 41 µg/mL; chamomile flower ¼ 364 µg/mL; coffee charcoal ¼ 447 µg/mL) with comparably high IC50 values. However, application of the herbal combination, significantly reduced the IC50 of the plant extracts (myrrh ¼ 25 µg/mL; DRI ¼ 1.7; chamomile flower ¼ 124 µg/mL; DRI ¼ 2.9; coffee charcoal ¼ 124 µg/mL; DRI ¼ 3.6). IL8 release from cytokine-challenged Caco2 cells was inhibited after myrrh (IC50 ¼ 3 µg/mL; 28% max inhib.) and coffee charcoal (IC50 ¼ 218 µg/mL; 75% max inhib.) but increased after chamomile flower treatment (IC50 ¼ 39 µg/mL; 29% max stim.). Treatment with all three plant extracts resulted in a moderate IL8 inhibition with an inverted U-shape concentration-response curve (IC50: myrrh ¼ 56 µg/mL; coffee charcoal ¼ 281 µg/mL; 77% max inhib.).

Conclusion:

The herbal components myrrh, chamomile flower and coffee charcoal influenced chemokine signalling of simulated intestinal epithelial cells and activated macrophages. Myrrh and chamomile flower additionally exerted anti-inflammatory effects. Synergistic and additive effects between the plant extracts justifies the composition of the traditional herbal medicinal product (Myrrhinil Intes®) and its application for the treatment of inflammatory intestinal disorders. P1066 IMMUNOSUPPRESSIVE CO-TREATMENT WITH INFliximab AND ADALIMUMAB IS NOT SUPERIOR TO ANTI-TNF MONOTHERAPY TO PREVENT TREATMENT FAILURE AND TREATMENT DISCONTINUATION IN ULCERATIVE COLITIS

S. Vieujean1, E. Louis2, C. Reenaers1

1Gastroenterology, CHU Liège, Liège/Belgium

2University Hospital CHU of Liège, Liège/Belgium

Contact E-mail Address: catherine.reenaers@chu.ulg.ac.be

Introduction:

In Crohn’s disease there is clear benefit from combination therapy with infliximab (IFX) and immunosuppressive drugs (IS), while the benefit seems more limited for adalimumab (ADA). Although some studies suggest a benefit of combination therapy with IFX in ulcerative colitis (UC) few data are available for adalimumab.

Aims & Methods: Our aim was to compare real life efficacy of anti-TNF mono-therapy (IFX and ADA) and anti-TNF + IS for UC maintenance. This was a retrospective study of patients with UC treated with IFX or ADA in 2 Belgian academic and regional Hospitals. Treatment periods were divided into 6 months. We categorized patients into 3 groups: 1. monotherapy (IS during the first semester); 2. combination therapy (IFX + IS during the first semi-ster); 3. single agent (IFX or ADA during the first semester with or without failure and with or without optimisation). Patients were followed-up for the next 2 years.

Conclusions:

Conclusions: In this real-life experience, combination therapy of IFX or ADA with IS during the first semester did not achieve clinical benefit with less side effect burden compared to monotherapy.
Disclosure of Interest: All authors have disclosed no conflicts of interest.

Introduction: The objective of the present study was to evaluate the effectiveness and safety of adalimumab (ADA) in children with ulcerative colitis (UC) who experienced previous infliximab (IFX) failure or intolerance.

Aims & Methods: This retrospective study included all children with UC from a national pediatric registry who received ADA therapy. The primary endpoint was the rate of corticosteroid (CS) free remission (PUCAI <10) at week 52. Secondary outcomes were: the rate of continuous clinical response and remission, primary non-response and loss of response at Weeks 12, 30, and 52 and rate of mucosal healing (MH) at week 52.

Results: A total of 32 children with UC received ADA (median age 10 ± 4 years). Median disease duration before ADA therapy was 27 months. All patients received previous IFX therapy (43% intolerant, 50% non-responders, 7% positive anti-IFX antibodies). Fifty-two weeks after ADA initiation 13 patients (41%) were in CS-free remission. MH occurred in 9 patients (28%) at 52 weeks. The cumulative probability of clinical relapse-free course was 69%, 59% and 53% at 12, 30 and 52 weeks, respectively. Ten patients (31%) had a primary failure and 5 (15%) loss of response to ADA. No significant differences in terms of efficacy were reported between not-responders and intolerant to IFX (p = 1.0). Overall, 19 patient (59%) maintained ADA therapy during 52-week follow-up. Seven patients (22%) experienced an adverse event. No serious side effects were observed and none resulted in ADA discontinuation.

Conclusion: In this cohort of children with UC ADA had a favorable short- and long-term efficacy, allowing to recover a significant percentage of patients intolerant or not-responding to IFX. The efficacy was not related to the cause of IFX discontinuation (intolerance/failure). Overall, safety profile was good. Larger, prospective, controlled trial with longer follow-up should be suggested to better clarify the role of ADA in pediatric UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1068 LOW FODMAP DIET IMPROVE DISEASE ACTIVITY AND QUALITY OF LIFE IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

G. Bodini1, E.G. Giannini2, V. Savarino1, M. Crespi1, S. Lo Pumo1, C. Zanella1, I. Baldiescara1, F. Savarino1

1Department Of Internal Medicine, IRCCS San Martino DIMI, Genova/Italy
2Department Of Surgery, Oncology And Gastroenterology, University of Padua, Padua/Italy

Contact E-mail Address: giorgia.bodini@gmail.com

Introduction: Inflammatory Bowel Diseases (IBD), Crohn Disease (CD) and Ulcerative Colitis (UC), are idiopathic autoimmune conditions whose pathogenesis is still unknown. It has been hypothesized that, in genetic predispose subjects, a deregulated immune response associated to an increase of intestinal permeability may lead to bowel damage and clinical manifestations. Thus, environmental factors and, in particular, food intake may play a pivotal role in IBD pathogenesis.

Aims & Methods: The aim of this prospective study was to evaluate the effects of a 6-week low fermentable Oligosaccharides, disaccharides, monosaccharides and polyols (FODMAP) diet on disease activity and quality of life in patients with IBD. At first visit (T0), patients were clinically evaluated by a gastroenterologist and a nutritionist, filled a questionnaire on quality of life (the IBD-Q) and underwent blood tests as well as fecal calprotectin assessment. Disease activity was defined using the Mayo score and the Harvey Bradshaw Index (HBI) for UC and CD respectively. After the baseline visit, patients were randomized into two groups: A) patients underwent a low FODMAP diet; B) patients underwent a diet with normal FODMAP amount. A food diary was used to assess patients’ adherence to the different diets. After six weeks (T1), patients had a second visit to assess disease activity, complete the IBD-Q, and repeat blood tests as well as fecal calprotectin assessment.

Results: In this prospective, interventional, cohort study, we enrolled 55 consecutive IBD patients who agreed to participate from an initial cohort of 127 IBD patients. Twenty-six patients were randomised to a low FODMAP diet (group A), while 29 patients to a standard FODMAP diet (group B). Among CD patients (n = 35, 63.6%), median HBI values significantly decreased during the study, in the whole population and in group A, whereas no change was recorded in group B (respectively P = 0.02, P = 0.02, P = 0.3). Among UC patients (n = 28, 36.4%), median Mayo scores did not significantly decrease during the study, both in the whole population and the two groups (P = 0.3, P = 0.3, and P = 0.8, respectively). Moreover, despite no statistically significant difference in quality of life in both groups at T0, in group A quality of life improved after the diet compared to group B (respectively, P = 0.06, P = 0.05 and P = 1).

Conclusion: We demonstrated that a low FODMAP diet, for a limited period of 6 weeks, is able to improve both disease activity, at least for CD, and quality of life in IBD patients. Further, larger multicentre studies are needed to confirm these preliminary data.

Introduction: Ustekinumab has shown a good safety profile and efficacy to induce and maintain remission in adult patients with refractory Crohn’s Disease (CD). Data are lacking in children.

Aims & Methods: All CD patients under 18 years who received ustekinumab were included in this retrospective observational study performed in a single tertiary paediatric centre.

Results: See table.

Conclusion: Subcutaneous ustekinumab is effective to induce and maintain remission in severe pediatric CD refractory to anti-TNF-α antibodies.

Disclosure of Interest: All authors have declared no conflicts of interest.

| Prior exposure to Biotherapies | Primary inefficacy | Loss of efficacy | Loss of efficacy | Allergy to IFX | Loss of efficacy | Primary inefficacy | Loss of efficacy | 12.5 points since inclusion without a remission as defined above; (3) absence of partial response or remission.

Results: We analyzed 107 patients with CD, with a total of 428 visits until W14. The principal reason to start infliximab was failure of immunosuppressive therapy (60%). Infliximab proved to be an effective treatment in our cohort since 75.7% (n = 81) patients were responders to infliximab and 40% (n = 42) were in clinical remission whereas 24.3% (n = 26) were non responders at W14. At week 14, 107 patients were divided in three groups related to the clinical activity of their disease: lack of clinical response, partial clinical response, clinical remission. It concerns respectively 26, 39 and 42 patients. Major baseline characteristics were not associated with clinical remission: sex, age at diagnosis, disease location, time between diagnosis and induction, age at induction. Drugs associated with infliximab at W0, W2, W6 or W14, whether it was immunosuppressive agents or corticoids were not associated with remission. Patients with low albumin levels had a worse response at induction Activity score at induction was also statistically associated with clinical remission: each decreasing of 10 points of activity score at induction increase of 0.48 times the risk to obtain clinical remission. Trough residual of infliximab > 8.5 μg/ml at W6 increase of 4.5 times the risk to obtain clinical remission at W14. Lack of growth retardation at induction increase of 3.98 times the risk to obtain clinical remission at W14.

Conclusion: Infliximab measurement in combination with evaluation of clinical severity (low body weight, growth retardation, hypoalbuminemia, severe disease) appears to be a reasonable strategy for predicting both short- and long-term treatment outcomes with IFX in the initial stage of treatment. Early detection of response to IFX is critical for the management of CD, especially in acute severe patients: it seems that the infliximab trough level at week 6 (more than 8.5 μg/ml) is predictive of a remission at week 14. Severe patients, especially patients with low body weight, growth retardation, hypoalbuminemia and severe disease may require higher doses than standard doses.

Conclusion: Corticosteroids have been effectively used for decades for the rapid induction of clinical remission in patients with Inflammatory Bowel Disease (IBD). However their adverse event profile is well-known, particularly with long-term use and in younger populations, and they have no role in maintenance of remission. Steroid-sparing agents and more recently biological therapy have reduced systemic steroid use and the incidence of steroid prescriptions especially in the outpatient setting is not known.

Aims & Methods: The aim of this study was to capture real-life steroid use in both adult and adolescent populations older than 13 years old who attend a dedicated IBD clinic in a tertiary referral centre. We tried to identify risk factors associated with appropriate or excessive steroid use in the whole cohort and in the two subgroups separately. All consecutive IBD patients who were followed up for at least one year in the adult and adolescent clinic in UCLH and attended their IBD appointment during February and March 2017 were included in the study.

A steroid assessment questionnaire was completed by the clinician during the visit for eligible patients. Use and type of steroids prescribed during the past year was recorded, as well as appropriate bone protection and disease activity based on patient and Global Assessment.

Results: 60 adolescents and 59 adults were included in the study. Two thirds of adolescents had Crohn’s disease while in the adult population Crohn’s and ulcerative colitis (UC) were equally distributed. 57 (95%) adolescents had been exposed to thiopurines and 47 (78%) to anti-TNFs as opposed to 69% (p = 0.002) and 39% (p < 0.001) of adults respectively. Vedolizumab exposure was similar in adults and adolescents. The percentage of patients with moderate to severe disease at last visit was comparable between two groups (60, 30% vs. 18, 31% adults, p = NS). 27 (21.3%) of patients were offered steroids during the past year and the incidence was the same in the adult and adolescent populations. 427 (15%) received excessive steroids, ie > 2 courses with a mean age of 25, 17 (62%) of them were an adult and 17 (62%) adults and adolescents were treated with Vedolizumab, while the choice of steroid was associated with a diagnosis of Crohn’s disease and was not different between the two groups. One third of patients did not receive bone protection with the steroid prescription, however this was only observed in the UC population rather than Predisimone (7/10 vs 2/17, p = 0.003). Steroid use overall was not associated with the age group or initial diagnosis but was expectedly associated with severity of disease (severe > moderate > mild, p < 0.001). The use of thiopurines or anti-TNFs did not affect steroid prescriptions, but interestingly the majority of Vedolizumab users received steroids in contrast to Vedolizumab naïve patients (7/9, 78% vs 20,109, 18%, p < 0.001). This association remained significant even after adjustment for disease severity and other co-factors, suggesting possibly the higher need for “bridging” Crohn’s disease to Budesonide rather than Predisimone (binary logistic regression showed naïve to Vedolizumab patients were protected against steroid use, OR 0.043 CI 95% 0.005–0.382, p = 0.005).

Conclusion: The use of steroids in an outpatient population with IBD is still common regardless of age group and use of anti-TNFs, as almost 1 in 4 patients received some type of oral steroid during a period of one year. Newer biologics, such as Vedolizumab, may predispose patients to higher steroid use, possibly due to slow induction of remission.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
GMA sessions continued with GMA while non-responders received GMA in combination with a low dose prednisolone 0.5 to 1.0 mg/kg bodyweight. At entry and week 12, patients were clinically and endoscopically evaluated with each patient serving as her or his own control.

**Results:** At entry, all 30 patients were corticosteroid naïve and none had deep colonic lesions or extensive loss of the mucosal tissue at the affected sites (GMA non-responders features). Ten patients achieved stable remission with the first-line medications and did not receive GMA. Six patients did not respond well to the first 5 GMA sessions and received prednisolone together with GMA, while 12 patients responded well to GMA, and achieved stable remission, but 2 patients withdrew to receive high dose prednisolone (up to 2 mg/kg bodyweight). At entry, the average CAI was 14 ± 0.4. Prednisolone was tapered to 0 mg within 3 months in those who received. Therefore, at week 12, all 30 patients were in remission, majority with mucosal healing.

**Conclusion:** In this treatment design, GMA in young corticosteroid naïve patients with active UC refractory to the first-line 5-aminosalicylates was associated with clinical remission and mucosal healing, while in non-responders to GMA mono-therapy, addition of a low dose prednisolone enhanced the efficacy of GMA and tapering of the prednisolone dose was not associated with relapse. Therefore, the majority of young steroid naïve UC patients who fail to respond to first-line 5-aminosalicylates should respond well to GMA and avoid pharmacologicals. Additionally, GMA has a good safety profile, which is a very favourable feature in growing patients.

**Disclosure of Interest:** A.R. Saniabadi: Dr. Saniabadi has a non-regular employment position at JIMBO.

**Conclusion:** In our cohort 35% of children presenting with AILD were subsequently diagnosed with IBD. Possible risk factors for development of IBD in AILD are low haemoglobin, being leaner and younger at diagnosis. An elevated FC and the presence of GI symptoms are useful to assess the need for diagnostic endoscopy when considering diagnosis of IBD in the context of AILD. As current immunosuppression may mask mild to moderate signs and symptoms of IBD a lower threshold for endoscopy should be considered in these patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Results: Twenty-one patients with chronic refractory angiodysplasia bleeding were recruited in this study, included 10 women, aged between 40–85; 11 cases of massive hemorrhage due to self-withdrawal. Among the remaining 20 patients who were given thalidomide regularly for 6 months. (1) Eighty patients come across constipation, sleepiness and dry mouth. There were no skin rashes, peripher neuropathy and any other adverse reactions during the treatment. All side-effects resolved when thalidomide was discontinued. (2) The red blood cell after treatment was increased to 43.7 ± 10.6% (P < 0.05) compared to before treatment (35.6 ± 10.9%); hemoglobin after treatment (94.7 ± 13.5 g/L) compared with before treatment (83.2 ± 17.6 g/L); HCT after treatment (0.32 ± 0.05) compared with before treatment (0.29 ± 0.08); the difference was statistically significant (P < 0.05). (3) The ALT after treatment (32.9 ± 18.5 U/L) compared with before treatment (30.6 ± 12.8 U/L); AST after treatment (25.1 ± 8.56 U/L) compared with before (28.0 ± 12.4 U/L); γ-GT after treatment (34.4 ± 8.4 U/L) compared with before (35.6 ± 12.7 U/L); AKP after treatment (85.5 ± 19.8 U/L) compared with before (83.0 ± 20.8 U/L); ALB after treatment (36.2 ± 3.1 g/L) compared with before (36.3 ± 4.3 g/L); there was not statistically significant difference (P > 0.05). (4) Prothrombin time (PT) after treatment (12.1 ± 1.3s) compared with before (11.8 ± 1.4s); APTT after treatment (30.2 ± 3.7 s), compared with before (31.0 ± 6.2s); the difference was not statistically significant (P > 0.05). (5) cases of colonic capillary malformation review colonoscopy, and the vascular malformation improved significantly after treatment.

Conclusion: Thalidomide, with its antiangiogenic mechanism of action, seems to be a promising drug in bleeding angiodysplasia as a treatment option for patients unable to benefit from other available modalities of treatment. The study drug was well tolerated.

Introduction: Colonic diverticular bleeding is the most common cause of lower gastrointestinal bleeding. We have reported the preliminary safety results of endoscopic detachable snare ligation (EDSL), a new method for diverticular hemorrhage. The bleeding diverticulum was ligated with a detachable snare. Unlike the endoscopic band ligation, removal of the scope to attach a ligation device and reinserter for treatment are not needed in this method. We performed a clinical trial to evaluate the efficacy and safety of EDSL.

Aims & Methods: This multicenter single arm phase II study was conducted in 12 Japanese institutions. Patients suspected of diverticular bleeding were enrolled from June 2015 to March 2017. Patients with serious heart, renal, or liver failure, sepsis, disseminated intravascular coagulation, and high-dose steroid use (pre-dnisolone dosage >10 mg/day) were excluded. The primary endpoint was the early (within 1 month) rebleeding rate in patients who were treated with EDSL. The secondary endpoints were overall early rebleeding rate in patients who had colonoscopic diverticular bleeding (intention to treat:ITT), success rate of EDSL total procedure time, EDSL procedure time, identification rate of bleeding diverticula, and adverse events. This study was approved by the ethics committee of each participating hospital and conformed to the Helsinki Declaration and the Japanese Clinical Research Guidelines.

Results: Of 123 patients with diverticular hemorrhage, 101 were treated with EDSL and the early rebleeding rate was 5% (5/101). The rebleeding rate in ITT population was 9% (11/123). Success rate of EDSL was 78% (96/123). EDSL and the early rebleeding rate was 5% (5/101). The rebleeding rate in ITT population was 9% (11/123). Success rate of EDSL was 78% (96/123). Early re-bleeding occurred in 112 patients (26%; 86 men and 26 women, mean age: 71 ± 12 years) to our hospital for treatment following a diagnosis of colonic diverticular bleeding based on abdominal CT and endoscopy findings. Early and late re-bleeding was defined as macroscopically bloody stools as a result of colonic diverticular bleeding during hospitalization and after discharge, respectively. Risk factors for early and late re-bleeding were retrospectively examined using univariate and multivariate analysis.

Results: Early re-bleeding occurred in 112 patients (26%; 86 men and 26 women, mean age: 71 ± 12 years). The mean duration until re-bleeding was 3.9 ± 2.4 days, and the average, early re-bleeding occurred 1.7 ± 1.2 times. On average, lower gastrointestinal endoscopy was performed 2.7 ± 1.2 times and endoscopic hemos- tatic treatment was performed 1.0 ± 1.0 times. In the univariate analysis, significant differences were seen in males (P = 0.005), in the use of oral antiplatelet agents (P = 0.012), and in patients not undergoing endoscopic hemostasis (P = 0.004). In the multivariate analysis, male gender (P = 0.006; odds ratio 2.06, 95%CI 1.23–3.44), the use of oral antiplatelet agents (P = 0.008; odds ratio 1.85, 95%CI 1.17–2.93), and patients not undergoing endoscopic hemostasis (P = 0.005; odds ratio 1.5, 95%CI 0.31–0.81) were independent risk factors for early re-bleeding. Late re-bleeding was seen in 72 of 345 patients who were able to follow up (21%; 46 men and 26 women, mean age: 73 ± 12 years). The mean duration until late re-bleeding was 41 ± 40 months, and on average, late re-bleeding recurred 1.5 ± 1.2 times. Only the use of oral antiplatelet agents (P = 0.05; odds ratio 1.72, 95%CI 0.98–2.98) was identified as an independent risk factor for late re-bleeding in the univariate and multivariate analysis.

Conclusion: Not undergoing endoscopic hemostasis and male gender were identified as risk factors for early re-bleeding, indicating the importance of choosing measures and hemostatic treatments to improve the detection rate of bleeding sources during endoscopy. The use of oral antiplatelet agents was a risk factor for both early and late re-bleeding, suggesting the need for patient management through multi-departmental cooperation.

Introduction: Acute lower gastrointestinal bleeding (ALGIB) constitutes an important gastroenterological emergency. A new score (NOBLADS) that intends to determine the risk of severe ALGIB was recently developed. We aimed to assess the validity of this score in a cohort of patients with ALGIB.

Aims & Methods: Retrospective study. Emergency consecutive admissions for ALGIB were reviewed. Severe ALGIB was defined as transfusion of ≥2 units of packed red blood cells (PRBC) and/or hematocrit decrease of ≤20% within the first 24 h and/or recurrent bleeding after 24 h of stabilization. NOBLADS score was calculated and its discriminative capacity for severe ALGIB as well as for other outcomes was assessed.

Results: Included 118 patients with a mean age of 73.6±14.4 years and 52.5% males. Most frequent etiologies for ALGIB were diverticular bleeding (23.7%) and post-polypectomy (21.2%). ALGIB was severe in 38.1% of patients. NOBLADS score showed a weak discriminative capacity to determine severe ALGIB (AUC = 0.68, p < 0.01). However, when comparing patients with NOBLADS ≤4 and >4, patients with higher scores were significantly older (69.2±15.7 years vs 78.6±10.0 years, p < 0.01), had lower hemoglobin levels as admission (11.8±2.3 g/dL vs 10.2±2.5 g/dL, p < 0.01), were transfused with more units of PRBCs during the first 24 hours and during hospital in-stay (0.4±0.9 vs 1.1±1.3, p < 0.01 and 1.0±2.2 vs 3.0±3.3, p < 0.01, respectively) and were more frequently admitted to intermediate care units (35.2% vs 59.6%, p < 0.01). No differences were found between the two groups regarding in-stay length, rebleeding rate, need for surgery or death.

Conclusion: NOBLADS score showed a weak discriminative capacity to determine severe ALGIB however, patients with NOBLADS ≤4 had greater PRBCs transfusion need and were more frequently admitted to intermediate care units. New or improved scores that can predict severe ALGIB are needed to determine more precisely appropriate care and to allow for a standardized approach.

Introduction: In Japan, CRC screening was launched as a national policy for all people aged over 40 years in 1992. 2-day FIT has been widely accepted, and has been recommended performing in every year.

Aims & Methods: The aim of this study is to analyze the concentration of FIT for colorectal cancers (CRCs) from the screening. The cut off value is adapted 20 µg Hb/g stool and the rate of further examination is around 75% for many years. In Ibaraki prefecture, CRCs were detected 3,421 cases from the screening (2000–2014) with 2-day FIT. The concentration of FIT was grouped in 20–80, 80–140, 140–200 and over 200 µg Hb/g stool. Screening have been performed with the OC-SENSOR DIANA (EIKEN, JAPAN) automated analyzer. CRCs were analyzed with age group (40–49, 50–59, 60–69, over 70-year-old), size (1–24, 25–49, over 50 mm), location (proximal, distal), Dukes’ classification (Dukes A, C, D) depending on the concentration. The chi-square test was used to compare of each group.

Results: There was no difference in gender and age group for concentration. The concentration of CRCs in the distal colon was significantly higher in the proximal colon [distal 39% (861/2,200) and proximal 32% (337/1,053) with over 200 µg Hb/g stool]. The concentration of CRCs with larger size was significantly higher than smaller size [1–24 mm 27% (533/1,961), 25–49 mm 54% (439/818) and over 50 mm 64% (169/263) with over 200 µg Hb/g stool]. The concentration of invasive CRCs was significantly higher than intra-mucosal CRCs [intra-mucosal 23% (370/1,617) and invasive 50% (888/1,793) with over 200 µg Hb/g stool]. The concentration of Dukes B, C and D were significantly higher than Dukes A except for intra-mucosal. There was no difference between Dukes B and D [Dukes A except for intra-mucosal 36% (325/910), B 68% (247/363), C 60% (232/385) and D 69% (61/89) with over 200 µg Hb/g stool].

</tbody>
</table>

Conclusion: In 20–80 µg Hb/g stool, there were CRCs with smaller size, no inva- sion, in the proximal colon, Dukes A except for intra mucosal CRCs and so on. When the cut off value is raised over 80 µg Hb/g stool, the detection of early stage CRCs and proximal CRCs may be lost. There were many advanced CRCs with concentration over 200 µg Hb/g stool. Therefore, when the participants, who are positive with high concentration of FIT, need to take a further examination as soon as possible. Why concentration of CRCs in the distal colon were higher than in the proximal colon? It may be related to the fact that the number of developable CRCs in the distal colon are more than in the distal colon. We will go on researching mechanism about this.

Introduction: Hodgkin lymphoma (HL) survivors treated with abdominal radiotherapy and/or alkylating chemotherapy have a high prevalence of colorectal cancer. This study evaluated the prevalence of colorectal neoplasia in HL survivors.

Aims & Methods: The primary aim of this multicenter cohort study was to assess the diagnostic yield of advanced colorectal neoplasia detected by a first surveillance colonoscopy in HL survivors treated with abdominal radiotherapy and/or procarbazine. Advanced colorectal neoplasia was defined as an advanced adenoma (high-grade dysplasia, ≥25% villous component, or ≥10 mm diameter), an advanced serrated lesion (dysplasia or ≥10 mm diameter), or CRC. Results were compared with general population data that underwent a primary screening colonoscopy (n = 1276 asymmetrical individuals between 50–70 years of age). This study demonstrates the results of a predefined interim analysis.

Results: A colonoscopy was performed in 101 HL survivors, who were significantly younger than general population controls (median 51 years (interquartile range 45–57) vs. 60 years (interquartile range 55–65), p < 0.001). A mean of 3.5 neoplastic lesions was detected per HL survivor (standard deviation 4.9) vs. 1.1 per control (standard deviation 1.8, p < 0.001). Despite their young age, the prevalence of advanced neoplasia was higher in HL survivors than in controls (25% (95% confidence interval 16–33%) vs. 12% (10–14%), p < 0.001). Advanced adenomas were detected in 14% (6–21%) of HL survivors and 9% of controls (7–17%, p < 0.001). The prevalence of advanced serrated lesions was higher in HL survivors than in controls (12% (6–18%) vs. 4% (3–5%), p < 0.001). Serrated polyposis syndrome was present in 6% (2–11%) of HL survivors and 0% of controls (p < 0.001).

Conclusion: HL survivors treated with abdominal radiotherapy and/or procarbazine have a high prevalence of advanced colorectal neoplasia. Colonoscopy surveillance should therefore be implemented as standard of care.

Aims & Methods: We aim to investigate the incidence of prostate cancer as a second primary malignancy among patients with prior primary colorectal cancer (CRC) using a nationwide population-based dataset. This study is a nationwide population-based retrospective cohort study. We followed up with patients registered in the Republic of Korea National Health Insurance Corporation who were diagnosed with colorectal cancer between 2007 and 2014 and investigated the incidence of prostate cancer (one year lag period). The incidence of prostate cancer was also evaluated in age and gender-matched controls using a cohort of patients diagnosed with colorectal cancer during the same period. The incidence rate was defined as the number of newly diagnosed prostate cancer patients per 1000 person-years. To assess the role of detection bias-related to the follow-up of CRC, follow-up started at the date of CRC diagnosis and continued until the earliest date of prostate cancer diagnosis, death, loss to follow-up, or the 2015 end of follow-up. We used Cox proportional hazards models to identify prostate cancer occurrences among CRC patients. We also performed the multivariable analysis. Multivariable models included the variables of age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income.

Results: We analyzed a total of 85,462 first primary CRC survivors. During the follow-up period of 494,222 person-years, 2005 (2.3%) developed prostate cancer (incidence rate 4.06/1,000 person-years). The median duration of follow-up was 5.78 years. Compared with the general population, CRC patients had a significantly increased risk of secondary prostate cancer (HR = 2.30, 95% CI: 2.182–2.426; P = 0.001). Multivariable analysis (including age, sex, body mass index, hypertension, diabetes mellitus, dyslipidemia, and income) showed that age ≥ 55 years (HR = 20.85, 95% CI: 11.88–36.59; P < 0.001) is a significant independent predictor of prostate cancer.

Conclusion: Men who develop colorectal cancer are at an increased risk of prostate cancer, with the greatest risk in men under the age of 55. This data suggests that CRC patients under 55 years old require regular screening for prostate cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1086 SITE AND STAGE DISTRIBUTION OF SCREEN DETECTED AND CLINICALLY DETECTED COLORECTAL CANCERS IN THE NETHERLANDS
E. Toes-Zoutendijk1, A. Kooyker1, M. A. Elferink2, V. Lennema2, M. E. Van Leerdam1, L. S. Rigter3, M. A. Elferink2, V. Lennema2

4Department Of Public Health, Erasmus University Medical Center, Rotterdam/Netherlands

Contact E-mail Address: e.toes-zoutendijk@erasmusmc.nl

Introduction: The primary aim of this multicenter cohort study was to assess the proportion of site and stage distribution of screen detected and clinically detected colorectal cancers (CRC). The study addressed the question whether long-term colorectal cancer (CRC) mortality, screening has been introduced. Screening can be beneficial if cancers are detected in an earlier stage or in a pre-malignant stage, as survival rates of these patients will improve.

Aims & Methods: In this study stage distribution of screen detected CRCs were compared with clinically detected CRCs in the Netherlands. All CRCs detected in men and women aged 55 to 75 years in the Netherlands in 2015 were included in the analysis. Data were gathered from the Dutch Cancer Registry. The current analysis is based on 70% of these cancers that had staging information available at initial data retrieval. Data will be updated in May 2017. Proportions of site and stage distribution of screen detected and clinically detected CRCs were compared.

Results: A total of 6,517 CRCs in 2015 with staging information were available for the preliminary analysis. Of those, 2,591 (39.8%) were diagnosed as a result of CRC screening (screen detected), 3,463 (53.1%) presented with symptoms and were diagnosed as a result of CRC screening (screen detected), 1,188 (1.8%) were detected during surveillance colonoscopy and 203 (3.1%) as coincidental finding and of 143 (2.2%) the method of detection was unknown. Screen detected cancers were more often detected in an earlier stage (stage I and II) compared with clinically detected cancers, 1,687 (66.5%) and 1,188 (1.8%) respectively (p < 0.001). Screen detected cancers were more often diagnosed in the left side of the colon compared with clinically detected cancers, 46.2% vs 31.5% (p < 0.001). Comparison of stage distribution by location showed that left sided cancers were most often diagnosed in an early disease stage with 59.0% of the CRCs in stage I or II, followed by the right sided cancers with 52.8% of the CRCs in stage I or II. The CRCs of the rectum were most often diagnosed in a late disease stage, only 39.4% in stage I or II. Table 1 shows the comparison of stage distribution by location and method of detection. With screening, 68.8% of the right sided cancers, 71.0% of the left sided cancers, and 56.5% of the rectum CRCs were diagnosed in an early disease stage (stage I and II) which was all higher than clinically detected cancers (p < 0.001).

Table 1: Stage distribution of screen detected and clinically detected colorectal cancers by location and method of detection

<table>

</tr>
</tbody>
</table>

Conclusion: Screen detected CRCs show a more favourable stage distribution compared with clinically detected cancers, with two third of the cancers
diagnosed in stage I or II. As those patients will have better survival rates, it is expected that this will decrease CRC mortality rates.

Contact E-mail Address: lucie.bienfait@erasme.ulb.ac.be

Introduction: According to European and American series, 1,2 up to 20% of colorectal cancers are characterised by instability at microsatellite sites and have deleterious mutations in mismatch repair (MMR) genes (MLH1, MSH2, MSH6 and PMS2) or hypermethylation of the MLH1 promoter gene. MMR deficient colorectal cancers are predominantly found in the right colon. Although an increasing rate of colorectal cancer has been observed in many low- and middle-income countries including in West-Africa,3 data on epidemiology and biology of colorectal cancer in native Africans from this region are scarce.

Aims & Methods: We aimed to study the incidence of MMR deficient in Ivory Coast and to compare the data with those from a tertiary center in Belgium. Immunohistochemistry for MLH-1, MSH-2, MSH-6 and PMS-2 was performed on paraffin-embedded tissue samples from 83 colorectal cancers (54% males) operated in Abidjan and from 343 colorectal cancers (48% males) from Erasme University Hospital in Brussels. Immunohistochemical staining was interpreted as normal or loss of expression.

Results: Colorectal cancer is occurring at a younger age in Ivory Coast compared to Belgium (median age: 53 vs. 66). In both populations, MMR deficiency was detected in 13% of cases (11 and 43 cases, respectively). Whereas MMR deficient cancers in Brussels were mainly found in women (26/43 i.e. 61%) only 3/11 (27%) of the MMR deficient cancers from the Abidjan series occurred in females. The predominant location of MMR deficient tumours was different between both series: in the Brussels patients group, MMR deficient tumours were mainly located in the right colon (33/43 i.e. 77%) whereas in the Abidjan group they were predominant (10/11 i.e. 91%) in the left colon. With regard to the involved proteins, 6/11 (55%) of the MMR deficient cases from Ivory Coast were characterised by loss of expression of MSH2 and MSH6 whereas this immunohistochemical staining pattern was observed in only 9/43 (20%) cases from Belgium.

Conclusion: Our pilot study reveals marked differences in presentation of MMR deficient colorectal cancer between the two geographic regions. In contrast to Europe, MMR deficient colorectal cancer in Ivory Coast is mainly found in male patients and in the left colon. Moreover, there are differences with regard to the involved mismatch repair proteins. Together with the younger age at presentation, these data suggest differences in epidemiology and biology of colorectal cancer in native Africans from West Africa compared to the European population.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1088 ROUTINE MOLECULAR ANALYSIS FOR LYNCH SYNDROME IN PATIENTS WITH ADVANCED ADENOMA OR COLORECTAL CANCER WITHIN A NATIONAL SCREENING PROGRAM FOR COLORECTAL CANCER
A. Goverde1, W. Nm Dinjens2, M.J. Bruno1, R.M.W. Hofstra1, M. Doukas3, M.M. Van Der Weiden1, H.J. Dubbink1, A. Wagner1, M.C.W. Spanader1

Introduction: Lynch syndrome (LS) is the most common hereditary cause of colorectal cancer (CRC). Identifying LS carriers and their affected family members is of great importance for prevention of CRC. Routine screening for LS by immunohistochemical staining (IHC) in CRC patients <70 years of age is recommended. LS screening in adenoma patients could yield more benefit, since CRC can still be prevented in these patients. A small number of participants of the national CRC screening program is expected to have LS. We aimed to assess the diagnostic yield of IHC for LS in patients with advanced and multiple adenomas or CRC within the Dutch national fecal immunochromatographic test (FIT)-based CRC screening program.

Aims & Methods: We included participants of the national CRC screening program, referred to our center after a positive FIT from December 2013 to December 2016. IHC for MLH1, MSH2, MSH6 and PMS2 protein was performed on advanced adenomas and CRCs found at colonoscopy. Adenomas were considered advanced if they had a villous component, high-grade dysplasia or were ≥10 mm in size. Also, in cases with ≥4 non-advanced adenomas, IHC was performed on the largest adenoma. MLH1 hypermethylation analysis was added as a distinguishing sporadic from LS. All LS cases referred for genetic counselling were included. For LS patients with IHC suspect for LS were offered germline mutation analysis. If no pathogenic mutation was found, we performed somatic mutation analysis.

Results: A total of 1006 patients (54% male; mean age of 67 years (±6 years)) with positive FIT were included in the study. At colonoscopy, 355 (35%) patients (63% male; mean age of 67 years (±6 years)) had a CRC and/or adenoma eligible for IHC. A total of 322 adenoma patients were analyzed. None had aberrant MLH1 staining. A few adenomas had MLH1 promoter hypermethylation. The two patients without MLH1 promoter hypermethylation were referred for genetic counselling. Both patients had no family history suspect for LS. In both cases no germline MLH1 mutation was found and somatic mutation analysis showed that both had a likely sporadic tumour.

Conclusion: Our results indicate that routine LS screening by IHC and MLH1 hypermethylation in patients with advanced and multiple adenoma within a national FIT-based screening CRC program is not an effective strategy. The diagnostic yield of LS screening in younger adenoma patients should be assessed.

Introduction: Colorectal cancer (CRC) is a leading cause of cancer mortality in the Veneto Region (North-eastern part of Italy). Population screening of adults between 50 and 75 for CRC was begun in 2002, and it became standard practice in the Veneto local health units (LHU) of the region in 2008. In both periods, the LHU provided an FIT-based CRC screening program and the Veneto Region (NB) also provided follow-up colonoscopies and 7 LHU no. The current prospective cohort study was carried out to evaluate the impact of CRC screening on the rate of surgical oncology procedures to treat colon and rectal cancer.

Aims & Methods: Data from hospital discharge records (HDR) regarding CRC patients hospitalized between 2000 and 2015 were collected. All CRC patients whose principal diagnosis was colon and/or rectal cancer were included in the study. The number of patients studied rose approximately 18% reaching 1,547,097 for the last year (2015). The Standardized Hospitalization Ratio (SHR) using five-year age groupings was calculated and expressed per 10,000 population.

Results: During the study period, 30,399 surgical procedures for colorectal cancer were performed (colon 63%, rectum 36%, secondary malignant neoplasm 1%) with a SHR of 139.1; the number was higher in males (1.69 vs. 1.02; OR: 1.66; CI 95%: 1.62–1.7; p < 0.05). An analysis of the annual SHR distribution uncovered two distinct phases: during the first phase there was a rising tendency that reached a maximum value in 2007 (166.9; X2 trend: 46.731; p < 0.05) and during the second there was a falling tendency that reached its minimum value in 2015 (102.3; X2 trend: 429.791; p < 0.05). When the cancer sites were ana- lyzed, it was seen that despite the peak in 2007, the rate of surgical procedures of the proximal colon during the last year was the same as the 2000 value (41.5); there was, instead, a relevant decrease in the rate of procedures on the distal colon and rectum which fell from 94.4 to 59.2 (–37.5%). The study also shows that there was no significant difference in the reduction in surgical procedures for CRC in LHU in which the screening program included a follow-up colonoscopy (SHR 2015: 139.8; –29%) with respect to those centers where it was not forseen (SHR 2015: 138.5; –28%).
P1090 ETHNIC VARIATION IN ADENOMA DETECTION IN THE UK FLEXIBLE SIGMOIDOSCOPY BOWEL CANCER SCREENING PROGRAMME

Diseases Digestive Centre, University Hospital of Leicester NHS Trust, Leicester/United Kingdom

Contact E-mail Address: dennis.lim@uhl-tr.nhs.uk

Introduction: The NHS bowel scope screening programme was introduced in 2013 as a result of adults aged 55 invited for a ‘one-off’ flexible sigmoidoscopy followed by a colonoscopy if significant adenomas are detected. University Hospitals of Leicester Bowel Cancer Screening Centre serves an ethnically diverse community with approximately 25% of the population eligible for sigmoidoscopy screening being British Asian Indians and 45% being British White. Within the faecal occult blood based bowel cancer screening programme we have previously reported a lower polyp detection rate (PDR) and adenoma detection rate (ADR) in Asians undergoing colonoscopy compared to White British2. This study aims to evaluate PDR, ADR and cancer detection (CDR) in British Asian Indians taking part in the bowel scope screening programme.

Aims & Methods: Patients who underwent screening sigmoidoscopy between February 1st 2015 to March 31st 2017 were included. All individuals participating in screening sigmoidoscopy routinely report their self-selected ethnic origin. This database was cross referenced with the endoscopic and histology findings from the ‘Exeter’ online database. The findings in British Asian Indians were compared with British Whites.

Results: A total of 4287 patients underwent screening sigmoidoscopy over the 2-year period. 1169 individuals had polyps (500 adenomas). Overall polyp detection rate (PDR) was 1169/4287 (27.3%), adenoma detection rate (ADR) was 500/4287 (11.7%), hyperplastic polyps were 642/4287 (15%), sessile serrated lesions were 13/4287 (0.3%), and other polyps were 14/4287 (0.3%) (Inflammatory polyps 13, Juvenile polyp 1). Cancer detection rate was 6/4287 (0.14%). During the period studied, 3509 British white individuals (82%) and 778 British Asian Indians were detected in British White (CDR = 0.17%) but none in British Asian Indians.

Conclusion: This study found no cancers and significantly lower PDR and ADR in British Asian Indians compared to British White participants in the bowel scope screening programme. Further long term evaluation of these differences is needed and may shed light on factors contributing to the development of bowel cancer.

P1091 DEAD BOX POLYPEPTIDE 27 PROMOTES TUMORIGENICITY IN COLORECTAL CANCER THROUGH ACTIVATING NUCLEAR FACTOR KAPPA B PATHWAY AND ITS EXPRESSION IS ASSOCIATED WITH POOR SURVIVAL IN PATIENTS

1Institute Of Digestive Disease And Department Of Medicine And Therapeutics, State Key Laboratory Of Digestive Disease, The Chinese University of Hong Kong, Hong Kong/Hong Kong Pre
2Division Of Gastroenterology And Hepatology, Shanghai Institute Of Digestive Disease, Ren Ji Hospital, Shanghai Jiao Tong University, Shanghai/China

Contact E-mail Address: inflyings@gmail.com

Introduction: We identified for the first time that DDX27 (DEAD box polypep-
tide 27) gene was amplified in colorectal cancer (CRC) by whole genome sequenc-
ing. Amplification of DDX27 was detected in 47% (41/100) of primary CRC tumors and positively correlated with its mRNA overexpression. DDX27 plays a pivotal oncogenic role in colorectal carcinogenesis by promoting cell prolifera-
tion and inhibiting apoptosis. In this study, we investigate its function, mechan-
ism of action and clinical implication in CRC.

Aims & Methods: Downstream effectors and pathways of DDX27 were identified by promoter luciferase reporter assay, RT2 Profiler PCR array and western blot. The interacting partners of DDX27 were screened by BioID method and further validated using immunoprecipitation assay and immunofluorescence staining method. Clinical implication of DDX27 was assessed in two human CRC cohorts by quantitative PCR method and immunohistochemical staining of tissue microarrays.

Results: Promoter luciferase reporter assays revealed that DDX27 mainly acti-
vated nuclear factor kappa B (NF-κB) pathway in CRC cell lines (HCT116 and SW480). Ectopic expression of DDX27 promoted transcription of NF-κB signaling targets including BCL2A1, BIRC3, CCL20, CXCL3, NFKBIA, TNF and TNFAIP3. Conversely, silencing of DDX27 showed an opposite effect on NF-κB signaling. Treatment of NF-κB inhibitors CAPE and JSH-23 abrogated the pro-
motive effect of DDX27 on CRC cancer cells. We revealed that DDX27 enhanced and prolonged NF-κB signaling via reducing the accumulation of nuclear IκBα, which negatively regulates transcriptional activities of NF-κB and transport NF-κB proteins back to the cytoplasm. DDX27 overexpression marked by endogenous immunoprecipitation assay and immunofluores-
cence staining. Knockdown of NPM1 abrogated DDX27-activating NF-κB signaling, as well as its tumor-promoting function. Kaplan-Meier curves showed that higher DDX27 expression was significantly associated with shorter survival in patients with CRC of two independent cohorts (N=199 for Beijing cohort using quantitative PCR method, and N=275 for Shanghai cohort using immunohistochemical staining of tissue microarrays; both P < 0.05).

Conclusion: DDX27 plays an important oncogenic role in promoting CRC tumorigenicity via activation of NF-κB pathway. Higher expression of DDX27 is correlated with poor prognosis in CRC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
significantly different between serrated lesions, SSA/Ps and HPs were positive for MUC1/C/CA19-9 with SSA/P.

Conclusion: Our studies showed the three types of serrated lesions have their own distinct features and could be helpful to distinguish between them. SSA/P and TSA are premalignant lesions of colorectum and we should detect these lesions and control the disease endoscopically.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1093 IN SITU DETECTION OF MIGRATING COLORECTAL CANCER CELL-RELEASED LARGE EXTRACELLULAR EXOSOME CLUSTERS

1 2nd Dept. Of Internal Medicine, Semmelweis University, Budapest/Hungary
2 5th Department Of Genetics, Cell- And Immunobiology, Semmelweis University, Budapest/Hungary
3 1st Department Of Pathology And Experimental Cancer Research, Semmelweis University, Budapest/Hungary
4 Institute Of Enzymology, Research Centre For Natural Sciences, Hungarian Academy Of Sciences, Budapest/Hungary
5 Computational Health Informatics Program (chip), Boston Children’s Hospital, Boston/United States of America/MA

Aims & Methods: Our study demonstrates in situ for the first time that besides conventional exosome release, migrating CRC cells also secrete large, extracellular membrane proteins, but they were also detected extracellularly, in the plasma membrane resulting in the release of individual exosomes into the extracellular space. Recently, sporadic in vitro observations of a novel, unconventional mechanism have been reported in which the exosome-like vesicles remain in one body during their secretion.

Results: 3D reconstructions showed ALIX-positive and CD63-positive exosome clusters (ECs) with 0.62 to 1.94 µm diameter (mean ± SD: 1.17 ± 0.34 µm) localized partially inside, and/or outside the cytoplasm in 85.96% (n = 28/33) of migrating CRC cells. E-cadherin HHC showed that ECs were not only captured during their exit from the cytoplasm and localized among plasma membrane proteins, but they were also detected extracellularly, in the plasma membrane-stroma interface. STEED-microscopic images showed that released ECs were composed smaller, distinguishable ALIX-positive spheroids of 98/114/150 µm diameter. Confocal and stimulated emission deconvolution (SEED) microscopy-based 3D reconstructions were used. Parametric statistics was used.

Conclusion: Our studies demonstrate in situ for the first time that besides conventional exosome release, migrating CRC cells also secrete large, extracellular ECs. These structures might fundamentally contribute to the autocrine/paracrine mechanism have been reported in which the exosome-like vesicles remain in one body during their secretion.

**Conclusion:** We observed a different behavior between mutated and wild-type patients. Patients with genetic involvement still developed adenomas during the follow-up and some needed colectomy. Instead, wild-type patients had mostly no recurrence. Constitutional genetic background could be suspected in wild-type patients when a continuous development of new polyps has occurred and further genetic investigation should be offered by multi-gene testing.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** Global DNA hypomethylation along the colorectal normal-adenoma-carcinoma sequence.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Extracellular miRNAs are stable and its expression is less characterized in plasma. Altered and overlapped miRNA profiles between tissue and plasma are less explored.

**Aims & Methods:** The present study was designed to characterize the tissue and circulating miRNA profile through colorectal adenoma-carcinoma sequence in humans. Two parallel sets of mRNAs were analyzed: (a) mRNAs in human CRC cells, (b) mRNAs in human primary normal cells (primary tumor location). To achieve that goal, human peripheral blood and biopsy of normal (N), tumoral (AT), tumor biopsies (TV) and colorectal adenoma (CRC) volunteers were also cultured and plasma were also collected two times a week over 45 days from C37BL/6-/-C38, CB/AJ mice. MiRNAs were isolated and Affymetrix GeneChip miRNA array analysis was performed for screening of the altered miRNA profile. RT-qPCR miRNA quantification was performed for validation.

**Results:** In the case of human samples out of 173 detectable miRNAs, 306 miRNAs were expressed in normal, 334 in adenoma and 321 in CRC. Characteristic miRNA expression alteration was observed in the comparison of AD vs. CRC (miR-3198, miR-340), and in CRC vs. plasma. In the case of N, CRC, overexpression of miR-612, miR-1296, miR-933, miR-937 and miR-1207 was validated by RT-PCR (p < 0.05). Partial co-expression of these miRNAs was observed in tissue pairs as well. We identified high plasma levels of 94 miRNAs in miR-126 silenced CRC cells. Furthermore, 176 miRNAs in late metastatic stages. Based on CBAJ-C38 mice model experiment where the injected tumorous cells could not adhere miR-676 found to be a host originated while miR-92a was a tumor-derived miRNA. MiR-676 and miR-92a shown significant overexpression (388x and 37x p < 0.05) in plasma samples based on real-time PCR and microarray results.

**Conclusion:** Circulating miRNAs alteration could observe in animal models and in human system. Cancer-associated miRNAs in the circulation may originate from the immunologic system or from other metastatic regions far from the primer tumor location.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1109 DNA METHYLATION CHANGES PRECEDE AND CONTRIBUTE TO SPORADIC MUTATIONS IN COLORECTAL ADENOMA AND CANCER DEVELOPMENT THROUGH INDUCED GENOMIC INSTABILITY**

**2nd Dept. Of Medicine, Semmelweis University, Budapest/Hungary**

**Contact E-mail Address:** mb@hel2.sote.hu

**Introduction:** Colorectal cancer development is characterised by sporadic mutations and epigenetic alterations. DNA mutations occur randomly and sporadically in growth-related genes, mostly on cytokine nucleotides. Active demethylation of cytosines in relation to RNA expression alterations may lead to genetic instability and DNA mutations. Whole genome DNA methylation and mutation analysis with RNA expression profiling could demonstrate the primary and secondary order of the genetic and epigenetic changes and their relation to the malignant phenotype development.

**Aims & Methods:** In this study we aimed the whole genome methylation analysis and targeted mutation analysis of colorectal cancer (CRC)-related genes (12) with upstream whole genome mRNA expression evaluation. Special focus was set on the p53 pathway and the involved genes. Methyl capture sequencing (Illumina) was performed on normal (N); adenomatous (Ad; 15) and colorectal cancer (CRC; 9) biopsy specimens. Methylation results were confirmed in silico methylation studies’ results (TCGA) and by methylation array-PCR (Quagen Methylation array). Specimens were further evaluated for 32 mutations of 12 CRC-related genes (APC, BRF, CTNNB1, EGFR, FBXW7, KRAS, BRAF, p53, SMAD4, TP53) by novel generation sequencing (Roche 454 Junior). mRNA expression evaluation was performed by whole genome expression analysis (HGU 133, Affymetrix). Tageted pathway analysis was performed for the p53 pathway. Bioinformatic analysis included overall and correlation analysis of the detected methylations and correlation of the top hyper/hypermethylation genes, methylation changes on the tumor mutation regions and related pathway gene promoters were evaluated by targeted analysis.

**Results:** Overall hypomethylation was observed on the N-Ad-CRC sequence in the gene body and non coding genomic regions. In Ad-N comparison e.g. p73, NGFR, PDGFR genes were hypermethylated for their promoters, FMN1, SLC16A7 genes were hypomethylated, respectively. In CRC-N comparison DK2, SDC2, SOX1 genes showed hypomethylation, while ERBB4, CREBS, CNTN1 genes were hypomethylated in the promoter regions. In silico analysis on the TCGA database yielded confirmatory results. The common hyper- and hypomethylated genes were also in correlation with methylation array results yielded by of p53 pathway genes showing promoter methylation alterations. DNA methylation with consecutive phenotypic effect can be observed in a diverse range of cellular events related to infection and metastasis of cancer cells. Our previous study found that miR-126 over-regulated expression and HOC activity in CRC cells. Whether RhoA activity and RhoA signaling pathway play an important role in miR-126 regulating EMT process, cell proliferation, migration and invasion of CRC remains unclear.

**Aims & Methods:** To identify RhoA signaling pathway associated with the function of proliferation, migration, invasion and expression of CRC cells. Constructed CRC cell lines of miR-126 over-expression or knockdown. Performed MTT, colony formation, wound-healing, migration, invasion assays and RT PCR, western blot analysis to study the functions of miR-126 in EMT, proliferation, migration, invasion and expression RhoA signaling pathway of CRC cells. Constructed pDsRed2-V14RhoA (constitutively active RhoA, V14RhoA) and pDsRed2-N19RhoA (domain-negative, N19RhoA) mutants, then transfected them into CRC cell lines of miR-126 over-expression or knockdown RhoA activity. Pulldown assay detected RhoA activity after transfected. Then repeated the experiments above to investigate the biological behavior changes of CRC cells.

**Results:** MiR-126 promoted the expression of E-cadherin and suppressed the expression of SLUG, Snail, Vimentin, Fibronectin of CRC cells. MiR-126 also inhibited proliferation, migration and invasion of CRC cells, and negatively regulating RhoA signaling pathway. V14RhoA mutant effectively increased the activity of RhoA and reversed the role of miR-126 by promoting EMT, proliferation, migration and invasion in miR-126 overexpressing HCT116 cells. Conversely, N19RhoA mutant effectively decreased the activity of RhoA and suppressed EMT, proliferation, migration and invasion in miR-126-silenced SW480 cells.
P1101 MIR-126 REGULATES TUMOR GROWTH AND METASTASIS IN COLORECTAL CANCER BY RECRUITING TUMOR ASSOCIATED MACROPHAGES THROUGH PARACRINE SIGNALING OF CXCL12

Introduction: Colorectal carcinoma is one of the leading causes of cancer-related mortality worldwide. Tumor associated macrophages (TAMs) are critical stromal components intimately involved with the progression, invasion, and metastasis of cancer cells. Recently, increasing studies have demonstrated that microRNA-126 (miR-126) had an important role in colorectal cancer. The expression of miR-126 was decreased significantly in colorectal cancer, particularly in high metastatic cell lines, indicating that miR-126 may inhibit tumor development and metastasis. However, the mechanism underlying miR126 inhibiting cancer is uncertain, and its function in cross-talk between colorectal cancer cells and TAMs are still in its infancy.

Aims & Methods: In this study, we investigate the cross-talk between cancer cells and TAMs in colorectal cancer microenvironment, and find out what role the miR-126-CXCL12-IL6 axis plays in it. Methods: (1) The effect of miR-126 on CXCL12 expression was assessed in the CRC cell line CaCo2 transferred with a miR-126 mimic or inhibitor to increase or decrease miR-126 expression; (2) We build a co-culture system of TAMs and transferred cancer cells, and use AMD3100 to block CXCL12/CXCR4 axis, then detect the TAM recruitment and inflammation factors secretion of TAMs; (3) Furthermore, the TAMs co-cultured before were taken away from the previous system and put into a new co-culture system with untreated colorectal cancer cells, and IL6 neutralizing antibody was involved in. We detect the expression of EMT-associated factors and STAT3 pathway activation by western blot, cell growth by CCK8, metastasis by Transwell. The definition of statistical significance was defined as P < 0.05 (two-tailed).

Results: (1) miR-126 negatively regulate CXCL12 expression in post-transcript level; (2) Inhibiting miR-126 of colorectal cancer cells could promote TAMs recruitment and up-regulate inflammation factors IL1β and IL6 expression. However, blocking CXCL12/CXCR4 axis by AMD3100 could reverse this effect; (3) Inhibiting miR-126 of colorectal cancer cells could recruiting TAMs, therefore down-regulate-Ecadherin protein, up-regulate slug protein, and activate STAT3 pathway of untreated cancer cells. It could also promote cancer cells growth and metastasis. In addition, IL6 neutralizing antibodies could block this effect; (4) The result of these experiments are consistent with the common knowledge.

Conclusion: Our results reveal a novel mechanism by that miR-126 repress recruitment and inflammatory factor secretion of TAMs through controlling secretion and paracrine signaling of CXCL12 to inhibit colorectal cancer growth and metastasis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1102 THE EFFICACY OF NEXT-GENERATION OF IMAGE ENHANCED COLONOSCOPY (BLUE LASER IMAGING) IN THE DETECTION OF COLONIC LESIONS: A PILOT STUDY

Introduction: Narrow Band Imaging (NBI) enable detection for vascular-rich small, flat lesion and recognition of mucosal surface compared with normal colorectal mucosa and vascular pattern in colonoscopy. However, recent studies reported no significant difference in overall adenoma detection rate with the use of NBI compared with white light imaging (WLI). Blue Laser Imaging (BLI) is next-generation of image enhanced endoscopy technique using LASER light source that were realized with lighting and image processing suitable for visualization of microvessels and structures in the superficial portion of the mucous membrane.

Aims & Methods: Our aim was to determine whether the use of BLI enhances the adenoma detection rate (ADR) and miss rate compared with WLI. A total of 130 patients who underwent screening or surveillance colonoscopy in Saga University Hospital were included. Three patients were excluded because of poor bowel preparation. One hundred and twenty-seven patients were randomized to tandem colonoscopy with BLI followed by WLI (BLI-WL group) or WL followed by BLI (WL-BLI group). Polyp (adenoma) detection rates, miss rates, and the number of polyps (adenoma) detected per person (mean adenoma detection rate) were examined between the two groups.

Results: The BLI-WL group and WL-BLI group comprised 64 and 63 patients, respectively. The proportion of patients with polyps (adenoma) was 62.5% in BLI-WL group compared with 63.5% in WL-WL group. There was no significant difference between two groups regarding ADR. The number of adenomas detected per person (ADR) of BLI-WL group and WL-WL group was 2.84 and 2.90, respectively. However, the polyp miss rate of BLI-WL group was less than that of WL-WL group (1.6% vs 10.0%, P = 0.0014). Conclusion: There were no significant difference in the overall polyp (adenoma) detection rate with BLI-WL group or WL-WL group. However, miss rate was higher in WL-WL group compared with BLI-WL group (10.0% vs 1.6%, P = 0.0014). Further, BLI detected more polyps per patient compared with WL group (2.84 vs 1.90). BLI may improve polyp miss rate and the number of polyps per subject (mean adenoma detection rate) in the colonoscopy.

Introduction: The National Health Service Bowel Cancer Screening Programme (NHS BCSP) offers colonoscopy to people testing positive for Faecal Occult Blood Test (FOBT) after the age of 60. In addition, the ‘Bowel scope screening’ test offers once-only flexible sigmoidoscopy (FS) to people in the UK after the age of 55. The Norwegian (NORCAP) and Italian (SCORE) trials evaluated the effectiveness of FS screening and reported a non-statistically significant decrease in colorectal cancer (CRC) specific mortality at follow-up. It is unclear if significant proximal neoplasia is being missed in people undergoing flexible sigmoidoscopy alone.

Aims & Methods: We aim to investigate the distributions of pathology within the BCSP at a busy district general hospital in London. In 2015, 22,539 FOBT kits were returned out of the 43,884 (51.4%) sent out in the boroughs of Barking, Havering and Redbridge (BHR). Of those returned, 398 (1.8%) tested positive. We collected data for the 326 patients who attended for colonoscopy at BHR University Hospitals (81.9%). Subgroup analyses included age, sex, history, location of polyps, number of polyps, polyp size and therapies.

Results: Mean age 67, Male 60.4%. Polyps were found in 199 patients (61%), 48 polyps found in total, mean number of polyps 2.5 (Range 1–14), mean size 7 mm (Range 1 mm–60 mm), 49 (15%) hyperplastic, 156 (47.9%) adenomas and 16 (4.9%) adenocarcinoma. Patients with adenoma/carcinoma were older (67.6 vs. 66.5, P = 0.02) but there was no difference in sex (Male 61.4% vs. 59.4%, P = 0.49) when compared to those without adenoma/carcinoma. Of 172 patients with adenoma/carcinoma, 111 (64.5%) were proximal to the splenic flexure (SF). 5 out of 16 (31.2%) adenocarcinomas were proximal to SF and 2 (40%) of these patients had no polyps distal to the SF.

Adenoma/Carcinoma according to location in colon

<table>
<thead>
<tr>
<th>Adenoma/ Carcinoma</th>
<th>SF + Distal (n=61)</th>
<th>Proximal to SF (n=111)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Age</td>
<td>67.4</td>
<td>67.7</td>
</tr>
<tr>
<td>Male</td>
<td>41 (67.2%)</td>
<td>67 (60.4%)</td>
</tr>
<tr>
<td>Number of polyps</td>
<td>1.7</td>
<td>3</td>
</tr>
<tr>
<td>Size of polyps</td>
<td>8.6</td>
<td>6.0</td>
</tr>
<tr>
<td>Carcinoma</td>
<td>11</td>
<td>5</td>
</tr>
</tbody>
</table>

Conclusion: Patients with adenomas/carcinomas are older and those with proximal adenomas/carcinomas have more polyps but are smaller in size. One in three adenocarcinomas picked up during colonoscopy would be out of reach of a flexible sigmoidoscopy. Furthermore, over one third of the proximal cancers did not have distal polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Colorectal cancers have two development theories. One of the development theories is "adenoma-adenocarcinoma sequence" developing from protruded-types "polypes" we know generally. The other is considered to emerge directly from normal epithelium, not through the adenomatous stage. Recently, it is revealed most of this type are depressive-type carcinomas. This theory is called "de novo" pathway. We studied clinicopathological characteristics and long-term prognosis mainly on depressive-type colorectal carcinomas. And clarified the pathologic characteristics of depressive-type colorectal carcinomas compared with flat- and protruded-type. A total of 2930 colorectal neoplasms excluding advanced carcinomas were resected endoscopically or surgically in our Center from April 2001 to December 2016. Of these, 112 tumors were depressive-type. Aims & Methods: Among these 10 cases, 5 cases were developed from depressive-type lesions and one showed a para-aortic lymph node metastasis and four showed a lung metastasis. The rate of lymph node metastasis in all the depressive-type lesions was 72.4% in depressive-type, 3.2% in flat-type and 2.9% in protruded-type. Within less than 5 mm in diameter, that was 10.6%, 0% and 0% respectively. Among T1 carcinomas, the rate of vessel invasion was 64.3% in depressive-type, 34.3% in flat-type and 38.4% in protruded-type. Most of poorly differentiated or mucinous adenocarcinomas were 17.2%, 10.4% and 13.5%, that of massively submucosal invasion was 94.7%, 71.7% and 69.7%, and that of tumor budding was 36.5%, 16.1% and 17.3%, respectively. The rates of these pathological factors were significantly higher in depressive-type lesions. On the other hand, the rate of adenomatous component was 4.9%, 52.2% and 50.8% respectively. It was significantly lower in depressive-type lesions, suggesting that they emerge directly from normal epithelium without going through the adenoma stage. The rate of lymph node metastasis was 11.6%, 0.8% and 3.0% respectively. And 2 depressive-type lesions had synchronous liver metastasis. Conclusion: Depressive-type colorectal carcinomas invade massively even when they are small. They had higher risks of vascular invasion, poorly differentiated or mucinous adenocarcinoma, massive invasion and tumor budding than flat- or protruded-types. For their rapid growth and malignant potential, whether the lesion is depressive-type or not is very important in the diagnosis of colorectal carcinomas.

Disclosure of Interest: All authors have declared no conflicts of interest.

Result: The rate of distant metastasis or recurrence was 0% (9/10127). Among these 10 cases, 5 cases were developed from depressive-type lesions and one showed a para-aortic lymph node metastasis and four showed a lung metastasis. The rate of lymph node metastasis in all the depressive-type lesions was 72.4% in depressive-type, 3.2% in flat-type and 2.9% in protruded-type. Within less than 5 mm in diameter, that was 10.6%, 0% and 0% respectively. Among T1 carcinomas, the rate of vessel invasion was 64.3% in depressive-type, 34.3% in flat-type and 38.4% in protruded-type. Most of poorly differentiated or mucinous adenocarcinomas were 17.2%, 10.4% and 13.5%, that of massively submucosal invasion was 94.7%, 71.7% and 69.7%, and that of tumor budding was 36.5%, 16.1% and 17.3%, respectively. The rates of these pathological factors were significantly higher in depressive-type lesions. On the other hand, the rate of adenomatous component was 4.9%, 52.2% and 50.8% respectively. It was significantly lower in depressive-type lesions, suggesting that they emerge directly from normal epithelium without going through the adenoma stage. The rate of lymph node metastasis was 11.6%, 0.8% and 3.0% respectively. And 2 depressive-type lesions had synchronous liver metastasis. Conclusion: Depressive-type colorectal carcinomas invade massively even when they are small. They had higher risks of vascular invasion, poorly differentiated or mucinous adenocarcinoma, massive invasion and tumor budding than flat- or protruded-types. For their rapid growth and malignant potential, whether the lesion is depressive-type or not is very important in the diagnosis of colorectal carcinomas.

Conclusion: Our results demonstrate that degree of ITH of KRAS/TP53 mutations increases during the progression of colorectal tumor. Intratumoral genetic variations in the microcapsule structure may represent molecular subclones in early colorectal lesions and may be predictive of the malignant progression.

Introduction: Hypoxia signalling has been found to enhance mechanical cell survival, chemoresistance, motility, tumour angiogenesis as well as self-renewal capacity and proliferation of putative cancer stem cells. One of the key player in hypoxia is carbonic anhydrase IX (CAIX) which is a hypoxia-inducible enzyme. CAIX is overexpressed in a variety of cancers including colon cancer and plays a crucial role in maintaining favourable intracellular pH in hypoxia. There is also evidence that extracellular vesicle (EV) production is increased in response to hypoxia and promotes adaptive response of cancer cells and we have previously demonstrated, that CAIX positive EVs secretion is increased in response to hypoxia in colorectal cancer cell line.

Aims & Methods: Within this study, we explored a possibility to use CAIX for the isolation of hypoxic EVs from colorectal cancer (CRC) patients’ plasma. EVs were isolated from plasma samples of 27 CRC patients and 25 healthy donors (HD) by using sequential centrifugation, filtration and size-exclusion chromatography steps. EVs where quantified by Nanoparticle tracking analysis (NTA) and CAIX positive EVs where determined by ApoeeA50.

Results: Statistically significant increase in the amount and size of EVs was seen in CRC plasma samples. Median CAIX positive EVs secretion was significantly higher in CRC patients than in HD. In addition, it is higher in patients with metastasis than without distant metastases.

Conclusion: There is an increased total EV number, EV size and CAIX positive EV amount in CRC patient plasma compared to HD plasma, that might have diagnostic and prognostic value. (Financed by Latvian Council of Science and collaboration Project No: 19-05-01011).

Introduction: Colorectal cancer (CRC) is an important contributor to cancer mortality and morbidity worldwide. 80% of CRCS arise via the adenoma-carcinoma sequence, 10–20% CRCS by sessile serrated adenomas (SSA). Hyperplastic polyps are regarded harmless. Current surveillance strategies for CRC following polypectomy are determined by endoscopic and histopathological factors. Such a distinction has also been challenged.

Aims & Methods: The study was aimed for molecular characterization of colonic polyps in patients who underwent screening colonoscopy. Correlation of the genetic analysis with endoscopic, clinical and histopathological data was attempted to potentially better define relevant risk marker or sub-groups at risk for prediction of surveillance intervals. 100 Patients were enrolled in this multicenter study (NCT02595645; Median age: 62.9 y, 50 males, 50 female). Up to 100 representative biopsy specimens were collected and stored in a formalin-free medium and finally embedded in paraffin-blocks, followed by histopathological assessment. Targeted Next Generation Sequencing (tNGS) was performed from isolated exons (38 colorectal cancer-related genes; GeneRead DNAseq Targeted Panels V2, Qagen® on a MiSeq platform (illumina®). Genetic and histopathological analysis was done blinded to the endoscopic and clinical data.

Results: In 100 patients, 234 polyps were removed. 121 polyps (54.0%) are sized <10 mm, 71 (31.7%) were ≥10 mm. For 32 polyps (14.3%) no size was available. 90 polyps (40.2%) were located in the left, 126 polyps (56.3%) in the right colon, for 8 polyps (3.6%) no location was noted. 112 polyps (50.0%) were adenomata and 110 polyps (49.1%) non-adenomatous lesions. No data were available.
P1108 QUANTITY, FRAGMENT LENGTH AND GLOBAL DNA METHYLATION LEVEL ALTERATIONS OF CIRCULATING CELL-FREE DNA IN COLORECTAL ADENOMA, CANCER AND INFLAMMATORY BOWEL DISEASES

1 2nd Department Of Internal Medicine, Semmelweis University, Budapest/Hungary
2 Hungarian Academy of Sciences, Budapest/Hungary
3 Contact E-mail Address: ezter1991@gmail.com

Introduction: Cell-free DNA (cfDNA) is circulating in human plasma and its amount is different in certain physical conditions. It is well known, that in healthy people the quantity of cfDNA is very low, but it rises in chronic disorders such as cancer. At the same time, very high cfDNA level can be measured in healthy people during physical exercise.

Aims & Methods: We aimed to analyze cfDNA changes (quantity, fragment length, global DNA methylolation level) in physiological conditions (during physical exercise) and in neoplastic and inflammatory coloectal diseases.

Results: Plasma was separated from 64 patients (16 colorectal carcinomas (CRC), 13 colonic adenomas (AD), 19 inflammatory bowel disease (IBD), and 16 normal (N) donors without evidence of disease). Plasma samples were also collected from 6 healthy athletes before, during and after physical training. DNA was isolated with High Pure Viral Large Volume NA isolation kit (Roche). cfDNA was quantified with Qubit fluorometry (Invitrogen). CDNA fragment length distribution was assessed by Bioanalyzer 2100 using High Sensitivity DNA assay (Agilent). Global DNA hypermethylation was estimated by base cut profiling (Enzyme I)-qPCR.

Discussion: High cfDNA amounts was observed in plasma samples of patients with colonic adenoma (20.6± 1.70 ng/ml), colorectal cancer (24.1± 20.02 ng/ml) and IBD (22.27±14.60 ng/ml) compared to healthy subjects (10.33±3.22 ng/ml). Highly elevated cfDNA amounts were found in plasma samples of athletes during physical exercise (66.17±29.00 ng/ml), while the cfDNA amount decreased after physical activity (51.87±39.80 ng/ml). Characteristic cfDNA fragment length distribution pattern (with different peak heights at 180 bp, 360 bp, 550 bp) was observed in each patient group. Global DNA hypomethylation was shown in CRC plasma samples with advanced tumor stage (N: 79%, 79%, advanced CRC: 72.3%, 89.4% and 80.9% in the plasma fraction of patients with CRC and 89.2%, 83.8%, 81.1% and 70.3% of adenoma patients, respectively). In multiple logistic regression analysis, the four markers together with sex and smoking showed distinct CRC patients from healthy individuals with 91.5% sensitivity and 97.3% specificity (AUC = 0.978) and could differentiate adenoma samples from healthy controls with 89.2% sensitivity and 86.5% specificity (AUC = 0.937). In silico analyses confirmed our results on the altered methylolation of the four markers in colorectal adenocarcinoma.

Conclusion: Our findings suggest that SFRP1, SFRP2, SDC2 and PRIMA1 can be used as epigenetic biomarker candidates for colorectal adenoma and cancer diagnose with high sensitivity and specificity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Metabolome, a dynamic portrait of the metabolic status of living systems, has demonstrated its great potential for use in the diagnosis of various cancers by applying advanced analytic techniques and bioinformatics tools. Recently, very few metabolomic markers in CRC have been consistently discovered, but metabolic profiles of patients with CRC including advanced colorectal cancer remain poorly understood and warrants investigation due to its non-invasive sampling method. In the last decade, several metabolomic approaches have been applied toward identifying metabolic alterations in CRC using variety of sample types including urine, tissue, serum, and feces. However, there are only few urinary metabolomic studies and especially nuclear magnetic resonance (NMR) spectroscopy, which has several advantages including relative high degree of reproducibility, easy-to-identify metabolites, high throughput, and non-destructive sample treatment, has not been applied to urine samples.

Aims & Methods: In this study, we investigate the differences in urine metabolic profiles of patients with colorectal neoplasia (CRN) including CRC and precancerous lesion, and healthy volunteers using a NMR-based urine metabolic study. In addition, we evaluate applicability as diagnostic tool of urine metabo-lomics for early detection of precancerous colorectal lesion with high sensitivity and specificity. Urine metabolomic profiles from patients with colorectal neoplasia including CRC and healthy controls (n = 156) were analyzed by NMR spectroscopy. Healthy and CRN groups were statistically discriminated using orthogonal projections to latent structure discriminant analysis (OPLS-DA). The class prediction model was validated by three-fold cross-validation. The advanced adenoma and stage 0 CRC were grouped as pre-invasive CRN.

Results: After patients underwent endoscopic resection or surgical resection for CRN, advanced adenoma has been diagnosed in 36 patients, stage O CRC in 24 patients, stage I CRC in 8 patients, stage II CRC in 7 patients, stage III CRC in 13 patients and stage IV CRC in 4 patients. CEA and CA 19-9 levels for patient with stage I to IV CRC and healthy control were also assessed. Among patients with stage I to IV CRC, CEA and CA 19-9 were increased in 19.4% and 9.0% of patients, respectively. The sensitivity and specificity of CEA and CA 19-9 were 6.2% and 99.3%, respectively. The OPLS-DA score plot showed statistically significant discrimination pre-invasive CRN as well as advanced CRC and normal with a Q2 value 0.978. As the prediction validation study, the sensitivity and specificity for diagnosing pre-invasive CRN was 96.2% and 95%, respectively. The grades predicted by the PLS-DA model showed that area under the curve was 0.823 for taurine, 0.783 for alanine and 0.842 for 3-aminoisobutyrate. In multiple receiver operating characteristics curve analyses, taurine, alanine, and 3-amino-sobutyrate were good discriminator for CRC patients.

Conclusion: NMR-based urine metabolic profiles significantly and accurately discriminate between patients with pre-invasive CRN as well as...
advanced CRC, and healthy control with high accuracy. It demonstrates an applicability of urinary NRT metabolomics as screening tool for accurate diagnosis of pre-invasive CRN.

Introduction: Symptoms alone are poor predictors of underlying colon pathology. Only 14% of patients referred for colonoscopy from primary care have significant bowel disease (SBD), colorectal cancer (CRC), high risk adenoma (HRA, defined as ≥3 or any ≥1 cm) and inflammatory bowel disease (IBD). We have reported that undetectable faecal haemoglobin (f-Hb), measured by a faecal immunochromatographic test (FIT) is a good rule-out test for SBD.2,3 Since December 2015, GPs in Tayside have been encouraged to use FIT test as an adjunct to history, examination and mandatory blood tests in patients referred with bowel symptoms. Referrals are vetted by a Consultant and triaged to test or clinic. We have examined the impact of the introduction of the FIT test on referral rates and colonoscopy yield.

Aims & Methods: Patients in primary care with new bowel symptoms were encouraged to complete a FIT in addition to blood count and renal function check. We prospectively recorded FIT tests received, referrals to secondary care and colonoscopy findings over 1 year from December 2015 to December 2016. FIT tests were analysed by HMJACKarc (Kyowa Medex Co. Ltd., Japan) with encouragement to complete a FIT in addition to blood count and renal function test.

Results: 5,655 FIT tests were received. 76.2% had undetectable f-Hb, and 152 (2.7%) were untiable. 4,108 patients were referred of whom 2,238 (55%) returned a FIT. In 1,378 patients with a FIT result vetted to colonoscopy, 284 had SBD (20.6%); 86 CRC, 124 HRA and 74 IBD. 44% of patients scoped had undetectable f-Hb in whom prevalence of SBD was 6.6%. Only 13% of those referred; 77 CRC patients had co-existing iron deficiency anaemia, 14/25 HRA and 3/6 IBD had anaemia or diarrhoea. 32.2% of those with f-Hb >10 µg Hb/g faeces had SBD rising to 54.9% in those with f-Hb >400 µg Hb/g faeces. 2,677 patients completed a FIT but were not referred, in whom 100 (4%) had undetectable f-Hb. Referrals to secondary care were 14% down on the previous year.

Conclusion: A FIT test is an essential adjunct to the history, examination and blood tests in the assessment of bowel symptoms. Undetectable f-Hb is reassuring Primary Care that SBD is unlikely and referrals to secondary care have reduced. At colonoscopy, yield of SBD has increased and is high in those with detectable f-Hb. Excluding patients with co-existing anaemia or diarrhoea, an undetectable f-Hb is a good rule-out test and will miss only 5% of all SBD. Furthermore, f-Hb concentration could aid triage irrespective of symptoms.

Introduction: The immunological screening test (FIT) for colorectal cancer (CCR) was introduced in January 2015 in Ile de France (15 million inhabitants) after Hemocult was abandoned due to its low sensitivity. The Hemocult (HC) launched in 2007 had reached less than 30% participation rate.

Aims & Methods: We report one-year on FIT in CCR screening in Ile de France and compare results to those with HC test for speculating on adjustment actions. The raw data were extracted by request from the registry of the screening structure (in various areas 75, 77, 78, 91, 92, 94 and 95) covering a target population of 3026366 inhabitants. Rates of participation were calculated, and after one-year experience period, profiles of individual with positive tests, rates of those with normal colonoscopy, with polyps (all stages combined) and with high grade dysplasia (HGD) were described. Results were compared to those with HC from the launch to the end of the last campaign (Dec 2014) normalized for mean one-year output. The comparisons were made by an X2 test (qualitative variable) and multivariate stepwise analysis was performed to identify predicting factors for cancer diagnosis.

Results: At the end of the HC-based screening campaigns 2014, 2.5 million individuals were annually invited and the participation rates since 2009, ranged from 28.9% (2009) to 24.6%, with females showing higher rates for participation (30.9%) than (25.6%) to 26.1% (men). 52% of all FIT results were positive. More than 100,000 Colonoscopies and a higher positive predictive value for cancer leads to more interventions because to its simplicity and a wider distribution. The lower rate of normal colonoscopy, with polyps (all stages combined) and with cancer (advanced CRC, and healthy control with high accuracy. It demonstrates an applicability of urinary NRT metabolomics as screening tool for accurate diagnosis of pre-invasive CRN.

Disclosure of Interest: All authors have declared no conflicts of interest.

References
accuracy and calculated compared with American, European and Japanese guidelines (1–5).

Results: Sensitivity was 100% (95% CI, 56%–100%) in all models. Specificity and accuracy of the AI model, American, European and Japanese guidelines were 68% (58%–78%) vs. 45% (35%–56%) vs. 12% (6%–21%) vs. 8% (3%–13%); and 71% (61%–86%) vs. 50% (40%–60%) vs. 20% (13%–29%) vs. 16% (9%–25%), respectively. The rate of unnecessary surgeries of the AI model was calculated as 29% in comparison with American 50% (P = 0.004, odds ratio [OR] 2), European 80% (P = 0.001, OR 10), and Japanese 84% (P = 0.001, OR 13). Consequently reducing unnecessary surgeries compared with current guidelines while providing high sensitivity. AI will help in making decisions as to whether additional surgery is indicated after endoscopic resection of T1 CRCs. Introduction: Regular surveillance colonoscopy after colon cancer resection is recommended to detect metachronous adenoma and cancer. However, risk factors of advanced metachronous neoplasm during postoperative surveillance have not been fully evaluated yet.

Aims & Methods: This study aimed to assess the risk of advanced metachronous neoplasm during surveillance colonoscopy in patients who underwent curative colon cancer resection. The patients who underwent curative colon resection for non-metastatic colon cancer between January 2002 and December 2012 in a single tertiary center were retrospectively reviewed.

Results: A total of 278 patients were enrolled in this study. Surveillance colonoscopy was performed after peroperative clearing colonoscopy. Among the patients, 182 (61.6%) were male, and the median age was 65 years. On peroperative clearing colonoscopy, accompanying high-risk adenomas (≥3, size ≥10 mm, with high-grade dysplasia and villous histology) were detected in 95 patients (31.9%) and were significantly associated with old age (≥65 years), male sex, alcohol use, smoking, and stage 3 colon cancer (P < 0.05). During the postoperative follow-up periods (median, 5.35 years), advanced metachronous neoplasm was found in 45 patients (15.1%) during surveillance colonoscopy, including colon cancer in 4 patients (1.3%). In the multivariate analysis, distal colon cancer (distal to splenic flexure; odds ratio [OR] = 4.463; P = 0.002), accompanying high-risk adenomas on peroperative clearing colonoscopy (OR = 3.414; P = 0.001), and hypertension (OR = 2.344; P = 0.026) were significant risk factors of advanced metachronous neoplasm during surveillance colonoscopy.

Conclusion: Patients who had distal colon cancer, accompanying high-risk adenoma on peroperative clearing colonoscopy, and hypertension may need a shorter colonoscopic surveillance interval. A more tailored surveillance strategy is needed to improve overall outcome in patients who undergo curative colon cancer resection.

P1115 PROSPECTIVE COMPARISON OF THE NOVEL FULL SPECTRUM ENDOSCOPY (FUSE) AND ADVANCED HIGHER DEFINITION-WHITE LIGHT ENDOSCOPY FOR DETECTION OF POLYPS IN ROUTINE PRACTICE

A. Martinez-Alcalá García1, F. J. Martínez-Alcalá1, C. Martínez-Alcalá1, K. Thakar2, R. Maroto2, K. Mönkenmüller2, F. Martínez Alcalá2
1Centro de Innovaciones Digestivas Martínez Alcalá, Seville/Spain; 2Biostadistica, Complejo Hospitalario La Paz, Madrid/Spain

Introduction: Despite major advances in white light endoscopy detection of colon polyps remains challenging with significant polyp miss rates. The novel second generation full spectrum endoscopy (FUSE) is a new scope with two additional cameras in the sides that provides a panoramic 360° field of view.

Aims & Methods: The aim of this study is to identify the role of the FUSE in improving polyp detection. This was a single-center, prospective, randomized, open label study in patients that presented for routine colonoscopy at an outpatient unit during a six months period. Patients were randomized to either FUSE (FUSE colonoscopy CDVL slim c38) or standard frontal view (SFV) colonoscopy (Olympus Evis Exera III 190). The primary outcomes were polyp detection rates (PDR), diverticular detection rate (DDR) and complete colonoscopy. Secondary outcomes were procedure time, adverse event rates, size and characteristics of the polyps and success of endoscopic treatment (R0 resection). All procedures were performed by experienced endoscopists, who had carried out > 5000 colonoscopies and had each polypation rates of > 95%.

Results: A total of 197 patients (49.2% female, 50.8% male, median age 60 years, range ±16 years) were studied. No significant difference was seen between the 2 groups on the primary endpoints of polyps detection rate (PDR), diverticular detection rate (DDR) or complete colonoscopy (table 1). About secondary endpoints: R0 endoscopic resection was achieved in 95% in both groups (P = 0.68). The median procedure time in minutes was higher with SFV (36.7 ± 13.1 min) than FUSE (21.5 ± 10.7 min; P = 0.68; 95% confidence interval 0.38). The rate of unnecessary surgeries of the AI model was calculated as 1–2% (P = 0.008). There were no significant differences regarding adverse events, determination of colon cleanliness, or others epidemiologic factors. 2 case were excluded from the statistical analysis due to surveillance of polyposis syndrome, to avoid skewing of results.

Conclusion: In expert hands, PDR and DDR exceed 50% with advanced white light and FUSE systems. FUSE was not superior to advanced white light endoscopy for the PDR and DDR. However, with FUSE we can reduce procedure duration without any additional adverse events or increased discord rate. These data further demonstrate the safety and feasibility of the new FUSE system.

3.65% were superficial mucosal carcinomas (<1000 μm). During UEMR, two cases (both using AUTOCUT mode) of spurting bleeding were observed (4.45%). Hemostasis was easily achieved in both cases by clamping. No patient required blood transfusion. One patient had abdominal pain on the day after resection without signs of pneumoperitoneum on CT scan. There was no perforation or delayed bleeding. In any of the cases, PAEM was able to be performed en bloc. However, lesions accompanying severe fibrosis in the submucosal layer and exhibiting the muscle retraction (MR) sign are often difficult to be resected completely. We devised a new method called “Per Anal Endoscopic Myectomy” for any lesions involving severe fibrosis, in which dissection is done between the inner circular and outer longitudinal muscles instead of between submucosal layer and muscle layer. Aims & Methods: The aim of this study is to examine the usefulness and safety of PAEM in colorectal cases that were performed in our hospital and an affiliated hospital were retrospectively reviewed. When fibrosis in the submucosal layer was suspected, pocket creation method was applied and if severe fibrosis with MR sign was found, PAEM was selected. In PAEM procedure, after dissecting circumferentially around the fibrotic area with a double tunneling method, the inner circular muscle is cut in a circular manner, which makes the outer longitudinal muscle clearly visible. The space between the inner circular and outer longitudinal muscles is sparse and suitable traction with the tunneling method makes it easier to dissect this space. PAEM was performed only for rectal lesions, and no clip closure was carried out after the procedure in most cases.

Results: Ten rectal lesions were treated with PAEM between July 2015 and March 2017. Among them, 7 cases including 2 cases with mucosal cancer, 1 case with early cancer, and 4 cases with advanced cancer were resected en bloc with negative margin. The other 3 cases showed tumor invasion to the muscle layer and the vertical margin was positive. The clinical course after PAEM was preferable in all cases. Three cases which achieved resection with negative margin but found lymphovascular invasion of the tumor underwent additional surgical intervention or adjuvant chemotherapy. In surgical cases, they could permit anus-preservation. Conclusion: PAEM for lesions exhibiting MR sign with severe fibrosis will enable en bloc resection with accurate pathological diagnosis. No complications were recorded in our experiences. Further investigation into the significance of PAEM would be needed.

P1117 ADENOMA DETECTION RATE INFLUENCES RISK PREDICTION OF METACHRONOUS ADVANCED COLORECTAL NEOPLASIA IN LOW-RISK PATIENTS
S.H. Kim, S.J. Lee, T.J. Kim, E.R. Kim, S.N. Hong, D.K. Chang, Y. Kim Gastroenterology, Samsung Medical Center, Seoul/Korea, Republic of

Introduction: Current guidelines recommend surveillance colonscopy after 10 years or surveillance in 5–10 years in individuals with no or 1–2 non-advanced adenomas. Aims & Methods: We hypothesized that risk of metachronous advanced colorectal neoplasia would vary based on clinical characteristics and colonoscopy quality. We identified 7,171 participants with no or non-advanced adenomas at first-time screening colonscopy. The risk of metachronous AN at surveillance colonoscopy 3–5 years later was investigated according to clinical characteristics and endoscopist adenoma detection rate (ADR). Results: In multivariate analyses, strong associations between increasing age, male sex, current smoking, family history of colorectal cancer, follow-up interval, increasing number of adenoma, and low ADR and risk of any metachronous colorectal neoplasia were observed. For metachronous AN, increasing age, male sex, increasing number of adenoma, and low ADR were independent risk factors. Among patients with 1–2 small adenomas, women with age ≥60 years or men comprised a high-risk group, which had 5.3% risk of metachronous AN at surveillance. Women <60 years old with 1–2 low-risk adenomas had very low risk (1.2%) of metachronous AN as individuals with no adenoma. Furthermore, incidence of metachronous AN was significantly higher in individuals who were considered to have low ADR compared to those without surveillance colonoscopy (1.5% vs. 0.5%, respectively; P = 0.001). Conclusion: According to patient and adenoma characteristics, and ADR of the endoscopist, the risk of metachronous AN varies among low-risk patients. In recommending surveillance colonoscopy, these factors should be taken into consideration.

Introduction: The technique of endoscopic submucosal dissection has recently been improved, and large and completed lesions such as those invading ileocecal valve and appendix orifice can be resected en bloc. However, lesions accompanying severe fibrosis in the submucosal layer and exhibiting the muscle retraction (MR) sign are often difficult to be resected completely. We devised a new method called ‘Per Anal Endoscopic Myectomy’ for any small lesions involving severe fibrosis, in which dissection is done between the inner circular and outer longitudinal muscles instead of between submucosal layer and muscle layer.

Aims & Methods: The aim of this study is to examine the usefulness and safety of PAEM in colorectal cases that were performed in our hospital and an affiliated hospital were retrospectively reviewed. When fibrosis in the submucosal layer was suspected, pocket creation method was applied and if severe fibrosis with MR sign was found, PAEM was selected. In PAEM procedure, after dissecting circumferentially around the fibrotic area with a double tunneling method, the inner circular muscle is cut in a circular manner, which makes the outer longitudinal muscle clearly visible. The space between the inner circular and outer longitudinal muscles is sparse and suitable traction with the tunneling method makes it easier to dissect this space. PAEM was performed only for rectal lesions, and no clip closure was carried out after the procedure in most cases.

Results: Ten rectal lesions were treated with PAEM between July 2015 and March 2017. Among them, 7 cases including 2 cases with mucosal cancer, 1 case with early cancer, and 4 cases with advanced cancer were resected en bloc with negative margin. The other 3 cases showed tumor invasion to the muscle layer and the vertical margin was positive. The clinical course after PAEM was preferable in all cases. Three cases which achieved resection with negative margin but found lymphovascular invasion of the tumor underwent additional surgical intervention or adjuvant chemoradiation. In surgical cases, they could permit anus-preservation.

Conclusion: PAEM for lesions exhibiting MR sign with severe fibrosis will enable en bloc resection with accurate pathological diagnosis. No complications were recorded in our experiences. Further investigation into the significance of PAEM would be needed.

P1119 LOCAL RECURRENT AFTER ENDOSCOPIC MUCOSAL RESECTION FOR HIGH-RISK LESIONS: MAY WE BETTER PLAN THE ENDOSCOPIC FOLLOW-UP ACCORDING TO PROCEDURAL MORPHOLOGICAL AND HISTOLOGICAL CHARACTERISTICS?
C. Quondamcarlo, C. Lucidi, R. Lupenta
Gastroenterology, Regina Elena Cancer Institute, Rome/Italy

Contact E-mail Address: qcunzia@yahoo.it

Introduction: Endoscopic mucosal resection (EMR) is an increasingly used technique for the removal of large sessile and flat-laterally-spreading colorectal lesions. At present, surveillance colonscopies are ever performed to ensure detection and adequate treatment of residual or recurrent adenoma (RRA), which, occurring in 10–40% of non-pedunculated lesions, currently represents the main limitation of this technique. Fortunately, endoscopic detection of RRA in the post EMR scar is currently highly accurate using HD-WL (high definition-white light) and NBI (narrow band imaging). Anyway, indications for follow-up
Local recurrence after endoscopic mucosal resection of nonpedunculated color-morphological pattern and presence of in situ carcinoma. Moreover, RRA seems to be higher in pT1, lesions of location were sigmoidal colon (40%), ascending colon (25%) and cecum (12%). According to the morphological characteristics, 60% of lesions were sessile, 35% were pedunculated, grading medium, microinvasion, margins, submucosal extension for all pT1 removed “en bloc”. Results: 50 patients were included (mean age 63 ± 12 years, 54% females). The mean size of lesions was 21 mm (range 10–50 mm), 40% were sessile, 35% granular LST and the remaining 25% non-granular LST, the most frequent sites of location were sigmoidal colonic (40%), ascending colon (25%) and cecum (12%). According to the morphological characteristics, 60% of lesions were removed “en bloc” and 40% “piecemeal”. No sténoses were used as prophylaxis in 35% of patients and only in 1 for intraprocedural bleeding. No post-procedural bleeding or perforation occurred. APC has never been used. During the endoscopic follow-up a suspect early (3-months) RRA was documented and immediately treated in 16% and histologically confirmed only in 8%. At 6-month controls a RRA was again detected only in 2 of these patients. New cases of RRA were not found both at 6 and 12 month controls. Only 1 case of RRA was documented for lesions treated “en bloc” but this was the only one histologically suggesting an incomplete endoscopic resection. Conclusion: EMR results a technique safe and effective particularly for lesions removable “en bloc”; in this case in fact the rate of RRA seems to be low and easily histologically predictable. Although factors related to RRA in “piecemeal” EMR are still unknown, more attention would be required in relation to determined morphological pattern and presence of in situ carcinoma. Moreover, RRA seems to be ever early suggesting a close follow up only in the first period.

P1120 TREATMENT STRATEGY FOR LOCAL RECURRENCES AFTER ENDOSCOPIC RESECTION OF COLORECTAL NEOPLASMS
Division Of Endoscopy, Shizuoka Cancer Center, Shizuoka/Japan
Contact E-mail Address: saito@scchr.jp
Introduction: Local recurrences after endoscopic resection (ER) frequently occur after endoscopic treatment. Recently, the efficacy of submucosal dissection (ESD) for local recurrences has been reported. However, an appropriate treatment strategy for these lesions including ESD remains unclear.

Aims & Methods: This study aimed to clarify the appropriate treatment strategy for local recurrences after ER. A total of 81 patients (81 lesions) who received treatment for local recurrences after ER for colorectal neoplasms between January 2010 and December 2016 were enrolled. Patients with pathological diagnosis of hyperplastic polypl, sessile serrated adenoma/poly, and submucosal invasive cancer in their first ER were excluded. Seven patients who underwent surgery because of submucosal invasion or technically difficult locations were also excluded. Procedural outcomes, recurrence rate and disease control rate (DCR) were evaluated according to preoperative endoscopic diagnosis of recurrent lesions (adenomatous or carcinomas). The DCR was defined as proportion of patients who were diagnosed with curative resection after ER or received additional surgery based on pathological diagnosis after ER.

Results: Seventy one patients were included allowing an appropriate analysis. Forty-nine patients diagnosed with adenomatous recurrences were treated by cold polypectomy in 15, by endoscopic mucosal resection (EMR) in 26, and by ESD in 8 patients. Cold polypectomy was applied only to diminutive (<5 mm) lesions and was not used as primary treatment. The en bloc resection rates of EMR and ESD were 53.8% and 88%, respectively (P = 0.030). Two cases (7.7%) in the EMR group developed local recurrences, but additional ER achieved curative resection. The DCR of three methods were all 100%. Meanwhile, 23 patients diagnosed with carcinous recurrences were treated by EMR in 7 and by ESD in 18 patients. The en bloc resection rates of EMR and ESD were 28.6% and 83.3%, respectively (P = 0.017). Thirty cases (42.9%) in the EMR group developed local recurrences. One case required surgery because of invasive local recurrence, the second case required chemotherapy because of distant metastasis, and the third case was followed to identify risk factors to provide local treatment. In the ESD group, the DCR in the EMR group was significantly lower than that of in the ESD group (26.4% vs. 83.3%, P = 0.017).

Conclusion: The selection of ER for local adenomatous recurrences could be based on lesion size. On the other hand, ESD is desirable for local carcinous recurrences to achieve complete disease control.

Contact E-mail Address: ohana@pastel.ocn.ne.jp
Introduction: Endoscopic stent placement in acute large-bowel obstruction due to colorectal cancer has been established as a palliative therapy or bridge to surgery with good outcomes in Japan. While, efficacy of chemotherapy after endoscopic colorectal stenting has been less known.

Aims & Methods: The aim of this study was to evaluate efficacy of chemotherapy after endoscopic colorectal stenting comparing with that after surgery. Sixty five patients with colorectal cancer of stage IV presenting obstructive symptom visited our hospital from January 2010 to December 2016. We classified into two groups who had undergone chemotherapy after endoscopic colon stenting (32 patients) and OC group who had undergone chemotherapy after surgery (23 patients). The patient’s background, adverse effects of chemotherapy and prognosis were compared in two groups.

Results: There have not been any significant differences in patient age (65.5 ± 9.3 in SC vs. 61.5 ± 14.1 in OC, p = 0.21), male to female ratio (25:7 in SC vs. 14:9 in OC, p = 0.16) and performance status (0.6 ± 0.7 in SC vs. 0.7 ± 0.8 in OC, p = 0.66). No significant difference was found in SC vs. OC in terms of obstruction severity (p = 0.6), obstruction duration (p = 0.6), and tumor location (p = 0.7). However, chemotherapy after surgery was found to significantly improve the survival of SC (p = 0.004). The median survival time was significantly different between SC (595, n = 29) and OC (459, p = 0.93). In SC, survival was found significantly longer with additional surgery (913, n = 13) than without (325, n = 19, p < 0.01). In OC, survival did not significantly differed between with resection of the primary tumor (666, n = 16) and without (595, n = 7, p = 0.93).

Conclusion: This study has demonstrated that the survival of SC was identical to that of OC, and additional surgery was found to significantly improve the prognosis in SC. Chemotherapy after endoscopic colorectal stenting can be considered tolerable as a palliative therapy or bridge to surgery for obstructive colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1122 A NEW MANEUVER TO PLACE A THROUGH-THE-SCOPE STENT IN A MALIGNANT COLONIC STRicture INACCESSIBLE WITH A STANDARD-CALIBER COLONOSCOPE, ‘OVER-THE-CATHETER’ COLONOSCOPE REPLACEMENT TECHNIQUE
Y. Iwash1, Y. Sumida1, N. Harada1, H. Tsura1, M. Tomonori1, M. Wada1, T. Ooeogawa1, M. Nakamata1, E. Iihara1

2Medicine And Bioregulatory Science, Kyushu University, Fukuoka/Japan
Contact E-mail Address: yoshiiroiboshi@gmail.com
Introduction: A self-expandable metallic stent (SEMS) placement is potentially a cost-saving-sparring option to manage a malignant colonic obstruction (MCO). However, in patients with coexisting peritoneal dissemination (carcinomatous adhesion), for example, insertion of a standard caliber colonscope (SC) is difficult, whereas such an endoscope combined with a large working channel is suitable for through-the-scope (TTS) SEMS placement. Failure in stenting necessitates continuous tube drainage, stoma formation, or other surgical procedures and decreases quality of life (QOL). The purpose of this study was to examine the feasibility and efficacy of “Over-the-Catheter” Colonoscope Replacement technique (OTC-CR) detailed below, in palliative (not preoperative) SEMS placement for MCO. From Oct 2012 to Dec 2016, MCO patients were consecutively considered for decompression by SEMS placement. When a conventional TTS procedure was unsuccessful, specifically, when the MCO site was inaccessible with an SCC, the patient’s background, adverse effects of chemotherapy and prognosis were compared in two groups.

Results: There have not been any significant differences in patient age (65.5 ± 9.3 in SC vs. 61.5 ± 14.1 in OC, p = 0.21), male to female ratio (25:7 in SC vs. 14:9 in OC, p = 0.16) and performance status (0.6 ± 0.7 in SC vs. 0.7 ± 0.8 in OC, p = 0.66). No significant difference was found in SC vs. OC in terms of obstruction severity (p = 0.6), obstruction duration (p = 0.6), and tumor location (p = 0.7). However, chemotherapy after surgery was found to significantly improve the survival of SC (p = 0.004). The median survival time was significantly different between SC (595, n = 29) and OC (459, p = 0.93). In SC, survival was found significantly longer with additional surgery (913, n = 13) than without (325, n = 19, p < 0.01). In OC, survival did not significantly differed between with resection of the primary tumor (666, n = 16) and without (595, n = 7, p = 0.93).

Conclusion: This study has demonstrated that the survival of SC was identical to that of OC, and additional surgery was found to significantly improve the prognosis in SC. Chemotherapy after endoscopic colorectal stenting can be considered tolerable as a palliative therapy or bridge to surgery for obstructive colorectal cancer.

*CROSS, ColoRectal Obstruction Scoring System (Reference 1)

Among 63 palliative MCO cases, initial attempt to place a 22 mm SEMS by TTS procedure was unsuccessful in 6 cases (Table), all of whom had peritoneal dissemination. The reasons for technical failures were; impossible insertion of an SCC to the stricture due to carcinomatous adhesions or narrowing in 5 cases and failure in passing GW through the stenosis due to a limited viewing angle to the stricture in one case. With OTC-PR, approach to the main stenosis with a thinner (alternative) scope, GW traverse, "over-the-catheter" replacement to the SCC, and a 22 mm SEMS placement were successful in all of the 6 cases with adequate clinical improvements (CROSS score change). Notably, ultimate TTS procedures were possible from reinserted SCC distant from the stricture in 3 cases. No adverse events occurred during the procedures.

P1123 RESULT OF THE FIRST ROUND OF THE COLORECTAL CANCER SCREENING PROGRAMME IN THE BALEARIC ISLANDS (SPAIN)

1Gastroenterology, Hospital Comarcal de Inca, Inca/Spain
2Gastroenterology, Hospital Can Misses, Ibiza/Spain
3Gastroenterology, Hospital Mateu Orfila, Mahon/Spain
4Direcció General De Salut Publica I Participació, Consellera de Sanitat, Palma/Spain

Contact E-mail Address: monica.florido@hcn.es

Introduction: Colorectal cancer (CRC) is the most common cause of cancer in western countries. In Balearic Islands 700 new cases per year are diagnosed. The cost-effectiveness of CRC screening programmes are clearly demonstrated in the studies and the important public health problem of CRC justifies the development of control strategies. The aim of this study is to present the results and impact during the first round of the programme in Balearic Islands.

Aims & Methods: The first round includes the period from January 2015 through December 2016. The program has been developed in the areas of Menorca, Ibiza, Formentera and Tramuntana (Mallorca), including 30% of the Balearic Islands population. The target population (people who reside in these areas aged between 50 and 69 years old) was 75,575 individuals. Exclusion criteria. Colonoscopy performed in the previous 5 years, previous diagnosis of CRC, follow-up colonoscopies because colon disease and severe illness-contraindication for the participation. People received the invitation by letter. Quantitative immunochromatographic fecal occult blood testing (i-FOBT; OC-Sensor) was the screening method. The kit was delivered at pharmacies joined the program. The samples were deposited in urns placed in health centres. Participants who tested positive (≥100 ng/ml) were referred to pre-endoscopy evaluation and follow-up colonoscopy. The colonoscopies were performed according to the quality criteria of guidelines.

Results: Overall participation rate (number of people who provide their i-FOBT sample) was 36.5% (n = 21,555). Positive rate of i-FOBT was 7% (1438) and 94.3% of these positive tests underwent a colonoscopy (5.7% of exclusions in pre-endoscopy evaluation). 996 colonoscopies were performed. 47 adenomas with high grade dysplasia, 24 carcinomas in situ and 60 adenocarcinomas were found. Only 19% of these adenocarcinomas were T3 or T4 lesions while the rest presented earlier stages. 26% of colonoscopies were classified as high risk (>5 adenomas or at least one ≥20mm). They have been reported 2 cases of colon perforations, both resolved by endoscopic treatment.

Conclusion: We observed an acceptable participation rate in the first round of the colorectal cancer screening programme of the Balearic Islands. The index of positivity rate of i-FOBT and the results of the endoscopic explorations are according with the observed in other colorectal cancer screening programmes. We can conclude a successful development of the first round of the programme in our area.

Introduction: The prevalence, gender distribution, and clinical presentation of irritable bowel syndrome (IBS) differ between Asian and Western countries. The densities of enteroendocrine cells are abnormal in Western IBS patients. This study aimed at studying large-intestine enteroendocrine, Musashi 1(Msi 1; a marker for both intestinal stem cells and their early progeny), and neurogenin 3 (neuro 3; a marker for early intestinal endocrine cell progenitors) cells in Thai and IBS patients.
Aims & Methods: Thirty Thai IBS patients, and age and sex matched 20 Thai controls were included. Four biopsy samples were taken from each of the sigmoid colon and the rectum during a standard colonoscopy. Sections from these biopsy samples were immunostained for serotonin, peptide YY, oxyntomodulin (enteroglucagon), pancreatic polypeptide, somatostatin, Msi 1, neurog 3. The densities of immunoreactive cells were determined with computerized image analysis (1).

Results: In both the colon and rectum the density of serotonin cells was lower in IBS patients than controls. Whereas the density of PYY cells was increased in both the colon and rectum of IBS-D, it was reduced in IBS-M and IBS-C. The density of oxyntomodulin cells was reduced in both the colon and rectum of all IBS subtypes. While the density of PP cells was unaffected in the colon, it was reduced in the rectum. Somatostatin cell density was unaffected in both the colon and rectum. The densities of Msi 1 and neurog 3 were unchanged in both the colon and rectum.

Conclusion: The present findings of abnormal densities of the large-intestine enteroendocrine cells in Thai patients combined with previously reported changes in Western IBS patients (2) support the notion that intestinal enteroendocrine cells are involved in the pathophysiology of IBS. However, the changes in the enteroendocrine cells differed from those in Western patients. The present observations highlight that IBS differs in Asian and Western countries, and show that the changes in large-intestine enteroendocrine cells in Asian and Western IBS patients might be caused by different mechanisms.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Opioid-induced constipation (OIC) is a common side effect of opioid therapy that significantly affects multiple aspects of a patient’s life. Naldeenedine (NAL) is a peripherally-acting mu opioid receptor antagonist developed for the treatment of OIC. In Phase 3 studies, NAL improved the frequency of spontaneous bowel movements, straining, consistency of stools, and patient assessment of constipation symptoms (PAC-QOL) measures of patient’s quality of life, compared with placebo (PBO). The aim of this analysis is to assess the impact of NAL on overall satisfaction and to show if a simple score can assess the impact of treatment of OIC with NAL 0.2 mg once daily on patient’s satisfaction with constipation and abdominal pain in subjects with chronic non-cancer pain.

Aims & Methods: In three Phase 3 randomized, double-blind, PBO-controlled trials of NAL (2 of 12-week duration [COMPOSE 1 and COMPOSE 2] and 1 of 52-week duration [COMPOSE 3]), a 7-grade scale (1 = markedly, 2 = moderately, or 3 = slightly worsened; 4 = unchanged; 5 = slightly, 6 = moderately, or 7 = markedly improved) was used to assess overall satisfaction with constipation and abdominal symptoms at the last visit study. The number and proportion of subjects in each grade were calculated and the overall difference between groups was assessed by Wilcoxon rank sum test. The mean subject global satisfaction score (SGSS) was also compared between groups. For SGSS scores, from 1 to 7 were replaced with scores from -3 to +3, with 4 (unchanged) replaced with 0.

This proposed new approach provides a single score that may be easier to interpret than the 7-grade scale.

Results: There were 547 subjects in COMPOSE 1, 550 in COMPOSE 2, and 1246 in COMPOSE 3 (all ≥18 years of age) randomized (1:1) to NAL 0.2 mg once daily or PBO. The baseline characteristics of the study population were consistent between groups in each trial and between trials. Overall satisfaction assessment was completed in 372 subjects in COMPOSE 1, 296 in COMPOSE 2, and 1101 in COMPOSE 3. There were greater improvements in satisfaction with constipation and abdominal symptoms in the NAL group compared with the PBO group in all three studies (all P<0.0005; Table). The mean SGSS was 1.5 and 0.9 with NAL and PBO, respectively, in the two 12-week studies pooled, and 1.7 and 1.0, respectively, in the 52-week study.

Total subjects assessed | COMPOSE 1 | COMPOSE 2 | COMPOSE 3
------------------------|------------|------------|------------
NAL total                | 185        | 187        | 192        |
PBO total                | 204        | 194        | 207        |
Global satisfaction category, n (%) |           |            |            |
Markedly worsened (1)    | 3          | 7          | 6          |
          | (1.6)      | (3.7)      | (2.9)      |
Moderately worsened (2)  | 11         | 8          | 10         |
          | (5.9)      | (4.3)      | (2.5)      |
Slightly worsened (3)    | 7          | 4          | 5          |
          | (1.5)      | (3.7)      | (1.5)      |
Unchanged (4)            | 27         | 58         | 28         |
          | (14.6)     | (31.0)     | (13.7)     |
Slightly improved (5)    | 49         | 38         | 37         |
          | (26.5)     | (20.3)     | (21.8)     |
Moderately improved (6)  | 39         | 41         | 39         |
          | (21.1)     | (21.9)     | (26.0)     |
Markedly improved (7)    | 52         | 28         | 32         |
          | (28.1)     | (15.0)     | (16.7)     |
P-value between groups*  | 0.0005      | <0.0001    | <0.0001    

*Wilcoxon rank sum test

Conclusion: Treatment of OIC with NAL 0.2 mg once daily for 12 or 52 weeks led to greater satisfaction with constipation and abdominal symptoms compared with PBO, consistent with previously-reported improvements of PAC-SYM and PAC-QOL with NAL compared with PBO. The proposed SGSS appears to be a simple way to assess the impact on quality of life of OIC treatment.

PI1127 IBEROGAST PREVENTS CHANGES IN INTESTINAL PERMEABILITY INDUCED BY PSYCHOLOGICAL STRESS IN MICE

P. Aubert1, J. Chevalier1, T. Durand1, A. Bessard1, O. Kelber2, H. Abdel-Aziz2, M. Neunlist1

Introduction: The herbal preparation STW 5 has been reported to increase intestinal chloride secretion. However, the ability of STW 5 to modulate paracellular and transcellular permeability remains currently unknown. Therefore, we aimed to determine the effects of STW 5 on intestinal leakage in mice submitted to psychological stress.

Materials & Methods: Male C57Bl/6 mice (n=12 per group) were allocated to the following groups: STW5 (200 mg/kg), control (C), sham operated control (SOC) and saline control (SC). After 1 week of adaptation, mice were submitted to psychological stress (PS) or control conditions for 45 minutes. Following 24 hours of re-adaptation, mice were killed and jejunal samples were collected for measuring markers of paracellular (claudin-1) and transcellular (iNOS) permeability.

Results: STW 5 significantly reduced the leakage of fluorescein isothiocyanate (FITC) and diethylenetriaminepentaacetic acid (DTPA) in the jejunal samples of mice submitted to PS. However, the leakage of these markers was not different between the SOC and SC groups. Furthermore, STW 5 did not affect the leakage of DNP in the jejunal samples of mice submitted to PS.

Conclusion: STW 5 prevents changes in intestinal permeability induced by psychological stress in mice.

Disclosure of Interest: All authors have declared no conflicts of interest.
to study the ability of STW 5 to modulate intestinal permeability under basal and response to stress conditions.

Aims & Methods: C57 bl6 mice were gavaged for 14 days with STW 5 (5 mL/kg). After 10 days of treatment, mice were subjected to water avoidance stress (WAS) during 4 consecutive days. In vivo permeability to FITC – Sulfonic Acid (F4, 40 mg/kg in PBS), HRP, (4kDa), total transit time of colonic transit (fetal pellet output - FPO) were measured at Day 0 (D0), D10 and D14 of IB treatment. Ex vivo permeability to FSA and HRP was assessed on jejunum, ileum, proximal colon and distal colon at D14 using Ussing chambers. Caco-2 cell monolayers were treated with STW 5 and cells were assessed at D14.

Results: In vivo permeability to FSA and HRP as well as total transit time were not modified by STW 5 in basal and WAS conditions. However, STW5 prevented the increase in permeability to FSA induced by WAS in the distal colon only. Conversely, STW 5 prevented the increase in permeability to HRP induced by WAS in the jejunum and proximal colon. Furthermore, while STW 5 tended to increase colonic transit as compared to control in basal conditions, it prevented the increase in transit induced by WAS. Finally, STW 5 did not modulate corticosterone induced by WAS.

Conclusion: Our study suggest that STW 5 can prevent WAS induced changes in paracellular and transcellular permeability in specific regions of the gastrointestinal tract. Such effects could contribute to the therapeutic effects of STW 5 in irritable bowel syndrome and support novel therapeutic indications for pathologies in which barrier functions are altered.

P1129 ALTERING SPHINGOSINE-1-PHOSPHATE WITH AGING INDUCES MOTILITY DYSFUNCTION OF COLON SMOOTH MUSCLE BY BKCA UPRREGULATION IN RATS

S. Xiaoanxue The First Affiliated Hospital Of Nanjing Medical University, Nanjing Medical University, Nanjing/China

Contact E-mail Address: shenxiaoxue0066@163.com

Introduction: Large conductance Ca2+-activated K+ channel (BKca channel) was shown to play critical roles in regulating smooth muscle contractility by modulating membrane potential, at the same time, age-associated changes in BKca expression may contribute to the development of motility disorders of the gastrointestinal tract. Sphingosine-1-Phosphate (SIP), component of Sphingolipid, is a cell membrane phospholipid, may affect BKca expression. Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (Csm) in rats.

Aims & Methods: Thus, in this study, we investigated whether altered SIP due to aging may affect the motility of colon smooth muscle (Csm) in rats. Forty Sprague-Dawley rats at the same age were randomly divided into five groups. After different times of administration, finally they were divided into different-age group: 10-week group, 20-week group, 40-week group, 60-week group and 80-week group. Colonic motility function and contractility of circular muscle strips were measured. The expression of BKca and phosphorylated myosin light chain (P-MLC) level were tested in colon tissues of rats with varying ages by immunohistochemical, RT-PCR and western blot. SIP levels in colon tissues were tested by LC-MS/MS analysis. Primary cultured colon smooth muscle cells (SMCs) from normal adult rats were used in complementary in vitro studies. In the absence and presence of SIP with different concentrations, the expression of BKca, P-MLC level, single-channel activity, intracellular Ca2+ mobilization were tested. At the same time, in the presence and absence of SIP, SMCs were transfected with anti-SIP antibody. BKca siRNA transfection was used to investigate whether P-MLC expression and intracellular Ca2+ mobilization were affected by BKca expression in SMCs. The expression and phosphorylation of Akt, JNK, ERK, NFKB, and PKC was examined by western blot analysis to investigate the effect between SIP and BKca.

Results: Aged rats showed prolonged colonic transit time and weakness of circular muscle contraction compared with the young (10 weeks old) SD rats. LC-MS/MS analysis exhibited that the levels of SIP were significantly greater in the CSM from aged rats, demonstrating that S1P varies depending on age. BKca (α-subunit and β-subunit) levels in CSM were shown to increase in an age-dependent manner from 10- to 80-week-old rats by mRNA and protein and immunohistochemical, but P-MLC expression decreased. In colon SMCs by BKca siRNA transfection, we found P-MLC levels increased. Exogenously added SIP upregulated BKca in colon SMCs in a concentration-dependent manner and intracellular Ca2+ mobilization though inhibiting Ca2+ influx and induced the decline of P-MLC. Our results also proved that SIP upregulated BKca through the Akt/ERK/JNK pathways. The expression of BKca decreased by treatment with inhibitor of Akt/ERK/JNK pathways or siRNA.

Conclusion: The results of our study show that altered SIP due to aging upregulates BKca via the Akt/ERK/JNK mediated pathway in CSM. BKca upregulation inhibits Ca2+ influx and MLC phosphorylation and thereby reduces the contractile response, which may be characterized by the assembly of enteric neurons into ganglia and the formation of a highly organized pattern of neuronal connectivity. However, the mechanisms underlying these maturation processes are poorly understood.

P1130 DIABETES-RELATED ALTERATIONS IN THE EXPRESSION OF THE INFLAMMATORY CYTOKINES, TUMOR NECROSIS FACTOR ALPHA AND INTERLEUKIN 6 IN THE MYERIC GAGNIA AND ITS MICROENVIRONMENT OF DIFFERENT INTESTINAL SEGMENTS

L. Chandrakumar, D. Mezei, B. P. Barta, Z. Szalai, N. Bödi, M. Bagyanszki

Department Of Physiology, Anatomy And Neuroscience, University of Szeged, Szeged/Hungary

Contact E-mail Address: lalitha.biochem87@gmail.com

Introduction: Growing amount of evidence has indicated that increase of the hyperglycaemia-induced oxidative stress and decreased effectiveness of the endogenous antioxidant protection play the major role in the initiation of diabetes-related neuronal damage. Using a streptozotocin-induced diabetic rat model we recently demonstrated that nitricyergic neuronal, which are key regulators of peristalsis, display different susceptibilities to diabetic damage and also to treatment in the different parts of the intestinal tract. On these results we suggested the importance of the molecular differences in the neuronal microenvironment in the pathogenesis of diabetic nitricergic neuropathy.

Aims & Methods: Aim to reveal the quantitative differences in the expression of the pro-inflammatory cytokines like tumor necrosis factor alpha (TNFa) and interleukin 6 (IL6) in the myentric ganglia and its microenvironment of the different intestinal segments, quantitative immunogold electron microscopy was used. Ten weeks after the onset of diabetes, segments from the duodenum, ileum and colon of streptozotocin-diabetic, streptozotocin-controlled diabetic, and control rats were processed for post-embedding immunohistochemistry.

Results: The density of TNFa- and IL6-labeling gold particles was strictly region-dependent, with increasing to the distal part of the gastrointestinal tract of diabetic rats, the number of TNFa gold particles was significantly increased in the duodenum, decreased in the colonic myenteric ganglia, while did not show any significant differences in the ileal ganglia. The number of IL6 gold particles was not affected by diabetes in the myentric ganglia of different gut regions. The diabetes-related alterations of TNFa- and IL6 expression were not protected by the immediate insulin replacement in any of the investigated intestinal segments. The differences in TNFa- and IL6 density were not significant in the capillary endothelium under different experimental conditions.

Conclusion: Based on these findings we presume that regionally alterations in the TNFα and IL6 expression are correlated with the diabetes-related region-specific nitricergic myenteric neuropathy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Method: Gene and protein expression of SEMA3A and its receptor NR1P1 in rectal and distal colonic tissue of young and adult rats was analyzed by qRT-PCR and Western blot respectively. The cellular distribution of SEMA3A and NR1P1 was performed at P7 and P36 in whole-mount distal colon tissue by double immunofluorescence for SEMA3A or NR1P1 with specific monoclonal antibodies (H-126, sc-527, and muscle cells (a-SMA)). The impact of SEMA3A on neural outgrowth was assessed in cultures of enteric neurons cocultured with SEMA3A-transfected COS-7 cells.

Results: A peak of mRNA expression for SEMA3A and NR1P1 was observed in distal colonic tissue at P7, corresponding to a stage of intense neural circuit remodeling. At the protein level, NR1P1 was also found to be predominantly expressed during the early postnatal period. Immunohistofluorescence of colon tissue indicated that SEMA3A immunoreactivity was not associated with any specific cellular profile, but was distributed in small clusters disseminated throughout the tissue, a pattern consistent for a secreted protein. NR1P1 was found in neurons, mainly associated with axonal processes, and was not detected in glial or muscle cells. Enteric neurons cultured in the presence of SEMA3A-expressing COS cells showed a strong reduction in axon length and complexity, while the ganglion size was unaffected.

Conclusion: This study shows the expression of SEMA3A and its receptor NR1P1 in the ENS during early postnatal period. By controlling axonal outgrowth, SEMA3A might be an important factor to restrict the axonal trajectories in the appropriate paths between ganglia.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1132 A POPULATION-BASED STUDY ON BOWEL HABITS IN A PORTUGUESE COMMUNITY: PREVALENCE OF CONSTIPATION

6Centro Hospitalar Sao Joao, Porto Medical School, Porto/Portugal

Contact E-mail Address: marcoopcostas89@gmail.com

Introduction: Constipation is a chronic disorder with an estimated prevalence of 17% in Europe. Epidemiological studies on bowel habits in the Portuguese general population have not been previously done, as in many other western countries. The aim of this population-based study was to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community.

Aims & Methods: We aimed to describe bowel habits and the prevalence of self-reported constipation in a Portuguese community. Methods: Cross-sectional study with convenience sampling between November 2015 and November 2016. The physician applied a questionnaire, to adult patients at primary health care consultation. The questionnaires were anonymous, and the only personal information the participants were required to give was their age and sex. The questionnaire contained objective questions on possible causes and constipation-associated conditions and medications (according to the criteria defined by the World Gastroenterology Organization), daily water and fiber intake, physical activity, bowel habits and Bristol stool scale (BSS). Descriptive statistics and uni and multivariate analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: A total of 826 questionnaires were completed by individuals from 35 different municipalities (54% women; mean age 46 ±18 years). Concerning possible causes of constipation, 43% subjects had a history of constipation-associated condition and 36% were taking constipation-associated drugs. Regarding bowel habits, 35% subjects had <1 bowel movement per day and 2% had >1 bowel movement per week. Using BSS, 66% of the cases reported type III or type IV stool consistency. Among women, 19% reported a change in bowel movements according to the phase of the menstrual cycle. In total, 22% of subjects considered to be constipated, and 78% of these, compiled the Roma III criteria for functional constipation. Noteworthy, 6% of subjects with daily bowel movements and 38% of those with <1 weekly bowel movement considered to have constipation. Complaints of excessive straining, tenesmus, feeling of incomplete bowel movement per week. Using BSS, 66% of the cases reported type III or type IV stool consistency. At the protein level, NR1P1 was also found to be predominantly expressed during the early postnatal period. Immunohistofluorescence of colon tissue indicated that SEMA3A immunoreactivity was not associated with any specific cellular profile, but was distributed in small clusters disseminated throughout the tissue, a pattern consistent for a secreted protein. NR1P1 was found in neurons, mainly associated with axonal processes, and was not detected in glial or muscle cells. Enteric neurons cultured in the presence of SEMA3A-expressing COS cells showed a strong reduction in axon length and complexity, while the ganglion size was unaffected.

Conclusion: This study shows the expression of SEMA3A and its receptor NR1P1 in the ENS during early postnatal period. By controlling axonal outgrowth, SEMA3A might be an important factor to restrict the axonal trajectories in the appropriate paths between ganglia.

P1133 DIAGNOSTIC DISCORDANCE BETWEEN TESTS OF EVACUATION: A PROSPECTIVE STUDY

D. Carter, E. Bardin, M. Beer-Gabel
1Sackler Faculty Of Medicine, Tel Aviv University, Tel Aviv/Israel
2Gastroenterology, Sheba Medical Center Dept. of Gastroenterology, Ramat Gan/Israel

Contact E-mail Address: dr.dancarter@gmail.com

Introduction: Objective means of evaluating of the defecatory process include anorectal manometry (ARM), balloon expulsion test (BET) and imaging of the defecatory process (X-ray defecography, dynamic trans-pelvic ultrasound (DT-PUS) or MR defecography). These tests have a place in the evaluation of suspected evacuation dysfunction (ED), fecal incontinence (FI) and chronic pelvic pain (CPP). Test choice may influence subsequent patient management; however, there is only limited information regarding the agreement between HRM, DT-PUS and BET.

Aims & Methods: The aims of this study were to compare the diagnostic yield and agreement between different tests of evacuation and to define the relation between the diagnoses of evacuation dysfunction to objective evacuation failure. 63 consecutive patients (60 females, mean age 51yrs) were prospectively evaluated with HRM, BET and PUS. Inter test agreement for the diagnosis of anismus was assessed using the Kappa statistic. Correlation between anismus to evacuation failure (assessed by PUS) was also assessed.

Results: 36 patients were assessed for ED, 6 for CPP and 21 for FI. Anismus was diagnosed in 26 patients by HRM and 45 patients by DT-PUS. All cases of anismus diagnosed by HRM or DT-PUS had a positive BET. The Kappa agreement for the diagnosis of anismus between HRM and DT-PUS was poor (0.143 ±0.01). 9 patients had significant pelvic floor anatomic pathology (4 rectal prolapse, 6 pathological pelvic descent, 4 enterocele and 3 rectocoele >3.5cm). There was a moderate correlation between diagnosis of anismus on DT-PUS to failure to evacuate the rectum (r = 0.636). The correlation between rectal evacuation on DT-PUS to the diagnosis of anismus on manometry was weak (r = 0.296).

Conclusion: There is considerable disagreement between the results of various evacuation tests, and between the diagnoses of evacuation dysregulation to failure of rectal evacuation. Therefore, more than one test should be applied in order to evaluate the defecatory dysfunction.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1134 DIAGNOSTIC USE OF ENDOSCOPIC FULL-THICKNESS WALL RESECTION (EFTR) IN PATIENTS WITH SYMPTOMS OF CHRONIC INTESTINAL PSEUDO-OBSTRUCTION (CIP0)

P.V. Valli, D. Pohl, M. Friedl, R. Caduff, P. Bauerfeind
1University Hospital Zurich, Zurich/Switzerland
2Institute Of Surgical Pathology And Molecular Pathology, University Hospital Zurich, Zurich/Switzerland

Contact E-mail Address: piero.valli@usz.ch

Introduction: Complex gastrointestinal motility disorders such as chronic intestinal pseudo-obstruction (CIP0) or Hirschsprung’s disease (HD) are challenging to diagnose and treat appropriately. Thorough assessment of patient history, radiographic exams, endoscopy and motility measurements aid in diagnosis and work-up, yet underlying histology is the cornerstone to enable a more distinct diagnosis of neuromuscular GI disorders. Traditionally, surgical procedures have been performed to obtain specimen suitable for accurate histologic analysis.

Aims & Methods: We performed endoscopic full-thickness resection (eFTR) using a full-thickness-resection device (FTRD) under moderate propofol sedation in four patients with suspected severe neuromuscular gut disorders including CIP0.

Results: Patient 1: A 21-year-old male patient with cerebral palsy suffering from acute small bowel ileus with a history of laparotomy, detorquation and appendectomy after colic volvulus at the age of 15. Histologic analysis revealed irregular configuration of the myenteric plexus, but primary neuro- or myopathic dysmotility, such as HD were excluded. GI dysmotility due to cerebral palsy syndrome was suspected. Patient 2: After a life-long history of recurrent obstipation, colonic dilatation, ileus symptoms and various colonic segment resections, diagnostic eFTR was performed in a 55-year-old female patient. The diagnosis of hypoganglionosis was excluded by LDH histochemical and by immunohistochemical reactions with Calretinin and Map-2 Kinase. Patient 3: A 19-year-old male patient with a history of a sigmoid volvulus and massively dilated large bowel segments. Enzyme histochemistry excluded HD upon histopathological analysis. The inner muscle layer showed fibrosis, eosinophilic leiomysitis and lymphocytic ganglionitis. Congenital CIP0 was diagnosed due to degenerative leiomysopathy. Patient 4: A 56-year-old male patient with acute ileus and a year-long history of constipation and abdominal pain. Histopathological analysis
revealed hypoganglionosis, severe fibrosis of the inner muscle layer and reduced ICC networks. Histological analysis for the diagnosis of hypoganglionosis was compared between the resected specimen and normal colon. There was hypoganglionosis in all 5 patients. Technical success in all 5 patients was achieved with mean (range) of 21 mm (20–22 mm) of resection. In all 5 patients, there were no adverse events connected to the procedure itself. The mean procedure time was 12 minutes (10–16 minutes) and the mean diameter of the resected specimen was 21 mm. Outcomes were assessed using the validated PAC-SYM and PAC-QOL questionnaires. All 5 patients completed the stimulation period. There were no adverse events or complications related to interferential electrical stimulation. The mean procedure time was 12 minutes (range 5–20 minutes). The mean diameter of the resected specimen was 21 mm (range 20–22 mm). No adverse events were reported during the follow-up period.

Disclosure of Interest: The authors have declared no conflicts of interest.

P1136 YH12852, A NOVEL AND HIGHLY SELECTIVE 5-HT4 RECEPTORAGONIST, INCREASES STOOL FREQUENCY IN HEALTHY VOLUNTEERS

J. Moore, P.R. Gibbons, R. Eggerli
Gastroenterology, Monash University, Melbourne/Australia/VIC

Contact E-mail Address: judith.moore@monash.edu

Introduction: There is emerging interest in non-pharmacological management of gastrointestinal dysmotility via neuromodulatory techniques. A new method of non-invasive neuromodulation - transabdominal interferential electrical stimulation - has apparent efficacy in a paediatric population with difficult constipation.

Aims & Methods: We report our experience of its use in adult patients with functional constipation who are refractory to conventional management. This is a descriptive case series of consecutive adult patients presenting to a tertiary referral functional gastrointestinal disorders clinic with refractory constipation that were taught and used home-based interferential stimulation for at least 4 weeks. All patients completed a functional gut nurse audit after three-months stimulation. A functional gut nurse specialist between October 2015 and Feb 2017. The validated PAC-SYM and PAC-QOL questionnaires were given at commencement of stimulation and after three months of follow up. The mean age was 47 (26–73) years and 2 were male. All 7 patients completed the stimulation period. There was a reduction in PAC-SYM in all patients (median IQR 24 [18–36] to 14 [10–21]) and PAC-QOL median IQR 8 [7–9] vs 4 [2–5] (p = 0.004). PAC-QOL was assessed in 4 patients and fell from 75 [69–85] to 38 [19–52]. Four were able to cease previously heavy daily laxative use and 2 were able to halve their use, one currently weaning off prucalopride. One remained on daily laxative use despite soft, formed stool. One reported satisfaction with stool type. All noted benefit remained in 2 after 4 and 12 months since ceasing its use, where the rest tended to use the stimulator intermittently.

Disclosure of Interest: Interpersonal electrical stimulation improved symptoms in patients with functional constipation. Randomized placebo controlled trials are justified.

Introduction: Constipation is a common side effect of opioid use. Available laxative therapies for opioid-induced constipation (OIC) leave the patient with significant residual symptoms, which may lead them to adjust or stop their opioid intake in order to have a bowel movement, unless effectively counselled.

Aims & Methods: This subgroup analysis of an international survey investigated counselling resources, information-seeking, and sources of support in subjects with constipation caused by the use of strong opioids (e.g. buprenorphine, fentanyl). This was a quantitative, questionnaire-based, online survey conducted in France, Germany, Italy, Spain and the UK among respondents aged ≥40 years with largely non-cancer-related chronic pain, treated long-term with strong opioids and having constipation (N = 2016). The survey assessed past medical history of opioid use, treatment with specific opioids, symptoms, burden of disease, and effects on quality of life of constipation.

Results: In general, responders find it difficult to combine pain management relief and constipation and dislike having to balance them (36%). Approximately one-fifth (22%) of respondents were very or somewhat dissatisfied with the effectiveness of their current constipation treatment and only 43% strictly adhered to prescribed treatment regimens, with 32% researching other treatment options. A significant number of responders (44%) admitted that their constipation becomes so bothersome that they have to combine different methods to relieve it, and 40% often cut down their opioid medication or even skip it entirely (9%) to relieve constipation. To manage their constipation, respondents regularly used a variety of approaches, including dietary measures (48%), exercise (23%) and single (32%) or multiple (15%) laxative treatments. Only 45% of responders reported that their healthcare professionals (HCPs) had warned them about constipation as a potential side effect of opioid use. Approximately two-thirds (63%) of responders believed that the health care team is not doing enough to inform patients about the potential for opioid-induced constipation. Without this information, patients might be less likely to take necessary steps to alleviate their symptoms. In general, patients felt that their healthcare professionals (HCPs) had not provided enough information about opioid-induced constipation and its management. Patients also reported feeling left to their own devices to manage their symptoms and that they had received little or no support from their healthcare providers.

Conclusion: A large number of patients are not satisfied with their current constipation treatment and they sometimes find balancing the need for adequate pain relief with constipation side effects challenging; consequently, many fail to adhere to their prescribed treatment regimens, or resort to using suboptimal strategies, such as reducing their opioid intake, to relieve constipation. Despite this dissatisfaction, many HCPs are not counselling patients adequately about constipation as a common potential side effect of opioid use. While most patients would like to have more support from their HCP, nearly half prefer to deal with constipation on their own, perhaps due to embarrassment or resignation.

P1135 TRANS-ABDOMINAL INTERFERENCE ELECTRICAL STIMULATION IS EFFECTIVE IN MANAGING REFRACTORY LOWER GASTROINTESTINAL DYSMOTILITY DISORDERS

J. Moore, P.R. Gibbons, R. Eggerli
Gastroenterology, Monash University, Melbourne/Australia/VIC

Contact E-mail Address: judith.moore@monash.edu

Introduction: Lower gastrointestinal motility disorders are frequent and have a significant impact on the quality of life of patients. Non-pharmacological therapies for these disorders include biofeedback, pelvic floor muscle training and biofeedback combined with physiotherapy. However, a significant number of patients are refractory to these therapies. Interferential electrical stimulation improved symptoms in patients with refractory constipation. Randomized placebo controlled trials are justified.

Aims & Methods: This is a descriptive case series of consecutive adult patients presenting to a tertiary referral functional gastrointestinal disorders clinic with refractory constipation that were taught and used home-based interferential stimulation for at least 4 weeks. All patients completed the stimulation period. The validated PAC-SYM and PAC-QOL questionnaires were given at commencement of stimulation and after three months of follow up. The mean age was 47 (26–73) years and 2 were male. All 7 patients completed the stimulation period. There was a reduction in PAC-SYM in all patients (median IQR 24 [18–36] to 14 [10–21]) and PAC-QOL median IQR 8 [7–9] vs 4 [2–5] (p < 0.004). PAC-QOL was assessed in 4 patients and fell from 75 [69–85] to 38 [19–52]. Four were able to cease previously heavy daily laxative use and 2 were able to halve their use, one currently weaning off prucalopride. One remained on daily laxative use despite soft, formed stool. One reported satisfaction with stool type. All noted benefit remained in 2 after 4 and 12 months since ceasing its use, where the rest tended to use the stimulator intermittently.

Disclosure of Interest: Interpersonal electrical stimulation improved symptoms in patients with functional constipation. Randomized placebo controlled trials are justified.

2Dept. Of Pediatric Surgery, Medical University of Warsaw, Warsaw/Poland
Contact E-mail Address: mbanasuk@tlen.pl

Introduction: Three-dimensional high-resolution anorectal manometry (3DHRA) is the most precise tool to assess function of the anal canal and may be useful in evaluation of children after surgery on lower gastrointestinal tract that may present wide spectrum of symptoms from gastointestinal tract. Our aim was to evaluate children after surgery for ano-rectal disorders using 3DHRA.

Aims & Methods: We performed a prospective study of 43 children (30 male, mean age: 7 years) after surgery for ano-rectal disorders at the Departments of Pediatric Gastroenterology, Surgery and Psychiatry, Medical University of Warsaw, Poland. The group consisted of 24 children after surgery for Hirschsprung’s disease (HD), 12 children after surgery for anal atresia (AA) and 7 children after proctocelectomy for other reasons (PC). In all children conventional manometry was performed. Pressures of the anal canal was divided into 8 segments and the resting and squeezing pressures of puborectalis muscle (PRM) were recorded in segments covering its anatomical localization. These data were compared to raw data obtained in our laboratory from healthy children published previously (HC group). To assess correlation between manometry and symptoms, all children (after surgery and HC group) were divided into groups with respect to symptoms, as follows: asymptomatic (A), nonretentive fecal incontinence (NRFI), retentive fecal incontinence (RFI).

Results: The lowest values of resting, squeeze and the pressure of PRM were observed in AA (55.6 mmHg, 121.7 mmHg and 44.17 mmHg, respectively). As compared to asymptomatic children, the lowest mean and maximum resting pressures were observed in NRFI (69.6 mmHg and 61.3 mmHg, respectively; p < 0.000). Significantly lower maximum squeeze pressure was recorded in both, NRFI and RFI (168.1 mmHg and 103.8 mmHg, respectively; p = 0.03). ROC cut-off value for mean resting pressure between asymptomatic children and children with fecal incontinence was 64.5 mmHg. Significantly lower PRM resting pressure were observed in NRFI group and lower PRM squeeze pressure in RFI (45.6 mmHg and 63.6 mmHg, respectively). Threshold of urge were significantly higher in group C as compared to A group (87.5 mmHg and 30 cm3, respectively; p = 0.003).

Conclusion: Our study demonstrated lower pressure parameters in children after surgery with the lowest values in patients suffering from anal atresia, which was correlated with incontinence. 3DHRA may be useful tool for assessing the functional outcomes of the anorectum after surgery.

Introduction: Linacotide, a guanylate cyclase C agonist, has been shown in clinical trials to relieve constipation and improve abdominal pain and discomfort in patients with irritable bowel syndrome with constipation (IBS-C), but there are limited UK-specific real-world data to support this.

Aim & Methods: A multi-centre, observational prospective 52-week study was conducted in eight specialist hospitals in England and Scotland. The primary objective was to describe the change in IBS-Symptom Severity Scale (IBS-SSS) score from baseline at 12 weeks after linaclotide initiation. Consenting patients aged ≥2 years and with fecal incontinence were included. Pressures of the anal canal was divided into 8 segments and the resting and squeezing pressures of puborectalis muscle (PRM) were recorded in segments covering its anatomical localization. These data were compared to raw data obtained in our laboratory from healthy children published previously (HC group). To assess correlation between manometry and symptoms, all children (after surgery and HC group) were divided into groups with respect to symptoms, as follows: asymptomatic (A), nonretentive fecal incontinence (NRFI) and retentive fecal incontinence (RFI).

Results: The lowest values of resting, squeeze and the pressure of PRM were observed in AA (55.6 mmHg, 121.7 mmHg and 44.17 mmHg, respectively). As compared to asymptomatic children, the lowest mean and maximum resting pressures were observed in NRFI (69.6 mmHg and 61.3 mmHg, respectively; p < 0.000). Significantly lower maximum squeeze pressure was recorded in both, NRFI and RFI (168.1 mmHg and 103.8 mmHg, respectively; p = 0.03). ROC cut-off value for mean resting pressure between asymptomatic children and children with fecal incontinence was 64.5 mmHg. Significantly lower PRM resting pressure were observed in NRFI group and lower PRM squeeze pressure in RFI (45.6 mmHg and 63.6 mmHg, respectively). Threshold of urge were significantly higher in group C as compared to A group (87.5 mmHg and 30 cm3, respectively; p = 0.003).

Conclusion: Linacotide was associated with a significant improvement in IBS-SSS score at 52 weeks and was reasonably well tolerated. These results provide valuable insights into the longer-term outcomes of linaclotide treatment in patients with IBS-C in real-world clinical practice.

Introduction: Irritable bowel syndrome (IBS) may be associated with disturbances of gut microbiota composition and functions, such as altered bacterial fermentation.

Aims & Methods: The aim was to study the effect of faecal microbiota transplantation (FMT) on gut bacterial fermentation products: short-chain fatty acids (SCFAs). Patients diagnosed with IBS according to Rome III criteria (n = 13) were included. They received freshly donated faeces from relatives, instilled into the descending part of the duodenum via gastroscope. Faecal samples were collected from the donors and the patients before FMT and from the patients after FMT at weeks 1, 3, 12 and 20/28. All the samples were stored at −80°C until analysis. Faecal concentrations of major SCFAs (acetic, propionic and n-butyric acids) and minor SCFAs (iso-butyric, n-valeric, iso-valeric, n-caproic and iso-caprylic acids) were analysed by vacuum distillation followed by gas chromatography. The patients completed IBS symptom questionnaire (IBS-SQ) before and after FMT at weeks 1, 3, 12, and 20/28, assessing the following domains: nausea, bloating, abdominal pain, diarrhea, constipation and anorexia.

Results: Before FMT, concentrations of several SCFAs were significantly lower in IBS patients compared to donors (Table 1). After FMT, concentrations of SCFAs increased within the first 3 weeks, and the increment lasted up to 28 weeks (Table 1).

Table: Change in IBS-SSS score at 52 weeks from start of linaclotide

2Department Of Psychiatry And Psychology, Maastricht University Medical Center+, Maastricht/Netherlands

Contact E-mail Address: l.vork@maastrichtuniversity.nl

Introduction: Selective Serotonin Reuptake Inhibitors (SSRIs)’s have shown efficacy in reducing symptoms but less so on pain in irritable bowel syndrome (IBS). Comorbid anxiety frequently occurs in IBS. We hypothesized that SSRIs will particularly be effective in reducing abdominal pain in IBS patients with pronounced comorbid anxiety. As methods for symptom evaluation were used 1) gastrointestinal symptom rating scale (GSRS) as primary parameter and 2) a new method called the Experience Sampling Method (ESM). With ESM diagnostic assessments are completed randomly and repeatedly during daily life, therewith capturing fluctuating symptom patterns more accurately than retrospective questionnaires methods.

Aims & Methods: IBS patients with comorbid panic disorder were included in a randomized controlled trial on escitalopram versus placebo. Measurements were completed at baseline (t=0) and after 3 (t=3) and 6 months (t=6). At each time point, the gastrointestinal symptom rating scale (GSRS) and a 7-day ESM period were completed. Subjects completed ESM assessments on a palmpilot computer at 10 random moments each day during 7 consecutive days. ESM periods were assessed when at least one of the assessments were completed. Mixed linear models were used with the GSRS scores as the primary end point and as associated with a reduction in extra-gastrointestinal symptoms. Change in pH across the ileocecal junction correlated with improvement in GSRS and ESM analyses, at t=6, average abdominal pain scores were significantly lower (B: 1.30, SE: 0.623, p = 0.670). For the ESM analyses, at t=6, average abdominal pain scores were significantly lower (B: 1.30, SE: 0.623, p = 0.037) on a 1–7 scale in the esctalopram group compared to placebo. With increasing anxiety levels (scores 2, 3 and 4) this difference further increased to 1.57, 1.84 and 2.11, respectively.

Conclusion: Using GSRS as primary outcome, no significant effect of escitalopram on placebo on abdominal pain was found over a 6-month period. However, using ESM, a significant improvement in abdominal pain was observed, related to anxiety scores. These data 1) challenge the value of traditional retrospective methods with end-of-period symptom recording and 2) are in favour of novel more accurate momentary symptom registrations such as the Experience Sampling Method.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI1143 LINACLIDOTE ACCELERATES COLONIC TRANSIT AND IMPROVES COLONIC CONTRACTILITY IN IBS WITH CONSTIPATION

A. D. Farmer1, A. R. Hobson1
1Gastroenterology, University Hospitals of North Midlands, Stoke on Trent/United Kingdom
2Functional Gut Clinic, London/United Kingdom

Contact E-mail Address: a.farmer@qmul.ac.uk

Introduction: Linclotide, a guanylate-cy clase-C agonist, stimulates intestinal fluid secretion and decreases visceral hypersensitivity and is licensed for use in irritable bowel syndrome with constipation (IBS-C). There is a relative paucity of data concerning its effect on gastrointestinal (GI) motility.

Aims & Methods: We aimed to compare the effect of linclotide on segmental and pan-enteric motility in IBS-C. 14 patients with Rome III defined IBS-C (male, mean age 37 years, range 20–64) underwent a wireless motility capsule (WMC) using a standardized protocol. Segmental transit was derived from measures around known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires assessing GI symptom-related quality of life (EQ-5D) were administered. The WMC and questionnaires were repeated after 28 days of linclotide 290mg po od.

Results: Changes in GI motility are shown in Table 1. Linclotide improved VDVAS-I and VDVAS-U (130.7±20.8 vs. 106.5±33, p=0.03 and 113±22 vs. 85.8±33, p=0.01) and quality of life (58.4±21.2 vs. 68±17.6, p=0.02). Linclotide reduced somatic symptoms (8.3±2.2 vs. 5.9±1.4, p=0.007).

Change in pH across the ileocecal junction correlated with improvement in VDVAS-U and t (r=0.6, p=0.03 and t=0.64, p=0.02).

Table 1: Changes in GI physiology following linclotide.

Baseline Post treatment
(mean and (mean and standard deviation) standard deviation) Value

Gastric emptying time (minutes) 154±64 177±57 0.4
Small bowel transit time (minutes) 353±152 299±139 0.3
Colonic transit time (minutess) 3017±1305 1983±1216 0.04
Whole gut transit time (minutes) 3517±1375 2432±1180 0.04
Ileal contractility (AUC) 262±142.2 221±113.5 0.5
Colonic contractility (AUC) 90.9±78.3 134.6±93 0.006
Change in pH across the ileocecal junction -2.4±0.2 -2.1±0.4 0.03

Linclotide improved VDVAS-I and VDVAS-U (130.7±20.8 vs. 106.5±33, p=0.03 and 113±22 vs. 85.8±17.6, p=0.02). Linclotide reduced somatic symptoms (8.3±2.2 vs. 5.9±1.4, p=0.007). Change in pH across the ileocecal junction correlated with improvement in VDVAS-U and t (r=0.6, p=0.03 and t=0.64, p=0.02).

Conclusion: Linclotide reduced colonic transit and enhances contractility. These changes in GI motility are accompanied by improvements in symptoms and quality of life (58.4±21.2 vs. 68±17.6, p=0.02). Change in pH across the ileocecal junction has been proposed as a surrogate marker of caecal fermentation. Thus the beneficial effect of linclotide on symptoms may therefore be related to a reduction in fermentation. This potential biomarker will be further investigated.

PI1144 RELATIONSHIP BETWEEN RIFAXIMIN THERAPY AND SEHCAT TEST IN PATIENTS WITH DIARRHEA-PREDOMINANT IRRETTIBLE BOWEL SYNDROME OR FUNCTIONAL DIARRHEA

Gastroenterology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat/Spain

Contact E-mail Address: alexandraruizcerulla@gmail.com

Introduction: Bile acids (BAs) and gut microbiota have been involved in IBS pathophysiology. BA diarrhea (BAD) is often found in patients with irritable bowel syndrome (IBS-D) or functional diarrhea (FD). Rifaximin modifies SeHCAT result. This potential biomarker will be further investigated.

Aims & Methods: a) To determine if a SeHCAT test may be used to predict response to rifaximin or whether rifaximin treatment affects SeHCAT test result. b) To assess if rifaximin modifies SeHCAT result.

Consecutive patients diagnosed with IBS-D or FD were prospectively included in the study. All patients received rifaximin (400mg TID for 2w). A SeHCAT test was performed to evaluate presence of BAD before and 1 month after rifaximin treatment. BAD was defined as SeHCAT retention <10%. Number of daily stools, number of daily watery stools, Bristol stool scale, abdominal pain, tension and presence of urgency were recorded before and after treatment. IBS severity score (IBS-SS) was also calculated.

Results: Forty-one patients were included. BAD was present in 23 patients (56%). No clinical differences were found between BAD or non-BAD patients at study entry. Rifaximin resulted in a significant improvement in the number of daily stools (Δ −1.5; P< 0.01), daily watery stools (Δ −2.1; P < 0.01), Bristol scale (Δ −1.1; P < 0.01), abdominal pain (Δ −0.5; P < 0.01), distension (Δ −0.3; P < 0.01), urgency (Δ −0.7; P < 0.01) and in the IBS-SS (Δ −7.8; P < 0.01). No differences were found between BAD and non-BAD patients in the improvement of any item. Rifaximin treatment did not modify SeHCAT value (9.5% before treatment and 10.7% after treatment; P = 0.4).

Conclusion: Half of the patients diagnosed with IBS-D or FD present BAD according the SeHCAT test. Rifaximin treatment confers significant clinical improvement irrespective of the presence of BAD. Rifaximin treatment does not affect SeHCAT test.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Conclusion:** Responders initially also did (which was associated with IBS-SSS improvement), symptoms on daily life (p ¼ 0.039), satisfaction about bowel habit (p ¼ 0.018), and influence of IBS symptoms?'' (Yes/No) on a weekly basis, via an electronic diary. As previously described, patients answering “Yes” for ≥50% of the total weeks during the target time interval were considered AR responders.2,3 Patients answering “No” were considered to have IR. This analysis evaluated the number of consecutive weeks that patients reported IR over Weeks 1–12 and 13–24 of treatment. Patients without analysis were ineligible for intention-to-treat (ITT) analysis; missing data were not imputed.

**Results:** Overall, 2428 patients with IBS-D were enrolled across the two Phase 3 trials and 2423 were included in the ITT analysis. In the pooled dataset, a significantly greater proportion of patients were AR responders2 with either ELX 100 or 75 mg BID vs PBO at 12 weeks (56.1% [p < 0.001] and 56.3% [p < 0.001] vs 41.8%, respectively). Over the first 12 weeks of treatment, a greater proportion of patients reported no IBS-D symptoms with ELX 100 or 75 mg BID vs PBO (Table). Greater proportions of patients reported only 1–<5 consecutive weeks of IR with ELX 100 or 75 mg BID vs PBO. A significantly lower proportion of patients reported IR for >8 consecutive weeks with ELX 100 or 75 mg BID vs PBO (13.2% [p < 0.0001] and 15.6% [p < 0.004] vs 22.6%, respectively). In contrast, a greater proportion of patients reported IR for the full 12 consecutive weeks with PBO vs ELX 100 or 75 mg BID (Table). Similar results were observed in Weeks 13–24 of treatment, with ELX-treated patients generally having fewer consecutive weeks of IR compared to PBO-treated patients (Table).

**Table:** Consecutive weeks of inadequate relief

<table>
<thead>
<tr>
<th>Weeks 1–12</th>
<th>Weeks 13–24</th>
</tr>
</thead>
<tbody>
<tr>
<td>ELX 100 mg BID</td>
<td>ELX 100 mg BID</td>
</tr>
<tr>
<td>ELX 75 mg BID</td>
<td>ELX 75 mg BID</td>
</tr>
<tr>
<td>PBO (n = 809)</td>
<td>PBO (n = 808)</td>
</tr>
<tr>
<td>ELX (n = 808)</td>
<td>ELX (n = 806)</td>
</tr>
</tbody>
</table>

**Conclusion:** In this post hoc analysis of the pooled ELX Phase 3 studies, ELX-treated patients experienced fewer consecutive weeks of IR compared to those receiving PBO, within both Weeks 1–12 and 13–24 of treatment. As IR is thought to drive increased healthcare provider visits, these data suggest that ELX could potentially reduce healthcare resource use and subsequent healthcare costs associated with IBS. Further prospective study of the impact of ELX on AR and any subsequent reduction in healthcare costs is required, including the relationship between the number of consecutive weeks of IR and patients’ behaviour towards healthcare resource use.

**Table 1:** Changes in segmental/whole gut transit times and ileal/colonic motility, relative to baseline between the low FODMAP and m-NICE diets. Both the low FODMAP and NICE diets improved VDVAS-I and VDVAS-U (−18 ± 17 vs. −20 ± 17, p = 0.04 and −13 ± 8 vs. −16 ± 8, p = 0.02, respectively). Similarly, both diets reduced somatic symptoms (−2 ± 1.4 vs. −0.8 ± 1.1, p = 0.07) and improved quality of life (9.5 ± 10.2 vs. 4.4 ± 9.8, p = 0.23).

**Introduction:** Diets reducing the content of fermentable short chain carbohydrates (fermentable oligo-, di-, mono-saccharides, and polyols (FODMAPs)) as well as the National Institute of Health Care Excellence (NICE) diet have been reported to be effective in the treatment of patients with irritable bowel syndrome (IBS) (1,2). The mechanisms by which this efficacy is achieved are incompletely understood but it has been proposed that such diets reduce fermentation, mediated by changes in the microbiota (3). Change in pH around the ileo-caecal junction is considered to be a surrogate biomarker of caecal fermentation (4,5).

**Aims & Methods:** We aimed to compare the effect of a low FODMAP diet vs. the NICE diet on change in ileocaecal pH. We performed a single centre, randomized controlled trial of adult patients with Rome III defined IBS-mixed bowel habit (IBS-M) comparing the two dietary interventions. At baseline, patients ingested a wireless motility capsule (WMC) using a standardized protocol. Segmental transit times were derived from measures across known anatomical landmarks as identified by compartmental pH changes. Ileal and colonic motility measures are presented as area under the curve (AUC) derived from contraction amplitude and frequency. Validated questionnaires evaluating GI (verbal descriptor pain; VDVAS; 0–10 scale, with 0 = no pain and 10 = worst imaginable pain), stool consistency (Bristol Stool Form Scale [BSFS]), and Global Symptom Score (GSS; 0–4 scale, where 0 = no symptoms and 4 = very severe symptoms). A responder was defined as a patient with a simultaneous daily improvement of ≥30% in WAP score vs baseline and BSFS score < 5 with ≥50% of days demonstrating a response and a minimum of 20 days of diary data. The intention-to-treat (ITT) analysis set included all randomized patients who had any WMC data. For patients meeting Rome III criteria for IBS-M, including in patients with severe and inadequately managed symptoms.

**Results:** Of the 2423 patients in the pooled Phase 3 ITT population, 249 were classified as having severe IBS-D. Over Weeks 1–4, 26.8% and 30.3% of patients were responders with eluxadoline 75 and 100 mg, respectively, vs 8.1% of patients on placebo (Table). Higher proportions of patients were responders with eluxadoline vs placebo over each subsequent 4-week period, with response rates observed at Weeks 1–4 consistently maintained across all subsequent 4-week time intervals. With both eluxadoline and placebo, proportions of responders discontinuing were <2% across each 4-week interval, and discontinuation rates in non-responders were higher than in responders (Table). Similar findings were observed in the ITT analysis set: over Weeks 1–4, 22.7% vs 8.1% of patients on placebo (Table). Higher proportions of patients were classified as having severe IBS-D. Over Weeks 1–4, 26.8% and 30.3% of patients were responders with eluxadoline 75 and 100 mg, respectively, vs 12.5% of patients on placebo (Table). Higher proportions of patients were responders with eluxadoline vs placebo over each subsequent 4-week period, with response rates observed at Weeks 1–4 consistently maintained across all subsequent 4-week time intervals. With both eluxadoline and placebo, proportions of responders discontinuing were <2% across each 4-week interval, and discontinuation rates in non-responders were higher than in responders (Table). Similar findings were observed in the ITT analysis set: over Weeks 1–4, 22.7% vs 8.1% of patients on placebo (Table). Higher proportions of patients were classified as having severe IBS-D.

**Conclusion:** Proportions of responders with eluxadoline 75 and 100 mg were consistently higher vs placebo across all 4-week intervals in the treatment period in patients defined as having severe IBS-D. Furthermore, discontinuation rates among patients showing a treatment response remained consistently low compared to non-responders. However, as these analyses were conducted in a clinical trial setting, the relatively high continuation rates in non-responders may not reflect the real-world situation. These findings suggest that eluxadoline has sustained efficacy in treating the diarrhoea and abdominal pain associated with IBS-D, including in patients with severe and inadequately managed symptoms.
associated with triggering gastrointestinal symptoms in irritable bowel syndrome (IBS).

**Aims & Methods:** This study aimed to assess whether oral α-galactosidase co-administration with high GOS foods provides a clinically significant reduction in symptoms in GOS-sensitive individuals. The study was conducted in a double-blind, placebo-controlled, crossover trial approved by the University Ethics Committee. Participants meeting the Rome III criteria for IBS who produced >10 ppm hydrogen on two consecutive breath samples following 10 g fructan were recruited. Participants were randomly assigned to full-dose enzyme (300 GALU α-galactosidase), half-dose (150 GALU α-galactosidase) and placebo (glucose). Following a 3-day low FODMAP run-in period, participants consumed provided diets high in GOS for a further 3 days. Gastrointestinal symptoms were measured daily using a 100 mm visual-analogue scale. Breath samples were taken hourly on the second last and analysed as area-under-the-curve, faecal samples were taken on the final day.

**Results:** Thirty-one participants with IBS (20 IBS-D, 4 IBS-C, 7 IBS-M) completed the study. The addition of high GOS foods resulted in a significant increase in overall symptoms (median 13.0 [IQR 1.5–22.0] to 35.5 [12.8–54.0] mm; p = 0.000, Wilcoxon signed-rank test). No significant increase in overall symptoms was seen with the full-dose enzyme (14.0 [3.5–24.0] vs 14.7 [2.3–32.7] mm; p = 0.422). Twenty-one participants exhibited GOS-sensitivity (>10 mm increase for overall symptoms). Of those, full-dose enzyme reduced overall symp-

**Conclusion:** The performance characteristics of balloon expulsion could support the use of BET as a novel bedside test to screen for dysmotility in constipated subjects.

**Disclosure of Interest:** W.D. Chey: Dr. Chey is a consultant for Ironwood Pharmaceuticals and Allergan. He is co-CMO of My Total Health and holds a patent on My GI Health. All other authors have declared no conflicts of interest.
**Aims & Methods:** The study was retrospective. The GMA group consisted of 21 patients with diagnosed food allergy. The control group (CG) included 17 patients with neither food allergy nor food intolerance. Tissue samples from esophagus, cardia (subdivided in esophageal and gastric region), corpus, antrum and duodenum already obtained during endoscopy were immunohistochemically stained for DAO. The expression of DAO was semi-quantitatively analysed with the following scale based on the staining intensity of DAO (SI-DAO): 0 = none, 1 = low, 2 = medium, 3 = high intensity. The localisation of DAO was also examined vertically from the epithelium to the submucosa in all tissues. The analysis was performed twice by the same examiner in two separate points of time. Furthermore, the tissue samples were immunohistochemically stained for MBP and CD117 in order to count the number of eosinophils and mast cells respectively. Two measurements were performed inside an area of tissue. The measurements performed twice by the same examiner in two separate points of time. Two measurements constituted the number of these cells for each tissue.

**Results:** Immunohistochemical analysis found DAO in all segments of the upper GIT of patients with or without GMA. DAO strengthens the theory that DAO acts extracellularly and is responsible for the elimination of the transepithelially absorbed exogenous histamine as well as for the endogenous histamine, as its highest staining intensity is found at the subepithelial superficial lamina propria (SLP) and one in the deeper lamina propria (DLP). The average of these two measurements constituted the number of these cells for each tissue.

**Results:** Immunohistochemical analysis found DAO in all segments of the upper GIT. The SI-DAO was vertically analysed from the epithelium to the submucosa in all tissues. The analysis was performed twice by the same examiner in two separate points of time. Furthermore, the tissue samples were immunohistochemically stained for MBP and CD117 in order to count the number of eosinophils and mast cells respectively. Two measurements were performed inside an area of tissue. The measurements performed twice by the same examiner in two separate points of time. Two measurements constituted the number of these cells for each tissue.

**Conclusion:** The above findings indicate that DAO is present in low amounts in all segments of the upper GIT. But only in the duodenum a significant difference was found between GMA and CG, thus indicating that histamine-mediated symptoms most likely arise in duodenum. Therefore, regarding the upper GIT, the immunohistochemical staining for DAO only in duodenum could serve as an additional diagnostic parameter for detecting patients with GMA and possibly other histamine-mediated diseases. The above mentioned distribution pattern of DAO strengthens the theory that DAO acts extracellularly and is responsible for the elimination of the transepithelially absorbed exogenous histamine as well as of the endogenous histamine, as its highest staining intensity is found at the SLP throughout the upper GIT.

L-cysteine has been proposed as adjuvant therapy in CAG; the amino acid binds covalently to acetaldehyde (a Group I human carcinogen), removing it from the stomach. The aim of present study was to use L-cysteine to improve the symptoms in patients with diagnosis of CAG.

**Aims & Methods:** One hundred fourteen consecutive patients (M=43, mean age 64.21 years) (with histological diagnosis of CAG) by means of both gastric histology (moderate to severe chronic, atrophic, body gastritis according to the OLGA staging system) and serology (pepsinogen 1 <25 µg/l gastrin-17 >14 pmol/l) underwent upper endoscopy, biopsies and biopsy were recorded and multiple gastric cells units per patient, endoscopic therapy, intervention radiology procedures, and surgery. Clinical outcomes were documented, including the need for blood transfusion and the number of packed red cells units per patient, clinical outcomes were documented, including the need for blood transfusion and the number of packed red cells units per patient.

**Results:** The global symptomatic score results as follows, lasting the 24 months follow-up. Group 1: baseline 4.93; 3 months 3.36; 6 months 2.96; 24 months 2.64. Group 2: baseline 5.9, 3 months 6.2, 6 months 5.6, 24 months 5.8 (p < 0.01). Subdividing the CAG patients according to the etiology (autoimmune gastritis or previous *Helicobacter pylori* infection) no differences were found in improving symptoms. No relevant side effects were observed during the study.

**Conclusion:** The administration of L-cysteine to subjects affected by moderate-severe chronic atrophic gastritis seems able to improve the symptoms in a two-year follow-up. 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Upper gastrointestinal bleeding (UGIB) is one of the main causes of hospital admission and urgent endoscopy in Gastroenterology departements. In-hospital mortality from UGIB has decreased throughout the last 2 decades with a corresponding increase in the performance of endoscopy and endoscopic therapy. However, studies suggest that improvements in the therapeutic procedures for patients with UGIB could be responsible of the mortality decline. Despite this, UGIB represents a true emergency, associated with significant morbidity, mortality and healthcare costs. Furthermore, rebleeding after initial endoscopic therapy is observed in 10–25%, and it has been associated with a higher mortality rate. Therefore, the definition of predictive factors for rebleeding is of outstanding importance.

**Aims & Methods:** The aim of our study is to analyze risk factors and outcomes in a population of patients who suffered rebleed. We present a retrospective study on a prospectively built database of patients with GI bleeding admitted to the Emergency Room of ‘Virgen de las Nieves’ University Hospital over 42 months, from January 2013 to July 2016. All patients underwent upper endoscopy, and a database was created regarding patients' demographic data, current medications (including antiplatelet drugs, NSAIDs and oral anticoagulants), clinical presentations, hemodynamics, admission laboratory test results, and endoscopic findings was collected. Interventions were documented, including the need for blood transfusion and the number of packed red cells units per patient, endoscopic therapy, intervention radiology procedures, and surgery. Clinical outcomes were documented in hospital and delayed 6-months mortality, rebleeding and delayed 6-months bleeding and cardiovascular events.

**Results:** 507 patients were included (339 males; aged 42 ± 16.4). The incidence of rebleeding was 17.3% (n = 88). In the univariate analysis, factors related with rebleeding were creatinine levels (1.52 vs. 1.15; p < 0.001), tachycardia (96.28 vs. 88.24; p < 0.001), low levels of albumin (2.80 vs. 3.238; p < 0.001) and low CO2 arterial pressure (103 vs. 107.9; p < 0.001). In a logistic regression analysis tachycardia and high creatinine were independent risk factors for rebleeding, and albumin showed as an independent protective factor (Table 1). Rebleeding was associated with in-hospital mortality (p < 0.0001), by contrast, it was not related to delayed 6-months mortality, nor with GI bleeding and hemorrhagic events. The UGIB risk scores AIMS 65 and Rockall showed poor predictive ability for acute death in the rebleeding patients’ group and was similar for Blatchford score (based on AURC).

**Conclusion:** Rebleeding in UGIB is associated with increased in-hospital mortality; nevertheless, it is not related with delayed 6-months mortality, hemorrhagic and cardiovascular events. High creatinine and low albumin levels were independent risk factors for rebleeding, suggesting a potential predictive role of these parameters. AIMS65, Rockall and Blatchford were then been used in the present study: the hospital mortality but worked poorly in the patients who suffered rebleeding.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

3Dept. Of Internal Medicine, Saga Medical School, Saga/Japan

**Contact E-mail Address:** nobuyuki_sugisaki@eapharma.co.jp

**Introduction:** Upper gastrointestinal (GI) adverse effects induced by NSAIDs and anti-thrombotic drugs are increasing along with progressive aging of society. Recently it is essential to perform pharmaco-epidemiological studies to identify adverse effects in the real-world setting using a large-scale medical database. We conducted a case-control study to evaluate the risk of upper GI mucosal injuries in subjects prescribed NSAIDs and anti-thrombotic drugs using the large organized database of claims in Japan.

**Aims & Methods:** The medical claims database developed by Japanese Medical Data Center (JMDC) Co., Ltd. was selected as data source in the present retrospective observational study. The JMDC claims database comprised of integrated medical and pharmacy claims, and includes both hospital and outpatient care from over 90 payers (approximately 3.7 million of population on an accumulated basis). Eligible subjects were aged 20 to 74 and registered for at least 3 months in the database from January 2009 to December 2014. The evaluated upper GI mucosal injuries were peptic ulcers (143,271 cases), upper GI bleeding (10,545 cases) and gastroesophageal reflux disease (GERD: 154,755 cases) with diagnosis by ICD-10 codes and implementation of the upper GI endoscopy. For the each test-case, ten controls who matched age, sex and diagnosis month were identified from the database. Multivariate logistic regression analysis was used to calculate odds ratios of occurrence of each upper GI mucosal injuries caused by NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antiplatelet drugs (except low-dose aspirin) and anticoagulants.

**Results:** The odds ratios of peptic ulcers were 1.45, 1.31, 1.50, 1.53 and 1.62 for NSAIDs, COX-2 selective inhibitors, low-dose aspirin, antiplatelet drugs, and anticoagulants respectively. The odds ratios of all the upper GI mucosal injuries were the highest in the patients with anticoagulants, and the ratios were relatively low in those with NSAIDs and COX-2 selective inhibitors. The odds ratios tended to increase with the number of prescribed
medicines (1 agent <2 agents <3 agents, peptic ulcers: 1.38 < 2.49 < 4.52, upper GI haemorrhage: 1.74 < 3.65 < 7.77, GERD: 1.61 < 2.96 < 5.58, respectively). The upper GI mucosal injuries were exacerbated in complication of lifestyle-related diseases, including hyperlipemia and diabetes mellitus.

Conclusion: Prescribing NSAIDs and anti-thrombotic medicines was associated with increased risks of developing upper GI injury. The present multi-centre study utilizing the large organized database of claims in Japan provided precise clinical evidence for safety management of medical drugs in the clinical settings in Japan.

Contact E-mail Address: alia.hadeli@gmail.com

Introduction: Percutaneous left atrial appendage occlusion (LAAO) is increas-ingly recognized as valid alternative therapy to reduce thrombo-embolic risk in patients with valvular atrial fibrillation (AF) and contraindications for long term oral anticoagulation (OAC) therapy.1,2 Patients at high thromboembolic risk with previous gastrointestinal bleeding (GIB) might be at risk of bleeding recurrence in case of resuming anticoagulation. They could be selected for alternative therapies like LAAO. Up to now, there is no scientific consensus for patient selection for LAAO based on recurrent GIB risk.

Aims & Methods: We aimed to review the literature on gastrointestinal (GI) bleeding complications1 during OAC withdrawal in order to define the reversibility profile of each lesion in an organ by organ and lesion by lesion approach to stratify the risk of bleeding individually. We systematically collected data from both prospective and retrospective studies from pubmed in order to extract rebleding risk by etiology. The reversibility profile was defined by type of treatment needed to cure the lesion. Low reversibility (LR) profile was defined as a need for heavy surgery, radiotherapy, embolisation to cure the lesion or as diffuse lesions.

Results: The most frequent reported causes of bleeding are peptic gastroduodenal ulcer (60%) for upper GI, diverticulosis (40%), colitis (20%) and anorectal diseases (20%) for lower GI and angiodysplasia (23%) for the midgut, these latter being responsible for 5% of all GI bleeding causes. The rate of bleeding recurrence under OAC withdrawal is variable due to different GI and hepatic endoscopic findings, whilst 5-70% of patients experienced major GI bleeding requiring early intervention. Aspirin resumption was observed in 4/20 (20.0%) after haemostasis for PUD, whilst rebleding planning was documented on the endoscopy report in 33.0%. Regarding H. pylori, 51% under untreated H. pylori infection, 10 (36%) had positive resection of whom 7 (70%) received eradication. 12/25 (52.2%) patients underwent follow-up endoscopy following gastric ulcer. The median transfusion requirement per patient was 2 units. Despite this, rates of anemia at discharge and at 6 months were 83.5% and 62.9% respectively, with iron therapy initiated in 12.1%. Overall, our 30-day mortality rate was 12.1%.

Conclusion: In this single-centre study, the management of PUD could be improved in multiple areas in line with international guidelines. Audits in other centres are required to quality assure the management of PUD. Interestingly, rates of anemia at discharge and on follow-up are high. Such patients may benefit from iron replacement at discharge.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1159 AN AUDIT INTO THE MANAGEMENT OF BLEEDING PEPIC ULER BLEEDING

K. Siau1, A. Vijayasingham2
1Royal College Of Physicians, JAG Clinical Fellow, London/United Kingdom
2Postgraduate School of Medicine, Birmingham/United Kingdom

Contact E-mail Address: keithk@siau.org

Introduction: Peptic ulcer disease (PUD) accounts for 25–56% of acute gastrointestinal bleeding (AUGIB) and is associated with high mortality.

Aims & Methods: In line with international guidelines, we aimed to audit our practice of bleeding PUD at a district general hospital within the West Midlands, UK. We retrospectively identified all patients with AUGIB who had inpatient endoscopic confirmation of PUD between November 2012- 2014. We scrutinised case notes and endoscopy and case records to assess management related to PUD, in addition to follow-up records with the general practitioner.

Results: We identified 91 patients (median age 78.4, 65.9% male), of whom 63.7% were admitted with AUGIB, whereas 36.3% developed bleeding during their hospital stay. The major risk factors were female (74.7%) vs. male (25.3%), 31.8% were related to asprin/non-steroidal anti-inflammatory drug use. 48 (52.7%) had high risk ( Forrest 1a-2b) lesions, of whom 38/48 (79.2%) received dual endoscopic therapy and 6/49 (12.5%) received adrenaline mono-therapy, 18.8% received the recommended adrenaline volume of 15 mL. Of 90% prescribed intravenous proton pump inhibitor infusion, 85% did not complete the full 72-hour duration. Rebleeding occurred in 12 patients (13.2%) after a median of 3-days post endoscopy, 10 (83.3%) underwent repeat OGD 2 (16.7%) under- went CT embolisation, whilst 5 (25.0%) underwent surgery. Aspirin resumption was observed in 4/20 (20.0%) after haemostasis for PUD, whilst rebleding planning was documented on the endoscopy report in 33.0%. Regarding H. pylori, 51% under untreated H. pylori infection, 10 (36%) had positive resection of whom 7 (70%) received eradication. 12/25 (52.2%) patients underwent follow-up endoscopy following gastric ulcer. The median transfusion requirement per patient was 2 units. Despite this, rates of anemia at discharge and at 6 months were 83.5% and 62.9% respectively, with iron therapy initiated in 12.1%. Overall, our 30-day mortality rate was 12.1%.

Conclusion: In this single-centre study, the management of PUD could be improved in multiple areas in line with international guidelines. Audits in other centres are required to quality assure the management of PUD. Interestingly, rates of anemia at discharge and on follow-up are high. Such patients may benefit from iron replacement at discharge.

Aims & Methods: Data related to the three scoring systems were collected prospectively and scores calculated in consecutive patients who were admitted with acute UGHB to the Royal Adelaide Hospital over 24 months. The performance of these scoring systems was evaluated using the operating characteristic (ROC) curves, in predicting the outcomes was assessed: the need for endotherapy, rebleding risk, transfusion requirement, surgical intervention and death. All patients received high dose acid suppression therapy.

Results: Of the 777 patients (491M; 66.4±yrs) patients were treated conservatively due to medically unstable condition. 320 patients (41%) were referred to hospital for UGIB. Aims & Methods: There are several risk-scoring systems available to assist the management of upper gastrointestinal bleeding (UGIB). The aim of this study is to compare the performance of pre-endoscopy (pre-RS), post-endoscopy Rockall score (post-RS), GBS and AIMS65 scores in predicting the need for interventions and complications in patients admitted to hospital for UGIB.

Aims & Methods: Aims & Methods: Contact E-mail Address: waku-style@festa.ocn.ne.jp

Antral gastritis is commonly observed in clinics, especially after endoscopic operation. Besides from hemoclip, APC or electrocoagulation, more novel hemostasis approaches should be developed to improve endoscopic bleeding management. Granular smeicite is bioinert mineral and efficient for curing diarrhea. Inspired by its dehydration and tissue-covering effect, this pilot study was to investigate its efficacy and safety for controlling hemorrhage in rats.

Aims & Methods: Study design: A total of 30 male rats (Sprague-Dawley strain) were randomly divided into four equal groups. For hemorrhage model, a horizontal 10-mm incision was made on the lower part of the left hepatic lobe. Commercial hemostatic powder, smeicite, starch and normal saline were respectively applied. Bleeding duration and blood loss were recorded. 1 week later, rats were sacrificed and liver tissue was collected for histopathology. Results: Smeicite demonstrated the best hemostasis effect, and its mean coagulation time was 1.45 ± 0.026 min. Commercial hemostatic chitosan stycopic powder need 2.5 ± 0.04 min for complete clotting, while Starch group was 4.275 ± 0.056 min and 4% saline was 4.925 ± 0.108 min. Similarly, smeicite led to less blood loss (0.6188 ± 0.034 g), while rats lost 2.3288 ± 0.123 g blood (p < 0.05) under normal saline treatment. For starch and commercial chitosan, the blood loss was respectively 2.0862 ± 0.061 g and 1.9252 ± 0.0238 g. Histopathologic results confirmed that smeicite was biocompatible to tissue.

Conclusion: The mineral smeicite powder was the superior candidate for hemostasis treatment in vivo. Compared with common polysaccharide agents, smeicite could induce faster coagulation and reduce blood loss. More importantly, bioinert smeicite was biocompatible and even promoted the wound healing. For gastrointestinl application, smeicite powder could be delivered through endoscopic spray tube, while its inspiring efficacy required more endoluminal hemostasis tests.

Aims & Methods: Aims & Methods: Contact E-mail Address: dr_amr_hanafy@yahoo.com

Introduction: Life-threatening bleeding could occur early after variceal sclerotherapy in cirrhotic patients. Aims & Methods: We aimed to determine simple predictive factors of this complication in cirrhotic patients. Among 750 patients treated with variceal sclerotherapy (esophageal varices, EV) (605; 87.5%) and (gastroic varices, GV) (n = 95, 12.7%) Zagazig University hospital-endoscopy unit- Internal medicine department, in the period from October 2014 till July 2016. 150 patients (20%, mean age 46 ± 9.4 years) (EV = 129, GV = 21) developed bleeding due to sclerotherapy induced ulcers confirmed by endoscopy 6.4 ± 2.1 days after the procedure. Cirrhosis was post viral hepatitis C (89%), hepatitis B (10%) and cryptogenic in (1%). A case-control study was performed comparing these
patients with 150 patients who underwent endoscopic variceal sclerotherapy without the development of bleeding due sclerotic ulceration.

**Results:** Bleeding occurred 6.4±2.1 days (2–10) following sclerotherapy. Twenty-three patients died following the bleeding (15.3%). Using a multivariate analysis; pre-procedural factors as serum albumin <2 g/dl [OR 1.3], total bilirubin >1.6 mg/dl; and platelet ratio index (APRI) >1 [OR 1.2], low prothrombin concentration <50% [OR 1.5]. Intra-procedural factors as amount of ethanolamine >15.5 ml [OR 2.6], amicarate >3.5 ml [OR 2.9]. Post-procedural factors within 24 hours after endoscopy: leukocytosis >12,000 cell/µl [OR 1.9], drop of hemoglobin >10% of the pre-endoscopic value [OR 3.2], prolonged INR >1.55 [OR 1.2].

**Conclusion:** Bleeding related to sclerotic ulcers is not uncommon, but may be life threatening. The proposed predictive factors should be watched and minimized before and during variceal sclerotherapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

1. Carbonell N, Pauwels A, Serfaty L, Fourdan O, Levy VG, Poupon R. Functional gastrointestinal (GI) disorders (FGIDs) have been theorized to be a disorder of the brain-gut axis with both somatic markers (e.g., visceral pain or abnormal bowel habits) and psychological traits and only quite general GI symptoms. There remains a need for more accurate criteria to be established for FGID. In the current study, the aim was to test the predictive power of a series of psychological traits and whether this association remains stable depending on the criteria used to define FGID in those with weekly GORS was 43.9% (95% CI, 35.1–52.9%). The pooled OR for dyspepsia in individuals with weekly GORS, compared with those without, was 6.94 (95% CI 4.33 to 11.12). The OR for dyspepsia in weekly GORS was significantly higher in all geographical regions and significantly higher in those with the diagnostic criteria used. The pooled degree of overlap between the two conditions was 25.9% (95% CI, 19.9–32.4%), varying from 22% when the Bowel Disease Questionnaire was used to define weekly GORS, to 42.6% with the Mayo Reflux Disease Questionnaire. 

**Conclusion:** The OR of dyspepsia in individuals with weekly GORS was seven-fold that of individuals without GORS, and that there is overlap between the two conditions in up to one-quarter of individuals.

**Aims & Methods:** We conducted a systematic review and meta-analysis to estimate the prevalence of dyspepsia in individuals with gastro-oesophageal reflux symptoms, and to quantify the overlap between the two disorders. MEDLINE, EMBASE, and EMBASE Classic were searched (up until September 2016) to identify population-based studies reporting the prevalence of dyspepsia and GORD in adults (>15 years), defined using specific symptom-based criteria or a questionnaire. The prevalence of dyspepsia and weekly GORS were extracted for all studies. Pooled prevalence, according to study location and criteria used to define weekly GORS or dyspepsia, as well as odds ratios (OR), with 95% confidence intervals (CIs) were calculated. The degree of overlap between the two was examined.

**Results:** Of 14,132 papers evaluated, 79 reported prevalence of weekly GORS. Nineteen of these study populations, containing 111,459 participants, also reported the proportion of individuals with dyspepsia. The prevalence of dyspepsia in those with weekly GORS was 43.9% (95% CI, 35.1–52.9%). The pooled OR for dyspepsia in individuals with weekly GORS, compared with those without, was 6.94 (95% CI 4.33 to 11.12). The OR for dyspepsia in weekly GORS was significantly higher in all geographical regions and significantly higher in those with the diagnostic criteria used. The pooled degree of overlap between the two conditions was 25.9% (95% CI, 19.9–32.4%), varying from 22% when the Bowel Disease Questionnaire was used to define weekly GORS, to 42.6% with the Mayo Reflux Disease Questionnaire.

**Conclusion:** The OR of dyspepsia in individuals with weekly GORS was seven-fold that of individuals without GORS, and that there is overlap between the two conditions in up to one-quarter of individuals. Reasons for this remain speculative, but may include shared pathophysiological mechanisms or residual confounding.

**Introduction:** Few studies were reported on the association between sleep disorders and Rome III-based functional dysphagia (FD).

**Aims & Methods:** The aim of this study is to investigate the prevalence of sleep disorders in FD patients and the risk factors associated with sleep disorders. This multicenter, cross-sectional study had been conducted from August 2014 to December 2016 at 6 hospitals in Korea. Inclusion criteria were FD patients (>18years) met the Rome III criteria among the patients visited the gastroenterology department for dysphagia. Exclusion criteria were prior surgery to the upper gastrointestinal tract, history of ulcer disease, erosive GERD, history of malignancy, and severe comorbidity. Healthy control group who had no clinical history of gastroesophageal related disorder and no abnormal finding on endoscopy recruited from health examination center for screening. The Pittsburgh Sleep Quality Index was used to assess sleep disturbance. Hospital anxiety and depression scale was used to identify anxiety and depression.

**Results:** This study included 160 FD patients and 223 healthy control groups. The total Pittsburgh Sleep Quality Index score was higher in FD patients than health controls (7.8±4.3 vs 5.6±3.1, p = 0.000). The prevalence of sleep disorder was significantly higher in FD patients than healthy control (41.2% vs 18.8%, p = 0.000). In univariate analysis, FD was significant risk factor for sleep disorder (OR 3.12, p = 0.001). The independent risk factors for sleep disorder in multivariate analysis were FD (OR 1.80, p < 0.001), sleep apnea (OR 1.90, p = 0.026), female (OR 1.78, p = 0.028) and depression (OR 2.91, p = 0.001).

**Conclusion:** FD significantly impacted on sleep disorder. FD was independent risk factor in sleep disorder.

**Introduction:** Functional gastrointestinal (GI) disorders (FGIDs) have been theorized to be a disorder of the brain-gut axis with both somatic markers (e.g., visceral pain or abnormal bowel habits) and psychological ones. Exactly how abdominal and psychological disorders are related remains poorly understood. While there have been a small number of methodologically rigorous longitudinal studies that examine this question (1,2), even these have typically only studied a small number of psychological traits and only quite general GI symptoms. There remains a need for further longitudinal studies of how psychological traits predict subsequent FGID symptoms.

**Aims & Methods:** The present study is a longitudinal examination of the influence of a broad range of psychosocial predictors on later bowel-related and epigastric discomfort in a community sample. A sample of 188 individuals randomly sampled from the Australian electoral roll were surveyed, and, of them, 123 met Rome III criteria for irritable bowel syndrome (IBS) or functional dysphagia (FD) while 65 did not meet criteria for FGIDs. Subjects were of mean age 49 (SD = 15, range 20-87) and 73% were female. A broad range of psychological constructs (24 in total) were measured at baseline. Among them were anxiety, depression, somatization, childhood abuse, neuroticism, hypochondriasis, somatic vs psychological symptom attribution, coping, and social support. GI symptoms were measured 18 months later using two Likert-type scales: one concerning epigastric pain and the other concerning bowel symptoms. Exploratory factor analysis (EFA) was used as a data-reduction technique to create a smaller number of composite predictors. Statistical analysis was based on ordinal regression.

**Results:** Ten composite scores were derived via EFA to be examined as predictors of bowel symptoms (N =188) a number of psychosocial traits (e.g., general life worry, non-sexual childhood abuse, psychological symptom attribution and childhood sexual abuse; see Table 1) were individually related to subsequent bowel symptom severity 18 months later (Table 1). There was evidence of variation in psychosocial predictors of gastrointestinal symptoms between individuals who met and did not meet criteria for IBS or FD. With respect to bowel symptoms, no psychological trait reached statistical significance.
as a predictor among individuals with FGIDs (Table 1). Epigastric symptom severity was predicted by worry and psychological attribution of symptoms among FGID individuals but no psychological trait predicted symptom severity among non-FGID individuals (Table 1).

Conclusion: A range of psychosocial factors predict later gastrointestinal symptom burden. For bowel symptoms, associations between psychological traits and symptom burden appear to be most clearly driven by the non-FGID subgroup, among whom psychological attributions for symptoms and problem-focused coping are positively related to later symptom burden. For epigastric symptoms, a range of psychological traits were relevant, with the predictive patterns being most clearly driven by individuals who qualified for FGIDs. In light of these results, studies of the brain-gut axis need to consider a greater array of psychological traits, particularly outside of anxiety and depression. Further, the complexity of associations between psychological traits and gastrointestinal symptoms may be moderated by symptom level but are relatively similar across upper and lower gastrointestinal symptoms.

Introduction: In the recent years, there has been an increasing recognition of the presence of gastrointestinal (GI) dysfunction in patients with neurologic diseases. There are no studies examining a relationship between psychological traits and gastrointestinal symptoms in patients with neurologic diseases and symptoms in their personal and family history. Those with a suspicion of a neurological disease were referred for a detailed clinical resolution manometry, endoscopy and esophagogram. A total of 140 consecutive patients with a neurodegenerative/demyelinating disease were examined (28%) described dysphagia as a symptom of their personal history. These patients will be examined by esophageal manometry.

Conclusion: Our results imply an increased prevalence of neurodegenerative/demyelinating diseases in patients with achalasia (3.6% vs. approx. 1.4% in the Czech controls). Also, a high prevalence of dysphagia was found among patients with a neurodegenerative/demyelinating disease. These results warrant further confirmation in a large population-based study.

Introduction: Visceral pain is a complex percept influenced by numerous factors. Of these, differences in the autonomic nervous system (ANS)-in particular, parasympathetic cardiac vagal tone (CVT)-has been suggested to have a physiological role in the regulation and modulation of painful sensory signalling, to the extent of vagal nerve stimulation (to raise subject CVT) being tested as a possible anti-nociceptive.

Aims & Methods: To date, no studies have explored the brain functional connectivity or network properties of CVT in relation to a painful stimulus, and thus this was our aim. In 21 healthy participants (10 male; mean age 30 years (range 21-53 years), we quantified resting CVT using a Neuroscope. For all subjects, functional MRI data were acquired using a 3T MRI scanner during painful oesophageal balloon distension, as described elsewhere(). The effect of resting CVT on brain networks during acute oesophageal pain were determined by means of network based statistics(). Brain nodes were selected a priori of previous autonomic/visceral pain literature and included the following: bilateral anterior insula, amygdala, insula, pallidum, thalamus and single hypothalamus (nodes = 31). Blood oxygen level dependant (BOLD) signal during oesophageal balloon distention to pain tolerance threshold was extracted from each of these regions and cross-correlated to produce nodal correlation maps. The results were then expressed by means of median split based upon resting CVT value, and a two-tailed t-test of was undertaken. A primary threshold was applied (t=1.65; p<0.05) and permutation tested 50,000 times to ensure statistical stringency applied.

Results: We identified a unique subcortical brain connectivity network in the high resting CVT individuals when exposed to acute oesophageal pain. This complex symmetrical network comprised all 11 nodes with a total of 18 edges (significant

When considered jointly with other predictors, psychological attribution of symptoms was significantly positively related to both bowel symptom severity (non-FGID: OR = 0.31, SE = 0.13; Full: OR = 0.74, SE = 0.11) and epigastric symptom severity (FGID: OR = 0.63, SE = 0.09; Full: OR = 0.63, SE = 0.11). The same was the case for worry (Bowel: Full: OR = 1.40, SE = 0.21; Epigastric: FGID: OR = 1.58, SE = 0.27; Full: OR = 1.54, SE = 0.23). For bowel symptoms, problem-focused coping (OR = 2.30, SE = 0.98) was an additional independent positive (notably, not negative) predictor among participants without FGIDs.

*P < 0.05, **P < 0.01, ***P < 0.001.
functional connections). These interconnections included the following: thala-
mus-amygdala, thalamus-hypothalamus, hypothalamus-NAc, amygdala-pu-
tamen amygdala-NAc and insula-putamen. No significant network was identified for the low CVT group.

Conclusion: During acute oesophageal pain, resting cardiac vagal tone yields a unique combination comprising numerous complex subcortical brain
regions, many of which have been previously reported with either visceral pain or modulation of baseline autonmics either at the physiological or neuroana-
tomical level (3). Previous research has suggested that a high resting CVT may be
protective of noxious signaling, and furthermore studies investigating vagal
nerve stimulation have included and report that of anti-nociception (4). Given
the well-established role of these subcortical regions in pain processing, we
suggest that this network identified may be of significance as to the neurophysi-
ological process of parasympathetic modulation of painful sensory
signalling. Lastly, to date, no studies have undertaken real-time assessment of the ANS
(including CVT) during functional brain imaging and acute visceral pain.
Future studies should investigate for this.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1170 RAPID DRINK CHALLENGE (RDC) TEST DURING
OESOPHAGEAL HIGH RESOLUTION MANOMETRY (HRM) IN
PATIENTS WITH OESOPHAGO-GASTRIC JUNCTION OUTFLOW
OBSTRUCTION
D. Biasutto, F. Mion, A. Garros, S. Roman
Digestive Physiology, Lyon I University and Hospices Civils de Lyon, Lyon;France

Contact E-mail Address: d.biasutto@unicampus.it

Introduction: Oesophageo-gastric junction outflow obstruction (OGJOO) is of
unknown significance. It may be secondary to an incomplete form of achalasia,
a mechanical obstruction or be idiopathic. Rapid drink challenge (RDC) test is
easy to perform during oesophageal HRM.

Aims & Methods: We aimed to assess the yield of RDC in patients with OGJOO.
From a database of 3226 consecutive oesophageal HRM performed from 01/
2012 to 03/2017, we extracted patients with OGJOO according to the Chicago
Classification V3.0. HRM protocol consisted of 10 ml water swallows in supine
position and RDC test (200-ml free drinking) in sitting position. Distal contrac-
tile integral (DCI) integrated relaxation pressure (IRP), distal and pan-oesopha-
gal pressure pulsation (POP); homogeneous oesophageal pressure pulsation >30 mmHg
were reported for 3 ml swallows. POP and oesophageal shortening (OS)
were analysed during RDC. Symptom severity was assessed with Eckardt score.
Causes of OGJOO were determined by reviewing patients’ chart for previous
history, complementary work up and treatment. Quantitative data were
expressed as median (range) and qualitative data as percentage. They were com-
pared using non parametric and Chi square tests.

Results: 75 patients (29%) (29 males, mean age 62 years (25–92)) were included.
The dominant symptom was dysphagia (69%), regurgitation (9%), chest pain
(5%), other (13%), no symptom (3%). The causes of EGJOO were previous
oesophageo-gastric surgery (43%), incomplete achalasia (7%), mediastinal neo-
plasia (7%), miscellaneous (19%) and unknown (25%). RDC test was success-
fully performed in 70 patients (93%) and associated with POP and OS in 41% and
15% respectively. Dysphagia as dominant symptom was more frequent (79% vs
59%, p = 0.0157) and more severe (Eckardt score 5 [1–11] vs 3 [0–10], p = 0.01)
in patients with POP during RDC compared to those without. The same obser-
vation was achieved in patients with OS vs those without (dysphagia 100% vs 62,
p = 0.02 and Eckardt score 6 (2–10) vs 1 (0–11), p = 0.02). Manometric para-

Manometry parameters
Mean % ineffective peristalsis 15% 28%
Mean % ineffective peristalsis 12% 23%
Mean % ineffective peristalsis 11% 25%
Mean % ineffective peristalsis 14% 25%
Mean % ineffective peristalsis 16% 27%
Mean % ineffective peristalsis 18% 28%
Mean % ineffective peristalsis 19% 29%
Mean % ineffective peristalsis 20% 30%
Mean % ineffective peristalsis 22% 31%
Mean % ineffective peristalsis 24% 33%
Mean % ineffective peristalsis 26% 34%
Mean % ineffective peristalsis 28% 35%
Mean % ineffective peristalsis 30% 36%
Mean % ineffective peristalsis 32% 37%
Mean % ineffective peristalsis 34% 38%
Mean % ineffective peristalsis 36% 39%

Conclusion: While RDC test cannot be used to determine EGJOO cause, patients
with POP or OS during RDC had more severe dysphagia than those without.
In patients with POP, the highest DCI might be secondary to obstruction. Further
prospective studies should determine if RDC test could help to select patients
who might benefit from treatment.

Introduction: The Chicago Classification (CC V3.0) defined ineffective esophageal motility (IEM) by the presence of 50% or more of weak or failed peristaltic waves during high resolution manometry (HRM). Both low-volume (10ml) multiple rapid swallow (MRS) and high-volume (200ml) rapid drinking test (RDT) have been suggested as test to recognize the esophageal peristaltic reserve. Which test might better represent the esophageal peristaltic reserve is still a matter of discussion.

Aims & Methods: The aim of this study was to compare the diagnostic value of MRS and RDT in patients with IEM. From a larger group of patients evaluated for heartburn, weak/weak with poor response to standard dose proton pump inhibitors, we enrolled consecutive patients with IEM and with functional heartburn (FH). FH were enrolled as controls. IEM was defined according to the CC V3.0. All patients underwent 3 MRS (10ml of water in 5 swallows in less than 10s) and 1 RDT (200ml of water freely drunk). All patients underwent 24h impedance and pH recording (MII-pH). Mean DCI of MRS and DCI of RDT were compared with mean DCI of 10 single swallows (SS). The MRS/SS and RDT/SS ratio were calculated.

Results: We evaluated 30 patients with IEM (18 males and 12 females; mean age 45.7 ± 11.4 yrs) and 30 patients with FH (15 males and 17 females; mean age 41.2 ± 13.6 yrs). The MII-pH showed higher acid exposure time (AET) and number of reflux events in IEM than in FH (p < 0.05). Mean DCI of SS resulted lower in patients with IEM compared to FH (p < 0.05). One-hundred and eighty MRS and 60 RDT were evaluated. DCI of MRS was lower than 450 mmHg·s·cm in 77% (23/30) of IEM patients, and in 50% (15/30) of FH patients. DCI of RDT was lower than 450 mmHg·s·cm in 7% (6/90) of FH patients. A comparison of the esophageal body inhibition during multiple swallows test showed that if definition was contrasted identifying >3 cm using the 30mmHg isobaric contour tool.

Conclusion: We evaluated 30 patients with IEM (18 females; mean age 49.5 ± 12.4 yrs) and 30 patients with FH (17 females; mean age 41.2 ± 13.6). Impedance and pH 24h-analysis was performed to select patients with FH (normal AET and number of reflux and lack of reflux-symptom correlation). During HRM the mean DCI resulted similar in patients with EGJ-OO compared to FH (p > 0.039). One-hundred and eighty MRS and 60 RDT were evaluated. The lack of body inhibition was found in 11% (20/180) in MRS and in 53% (16/30) in RDT in EGJ-OO. No patients in FH showed lack of body inhibition during both MRS and RDT. All results are reported in Table 1.

Introduction: Esophageal motor dysfunction and abnormal bolus transit are often encountered on high resolution impedance manometry (HRIM) performed prior to anti-reflux surgery (ARS) in gastroesophageal reflux disease (GERD). Esophageal motor dysfunction can be characterized using established software tools embedded in HRIM software, while new paradigms of interrogation of bolus presence and flow have been introduced with automated pressure flow analysis (PFA). The prevalence, and clinical relevance of these motor and bolus flow abnormalities to symptom presentation or symptom outcome from ARS are incompletely understood.

Aims & Methods: Our aim was to evaluate the interrelations between esophageal motor function and bolus transit using varying bolus consistencies, in health and in the context of symptomatic GERD prior to ARS. HRIM studies (Medtronic, Duluth, GA) from 18 controls (28.4 ± 7.1 yr, 50% F) and 86 GERD patients (56.2 ± 8.7 yr, 58% F) were reviewed, all of which were performed using 5 mL water (10 swallows), 5 mL viscous (5 swallows) and 1 cm³ bread boluses (2 swallows). All controls were asymptomatic; all GERD patients completed symptom questionnaires evaluating dominant and secondary symptoms using 5 point Likert scales for symptom frequency and severity (0 = none, 4 = frequent.

Conclusion: Patients with EGJ-OO showed less peristaltic reserve during MRS and RDT. The RDT evidenced more frequently lack of body inhibition in patients with EGJ-OO.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1174 ESOPHAGEAL BOLUS FLOW METRICS ON PRESSURE FLOW ANALYSIS (PFA) OF ESOPHAGEAL HIGH RESOLUTION IMPEDANCE MANOMETRY (HRIM) IN GASTROESOPHAGEAL REFLUX DISEASE (GERD)
**HMR metrics with comparisons between wet swallows in controls and patients, and between wet and solid swallows among patients.** *p < 0.05 *** p < 0.001 ** p < 0.01

**Introduction:** Oesophageal diverticula are rare diverticula of the gastrointestinal tract known to be associated with oesophageal motor disorders.

**Aims & Methods:** The aim was to study manometric abnormalities associated with oesophageal diverticula, using both wet and solid swallows. Patients underwent high resolution oesophageal manometry (HREM) in the upright position. 18 patients with oesophageal diverticula were found and were free of previous surgery. Traction diverticulism was excluded in all patients. We also included 10 healthy controls. HREM was performed using wet (5 mL of water) swallows in both groups, followed by solid (meat) swallows in patients. Mean age of the controls was 50 years old while for patients was 47 years old.

**Results:** The main reported symptom was dysphagia (76%). HREM found 11 (61%) patients with an oesophageal motor disorder, including 2 oesopha-gastric junction outflow obstruction (OGJOO), 4 achalasia (subtype 2: n = 2; subtype 3: n = 2), 4 distal oesophageal spasm (DES) and 1 jackhammer oesophagus, and was normal in 7 (39%) patients. In those patients with normal findings, solid swallows identified 4 (57%) additional motor disorders, including 2 OGJOO, 1 jackhammer oesophagus and 1 DES. Provocative testing using solid swallows doubled the diagnostic yield by 22% in overall patients and by 57% in patients with normal manometry using wet swallows only. Mean pressure slopes at mid-oesophagus and oesophageal diverticulism were greater in patients than healthy controls (p < 0.05 for wet swallows), as previously reported. Other metrics are summarized in the table.

**Conclusion:** While more than one-third of HREM using wet swallows were normal, provocative testing using solid increased the diagnostic yield of the procedure by more than 50% in these patients. Analysis of pressure slopes confirmed the association of propagating peristalsis with the disease.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The management of achalasia targets relieving the obstruction at the esophagogastric junction (EGJ) by pneumatic dilatation (PD), laparoscopic Heller myotomy (LHM) plus a fundoplication variant (Dor, Toupet, and more rarely Nissen/Nissen-Rossetti). However, effective ablation of the LES barrier can induce gastroesophageal reflux disease (GERD). Recently, new metrics to evaluate EGJ function with high resolution manometry (HRM) have been introduced, such as EGJ contractile integral (EGJ-CI). Currently there are few data investigating how achalasia treatments impact EGJ function based on these metrics.

**Aims & Methods:** We aimed to assess the EGJ-CI metric in achalasia before and after different treatments, to verify if post-operative changes in this metric correlate to symptom relief and iatrogenic GERD following surgical treatments. Methods Between 2014 and 2015, we enrolled consecutive achalasia patients. All patients underwent clinical evaluation with Eckardt and GERDQ score, as

**Introduction:** The management of achalasia targets relieving the obstruction at the esophagogastric junction (EGJ) by pneumatic dilatation (PD), laparoscopic Heller myotomy (LHM) plus a fundoplication variant (Dor, Toupet and more rarely Nissen/Nissen-Rossetti). However, effective ablation of the LES barrier can induce gastroesophageal reflux disease (GERD). Recently, new metrics to evaluate EGJ function with high resolution manometry (HRM) have been introduced, such as EGJ contractile integral (EGJ-CI). Currently there are few data investigating how achalasia treatments impact EGJ function based on these metrics.

**Aims & Methods:** We aimed to assess the EGJ-CI metric in achalasia before and after different treatments, to verify if post-operative changes in this metric correlate to symptom relief and iatrogenic GERD following surgical treatments. Methods Between 2014 and 2015, we enrolled consecutive achalasia patients. All patients underwent clinical evaluation with Eckardt and GERDQ score, as
well as upper endoscopy, barium esophagogram and HRM before and 6 months after treatment. Achalasia was classified according to the Chicago Classification V3.0. The EGJ-C1 was calculated using the distal contractile integral tool-box during three consecutive respiratory cycles. Patients underwent to pneumatic dilatation (PD), or LHM plus a Dor (LHM-D), Toupet (LHM-T) or a Nissen-Rossetti (LHM-NR) fundoplication. Ethical approval for the study was obtained.

Results: We enrolled 35 achalasia patients (14 Type I, 16 Type II and 5 Type III). Ten patients underwent PD, 11 LHM-D, 8 LHM-T and 6 LHM-NR. At baseline, none of patients had GERD manometry score, age, sex, pre-operative mean Eckardt score, GERDQ score, integral relaxation pressure (IRP) and EGJ-C1 were recorded. All Type III subjects underwent LHM-D (3) and LHM-T (2). After all the procedures, in all the patients there was a significant decrease in Eckardt score, IRP and EGJ-C1 (p < 0.01) and < 0.05, respectively). PD and LHM-NR showed higher EGJ-C1 (20.9 ± 3.2 and 23.5 ± 11.1 mmHg·cm, respectively) and IRP (12.2 ± 3.4 and 13 ± 4.5, respectively) than LHM-D and LHM-T (18.4 ± 5.9, p < 0.05 and 9.3 ± 4.1 p < 0.05 mmHg·cm, respectively for EGJ-C1; 5.2 ± 2.5 p < 0.005 and 2.3 ± 3.7 p < 0.01 mmHg·cm, respectively for IRP). Post-operative Eckardt score was lower in LHM-D and LHM-T (2.1 ± 0.5 and 2.5 ± 0.6, respectively) than PD and LHM-NR (4.2 ± 1.0, p < 0.01 and 3.7 ± 1.5, p < 0.05). Post-operative GERDQ score was significant higher in LHM-T (3.0 ± 1.7 vs. 8.2 ± 3.9, p < 0.005). Low post-operative EGJ-C1 values correlated with an increased risk of higher post-operative GERDQ score (p < 0.05, odds ratio 4.223, 95% CI 0.964–2.123).

Conclusion: All procedures performed to treat achalasia produced an adequate relief of dysphagia. LHM-D and LHM-T seemed to result in a stronger alteration of the EGJ with LHM-T resulting in an increased risk of post-operative reflux.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1177 MULTIPLE RAPID SWALLOWING IN JACKHAMMER ESOPHAGUS PATIENTS: EVIDENCE FOR ALTERED NEURAL CONTROL

A. Mauro1, S. Tolone1, E. Savarino2, N. De Bortoli2, M. Franchina3, R. Barabino3

3Division of Gastroenterology, Department of Surgery, Oncology and Gastroenterology, University of Padua, Padua/Italy

Contact E-mail Address: aURELIO.MAURO88@gmail.com

Introduction: Jackhammer esophagus is a rare esophageal motility disorder. Little is known about its physiopathology; however, an excess of cholinergic drive has been suggested as an important etiologic factor.1 Multiple rapid swallowing (MRS) is an adjunctive test in order to evaluate integrity of inhibitory and excitatory neural pathways. In healthy subjects body motor inhibition is observed during MRS and a contraction stronger than single swallows (SS) occurs after MRS, the so-called peristaltic reserve (MRS/SS DCI ratio > 1). In patients with nutcracker esophagus preservation of motor inhibition during MRS has been described with traditional manometry.2 No study has evaluated peristaltic reserve and motor inhibition with high-resolution manometry (HRM) in patients with jackhammer esophagus.

Aims & Methods: To evaluate MRS in a consecutive multicenter series of 42 Jackhammer esophagus patients (18 Male; 63 years; 55–71) according to Chicago 3 classification. 18 healthy subjects (HS) (seven male; 28 years; 23–33) from a published series were used as a control group.3 All patients underwent solid state HRM with ten 5 ml SS and one to three 10 ml MRS (30 patients performed at least two MRS). Standard HRM parameters during SS were evaluated. During MRS presence/absence of motor inhibition and 4 second integrated relaxation pressure (4 sec IRP) were evaluated. After MRS distal contractile integral (DCI) was evaluated and DCI ratio between MRS and SS was measured. Mann Whitney, Wilcoxon and chi-squared tests were used when appropriate; data are shown as median-IQR range.

Results: Descriptive data in jackhammer patients are shown in table 1. Twelve patients did not have motor inhibition during at least one MRS (28% vs 5% in HS, p < 0.05). There was a trend toward a lower 4 sec IRP during MRS compared to SS (see table 1); however, values were higher than those of 4 sec IRP MRS in HS (5.1 mmHg; 2.2–11 vs 1.6 mmHg; 0.3–2, p < 0.0001). MRS DCI was significantly lower than SS DCI, interestingly 26 patients had a MRS/SS DCI ratio < 1 (62% vs 22% in HS, p < 0.0005) and it was lower than the MRS/SS DCI ratio of HS (0.8; 0.4–1.1 vs 1.9; 1.1–2, p < 0.0001) suggesting a reduction of the hypercontractile activity in the esophageal body.

HRM parameters during single and multiple rapid swallows in jackhammer patients. Median; interquartile range.

<table>
<thead>
<tr>
<th>SS</th>
<th>MRS</th>
<th>p value</th>

</tr>
</tbody>
</table>

Conclusion: Contrary to what occurs in healthy subjects, MRS reduce DCl value compared to SS in jackhammer esophagus patients, suggesting altered neural control of peristalsis. Differently to what previously observed with traditional manometry, motor inhibition during MRS is altered in a quarter of patients.

P1178 GASTRIC PERORAL ENDOSCOPIC MYOTOMY (G-POEM) AS TREATMENT FOR FUNCTIONAL DELAYED DYSPEASIA: INITIAL ASIAN EXPERIENCE

M. Cai1, J. Xu2, P. Zhou3
1Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China
2Division of General and Bariatric Surgery, Department of Translational Research and New Technology in Medicine and Surgery, University of Pisa, Casinello Hospital, Pisa/Italy

Contact E-mail Address: cai.mingyan@zs-hospital.sh.cn

Introduction: Functional delayed gastric emptying is a difficult-to-treat disorder, which is often expressed clinically as nausea/vomiting, fullness/early satiety, bloating and weight loss. Gastric peroral endoscopic myotomy (G-POEM) has been regarded as a novel and minimally-invasive therapy for functional delayed gastric emptying refractory to medical therapy. We herein report our initial experience of G-POEM in an Asian population with focus on technique in addition to safety and efficacy of this promising endoscopic therapy.

Aims & Methods: The data of consecutive patients who underwent G-POEM by a single expert endoscopist from October 2015 to November 2016 was collected. Procedures were performed, similar to POEM for achalasia, including initial mucosal incision, creating a submucosal tunnel, full-thickness (pyloro)myotomy, and closure of the mucosal entry. Patient demographics, etiology, Gastroparesis Cardinal Symptoms Index (GCSI) and gastric emptying scintigraphy (GES) were recorded before and after the procedure. Treatment outcomes and procedure related adverse events were also evaluated.

Results: A total of fourteen patients with refractory functional delayed gastric emptying, including eleven post-surgical (78.6%) and three diabetic (21.4%), were enrolled. The median age was 60 (range, 26–82) years. All patients were suffering from nausea, vomiting, bloating and weight loss. They all failed medical therapy including proton pump inhibitor, metoclopramide, mosapride, or domperidone. All fourteen patients underwent G-POEM successfully (100%) with the mean procedure time of 43.71 ± 13.08 mins. Gastric emptying scintigraphy (GES) was performed in five patients with improvement of mean half empty time (191.88 ± 83.19mins vs. 91.44 ± 32.92mins), and retention at 2 hours (70.02 ± 12.68% vs. 33.48 ± 20.32%). The median hospital stay after procedure was 6 days (range, 4–10). No procedure related adverse event (0%) was observed. During a median follow-up of eight months (range, 3–17.5 months), one patient (post-surgical) had symptom recurrence after 45 days by the procedure because of stenosis related to scan formation. One of the two diabetic patients with severe diabetes and diagnosis as diabetic peripheral neuropathy showed little response to G-POEM, while the GCSI was 54 before and 29 after. The other showed initial improvement with GCSI score 22 before and 10 after the first follow-up. However, his symptoms reoccurred seven months after G-POEM and the latest GCSI score was 19. Overall GCSI after G-POEM (mean, 5.00 ± 2.57) decreased significantly comparing with the one before (mean, 22.55 ± 3.42).

Conclusion: G-POEM is a promising new endoscopic treatment option for functional delayed gastric emptying. Our initial data suggest it is safe and effective. Large studies are needed to determine safety, efficacy, long-term outcomes and determine which patient population benefits the most from this treatment option.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI179 EFFECTIVENESS OF CAP-ASSISTED DEVICE IN THE ENDOSCOPY MANAGEMENT OF FOOD BOLUS OBSTRUCTION IN THE UPPER ESOPHAGUS

M. Ooi, E. J. Young, N. Q. Nguyen
Department Of Gastroenterology And Hepatology, Royal Adelaide Hospital, Adelaide/Australia/SA

Contact E-mail Address: marieool_au@yahoo.com

Introduction: Although cap-assisted technique has been shown to be effective in removing food bolus from the upper gastrointestinal tract, there is no data on food bolus obstruction (FBO). This study aimed to assess the performance of cap-assisted technique in the management of esophageal FBO, as compared to conventional endoscopic methods.

Aims & Methods: Records of all patients who present with FBO requiring emergency endoscopic management between 2011 and 2016 were prospectively collected. The main measured outcomes were procedural success, procedural time, complications and length of hospital stay.

Results: Patients (214M:183F; 18.3±18.3 years) with FBO, 267 (84.7%) had evidence of food bolus in the esophagus on endoscopy and 48 (15.2%) patients had spontaneous passage of bolus food. Out of the 199 patients who had impacted FBO, 93 had cap-assisted technique and 106 had conventional approach, with no differences in the type and location of FBO. The success rate of cap-assisted technique (100%) was comparable to that of conventional techniques (97.2%, P=0.10). Patients who had failed extraction by conventional techniques (n=3) were successfully treated when switched to cap-assisted approach. Cap-assisted approach was associated with a shorter total procedural time (34.8±22min, P=0.006), a shorter length of hospital stay (0.95±0.36 and 1.38±1.36 days, P=0.0017) and more en-bloc removal (98% vs 22%, P<0.001). There were more complications in the conventional than the cap-assisted group (7/106 vs. 0.93; P=0.01).

Conclusion: Cap-assisted technique is 100% effective in the management of impacted FBO in the esophagus, with a significantly shorter procedural time and hospital stay. Although the findings suggest that cap-assisted technique should be the first line technique in the management esophageal FBO, further evaluation with a randomized multicenter trial is warranted.

2Gastroenterology And Hepatology, Gamma University Hospital, Gamag/Japan

Contact E-mail Address: yshimada@juntendo.ac.jp

Introduction: Functional dyspepsia (FD) is defined that there is no evidence of organic disease which is likely to explain the symptoms. However, there was no obvious definition about “organic disease”. Therefore, during the endoscopic examination, we do not think that we can justly consider the esophageal findings like gastric erosion fulfill the exclusion criteria or not. Indeed, this issue was pointed out that there is notable inconsistencies in the exclusion criteria of FD (1). Recently, the Kyoto classification of gastritis has been published and used worldwide for the management of gastritis in Japan (2). In this classification, endoscopic findings are defined precisely. However, it is not discussed whether we can consider such findings as the “organic disease” or not. If these findings have no relationship with FD symptoms, we can diagnose patients group as FD even if they have such endoscopic findings.

Aims & Methods: The aim of this study is to explore which endoscopic findings defined in the Kyoto classification of gastritis bring FD symptoms. To assess the symptoms of patients, we employed the Modified-FSSG (frequency Severity Symptom Questionnaire) (3). Symptoms of GERD questionnaire (m-FSSG) (3), which was developed for evaluation of dyspeptic symptoms in patients. It comprised 14 symptoms and was rated on a scale of zero to four in each question. This questionnaire is useful for the Symptoms of Patients with gastroesophageal reflex disease to distinguish functional dyspepsia from non-erosive reflux disease. J. Gastroenterol Hepatol. 27: 1187-91. 2012.

Results: This study included 55 subjects in FD group and 200 subjects in Control group. The ratio was statistically lower in men than women in FD group than in Control group (43.6% vs. 61.0%, P=0.02). Atrophy (16.6% vs. 30.4%, P=0.01), spotted redness (9.1% vs. 23.0%, P=0.02), hyperplastic polypl (9.0% vs. 0%, P=0.016), were frequently seen in Control group than in FD group.

RAC (43.0% vs. 67.3%, P=0.002) were frequently seen in Control group than in FD group. Multivariate logistic regression (stepwise selection) showed that age (under 65 years old) (OR 2.427, 95%CI 0.209-8.12, p=0.01) and RAC (OR 2.123, 95%CI 0.206-8.21, p=0.012) were related to FD. None of the findings of gastritis examined were related to FD.

Conclusion: It is revealed that endoscopic gastritis is NOT related to FD symptoms.

Introduction: There was not available data about the overlap between functional dyspepsia (FD) and pancreatic diseases.

Aims & Methods: We aimed to determine whether epigastric pain syndrome (EPS) accompanying with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by Japan Pancreas Society (JPS) using endosonography. We enrolled 99 consecutive patients presenting with typical symptoms of FD, including patients with postprandial distress syndrome (EPS grade 3) were almost equally distributed among EPS patients with pancreatic enzyme abnormalities (n=41) and EPS patients without pancreatic enzyme abnormalities (n=42) based on Rome III criteria. Gastric motility was evaluated using the ¹⁸-Ceretate breath test. Early chronic pancreatitis was detected by endosonography and graded from 0 to 7.

Results: The ratio of female patients among EPS patients (34/41) with pancreatic enzyme abnormalities was significantly (p=0.0018) higher than the ratio of female EPS patients (20/42) without it. Postprandial abdominal distention and physical component summary (PCS) scores in EPS patients with pancreatic enzyme abnormalities were significantly (P<0.001) increased compared to those in EPS patients without it. Interestingly, AU C₀ and AU C₆₀ values (24.85±1.31 and 56.11±1.25, respectively) in EPS patients with pancreatic enzyme abnormalities were also significantly (p=0.002 and p=0.001, respectively) increased compared to those (19.75±1.01 and 47.02±1.99, respectively) in EPS patients without it. Overall, 64% of EPS patients with pancreatic enzyme abnormalities were diagnosed by endosonography as having concomitant early chronic pancreatitis proposed by JPS.

Conclusion: Further studies are warranted to clarify how EPS patients with pancreatic enzyme abnormalities were associated with early chronic pancreatitis proposed by JPS.

Introduction: Caustic esophageal injury is corrosive burns of esophagus and mostly caused by ingestion of chemical caustic substances such as strong acid or alkali. The caustic esophageal stricture is refractory and patients suffered from multiple clinical. Causal ESID revealed that benign stricture would be usually caused by more than 75% mucosa loss of circumferential esophagus. Cultured skin tissue was effective for wound healing and preventing undesired fibrosis. We hypothesized that autologous esophageal mucosa transplantation might inhibit refractory fibroplasia and delay the recurrence of esophageal strictures.

Aims & Methods: A man presented with the caustic esophageal stricture (32–40 cm from the incisors), which was caused by accidental exposure of anhydrous acid (H₂SO₄). Under X-ray, routine endoscopic dilation was firstly applied to a diameter of 1.28 cm. Three days later, with the informed consent, ESID operation was utilized to dissect 570.5 cm normal esophageal mucosa at the 18–23 cm location from the incisors. Macosal defect was cured by fibrin glue after Argon plasma coagulation. Under endoscopic surveillance, the excised mucosa was transplanted to the surface of the narrowed segment and fixed with 3 titanium clips.
Conclusion: The endoscopic follow-up was planned every month. After 1 months, 18-23 cm esophageal region has healed to be normal. Within 6 months, the stricture process was excitingly delayed as expected. The patient stated his symptom was remarkably improved. Gastroscopy revealed the esophageal implanted lesion was covered with an epithelium and the lumenal surface was flat, without ulceration.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Functional dyspepsia (FD) is commonly associated with sleep disturbance, which has been attributed to comorbid anxiety, depression and bother-some gastrointestinal symptoms. However, it is unclear whether obstructive sleep apnea (OSA) is specifically associated with FD.

Aims & Methods: We aimed to compare the prevalence of FD in patients with OSA and healthy volunteers. A total of 60 consecutive OSA patients (defined as Eposworth sleepiness scale > 10, and apnea-hypopnea index > 10/hour during polysomnography for age: 47.6 years, [SD 16.7 years]; 60 healthy age-and sex-matched volunteers were recruited in a prospective case-control study. Questionnaires were applied for the diagnosis of functional gastrointestinal disorders (FGIDs) according to Rome III criteria. Anxiety and depression were evaluated using the Hospital Anxiety and Depression Scale (HADS), sleep quality was evaluated by the Pittsburgh Sleep Quality Index, and fatigue was assessed by the Multidimensional Fatigue Inventory (MFI-20) Chinese version.

Results: The prevalence of FD was 28.3% and 8.3% (17 vs 5, P = 0.005), and the prevalence of symptomatic gastro-oesophageal reflux disease was 18.3% and 5% (17 vs 3, P = 0.023) in the OSA group and healthy volunteer group, respectively. OSA patients had higher anxiety and depression symptom scores, worse sleep quality, and more fatigue compared with healthy volunteers. In the multivariate logistic regression analysis, age, sex and BMI were predictor variables for FD diagnosis. In the case-control study, anxiety and depression symptom scores, the HADS depression subscale score, the MFI-20 fatigue subscale score, the Pittsburgh Sleep Quality Index total score, and the Hospital Anxiety and Depression Scale total score were significantly higher in the OSA group compared to healthy volunteers. The association of FD with OSA was not different after adjusting for the above-mentioned variables.

Conclusion: To our knowledge, this is the first study showing that OSA is independently associated with functional dyspepsia. Sleep disturbances previously attributed to psychological comorbidities in FGID may in fact arise from undiagnosed OSA. We recommend screening for OSA as part of the management of FD.

Introduction: The assessment of acid secretion is important in order to prescribe PPIs. The gold-standard to measure the maximal acid output (M.A.O.) is the collection of gastric after an i.m. injection of pentagastrin. However, this method is not currently used in clinical practice. Serum pepsinogen I (PGI) has been proposed as a non-invasive surrogate. Aim of this study was to compare in a group of patients with different acid related diseases serum levels of PGI and M.A.O.

Aims & Methods: We enrolled 124 patients (M = 84, mean age = 45.3 +/− 13.05 years; 68 DM patients). Of the 36 non-DM patients with severe endoscopic GERD, 30 patients (83.3%) had positive GSRS score of acid regurgitation; however, of the 40 DM patients with severe endoscopic GERD, 19 patients (47.5%) had positive GSRS score of acid regurgitation. The prevalence ratio of patients with positive GSRS score in severe endoscopic GERD was statistically lower in DM patients than in non-DM patients (p = 0.0016).

Conclusion: There is a discrepancy between the subjective symptoms and endoscopic GERD grade in DM patients. DM patients’ ability to feel acid regurgitation could decrease.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Obesity is considered one of the 21st century plagues in the Western world. Although its etiology is multifactorial, eating habits represent an important factor in its development. (1). The caloric load, the proportion of its components, and its patterns have been the object of multiple studies (1–5). One of the most controversial aspects is the relationship between the frequency of meals and body weight.

Aims & Methods: The aim of the study was to determine the food rhythm (frequency and time spent in eating) in patients with morbidity obesity. Differences and similarities between men and women.

Methods: We conducted a cross-sectional study of 32,762 asymptomatic adults who underwent routine health check-ups including screening endoscopy from August 2006 to December 2011. Sarcopenia was defined as appendicular skeletal muscle mass (ASM)/body weight (%) value beyond two standard deviations below the mean for healthy young adults. Participants were categorized into four groups according to obe and sarcopenic obese: normal, obese, sarcopenic, and sarcopenic obese.

Results: In a multivariate model adjusted for age, sex, smoking status, alcohol intake, regular exercise, and metabolic variables, risk of reflux esophagitis was higher in obese (adjusted odds ratio [aOR], 1.38; 95% confidence interval [CI], 1.26–1.52), sarcopenic (aOR, 2.20; 95% CI, 1.48–3.29), and obese sarcopenic obese participants (aOR, 1.68; 95% CI, 1.39–2.03) than in normal participants. The ORs comparing sarcopenic and sarcopenic obese participants to obese participants were 1.59 (95% CI, 1.06–2.38) and 1.32 (95% CI, 1.02–1.47), respectively. In addition, the risk of reflux esophagitis according to sarcopenic and obese status was observed similarly in all subgroups that were evaluated.

Conclusion: Our findings suggest that sarcopenia, regardless of obesity, is more harmful condition for reflux esophagitis than obesity without sarcopenia.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: We considered one of the 21st century plagues in the Western world. Although its etiology is multifactorial, eating habits represent an important factor in its development. (1). The caloric load, the proportion of its components, and its patterns have been the object of multiple studies (1–5). One of the most controversial aspects is the relationship between the frequency of meals and body weight.

Aims & Methods: The aim of the study was to determine the food rhythm (frequency and time spent in eating) in patients with morbidity obesity (MO), based on data from the pH meter was analyzed.

Results: This was a retrospective study, including 100 patients (77 women), with MO in the last 4 months. 24-H esophageal pH-monitoring studies was performed in all patients. The mean time spent at each meal showed statistically significant differences between controls and obese (17.2 min) vs. 4th quartile, p < 0.02) were strongly associated with the mucosal breaks in LC group. Moreover, VAT, ratio of VAT to SAT, and TAT were significantly higher in LC group. In the multivariate analysis, a higher VAT area (odds ratio [OR] 3.47, 95% confidence interval 1.38 to 8.73, 1st quartile vs. 4th quartile, p < 0.01) and ratio of VAT to SAT (OR 2.99, 95% CI 1.15 to 6.70, 1st quartile vs. 4th quartile, p = 0.02) were strongly associated with the mucosal breaks in LC.

Conclusion: Light drinking including even one alcoholic drink a day is associated with increased risks of esophageal, gastric and colorectal cancer. No association was observed between prediagnostic alcohol consumption and all cause mortality.

Disclosure of Interest: All authors have declared no conflicts of interest.

References:
side. However, TAT was not significant in the multivariate analysis. Lower 24 h pH test (all levels) and 24 h coffee consumption (OR 2.50, 95% CI 1.06 to 5.86, p = 0.035) were associated with the severities of GERD.

Conclusion: Mucosal breaks in LC side of EGI were associated with visceral obesity measured by VAT, ratio of VAT to SAT, BMI and WC. Life style modification such as in left decubitus sleeping position might be emphasized in the subjects with visceral obesity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1190 A LESS COMPLICATED OESOPHAGO-GASTRIC JUNCTION IS ASSOCIATED WITH OESOPHAGEAL ACID HYPERSENSITIVITY EVEN IN HEALTHY CONTROLS

C. Lottrup1, A. L. Krarup1, P. Ejstrup2, B. P. Mcmahon1, A. M. Drewes1
1Mech-sens, Department Of Gastroenterology And Hepatology, Aalborg University Hospital, Aalborg/Denmark
2Surgery A, Aalborg University Hospital, Aalborg/Denmark

Introduction: In normal subjects, the oesophago-gastric junction (OGJ) sphincter complex maintains a tight barrier between the oesophagus and stomach acid. However, gastro-oesophageal reflux disease (GERD) caused by acidic reflux has a prevalence of up to 26% [1]. One major factor determining whether gastro-oesophageal reflux occurs and eventually generates symptoms is the competency of the OGJ, which can be studied using distensibility testing. This way, we have previously shown in patients with Barrett’s oesophagus and healthy controls that an incompetent sphincter function was associated with more frequent reflux symptoms [2]. In the same patient groups, we also found greater oesophageal acid exposure and lower mucosal baseline impedance to be associated with impaired sphincter function. The latter probably represents a proxy for mucosal damage [3]. Other factors known to increase the perception of gastro-oesophageal reflux episodes are greater acidity, larger volume, and more proximal extent of the reflux content along with impaired mucosal integrity and sensitisation (peripheral and central) [4]. All of this said no studies of our knowledge have specifically addressed the possible association between sphincter function of the OGJ and oesophageal sensitivity.

Aims & Methods: We aimed to characterize oesophageal acid sensitivity in relation to OGJ competence, hypothesizing that sensitivity increases with impaired sphincter function. Twenty-three patients with Barrett’s oesophagus (mean age: 64.2±7.7 years) and 12 healthy controls (mean age: 54.9±10.8 years) were examined. A standard upper endoscopy to locate the OGJ was followed by distensibility testing of the OGJ using the EndoFLIP probe. At a later visit, experimental oesophageal sensitivity was assessed using a multimodal stimulation probe. After placement in the oesophagus just above the OGJ, the probe allows the filling and emptying of an attached polyurethane bag with water, stimulation with electrical current, and infusion of acid. Using this probe, mechanical distension of the bag, thermal stimulation at increasing temperature, electrical stimulation, and acid perfusion with 0.1 M hydrochloric acid (a Bernstein test) were performed. All stimulations were stopped when the subject felt moderate pain, equal to seven on a 0–10 visual analogue scale validated for visceral pain. Data were analysed using multi-level, mixed-effects regression analysis in Stata 12.

Results: Oesophageal acid sensitivity increased with a more incompetent sphincter. The latter mechanism probably constitutes a reflux protective mechanism towards acid reflux.

Disclosure of Interest: B.P. McMahon: Barry P McMahon holds a minor share in Crospin Inc., Galway, Ireland who manufactures the EndoFLIP probe. All other authors have declared no conflicts of interest.

Contact E-mail Address: pelnergurun@yahoo.com

Introduction: Three different phenotypes of gastroesophageal reflux disease (GERD) such as erosive reflux (ERD), nonerosive reflux (NERD), esophageal hypersensitivity (EH) and functional heartburn (FH) might have different pathophysiological changes within the esophageal epithelium and the data is limited.

Aims & Methods: We aim to investigate the electrophysiological differences and diffusion characteristics as a reflection of tissue integrity using Ussing chamber system. Distal esophageal mucosal biopsies from 14 healthy controls (5 men, 40.6±11.2 years) and 62 patients with GERD (40 men, 42.9±12.3 years, n = 26 LA grade A/B, n = 8 LA grade C/D, n = 22 NERD, n = 6 EH) and 11 patients with FH were studied from November 2015 until March 2017. GERD and quality of life questionnaires, high-resolution esophageal manometry, 24 h impedance-pH monitoring, upper gastrointestinal endoscopy with esophageal biopsies were performed in all patients. Biopsies were put into the chambers to measure the transepithelial resistance (TEER), potential difference (PD) and tissue permeability via fluorescein diffusion within two hours as well as evaluation of dialted intercellular spaces with light microscopy.

Results: Esophageal biopsies of healthy volunteers (163.6±41.1 ohms) had significantly higher TEER when compared to total GERD patients (132.5±38.7 ohms). Although the TEER results of whole GERD subtype decreases compared to healthy controls, only ERD groups were significantly lower (123.3±29.8 ohms) (Table 1). There was also no significant difference in any PD and TEER results between NERD, FH and EH groups. The mucosal permeability of GERD subtypes was significantly higher than the healthy controls. The PPI-unresponsive subjects (n = 10, 94.8±36.5 pmols) were much more permeable to fluorescein compared to PPI-responsive subjects (n = 52, 56.0±32.4 pmols) within all GERD patients (p = 0.009).

Table 1

<tr>
<td>Functional Heartburn</td>
<td>145.3 ± 42.7</td>
<td>3.9 ± 4.0</td>
<td>67.0 ± 35.2</td>
</tr>
</tbody>
</table>

Conclusion: The TEER and permeability results imply that ERD and NERD groups showed a barrier disruption. However, epithelial permeability was not different in EH and FH groups. The dilatation of intercellular spaces may contribute to increased mucosal permeability in true-NERD and ERD patients. EH and FH patients might have different pathophysiology than others.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1192 PEPHISIN AND PH LEVELS OF HUMAN GIAC JUICE IN GASTROESOPHAGEAL REFLUX DISEASE SUBGROUPS AND FUNCTIONAL HEARTBURN

P. Ergun1, S. Kipcak1, P. Detmar3, A. Woodcock2, S. Bor1
1Gastroenterology Sec., Ege Reflux Study Group, Ege University, Izmir/Turkey

Contact E-mail Address: pelnergurun@yahoo.com

Introduction: The major noxious agents of gastroesophageal reflux disease (GERD) on the esophageal epithelium are gastric acid and pepsin. Nevertheless, there is no precise information about pepsin concentrations in gastric juice.

Aims & Methods: We aim to address the pepsin values and pH results among subtypes of GERD and functional heartburn. 46 patients with GERD (23 erosive reflux disease LA grade A/B (ERD-A/B), 5 ERD-C/D, 14 nonerosive reflux disease-NERD, 4 esophageal hypersensitivity-EH), 8 functional heartburn (FH) and 17 healthy controls (HC) were included into the study. Upper gastrointestinal endoscopies were performed off PPI. Patients were instructed not to aspirate the local anaesthetic solution and biopsy channel of the endoscope was dried before the suction. The gastric juices from the subjects were aspirated during endoscopy into a special beaker and their pH values were measured immediately. The specimens were analysed using the Pepsit lateral flow device (RD Biomed Ltd UK), a colorimetric assay containing two unique human monoclonal antibodies that capture and detect pepsin protein.

Results: There were no significance between pepsin levels in any GERD phenotypes, FH and healthy controls (Table 1). The pH results of patients with ERD (1.8±0.6) were significantly lower versus HC (2.6±1.5). The pH levels of the
esophageal hypersensitivity (1.5 ± 0.2) were significantly decreased when compared to HC (2.6 ± 1.6) and also true NERD (4.0 ± 2.0).

</tbody>
</table>

Conclusion: Pepsin may be considered a damaging factor in pathophysiology of GERD, but we could not find any difference between GERD phenotypes and unaffected controls. NERD group had less gastric acid versus other groups but this finding needs more studies to confirm.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1193 NON INVASIVE DIAGNOSIS OF UPPER GI DISEASES IN A PRIMARY CARE SETTING: A STUDY ON 1,900 PATIENTS

F. Di Mario1, S. Cesario1, S. Grillo1, S. Landi1, G. Baldassarre2, R. Cannizzaro3, A. Marcheschi2, M. Rugge5, M.F. Roberti1

Introduction: Gastropan® is a non invasive test suggested able to perform a kind of “serological biopsy” of gastric mucosa. Aim of the study was to assess a proper diagnosis of different upper gastrointestinal (GI) diseases in a population suffering from upper GI disturbances in a primary care settings by means of a blood sample. The diagnosis of upper GI surgery, alarm symptoms. All patients underwent a blood sample for proper diagnosis of different upper gastrointestinal (GI) diseases in a population suffering from upper GI disturbances in a primary care settings by means of a blood sample.

Aims & Methods: We enrolled 1900 consecutive patients (M=769; mean age 56.4 ys, range 29-78 ys) showing upper GI troubles. Exclusion criteria: upper GI surgery, alarm symptoms. All patients underwent a blood sample for Gastropan® (BioHit Oy, Finland): pepsinogen I (PGI), pepsinogen II (PGII), gastrin-17 (G-17) and IgG against Helicobacter Pylori (Hp-IgG). The normal values: PGI: 30-120 µg/L, PGII: 2.1-15 µg/L, G-17: 1-9 pmol/L, Hp-IgG: <30 U/L. The diagnosis of Hp-related non-atrophic gastritis was made by means of the levels of PGI > 10 µg/L and Hp-IgG > 30 U/L; the diagnosis of gastroesophageal reflux disease (GERD) was made when G-17 was low: <2 pmol/L; the diagnosis of chronic atrophic gastritis (CAG) was made when PGI was <30 µg/L and G-17 > 14 pmol/L. Finally when all the four parameters were normal, the subjects were classified as normal. All patients underwent upper GI endoscopy to support the serological diagnosis, with appropriate gastric biopsy according with OGAI classification.

Results: Four hundred and eighty eight patients were classified as affected by Hp-related non-atrophic gastritis (26%); 782 patients were classified as GERD patients (41%); 547 patients were classified as normal (29%). 83 patients were classified as CAG (4%). In 96% out of the 488 patients with Hp-related non-atrophic gastritis the features was confirmed by gastric histology (OGAI 0, 1, 2); in 91% out of the 782 patients diagnosed as GERD subjects, the diagnosis was confirmed by oesophagostomy at endoscopy in 313 patients, positive Demester score in 170 out of 221 patients at 24 hours pHmetry or presence of typical symptoms (heartburn and/or regurgitation) in 547 patients. The great majority of 83 patients in which the diagnosis was CAG showed a picture of OGAI 3 (56.6%) or OGAI 4 (23%).

Conclusion: Non-invasive diagnosis of upper-GI diseases when alarm symptoms are absent seem to be promising to improve the appropriateness of endoscopy, as well as to address subjects affected by Hp infection to the cure and GERD patients to the therapy for reflux. The diagnosis of a precancerous condition like CAG before performing endoscopy could address to a better biopsy sampling.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1194 CHANGES IN ANTHROPOMETRIC AND METABOLIC PARAMETERS RELATED TO GASTROESOPHAGEAL REFLUX DISEASE IN NON-OBSE CASES

S. Yavuz1, Ö. Gür Utku1, A. Gungun2, N. Dindar Badem2, B. Ergül1, D. Öğuz1, 2Gastroenterology, Kirkkale University, Kirkkale/Turkey, 3Endocrinology, Kirkkale University, Kirkkale/Turkey, 4Biochemistry, Kirkkale University, Kirkkale/Turkey

Contact E-mail Address: ozlemgulx@yahoo.com

Introduction: Prevalence of obesity and the obesity-related diseases have been increasing in recent years(1). In the studies conducted there are views claiming that visceral fat-related central obesity causes digestion system diseases and increase in the number of gastroesophageal reflux symptoms in particular (1–6).

Aims & Methods: In this study, in order to investigate the frequency and severity of gastroesophageal reflux symptoms in non-obese (BMI < 30), it is aimed to assess the effects of insulin resistance and the changes observed in the anthropometric and biocellulare impedance measurements upon the reflux symptoms. Our study 120 BMI < 30 non- obese, gastroesophageal reflux disease (GERD) patients diagnosed according (Frequency scale for the symptoms of gastroesophageal reflux disease) and 50 BMI < 30 non-obese, non- not (GERD) diagnosed according to FSSG cases have been included. The cases included in the study concerned have been surveyed by means of the questionnaire including the demographic data and the extra esophageal reflux symptom. Serum biochemistry analyses (fasting glucose, insulin, lipid panel, uric acid, TSH, ALT) have been checked. Waist circumference has been measured. Body compositions and anthropometric measurements have been assessed through the biocellulare impedance method (TANITA).

Results: In this study a statistically significant difference (p < 0.05) has been found when GERD-diagnosed group is compared with healthy control group in regard to waist circumference, BMI; LDL, Fat, Mass, Total Body Water(TBW), obesity level, reflux score, acid reflux score and total score measurements. Fat free mass (FFM), muscle mass, bone mineral density (BMR) measurements in between the both groups have not been found statistically significant difference (p > 0.05) (Table 1). Considering the extra esophageal reflux symptoms a significant difference (p < 0.05) between the group suffering from sore throat, apnea, teeth grinding and GORH and the healthy control group has been found. Within the patients group a positive correlation between acid reflux score and BMI (r = 0.298) (p < 0.001), LDL (r = 0.387) (p < 0.001), visceral fat (r = 0.180) (p < 0.049) has been determined. A negative correlation between acid reflux score and TBW (r = 0.273) (p < 0.003) has been determined.

**Introduction:** Esophageal baseline impedance (BI) levels have been recently proposed as a marker of mucosal integrity. Indeed, patients with non-erosive reflux disease (NERD) showed lower distal esophageal BI levels compared to healthy controls (HCs) due to the presence of abnormal distal esophageal acid exposure time (AET). On the other hand, there were no differences between patients with esophageal involvement and HCs. Esophageal involvement and hypersensitivity are two distinct phenotypes of GERD; however, they are difficult to be discriminated. Therefore, we aimed to prospectively compare BI levels between a group of NERD patients and a group of patients with esophageal involvement to assess the presence of esophageal mucosal lesion.

**Aims & Methods:** We prospectively enrolled 221 consecutive GERD patients (F 113, mean age 52.5 years; range 28–74 years) with endoscopically proved diagnosis of esophagitis, according to the L.A. classification, all symptomatic (heartburn and/or regurgitation). All patients were treated with rabeprazole 20 mg once a day for 6–8 weeks, assessing at the end of the therapy the symptoms’ modifications by means of a questionnaire. In the group of asymptomatic patients, we performed a one-year follow-up, recording the GERD relapse episodes, only on-demand antacids were permitted. All patients underwent at baseline a blood sample and after the acute course of PPI therapy.

**Results:** One hundred eighty five patients were asymptomatic after the 6–8 weeks of PPI therapy and entered in the prospective evaluation for 12 months. Nineteen subjects were lost lasting the follow-up and finally 166 patients were available for the study analysis. 72 patients experienced at least one GERD relapse episode (first group) against 94 ones free of symptoms for one year (second group). The mean values of both PG I and G-17 after the 6–8 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 164 g/L, G-17 2.9 pmol/L; after therapy: PG I 164 g/L, G-17 19 pmol/L; p < 0.001; second group: baseline PG I 98 g/L, G-17 2.9 pmol/L; after therapy: PG I 116 g/L, G-17 6.3 pmol/L; p: ns). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

**Conclusion:** Gastrin-17 and pepsinogen I increase after full-dose of PPI in GERD acute phase seem to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Gastroesophageal reflux disease (GERD), is characterized by frequent relapses after withdrawal of therapy and no prognostic markers of relapse are available to predict the outcome of the patients. Gastrin-17 (G-17) has been proposed as a non-invasive marker of reflux disease as well as a good marker of response to the therapy. Pepsinogen I (PG I) and Gastrin-17 (G-17) are claimed to increase in a statistically significant manner after proton pump inhibitors (PPIs) therapy. Aim of the study was to assess the prognostic value of G-17 and PG I in determining GERD patients more prone to develop an early reflux relapse in a prospective open study.

**Aims & Methods:** We prospectively enrolled 221 consecutive GERD patients (F 113, mean age 52.5 years; range 28–74 years) with endoscopically proved diagnosis of esophagitis, according to the L.A. classification, all symptomatic (heartburn and/or regurgitation). All patients were treated with rabeprazole 20 mg once a day for 6–8 weeks, assessing at the end of the therapy the symptoms’ modifications by means of a questionnaire. In the group of asymptomatic patients, we performed a one-year follow-up, recording the GERD relapse episodes, only on-demand antacids were permitted. All patients underwent at baseline a blood sample and after the acute course of PPI therapy.

**Results:** One hundred eighty five patients were asymptomatic after the 6–8 weeks of PPI therapy and entered in the prospective evaluation for 12 months. Nineteen subjects were lost lasting the follow-up and finally 166 patients were available for the study analysis. 72 patients experienced at least one GERD relapse episode (first group) against 94 ones free of symptoms for one year (second group). The mean values of both PG I and G-17 after the 6–8 weeks of PPI therapy in comparison with the baseline levels, were higher in first group than in the second one (first group: baseline PG I 164 g/L, G-17 2.9 pmol/L; after therapy: PG I 164 g/L, G-17 19 pmol/L; p < 0.001; second group: baseline PG I 98 g/L, G-17 2.9 pmol/L; after therapy: PG I 116 g/L, G-17 6.3 pmol/L; p: ns). The good response to full dose of PPI, assessed by an increase of both PG I and G-17, seems to be the pathophysiological background to explain the prognostic value of such markers.

**Conclusion:** Gastrin-17 and pepsinogen I increase after full-dose of PPI in GERD acute phase seem to be a simple non-invasive marker to predict early GERD relapse in one-year follow-up.

**Introduction:** Various biomarkers have been studied to evaluate the integrity of esophageal epithelium in distinguishing phenotypes of gastroesophageal reflex disease (GERD). Baseline impedance (BI) measurement is likely to be one of these and can be measured during the 24-hour ambulatory intra-esophageal impedance-pH study. Mucosal impedance (MI) measurement is a technique that has been introduced in recent years and is a practical method that can be applied during endoscopy, but the validation studies are insufficient. BI & MI measured with the same regular impedance catheter and data from 118 patients with different reflux phenotypes and controls were evaluated.

**Aims & Methods:** Patients were divided into five groups: mild (ERD A-B, n = 31), severe erosive esophagitis (ERD C-D, n = 11), non-erosive reflux disease (NERD, n = 26), functional heartburn-esophageal hypersensitivity (FH-EH, n = 17), healthy controls. High resolution manometry, 24-h MI-PH, upper gastrointestinal endoscopy were performed. BI values were taken at the sleeping period at night where reflux and swallowing did not occur. MI measured during endoscopy, a regular impedance-pH catheter passed through the biopsy

**References**

channel of the scope. Distal two rings were contacted to the distal and proximal parts of the esophagus respectively 20–25 cm. MMS Omega ambulatory recorder and Greenfield (6 imp, 1 pH) impedance catheter were used.

**Results:** MI can differentiate ERD from non-erosive groups but do not have a diagnostic value to discriminate NERD from FH-EH or controls. However, BI might be a better tool to discriminate NERD from controls. This implies that the esophageal epithelial resistance is impaired in this particular group compared to controls.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Gastroesophageal reflux disease (GERD) is considered a multifactorial disease characterized by the presence of both typical and extra-oesophageal symptoms, as well as related risks factors, such as smoking habits. In primary care setting, dyspeptic symptoms could overlap GERD symptoms, being the differential diagnosis sometimes difficult, almost because when we performed in such patients upper-gastrointestinal (GI) endoscopy, a picture of esophagitis is observed in no more than 30–40% of the subjects. Aim of the study was to search in a primary care settings possible differences in clinical presentations in a group of patients with GERD. The majority of GERD patients

**Aims & Methods:** One thousand and six hundred consecutive dyspeptic patients (M = 766; mean age = 51.5 years; range = 27–79 yr) were enrolled in the study, according with presence of upper-GI troubles like epigastric pain, fullness, nausea/vomiting but not heartburn or regurgitation. All patients showed a negative upper-GI endoscopy and were helicobacter pylori (H.p.) negative (Urea Breath Test and HpSA). Patients with history of peptic ulcer, neoplasms or upper-GI surgery were excluded. Seven hundred and one patients showing heartburn and/or regurgitation, a picture of esophagitis according with LA classification or a positive DeMeester score (> 14) at 24 hours pHmetry were enrolled in GERD group. By using a questionnaire, we collected data on both alcohol and smoking habits.

**Results:** No differences were found for sex and age between the two groups (M = 766; mean age = 51.5 years; range = 27–79 yr). All patients showed a negative upper-GI endoscopy and were helicobacter pylori (H.p.) negative (Urea Breath Test and HpSA). Patients with history of peptic ulcer, neoplasms or upper-GI surgery were excluded. Seven hundred and one patients showing heartburn and/or regurgitation, a picture of esophagitis according with LA classification or a positive DeMeester score (> 14) at 24 hours pHmetry were enrolled in GERD group. By using a questionnaire, we collected data on both alcohol and smoking habits.

**Introduction:** In China, 13.6% of gastrointestinal outpatients suffer from gastroesophageal reflux disease (GERD), among which only 36.9% undergo endoscopy [1]. For patients with symptoms of GERD, empirical proton pump inhibitor (PPI) treatment is recommended as a diagnostic test of GERD and as a therapeutic trial to control symptoms by Chinese GERD consensus guidelines [2].

**Results:** MI can differentiate ERD from non-erosive groups but do not have a diagnostic value to discriminate NERD from FH-EH or controls. However, BI might be a better tool to discriminate NERD from controls. This implies that the esophageal epithelial resistance is impaired in this particular group compared to controls.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Currently, there are no real-world data assessing the efficacy of short-term empirical treatment with PPIs in GERD patients in China.

**Aims & Methods:** This was a multicenter, prospective, observational study carried out in a real-world setting. The primary objective was to determine the overall responder rate in patients with typical GERD symptoms after 4 weeks of empirically treated PPIs. Patients were enrolled at 18 centers across China. The study included patients with pathological reflux and symptom frequency were recorded. Data were collected at baseline, 2 weeks and 4 weeks after initiating PPI treatment. Results from the full analysis set (FAS) are presented.

**Results:** A total of 1,000 patients from 10 centers were screened for this study, of which 987 met the inclusion criteria and were included in the FAS. The mean age was 45.2 ± 11.6 years. The mean body mass index was 23.4 ± 3.3 kg/m², and 50.3% of the patients were male. The mean duration of GERD was 6.8 ± 2.6 years, with a mean baseline GERD-Q score for the week before screening of 10.5 ± 1.9. During the 4 weeks' treatment, the proportion of patients receiving at least 19 days PPI was 99.5%. Esomeprazole was the most frequently received PPI (57.1% of patients). Other PPIs (ranitidine, lansoprazole, pantoprazole, and omeprazole) were received by 50.1% of patients and 7.2% of the patients sequentially received ≥2 PPIs in the duration of the study. A total of 787 (79.7%) patients either completed the 4-week PPI treatment or withdrew after response, of which the responder rate was 74.0% [95% CI 70.7%–77.0%] (Table 1). Among the 818 patients who completed 2 weeks' treatment, the responder rate was 57.0% [95% CI 53.5%–60.4%]. The overall median time to response was 13 days [95% CI 12–15]. Over the study duration, patients' adherence was increased significantly in stimulation group than sham group (stimulation 9.00 vs. sham 5.0 days [95% CI 4.2–9.8]). During the 4 weeks' treatment, the proportion of patients with a GERD-Q score ≥8 reduced from 100% at baseline to 29.5% and 17.4% at 2 and 4 weeks, respectively.

**Conclusion:** In Chinese clinical practice, short-term PPI empirical treatment effectively improves symptom control in GERD patients and gains a satisfactory overall responder rate.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1202 SYSTEMATIC REVIEW AND META-ANALYSIS OF OUTCOMES AFTER LAPAROSCOPIC ANTI-REFLUX SURGERY RELATED TO OBESITY**
T. Abdelrahman1, A. Latif2, D. Chan3, N. Patel4, C. Brown5, W. Lewis1, T. Havid1, X. Escotet6
1General Surgery, University Hospital of Wales, Cardiff/United Kingdom
2General Surgery, Royal Glamorgan Hospital, Llantrisant/United Kingdom

**Introduction:** Laparoscopic Anti-Reflux Surgery (LARS) is an established alternative treatment to pharmacological therapy for patients with Gastro Esophageal Reflux Disease (GERD), yet its safety and efficacy in obese patients is controversial. A systematic review and meta-analysis was performed to compare LARS-related to obesity.

**Aims & Methods:** The primary outcome measure was the relative incidence of recurrent reflux related to BMI. Secondary outcome measures were relative incidence rates in the form of endoscopic dilatation or surgery, conversion to open surgery, and early return to theatre. Embase, MEDLINE and the Cochrane Library (January 1970 to November 2016) were searched for studies reporting clinical outcomes of LARS in patient cohorts stratified by Body Mass Index (BMI). Data was grouped according to BMI, <30 kg/m² (non-obese) and ≥30 kg/m² (obese). Results were pooled in meta-analyses as Odds Ratios (OR).

**Results:** Eleven eligible observational studies comparing LARS in non-obese (n = 1620) and obese (n = 1632) patients were identified. The relative incidence of reflux was significantly lower in the non-obese cohort (OR 0.34, 95% CI 0.19 to 0.60, p < 0.001), however no significant differences were observed in rates of operative morbidity (OR 0.87, 0.65 to 1.18, p = 0.38), redo surgery (OR 1.08, 0.68 to 1.72, p = 0.73), endoscopic dilatation (OR 1.06, 0.49 to 2.33, p = 0.88), conversion to open surgery (OR 1.17, 0.55 to 2.48, p = 0.68), or early return to theatre (OR 0.77, 0.44 to 1.37, p = 0.38).

**Conclusion:** LARS can be performed safely in obese patients, but risks higher for BMI ≥30. Patients should be aware that obesity may adversely affect LARS outcome and careful consideration be given in the consent process inherent within the optimal management of GORD.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1203 GASTROESOPHAGEAL REFLUX DISEASE REFRACTORY TO PROTON PUMP INHIBITOR THERAPY. INCOMPLETE ACID INHIBITION OR DIAGNOSTIC ERROR?**
Gastroenterology, Hospital Clinico San Carlos, Madrid/Spain

**Contact E-mail Address:** jercasserna@gmail.com

**Introduction:** The use of PPIs represents the main treatment in gastroesophageal reflux disease (GERD), having demonstrated its effectiveness both in the control of inflammation and symptomatology. However, between 10-20% of patients present persistent symptoms or lesions despite the treatment.

**Aims & Methods:** The aim of the study was to assess the presence of acid reflux in patients submitted to our department with the diagnosis of refractory GERD, due to low or no response to PPIs. This was a retrospective study including 190 patients (55 men, 135 women) referred to our service with the diagnosis of GERD from January 2008 to December 2015. Based on the diagnostic criteria, two groups were made. Group 1: included 63 patients (33.2%) diagnosed of GERD due to typical symptomatology and at least one positive complementary test (24 H pH monitoring). All of them underwent a 24-H pHmetry study with a dual channel, esophageal and gastric, on-PPI treatment. In 17 patients the pHmetry was completed with multichannel intraluminal impedance study (15 cases) or Bilitec (2 cases). Group 2: included 127 patients (66.8%) who had been diagnosed of GERD only on the basis of typical symptoms; all of them underwent esophageal double channel 24-H pHmetry off-PPI. All of the studies (24-hour pH monitoring or multichannel intraluminal impedance-pH studies) (MARK III, Delta and Digitrapper pH-Z, Synectics, Gyen, Medtronic) were performed according to standard technique.

**Results:** Pathological reflux was present in 91 patients (47.9%), 24 from group 1 and 67 from group 2. Pathological acid reflux was therefore ruled out as a cause of symptoms in 52.1% of all cases studied: 60 patients (47.2%) from group 2 and 39 patients (61.9%) from group 1. In addition, out of the 24 patients with pathological reflux in group 1 (true refractory patients), 9 had an incomplete response, with a percentage of time with pH < 4 less than 7.5% (mild reflux), which probably was not the cause of the symptomatology.

**Conclusion:** Proton pump inhibitors (PPIs) are the drugs of choice in the treatment of GERD. However, its efficacy may be compromised for a variety of reasons including: non-compliance, bioavailability, episodes of nocturnal acid break-through, poor gastric emptying, etc. In most of the patients referred for implantation or stimulation-related adverse effects were reported in the two-month follow-up.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
studying with the diagnosis of refractory reflux to PPIs, this diagnosis had only been made on an individual basis for non-compatible symptoms. When this diagnosis is exclusively clinical, about half (47.2%) of the patients with persistent symptoms on double doses of PPIs, considered as GERD patients refractory to PPIs, have an incorrect diagnosis (patients do not have pathological reflux). More than half of the patients (61.9%) who have a diagnosis of GERD confirmed by complementary tests that do not respond to treatment with PPIs, acid reflux is not the cause of their symptoms.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1204 LOW-FODMAP DIET RESULTED EFFECTIVE IN REDUCING SYMPTOM PERCEPTION IN PATIENTS WITH FUNCTIONAL HEARTBURN

Introduction: Recently, low-FODMAP diet has been proposed as a potential treatment in patients with irritable bowel syndrome (IBS) given its high efficacy in symptoms relief. Recent data showed that IBS frequently overlap with functional heartburn (FH) and functional dyspepsia.

Aims & Methods: The aim of this study was to evaluate the efficacy of low-FODMAP diet in reducing heartburn in patients with FH and no pathophysiological evidence of gastroesophageal reflux (GERD) compared to patients with non-erosive reflux disease (NERD). As secondary aim we investigated the reduction of lower gastrointestinal symptoms in both groups. We enrolled patients with heartburn and negative upper endoscopy who were scheduled for upper endoscopy to confirm the diagnosis of reflux disease.

Methods: The inclusion criteria were: (1) mean age 50.9 yrs; mean BMI 23.9. All patients showed symptom improvement into the study. NERD group was composed of 13 patients (6 female; mean age 58 yrs, IQR 51–67) and 197 females (median age 64 yrs, IQR 57–70) were included with a median follow-up of 8.2 years (IQR 5.3–10.3). High-grade dysplasia (HGD) was detected in 35 males versus 4 females. EAC in 12 males versus 5 females. The total number of patients with neoplastic progression was 56 (8%), which was twice as high among males compared to females (HR 1.90, 95% CI 0.92–3.92). Especially the risk of HGD was higher in males than in females (HR 3.34, 95% CI 1.17–9.50). The ratio HGD/EAC in males was 2.92, in females 0.80. Apparently in females proportionally more EAC was identified compared to males. Though these data might suggest accelerated neoplastic progression rates in females, time to event was significantly shorter for males in HGD (AR 0.45, 95% CI 0.22–0.94). There was no difference for overall neoplastic progression (AR 0.59, 95% CI 0.16–2.06). Stage distribution is shown in Table 1, females tend to have a higher stage of neoplastic progression than males.

Conclusion: The risk of HGD and overall neoplastic progression and acceleration rate of HGD development is higher in male BE patients compared to females. On the other hand descriptive statistics show proportionally more EAC in females as well as an advanced stage of EAC at diagnosis. Further research into the differential aspects of neoplastic progression in BE between men and women, may have future consequences for gender specific guideline recommendations, including the timing of follow-up.

P1205 SINGLE SESSION FOCAL CRYOBALLOON ABLATION THERAPY IS SAFE AND EFFECTIVE IN THE TREATMENT OF DYSPLAGIA BARRETT’S ESOPHAGUS
S. Van Munster1, A. Overwater2, J.J. G.h.m. Bergman1, B.L.a.m. Weusten4

Introduction: Given its proven safety and efficacy, RadioFrequency Ablation (RFA) is the preferred ablation modality for dysplastic Barrett’s Esophagus (BE). However, RFA is associated with significant drawbacks, such as the need for large controller units, multiple deployment steps and capital investment. Transluminal CryoBalloon Ablation (FCBA; C2 Therapeutics Inc. Redwood City, CA, USA) is another ablation method based on the application of extreme cold—has been recently developed to overcome these RFA drawbacks. Additionally, FCBA might be better tolerated. FCBA comprises a handheld, through-the-scope system with a conformable balloon that is simultaneously inflated and cooled using nitrous oxide, resulting in ice patches of approximately 2mm2 on the targeted mucosa. Previous studies applying FCBA to limited areas of BE (1 to 2 small BE islands per patient) have shown promising results. Data on

Disclosure of Interest: All authors have declared no conflicts of interest.
efficacy and safety of FCBA in the treatment of larger BE segments, however, are lacking. Therefore we aimed to assess the safety and efficacy of a single treatment with FCBA for dysplastic BE.

Aims & Methods: Patients were seen between March and December 2016 at two tertiary referral centers in the Netherlands. Patients with a BE ≥6 cm in length and with a confirmed diagnosis of low-grade (LGD) or high-grade dysplasia (HGD) or after endoscopic resection for visible lesions, were included. Exclusion criteria included previous focal ablation therapy and strictures. At baseline, all visible BE was treated with side by side ablations of 10 seconds, including the circumferential treatment of the gastroesophageal junction (GEJ). Pain scores were assessed directly post-treatment and at days 2 and 7. Follow-up endoscopy with biopsy and photo documentation was scheduled after 3 months. Primary outcomes included dysplasia regression rate and incidence of esophageal stricture or other adverse events.

Results: We enrolled 20 patients with dysplastic BE (85% male, mean age 66 ±8 years), with a median BE length of 2.0 cm (IQR 0–4; 1–3) and with a baseline diagnosis of LGD (10; 50%), HGD (1; 5%), or mucosal adenocarcinoma (9; 45%). Ten (50%) had undergone endoscopic resection of a visible lesion before cryoballoon and 8 (40%) had undergone previous circumferential RFA. During a median ablation time of 16 minutes (IQR 11–19), all BE, including circumferential ablation of GEJ was successfully ablated in all patients. No adverse events occurred, and median pain directly post-treatment was 4 out of 10 (IQR 0–5), whereas this was 1 (IQR 0–2) and 0 (IQR 0–1) at days 2 and 7. At the 3-month follow-up endoscopy, median endoscopic regression of initial BE was found to be 95% (IQR 93–96%), this included 3 patients (15%) with a complete 100% regression. All biopsies confirmed squamous regeneration without evidence for subsquamous BE. No significant esophageal strictures or other complications were noted.

Conclusion: Our multicenter, prospective trial shows that a single treatment with Focal Cryoballoon ablation therapy is safe, well-tolerated and effective for eradication of dysplastic BE.

Conclusion: In this multicenter, non-randomized, open prospective cohort study, patients reported less post-procedural pain and dysphagia after FCBA as compared with RFA and, moreover, FCBA patients used less analgesics. Although a randomized trial should provide definitive evidence for differences in post-procedural tolerability, our results strongly suggest a significantly different post-procedural course, thus favoring FCBA over RFA.

P1207 CRYOBALLOON ABLATION OF DYSPLASTIC BARRETT'S ESOPHAGUS CAUSES SHORTER DURATION AND LESS SEVERE POST-PROCEDURAL PAIN AS COMPARED TO RADIOFREQUENCY ABLATION

S. Van Munster1, A. Overwater2, J.J. G.h.m. Bergman3, B.L.a.m. Weusten2

Introduction: Radiofrequency ablation (RFA) is safe and effective for eradication of dysplastic Barrett’s Esophagus (BE), but may be associated with significant post-procedural pain. As an alternative, cryobalization using the Focal Cryoballoon Ablation system (FCBA) has recently been developed, which ablates BE by freezing it using nitrous oxide. Early uncontrolled studies suggest comparable safety and efficacy of FCBA and RFA in eradicating dysplastic BE. Therefore we evaluated endpoints like pain may play a determining role in selecting the best treatment modality. In contrast to heat-based ablation, FCBA preserves the extracellular matrix which might be associated with less pain while maintaining sufficient depth of ablation. In this study, we aimed to compare post-procedural pain between focal RFA and FCBA.

Aims & Methods: Between January 2016 and March 2017 all patients undergoing focal ablation therapy of BE, either with RFA or FCBA performed in two tertiary referral centers in the Netherlands, were approached to complete a digital diary. A short questionnaire was daily sent to patients for 14 days post-treatment, to assess (1) odynophagia, (2) chest pain in rest (both were assessed using VAS score ranging from 0 to 10), (3) dysphagia (assessed using a score ranging from 0 to 4) and (4) use of analgesics. Primary outcome included maximum VAS score (maximum VAS score for either item 1 or 2), secondary outcomes included area under the curves (AUCs) for all items assessed, maximum reported VAS score at any time, time to VAS 0 and analgesics use. According to national guidelines, all visible BE was ablated, including circumferential treatment of the gastro-esophageal junction (GEJ). In a standardized way, all patients were advised to use paracetamol (up to 4 times 500 mg daily) as necessary with additional ibuprofen, if needed.

Results: Fifty-five patients were included (35 with focal RFA; 20 with FCBA) and median BE length was similar for the two groups (FCBA: 2022, RFA: 2016, p=0.72). All other baseline characteristics were similarly comparable for both groups (table 1A). Maximum VAS score was lower after FCBA compared with RFA at all days, reaching statistical significance at 13/14 days (table 1B). All AUC curves were significantly smaller after FCBA compared to RFA; for maximum VAS score (12.3 vs. 26.7, p<0.01), for odynophagia (11.6 vs. 26.7, p<0.01), for pain in rest (7.8 vs. 20.5, p<0.01), for use of analgesics (0.9 vs 3.1, p<0.01) and for dysphagia (2.6 vs 8.2, p<0.01). The maximum median VAS score reported on any of the 14 days was 2 (IQR 0–4) after FCBA and 4 (IQR 3–7) after RFA (p<0.01). After 4 (IQR 1–10) days, half of the FCBA patients reported a pain score of 0, whereas this was 13 (IQR 10–15) days for RFA.

Conclusion: In this multicenter, non-randomized, open prospective cohort study, patients reported less post-procedural pain and dysphagia after FCBA as compared with RFA and, moreover, FCBA patients used less analgesics. Although a randomized trial should provide definitive evidence for differences in post-procedural tolerability, our results strongly suggest a significantly different post-procedural course, thus favoring FCBA over RFA.

Introduction: Radiofrequency ablation (RFA) with endoscopic mucosal resection is recommended for Barrett’s Oesophagus (BO) related neoplasia. In this study, we evaluated RFA treatment outcomes for BO stratified according to baseline histology, i.e. low-grade dysplasia (LGD), high-grade dysplasia (HGD) and intramucosal carcinoma (IMC). We retrospectively reviewed the treatment outcomes of patients with dysplastic BO between January 2007–2017. Patients received 3-monthly RFA until endoscopic and histologic remissions were achieved. Outcomes measured were: 1) complete remission of dysplasia (CRD) and intestinal metaplasia (CRIM), 2) stricture rate, and 3) durability of CRD and CRIM. Patients on active treatment protocol were excluded.

Results: We identified 113 patients who completed RFA treatment (21 LGD, 46 HGD and 46 IMC). There were no significant difference between the groups in the age, gender, circumferential and maximum length of BO, and stricture rate. CRD and CRIM were achieved in 94.7% and 78.8% of patients, respectively. When stratified according to baseline histology, there was no significant difference in CRD rate among LGD (95.2%), HGD (95.7%) and IMC (93.5%) (p=0.89). Similarly, there was no significant difference in CRIM rate among LGD (71.4%), HGD (76.1%) and IMC (84.8%) (p=0.31). CRD durability at 12 and 36 months (n=107) were 99.0% and 97.0%, respectively. CRIM durability (n=89) at 12 and 36 months were 98.5% and 92.7%, respectively. When stratified according to baseline histology, CRD durability at 12 and 36 months for LGD and IMC were 100% at both time points, and 97.7% and 93.6% for HGD, respectively (log rank p=0.31). CRIM durability at 12 and 36 months for LGD, HGD and IMC were 100%, 96.4%, 100%, and 88.5%, 95.5%, respectively (log rank p=0.66).

Conclusion: The treatment outcomes for BO were similar in patients with different baseline histology. Our results showed that once CRD and CRIM were achieved, these were durable over time.

Disclosure of Interest: All authors have declared no conflicts of interest.
After neoadjuvant CT-RT, 23 patients had CR, while 65 had partial response. The discordance between biopsy sample (BS) and EMR specimen was in cases of HG, as well as cytologists’ inter and intra-observatory variability.

Aims & Methods: This was a retrospective study including a prospective histological relecture (BS and specimen) in two expert centers. The inclusion criteria were BE with HG and on pre-operative biopsies resected by the endoscopist. The discordance rates from other centers were collected and re-examined by our cytologists.

The BS discordant with EMR specimens were recorded in a numeric file (Teleslide) and a second lecture was carried out by 2 experts and 2 fellows (1 of each per center). Five diagnoses were considered: no metaplasia (no BE), metaplasia without dysplasia, LGD, HG, Adenocarcinoma. Concordance statistical tests were performed to assess the variability between BS and EMR specimens among the clinical CR and recurrence/relapse rate was significant higher in patients who had CR compared to those who had no CR (p=0.0014, p<0.001 and p=0.004 respectively).

The accuracy of leukocyte expression of PDL1 and CD8- lymphocyte rate was 0.76 (p=0.001), 0.81 (p=0.0001) and 0.75 (p=0.0001), respectively. Within the CR group, all patients with high infiltration of CD4+ T cell recurred relapsed while only the 38.9% of those with low CD4+ T cell infiltration did the same (p=0.058).

Conclusion: In our group of patients, CD4+ and CD8+ lymphocyte rate and PDL-1 lymphocyte expression were predictive of clinical complete response after neoadjuvant chemoradiotherapy. Advanced squamous cell carcinoma of the thoracic oesophagus with adequate accuracy. Moreover, high infiltration level of CD4+ T cell was associated to recurrence/relapse. These preliminary observations might be used to plan further study aimed to identify reliable predictors of response to chemoradiation in oesophageal SCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Esophageal squamous cell cancer (ESCC) is one of the most common carcinomas worldwide. Long noncoding RNAs (lncRNAs) have been reported to play an important role in the progression of many diseases especially in cancers. Recent studies reveal that lncRNA TRPM2-AS is upregulated in many cancers and may function in tumor development and metastasis. This study aimed to explore the expression of TRPM2-AS and its clinical value in ESCC.

Aims & Methods: To investigate the function of long noncoding RNA TRPM2-AS in ESCC, RT-qPCR was used to monitor the expression level of long noncoding RNA TRPM2-AS in 50 paired ESCC tissues and ESCC cell lines. Moreover, the associations between long non-coding RNA TRPM2-AS expression level and clinical characteristics was analyzed. In addition, over-expression and RNA interference (RNAi) approaches were used to study the biological functions of TRPM2-AS in ESCC cells. Cell growth and proliferation was
analyzed by cell counting kit-8 assay. Cell cycle and apoptosis were evaluated by flow cytometric analysis. Protein levels of p53 were determined by western blot analysis. Differences between groups were tested for significance using Student’s-t test (two-tailed).

Results: ESCC tissues examined in this study showed an obvious increment in TRPM2-AS expression when compared to normal samples. Moreover, TRPM2-AS expression was positively correlated to lymph nodes metastasis, TNM stage and clinical stage. And upregulated TRPM2-AS expression was turned to be remarkably correlated with the shorter survival of ESCC patients which could act as an independent predictor for both overall survival time and disease-free survival. In addition, overexpression of TRPM2-AS could promote the proliferation and inhibit the apoptosis of ESCC cells, while knockdown of TRPM2-AS had a reverse function. Furthermore, downregulation of TRPM2-AS enhanced the expression of p53 in ESCC cells.

Conclusion: This study suggested that long non-coding RNA TRPM2-AS could be a potential oncogene of ESCC. TRPM2-AS expression might be served as another potential therapeutic target and prognostic biomarker. In addition, our study further confirms that TRPM2-AS contributes a lot to inhibiting apoptosis of ESCC by regulating the expressions of p53 in vitro, which may be a potential oncogene and therapeutic target for ESCC.

Introduction: Esophageal adenocarcinoma (EAC) is an increasingly common cancer with a poor prognosis. EAC is the final step of a pathway starting with esophageal reflux disease, intestinal metaplasia, and dysplasia. The expression of costimulatory molecules such as CD80 and CD86 in the esophageal cancer tissue is significantly lower than in the normal mucosa of healthy patients. This may be one of the mechanisms of immune escape of cancer cells in the esophageal cancer. In EAC, CD8 and NK cytolytic activity within the tumor was associated to nodal metastasis and CD107 expression might be used as a marker of it. Moreover, nuclear p53 overexpression within the tumor might be used as a marker of early recurrence after esophagectomy and then used to plan follow-up strategies. No apparent relation between progression and mismatch repair gene mutation was observed.

Disclosure of Interest: All authors have declared no conflicts of interest.

P2125 PHARMACOLOGICAL INHIBITION OF MONOCARBOXYLATE TRANSPORTER 1 INDUCES APOPTOSIS IN METASTATIC ESOPHAGEAL ADENOCARCINOMA CELLS

Introduction: Altered glucose metabolism has become a recognised feature of tumor cells, which is characterized by an increased glucose uptake and preferential dependence on glycolysis for energy production. As a consequence, cancer cells produce large amounts of lactate, which is pumped out the cytosol by monocarboxylate transporters (MCTs), mainly MCT 1 and 4. MCT inhibition has previously been related to increased apoptosis in cancer cells, but this aspect has not been investigated in esophageal adenocarcinoma (EAC) yet.

Aims & Methods: We aimed to evaluate the expression of MCT 1 and 4 in human samples of ESCC and to evaluate in vitro the effect of extracellular glucose concentration and pharmacological inhibition of MCT 1 on lactate concentration, intracellular pH (pHi), and cell apoptosis. MCT1 and MCT4 expression was assessed by immunohistochemistry in human samples of ESCC. For the in vitro study, two different EAC cell lines were used: OE33 (ECACC), established from an EAC of the lower esophagus and OACM5.1C (ECACC), obtained from a lymph node metastasis derived from an EAC. MCT1 and MCT4 expression and localization were assessed by immunohistochemistry in both cell lines. The MCT1 selective inhibitor AZD3965 (0, 10 and 100 nM) was added to the culture medium under a normoxic and hypoxic atmosphere in standard (11 mM) or high (30 mM) glucose content in the media. Apoptosis was determined by flow cytometry (Annexin V-FITC and propidium iodide). Intracellular lactate concentration and pharmacological inhibition of MCT1 on lactate concentration, intracellular pH (pHi), and cell apoptosis. MCT1 and MCT4 expression was assessed by immunohistochemistry in human samples of ESCC.
increased apoptosis of OACM5.1C cells whereas did not affect apoptosis of OE3.cell.

Conclusion: Metastatic and non-metastatic esophageal adenocarcinoma cells exhibit different glycolytic metabolism and response to pharmacological inhibition of MCT1, which increases apoptosis in metastatic cells. Further preclinical studies will be necessary in order to define the potential of blocking lactate transporters on the treatment of metastatic EAC.

Introduction: Although endoscopic submucosal dissection (ESD) is accepted as a standard treatment for early stage esophageal neoplasia, esophageal perforation is sometimes experienced as main adverse event. Esophageal perforation causes mediastinal emphysema, mediastinitis, and pneumothorax, those sometimes require emergency surgery.

Aims & Methods: We evaluated the predictive factors for esophageal perforation in patients who received esophageal ESD. This was a retrospective observational study in a single institution. Between May 2004 and March 2016, 549 consecutive patients with 927 lesions were treated with ESD. Endoscopic resection for esophageal squamous-cell carcinoma who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preserving strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: According to the current Japanese guidelines for the diagnosis and treatment of oesophageal cancer, endoscopic resection is indicated for pathological T1a (epithelium/lamina propria mucosae) and relatively indicated for T1a(muscularis mucosae) and T1b(a tumor invading the submucosa to a depth of 200µm or less). In accordance with the guidelines, we have actively performed endoscopic resection for esophageal squamous-cell carcinoma(ESCC). Evidence of submucosal or lymphovascular invasion on histopathological examination of the resected specimens was considered to indicate non-curative resection, chemoradiotherapy (CRT) was additionally administered, taking into account the risk of lymph-node metastasis. In principle, CRT comprised 2 courses of cisplatin plus 5-fluorouracil. Patients who were 76 years or older or who had mild renal dysfunction received 2 courses of nedaplatin plus 5-fluorouracil. The median tumor diameter was 22 mm (6 to 55) in the CRT group and 25 (3 to 47) in the follow-up group (p = 0.63). The tumor invades the MM in 9 patients, the SM1 in 3, and the submucosa to a depth more than 200µm (SM2) in 29 in the CRT group and the LPM in 3 patients, the MM in 16, the SM1 in 18, and the SM2 in 15 in the follow-up group (p = 0.91). Lymphatic invasion was positive in 21 patients in the CRT group and 12 in the follow-up group (p < 0.01). Vascular invasion was positive in 27 patients in the CRT group and 29 in the follow-up group (p = 0.32). Involvement of the submucosal or lymphovascular invasion at the vertical margin was found in 7 patients in the CRT group and 9 in the follow-up group (p = 0.09). CRT-related grade 3 or 4 early adverse events were leukopenia 24.3% (10 patients), neutropenia 29.3% (12), febrile neutropenia 4.9% (2), diarrhea 2.4% (1), anorexia 17.0% (7). In the CRT group, 38 of 40 patients received chemotherapy as scheduled. Treatment was discontinued in the second course in 2 patients, and 7 required dose reduction. Lymph-node metastasis were found in 2 patients in the CRT group and 7 in the follow-up group (p = 0.15). In 2 patients with recurrence in the CRT group, lymph-node metastases were seen in the irradiated field 46 and 49 months after treatment, respectively. 1 patient in the CRT group and 3 in the follow-up group died of esophageal cancer (p = 0.43). The overall survival (OS) rate at 2 years was 83.4% in the CRT group and 93.8% in the follow-up group (p = 0.02). Disease-free survival (DFS) at 2 years was 97.1% in the CRT group and 83.4% in the follow-up group (p = 0.02).

Conclusion: Additional CRT after endoscopic resection in patients with esophageal squamous-cell carcinoma who have submucosal invasion, lymphovascular involvement, or vertical-margin invasion can become an effective organ-preserving strategy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) was developed in Japan for the resection of large gastrointestinal neoplasia and has progressively been adopted in the West. Currently, early Barrett’s neoplasia is mainly treated with endoscopic mucosal resection (EMR) and/or radiofrequency ablation, being the ESD in this context not well-established yet. Our aim is to evaluate the safety, efficacy and outcome of ESD for the treatment of early Barrett’s neoplasia.

Aims & Methods: Fifty consecutive ESD cases of early Barrett neoplasia were performed in 42 patients in our center between 2011 and 2016. All ESDs were performed under full narcosis after multidisciplinary team conference discussion and patient’s consent. The primary endpoint was the rate of en bloc resection. Secondary endpoints included rate of R0 and curative resection, a comparison of pre- and post- ESD histology, procedure time, procedure-related adverse events, and rate of remission at follow-up. This study was approved by the Stockholm Regional Ethical Committee.

Results: Mean age was 67 years (range 46-84), being 74 male and 72% long segment BE. The mean specimen size was 52 mm (range 16-150 mm). ESD resections included <25%, 25-50%, 50-75% and 75-100% of the lumen circumference in 4/31/12/3 of cases, respectively. En bloc, R0 and curative resection were obtained in 96% (48/50), 80% (40/50) and 70% (35/50) of cases, respectively. The pre- and post- ESD histology corresponded to low-grade dysplasia and Barrett’s neoplasia (n = 36) and adenocarcinoma (n = 15). One case of LGD was upstaged to intramucosal AC, 10/30 cases of HGD were upstaged to adenocarcinoma. In 8/13 cases of AC, there was submucosal invasion on the ESD specimen. In 14/50 of the ESD specimens there was multifocal neoplasia. The mean procedure time was 120 minutes. There were 2 perforations (4%) treated endoscopically and 2 (4.0%) postoperative bleedings treated conservatively. Six patients (12%) developed esophageal strictures that were managed endoscopically. The 30 days mortality rate was 1%. The 15 non-curative cases were followed-up, 2 patients went through ESD, 1 received chemoradiotherapy and 2 patients are under surveillence. In the 10 esophagectomy cases, 4 patients had AC in the remnant Barrett’s esophagus and 2 patients had lymph node metastasis. Complete remission was
P1219 ENDOSCOPIC EVALUATION AT THE PRIMARY SITE OF CTI ESOPHAGEAL CANCER AFTER PROTON BEAM THERAPY AND CLINICAL RESULTS OF SALVAGE ENDOSCOPIC THERAPY FOR LOCAL RECURRENCE

Introduction: Recently, it has been reported that proton beam therapy (PBT) is the effective treatment for patients with esophageal squamous cell carcinoma (ESCC). However, there are few reports regarding the endoscopic evaluation of efficacy after PBT at the primary site.

Aims & Methods: The aim of this study is to clarify the adequate endoscopic evaluation of eradication of ESCC after PBT, and the clinical results of salvage endoscopic treatment for local recurrence. Patients with clinical T1 ESCC, and who had been treated with PBT between April 2013 and June 2016 at the National Cancer Center Hospital East were investigated. The total dose of PBT was 60 Gray- Equivalent (GyE). The efficacy of PBT at the primary site was evaluated with endoscopy, and the definition of complete response (CR) was used according to the same criteria as that of conventional chemoradiotherapy (CRT) as follows; disappearance of tumor lesion and ulcer, and absence of cancer cells with biopsy was verified. The endoscopic evaluation was performed within 2 months after the completion of PBT, and we repeatedly evaluated every month if the lesion did not achieve CR. The treatment for local recurrence after PBT was chosen based on the depth of the tumor as follows; endoscopic resection (ER) for cT1a, endophagotomy or photodynamic therapy (PDT) for cTb or deeper depending on patient’s condition.

Results: Among 44 patients who underwent PBT, the median age was 70 years (range, 41–79). The number of patients with clinical stage I was 23 (52%), and stage II, III, and IV were 16 (36%), 2 (5%), and 3 (7%), respectively. All patients underwent concurrent systemic chemotherapy. 43 patients (98%) could achieve a CR at the primary site and only one patient (2%) did not show a CR (non-CR) at the primary site. The median time to CR from the start of PBT was 85 days (range, 70–554 days) and 6 months or longer period was required to confirm CR due to the remaining PBT induced erosion or ulceration in 7 patients (15%). One patients whose primary site did not reach to CR showed prolonged ulceration for 385 days. Of 43 patients (14%) developed local recurrence, 18 patients (42%) developed local recurrence at the primary site, 8 patients (19%) at the regional lymph node recurrence or distant metastasis, and the median time to local recurrence from CR was 257 days (range, 111–722 days). The endoscopic finding of local recurrence was resembling submucosal tumors (SMT) in 3 and flat lesion in other 3 tumors. All 6 patients with local recurrence were indicated for endoscopic treatment (ER-R, PDT-2). No complications, such as major bleeding or perforation, were observed. And, 6 patients (100%) were alive without any recurrence at the median follow up period of 11 months (range, 1–32 months).

Conclusion: Longer period was required to confirm CR after PBT with chemotherapy in some cases comparing with the historical reports of that of conventional CRT. Careful closed endoscopic follow-up according to the way of conventional CRT enabled early detection of local recurrence and preferable local control with salvage endoscopic treatment.

P1220 CLINICAL OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL ESCOPHAGEAL NEOPLASMS OF PATIENTS WITH HEAD AND NECK CANCER

Contact E-mail Address: kipennach@yahoomail.com

Introduction: Surveillance programs of gastrointestinal endoscopy for detection of a second primary cancer in patients with head and neck squamous cell carcinoma (HNSCC) are very important since it can detect synchronous or metachronous esophageal squamous cell carcinoma (ESCC) in up to 15%–25%. The detection of ESCC in an early phase has paramount importance, since superficial lesions are amenable to endoscopic submucosal dissection (ESD).

Aims & Methods: The aim of this study was to investigate the clinical outcomes of ESD of superficial esophageal neoplasms (SENs) of HNSCC patients in an oncologic tertiary center. From 2010 to 2016, 3280 endoscopies were performed in patients with HNSCC and in 1887 chromoscopy with Lugol and NBI were performed. A total of 26 SENs, submitted to ESD, in 25 patients were retrospectively analyzed.

Results: The median tumor size was 4.37 cm (±1.83). The en bloc resection were 100% and free margin (R0) were 92.3%. The two patients with positive margins had a depressed component in endoscopic evaluation. Recurrence occurred in 11.5% (2/18) and one of these recurrences was successfully treated.

The circumference of the resection ≥75% was significantly associated with post-operative stricture (OR = 3.5; P < 0.05). The average number of endoscopic dilations for resolution of stenosis was 9.16 (±7.62). No procedure-related mortality occurred. Follow-up data median was 11 months.

Conclusion: Endoscopic surveillance of HNSCC is very important for SENs that are amenable to ESD. Observations of these lesions are feasible and safe with acceptable complication rates despite the high rates of stenosis in recurrences >75% of the circumference.

Disclosure of Interest: All authors have declared no conflicts of interest.

enrolled. At baseline, side-by-side ablations of 10 seconds were performed on all patients treated every 3–4 months. Endoscopic enucleation of EUS-confirmed edemas was confirmed. Outcomes: safety and tolerability (11-point visual analog scale (VAS) for pain), complete response (CR) rates (absence of MGIN or worse in biopsies), neoplastic progression and adverse events.

Results: Patients (63 MGIN, 17 HGIN) with a median lesion of 2 (IQR 2–3) cm in length. Of these, 79 patients (99%) were successfully treated; 3 developed superficial, self-limited mucosal laceraions upon balloon inflation and 2 of them were successfully re-ablated 3 months later. A median of 5 (IQR 3–7) ablations were performed per patient, in a median ablation time of 8 (IQR 5–10) minutes. As of April 2017, 77/79 (97%) patients completed a 3-month follow-up endoscopy and 69/77 (89%) exhibited endoscopic and histologic CR. Eight patients had residual USL and were again treated with side-by-side balloon inflation the following 2 months later and all patients had complete healing. To date, 4 patients have undergone a 12 month endoscopy and all continue to exhibit endoscopic and histologic CR. No significant strictures have been noted on follow-up. Three patients developed fever shortly after treatment which was treated with aspirin. Post-procedure median VAS was 1 (IQR 0–2) at day 2, and 0 (IQR 0–0) at days 7 and 30.

Conclusion: Preliminary results of our multicenter open prospective cohort study suggest that FCBA of ESCN is safe, well-tolerated, and highly effective in inducing endoscopic and histologic remission. Longer term (12 month) follow-up data is pending.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1222 THE ENDOSCOPIC TREATMENT STRATEGY FOR SUPERFICIAL ESOPHAGEAL CANCER

N. Yamaguchi
Department Of Gastroenterology And Hepatology, Nagasaki University Hospital, Nagasaki-Japan

Contact E-mail Address: naoyuki3435@nagasaki-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) allows en bloc removal of endoscopic submucosal dissection (ESD) allows en bloc removal of superficial esophageal squamous cell carcinoma (SCC). However, endoscopic submucosal dissection often occurs after ESD when the lesion involves more than three-fourth of the circumference of the lumen. Frequent balloon dilatation via endoscopy is required in such situation, thus causing health economic problem. In this study, we investigated the clinical outcomes, and prevention of post-ESD stenosis.

Aims & Methods: A total of 667 cases in 516 consecutive patients were treated by ESD in our department from April 2006 to December 2016. We investigated the following 2 items. 1. Clinical outcomes and complications. 2. Usefulness of oral steroid administration, the local steroids injection, endoscopic transmural injection of tissue-engineered autologous oral mucosal epithelial cell sheets, or steroid oral + local injection combination therapy for the prevention of post-ESD stenosis.

Results: 1. Clinical outcomes: En bloc resection rate was 99.8% and en bloc curative resection rate was 90.0%. The rate of perforation, post-ESD bleeding, and post-ESD stenosis was 0.2%, 0.8% and 6.1%, respectively. 2. Prevention of post-ESD stenosis: (1) Oral steroid vs Steroid injection vs Cell sheet transplantation: In oral steroid group, the stenosis rate was 14.9%, and the ulcer healing period was 59.5 days. In steroid injection group, the stenosis rate was 12.9%, and the ulcer healing period was 66.0 days. In cell sheet transplantation group, the stenosis rate was 40.0% and the ulcer healing period was 36.0 days. There was no significant difference between these 3 therapies, and these therapies prevent post-ESD stenosis to significant extent. However, ulcer healing period of the cell sheet transplantation group was significantly shorter compared with the other 2 therapies. (2) The usefulness of SH oral + local injection combination therapy. We investigated limitations of steroid administration, and cell sheet transplantation in order to prevent stenosis. The followings were 4 factors (more than 9/10 of circumferential resection, more than 5 cm of longitudinal resection, cervical esophagus, post history of chemo-radiation therapy or endoscopic resection) were the stenosis prevention treatment-resistant factors. Therefore, we examined the stenosis rate according to the number of these 4 factors. The stenosis rate of the cases which have 0 or 1 factor, the case which has more than 2 factors in semicircular cases, and the complete circular cases is 4.9%, 30.3%, and 44.8%, respectively. The stenosis rate of the cases which have more than 2 factors and complete circular cases are significantly higher, compared to the cases which have 0 or 1 factor. As a result, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. In contrast, in SH oral + local injection combination therapy, the stenosis rate of the cases which have more than 2 factors and complete circular cases is 17.5% and 14.3%, respectively. Taken together, the stenosis rate of SH oral + local injection combination therapy is significantly lower, compared to the other 3 therapies.

Conclusion: Eophageal ESD achieved high en bloc resection rate and curability with low rates of complications. Oral steroid, steroid injection therapy and cell sheet transplantation may be effective treatment strategy for reducing post-ESD stenosis. However, the above-mentioned 4 factors are the stenosis prevention treatment-resistant factors in these 3 therapy cases. Furthermore, the cases which have more than 2 factors and complete circular cases were regarded as the stenosis prevention treatment-resistant cases. SH oral + local injection combination therapy is very useful for prevention of post-ESD stenosis and a potential treatment-resistant factor.

showed the greatest disparities, was evaluated. We retrospectively evaluated long-term follow-up study for oncological outcomes about follow-up duration, locoregional recurrence, distant recurrence. Results: The median follow-up duration is 40.36 ± 20.74 months in all patients. Based on the previous our study, we divided patients two groups who underwent operations after 29 days. Of the 302 patients, 133 were in Group A (≥29days) and 169 in Group B (>29days). There were more differences between two groups about ASA score, ER Specimen size, intra-op. transfusion, POD/1 Hemovac® discharge, Maximal postoperative CRP in the clinicopathological characteristics. Like previous study our study the operative time, EBL, tumor size was significantly longer and more in group A compared with group B. There were totally 7 patients locoregional and distance recurrence during follow-up period. There were no differences in oncological outcomes between two groups.

Oncological recurrence for Each Group

Conclusion: Based on long-term follow-up data, surgery time after ER in EGC does not affect oncological outcome. These long-term follow-up results suggest that adding surgery at about 1 month after ER is optimal for better surgical outcomes without affecting the oncological outcomes.

P1225 THE POINT TO DISTINGUISH EARLY GASTRIC CANCER FROM DEPRESSION TYPE OF GASTRIC INTESTINAL METAPLASIA

T. Wakatsuki, S. Furutachi, H. Yamashita
Department Of Gastroenterology & Hepatology, Okayama Medical Center, Okayama/Japan

Contact E-mail Address: twakatsuki0530@yahoo.co.jp

Introduction: This study discusses two endoscopic findings which improve the accuracy of the diagnosis of early gastric cancers (EGC). After successful Helicobacter pylori eradication, we often observe multiple reddish depressed lesions and “patchy redness” or “acute redness” in the gastric mucosa. Even though most are intestinal metaplasia (IM), EGC is found among these lesions. A light blue crust (LBC) has been a highly accurate sign of the IM. There are, now, additional two endoscopic findings that should improve the accuracy of diagnosis of EGC. They are 1) “intraperithelial microinvation (IEMI)”, and 2) “Over flow”, Over flow is that the endoscopic finding that the structure of the depressed lesion spreads to the outside of the depression.

Aims & Methods: The aim of this study is to clarify the usefulness of two endoscopic findings in order to detect the EGC in the group thought to be an IM. This study discusses two endoscopic findings which improve the diagnosis of EGC. They are 1) "intraepithelial microinvation (IEMI)" and 2) "overflow" with GI malignancy and age (75.2% vs 72.2%, p = 0.05), male gender (72.2% vs 40.8%, p = 0.01), GI symptoms (61.1% vs 11.7%, p < 0.01), weight loss (61.1% vs 5.8%, p < 0.01), need for hospitalization (88.9% vs 49.5%, p < 0.01), iron serum level and transferrin saturation (97.1 ± 10.1 mg/L vs 30.4 ± 18.9 mg/L, p < 0.01, and 6.1 ± 4.4% vs 9.2 ± 6.3%, p < 0.03, respectively). At logistic regression analysis only weight loss (p < 0.01), GI symptoms (p < 0.01), transferrin saturation (p < 0.01) and need for hospitalization (p < 0.01) showed a significant association with the diagnosis of GI malignancy. Transferrin saturation showed a weak discriminative capacity (AUC = 0.67, p = 0.01) however, values of transferrin saturation ≤11% had a sensitivity of 94.4% and a negative predictive value of 97.1% for GI malignancy (CI 95% 92.3%–98.7%).

Conclusion: In patients with IMA the diagnosed with the diagnosis of GI malignancy is established in a significant percentage of patients and patients with GI symptoms, weight loss or with need for hospitalization should be given priority in the performance of endoscopic examinations. Transferrin saturation may help the early detection of GI malignancy.

P1226 IRON DEFICIENCY ANAEMIA—ARE THERE ANY PREDICTORS OF GASTROINTESTINAL MALIGNANCY?

S. Xavier1, J. Magalhães2, J. Cotta3
1Health Sciences Research Institute (ICVS), School of Medicine, University of Minho, Braga/Portugal 2Gastroenterology Department, Hospital da Senhora do Oliveira, Guimarães, Braga, Portugal 3Pt Government Associate Laboratory, 4 ICVS/38’s, Braga/Guimaraes/Portugal

Contact E-mail Address: smaxavier@gmail.com

Introduction: Iron deficiency anemia (IDA) may be the only sign of gastrointestinal (GI) malignancy. The identification of predictive factors of GI malignancy in patients with IDA could help the physician to establish patients' priority to endoscopic assessment, contributing to an earlier diagnosis.

Aims & Methods: Retrospective study of 344 patients submitted to endoscopic assessment for IDA. Included adult patients with IDA and excluded patients with GI or extra-GI bleeding, total gastrectomy, exclusively vegetarian diet or insufficient medical records.

Results: Included 121 patients with mean age of 68.5 ± 17.0 years and 54.5% females. GI malignancy was identified in 14.9% of patients (gastric in 12, colonic in 6 patients). A statistically significant association was found between the presence of GI malignancy and age (72.2% vs 40.8%, p = 0.01), male gender (77.2% vs 40.8%, p = 0.01), GI symptoms (61.1% vs 11.7%, p < 0.01), weight loss (61.1% vs 5.8%, p < 0.01), need for hospitalization (88.9% vs 49.5%, p < 0.01) and transferrin saturation (97.1 ± 10.1 mg/L vs 30.4 ± 18.9 mg/L, p < 0.01). At logistic regression analysis only weight loss (p < 0.01), GI symptoms (p < 0.01), transferrin saturation (p < 0.01) and need for hospitalization (p < 0.01) showed a significant association with the diagnosis of GI malignancy. Transferrin saturation showed a weak discriminative capacity (AUC = 0.67, p = 0.01) however, values of transferrin saturation ≤11% had a sensitivity of 94.4% and a negative predictive value of 97.1% for GI malignancy (CI 95% 92.3%–98.7%).

Conclusion: In patients with IDA the diagnosis of GI malignancy is established in a significant percentage of patients and patients with GI symptoms, weight loss or with need for hospitalization should be given priority in the performance of endoscopic examinations. Transferrin saturation may help the early detection of GI malignancy.

Introduction: Endoscopic submucosal dissection (ESD) is believed to be a possible modality for early gastric cancer. But there is little report about long-term outcomes of the ESD directly compare with the surgery. The purpose of this study is the comparison between the two treatment modalities about the outcome in long-term.

Aims & Methods: We performed a retrospective analysis of 1243 patients with stage I early gastric cancer without lymph node involvement. 551 patients were treated with ESD, and 692 patients were treated with subtotal or total gastrectomy. Long-term overall and disease-specific survival rates, development of new lesions, and complications were analyzed.

Results: The mean age was higher in the ESD group (64.9 ± 9.5 vs. 58.5 ± 11.7, P = 0.001) and female distribution was higher in surgery group (30.5% vs. 38.9%, P = 0.001). In ESD group, diabetes was more frequent (12.8% vs. 7.1%, P = 0.001). The overall survival rate was similar (96.2% vs. 96.7%, P = 0.136), but disease-specific survival rate was significantly higher in ESD group (99.8% vs. 98.7%, P = 0.037, log-rank test). During 10 year follow up period, new lesions were observed in 3.6% of ESD group and in 1.3% of surgery group (P < 0.001). ESD group showed less complications (4.5% vs. 16.3%, P = 0.001) and shorter hospital day than surgery group (5.27 days vs. 12.09 days, P < 0.001).

Conclusion: Although the development of new lesions were more frequent than surgery, ESD was similar overall survival rate and even higher disease-specific survival rate than surgery. Also, ESD has less complications and shorter hospital day than surgery. Therefore, ESD is an effective therapeutic method in early gastric cancer as well as surgery.

Introduction: Gastric malignant lymphoma (ML) is most popular lymphoma of the gastrointestinal tract. Especially we often see gastric MALT lymphoma in case of GC, ML and gastritis due to those similarities.

Aims & Methods: There was significant difference of appearance of gastric MALT lymphoma between specialists and trainees. Therefore, hematologists should order endoscopic examination to experts of endoscopy knowledgeable of ML in case of endoscopic check-up of gastrointestinal malignant lymphoma.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1221 DEVELOPMENT OF AND EXPERIENCE WITH AN INSULATED SCISSORS-TYPE KNIFE (SB KNIFE)
M. Kobayashi
Yokkaichi Municipal Hospital Dept. of Gastroenterology, Yokkaichi/Japan

Contact E-mail Address: makoto-kobayashi@ aroma.ocn.ne.jp

Introduction: Endoscopic submucosal dissection (ESD) is technically difficult and is associated with risks of perforation and bleeding. Although knife-type instruments are primarily used to make incisions during ESD, it is necessary to be proficient in endoscopic procedures and be able to perform them simultaneously with electriﬁcation and incision. Scissors-type knives are fairly easy to manipulate in colorectal ESD. We have fabricated SB knife Jr type (SBJr), short scissors-type knife with outer insulated layer, in collaboration with SUMITOMO RAKELITE CO.

Aims & Methods: SB Jr is short length (electrode length: 3.5 mm) to be easy to handle in narrow colorectal lumen. The surface of the rotatable monopolar scissors is coated with insulating material in order to enhance the cutting power and prevent electric effects in the surrounding tissue. The shearing structure makes sharp cutting quality and very small round tips prevent to grasp the muscular layer. SB Jr was used in circumferential incision, submucosal dissection and hemostasis. After infected hyaluronic acid in submucosal layer, grasped the tissue, conﬁrming safety, make incision. SB Jr was used not only in incision but also in hemostasis. At sites containing blood vessels or bleeding, they were grasped and induced coagulation using SB Jr. It has been used on 180 colorectal lesions from January 2008.

Results: The circumferential incision and submucosal dissection were basically performed with High-frequency cutting wave. There were 3 cases of perforation during ESD and 1 case of post-operative bleeding. The procedure itself was fairly easy and was particularly effective at sites difﬁcult to visualize the submucosal dissection and sites containing blood vessels, where conventional devices would encounter difﬁculties. Due to the very small round tips of the instrument, detailed operation become simply. For coagulation of blood vessels or bleeding, it is not required to replace SB Jr which is used cutting and coagulation.

Conclusion: This short insulated scissors-type knife (SB Jr) made it easier to perform colorectal ESD, we conclude that it is an effective device and easy for a beginner in colorectal ESD.

Disclosure of Interest: All authors have declared no conﬂicts of interest.

Introduction: The gastrointestinal tract (GIT) is the most commonly extranodal site affected in lymphomatous pathology. Infection with Helicobacter pylori is associated with risks of perforation and bleeding. Although knife-type instruments are primarily used to make incisions during ESD, it is necessary to be proficient in endoscopic procedures and be able to perform them simultaneously with electriﬁcation and incision. Scissors-type knives are fairly easy to manipulate in colorectal ESD. We have fabricated SB knife Jr type (SBJr), short scissors-type knife with outer insulated layer, in collaboration with SUMITOMO RAKELITE CO.

Aims & Methods: We evaluated the effect of body mass index (BMI) on early gastric cancer in patients undergoing endoscopic treatment for early gastric cancer. A total of 748 patients with early gastric cancer undergoing endoscopic treatment (endoscopic submucosal dissection) including age and sex matched healthy controls consist of this case-control study. Body mass index was classiﬁed into underweight (BMI < 18.5), normal (BMI 18.5–23), overweight (BMI 23–25), and obese (BMI ≥ 25) by Asian body mass index classiﬁcation. Histological analysis using odds ratio (OR) and 95% conﬁdence interval (CI) was performed to evaluate the effect of BMI on early gastric cancer.

Results: The mean age was 57 years and male sex was 60% (n=447). BMI was higher in gastric cancer compared to healthy control (24 vs 23, P<0.001). The OR of gastric cancer was increased according to the BMI increase; 1.57 (95% CI, 0.89–2.79, P=0.12) in normal BMI, 1.85 (95% CI, 1.06–3.35, P=0.03) in overweight, and 2.28 (95% CI, 1.29–4.06, P=0.005) in obese persons compared to underweight (<18.5) group.

Conclusion: The early gastric cancer was strongly associated with the increased BMI and its effect has dose-dependent pattern.

Disclosure of Interest: All authors have declared no conﬂicts of interest.

Contact E-mail Address: t.osoegawa@gmail.com

Introduction: Gastrointestinal subepithelial tumors include potentially malignant tumors. When considering the diagnostic yield for subepithelial tumors, it is important to evaluate whether the samples obtained are adequate for histological analysis, as immunohistological analysis is indispensable for a definitive diagnosis. However, it may be difficult to make a correct histological diagnosis with only the endoscopic ultrasonography-guided fine-needle aspiration (EUS-FNA). Therefore, there has been an interest in exploring an alternative modality for tissue sampling as mucosal-incision assisted biopsy (MIAB) based on the endoscopic submucosal dissection.

Aims & Methods: The aim of this study was to compare the usefulness of EUS-FNA and MIAB in the histological diagnosis of gastrointestinal subepithelial tumors (SET). We performed the retrospective study comparing 37 patients who underwent either EUS-FNA (n=18) or MIAB (n=19). Diagnostic yield, histological accuracy and safety of these procedures (EUS-FNA and MIAB) were compared.

Results: The location of the SET was esophagus (n=6), stomach (n=29), and duodenum (n=2). The histological diagnosis were gastrointestinal stromal tumors (n=10), leiomyoma (n=17), aberrant pancreas (n=3), poorly-differentiated adenocarcinoma (n=2), metastatic carcinoma (renal cell carcinoma, n=1), and no-diagnosis (n=4). There were no signiﬁcant differences in the clinical characteristics-including sex and age-of the patients in the EUS-FNA and MIAB groups. In EUS-FNA, the mean diameter of the tumor was 12.9 mm. In MIAB, the mean diameter of the tumor was 15.6 mm. The mean procedure time was significantly longer in MIAB (55.15 ± 27.42 min in MIAB) compared to EUS-FNA (55.15 ± 27.42 min in EUS-FNA) (P=0.00234). Histological diagnosis was made in 72.2% of the EUS-FNA and 94.7% of the MIAB cases (P=0.00897). No complications were found in either method.

Conclusion: The mean procedure time was significantly longer in MIAB than in EUS-FNA. However, the mean diameter of the tumor was significantly smaller in MIAB than in EUS-FNA for the higher diagnostic yield in MIAB than in EUS-FNA was borderline signiﬁcant.

Disclosure of Interest: All authors have declared no conﬂicts of interest.

Introduction: In 2012 the reported incidence of gastric cancer in both sexes was 13.1/100,000 but the early detection strictly related to a better survival. Parma area is considered at medium-low incidence of gastric cancer. For early diagnosis, the detection of a precancerous condition like atrophic gastritis seems crucial, but the majority of such patient is affected by non invasive condition like serology (Pepsinogens and Gastrin 17) as suggested in the guidelines of Kyoto and Maastricht II is up to now limited in clinical practice. Aim of the study, therefore was to establish the burden of gastric cancer in the diagnosis of the last six years, focusing on the detection of early gastric cancer.

Aims & Methods: Six years (from July 2010 to July 2016) were considered in search for diagnosis of gastric cancer as reported in the archives of the Pathology Department of Parma University. Overall, 816 cases of gastric cancer were found but we decided to consider only the surgically removed cases, therefore the available sample is based on 584 cases. For every cases we classified the cancer in early, following the Kodama classification, and advanced. The presence of atrophic gastritis nearby the neoplasia was assessed according with OLGA classification. Both early and advanced cancer the node status was investigated.

Results: Overall, 584 cases of gastric cancer was detected in the six years considered interval (M = 318, F = 223, mean age 78.8 years, range 36–105y). The diagnosis of early gastric cancer was made in 24/584 (7.3%) (M = 24, F = 20 mean age 75.68y, range 47–92y). A diagnosis of advanced gastric cancer was established in 540 pts (M = 318, F = 222, mean age 78.20y, range 36–105y). The picture of chronic atrophic gastritis was found in more than 95% of the cases, both in early and advanced ones. The node status was also recorded. Early cancers showed a 25% of node metastasis compared with 84.65% in advanced ones. As regards the number of involved nodes, in early presentation of neoplasia we found 98% of pN1 staging whereas in advanced the pN1 cases were only 9.1%.

Conclusion: Cancer diagnosis is still confirmed as too infrequent and this could account for the high mortality rate for the gastric neoplasia. The search for precancerous condition like chronic atrophic gastritis is therefore mandatory.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1236 GASTRIC ADENOCARCINOMA OF FUNDIC GLAND TYPE: CANCER GENOMIC DATA

Introduction: Gastric adenocarcinoma of fundic gland type (GAFG) is an uncommon variant of gastric adenocarcinoma which has a distinct clinicopathological, immunohistochemical, and endoscopic features 1–3). However, the molecular background of GAFG, next generation sequencing (NGS) was perfomed for all patients with gastric adenocarcinoma of fundic gland type (chief cell predominant type) using magnifying endoscopy with narrow-band imaging. Stomach and intestine. 2015; 50(12): 1533–1547.

Contact E-mail Address: 4094108@qq.com

Introduction: Runt-related transcription factor 3 (Runx3) is a transcription factor playing an inhibitory role in the malignant behavior of gastric cancer. Long non-coding RNAs (LncRNAs) exert their functions mainly by binding with corresponding transcription factors. Among transcription factors the most common ones. However, the LncRNAs that could bind with and affect the expression or activity of Runx3 are still unclear.

Aims & Methods: Potential Runx3-binding LncRNAs were screened by an online promoter-based software RPSiQ3. A specific HOTTIAR binding site with Runx3 was confirmed further by RNA Pull down. The E3 ubiquitin ligases being involved in the ubiquitin-proteasome degradation of Runx3 were recognized through co-immunoprecipitation assay. Besides, the expressions of HOTTIAR and Runx3 were measured in human gastric cancer tissues and correlated with each other.

Results: A total of 11 IncRNAs that might bind with Runx3 were selected by in silico analysis, among which, HOTTIAR, MALAT1, PT1 and LET were significantly amplified in RNAs precipitated by Flag antibody. Ectopic expression of HOTTIAR inhibits the protein expression of Runx3, while addition of exogenous MG132 could partially recover this. RNA Pull down assay with a stepwise depletion of Runx3 shows that HOT-D2 (1951–2100) is a major Runx3 binding site along the sequence of HOTTIAR. MX3b was markedly enriched by Runx3 body, and siRNAs targeting either HOTTIAR or Mex3b could enhance the stability of Runx3 by impairing its ubiquitination. In addition, HOTTIAR was negatively associated with the protein level of Runx3 in gastric cancer tissue.

Conclusion: HOTTIAR induces the ubiquitin-proteasome degradation of Runx3 by enhancing its interaction with a E3 ubiquitin ligase Mex3b in gastric cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1237 LNCRNA-HOTAIR INDUCES THE UBIQUITINATION OF RUNX3 IN GASTRIC CANCER

Introduction: Promoter hypermethylation plays a vital role in cancer development through transcriptional silencing of tumour suppressor genes. Using Infinium Human Methylation 450 BeadChip (450K) array, we first identified calcium binding protein 39-like (CAB39L) to be preferentially methylated in gastric cancer (GC) and it may function as a potential tumour suppressor gene.

Aims & Methods: In this study, we aim to investigate the biological function, molecular mechanism and clinical implications of CAB39L in GC. Clinical relevance was validated by bisulfite genomic sequencing (BGS), western blot and immunohistochemistry (IHC). In vitro functional assays were carried out by cell viability, colony formation, apoptosis, cell cycle, cell invasion and migration assays in GC cell lines. In vivo tumorigenesis was evaluated in an orthopic nude mouse model. Pathway analysis was performed using RNASeq and Phospho-kinase Antibody Array. The interaction of CAB39L with its protein partners was determined by co-immunoprecipitation assay.

Results: CAB39L mRNA was down-regulated in 13 out of 14 GC cell lines. Silencing of CAB39L was associated with promoter hypermethylation, and demethylation 5·treatment using Azadeoxycytidine (5-Aza) restored the expression of CAB39L. In human GC, CAB39L mRNA and protein level (p < 0.0001)
were significantly decreased in GC tissues comparing to adjacent normal tissues both in Chinese cohort (n = 48 pairs) and TCGA cohort (n = 450). CAB39L hypermethylation was correlated with poor overall survival in Chinese cohort (n = 87, p < 0.005) and validated in TCGA cohort (n = 354, p < 0.005), suggesting that CAB39L might function as a tumour suppressor. The functional importance of PKNOX2 in GC was therefore examined. Ectopic expression of CAB39L in three GC cell lines (AGS, BGC823, MKN45) suppressed cancer cell proliferation in vitro (p < 0.01) and colony formation assays (p < 0.0001). CAB39L induced apoptosis and G1 cell cycle arrest in GC cells, concomitant with the enhanced expression of cleaved caspase-8, caspase-3, p21 and decreased cyclin D3 expression. Cell migration and invasion abilities were inhibited by CAB39L in wound healing and gel invasion assays, respectively. Conversely, CAB39L knockdown in MKN28 demonstrated opposite effects. Orthotopic mouse model also showed inhibited tumorigenicity with CAB39L-overexpressing BGC823 cells. Mechanically, RNAseq and gene set enrichment analysis (GSEA) revealed that AMPK and ERBB2/ERBB4 signaling were involved in the tumour suppressive role of CAB39L in GC. Consistent with our RNAseq data, we confirmed that AMPK was the top activated kinase; whilst ERK1/2 was the most strongly down-regulated in CAB39L over-expressing GC cells, suggesting that CAB39L up-regulates AMPK concomitant with down-regulation of ERBB2/4/ERK signalling. Moreover, co-immunoprecipitation experiment between CAB39L and LKB1, a bona-fide tumour suppressor that functions to activate AMPK to suppress tumorigenesis. Western blot confirmed activation of LKB1-AMPKα/β cascade in GC cells expressing CAB39L, whose opposite effect was observed in CAB39L silenced MKN28 cells. Administration of an AMPK activator, AICAR, inhibited growth of control cells but not CAB39L-expressing (thus AMPK activated) cells, suggesting that AMPK activation by CAB39L contributes to tumour suppression. Collectively, this novel tumour suppressor silenced by promoter methylation in GC, CAB39L inhibits gastric tumorigenesis via LKB1-mediated activation of AMPKα/β. CAB39L methylation may serve as an independent prognostic biomarker for GC patients.

PKNOX2 via activating p53 signaling pathway, as determined by western blot assay. Importantly, p53 transcriptionally regulated IGFBP5 gene is coordinately up-regulated in PKNOX2 over-expressing cells, leading to tumour suppression.

Conclusion: PKNOX2 functions as a novel tumour suppressor silenced in GC by promoter methylation. Its tumour suppressive effect is mediated via IGFBP5 and the activation of p53 signaling pathway. Promoter methylation of PKNOX2 may be a useful biomarker for predicting patient prognosis.

Introduction: The relationship between Helicobacter pylori (H. p.) eradication and atrophic changes is debated. Although some studies report a partial restoration of GC glandular (GC) levels after eradication therapy, it is not clear today that finding reflects gastric mucosal healing. L-cysteine, reducing acetaldehyde production after food intake, has been proposed for prevention of gastric carcinogenesis in patients with chronic atrophic gastritis (CAG). To assess modifications in gastric function after L-cysteine administration in CAG by means of PGI and gastrin 17 (G17) serum levels

Aims & Methods: 62 patients (18 men, mean age 47.2 yrs), with histological diagnosis of moderate to severe chronic, atrophic, body gastritis (according to the Updated Sydney) and PGI serum levels higher than 25 pg/L in histological gastrointestinal endoscopy with gastric biopsy samplings and PGI and G-17 measurement by means of Gastropan®. 22 out of 62 patients had autoimmune gastritis while 40 of them reported previous H. p. infection. All patients, Helicobacter pylori negative at baseline, were treated with L-cysteine (100 mg three times daily), up to now 44 out of 26 reached 36 months-treatment. Serum PGI and G-17 were measured at baseline and after 3, 6, 12, 24, 36 months after starting therapy.

Results: The G-17 serum increased level after the starting of L-cysteine administration, as it follows: PGI mean value at baseline was 8.42 µg/L, but after 3 months therapy was 10.58, after 6 months 11.65, after 12 months 12.19, after 24 months 13.88, and after 36 months was 14.21 (p < 0.0001). The G-17 serum level resulted gradually decreased over the 36 months therapy, as it follows: G-17 mean value was 51.33 mp/ml at baseline, 43.13 after 3 months therapy, 38.66 after 6 months, 28.34 after 24 months and 26.03 after 36 months (p < 0.0041).

Conclusion: After L-cysteine administration, patients with chronic, atrophic, body gastritis showed long-lasting improvements of physiological gastric function, reflected by a significant increase of PGI levels and a parallel decrease of G-17 serum levels over a 36 months follow-up period.

Introduction: Signaling pathway mediated by androgen receptor (AR) plays an important role in the development of gender-related tumors, such as hepato-cellular carcinoma, prostate cancer. Gastric cancer (GC) is the third cause of cancer related death all over the world, and its incidence in male is also much higher than female. However, the molecular mechanisms of AR in gastric cancer are still poorly characterized.

Aims & Methods: To investigate the role of AR in gastric cancer, we identify the transcriptional downstream targets of AR by chromatin immunoprecipitation. We detected mRNA and protein expression level of AR and its target in paired GC samples using RT-PCR and western blot. The biological functions of AR signaling pathway in GC cell lines were determined by colony formation and cell migration/invasion assay.

Results: CCRK was demonstrated as the direct target of AR by chromatin immunoprecipitation. AR expression was elevated in most (6/7) GC cell lines compared with the immortalized gastric cell lineGES1. CCRK was upregulated in all (7/7) tested GC cell lines. The correlation of AR and CCRK expression was statistically significant. Higher mRNA level of both AR and CCRK were detected in GC tissues compared with the adjacent normal tissues (P < 0.01). Ectopic re-expression of AR or CCRK by stable transfection promoted colony formation and invasiveness (P < 0.05). Consistently, the numbers of colony formation, migrated cells and invasive cell were reduced by knockdown of AR or CCRK in GC cells (P < 0.01).

Conclusion: Our results demonstrate that AR directly regulates CCRK expression in GC. AR and CCRK gene may act as a potential oncogene in gastric carcinogenesis by playing an important role in promoting of cell proliferation, migration and invasion, which may partially explain the higher prevalence of gastric cancer among males.

Disclosure of Interest: All authors have declared no conflicts of interest.
and 6 of these patients had coeliac, whilst 4 had other pathology such as granulomas or duodenitis. For all the patients who had abnormal D2 biopsies, they had other clinical markers of malabsorption, such as abdominal pain and diarrhoea, or biochemical indices such as anaemia or elevated TTG antibodies.

Conclusions: We conclude that yield of routine duodenal biopsies in patients endoscoped for the sole indication of weight loss is poor. In patients with weight loss in whom coeliac disease is identified on biopsy it is always associated with additional symptoms or abnormalities in blood indices. We conclude that there is no need to take biopsies of the duodenum on a routine basis for weight loss alone unless there are other signs of malabsorption. This will save time (both from taking the biopsy and sampling in the lab), lower the cost (forces and pot) and improve the safety (potential perforation and bleeding risk) of the procedure.

P1245 FUNDING DISPARITIES IN DIGESTIVE CANCER RESEARCH IN THE UNITED STATES

P. S. Liang1, K. O'Connell2, M. Du3
1Medicine, New York University, New York/United States of America
2Memorial Sloan Kettering Cancer Center, New York/United States of America

Contact E-mail Address: peterliang@gmail.com

Introduction: In 2015, the five most common digestive cancers (colorectal, pancreatic, liver, gastric, and esophageal) accounted for 16% of incident cancer cases and 14% of all cancer death. It is unclear whether the amount and recent trends in US federal funding for digestive cancer research corresponds to the burden of disease.

Aims & Methods: We obtained the total annual funding for cancer (including the five most common digestive cancers) from 2008 to 2015 using a public database of research funded by US federal agencies. We calculated funding in 2015 constant USD using the Consumer Price Index. Cases and deaths estimated by the American Cancer Society were used to calculate funding per death or case for each cancer. For comparison, we also extracted data for the three most common cancers (breast, lung, prostate) and all cancers combined. As funding for research in the United States was boosted by the American Recovery & Reinvestment Act in 2009–2010 and declined thereafter, we analyzed trends in funding and disease incidence in the United States. We determined whether the amount and recent trends in federal funding for digestive cancer research were proportional to the amount and recent trends in the five most common digestive cancers.

Results: In 2015, 8 billion USD in federal funding was issued to all cancer research and 658 million USD to the five common digestive cancers. The five common digestive cancers received less than 5% of all cancer funding. The ratio of the proportion of all cancer death to the proportion of all cancer research and 658 million USD to the five common digestive cancers. The five common digestive cancers received less than 5% of all cancer funding. The rate of the proportion of all cancer death to the proportion of all cancer research and 658 million USD to the five common digestive cancers. The five common digestive cancers received less than 5% of all cancer funding. The rate of the proportion of all cancer death to the proportion of all cancer research and 658 million USD to the five common digestive cancers.

Conclusion: The estimated number of deaths and cases decreased for colorectal cancer but increased for esophageal and gastric cancer among digestive cancers and for lung cancer overall. The funding disparity, measured by proportional death and funding, was highest for liver cancer in 2015. Gastric cancer was the only digestive cancer to measure in the top two for both funding per death and per incident case.

P1247 CURCUMIN DOWNREGULATES INTERLEUKIN (IL)-17 BY INCREASING THE EXPRESSION OF INDOLEAMINE 2,3- DIOXYGENASE (IDO) IN HELICOBACTER PYLORI INFECTED HUMAN GASTRIC MUCOSA

T. Larussa, R. Liprotti, S. Gervasi, E. Suraci, R. Marasco, M. Imenone, F. Luzzato
Department Of Health Sciences, University of Catanzaro, Catanzaro/Italy

Contact E-mail Address: tiziana.larussa@gmail.com

Introduction: IDO promotes the effector T-cells apoptosis by catalyzing the rate-limiting first step in tryptophan (Trp) catabolism. We demonstrated that the high expression of IDO in H. pylori-infected human gastric mucosa attenuates Th1 and Th17 immune response, as well as their Th2 and Th17 immune response. IDO has the potential to decrease the expression of the promotor CpG island hypermethylation in gastric carcinogenesis. H. pylori infection was associated with promotor hypermethylation of genes in gastric carcinogenesis, and H. pylori eradication might reverse p16 and CDH1 hypermethylation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1246 HELICOBACTER PYLORI ERADICATION MODULATES ABBRENT CPG ISLAND HYPERMETHYLATION IN GASTRIC CARCINOGENESIS

J. Choi1, S.G. Kim2, B.G. Kim2, S. Koh2, J.W. Kim2, K.L. Lee2
1Department Of Internal Medicine, SMG-SNU Boramae Medical Center, Seoul/Korea, Republic of
2Internal Medicine And Liver Research Institute, Seoul University College of Medicine, Seoul/Korea, Republic of

Introduction: H. pylori infection induces aberrant DNA methylation in gastric mucosa, which is under the influence of the effectiveness of the eradication therapy. The eradication therapy is associated with the hypermethylation of CpG island promoters in human gastric neoplastic cells. In this study, we evaluated the effect of the eradication treatment on promoter CpG island hypermethylation in gastric carcinogenesis.

Aims & Methods: H. pylori-positive patients with gastric adenoma or early gastric cancer who underwent endoscopic resection were enrolled. According to H. pylori eradication after endoscopic resection, the participants were randomly assigned to H. pylori eradication or non-eradication group. H. pylori-negative gastric mucosa from normal participants provided the normal control. CpG island hypermethylation of tumor-related genes (p16, CDH1, and RUNX-3) was evaluated by quantitative MethLight assay in non-tumorous gastric mucosa. The gene methylation rate and median values of hypermethylation were compared after one year by H. pylori status.

Results: In H. pylori-positive patients, hypermethylation of p16 was found in 80% (n=18) of CDH1 in 80.6% (n=17) and RUNX-3 in 48.4% (p=0.005). This was significantly higher than normal control (p16, 10%; CDH1, 44%; RUNX-3, 16%) (p<0.05). In the H. pylori eradication group, methylation rates of p16 and CDH1 decreased in 58.1% and 61.3% of the patients, and the median values of hypermethylation were significantly lower at one year compared with the non-eradication group. However, RUNX-3 hypermethylation did not differ significantly at one year after H. pylori eradication. The non-eradication group hypermethylation did not change after eradication.

Conclusion: H. pylori infection was associated with promoter hypermethylation of genes in gastric carcinogenesis, and H. pylori eradication might reverse p16 and CDH1 hypermethylation.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1248 ALTERATIONS IN SALIVARY MICROBIOTA IN SUBJECTS WITH HELICOBACTER PYLORI-ASSOCIATED GASTRYTIS

W.K. Leung1, K.S. Lai2, T.S. Tong3, K. Chu3, P.C. Sham3
1Department Of Medicine, University of Hong Kong, Hong Kong/Hong Kong PRC
2Department Of Surgery, The University of Hong Kong, Hong Kong/Hong Kong PRC
3Centre For Genomic Sciences, The University of Hong Kong, Hong Kong/Hong Kong PRC

Contact E-mail Address: waikingleung@hku.hk

Introduction: Alterations in salivary microbiota have been linked to elevated inflammatory responses and has been reported in patients with inflammatory bowel disease and pancreatic cancer. As yet, the potential association between salivary microbiota and patients with gastric disease has not be determined.

Aims & Methods: In this study, we characterized the salivary microbiota in patients with H. pylori-associated gastritis and the potential changes of salivary microbiota after receiving HP eradication. We enrolled subjects who were scheduled for diagnostic upper GI endoscopy. We excluded patients with peptic ulcer or cancer found on endoscopy, who have received prior HP eradication therapy, and who have recent exposure to antibiotics or acid suppressive therapies. Unstimulated saliva samples were obtained from subjects during fasting state. 16S rRNA gene sequences were determined for determination of HP statuses by rapid urease test and histology. Another gastric biopsy was obtained for characterization of gastric microbiota. Serial salivary samples were obtained from HP-infected subjects 8-week after completing HP eradication therapy. Bacterial DNA was extracted for 16S rRNA sequencing by using the MiSeq Platform (Illumina). OTU clustering was performed and taxonomy assigned to the Greengene and HOMD database. Alpha and beta diversities and Linear Discriminant Analysis Effect Size (LEfSe) was used to identify differentially expressed bacterial DNA in different groups.

Results: We enrolled 16 subjects with confirmed HP gastritis and 14 HP-negative subjects. Baseline salivary samples of all subjects were found to have significantly higher salivary microbial diversity than corresponding gastric samples. The predominant microbial family identified in the stomach is Helicobacteraceae (55.2%) whereas Helicobacteraceae constitutes only 0.1% of salivary microbiota. In contrast, the predominant families in saliva microbiota are Prevotellaceae (23.9%) and Neisseriaceae (20.3%). When compared to HP-negative subjects, salivary microbiota in HP-positive patients showed a significant increase in the Bacteroidetes and Spirochaetaceae, and a decrease in Flavobacteriaceae families. HP eradication therapy resulted in a significant reduction in the relative abundance of family Flavobacteriaceae and an increase in families Helicobacteraceae, Lachnospiraceae, Porphyromonadaceae, and Ruminococcaceae. Conclusion: There was a significant difference in the microbial diversity and compositions between gastric and salivary microbiota in HP-infected subjects, with Helicobacteraceae dominating the gastric microbiota. HP-infected subjects have a distinctive microbiota in the saliva which is reversed by HP eradication therapy. The significance of these microbial alterations in the saliva of HP-infected subjects and its correlation with gastric diseases deserves further investigation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Autoimmune gastritis (AIG) results in hypo/achlorhydria due to parietal cells destruction. It is characterized by lower levels of serum pepsinogen (Pg) I and PgI/PgII ratio and increased levels of gastrin. Some Authors support an association between AIG and Helicobacter pylori (HP) infection.

Aims & Methods: The aim of our study was to assess epidemiological, serologic and pathologic features of AIG patients with and without previous HP infection. Two hundred and eleven consecutive patients with AIG, undergoing endoscopy and biopsies, were included. Serum gastrin, PgI, PgII and Cromogranin A levels were determined in all patients. Multiple gastric biopsies were obtained for histology, OLGA staging and HP detection. Previous or current HP infection (HP+) was confirmed in patients by anamnestic and/or pathologic and/or serologic data. Statistics was performed using non parametric tests.

Results: Present or previous HP infection was confirmed in 50/211 patients while 161 were negative (HP-). When we compared HP+ vs HP- AIG, no differences were found for age and gender distribution, antral and fundic/body atrophy, OLGA staging, PgI and PgII ratio and Cromogranin A levels. Gastrin levels and Gastrin/PgI ratio, a global marker of gastric damage we previously identified, were higher in HP+ vs HP- (p < 0.02). Interestingly, 15% HP+ presented antrum atrophy. Severity of ECL hyperplasia was higher in HP+ (p = 0.02) with a 3.5 RR of developing nodular or carcinoid lesions when compared with HP+. Serum PgI, PgII, PgI/PgII and gastrin levels correlated with disease severity in HP+ (p < 0.01) but not in HP-.

Conclusion: HP+ AIG have/have had a mild infection without differences in OLGA staging when compared with HP- HP+ are characterized by lower gastrin and gastrin/PgI levels that, considered the lack of differences in OLGA staging, we suggest are related to a more extensive seroconversion process. HP- patients selected G Cell damage leading to lower levels of gastrin and Gastrin/PgI ratio. Consequently, they have lower degrees of ECL hyperplasia and a lower risk of developing carcinoids when compared with HP-. The presence of antrum atrophy in HP+ could be explained with the supposed autoimmune antrum damage hypothesis in AIG+. In conclusion, HP+ and HP- AIG have some differences in serological phenotype and HP infection may correlate in AIG with lower ECL hyperplasia and lower risk of neuroendocrine tumor. Disclosure of Interest: All authors have declared no conflicts of interest.

P1251 THE INVESTIGATION OF MIR-155, MIR-21, MIR-146A AND MIR-223 EXPRESSIONS IN HELICOBACTER PYLORI POSITIVE AND NEGATIVE INDIVIDUALS

N. Uyar Alpaslan1, E. Ucbilek2, I. O˘. Barlas1, O. Sezgin2, S. Yarar1

Effect: miRNA isolation. hsa-miR-155, hsa-miR-21, hsa-miR-146-a and hsa-mir-223 assessed by the rapid urease test. Serum specimens of patients, were taken for H. pylori infection. All patients were divided on two groups: with cagA (+) and absence in 10 patients (cagA (+) group). In cagA (+) patients mean level interleukin-1b was 395.6 pg/ml, but in cagA (-) patients-311.2 pg/ml (p < 0.05). Level of interleukin-1b in cagA (+) patients was 2.4 pg/ml but in cagA (-) patients-0.32 pg/ml (p < 0.05). Level of interleukin-4 in cagA (+) patients was 21.6 pg/ml, but in cagA (-) patients-83.4 pg/ml (p < 0.05).

Conclusion: presence in a genome of H. pylori cagA gene is accompanied by reliable increase in level of pro-inflammatory interleukin (IL-1b, IL-8) and decrease in level anti-inflammatory interleukin-4 that can be an additional factor of development of an inflammation during H. pylori infection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: baryshnikova_nv@mail.ru

Introduction: Change of interleukin level can be in patients with of chronic infections, in particular at Helicobacter pylori infection. Change of interleukin level in infected patients is significantly increased, for example, increase in level of interleukin-8 according to a number of works is accompanied by infection with virulent strains of a microorganism. CagA gene coding synthesis of the cytokotoxin (CagA) of the same name capable, in addition, to exert impact on development of interleukin-8, in particular at infection with CagA (+) is considered a marker of presence of pathogenicity island of H. pylori.

Aims & Methods: The aim was to define features of change of level of interleukin-1b, interleukin-4 of H. pylori (+) and interleukin-4 of H. pylori (-) strains. Levels of interleukins 1-β,4,-8 decided by immune-fluorescence analysis (the Vektor-Best sets, Russia).

Results: cagA gene was detected in 30 patients (cagA(+)-group) and absence in 10 patients (cagA(−)-group) in H. pylori (+) patients mean level interleukin-1b was 395.6 pg/ml, but in cagA (−) patients-311.2 pg/ml (p < 0.05). Level of interleukin-1b in cagA (+) patients was 2.4 pg/ml but in cagA (−) patients-0.32 pg/ml (p < 0.05). Level of interleukin-4 in cagA (+) patients was 21.6 pg/ml, but in cagA (−) patients-83.4 pg/ml (p < 0.05).

Conclusion: presence in a genome of H. pylori cagA gene is accompanied by reliable increase in level of pro-inflammatory interleukin (IL-1b, IL-8) and decrease in level anti-inflammatory interleukin-4 that can be an additional factor of development of an inflammation during H. pylori infection.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Potent acid inhibition with acid inhibitory drugs is crucial to the second-line eradication for H. pylori infection. Vonoprazan was comparatively inhibiting the binding of potassium ion to H+–K+-ATPase in gastric parietal cells and inhibits H+–K+-ATPase activity at 400-fold more potent than that of lansoprazole, proton pump inhibitor (PPI). Therefore, the eradication regimen containing vonoprazan has the potential for increasing eradication compared with a PPI-based therapy. Although vonoprazan is mainly metabolized by CYP3A4/5, it is unclear whether its acid inhibitory effect and outcome of H. pylori eradication differ among CYP3A4/5 genotypes. Our aim was to clarify whether CYP3A4/5 genotypes affect outcome of H. pylori eradication including vonoprazan in Japanese.

Aims & Methods: We investigated the influence of CYP3A4/5 and CYP2C19 genotypes and susceptibility of antimicrobial agents for outcome of vonoprazan-contained eradication regimen for 7 days in 105 Japanese: (1) with amoxicillin 750 mg and clarithromycin 20 mg twice daily (bid) as the first-line treatment (n=76); (2) with amoxicillin 750 mg and metronidazole 250 mg bid as the second-line (n=29). Eradication was assessed at eight weeks via 13C-Urea breath test. CYP3A4*22, CYP3A5*3 and CYP2C19*2/3*5 were genotyped for all patients.

Results: Eradication rate on intention-to-treat analysis was 82.9% (95% confidence interval (CI): 75.6–89.2%) in the first-line treatment and 93.1% (95% CI: 89.1–97.1%) in the second-line treatment. No CYP3A4*22 was observed. 38.3% of patients (46/120) were CYP3A5*1/*3 type and 55.0% were CYP3A5*3 type. In naive patients, the prevalence of clarithromycin-resistant strain was 42.4% (107/253). The eradication rate in patients with CYP3A5*1/*3 carrier type (CYP3A5*1/*1 and *1/*3 types) was 72.4% (54.5–86.7, 24.33), which was significantly lower than that in the CYP3A5*3 type (90.7%, 77.9–97.4, 39.43, p=0.039) in the first-line treatment. However, no significant differences of clinical outcome in the second-line therapy were seen among CYP3A4/5 genotypes.

Conclusion: Eradication rates of vonoprazan-based eradication therapy can be achieved high compared with PPI-based therapy. However, because CYP3A5*3 genotype may be one of determinate for outcome of eradication regimen including vonoprazan, genotyping of CYP3A5*3 will be required to be paid attention for clinical outcome before treatment.

such as erosion and diarrhea were reported in 6.6% (9/136) of patients in VPZ, in contrast to 4.3% (6/139) in LPRZ.

Conclusion: The first-line regimen with VPZ was superior to conventional PPI regimen, and was a result not to be inferior in the safety either.

P1257 CAN TWO WEEK BISMUTH BASED QUADRUPLE THERAPY FOR RESISTANT H. PYLORI INFECTION STILL BE USED IN THE UK?
H. Logan-Ellis, L. Bensaïd, R. P.H. Logan
Gastroenterology, King’s College Hospital, London/United Kingdom

Contact E-mail Address: hughloganellis@kshs.net

Introduction: Eradication of H. pylori infection cures peptic ulcer disease (PUD); however the most effective and ideal and many studies require repeated courses of treatment. We, and others, have recently documented that currently, within the UK, less than 30% of patients with proven PUD, are subsequently documented to have been cured by H. pylori eradication (7). Currently there is no consensus regarding 2nd line treatments, but the British National Formulary recommends a two regimen containing bismuth subcitrate, omeprazole, tetracycline and metronidazole. However since 2016, bismuth subcitrate has not been available in the UK, but is thought to be an important in treating persistent H. pylori infection (8,9).

Aims & Methods: The aim of this observational cohort study was to evaluate the effectiveness of a 2 week bismuth based quadruple therapy in patients who had previously failed first line eradication therapy. Patients were identified from electronic hospital records using endoscopy data set, patient administration records, and pathology data sets from Jan 2011 to Dec 2016. Initial failed H. pylori eradication was defined by either by a positive 13C-Urea Breath Test (13C-UBT) or positive HpStool Antigen test (HpSA) following H. pylori treatment in either primary or secondary care. All patients were seen, assessed and warned about the importance of compliance with treatment and of possible side effects by the specialist (RL) or the dyspepsia nurse specialist (E.Ierardi). After treatment, omeprazole 20 mg bd, tetracycline 500 mg qds, metronidazole 400 mg qds and bismuth sub citrate for 2 weeks, eradication was assessed at least 4 weeks after finishing treatment by 13C-UBT (or HpSA in those patients unable to attend hospital appointment). Endoscopy was also performed in those patients whom had failed multiple previous treatments to ascertain the clinical need for further treatment by assessing any underlying ulcer diathesis and for H. pylori culture and sensitivity testing.

Results: Within the inclusion period, (and from >560 patient records), 41 patients (22 male, 19 female, mean age 64 yr, range 17-84 yr) were identified as having persistent H. pylori infection by +ve 13C-UBT (n = 25), HpSA (n = 10) or histology/CL0Test (n = 6). All had failed at least one treatment, but 14/41 (34%) had failed 2 or more. Most patients were non or light drinkers (90%) and non-smokers (74%). OGD was performed in 19 patients to clarify indication for further attempts at H. pylori eradication and showed evidence of ulcer disease (ulcer, scarring or erosions) in 13/19 (68%). Culture and antibiotic sensitivity testing was unsuccessful in 3/5 patients. At least 6 weeks after the end of treatment, either by 13C-UBT or HpSA was negative in 34/36 (94%) (95%CI 82-98%). 5 patients failed to attend for assessment of eradication. During the follow up period from 2011 onwards, 11 patients underwent repeat 13C-UBT or HpSA testing, and all remained cured of infection.

Conclusion: Two week standard bismuth based quadruple therapy remains a highly effective treatment for persistent H. pylori infection in those patients in whom eradication of infection is mandated by the an underlying ulcer diathesis. The low eradication rate is likely due to the use of bismuth high doses of antibiotics, but also by specialists ensuring patients complied with their medication. These data, together with the poor outcomes of H. pylori eradication when undertaken by general physicians, also highlight the need for H. pylori eradication to be one of priority for specialists who have access to alternative sources of collodial bismuth subcitrate.

P1258 MAY PROBIOTICS MONOTHERAPY ERADICATE HELICOBACTER PYLORI IN PERSISTENT H. PYLORI INFECTION: A SYSTEMATIC REVIEW WITH POOLED-DATA ANALYSIS
G. Losurdo, R. Cubisino, M. Barone, M. Principi, E. Ierardi, A. Di Leo
Emergency And Organ Transplantation, University of Bari, Bari/Italy

Contact E-mail Address: giuseppelos@alice.it

Introduction: Despite several evidences in literature have demonstrated a role for probiotics as adjunctive treatment for Helicobacter pylori (H. pylori) eradication, national and international guidelines as well as meta-analyses suggest that only co-administration of probiotics may have a beneficial effect on the prevention of side effects and eradication rates. Herein, we performed a systematic review with pooled-data analysis aimed to clarify whether probiotics alone may eradicate the bacterium.

Aims & Methods: Methods of analysis and inclusion criteria were based on PRISMA recommendations. Relevant publications were identified by a research in PubMed, MEDLINE, Science Direct and EMBASE. The end-point was to estimate the mean eradication rate and variations of delta value at urea breath test across all studies and, overall, with a pooled data analysis. The data have been expressed ad proportions/percentages, and 95% confidence intervals (CI) were calculated. For continuous variables, we calculated the weighted mean difference. Odd ratios (OR) were calculated, where available, based on the Mantel-Haenszel method. Data were entered into the RevMan 5.3 software. Real-life studies (both randomized clinical trials and open label pilot studies) were selected. In one study patients with peptic ulcers were selected, while in the remaining 9 only dyspeptic patients were recruited. Probiotics eradicated H. pylori in 50 out of 391 cases. The mean eradication rate was 14%, with a 95% CI of 2-25% (p = 0.02). Most of studies investigated a probiotic formulation based on a single lactobacilli strain. Lactobacilli eradicated the bacterium in 30 out of 235 patients, with a mean weighted rate of 16% (95% CI 1–31%). Multistitution combinations were effective in 14 out of 105 patients, with a pooled eradication rate of 14% (95% CI 16–43%). In the comparison probiotics versus placebo, we found an OR = 9.65 in favor of probiotics, with a 95% CI of 1.97–47.36 (p = 0.005). Finally, probiotics induced a mean reduction in delta values of 8.61% (95% 5.88–11.34, p < 0.0001). No study provided data about adverse events.

Conclusion: Probiotics alone show a minimal effect on the eradication of H. pylori, thus suggesting a presumable direct effect. However, they cannot be indicated as a therapeutic regimen for the low eradication rate. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The new bismuth-containing quadruple therapy is currently advised as a third-line treatment for recurrent H. pylori infection, either in naive or previously treated patients. Our aim was to assess the real-life effectiveness and safety of this therapeutic regimen in a large population of patients who were infected by H. pylori.

Aims & Methods: Consecutive dyspeptic H. pylori-positive patients were enrolled, both naive for treatment and already unsuccessfully treated. Patients were treated with Pylera® (3-in-1 capsules containing bismuth subcitrate potassium 140 mg, metronidazole 125 mg and tetracycline 125 mg) 3 capsules four times a day plus omeprazole 20 mg or esomeprazole 40 mg two times a day for 10 days. Eradication was confirmed using a urea breath test (at least 30 days after the end of treatment). Efficacy and safety were assessed.

Results: Three hundred and twenty patients were included in the study: 131 (40.9%) patients were naïve, and 189 (59.1%) patients with previous failure treatment. H. pylori eradication was achieved in 299 (93.4%), 95% confidence intervals (CI) were 92.2–95.6%. Patients unable to attend hospital appointment (95.4% vs 92.1%, P = 0.336). Treatment-emergent adverse events occurred in 61 patients (19.1%, 95% CI 14.6 to 24.54). They were mild in all cases except in ten, who discontinued the study due to diarrhea (four patients) and diffuse urticarial rash (6 patients).

Conclusion: This bismuth-containing quadruple therapy achieved a remarkable eradication rate in real life, irrespective as first treatment or as a salvage therapy, despite the frequent occurrence of mild adverse events.

P1260 COMPARISON OF CLARITHROMYCIN- AND LEVOFLOXACIN-CONTAINING TRIPLE THERAPIES FOR FIRST-LINE HELICOBACTER PYLORI ERADICATION IN IRAN

H. Fakheri1, A. Sadoogh2, S. Taheri3

Introduction: Helicobacter pylori (H. pylori) eradication can be considered as a suitable option for first-line treatment in areas with less than 20% resistance to clarithromycin (CI). The aim of the present study was to evaluate the eradication rates to Clarithromycin. On the other hand, resistance to Clarithromycin is increasing in Iran, influencing the efficacy of standard triple therapy in this country. Therefore, regimens containing other antibiotics have to be considered in Iran.

Aims & Methods: One hundred and forty patients with peptic ulcer disease and negative H. pylori infection were randomly divided into two groups to receive either 10-day standard triple therapy (Pantoprazole 40 mg, Amoxicillin 1 g and Clarithromycin 500 mg, all given twice daily) or 10-day Levofloxacin-containing triple therapy (Pantoprazole 40 mg BD, Amoxicillin 1000 mg BD and Levofloxacin 500 mg q.d.). Eight weeks after the treatment, H. pylori eradication was assessed by 14C-urea breath test.

Results: One hundred and thirty-three patients completed the study. According to intention to treat analysis, H. pylori eradication rates were 75.7% (95% CI: 65.7%–85.7%) and 58.5% (95% CI: 47.1%–70%) in standard and Levofloxacin-containing therapies, respectively. Also, per-protocol eradication rates were 83% (95% CI: 74.9%–92%) and 61% (95% CI: 49%–73%), respectively. The rates of severe adverse effects of therapy were 7.1% and 2.9% in the mentioned groups, respectively.

Conclusion: Both Clarithromycin-containing triple therapy and Levofloxacin-containing triple regimen do not seem to be suitable options for first-line H. pylori eradication in Iran. We suggest using Clarithromycin in quadruple regimens such as hybrid or concomitant therapies and reserve Levofloxacin to be used in second-line eradication regimens, as it is recommended by Maastricht V Consensus Report.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1261 EFFICACY AND TOLERABILITY OF REBAMIPIDE IN TRIPLE THERAPY FOR ERADICATION OF HELICOBACTER PYLORI: A RANDOMIZED CLINICAL TRIAL

S. S. Vyalov
Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: svyalov@mail.ru

Aims & Methods: We aimed to determine eradication rate, the effectiveness and advantage of rebamipide in triple eradication therapy of H. pylori infection. Subjects comprised patients undergoing eradication therapy for H. pylori infection in clinics. Patients with a history of eradication therapy, gastrectomy, or allergy to medications in triple therapy were excluded. Written informed consent was obtained for each patient. This trial was performed as a randomised open-label study, and the permission was granted ethical approval (approval 1610-013), and was registered in the University Hospital Medical Network Clinical Trials Registry (UMP-IN-CTR) as number UMIN 000025390. Results: Definitive pathological and non-pathological GVHD were found in 22 patients (40%) and 32 patients, respectively, of severe adverse effects. In the analysis of all 54 lesions, for three observers (A, B, and C), sensitivity of the microvilli atrophy in the terminal ileum was 86.4%, 77.3%, and 79.2%, whereas specificity of the appearance were 62.5%, 62.5%, and 86.2%. In addition, the positive predictive value of the appearance was 61.3%, 58.6%, and 82.6%, and negative predictive value (NPV) was 87.2%, 87.2%, and 83.9%, respectively. The kappa coefficient of the inter-rater reliability was 0.85, 0.63, and 0.63 in observers A, B, and C. Conclusion: Microvilli atrophy in the terminal ileum is an effective colonic finding for real-time predictive histological diagnosis of acute intestinal GVHD. We achieved substantial inter-observer agreement for the analysis of microvilli atrophy in the terminal ileum and excellent agreement for predictive histological diagnosis. Introduction: Chemotherapy-induced mucositis is a common complication during

antitumor agent-induced chemotherapy-induced intestinal mucosal injuries. However, studies on EGCG for chemotherapy-induced mucositis have been

scarce.

Aims & Methods: In this study, we aimed to prove the protective effect of EGCG

in murine chemotherapy-induced mucositis model. Twenty-four 8-wk-old male

C57BL/6 mice were randomized to 4 groups: control, EGCG, 5-Fluorouracil

(5-FU), EGCG plus 5-FU. Mucositis was induced by intraperitoneal injection of

5-FU (400 mg/kg). EGCG (50 mg/kg) was administered orally for 5 days from

the day before administration of 5-FU. After 6 days of 5-FU injection, the mice

were sacrificed. Jejunal tissue was homogenized. WBC count was performed

with whole blood from Inferior vena cava of mice. The end points were villus

height, villus/crypt ratio, histologic characteristics, and mRNA expression of

tumor necrosis factor (TNF-α), and interleukin (IL)-6.

Results: In 5-FU group, neutropenia was confirmed by laboratory test (5-FU, 0.650 KµL; 5-FU, 3.517 KµL), indicating significant 5-FU effect. Histologic

findings showed that crypt dilatation, villus stunting, and villus atrophy were

reduced in EGCG plus 5-FU group than in 5-FU group (Figure 1). Quantitative

height (EGCG plus 5-FU, 352 µm; 5-FU, 319 µm) and villus/crypt ratio (EGCG plus 5-FU, 3.26; 5-FU, 2.31) in EGCG plus 5-FU

group, compared with 5-FU treated group, were significantly higher. mRNA

expression of TNF-α was significantly lower in EGCG plus 5-FU group com-
pared with 5-FU group (P < 0.05)(Figure 2). Figure 1. Effects of EGCG admin-

istration on chemotherapy-induced mucositis in mice jejunum (A) control (B)

Introduction: Proton pump inhibitors (PPIs) have become one of the most com-

monly prescribed medical drug due to their strong effects of suppressing gastric acid and high curative effects for acid related diseases. On the other hand, their side effects have been attracting more attention. One of them is the increased inci-
dence of infectious intestinal diseases. Those are mostly reported by clinical

publications, and the exact mechanism has not been clarified. To investigate whether PPIs can increase the susceptibility to peroral enteropathogenic bacterial infection, we used Citrobacter rodentium (C. rodentium), a well-known attaching-effacing-associated pathogen, which is used for the model of human enterohemorrhagic Escherichia coli (EHEC) and enteropathogenic Escherichia coli (EPEC) infection: the major causes of food poisoning.

Aims & Methods: To investigate whether LAZ can influence the steady-state intestinal environment, C57BL/6J mice were divided into two groups, and 8 mg/kg-day of lansoprazole (LAZ group) or saline (control group) were adminis-
terated intraperitoneally for two weeks. The ileal contents and feces were col-

lected before and after LAZ administration. Genomic DNA of the gut microflora

was analyzed by 16S ribosomal RNA (16S rRNA) gene sequencing, and the metabolites were analyzed by a CE-TOFMS platform. To examine the changes of immune cell distribution by LAZ, hematopoietic cells in the lamina propria

were analyzed by flow cytometry. The changes of gene expressions of the ileum

were comprehensively analyzed by microarray. Finally, mice were orally inocu-
lated with C. rodentium after LAZ administration, and the establishment of enteritis was evaluated by body weight loss, histology and inflammatory cytokine

expression examined by real-time PCR.

Results: At steady-state, no prominent change of metabolites and gut microflora

were observed in the feces of LAZ group. On the other hand, the concentrations

of short chain fatty acids, such as butyrate and propionate, were decreased in the

ileum of LAZ group. The result of 16S rRNA analysis also showed that the composition of ileal microflora were different between LAZ and control group. However, it did not show the change of the immune cell distribution in the intestine. The gene expression levels in the ileum were not altered either. Interestingly, the ileal microflora of LAZ group became similar to that of the feces. As mice have a habit of coprophagia, it was assumed that perorally invaded bacteria could sur-

vive and pass through the stomach due to suppression of gastric acid by LAZ.

Accordingly, in the LAZ group, infectious inflammation was established by less

numbers of C. rodentium inoculation, indicating that PPIs could raise the sus-

cceptibility to peroral enteropathogenic bacterial infection.

Conclusion: Our data showed that administration of PPIs could alter the intesti-

nal environment such as microflora and luminal metabolites. However, neither the gene expressions nor distribution of immune cells in the intestinal tissue were affected. It was assumed that the increased risk of peroral enteropathogenic bacterial infection was not because of the immunological modification by PPIs, but it was mainly because of the increased number of pathogenic bacteria passing through the stomach.

Introduction: Because recent studies have demonstrated that amino acid transporters, which transport amino acids into cells, are correlated to various cancers and are major transporters that supply essential amino acids to tumor cells, these transporters are considered as novel biological tumor markers. On the other hand, because anticanicancer agents are frequently used clinically, the number of patients suffering from anticanicancer agent-induced intestinal mucosal injuries is increasing; hence, it is important to take appropriate measures for reducing these side effects. Because the L-type amino acid transporter (LAT) transports a wide range of nonselective amino acids, including essential amino acids, it is considered to be an intestinal transporter that is important for nutrient absorption. Furthermore, the involvement of other amino acid transporters in inflammation has been reported by some researchers.

Aims & Methods: We aimed to clarify the pathophysiological role of an amino acid transporter in gastrointestinal tract inflammation caused by an antitumor agent in this study. The antitumor agent fluorouracil (5-FU) was orally adminis-
tered to mice. The severity of mucositis was assessed based on the length, villus

height, mucus production, cell infiltration, and immune response of the intestinal tract. We measured the mRNA expressions of LATs in the tissues of the small intestines. In addition, we measured the protein expressions among the small intestines using anti-LAT antibodies.

Results: After the administration of 5-FU, the body weight, food intake, water

consumption, and fecal volume decreased; thus, a systemic influence was observed. The length and villus height of the intestinal tract decreased because of the administration of 5-FU, and mucosal damage with histological change was observed. The number of PAS-positive cells decreased in the small intestinal mucosa, and it was assumed that the defense function of the epithelial cells had decreased. In addition, an increase in the mRNA expression of IL-1β, IL-6, and TNF-α in the Peyer’s patch along with an increase in the cell infiltration after the administration of 5-FU significantly enhanced the immune response associ-
ated with the inflammatory cytokine production. Furthermore, on investigating the mRNA and protein expressions of LAT1 and LAT2 in the tissues of the small intestines, we observed that LAT1 expression significantly increased and LAT2 expression decreased after the administration of 5-FU.

Conclusion: It was considered that the uptake capacity of amino acids, such as Gly, Ala, Ser, Thr, Cys, Asn, and Gin, that transported through LAT may be decreased in case of small intestinal mucosal injuries. On the other hand, LAT1 expression associated with the production of inflammatory cytokines suggested that LAT1 is a gastrointestinal inflammatory marker.

Introduction: Acetylsalicylic acid (ASA) has been used for the secondary prevention of cardiovascular diseases. Especially, the enteric coated ASA is widely used to prevent ASA-induced gastric mucosal injury. Recent technology such as video capsule endoscopy and balloon endoscopy enabled us to look inside the small intestine in more detail. Consequently, not a few cases of ASA-induced small intestinal mucosal injury have been reported. However, the effective prophylaxis and treatment is not clear yet. Previously, we reported direct detrimental effect of ASA on small intestinal epithelial cells using an in vitro model [1]. However, there are thick mucus layer between intestinal lumen and epithelial cells. The mucus has been reported to prevent foreign objects such as bacteria, medicine and food from epithelial cells.

Aims & Methods: This study was conducted to clarify the role of mucus on ASA-induced small intestinal mucosal injury using a rat model. Male Sprague-Dawley rats, 9 weeks old was used. These rats were divided into four groups; group 1: sham (carboxy methyl cellulose: CMC alone), group 2: polysorbate-80 (P80) alone, group 3: ASA alone, and group 4: P80 plus ASA. CMC and/or 50-200 mg/kg ASA was injected into the proximal duodenum of rats. P80, an emulsifier, which has been reported to reduce mucus thickness [2], was administered drinking water for 2 weeks before ASA treatment. Indeed, P80 also reduced the thickness of mucous layer in our analyses. One hour after ASA administration, blue was injected into a vein of rats to visualize small intestinal lesions. Ninety minutes after ASA treatment, the entire small intestine was removed for histological examination. To further investigate the importance of mucus, rebamipide (Reb, 300 mg/kg) or saline were orally administered for one week prior to P80 and ASA treatment. Reb is a gastric muco-protective drug widely used for the treatment of gastric ulcer, and increases mucous secretion by small intestinal goblet cell.

Results: Evans blue method suggested that high-dose ASA (200 mg/kg) induced severe intestinal damage, which was further confirmed by the histological examination. Although lower doses of ASA (50 and 100 mg/kg) did not cause mucosal damage, P80 significantly induced Evans blue exudate and severe mucosal lesions in jejnum at these concentrations, suggesting the pivotal role of mucus in these lesions. Moreover, pre-administered Reb significantly suppressed reducing small intestinal mucus and the exacerbation of ASA-induced mucosal lesions by P80, indicating that mucous is inevitable in the protection of ASA-induced small intestinal mucosal injury.

Conclusions: Preventing mucosal injury might be a useful improvement for the prevention of ASA-induced small intestinal mucosal injury.

Aim: A mucosal injury is a severe side-effect of chemotherapy with current deficiency in effective treatments.

Aims & Methods: This study investigated three prebiotics, galacto-oligosaccharide (GOS), mannan-oligosaccharide (MOS) and fructo-oligosaccharide (FOS) for their potential to reduce the severity of 5-Fluorouracil (5-FU)-induced intestinal mucositis in rats. Female Dark Agouti rats (n = 8/group) were orally gavaged with either 5% FOS, GOS, MOS or water (controls) for 16 days, and received an intraperitoneal injection of 5-Fluorouracil (5-FU; 150 mg/kg) or saline (controls), on day 13. Rats were housed in metabolic cages for the duration of the study, and metabolic data was recorded daily. Rats were killed on day 16 and visceral organ weights and lengths were analyzed post mortem. Cytokine detection, villus height and histological severity scores were quantified in haematoxylin & eosin stained sections. Sucrase and myeloperoxidase activity were quantified by biochemical assay. White and red blood cell types were quantified by whole blood analysis. Fecal volatile fatty acids were also measured. Statistical analysis was by one-way ANOVA or Kruskal Wallis and Mann Whitney U test, where p < 0.05 was considered statistically significant. Data are expressed as mean ± standard error of the mean.

Results: %Bodyweight loss was significantly decreased in all treatment groups following 5-FU injection, compared with FOS or pre and post 5-FU compared to saline treated controls (p < 0.05). Ileal villus height was significantly higher in GOS treated rats pre 5-FU (284.6 ± 11.95 μm) compared to respective water controls (240.0 ± 8.33 μm; p < 0.05). Ileal villus height and crypt depth was significantly decreased in all treatment groups after 5-FU injection (p < 0.05) and prebiotic treatment did not significantly modify this parameter. Similarly, jejunal and ileal sucrase activity was decreased in all groups after 5-FU injection (p < 0.05), correlating with histological measurements. Tissue MPO activity was significantly increased post 5-FU injection, reflecting increased neutrophil activation, and was unchanged by prebiotic treatment. Interestingly, MOS and GOS both lowered %circulating neutrophils pre 5-FU compared to water controls (p < 0.05). Pre 5-FU treatment with GOS significantly increased the fecal VFAs acetic acid (16.76 ± 1.22 mM/L) and propionic acid (4.60 ± 0.99 mM/L) compared to saline treated controls (7.73 ± 0.92 mM/L and 3.05 ± 0.28 mM/L respectively; p < 0.05). MOS and GOS treatment also significantly increased fecal acetic and propionic acid post 5-FU compared to water control (p < 0.05).

Conclusion: Our study has found that prebiotics, MOS, GOS and FOS modified both alone and in combination, during the repair phase of intestinal mucositis, their potential to reduce the severity of 5-FU-induced intestinal mucositis in rats. Female Dark Agouti rats (n = 8/group) were orally gavaged with either 5% FOS, GOS, MOS or water (controls) for 16 days, and received an intraperitoneal injection of 5-Fluorouracil (5-FU; 150 mg/kg) or saline (controls), on day 13. Rats were housed in metabolic cages for the duration of the study, and metabolic data was recorded daily. Rats were killed on day 16 and visceral organ weights and lengths were analyzed post mortem. Cytokine detection, villus height and histological severity scores were quantified in haematoxylin & eosin stained sections. Sucrase and myeloperoxidase activity were quantified by biochemical assay. White and red blood cell types were quantified by whole blood analysis. Fecal volatile fatty acids were also measured. Statistical analysis was by one-way ANOVA or Kruskal Wallis and Mann Whitney U test, where p < 0.05 was considered statistically significant. Data are expressed as mean ± standard error of the mean.

P1269 THE RELATION OF CHEMOKINE RECEPTOR CXCR3 AND GUT-LYMPHOCYTE GUT-HOMING MARKERS IN CROHN’S DISEASE PATIENTS

A. T. Do1, A. Shah, E. Shanahan2, P. Gashemi2, T. Hansen2, N. Koloski2, S. Keely2, N.J. Talley1, G. Holmman2
1Faculty Of Medicine, The University Of Queensland, Woolloongabba/Australia
2Princess Alexandra Hospital, Department Of Gastro and Hepatology, Woolloongabba/Australia/QLD

Introduction: Crohn’s disease has been thought to be caused by abnormal immune responses affecting many parts of digestive tract in which T1 cells act. The recruitment of T1 cells is regulated by interaction of their expression of chemokine receptor CXCR3 and its ligands. There have been many IBD murine models showing the increase of CXCR3 expression and its roles on the disease promotion. However, there are limited evidences in the roles of CXCR3 in human IBD. In fact, a small study in large bowel in a cohort of 10 Crohn’s disease patients showed lower expression of CXCR3 on T lymphocytes, compared to colon cancer patients. In terms of inhibition of T-lymphocyte migration into intestine in IBD patients, anti α4β7 (Vedolizumab) therapy is currently shown to be effective.

Aims & Methods: Our study aimed to assess expression of CXCR3 by different subsets of small intestinal lamina propria T-cells and its association with a4 and b7 integrins expression (CD) patients. Total of 56 duodenal biopsies were obtained from CD (n = 15), functional dyspepsia (FD)/irritable bowel syndrome (IBS) (n = 24) or iron deficiency patients (n = 17) with ethical approval. Lamina propria (LP) cells were isolated from biopsies using EDTA, collagenase and granzyme B centrifugation with Ficol. Expression of CXCR3, a4 and b7 on isolated T-lymphocytes was examined by flow cytometry. Statistical significance was assessed using T-test or Spearman correlation.

Results: The expression of CXCR3 on CD4 lymphocytes was significantly lower (75.8%) compared to 61.6% in control group (FD/IBS deficiency). Although the expression of CXCR3 on CD8 lymphocytes was higher than CD4 lymphocytes, it was different between CD and other group (75.8% in CD patients vs 82.2% in controls). Similar observation was obtained on the double positive CD4 and CD8 lymphocytes. Interestingly, only expression of CXCR3 on CD4 lymphocytes positively correlated with expression of the gut-homing integrins, a4 and b7.

Conclusion: These observations showed significant expression of CXCR3 across different subsets of immune cells which is unrelated disease activity. The consistently higher expression seen in CD8⁺ lymphocytes compared to CD4 lymphocytes. An unexpected reduction of CXCR3 expression was seen in small intestinal of CD patients, which associated with gut-homing integrins. This result showed CXCR3 expression may play a role in migration of CD4 lymphocytes but not CD8 lymphocytes into duodenum in relation with integrins, a4 and b7. However, CXCR3 expression on CD4 lymphocytes in CD patients’ small intestine may have protective role. This propose further study to clarify.

P1271 METHODOLOGICAL QUALITY OF CLINICAL PRACTICE GUIDELINES ON PROBIOTICS IN ACUTE GASTROENTERITIS IN CHILDREN USING THE APPRAISAL OF GUIDELINES FOR INTEGRATIV

A. Maru Saito1, J.C. Herrera Rodriguez1, R. Rojas Galarza1
1Dept. Of Pediatrics, U Peruana Cayetano Heredia, Lima/Peru

Contact E-Mail Address: aldo.maruy@gmail.com

Introduction: Acute Gastroenteritis (AGE) is one of the diseases that most frequently affects paediatric population. Successful treatment in AGE has been shown either in vivo or in vitro. There is a need to investigate the role of probiotics in prevention and treatment of its complications; every day, we find more publications on the use of probiotics to decrease its duration. Probiotics have gained greater importance because some of them report benefits. We look for Clinical Practice Guidelines (CPG) that recommend their use in AGE. The AGREE II instrument was developed to address the issue of variability in guideline quality, so it is a tool that assesses the methodological rigour and transparency in which a guideline is developed.

Aims & Methods: To assess the methodological quality of clinical practice guidelines (CPG) on the use of probiotics in infant diarrhoea. The search was conducted in December 2016, of CPG based on the evidence, the last 10 years and as contaminants in drinking water, has become a public health problem. Most of these substances are considered as endocrine disruptors and their daily consumption is likely to be severe and irreversible consequences. Indeed, preliminary studies have shown that chronic exposure to low doses of chlorpyrifos (CPF) causes intestinal imbalance (dysbiosis) in vitro.

Aims & Methods: The objective of this study is to evaluate the preventive potential of a probiotic (mulin) in co-exposure with the CPF on the intestinal dysbiosis, the bacterial translocation and the integrity of the intestinal mucosa. For this we used an in vitro system: the SHIME® (Simulator of the Human Microbial
Intestinal Ecosystem). The SHIME® consists of series of fermenters, mimicking the gut environment from the stomach to the colon. The SHIME® was exposed to a daily dose of 3.5 mg of CPF, combined with 10 g of inulin for 30 days. The samples were collected at day 0 (baseline, without CPF or inulin), D15 and D30 to determine the profile and microbial metabolism.

Results: Contrary to the previous results with CPF alone showing dysbiosis, prebiotic supplementation seems to reestablish CPF-induced imbalance, particularly in the potentially pathogenic microflora (Staphylococcus), which an increase in short term (D15: p < 0.001), and a recovery at D30. (difference vs D15: p < 0.001; p < 0.05). Inulin also benefitted the fermentation profile, with higher production of volatile fatty acids (VFA), especially propionic acid and butyric acid. Conclusion: The CPF/inulin co-exposure therefore had a positive impact on bacterial profile and metabolism, suggesting that prebiotic supplementation could reduce some intestinal damages caused by an exposure to CPF.

Perspective: In a second step, the Caco-2/TC7 cell line, which mimics a functional human intestinal epithelium, will be exposed to samples from the colic fermenters associated with CPF and inulin. The study will aim to determine the impact on the epithelial barrier.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Lactulose methane and hydrogen breath test (LMHBT) is now widely used in assessing small bowel bacterial overgrowth (SIBO) and irritable bowel syndrome (IBS). SIBO and IBS have similar clinical symptoms such as flatulence, bloating, abdominal pain. Although there is no clear relationship between IBS and SIBO yet, they are both in relationship with dysbiosis. Diet is associated with disease closely, especially for gastrointestinal diseases. Different dietary structures have different effects on the structure, metabolism and function of gut microbiota. Reduce fermentable oligosaccharides, disaccharides, monosaccharides and polyols (FODMAPs) diet can release parts of IBS symptoms obviously. There were rare reports for the effects of diet on LMHBT, especially for high-fat diet. Whether diet manipulation can influence the diet on intestinal microbiota profiles in IBS-D or SIBO patients. High fat diet may change the intestinal microbiota profiles and SIBO can be reported in the past researches, most of which were animal experiments, lacking of effects on the clinical manifestations and intestinal microbiota profiles in patients with IBS-D, especially for high-fat diet.

Aims & Methods: We aimed to analyze the characteristics of diet and lactulose methane and hydrogen breath test (LMHBT) in patients of diarrhea predominant irritable bowel syndrome (IBS-D) who may understand small bacterial overgrowth (SIBO), and comparing with health controls. IBS-D patients (18–65 years old), who met Rome III criteria were enrolled in Gastrointestinal outpatient clinic of Peking University Third Hospital from June 2017 to May 2018. Health volunteers were enrolled as control group. All subjects underwent colonoscopy to exclude colonic organic disorders. All subjects completed the case report form (CRF), IBS symptom severity scale (IBS-SSS), the MOS item short form health survey (SF-36). The patients were divided into IBS-D with SIBO (IBS-S) group and IBS-D without SIBO (IBS-N) group according to the LMHBT. Diet information was collected by food frequency questionnaire (FFQ) and three days recalls. The high fat diet is defined as the daily total calories supplying from fat is more than 50%.

Statistical analysis were performed by SPSS 20.0 software, P < 0.05 was considered statistically significant.

Results: Eighty-eight IBS-D patients and 32 HC were enrolled. The positive rate of LMHBT in IBS-D was significantly higher than that of HC [39.8% (35/88) vs. 12.5% (4/28), P = 0.005]. The 28 HC with negative LMHBT were enrolled in the following analysis. There were no significant differences in age and gender ratio among IBS-P, IBS-N and HC. The BMI of IBS-P was significantly lower than that of IBS-N [21.57 ± 0.54 vs. (23.30 ± 0.53)kg/m², P = 0.032]. High fat diet IBS-D patients and along with IBS-P had higher abdominal pain scores. The proportion of dietary protein and carbohydrate in IBS-D was significantly higher than that of HC (14.39% vs.12.22%, P = 0.001; 53.94% vs. 46.25%, P = 0.003, respectively), while the intake of fiber was a little lower than HC [(16.85 ± 1.54) vs. (21.29 ± 3.07)g/d, P = 0.169]. The proportion of diet fat was significantly higher in IBS-P than IBS-N [47.19 ± 2.62% vs. (40.74 ± 1.66%), P = 0.013]. IBS-D patients had more high fat diet individuals than IBS-N [37.1% (13/35) vs. 20.8% (11/53), P = 0.088]. (3) The positive rate of LMHBT in IBS-D was significantly higher than that of HC [39.8% vs. 12.5%, P = 0.005]. IBS-D patients with high fat diet had higher LMHBT positive rate than that of non-high fat diet patients [54.2% (13/24) vs. 17.2% (11/64), P = 0.001]. The baseline of breath methane in IBS-P was significantly higher than that of in IBS-N [8.69 ± 0.39] vs. (6.39 ± 0.47)ppm, P = 0.002]. Breath methane peak value was positively related with the fat proportion of diet (r = 0.413, P = 0.022).

Conclusion: High fat diet might be one of the risk factors for IBS with SIBO.

Introduction: Alterations to the gut microbiota and bacterial translocation have been implicated as relevant factors for the progression of chronic liver disease (CLD). While the sequence of events leading to translocation remains unclear, deficiencies in local host immune defences, increased permeability of the intestinal mucosal barrier and dysbiosis of the gut microbiota are suggested to play a role. Small intestinal bacterial overgrowth (SIBO), in which an excessive and/or abnormal type of bacteria is present in the small bowel has been implicated as a potential factor in translocation. However, systematic assessments of the extent of SIBO in CLD remain limited. We therefore aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and controls.

Aims & Methods: Using the search terms ‘small intestinal bacterial overgrowth (SIBO)’ and ‘chronic liver disease (CLD)’ or ‘small intestinal bacterial overgrowth (SIBO)’ and ‘cirrhosis’, 19 case-control studies that met inclusion criteria were identified. Data were extracted to calculate prevalence rates and 95% confidence intervals (CI).

Results: The final dataset included 1,000 adult patients with CLD and 488 controls. Nine studies employed glucose breath tests (GBT), four lactulose breath tests (LBT) and 10 methane and hydrogen breath test (LMHBT). Across all testing methods, the prevalence of SIBO in patients with CLD was 38.9% (95% CI 36.9–40.9) compared to 9.8% (95% CI 7.5–12.8) in controls. The prevalence of SIBO in CLD was increased as compared to controls (RR = 7.15, 95% CI 4.9–10.4). In patients with cirrhosis the prevalence of SIBO was 40.1% (95% CI 36.4–43.8) compared to 7.3% (95% CI 4.9–10.8) in controls. Nine studies performed PCR. Across all testing methods, the prevalence of SIBO in CLD remained limited. We therefore aimed to compare the prevalence of small intestinal bacterial overgrowth (SIBO) in patients with chronic liver disease (CLD) and controls.

Conclusion: Regardless of the diagnostic modality, prevalence of SIBO is significantly increased in patients with CLD when compared to controls. It is notable that culture-based detection leads to a higher prevalence in CLD, suggesting breath tests are more sensitive. Given the levels of SIBO detected, further studies need to explore the role of intestinal dysbiosis for the progression of CLD.

Disclosure of Interest: All authors have declared no conflicts of interest.
**Introduction:** In humans, enteric methane (CH₄) production is highly variable and related to the gastrointestinal microbiome and diet. Previous work suggests that CH₄ production is more common in patients with ‘constipating’ conditions such as encopresis and diverticulosis. We aimed to explore the link between gastrointestinal symptoms breath CH₄ exhalation in patients with unexplained GI symptoms.

**Aims & Methods:** Consecutive patients (n = 100) with unexplained GI symptoms underwent a combined H₂/CH₄ breath test after ingestion of 75 g of glucose. H₂ and CH₄ were measured by Breathex microlyser (Quintron, USA). Gastrointestinal symptoms were assessed utilising the (Structured Assessment of Gastrointestinal Symptoms Instrument (SAGIS). The association between methane exhalation and symptoms during the 2 weeks prior the test were evaluated using non parametric test.

**Results:** 100 consecutive patients (55%), aged 52.2 ± 15.7 years (mean ± SD) were included. Of these, 14 with positive GBT and 19 without SAGIS data were excluded, resulting in 67 data-sets available for analysis. Methane peak and methane baseline values were highly correlated (r = 0.96, p < 0.001). Methane peak (and baseline) were inversely correlated with the SAGIS diarrhoea score (r = 0.35, p < 0.01, Figure 1). Contrary to current opinion, CH₄ exhalation was not associated with constipation (r = 0.1, P > 0.4). In addition, excessive belching and acid eructation were significantly associated with the baseline and peak CH₄ exhalation (r all <0.3, p all <0.04).

**Conclusion:** There is an inverse association between CH₄ exhalation and diarrhoea symptoms. At the same time, CH₄ is associated with bloating and acid eructation. These data suggest that CH₄ or metabolic products from CH₄ producing microbes modulate human gut function.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** The prevalence of osteoporosis is higher among patients suffering a distal radius fracture than in healthy controls [1]. Celiac disease (CD) is associated with low bone mineral density [2], and overall findings indicate an increased risk of fracture in CD patients [3, 4]. This study is to our knowledge the first case control study investigating whether there is a higher prevalence of CD in adult patients suffering a peripheral fracture (distal radius or ankle) than in healthy age- and sex matched controls.

**Aims & Methods:** Main objective was to investigate if patients with a recent fracture of the distal radius or ankle have a higher risk of having CD than healthy controls. 400 consecutive patients over the age of 40 with acute distal radius fracture (n = 293) or ankle fracture (n = 107) were included in a case control study by referral from the orthopedic department at Forde General Hospital, Norway. The controls were 197 age- and sex- matched subjects from Sogn and Fjordane County identified from the National Population Registry, with no previous fracture history. BMD of the hips and spine was measured and history of previous fractures, comorbidities, medication, life-style factors, body mass index (BMI) and nutritional factors were registered. Serum analysis to detect presence of osteoporosis including IGA tissue transglutaminase was performed.

**Results:** See table.

**Conclusion:** The prevalence of celiac disease was in preliminary analyses not significantly higher among patients suffering a distal fracture (3.5%) than among healthy age- and sex- matched controls (2.8%). Osteoporosis and low Vitamin D levels are significant risk factors for distal radius fracture, but this is not the case with ankle fractures.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Celiac disease (CeD) is an immune disorder, triggered by gluten intolerance in genetically susceptible patients. Clinical outcome includes severe gastrointestinal manifestations, including neurologic complications in about 10% of patients. Previous studies confirmed the subclinical changes of an abnormal nervous system (ANS) activity resulting to impaired gastric myoelectric activity. In CdE disturbances of parasympathetic-sympathetic balance of the ANS activity with sympathetic dominance is observed. Tight junctions impairment is one of postulated pathomechanism in CeD and its complications. Transmembrane proteins of tight junctions include claudin and occludin. There is lack of publications referring to soluble claudin and occludin concentrations in CeD. Interleukin-1 beta (IL-1beta) is an important mediator of the, and there are no data concerning on its influence on gastric myoelectric activity and ANS activity in CeD.

**Aims & Methods:** The study was aimed to evaluate occludin, claudin and IL-1beta concentrations in serum in neurologically asymptomatic patients with CeD and its correlation with selected parameters of ANS activity markers (heart rate variability, electogastrography HRV) and gastric myoelectric activity (EGG). Thirty four patients with CeD (70% females, mean age 34 years, 41.2±16.6) without neurological symptoms tested for occludin, claudin, IL-1beta concentrations in serum using ELISA, and HRV and EGG.

**Results:** Biochemical parameters. Patients with CeD presented with lower average level of occludin (1.41(0-2.9) ng/ml) than healthy subjects (1.68(0.39-4.8) ng/ml) (P = 0.07, the Mann-Whitney test (2)). No significant impact of CeD on the average results of IL-1 beta concentrations was observed (P = 0.44, the Mann-Whitney test). The rest HRV. In the celiac group the assessment of HRV revealed a negative significant correlation of claudin concentration and very low frequencies (VLF-RRI; Spearman’s rank correlation coefficient: r=-0.51, P = 0.018) as well as positive correlation between IL-1beta and LF/HF was demonstrated (r=0.51, P = 0.032). Statistically significant, negative and strong correlation of IL-1 beta concentration and DP (Dominant Power of EGG) (r = -0.58, P = 0.038) was shown.

**Conclusion:** ANS activity measured by EGG and HRV seems to be correlated to presence of IL-1beta. In celiac group the serum concentration of claudin and occludin do not correlate to ANS activity. Due to former research on autonomic imbalance in CeD with sympathetic overdrive, the hypothesis of influence of IL-1beta on ANS activity should be considered.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1277 WIDE HETEROGENEITY AND HIGH MORTALITY IN UNDEFINED AND NON-COELIAC REFRACTORY SPRUE: A RETROSPECTIVE EVALUATION OF 7 CASES**

A. Schiappatti, F. Biagi, M. Zuffada, G. Maieron, G.R. Corazza

University of Pavia, Pavia/Italy

**Contact E-mail Address:** salimana@hotmail.it

**Introduction:** Small bowel villous atrophy (VA) is mainly related to coeliac disease (CD) that develops in HLA DQ2/DQ8 positive patients and improves on a gluten-free diet. Other forms of VA unrelated to CD are common variable immune-deficiency, autoimmune enteropathy, small bowel malignancies, medication-related enteropathies, HIV, tropical sprue, and giardiasis [1–3]. However, there are also forms of VA in which CD can be neither confirmed nor excluded and there are forms of VA in which, although CD is excluded, a definitive diagnosis cannot be made. Some years ago, we coined the terms undefined sprue (US) and non-coeliac refractory sprue (NCRS) to define these two
conditions [4]. Although other Authors described similar patients [2,3], it is still uncertain whether CRS are two independent conditions or whether they are two faces of the same coin. Alternatively, they could be umbrella terms covering one or more atrophic enteropathies still awaiting to be identified, as was the case of olmsertan-associated enteropathy until a few years ago. Aim was to clarify the nature of these forms of VA.

Results: 7 patients (2F, age at diagnosis of VA 46±26 years, all with severe malabsorption) were identified, 3 were DQ2 positive and so were diagnosed as UC: case 1 (F, 32 years) died of ulcerative jejunitis 8 years later; case 2 (M, 38) died of pulmonary embolism complicating systemic candidiasis 1 year later and case 3 (M, 71) died of intestinal lymphoma after 4.5 years. The remaining 4 patients were HLA DQ2/DQ8 negative, so a diagnosis of NCRS was made. 3 were DQ3 negative: 4 case, (F, 61) died of EATL type 2 after 4.5 years; case 5 (M, 38) died after 2 years after diagnosis of VA, and in good general conditions; case 6 (M, 69) is still alive but could be affected by a form of enteropathy due to celiacata. He is in good clinical condition and has been refusing follow-up. The last patient, case 7 (M, 29) is DQ3+7 positive. He is still alive 11 years after the diagnosis of VA, although complains of diarrhoea.

Conclusion: We described 7 patients with VA unrelated to CD or other known enteropathies. Although overall mortality among them is very high (57%) and mainly due to lymphoproliferative disorders (5/7) the 4 DQ2/DQ8 negative patients are alive many years after the diagnosis of VA with no evidence of malignancy. This suggest that these 7 patients are not affected by the same condition. We speculate that DQ2 positive patients who died of lymphoma could be affected by a form of CD who escaped diagnosis if get complicated. However, we feel that the D3Q2/8 negative patients with long survival are affected by a still unidentified form of VA.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Strict gluten-free diet (GFD) in celiac disease is burdensome and difficult to maintain, which might predispose to poor dietary adherence and impaired quality of life. We aimed to evaluate adult patients’ experience of living with celiac disease diagnosed in childhood, and identify factors associated with possible life restrictions caused by the disease.

Aims & Methods: 232 adults (women 69%, median age 27.0 yr) with a childhood diagnosis of celiac disease fulfilled a questionnaire evaluating their experiences about general health and lifestyle, possible co-morbidities, adherence and attitudes towards GFD and long-term follow-up of celiac disease. In addition, they covered one or more atrophic enteropathies still awaiting to be identified, as was the case of olmsertan-associated enteropathy until a few years ago. The intergroup comparison among HS patients showed that BMI (OR 3.8; p=0.001) and waist circumference (OR 6.9; p=0.001) were the only independent factors for the development of HS (OR 1.97; p=0.01 for G carriers and OR 6.9; p=0.001) at diagnosis, whereas the groups did not differ in age, gender or other clinical and histological presentation. Current age (OR 1.2; p=0.215) and time since diagnosis (18.6 vs 17.9 yr; p=0.468) were also comparable, as well as were self-experienced general health and concern about health, presence of co-morbidities and complications, smoking, physical exercise, socioeconomic status, membership of celiac society and presence of celiac disease in relatives. There was also no difference in specific gastrointestinal symptoms as assessed by GRSRS scores, but patients considering the disease restrictive reported more overall symptoms possibly related to celiac disease than those without restrictions (32% vs 17%; p=0.007). Furthermore, dietary adherence (strict GFD in 82%, p=0.770) and experienced adhering to the diet more challenging (somewhat difficult 33% vs 7%, p<0.001) and had significantly lower PGWB vitality scores (median 17 vs 18, p=0.023).

Conclusion: Almost half of the patients diagnosed in childhood experienced celiac disease to cause marked restrictions in adulthood. This was associated with current symptoms, lower vitality scores and difficulties to maintain GFD. Patients with severe symptoms and anemia at diagnosis might require special attention and tailored follow-up in these circumstances.

P1279 SYSTEMATIC REVIEW OF THE ECONOMIC BURDEN OF COELIAC DISEASE

N. Belanger1, A. J. Taylor2, D. A. Leffer3, E. S. Mearns4, M. Gerber5
1IBM Watson Health, Boston/United States of America/MA
2Takeda, London/United Kingdom
3Takeda, Cambridge/United States of America/MA

Introduction: The prevalence of diagnosed coeliac disease (CD) has rapidly increased in recently developed countries in the last 30 years. The economic burden of diagnosing, managing, and monitoring CD can be substantial but is poorly understood. To assess the economic burden of CD, we systematically reviewed current evidence quantifying economic costs and health resource utilization (HRU) for CD in North America and Europe.

Aims & Methods: Searches of Medline, Embase, EconLit, the Cochrane Library, and conference abstracts systematically identified literature published in English during the last 10 years assessing direct and indirect costs, cost-effectiveness studies and economic evaluations of screening and diagnostic tests for CD. We updated this search in March 2019.

Results: Of 33 studies meeting criteria for inclusion, most (20) were from Europe, and most (18) reported or modeled costs associated with screening and diagnosis. Cost per positive CD report of screening patients already undergoing upper gastrointestinal biopsy for other indications, such as anaemia or irritable bowel syndrome, ranged from approximately $1,300 in Canada to more than $44,000 in the Netherlands (costing year not reported). In these populations, screening was judged to be cost-effective with various strategies combining diagnostic modalities, including serology then biopsy, compared to no screening.

Discussion: Strategies using both endoscopy/biopsy or serology alone were not considered cost-effective. Direct annual excess costs to a US payer per diagnosed CD patient ranged from $600 to $8,800 (SUS 2007) to more than a person without CD, chiefly due to outpatient care, with higher costs among patients with poor disease control. High use of outpatient care is also reflected in studies of HRU, although hospitalization, emergency visits and medication use are also more common in individuals with CD than in controls. After initiation of a gluten-free (GF) diet, patients visit primary care providers less often, but use more medications. Patients often pay out of pocket for gluten-free (GF) foods, which cost 240–518% more than gluten-containing equivalents. Three studies on abstention from Scandinavia found fewer days missed from school and work following diagnosis and initiation of a GF diet.

Conclusion: Most economic studies of CD have focused on the cost of screening and diagnosis, especially in Europe. Methods of screening generally are considered cost-effective when they combine diagnostic modalities, such as serology then biopsy, in people being evaluated for symptoms. Much of the cost to a payer of managing CD derives from outpatient care, especially for patients with poorly controlled disease. Patients on a GF diet lose fewer days from work or school but pay higher costs for GF foods.

Contact E-mail Address: nicola.imperatore@alice.it

Introduction: Metabolic syndrome (MS) and hepatic steatosis (HS) are frequent in patients with celiac disease (CD) after commencing gluten-free diet (GFD), but data about predictive factors for such a condition are still scarce.

Aims & Methods: We aimed to evaluate the role of PNPLA3 rs738409 in the development of MS and HS in CD patients after starting GFD. From June 2014 to September 2016 we consecutively enrolled all patients referred to academic gastroenterological centre, suffering from CD, with our without HS. All patients underwent anthropometrics and serological investigations, ultrasonography (US) evaluation to assess the degree and severity of HS and genotyping of PNPLA3 rs738409 polymorphism.

Results: Finally, 370 subjects were enrolled (136 with HS and 234 without HS). Mean age (years) was 51 (18–82) in 194 subjects (52.4%), CD genotype was in 138 subjects (37.3%), while 38 individuals (10.2%) showed the GG genotype. At binary logistic regression, only G and GG alleles were predictive for the development of HS (OR 1.97; p=0.01 for G carriers and OR 6.9; p<0.001 for GG carriers), while BMI (OR 3.8; p=0.001) and waist circumference (OR 2.8; p=0.03) at CD diagnosis were the only independent factors for the development of MS. The intergroup comparison among HS patients showed that
the severe grade of HS was more frequently observed in GG than in CC carriers (p = 0.001, OR 21.8). In each of the last 3 clinic reviews 83% (n = 133) of patients that had osteoporosis, 4 patients were under 50 years old (57%). Of the 81 patients who did not warrant a DEXA scan, 77 results were available: normal in 48% (n = 37), osteopenia in 43% (n = 33) and osteoporosis in 9% (n = 7). Of the 7 patients that had osteoporosis, 4 patients were under 50 years old (57%). Of the appropriate DEXA requests, 25% (n = 7) were normal, 39% (n = 11) had osteopenia and 36% (n = 10) had osteoporosis.

Conclusion: Most CD patients require very little clinical input at their routine appointments. Annual blood checks and adherence to a gluten-free diet are standard enquiries. However, there is a cohort of patients who are not getting their regular blood tests: 33% for bone profile and 25% for haematins. Clinicians tend to order a DEXA in most CD patients because it is easier than attempting to judge an individual’s risk in the setting of conflicting guidelines. The pick-up rate of osteoporosis in 36% of appropriately screened patients (vs 9% in inappropriate scan requests) suggests that targeted screening allows for a more rational and cost-effective use of a limited resource. We hope that the guidelines can now be updated with more clarity for the practitioners who request DEXA scans in CD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1243 MONITORING PATIENTS WITH COELIAC DISEASE: WHO ACTUALLY NEEDS A DEXA SCAN?
M. Yalchin, R. Eckersley, T. Coysh, S. Mann
Gastroenterology, Barnet Hospital, DJ/United Kingdom

Contact E-mail Address: m.yalchin@nhs.net

Introduction: Patients with coeliac disease (CD) should be seen annually for a clinical review, blood tests and a DEXA scan if needed1,2. The indication for a DEXA scan is unclear due to conflicting recommendations in current guidelines1–3. The aim of our study was to audit our practice, with a focus on requests for DEXA scans.

Aims & Methods: This was a single-centre, retrospective study of CD patients under the care of 3 clinicians. We accessed the electronic records to identify if haematological and biochemical profiles were being monitored. We also identified when patients had their first DEXA scans and whether or not they were indicated.

Results: Data were collected on 160 patients (Female = 107[67%]). Annual checks of FBC occurred in 94% of patients, vitamin B12 in 74%, folate in 77%, calcium in 85% and vitamin D in 69%. DEXA scans occurred in 74% of patients (n = 119), including 66% (n = 77) who were screened around the time of diagnosis. However, only 24% (n = 28) actually warranted the scan according to guidelines1–3, and 68% (n = 81) did not fulfil criteria for a DEXA. In 8% of patients (n = 10), there was inadequate data. Of the 81 patients who did not warrant a DEXA scan, 77 results were available: normal in 48% (n = 37), osteopenia in 43% (n = 33) and osteoporosis in 9% (n = 7). Of the 7 patients that had osteoporosis, 4 patients were under 50 years old (57%). Of the appropriate DEXA requests, 25% (n = 7) were normal, 39% (n = 11) had osteopenia and 36% (n = 10) had osteoporosis.

Conclusion: Most CD patients require very little clinical input at their routine appointments. Annual blood checks and adherence to a gluten-free diet are standard enquiries. However, there is a cohort of patients who are not getting their regular blood tests: 33% for bone profile and 25% for haematins. Clinicians tend to order a DEXA in most CD patients because it is easier than attempting to judge an individual’s risk in the setting of conflicting guidelines. The pick-up rate of osteoporosis in 36% of appropriately screened patients (vs 9% in inappropriate scan requests) suggests that targeted screening allows for a more rational and cost-effective use of a limited resource. We hope that the guidelines can now be updated with more clarity for the practitioners who request DEXA scans in CD patients.

Introduction: A life-long gluten-free diet (GFD) is the only available treatment for patients with celiac disease (CD). Adherence to the GFD is associated with symptoms remission, reversal of mucosal atrophy and, possibly, prevention of CD-related complications. However, data on the long-term effects of a good or poor adherence to the GFD are limited.

Aims & Methods: The aim of this study was to assess the rate and accuracy of compliance to a strict GFD in patients with a CD history of more than 30 years and to compare endpoints such as complications, symptoms and histology between patients following a strict GFD and patients not compliant to the diet.

Between 2015 and 2016, data from all patients diagnosed with CD at the Fondazione IRCCS Ca’ Granda before 1985 were retrieved. Patients not undergoing regular follow-up at the clinic were contacted in order to collect recent clinical data. The study was funded by Shire International GmbH, Zug, Switzerland.

Results: Clinical data from 196 patients were collected and analyzed. Patients were divided into 3 groups according to their adherence to GFD: 133 patients reporting a lifelong strict GFD, 29 patients on GFD at the time of follow-up but with a history of at least 5 years of gluten-containing diet (GCD), and 35 patients who reported to be on a GCD. No significant differences were found between groups regarding symptoms and histology at diagnosis, onset of associated autoimmune disorders, family history of CD and compliance to follow up. The onset of complications at follow-up did not significantly differ in the three groups as well. Follow-up histology was available in 63 patients (32.1%). Persistence of villous atrophy was as expected more frequent in patients on GCD as on GFD (46% vs. 73%), however 20% patients had normal histology during long-term GCD. The questionnaire was returned by 90 patients and 66 parents: a slightly better knowledge about the GFD and its behavioral rules was found between patients on lifelong GFD and patients with ongoing or past GCD (p = 0.03).

Conclusion: Poor adherence to the GFD is reported by almost one-third of patients with a long-term history of CD, confirming the high rate of poor compliance to such a strict diet among patients. Poor adherence to the GFD could be due to a major predictor of persistence of villous atrophy, but this does not necessarily imply the development of CD complications. Moreover, results from follow up biopsies showed that a GCD does not imply recurrence of villous atrophy in all patients, attesting the possibility that some CD patients may have a latent tolerance over time.

Introduction: Parenteral support (PS) volume needs vary depending on disease severity in patients with intestinal failure associated with short bowel syndrome (SBS-IF). Patient classification has focused on the diagnosis that led to resection and the remnant bowel anatomy.

Aims & Methods: Recently, the idea that grading severity of SBS-IF is based on magnitude of PS volume needs led to this clinical trial data post hoc analysis of patients with SBS-IF based on their baseline PS volume. STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of teguldulide (TED) 0.05 mg/kg/day in patients with intestinal failure associated with short bowel syndrome (SBS-IF). STEPS (NCT00798967; EudraCT2008-006193-15) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS-IF. Plasma citrulline levels at baseline were significantly correlated with remnant small bowel length (R2 = 0.39; p = 0.02) and not with baseline PS volume (R2 = 0.03; p = 0.30; n = 39). The correlation between baseline plasma citrulline and plasma citrulline change at Week 24 was significant (R2 = 0.80; p < 0.0001; n = 39). No correlation was found between change in plasma citrulline levels and change in PS volume at Week 24 with TED (R2 = 0.05; p = 0.16; n = 39). When patients were analysed by bowel anatomy subgroups, significant increases in plasma citrulline were seen with TED but not placebo (Table).

volume reductions with TED. Plasma citrulline changes with TED may reflect a reduction in urea production with TED.

P1287 LACTULOSE, LACTOSE AND FRUCTOSE INGESTION INDUCES SPECIFIC PATTERNS OF GASTROINTESTINAL SYMPTOMS IN CHINESE SUBJECTS WITH FUNCTIONAL DYSPEPSIA AND IRRITABLE BOWEL SYMPTOMS

V. Tan1, N. H. S. Chu1, C. K. Yao1, P. R. Gibson2
1The University of Hong Kong, Hong Kong/Hong Kong PRC
2Dept. Of Gastroenterology, Alfred Hospital Dept. of Gastroenterology, Melbourne/Australia

Contact E-mail Address: vpetyan@hku.hk

Introduction: Prevalence rates of Functional Dyspepsia (FD) in East Asia are three times higher than Irritable Bowel Syndrome (IBS) rates. Many researchers have suggested that IBS subjects in the region experience their pain and discomfort in the upper abdomen, leading to misdiagnosis as FD.

Aims & Methods: We aimed to compare patterns of gastrointestinal (GI) symptoms in the Chinese population with FD or IBS during provocative hydrogen breath testing (HBT) with lactulose, lactose and fructose. Subjects fulfilling the Rome III classification of FD and IBS, and control subjects with no known GI disorder/symptoms were recruited. All subjects underwent HBT with lactulose (10ml), lactose (25g) and fructose (25g). Subsequent breath tests were performed after a washout period of at least one week. Breath tests were performed after an overnight fast, with the patient sedentary. Breath samples taken every 15 minutes for 3 hours. GI symptoms were recorded during these 3 hours and telephone follow-up 24 hours later.

Results: A total of 353 subjects completed at least one breath test examination and 373 subjects completed all three breath tests. 16%, 55% and 29% were control, FD and IBS subjects. All study subjects were ethnic Chinese. The median age was 53 (Range: 18-76) and 27% [95% CI: 23-32%] were male. 85% [95% CI: 82-89%] of subjects were women. Symptoms induced in a relatively low proportion of healthy controls. Both FD and IBS subjects experienced similar proportions of epigastric pain on consumption of lactulose, lactose and fructose. See Table 3. Subjects with FD experience more belching than subjects with IBS when lactulose (58 vs. 42%, p = 0.011) and lactose (62 vs. 46%, p = 0.014) were ingested, respectively. Subjects with IBS experience significantly more “lower GI” symptoms of abdinal pain and discomfort of loose stools when lactulose was ingested when compared with subjects with FD. In general subjects with IBS experienced both epigastric pain and abdominal pain when any of the three carbohydrate solutions were ingested. Healthy controls experienced minimal symptoms.

Conclusion: Chinese subjects commonly co-produced hydrogen and methane. Ingestion of poorly absorbed sugars induces symptom patterns in patients with FD in similar proportions. Chinese IBS subjects commonly experienced epigastric pain and abdominal pain when any of the three carbohydrate solutions were ingested. Subjects with FD experience more belching than subjects with IBS when lactulose and lactose were ingested.

7Shire International GmbH, Zug/Switzerland

Contact E-mail Address: Pall.Pekker.Jeppesen@regiondh.dk

Introduction: Inflammatory bowel disease (IBD) and mesenteric vascular (Vasc) disease are underlying conditions for intestinal failure associated with short bowel syndrome (SBS-IF). Fluid balance, urine production, and parenteral support (PS) volume are variable among patients with SBS-IF.

Aims & Methods: This is a post hoc analysis of the impact of teduglutide (TED) on fluid composite effect (FCE = sum of urine output volume increase, oral fluid intake reduction, and PS volume reduction) in patients stratified by diagnosis. STEPS (NCT00798967; EudraCT2008-006195-13) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS-IF. Three groups were evaluated: SBS-IBD, SBS-Vasc, and Other.

Results: The SBS-IBD group included more patients with stoma (95%; SBS-IBD, 19%; Other, 41%) and fewer with colitis-in-continuity (11%; SBS-Vasc, 78%; Other, 62%). At Week 24 (Table), PS volume reductions were significantly higher in SBS-IBD patients treated with TED vs placebo (P = 0.02) and vs SBS-Vasc patients in the SBS-IBD (P = 0.04) and Other (P = 0.02) groups. Change in FCE was greater in SBS-IBD patients treated with TED vs placebo (P < 0.02) and vs TED patients in the SBS-Vasc (P < 0.01) and Other (P < 0.05) groups.

5Shire International GmbH, Zug/Switzerland

Contact E-mail Address: Pall.Pekker.Jeppesen@regiondh.dk

Introduction: Intestinal resection resulting in short bowel syndrome (SBS) can lead to intestinal failure (SBS-IF). SBS-IF arises from different aetiologies, including vascular catastrophes and inflammatory bowel disease, resulting in a heterogeneous population.

Aims & Methods: This post hoc analysis reports baseline characteristics and clinical response to teduglutide (TED) in patients based on residual bowel anatomy. STEPS (NCT00798967; EudraCT2008-006195-13) was a 24-week, placebo-controlled study of TED 0.05 mg/kg/day in patients with SBS-IF. Three groups
were evaluated: Group 1 (no colon/stoma present/no colon-in-continuity), Group 2 (≥50% colon/stoma to colon-in-continuity), and Group 3 (other bowel anastomosis). Clinical response was defined as ≥20% reduction from baseline in weekly parenteral support (PS) volume at Weeks 20–24. Data presented as mean (SD).

**Results:** The predominant diagnosis in Group 1 was Crohn’s disease, whereas the predominant diagnosis in Group 2 was vascular complications (Table). Group 1 patients required the highest baseline PS volumes compared with Group 2 or Group 3. TED-induced PS volume reduction (change in L/week) took longer to be realised in Group 2 (Week 12 – 9.9 [1.2]; Week 24 – 2.5 [1.2]) compared with Group 1 (Week 12 – 5.5 [3.8]; Week 24 – 6.4 [4.5]) or Group 3 (Week 12 – 2.7 [1.2]; Week 24 – 5.1 [3.7]). Response rates were higher with TED versus placebo in all groups, but the difference was significant only in Group 1 (76% vs 19%, P < 0.001; Group 2, 56% vs 40%, P = 0.36; Group 3, 57% vs 29%, P = 0.035). Adverse events were reported by 94%, 72%, and 86% of Group 1, Group 2, and Group 3 patients receiving TED, respectively.

**Table: Baseline Patient Characteristics**

Introduction: Sporadic non-ampullary duodenal epithelial tumors (SNADETs) are rare, accounting for less than 1% of gastrointestinal neoplasms, and thus the mechanism behind the pathogenesis and carcinogenesis of these neoplasms is still poorly understood. However, with the overall increase of small bowel cancer in recent years, there is an increasing need to clarify the morphology of SNADETs. This study was conducted with the objective of identifying genetic markers and pathways specific to superficial SNADETs through gene-expression analysis.

**Aims & Methods:** This was a prospective pilot study on patients with a diagnosis of superficial SNADETs who were treated at the Department of Gastroenterology, Graduate School of Medicine, The University of Tokyo Hospital, Tokyo, Japan. All patients underwent complete endoscopic evaluation to preclude ampullary lesions, and had a preoperative histologic diagnosis of either adenoma or adenocarcinoma. Patients with familial polyposis were excluded. Immediately before resection of the target lesions, a single biopsy sample from the duodenal tumor and a paired sample from the surrounding normal duodenal mucosa were endoscopically obtained from each patient, followed by RNA extraction. Gene expression profiling with an oligonucleotide microarray was performed in a training set of 4 matched tumor-normal superficial SNADETs pairs. Genes and pathways with differences between pairs were identified, followed by a set-level gene enrichment analysis with a pre-validated cutaneous gene set. Results were confirmed with rt-PCR in all other independent SNADETs pairs.

**Results:** From Nov 2014 to Jan 2016, a total of 12 consecutive patients were enrolled in this study. One patient was excluded due to a post-treatment diagnosis of familial polyposis. In a training set of 4 tumor-mucosa pairs, 626 probes (168 up-regulated, 458 down-regulated) which consistently demonstrated over a 2-fold expression difference between tumor and normal mucosa in all matched pairs were identified. RT-PCR of genes most highly differentially expressed between the tumors and normal mucosa was performed in the 4 pairs in the training set as well as 7 independent pairs. Consistent gene expression patterns concurrent with microarray results were demonstrated in all pairs, confirming the results of this study. Gene set enrichment analysis of the training set using a curated data set demonstrated a strong association between SNADETs and colorectal adenomas (p < 0.0001) and APC down-regulation (p < 0.00001). No other significant associations were demonstrated.

**Conclusion:** Superficial SNADETs demonstrate gene expression characteristics congruent with those resembling colorectal adenomas. Gene expression characterization of these lesions has also demonstrated the significant role of APC down-regulation in the pathogenesis of SNADETs, suggesting that an adenoma-carcinoma sequence similar to colorectal adenomas may be seen in SNADETs. Further analysis of genes which may play a key role in the carcinogenesis of these neoplasms is required.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1292 USE OF 3D COMPUTED TOMOGRAPHIC ENTEROCLYSIS TO OBTAIN INFORMATION ON THE LENGTH OF THE SMALL INTESTINE AND ON THE SIZE, SHAPE, LOCATION OF INTESTINAL NEOPLASIAS**

T. Yoikawa, K. Ohno, T. Kurokami
Dept. Of Gastroenterology, Shizuoka General Hospital, Shizuoka/Japan

**Contact Email Address:** t-yoshi@med.nagoya-u.ac.jp

**Introduction:** We established a new imaging technique, 3D computed tomographic enteroclysis, to evaluate the small bowel (1). In our hospital, this examination is performed routinely to detect gross lesions in the small intestine. In our study, we analysed the clinical performance of 3D CT enteroclysis to evaluate its safety, feasibility, and usefulness for small intestinal neoplasias.

**Aims & Methods:** Data on 3D CT enteroclysis performed in our hospital from January 2010 to March 2017 were reviewed. In 3D CT enteroclysis, the small bowel was inflated with air using a nasoduodenal tube. CT images were taken, and the images’ overall, endoscopic, and virtual dissection views were generated using a virtual colonoscopy system. Total volume of injected air, intraintestinal pressure, and length of the depicted small bowel were recorded. The images of small intestinal neoplasias were collected and compared with the patients’ CT images.

**Results:** One-hundred thirty 3D CT enteroclysis were performed for 93 males and 46 females. The mean age was 49.2 (17–92) years. Examinations were performed for definitive/suspected Crohn’s disease in 35, intestinal obstruction in 34, and 3 cases of small intestinal neoplasias in 25 and others in 5 patients. Consistent gene expression patterns concurrent with microarray results were demonstrated in 10 and 5 patients, respectively, but no additional treatments were necessary. The volume of air and intraintestinal pressure were recorded in 77 examinations for patients without previous resection of the small bowel. The mean total volume of injected air was 1872 ± 656 mL, the mean maximal intraintestinal pressure was 2.7 ± 0.8 kPa, the mean length of the depicted small bowel was 517 ± 102 cm, and whole small bowel tracing was achieved in 71.4% of these 77 examinations. Twenty small intestinal neoplasias were depicted in 4 cases of submucosal tumors, 3 cases of gastrointestinal stromal tumors (GISTs), in 3 cases of neuroendocrine tumors, in 2 cases of cancers, in 2 cases of lipomas, in 2 cases of malignant lymphomas, in 1 case of metastatic cancer, 1 case of Peutz-Jeghers syndrome, 1 case of Peutz-Jeghers type polyps, and 1 case of pyogenic granuloma. Surgery was performed for 12 cases, the total length of the small intestine and estimated location of the lesion by 3D CT enteroclysis were comparable to intraoperative findings in 9 cases (no measurement in 3 cases). In a case of multiple GISTs, some of the lesions of 6–8 mm in size were missed and no lesion smaller than 4 mm was depicted.

**Conclusion:** 3D CT enteroclysis can be performed safely, and the whole small bowel could be examined in most cases. 3D CT enteroclysis can depict stenosis and lesions bigger than 1 cm, measure the length of the small intestine, measure...

P1293 INK TATTOOING FOR BALLOON-ASSISTED ENTEROSCOPY–TIME WELL SPENT?

C. Rimmele1, A. Ebigbo1, H. Messmann1, S. Gölder1
1Department Of Internal Medicine IIi, Klinikum Augsburg, Augsburg/Germany

Contact E-mail Address: christoph.roemmele@klinikum-augsburg.de

Introduction: Balloon-assisted enteroscopy is a well-established tool in the diagnosis and therapy of small bowel diseases. Ink tattooing of the small bowel is used in some centers to mark pathologic lesions or the depth of small bowel insertion.

Aims & Methods: The purpose of this study was to determine the safety, the detection rate within a surgical operation or video capsule endoscopy and the clinical relevance of ink tattooing during balloon-assisted enteroscopy (BAE).

Methods: Between 2011-2015 229 BAE were performed in 156 patients (pts) at the endoscopy unit of Klinikum Augsburg. We performed a retrospective analysis of all 81 (52%) patients who received an ink tattooing during BAE.

Results: Main indications for BAE were known angiodysplasia (37 pts), suspected bleeding of the small intestine (32 pts) and anemia (19 pts). Other indications were known or suspected tumor of the small intestine (17 pts) and Crohn’s disease (3 pts). In 27 patients no pathologic findings were found. In 41 patients an active bleeding, angiodysplasia or hemorrhangioma were found and further therapeutic interventions were performed. Tumor/polyps (11 pts), inflammatory lesions (7 pts) and ulcerative diverticula (1 pt) were other findings. In all 81 patients ink tattooing of the small intestine was performed with no complications. 46 (57%) of 81 patients received a follow-up mainly due to re-bleeding. 5 patients underwent surgery directly after endoscopy with ink-tattooing and therefore received no follow-up. In total 26 (32%) patients received a capsule endoscopy after BAE at our hospital. The ink tattooing could be detected via capsule endoscopy in 19 of these 26 patients (73%). All patients received a video capsule endoscopy with ink-tattooing and therefore received no follow-up. In 30 (26%) 26 patients received a capsule endoscopy after BAE at our hospital. The ink tattooing could be detected via capsule endoscopy in 19 of these 26 patients (73%). The ink tattooing of the patient could be detected via an intraoperative double balloon enteroscopy (DBE) in 2 of 11 (18%) patients. Nine patients received a second ink-tattooing of the small intestine within these examinations without any complications. Ink tattooing had no clinical relevance or therapeutic consequence in 62 of the 81 (72%) patients within the observation period. 5 of these 62 Patients received no further diagnostic or therapeutic steps due to their clinical situation. In 9 patients ink tattooing influenced the choice of approach (antegrade versus retrograde) for re-enterscopy after a video capsule endoscopy. In 7 patients the ink tattooing was used for intraoperative localization and in 3 patients for intraoperative localization as well as for enteroscopy. The intraoperative detection rate of the ink tattooing was 100%.

Conclusion: Ink tattooing of the small intestine is a minimally invasive and safe endoscopic procedure to mark the depth of scope insertion or a pathologic lesion during balloon-assisted enteroscopy. It is a useful tool to avoid unnecessary examinations and aids the intraoperative localization of pathologic lesions. A complete enteral enteroscopy via BAE from retrograde and antegrade BAE is achieved routinely in our setting.

P1295 VITAMIN D PREVENTS HEPATIC STEATOSIS AND CARDIOVASCULAR DAMAGE IN A RAT MODEL OF FATTY WESTERN DIET

G. Mazzone1, C. Morisco2, V. Lembó1, G. D’Argenio1, M. D’Armentino2, A. Rossi1, C. Del Giudice2, N. Caporaso1, F. Morisco1
1Department Of Clinical Medicine And Surgery, University of Naples Federico II, Napoli/Italy
2Department Of Advanced Biomedical Sciences, University of Naples Federico II, Napoli/Italy

Contact E-mail Address: v.lembo@hotmail.it

Introduction: The western diet (WD) high in fat and fructose is considered one of the most relevant cause of metabolic disorders and cardiovascular diseases (CVD). The aim of this study was to evaluate whether vitamin D supplementation is able to modulate hepatic steatosis, restore insulin resistance and the metabolic alterations contributing to CVD and hearth failure (HF) caused by a westernized diet, in a rat model without specific vitamin D deficiency.

Aims & Methods: Eighteen adult male Wistar rats were divided into three groups, each of 6 rats, fed with: Group 1: Standard Diet, 3.3kcal/g (SD); Group 2: Western Diet, 5.6kcal/g (WD containing 131U/day/rat of vitamin D3); Group 3: Western Diet+Vitamin D (WD Vit D) containing 25JU/day/rat of vitamin D3.

The experiment was conducted for 6 months. Standardized tail-cuff blood pressure (BP) measurements of conscious rats and transthoracic echocardiography were performed in basal condition (Time 0), and after 3 and 6 months of diet. Hepatic steatosis and collagen myocardial fibrosis were assessed using standard macroscopy, trichrome and Sirius red assays. Vitamin D (25(OH)D3) concentrations were determined using rat-specific ELISA kits. Insulin resistance was determined according to the Homeostasis Model of Assessment (HOMA-IR) method.

Results: In WD rats the percentage of hepatocytes with steatotic vacuoles was 61%, while in WDVitD group was only 27%. WD group HOMAIR was significantly higher than in SD (41.9±8.9 vs 6.17±1.3, p < 0.001) and it was reduced by vitamin D supplementation in WDVitD group (41.9±8.9 vs 19.4±5.2, p < 0.05). At baseline, no differences in systolic blood pressure (SBP) were detected among the three groups showing normal systolic blood pressure. SD did not increase SBP, significantly, during the study period. On the contrary, WD, enhanced SBP by 27±12% p < 0.001 at 3 months, and by 47±11%, p < 0.001 at 6 months. At the end of the study, SBP resulted to be higher in WD group compared to both SD (117±3 mmHg, p < 0.001) and with WDVit.D (101±4 mmHg, p < 0.01). During the study period, WD group showed a significant increase of left ventricular mass (LVM) (52±25% at 3 months p < 0.05, and 123±43% at 6 months p < 0.001), vs basal conditions. Supplementation of VD abolished the WD-induced increase of LVM (25±19% at 3 months, and 34±20% at 6 months, p < 0.05 vs baseline respectively). At the end of the study LVM resulted to be higher in the WD group in comparison to both SD and WDVitD groups, while...
no difference was detected between SD and WDVit.D. However, some collagen staining resulted still present in WDVitD rats. No difference was detected between SD and WDVit.D. However, some collagen staining resulted still present in WDVitD rats. No difference was detected between SD and WDVit.D. However, some collagen staining resulted still present in WDVitD rats.

Conclusion: These results suggest that a daily supplementation of vitamin D3 can reduce hepatic steatosis and prevent cardiac alterations such as the increase of systolic blood pressure and left ventricular hypertrophy in WD rats. We measured the utilization of the nutrition department services according to the actual consultations. Results: We included data from 461 patients (50% males, aged 67±19 yrs). MUST evaluation for malnutrition was not available in any of the reviewed charts. We therefore calculated the MUST score using the available data in the charts. There were 73 (15.8%) overweight-obese and 85 (18.4%) at high risk of malnutrition patients admitted at the internal medicine (n = 127) and surgery (n = 31) sections of the hospital. Nutritional consultation was requested in 4 (3.1%) and 1 (3.2%) internal medicine and surgery patients, respectively by the treating physician during hospitalization. Among the 383 patients discharged at the end of our observation, there were 72 (18.8%) overweight-obese and 46 (12%) at high risk of malnutrition patients. Nutritional consultation was recommended in 24 (6 obese, 13 undernourished and 3 patients with low MUST score) of them.

Conclusion: MUST -a simple screening tool for malnutrition- is not used by the medical staff and nutritional support services are significantly underutilized in a tertiary Greek hospital.

Disclosure of Interest: All authors have declared no conflicts of interest.

Roman S, Napoleon B, Mion F et al. Intragastric balloons (IGB) are an emerging option for overweight and obese patients with a body mass index (BMI) greater than 31 kg/m2 and they provide greater efficacy with lower risks than do conventional surgical procedures. The balloon treatment is based on gastric space-occupying effects that increase the feeling of satiety and may also effect gut neuroendocrine signaling. However, widespread use of current generation IGBs has been limited by several factors: placement and removal endoscopies require sedation, special training and equipment; patients lost to follow-up are susceptible to IGB deflation and unplanned passage into the gastrointestinal tract. The ElipseTM is the world’s first gastric balloon device that not require endoscopy or anesthesia.

Aims & Methods: We conducted a study to prospectively analyze the safety and effectiveness of IGB ELIPSE in overweight adults. Six patients, 1 male and 5 females (average age 40, mean BMI 40 kg/m2), were included in this study. Each patient swallowed ElipseTM balloon intended to remain in the stomach for 16 weeks. Each balloon was filled with 560 mL of filling fluid. Patients returned every 2 weeks for abdominal ultrasound which documented the correct positioning of the device. All patients were followed up by a nutritionist with a specific screening tool for weight loss.

Results: All 6 patients successfully swallowed the device. There were no major adverse effects. All 6 patients had a significant weight loss (about 16 Kg). In all of the patients, the balloon remained full throughout 16 weeks, self-emptied, and the patients were passed spontaneously without needing endoscopic removal. All 6 patients successfully swallowed the device. There were no major adverse effects. All 6 patients had a significant weight loss (about 16 Kg). In all of the patients, the balloon remained full throughout 16 weeks, self-emptied, and the patients were passed spontaneously without needing endoscopic removal.

Conclusion: This study demonstrates the efficiency, security and simplicity of the ElipseTM system. Moreover, we highlighted the non necessity of deep sedation or anesthesia. Aims & Methods: We conducted a study to prospectively analyze the safety and effectiveness of IGB ELIPSE in overweight adults. Six patients, 1 male and 5 females (average age 40, mean BMI 40 kg/m2), were included in this study. Each patient swallowed ElipseTM balloon intended to remain in the stomach for 16 weeks. Each balloon was filled with 560 mL of filling fluid. Patients returned every 2 weeks for abdominal ultrasound which documented the correct positioning of the device. One year after bariatric surgery, the prevalence of osteoporosis and osteopenia was low. The serum Vitamin D level increased significantly but no significant change of BMD was noted. Further longitudinal studies are warranted to clarify the long-term effect of bariatric surgery on BMD in Chinese population.

Introduction: Bariatric surgery is an effective treatment for morbid obesity. In Taiwan, the numbers of patients who received bariatric surgery increased gradually. However, for long-term follow-up, nutritional deficiency may develop in post-bariatric (metabolic) surgery patients, especially in patients who received mal-absorptive or combination procedure. Deficiency of nutrition may cause anemia, peripheral neuropathy, secondary parathyroidism and osteoporosis. Follow-up of the nutritional status for patients after bariatric surgery is an important issue.

Aims & Methods: The aim of our study is to evaluate the change of Vitamin D and bone Mineral Density after bariatric surgery in Chinese population. This prospective cohort study included 50 patients (ranged from 20 to 65 years old) who received bariatric surgery at one teaching hospital in Taoyuan, Taiwan. Patient with osteoporosis before surgery were excluded in this study. Baseline (2012-2014) and one year after bariatric surgery (2013-2015), venous blood was collected from each patients for assessment of the Calcium, Vitamin D and parathyroid hormone (PTH) levels. BMD (g/cm2) was also measured at lumbar spine (L2-L4) by dual energy x-ray absorptiometry (DEXA).

Results: Among 50 patients, 15 patients received laparoscopic sleeve gastrectomy, 24 patients received laparoscopic mini-gastric bypass (MGB), 5 patients received laparoscopic Roux-en-Y gastric bypass (RYGB) and 6 patients received laparoscopic duodenal-jejunal bypass with sleeve gastrectomy (DBSG). The characteristic of the study population was shown as table 1. The differences of mean for calcium, vitamin D, PTH and BMD after bariatric surgery were = 0.16 mg/dl (P < 0.001), 0.14 mg/dl (P < 0.05) and 0.04 g/cm2 (P = 0.14) respectively.
P1300 INTRAGASTRIC BALLOON: A LARGE BRAZILIAN MULTICENTRIC STUDY OVER 10,000 CASES AND 20 YEARS OF EXPERIENCE

Introduction: The intragastric balloon has been used for more than 20 years in Brazil. As a novel, non-invasive device for assisting weight loss, and some intercurrences were observed during more than 10,000 procedures performed. With the assistance of a multidisciplinary team the results have been satisfactory.

Aims & Methods: To assess the efficacy and complications of the weight loss with IGB in patients seen at the 07 private centers. A total of 10,255 patients with IGB implanted from 1997 to 2017 were analyzed from a prospective fed database. A liquid filled IGB with a volume in between 620 to 700 ml was used. Initial BMI started at 27 kg/m2 (as approved by Brazilian health authorities) and were followed up by a multidisciplinary team during implant. IGB maximum implant period was 09 months. Statistical analysis was performed according to sex and degree of excess weight (overweight and grade I, II and III). Data were analyzed using student t-test, and Tukey post-test. The level of significance was set at p < 0.05.

Results: 492 patients (4.8%) were excluded from the final analysis associated with weight loss: 226 (2.2%) due to early removal. These were analyzed in relation to the other 99%, and 5186/492/3764 patients were included. These patients were analyzed in relation to follow-up with nutritionist and psychological evaluation before the procedure, 158 (1.54%) due fail on weight intake and 588 (6.0%) did not undergo nutritional monitoring during the use of IGB, 108 (0.4%) had no follow-up complete data. There were also spontaneous hyperinflation on 0.99% (n = 101) and balloon spontaneous deflation or leakage in 0.82% (n = 84). Incidence of complications not leading to removal were 6.65% (n = 376).

Complications other occurred as fungal contamination in 7.9% (n = 810); Wound dehiscence in 0.03% (n = 2), pregnancy during implant period was 1.2% (n = 123) and Dieulafoy lesion 0.00% (n = 1). The incidence of complications with IGB removal was 0.05% (n = 0); gastric perforation. On the 9,763 remaining patients, 7,615 (78%) were women and 2,148 (22%) were men. Mean age was 43±5 years. 37% of patients showed a significant weight loss, with a significantly lower final BMI (27.16 ± 4.82 kg/m2; range: 15.71-31.74) than the initial BMI (33.42 ± 6.62 kg/m2; range: 27.79-39.35). The mean Weight Loss was −16.98 kg (−16.85 kg). Percent EW L was higher in the overweight group (41.33%) sequentially. A total of 5.2% (66/1,268) of the patients followed up for 18 months after withdrawal of the IGB were submitted to bariatric surgery.

Conclusion: The intragastric balloon has been established as an valid endoscopic tool for treatment of overweight, especially in patients with overweight and obesity grades I and II and multidisciplinary team follow-up is mandatory for successful treatment.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The weight regained has been a described growing problem in patients after bariatric surgery. This weight regained is multifactorial and is associated to dilation of GJ with the gastroenteric anastomosis (GJ). For the patients with significant weight regain some revisional procedures had been attempted and more recently endoscopic revisional procedures had been described.

Aims & Methods: To evaluate the safety and effectiveness of argon plasma coagulation (APC) decreasing the diameter of the gastroenteric anastomosis in patients who have undergone RYGB for morbidity obesity and regained weight associated to dilation of the GJ. From Jan-2014 to April-2017 554 RYGB subjects with weight regain a dilated anastomosis (>18 mm) and at least 2 procedures were submitted APC application. In relation to the anastomotic diameter, the majority of studies use a diameter of more than 20 mm to define anastomotic dilation, although some studies use smaller diameters such as 12 mm. In relation to that created mainly in the gastrojejunal anastomosis using a 36 Fr Fouchet bougie. In the patients in the present study, the minimum cross-section diameter was 18 mm and the maximum measured in the first session 40 mm. This anastomotic dilation was measured using a 33-mm long articulated device and an endoscope between an anastomotic dilation and its diameter with a maximum of 03 applications. APC set was at 2-3L with 65–85W. GJ diameter target was 8–12 mm estimated with pre-measured grasper. At first APC session, pre-op weight and BMI, post-op weight nadir, actual weight and BMI and estimated diameter of GJ were the variables collected. Complications during treatment were also collected. In the present study, psychological and nutritional evaluations were performed before APC and during treatment and physical activity was strongly recommended. Data were analyzed with descriptive statistics, student’s t test and Spearman correlation.

Results: Of the 554 patients, 79.06% were women and 20.94% were men. Average time between bariatric surgery and the first APC was 96.35 months (± 54.4). The mean and average weight loss in this interval was 22.08 kg (± 11.05). The mean diameter of the anastomosis was 24.78 mm (± 6.04) and the average number of APC sessions was 1.78 times (±0.61). The average reduction of anastomotic diameter was 14.86 mm (±7.24) and the final average diameter was 10.22 mm (±3.89). The mean weight loss between the first and last APC was 13.37 kg (±7.82) and the average decrease of BMI was 4.59 kg/m2 (±2.78). 122 patients (22.02%) did not achieve the target GJ diameter and 05 patient (0.9%) did not lose weight even with the desired GJ diameter. From the 146 (26.56%) patients followed up for 12 months the weight regained was less than 10% of the weight of. Of the 554 patients APC, 51 (9.2%) required dilatation balloon due to symptomatic stenosis at least once. No further complications were reported.

Conclusion: Argon Plasma Coagulation (APC) has been shown to be an effective and safe endoscopic technique for the reduction of gastro enteric anastomosis in patients undergoing bariatric surgery who have regained weight with dilation of the anastomosis. The reintroduction of the patient to the multidisciplinary team is mandatory in cases of weight regain and loss to postoperative follow-up. A psychological and/or psychiatric evaluation is mandatory, as well as nutritional therapy and encouragement of physical activity. The monitoring of food intake and body weight, closer follow-up of the operated patients, appropriate choice of technique according to the patient and the experience of the surgeon, and a good learning curve are all factors that can reduce the failure rate of bariatric surgery. The reintroduction of the patient to the multidisciplinary team is mandatory if better results and sustainable weight loss and comorbidity control are to be obtained.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: With the aging of the population, the incidence of obesity has also increased among the elderly. However, there is a higher incidence of severe comorbidities in this population comparing to adults, which often makes bariatric surgery unfeasible. In this segment, treatment with the intragastric balloon (IGB) may be an interesting option.

Aims & Methods: We aimed to assess the efficacy and complications of obesity treatment in the elderly using a non adjustable IGB. A total of 77 patients were analyzed. The minimal initial body mass index (BMI) was 28 kg/m². The level of significance was set at p < 0.05.

Results: 58 patients were women (75.3%). Mean age was 64.26 (60–80) years. Ten patients had no comorbidities, 32 had hypertension, 45 had dyslipidemia, 32 had insulin resistance, 12 had type II diabetes, and 10 had ischemic heart disease. There were no major complications. Results are shown on table 1. The treatment success rates according to the following criteria: ≥10% total body weight loss (TBWL) and ≥25% excess weight loss (EWL) were 96.11% (74 patients) and
Disclosure of Interest: gluten provocation and placebo, indicating no specific effect of gluten in a group between the diagnosed and the not-diagnosed group, or between symptoms after gluten diagnosed four patients with NCGS according to the Salerno criteria.

Conclusion: This randomized, double-blind placebo-controlled challenge with gluten showed more severe symptoms with placebo. The not-diagnosed group showed more severe symptoms with placebo than with gluten (p = 0.0001). The BA concentrations in feces were similar in both groups. There was no group-specific pattern in the fecal microbiota. A subgroup of 17 patients, one month of statin therapy increased the serum BA concentration from 0.68 ± 0.08 to 1.37 ± 0.213 μmol/l (P = 0.01).

Conclusion: There was no specific microbiota signature associated with CAD. However, the decreased serum BA concentration was a strong predictor of 6-month survival in humans. With respect to the powerful anti-atherosclerotic effect of BA in animal models, and their role in human lipid metabolism and diabetes, this study unraveled the existence of a new metabolic disturbance associated with CAD.

Introduction: The low-FODMAP diet (LFD) is used to treat patients with irritable bowel syndrome (IBS) even if some nutritional concerns have been raised. It starts with an elimination phase and is followed by a reintroduction phase to clearly detect the “symptom trigger” foods in order to suggest a definitive and less restrictive diet tailored to the patient's needs.

Aims & Methods: The aims of this study were to evaluate: 1) the effects of FODMAP reintroduction on a) body composition and nutritional status, using Bioelectrical Impedance Vector Analyses (BIVA), b) abdominal symptoms, c) quality of life, d) anxiety/depression, e) sleep quality, 2) if the patients' perception of the “trigger” foods was accurate.

Results: 66 IBS patients (54F, 12 M; 44±3±13.0 yrs.) started (T0) a LF D for 8 weeks (T1) and followed a 9–14 week reintroduction period (T2). They underwent blood tests at T0 and T1. BIVA, anthropometric data, IBS-Symptom Severity Score, Bristol Stool Chart (BSC), SF36, Hospital Anxiety and Depression Scale and Pittsburgh Sleep Quality Index were performed at T0, T1 and T2. The patients were monitored by a nutritionist to verify their compliance.

Aims & Methods: Neither change of blood tests at T1 nor variations of anthropometric data and BIVA were reported at T1 and T2 in comparison with T0. A significant improvement in abdominal symptoms (IBS-SSS), anxiety and quality of life, was recorded at T1, this remaining unchanged also at T2 (p < 0.0001). Depression improved at T2 (p < 0.01 vs. T0). Sleep quality improved at T1 (p < 0.05 vs. T0) and at T2 (p < 0.001 vs. T0).

Conclusion: All authors have declared no conflicts of interest.
both at T1 (8.4±1.6) and T2 (8.2±1.7). When starting, LFD patients considered an average 32 foods low-carbohydrate diet (57%), fructose (27%), fructose (17%), galacto-oligosaccharides (10%) and polysaccharides (3%); the reintroduction phase (T2) enabled us to detect lactose in 70%, fructose in 30%, fructose in 30%, GOS in 33% and polysaccharides in 27%, as real triggers. The agreement (Cohen’s kappa) was moderate for lactose (k: 0.50), fair for fructose (k: 0.39) and fructose (k: 0.32) and poor for polysaccharides (k: 0.01).}

Conclusion: Not only did reintroduction not affect the improved achievements during the elimination phase, but it also precisely identified the foods responsible for the effects and symptoms. This enabled us to suggest a personalized diet for the patients. The real role played by FODMAPs in generating symptoms was abundantly underestimated and misunderstood by our patients. This underscores the fact that LFD has to be administered and carried out under the guidance of an expert nutritionist.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1306 EXPRESSION OF THE FRUCTOSE TRANSPORTER GLUT5 IN PATIENTS WITH FRUCTOSE MALABSORPTION

Abstract: Fructose malabsorption (FM) is a frequent finding in patients with abnormal glucose-tolerance to high levels of fructose in Western diets. The role of monosaccharide transporter dysfunction in the small intestine is incompletely understood. The aim of this study was to investigate the histoanatomical distribution of the main fructose transporter GLUT5.

Aims & Methods: The study included 257 patients with FM diagnosed by hydrogen breath test and grouped according to the response to a fructose-free diet. 42 healthy individuals and 31 patients with coeliac disease (CD) served as controls. The fructose breath test was done with 50 g fructose. Fructose malabsorption was defined as an increase of 20 ppm of endogenous hydrogen. Formalin-fixed and paraffin-embedded duodenal biopsy specimens were obtained in all cases. Histology was assessed using hematoxylin and eosin stained tissue sections. Expression of GLUT5 was studied by immunohistochemistry. Expression pattern of GLUT5 was correlated with clinical and pathological patient characteristics.

Results: The expression of GLUT5 did not differ significantly between patients with FM complete diet responders (n = 183) and healthy controls (n = 42). Also patients with FM responding to a fructose free diet did not differ in GLUT5 expression or in max. H2 increase and AUC measured in fructose breath testing from patients not responding to the diet (n = 40). However, in patients with CD (n = 29) significant differences in GLUT5 expression were found compared to patients with FM and healthy controls (p = 0.009). The severity of CD assessed by the Marsh score significantly correlated with the GLUT5 expression (r = 0.563, p = 0.001).

Conclusion: Changes in GLUT5 expression may not cause symptoms in adult patients with FM. The symptoms induced by FM could be associated with mechanisms known to the pathophysiology of the fructose bowel syndrome. However, in secondary malabsorption decreased GLUT5 expression was detected. Further investigation is needed to understand the essential factors in FM and the influence on functional gastrointestinal disorders.

Contact E-mail Address: valeria.schindler@usz.ch

Introduction: Previous studies have shown a reduction of gastrointestinal symptoms in patients with disorders of gut-brain interaction (FGID) when following a diet low in FODMAPs. However, the influence of JH on host serotonergic pathway may represent a further step towards pathophysiological features in FGIDs and might help to select patients for individually appropriate therapies.

Aims & Methods: Data of patients presenting with FGID at the tertiary ambulatory functional bowel clinic between January 2015 and July 2016 were analyzed. FGIDs were diagnosed according to Rome III criteria. JH was assessed by physicians using Brighton score and rated positive for scores ≥4/9 points. Patients received professional nutritional counseling on a diet low in FODMAPs. A global symptom response was assessed by a professional nutritionist after 4 to 6 weeks following a low FODMAP diet.

Results: Of all 84 patients screened for JH, 62 (73.8%) were female and 22 (26.2%) male. Median age was 37 years (range 18-73). JH positive patients were more likely to exhibit JH compared to males (38.62 [61.3%] vs. 6/22 [27.3%]; p = 0.006). Global symptom response rate to a diet low in FODMAPs was 64/84 (76.2%). Our data showed significantly better response to a low FODMAP diet in JH negative patients than in JH positive patients (36/40 [90.0%] vs. 28/44 [63.6%], p = 0.005, ITT). Response of 7 patients was unknown because of early therapy discontinuation before nutritional re-counseling. When excluding 7 patients with therapy discontinuation from our calculations, the difference in diet response between JH negative and JH positive patients remained significant (36/39 [92.3%] vs. 28/38 [73.7%]; p = 0.036).

Conclusion: Our data indicate an association between global symptom response to a diet low in FODMAPs and joint hypermobility status in FGID patients. An underlying structural pathological feature (JH) might represent a further step towards pathophysiological features of FGIDs and intestinal permeability) causing gastrointestinal symptoms in JH positive patients and limiting response to low FODMAP diet should be considered. Our findings represent a further step towards pathophysiological features in FGIDs and might help to select patients for individually appropriate therapies.

Contact E-mail Address: saffouri.george@mayo.edu

Introduction: Gastrointestinal symptoms are often associated with dietary intolerances and are common in the developed world consuming a western diet low in fiber. Aims & Methods: To determine the effect of a high-sugar, low-fiber diet on GI symptoms, small intestinal bacteria, and duodenal physiology. This is a prospective single-center study. Healthy adults with baseline fiber intake ≥14 g/1000 calories/day; <10% daily calories from added sugar; ≥5 servings of fruits and vegetables/day; and ≤15% daily calories from saturated fat were recruited. Exclusion criteria included known GI disease or symptoms, antibiotic/probiotic use within 4 weeks of the study, pregnancy, and vulnerable adults. At baseline visit, participants completed a symptom and demographic questionnaire and underwent esophagogastroduodenoscopy (EGDY) with duodenal biopsies and aspirates. Symptoms associated with constipation, straining, incomplete evacuation, hard stools, abdominal pain associated with bowel movements, diarrhea, bloating, nausea/vomiting, heartburn, fatigue, and appetite. All participants consumed a 7-day standardized diet with typical United States diet with ≥10% of calories from 20% carbohydrate diet (≥35% fat, ≥15% protein). The diet was low in fiber (<10 g/1000 calories/day) and high in simple sugar (≥50% daily carbohydrates). After dietary intervention, participants filled out four symptom questionnaires and underwent repeat EGDY with duodenal biopsies and aspirates. Before and after the diet, quantitative aerobic and anaerobic cultures were performed on duodenal aspirates. Duodenal biopsies were mounted in an Using chamber. Intestinal permeability was evaluated using transmural electrical resistance (TEER) and FITC flux (4KDa); a measure of paracellular transport. Secretory responses were quantified in voltage clamp mode by measuring baseline short circuit current (Isc) and change in Isc (ΔIsc) in response to increasing concentrations (0.003-300 μM) of serotonin (5-HT) on the submucosal side. These measurements were repeated after the dietary intervention. Data are presented as mean ± SEM. Data were analyzed using paired t-test unless specified and p < 0.05 was considered significant.

Results: A total of 10 participants (5 female; median age 26; 70% Caucasian) were enrolled. Average BMI at baseline was 23.1 ± 2.1 kg/m². At baseline, 10% of the 6 who had no growth initially, 1 developed bacterial overgrowth following intervention. There was no significant difference in TEER (26.45 ± 1.98 vs 26.18 ± 2.45 Ohms/cm²), FITC flux (217 ± 34.72 vs 217 ± 6.25 ng/mL) or baseline Isc (48.27 ± 6.39 vs 51.58 ± 7.34 ng/mL/cm²) before and after dietary intervention. Interestingly there was a significantly lower ΔIsc response to increasing concentrations of 5-HT after dietary intervention (P < 0.05, two-way ANOVA).

Conclusion: A low-fiber, high sugar diet led to gastrointestinal symptoms improving in participants who normally consume a high-fiber diet. This was associated with a significant decrease in 5-HT evoked secretory response in the duodenum, suggesting a potential role for dietary modulation of host serotonergic pathway. There was no correlation with quantitative bacterial cultures and there was no overall significant change in intestinal permeability. Diet may mediate these

P1309 STRESS AND STRESS-RELATED PEPTIDE AMPHITROLE THE ANOREXIC ACTIONS OF CHOLECYSTOKININ
Gastroenterology And Hepatology, Saitama medical University, kawagoe/Japan

Contact E-mail Address: yamagouchta81@yahoo.co.jp

Introduction: Recently roles of gut hormones on appetite control have been known. Among them, CCK is well known to suppress appetite and gastric motility. On the other hand, patients of functional dispensisia (FD) have hyper sensitivity to CCK. And releves of CCK inbrad was shown to be high in FD patients. In FD patients, stress have important roles of pathogenesis of the disease.

Aims & Methods: We undertook to clarify whether stress influences the actions of cholecystokinin (CCK) on appetite and gastric emptying. As stress we gave restraint stress, corticosterone-releasing factor (CRF) or urocortin (UCN1) injection intraperitoneally (IP). We also examined the effects of CCK and restraint stress on c-Fos expression in the neurons of appetite center of the brain. In the gastric emptying study, SD rats were fasted overnight. The amounts of the mixture (food and glass beads) left in the stomach were measured at 2 hours after the perorally injection of mixed food, and gastric emptying rate was calculated. In the study on appetite, CCK was IP injected and the amounts of food was measured at 1 and 2 hours after the injection. In some experiments, CRF or UCN1 was IP injected and the interaction with CCK on food intake was examined. In another study, restraint stress was given to rats and the interaction with CCK was evaluated. To study the involvement of brain in the interaction between CCK and stress, c-Fos expression in the neurons was examined and evaluated.

Results: CCK dose-dependently inhibited gastric emptying. CCK dose-dependently inhibited food intake during 1 hr and 2 hr. CRF (10ng/kg rat) significantly inhibited food intake. However, there was no interactive action between CCK and CRF on food intake. UCN1 (3 nmol/kg rat) inhibited food intake at 1 and 2 hours. There was an synergistic action between CCK and UCN1 on food intake. Restraint stress amplified suppressive effect of CCK on gastric emptying and food intake. C-Fos expression of the neurons in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) by CCK was amplified by the addition of restraint stress.

Conclusion: The result suggests that stress might amplify anorexic effects of CCK through the activation of satiety center of the brain that might be the possible pathogenesis for postprandial distress syndromes of FD.

P1310 PEPTIDE TYROSINE-TYROSINE (PY) ENHANCES EFFECTS OF CHOLECYSTOKININ (CCK) ON GASTRIC MOTILITY AND FOOD INAKE INT HE RATS
Gastroenterology And Hepatology, Saitama medical University, Kawagoe/Japan

Contact E-mail Address: hosomi@saitama-med.ac.jp

Introduction: Cholecystokinin (CCK) and peptide tyrosine-tyrosine (PY) have been known to suppress appetite and gastric emptying. Both peptides are released in blood by feeding, and maintain high levels simultaneously for 1–2 hours. Therefore there might be possible to cause interactive actions between two peptides, inducing satiation to finish food intake.

Aims & Methods: In this study, we undertook to elucidate whether CCK and PY have the interaction to decrease food intake. Study on gastric emptying. Male SD rats were fasted overnight, and 1 mL of mixture of food and glass beads was given into the stomach and then PY or CCK or CCK followed by PY was given. Food left in the stomach 1 hr after the injection was measured and gastric emptying rate was calculated. Study on appetite. PY or CCK was IP injected to the rats just before setting food to eat. The amounts of food were measured at 1 and 2 hours after the injection. To clarify the involvement of the brain in the interaction between CCK and PY, c-Fos expression was examined.

Results: CCK (0.5–10 nmol/kg) dose-dependently inhibited gastric emptying (p < 0.001). CCK 10 nmol/kg maximally inhibited food intake (p < 0.01). PY 25–250 pmol/kg significantly inhibited gastric emptying for 1 or 2 hrs after the injection (p < 0.01). PY 250 pmol/kg significantly inhibited food intake for 1 hr after the injection (p < 0.01). The combination of CCK 10 nmol/kg and PY 250 pmol/kg inhibited gastric emptying more than CCK alone (p < 0.01) or PY alone (not significant). PY and CCK additively inhibited food intake when PY was injected 20 minutes later from CCK injection. PY significantly amplified c-Fos expression induced by CCK in the nucleus of solitary tract (NTS) and paraventricular nucleus of hypothalamus (PVN) in the brain.

Conclusion: The combination of PY with CCK amplified the suppression of gastric emptying of food and food intake. The result suggests that the sequence secretion of CCK and PY might strengthen the inhibition of food intake through the activation of satiety center in the brain, that is important for terminating food intake and adjusting energy intake.

Introduction: Transcriptions factors belonging to the p53 family (p53, p63, p73) respond to cellular stress signals by inducing an accurately defined set of genes. In a number of tumors, also in hepatocellular carcinoma (HCC), p53 proteins can exert cancerogenic or tumoursuppressing functions. MicroRNAs are small, non-coding RNA molecules which play an important role in gene regulation. It is known that expression patterns of microRNAs can be controlled by the p53 family. Depending on disease and cellular origin different sets of p53-induced microRNAs have been identified.

Aims & Methods: Little is known about p53-dependent microRNA signatures in HCC. The aim of the study was therefore to identify p53-family-regulated microRNAs in HCC. Hep3B cells were transfected with rAd-p53 and -p73. Microarray analyses were performed to identify p53- and p73-regulated microRNAs. Verification of p53- and p73-dependent microRNA expression was performed by qPCR.

Results: Overexpression of p53 and p73 induced a rash of microRNAs. p53 induced miR-34a by 2.4-fold, miR-145 by 2.7-fold and led to a slight reduction of miR-149. In the presence of p73 miR-34a was induced by 5.4-fold, miR-145 by 3.2-fold, and miR-149 by 5.5-fold. p53-dependent expression of miR-34a was further increased in the presence of Doxorubicin (5.7-fold), Regerofambin (2.5-fold) and Tivantinib (1.9-fold) compared to controls. Moreover, incubation with Regerofambin resulted in an up to 3.4-fold increase of p53-dependent expression of miR-149 and miR-192.

Conclusion: p53 proteins affect the microRNA signature in HCC. Beside the already known induction of miR-34a we demonstrate for the first time a regulation of miR-145 and –149 by p53 and p73. We hypothesize that regulation of tumoursuppressive microRNAs represents an effector mechanism by which p53 family members exert their role in tumor development and treatment response. The observed synergetic effect of p53 and HCC-relevant therapeutics on microRNA expression might provide new options for the development of therapeautic and prognostic measures in HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1312 IGF2BP2 IS REGULATED BY THE P53 FAMILY OF TRANSCRIPTION FACTORS IN HEPATOCELLULAR CARCINOMA

Introduction: p53 transcription factors (p53, p63, p73) respond to cellular stress by transcriptional regulation of specific sets of genes. In hepatocellular carcinoma (HCC) and other tumors p53 family members exert cancerogenic or tumor suppressive effects. Depending on their splice variants – with transactivation (TA)/dominant negative (DN) – and the characteristics of the particular binding site (BS) p53 proteins activate or inhibit specific target genes. We previously identified the IGF2BP2 gene (Insulin-Like Growth Factor Binding Protein 2) as one out of 7 putative target genes for p53 proteins with prognostic relevance in HCC.

Aims & Methods: The aim of this study was to characterize the so far unknown transcriptional regulation of IGF2BP2 gene by p53 family members in HCC. Hep3B cells were transfected with rAd-p53 and -p73 and transcriptional regulation of IGF2BP2 was determined by qPCR. Intra- and extracellular IGF2BP2 protein levels were analyzed by Western Blot and ELISA. Transfaced database analyses were performed to identify potential BS for p53 and p73. These sequences were cloned, mutated and analyzed for p53 family binding in luciferase reporter assays. Binding of p53 and p73 to the identified BS was confirmed by CHIP experiments.

Results: TaP73 transfection increased IGF2BP2 expression by up to 60-fold and revealed three elevated intra- and extracellular IGF2BP2 proteins. Intracellular IGF2BP2 protein was not detected in controls. p53 transfection induced IGF2BP2 expression by up to 7-fold. Two potential p53 and p73 BS are located in the promoter region, another 5 potential p73 and one p53 BS were identified in intron 1 of the IGF2BP2 gene. Intron 1-dependent luciferase activity was increased by up to 110-fold after TaP73 transfection and up to 20-fold after p53 transfection. Mutation and deletion of the identified p53 BS in intron 1 resulted in a reduction of luciferase activity by up to 85%. Deletion of one
P1313 HOW TO IMPROVE THE RELIABILITY OF LIVER FIBROSIS EVALUATION USING 2D-SWE

F. Bende, I. Speroe, R. Sirlé, M. Danila, S.A. Popescu
Gastroenterology And Hepatology, University of Medicine and Pharmacy "Victor Babes" Timisoara, Timisoara/Romania

Contact E-mail Address: bendefelix@gmail.com

Introduction: Liver stiffness (LS) evaluation as a marker of fibrosis is usually considered reliable when it fulfills some quality criteria. Classic criteria used for Transient Elastography (TE) are: ≥10 valid measurements, ≥60% success rate, and interquartile range/median ratio (IQR/M) < 0.30 [1]. However, new quality criteria were proposed using the IQR/M ratio, therefore the LS measurements can be classified into three categories: very reliable (IQR/M < 0.10), reliable (0.10 < IQR/M < 0.30), poorly reliable (IQR/M > 0.30) [2].

Aims & Methods: The aim of this study was to assess the impact of using quality criteria (LS) evaluation by means of 2D Shear Wave Elastography from General Electrics (2D-SWE.GE), while using Transient Elastography (TE) as the reference. We included 226 subjects in our study, with or without chronic liver disease, in whom LS was assessed using 2D-SWE.GE (LOGIQ E9, GE Healthcare) and TE (FibroScan, EchoSens). Reliable LS measurements were defined for TE as the median value of 10 measurements with a success rate of ≥60% and an interquartile range (IQR) <30% of the median LS values. For 2D-SWE.GE 10 LS measurements were acquired in a homogenous area and the IQR and the IQR/M were calculated in each case. We divided our subjects into 3 groups according to the 2D-SWE.GE IQR/M: IQR/M = < 0.10: 41 (18.1%) cases; 0.10 < IQR/M < 0.30: 155 (68.6%) cases; IQR/M > 0.30: 30 (13.3%) cases. We calculated the correlation coefficient between TE and 2D-SWE.GE in each group.

Results: All 226 (100%) subjects included had 10 valid measurements by means of 2D-SWE.GE and reliable results by TE. A strong positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M < 0.10 group (r = 0.84, p < 0.0001). A weak positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M > 0.30 groups. None of the correlations were significantly different between the LS values obtained by means of 2D-SWE.GE and TE in the R < 0.10 group (r = 0.80, p = 0.0001). A weak positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the R > 0.30 groups as compared to the R < 0.30 group (both p > 0.001). Statistical differences were found between the correlations in the IQR/M < 0.10 and 0.10 < IQR/M ≤ 0.30 groups (p = 0.043).

Conclusion: Using the IQR/M < 0.30 as quality criteria significantly increase the reliability of LS measurements by means of 2D-SWE.GE. Using IQR/M < 0.10 criteria does only slightly improve the reliability of 2D-SWE.GE LS measurements as compared to 0.10 < IQR/M ≤ 0.30 criteria. Contact E-mail Address: akskris@mail.ru

Introduction: 13C-methacetin breath test (13C-MBT) is used to specify the detoxification function of the liver by determination its metabolic capacity and degree of hepatocytes recovery.

Aims & Methods: The study involved 113 patients with MS aged from 37 to 82 years. The criteria for liver stiffness (LS) evaluation by means of 2D-SWE.GE and reliable results by TE. A strong positive correlation was found between LS values obtained by means of 2D-SWE.GE and TE in the IQR/M < 0.30 groups as compared to the IQR/M > 0.30 group (both p > 0.001). No statistical differences were found between the correlations in the IQR/M < 0.10 and 0.10 < IQR/M ≤ 0.30 groups (p = 0.043).

Conclusion: Using the IQR/M < 0.30 as quality criteria significantly increase the reliability of LS measurements by means of 2D-SWE.GE. Using IQR/M < 0.10 criteria does only slightly improve the reliability of 2D-SWE.GE LS measurements as compared to 0.10 < IQR/M ≤ 0.30 criteria. Contact E-mail Address: akskris@mail.ru

P1315 IDENTIFICATION OF P73 AS A NOVEL TRANSACTIVATOR OF IGFBP4 GENE EXPRESSION IN HEPATOCELULAR CARCINOMA

A. Chacón, S. Heckel1, E. Aschenbrenner1, K. Pollinger1, S. Schlösser1, C. Kunz1, M. Müller-Schilling2
1Department For Internal Medicine I, University Hospital Regensburg, Regensburg/Germany

Contact E-mail Address: sebastian-heckel@outlook.de

Introduction: Members of the p53-family, including p53, p63 and p73, are known for their involvement in the regulation of cell cycle, cell senescence and apoptosis. In their role as transcription factors and depending on their splice variants—with transactivation domain (TA) or dominant negative (DN) - p53 and its siblings are capable of activating or inhibiting the transcription of specific target genes. We previously identified the gene for Insulin-like Growth Factor Protein 4 (IGFBP4) as a potential p53-family target gene with prognostic relevance in hepatocellular carcinoma (HCC). In contrast to p53, the IGF system takes part in tissue growth and cell survival. IGFBP4 acts as inhibitor limiting IGF effects suggesting a possible interaction with p53 affairs. Aims & Methods: The aim of this study was to characterize the regulatory influence of p53 family members on the IGFBP4 gene. Hep3B cells were transfected with p53-transfected cells. Induction of intracellular IGFBP4 protein was detected by luciferase reporter assays to evaluate binding of p53-family members.

Results: IGFBP4 expression was increased by more than 30-fold in TA73-transfected Hep3B cells, by more than 15-fold in DNp63- and by 3-fold in p73-transfected cells. Induction of intracellular IGFBP4 protein was detected in all transfected Hep3B cells, whereas extracellular IGFBP4 levels were only measurable after TA73 and DNp63 transfection. Database analysis identified 2 putative p73 binding sites within intron 1 of the IGFBP4 gene. Intron 1-dependent luciferase activity was increased by up to 20-fold in TA73-transfected cells. This induction was reduced by up to 70% when one of the putative binding sites was deleted.

Conclusion: These results identify the IGF inhibitor IGFBP4 as novel target gene of p73. Further analyses on the role of p53-family members may shed light on the mechanisms of IGFBP4 expression and contribute to the understanding of p53-family network and IGF signaling. Since in an independent study we identified IGFBP4 as novel target gene, these results highlight the link between p53-family-mediated transcriptional activation and IGF-signaling pathways which may have therapeutic relevance in the treatment of HCC. Contact E-mail Address: akskris@mail.ru

Introduction: It is known that to determine nonalcoholic fatty liver disease (NAFLD), which develops in progress of body mass index (BMI) from 19% to 35%, using instrumental and laboratory methods, which include an ultrasound, the determination of the transmamline levels, steatostest, 13C-methacetin test. However, these research methods do not allow to clearly differentiate steatosis from the steatohepatitis, that reduces their credibility.

Aims & Methods: 163 patients (75 men, 88 women) with 2 type diabetes mellitus and coronary heart disease with metabolic syndrome, were examined. The average age age was 55.82 years, $\bar{S} = 15.04$. 25 patients were diagnosed as steatosis, 66 - steatohepatitis group. In 25 patients laboratory pathology was not found, which identified as a control group.

For verification of steatosis and steatohepatitis diagnosis the level of ALT, diameter of the portal vein, the degree of CHD and the metabolic rate of methacetin and the cumulative dose $^{13}$CO$_2$ in 120 minute has decreased in patients with steatohepatitis. We found that in ALT and the diameter of the portal vein negatively correlated with cumulative dose of $^{13}$CO$_2$ on 120 minute in patients with steatohepatitis.

Conclusion: There was found that in ALT and the portal vein diameter negatively correlated with cumulative dose of $^{13}$CO$_2$ on 120 minute in patients with steatohepatitis. Therefore, a decrease in the metabolic capacity from 15 to 10% accompanied by an increase in ALT levels (more 0.68 mmol/l) and the diameter of the portal vein (13 mm).

Introduction: Recent studies have demonstrated an association between decreased glucose tolerance, dyslipidemia and metabolic syndrome; and increased risk of colorectal polyps. Patients with non-alcoholic fatty liver disease (NAFLD) often have these risk factors. The association between NAFLD and colorectal polyps has been poorly studied.

Aims & Methods: We aimed to evaluate the prevalence and risk factors of colorectal polyps in patients with NAFLD. This was a retrospective observational study. Liver TTE was free of complications. The patients underwent breath test for methacetin, breath test for methacetin using 13C was performed, breath test for methacetin using 13C was performed.

Conclusion: It was found that the prevalence of colorectal polyps is 28.2% (n=29). The age group was 28.2% (n=29). The age group was 28.2% (n=29). The age group was 28.2% (n=29). The age group was 28.2% (n=29). The age group was 28.2% (n=29).

Introduction: Liver fibrosis (LF) is a progressive pathological process resulting in accumulation of excess extracellular matrix proteins. A metalloprotease BMP1–3 is involved in the liver fibrosis. We have recently discovered that BMP1–3 isoform circulates in the plasma and its neutralization reduces the accumulation of excess extracellular matrix proteins. A metalloprotease BMP1 which is involved in the liver fibrosis.

Aims & Methods: We used the models of CCl4-induced LF in rats. Animals were treated with BMP1–3 antibody at two different concentrations (20 and 50 μg/kg) for 3 and 8 weeks. Extent of LF was assessed by histology, morphometric analysis, shear wave elastography and hydroxyproline (HP) content measurement. BMP1 protein (50 μg/kg) was used as a comparative therapy.

Results: In our experiments the presence of BMP1–3 was immunohistochemically demonstrated in both healthy and cirrhotic liver suggesting that at least a part of circulating BMP1–3 is produced in the liver. Administration of BMP1–3 Ab resulted in inhibition of the progression of liver fibrosis. Administration of BMP1–3 Ab at a dose 20 μg/kg and 50 μg/kg exerted antifibrotic activity comparable to that of BMP1. Apart from blocking the BMP1–3 activity, it is important for collagen maturation, administration of BMP1–3 Ab was accompanied by the decrease in expression of collagen type I and II. BMP1 treatment decreases expression of Decorin mRNA was enhanced. Decorin has evident anti-fibrotic activity in the liver after injury with CCL4 and silencing caused an increased activation of HSCs both in vivo and in vitro. Rats treated with both BMP1–3 antibody concentration had significantly lower amount of collagen type I when compared to the CCL4-treated group. Direct proportionality was found between the degree of fibrosis and liver stiffness. We showed for the first time a distinct correlation between the HP level in liver, morphometric analysis and elastography of the liver.

Conclusion: Our results suggest that neutralization of BMP1–3 is a promising therapeutic approach in preventing the liver fibrosis progression.

Introduction: Non-alcoholic fatty liver disease (NAFLD) is a common clinicopathological condition which may progress from simple steatosis to NASH, cirrhosis and hepatocellular carcinoma (HCC). Although obesity is accepted as the main risk factor for NAFLD, non-obese individuals are often diagnosed with NAFLD suggesting that high BMI may not be a sine qua non for the presence of NAFLD. Recent studies suggested that there might be a correlation between weight gain and metabolic diseases.

Aims & Methods: In our research; the relationship between NAFLD in non-obese individuals and the amount of weight gain during adulthood was investigated and a new index that is different from BMI was proposed. 362 individuals were included in the survey. The subjects were selected among patients who had abdominal ultrasonography (USG) in our clinic, during the last 6 months. A 5% increase in echogenicity detected in the USG was defined as the diagnostic

---

A623
Results: Among 362 participants 169(46.7%) were men with an average age of 44.8±10.73. 78 (21.6%) participants were non-obese, the average age of the group being 46.78±9.12. Out of 78 obese individuals 73 (93.5%) were NAFLD(+). The average age of the 284(78.4%) non-obese subjects was 44±11.05. Among non-obese people 106(39.5%) were NAFLD(+) and average age was 48.07±10.13 while amongst NAFLD(+) people was 38±7.29. Non-obese NAFLD(+) patients reported they had gained significant amount of weight during their adulthood. This information led us to create, a new index named “Subtracted Adulthood Mass Index” (SAMI) to estimate the risk of NAFLD development in non-obese individuals. SAMI is calculated by dividing the difference between the subject’s current weight and his/her weight at the age of 20 years to his/her height squared (kg/m2). SAMI values for non-obese attendants were calculated. When the cut-off value was set as SAMI 4 kg/m2, sensitivity was 76.3%, specificity was 79.1, positive predictive value (PPV) was 84.3% and negative predictive value (NPV) was 69.4%. At a cut-off of SAMI 3 kg/m2 sensitivity was 85.2%, specificity was 66.9%, PPV was 79.1%, NPV was 75.4%. Conclusion: In this pilot study, we found that weight gain in adulthood is an important predictor of NAFLD development in non-obese individuals. The new index named SAMI can correctly identify non-obese people under the risk of developing NAFLD. Cut-off value of SAMI has been set as 3 kg/m2. We also observed that NAFLD prevalence increases as SAMI value goes up. We propose that SAMI is appropriate for clinical use to estimate the risk of NAFLD in on-obese individuals.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Recent studies have shown that the single nucleotide polymorphism (SNP) rs738049 in the PNPLA3 gene is strongly associated with severity of nonalcoholic fatty liver disease (NAFLD).1,2 However, the traditional direct sequencing (DS) method is time-consuming and labor-intensive. The i-density™ (ARKRAY, Inc.), which is based on the quenching probe (QP) method, automatically detects target genes in blood samples by fluorescence quenching within 90 min.3 Aims & Methods: The current study compared the QP and DS methods for detecting SNPs in the PNPLA3 gene, and established the impact of the genotype on prognosis of NAFLD. We enrolled 107 patients with fatty liver irrespective of etiology. We used the i-density fully automated genotyping system with QP. The requisite number of tips, reaction tubes, reagent packs and blood samples were set in their designated places. The forward and reverse polymerase chain reaction (PCR) primers and guanine QP were 5'-cttctctctcctttgctttcacag-3', 5'-gtgtgagca-

References

Conclusion: We suggest that ATP7B does not seem to be involved in cp resistance, at least in hepatic cells. OCT3 represents a novel marker of cp resistance. OCT3 expression could be a valuable tool for improved prognosis of cirrhosis therapy.

P1322 EFFECT OF ORLISTAT ON TOTAL LIVER FAT QUANTITATION USING NOVEL MAGNETIC RESONANCE IMAGING IN OBSESE PATIENTS WITH NON-ALCOHOLIC STEATOHEPATITIS: INTERIM ANALYSIS OF A PROSPECTIVE, RANDOMIZED, SINGLE-CENTER, OPEN-LABEL TRIAL.

J. Ye, W. Yanqin, H. Xuan, Z. Bihui
Gastroenterology, The First Affiliated Hospital Of Sun Yat-sen University, Guangzhou/China

Contact E-mail Address: sophiazhang@hotmail.com

Introduction: Orlistat is an effective pharmacologic weight loss treatment by inhibiting intestinal lipase to reduce dietary fat absorption. Previous studies have suggested that it lowers liver fat by ultrasound or semi quantitative histological scoring in nonalcoholic fatty liver disease (NAFLD).

Aims & Methods: We aimed to examine the efficacy of orlistat versus placebo in reducing liver fat content by the magnetic resonance imaging (MRI) based on chemical shift imaging. A total of 51 NAFLD patients diagnosed by MRI were randomly assigned to receive tricedaily 120mg oral Orlistat or placebo for 6 months, among them 30 (14 in the Orlistat group and 16 in the placebo group) were included in the interim analysis. Both groups received. Clinical parameters, laboratory tests and liver fat content were measured at baseline and 6 months including body mass index (BMI), waist hip ratio (VHR), liver enzymes, haemoglobin A1c, total cholesterol (CHOL), serum triglycerides (TG), fasting plasma insulin (FPI), homeostasis model assessment IR (HOMA-IR). The primary outcome was a change in liver fat quantified by MRI which is based on Dixon technique with two-point chemical shift-based fat-water separation method. The chi-squared test and paired t test were used to compare mean differences between fat fractions between two groups.

Results: Although both groups were comparable in demographics (31.38 ± 3.19) than that of the placebo group (26.78 ± 3.02, p < 0.001), while the other baseline characteristics including liver fat fraction and the proportion of hypertension, hyperlipidaemia, diabetes mellitus type 2, and hyperlipidaemia were similar. Compared to baseline, end-of-treatment liver fat content was significantly lower in the Orlistat arm (19.38% ± 9.52% to 11.56% ± 7.49%, change was 7.72 ± 6.39%; P = 0.001) but not in the placebo (16.05% ± 8.7% to 14.17% ± 9.58%, change was 1.43% ± 9.54%; P = 0.640) arm. Change of BMI was the only independent factors correlated with reduction of liver fat content (β = 0.522, p = 0.006).

Conclusion: Orlistat did significantly decrease liver fat in NAFLD patients via its effect of lowering weight.

P1323 LONG-TERM COPPER EXPOSURE OF HEPATIC CELLS LACKING FUNCTIONAL ATP7B

Transplantationsklinik, Universitätsklinikum Münster, Münster/Germany

Contact E-mail Address: guttmann.sarah@ukmuenster.de

Introduction: Copper transporter ATP7B is essential for hepatic Cu homeostasis and loss of its function is involved in the inherited autosomal recessive disorder Wilson Disease (WD). Symptoms of WD are i.e. elevated Cu accumulation in liver and brain. Understanding of molecular mechanisms involved in Cu homeostasis is essential to improve therapeutic options. The molecular impact following long-term elevated Cu in hepatic cells lacking functional ATP7B has not been explored.

Aims & Methods: HepG2 cells lacking functional ATP7B (KO) were used for generation of a copper resistant subline (CuR). Cell growth, cell viability (MTT), cell proliferation (XTT), cell death (TUNEL) and copper transporting activity of MT1 and CTR1 were measured. Additional measurements of Cu handling were performed by siRNA and drug activation (verapamil). Notably, cell viability and copper transporting activity were significantly affected such that reduction indicated that MDR1 is involved in Cu homeostasis. In addition, hepatic cells derived from a WD patient and from the rat animal model confirmed our observations.

Conclusion: Our analysis of long-term Cu exposure presents new insights in copper biology and suggests a new role of MDR1 in the pathogenesis of Wilson disease.

Introduction: Non-alcoholic fatty liver disease (NAFLD) and non-alcoholic steatohepatitis (NASH) are increasingly common cause of chronic liver diseases worldwide. Most patients with severe obesity who undergo bariatric surgery have NAFLD, which is associated insulin resistance, type 2 diabetes mellitus, hypertension, and obesity-related dyslipidemia. Identifying significant fibrosis in patients is crucial to evaluating prognosis and possible therapeutic indications. Currently, liver biopsy is the gold standard for diagnosis of liver fibrosis.

Aims & Methods: We aimed to evaluate the NAFLD fibrosis score for the assessment of significant fibrosis in patients with morbid obesity before undergoing bariatric surgery. A total of 69 NAFLD patients (median BMI 47 kg/m²) were prospectively enrolled from June 2015 to November 2016 at one Brazilian university hospital. All patients were evaluated with routine laboratory before bariatric surgery. Age, body mass index, hyperglycemia, platelet count, albumin and AST/ALT ratio were applied to the score formula. Biopsies were interpreted by a single experienced pathologist. NAFLD and fibrosis were classified according to the NASH Clinical Research Network NAFLD activity score. A comparison of the receiver operating characteristic curve (AUROC) was calculated for the diagnostic test.

Results: On liver biopsy, 29 patients (42%) had some degree of fibrosis, with 14 patients (20%) having significant fibrosis (F3–4). With standard thresholds for the specificity of the NAFLD fibrosis score for identification of significant fibrosis was 58.9%. Using modified thresholds, the specificity could increase. For predicting significant fibrosis, for a cut-off of 1.05, the score had 46.15% sensitivity and 96.43% specificity with AUROC of 0.74. Conclusion: The nonalcoholic fat liver disease fibrosis score has good accuracy to identify and significant fibrosis in morbidly obese patients subjected to bariatric surgery.

P1325 COMPARISON OF FIBROSCAN® AND FATTY LIVER INDEX (FLI) TO SCREEN FOR FATTY LIVER DISEASE IN A LARGE COHORT OF EMPLOYEES: WHERE IS THE OPTIMAL CUT OFF?

M. Teufelhart1, C. Rabisch, B. Mehl, R. Winker, B. Meyer, T. Scherzer
Health And Prevention Center, Sanatorium Hera, Vienna/Austria

Contact E-mail Address: manuela.teufelhart@hera.co.at

Introduction: FLI was developed as an alternative to steatosis (Bedogni et al.,2006) and a cut-off value ≥60 ruled in (positive likelihood ratio [LR+] 4.3) steatosis in Italians diagnosed with ultrasound. Fibroscan®CAP is more sensitive for the diagnosis of steatosis than ultrasound. Aim of this study is to evaluate the use of Fibroscan® in comparison with FLI to screen for fatty liver disease in Austrian bank employees and to recalculate optimal FLI cut-off values. Beside weight reduction and diet EASL guidelines recommend physical activity >150 min per week for prevention and treatment of steatosis.

Aims & Methods: More than 1000 Austrian bank employees will be screened for liver diseases with Fibroscan®. A kPa value ≥7.9 (M-probe) and ≥7.2 (XL-probe) is categorized as fibrosis. Additionally Fibroscan®CAP with a cut-off value ≥248 dB/m is defined as steatosis, ≥300 dB/m as high-grade steatosis. Heavy drinkers and patients with steatosis are identified with AUDIT and SIAC questionnaires. Weekly physical activity is classified into “none”, “<150 min” and “≥150 min”.

Results: To date 482 employees [age 45.9 ± 8.7 (mean ± SD); m:207; BMI 25.4 ± 4.4] have been included in this analysis. 1448 (29.3%) employees had signs of liver fibrosis and received further investigations. Fibroscan®CAP values ≥248 dB/m are shown in 156/482 (32.4%) employees (m:91 [58%], f:65 [42%]), 56/482 (11.6%) had CAP values ≥300 dB/m. Furthermore 15/156 (9.6%) patients with steatosis are heavy drinkers. FLI significantly predicts fibrosis. FLI cut-off values (adj. R² = 0.25; 55.0 CAP values [adj. R² = 0.29]; 28.1 M-probe and 32.2 XL-probe) which indicates a large effect size. For this study population, a FLI cut-off value ≥40 (CAP ≥248 dB/m) and ≥50 (CAP ≥300 dB/m) rules in fatty liver disease with a LR+ of 4.7 (SN:84%; SP:75%); and 4.8 (SN:83%; SP:83%), respectively. An additional consideration of physical activity level in the current cohort revealed that inactivity increases the LR+ of FLI values to predict NAFLD (trendwise significant, p = 0.051), indicating lower cut-off values.
Conclusion: We conclude that Fibroscan® represents an eligible tool to diagnose liver diseases in Austrian bank employees. Compared to the previous work of Bedogni et al. FLI predicts fatty liver at a lower cut-off level, at least for the examined population. This difference might be due to the fact that FibroScan® CAP is more sensitive than ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nonalcoholic fatty liver disease (NAFLD) is an affection with increasingly prevalence worldwide, having an important impact on morbidity and mortality, especially when it associated severe fibrosis. Aims & Methods: We aimed to assess the metabolites that are associated with fibrosis stages in NAFLD, using metabolic method. A total of 40 patients were included in the study, 30 diagnosed with nonalcoholic fatty liver disease (NAFLD) and 10 controls. Steatosis and fibrosis were assessed using Fibromax elaborated by Biopredictive (R) (Paris, France). New metabolomic techniques (high performance liquid chromatography coupled with mass spectrometry (HPLC-MS) and principal component analysis (PCA)) were used to identify final products of various metabolic pathways correlated with liver fibrosis.

Results: Of the 30 patients with NAFLD included in the study, 6 patients (20%) had severe fibrosis. The metabolic profile identified four metabolites that are associated with severe fibrosis: 1.25(OH)2vitamin D (p = 0.03), isosolphatidyl- letanolamine LPE 0:22:6 (p = 0.05), Lyso-phosphatidylcholine LPC 18:2 (p = 0.003), and high levels of butylen carnitine (p = 0.04). Of these, LPE was the strongest predictor of severe fibrosis (AUROC=0.795, Sensitivity (Se)=88.33%, specificity (Sp)=78.79%), but the others molecules were also significantly associated with severe fibrosis: vitamin D (AUROC = 0.776), butylen carnitine (AUROC = 0.737), LPC 18:2 (AUROC = 0.768). As the metabolomics permits the evaluation of all these molecules the same time, we can use them combined in order to increase the diagnostic accuracy. In our case, the combined use of the four metabolites determined an AUROC of 0.839, with Se of 100% and Sp of 68.5%.

Conclusion: In our metabolomics, we can identify patients with fatty liver and severe fibrosis who are significantly exposed to a progressive disease and a higher mortality.

Introduction: Chronic renal failure (CRF) is frequently associated bone metabolism disorders. Interestingly end stage renal failure (chronic hemodialysis) was significantly correlated with the development of NAFLD/NASH with significantly higher levels of AST/ALT and gGT. Hyperparathyroidism and hyperphosphatemia Transaminases were significantly lower if Vitamin D was supplemented.

Conclusion: Vitamin D deficiency is often present in patients with kidney diseases such as chronic renal failure. Vitamin D levels are correlated to age and sex of the patient. Patients suffering from renal failure are on high risk developing NAFLD/NASH if diminished vitamin D levels are present. Supplement of Vitamin D saves from NAFLD/NASH The correlation of hyperparathyroidism and NAFLD/NASH has to be further investigated in larger patient groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1328 NONINVASIVE DIAGNOSTICS OF NONALCOHOLIC FATTY LIVER IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

Introduction: Usually for the determination of nonalcoholic fatty liver disease (NAFLD) there are instrumental and laboratory techniques, including ultrasound diagnosis, determination of amino transferases, steatotest, 13C-methacetin breath test (13C-MBT). These methods in the diagnosis of NAFLD clinical forms is not specific and do not allow make difference between steatosis and steatohepatitis. The determination of NAFLD clinical forms is a priority in the prediction of further disease and choice of treatment. Steatohepatitis is the active form of NAFLD and progresses to fibrosis often with subsequent liver parenchyma degeneration into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Aims & Methods: The study involved 65 patients with type 2 diabetes and coronary heart disease with metabolic syndrome, aged 37 to 82 years (mean age 53.82 ± 3.46), 29 men, 36 women. According to the ultrasound, the stage of fatty infiltration were differentiated by such criteria for steatosis as diffuse liver par- enchyma degeneration into cirrhosis. Simultaneously, steatosis could be possibly treated in the early stages of disease.

Results: For steatosis and steatohepatitis determination the ALT monitoring was used, where the level exceeding 0.68 mmol/l to steatosis, and below 0.68 mmol/l to steatohepatitis. Portal vein diameter measurement above 13 mm was considered as liver enlargement. Liver volumes were measured by 13C-methacetin breath test (13C-MBT). These methods in the diagnosis of NAFLD clinical forms is not specific and do not allow make difference between steatosis and steatohepatitis.

Conclusion: Differentiation between steatosis and steatohepatitis should be perform by the cumulative dose 13C02 on 120 minute evaluation and ALT levels and portal vein diameter assessment.

Disclosure of Interest: All authors have declared no conflicts of interest.

176 patients, admitted to the department of nephrology of the University Hospital Marburg for renal disorders whose plasma vitamin D concentration, phosphate and parathormone levels and liver enzyme levels had been quantified beforehand, were enrolled and a retrospective investigation of laboratory para- meters (including electrolytes, hormones, and vitamins) and pre-existing medical conditions (including high blood pressure, diabetes, hyperlipoproteinaemia, and more) followed. Appropriate statistical tests were used to characterise the cohort (ANOVA; MANN-Whitney-U; FISHER-EXACT) using SPSS™. Other hepato- pathies were excluded. Steatosis was assessed by ultrasonography.

Results: Patients were divided into 4 groups according to plasma vitamin D levels (normal >25 ng/ml; low <25 ng/ml) and transaminase levels (AST/ALT >/G7 >30 U/l; normal: AST/ALT >/G7 <30 U/l). Low 1,25-hydroxivitamin D levels correlated significantly with high kreatinine, urea, and LDL levels, while low 25-hydroxivitamin D levels correlated with high cholesterol and triglyceride levels, suggesting a relationship between low vitamin D levels and fat metabolism disorders. Interestingly end stage renal failure (chronic hemodialysis) was significantly correlated with the development of NAFLD/NASH with significantly higher levels of AST/ALT and gGT. Hyperparathyroidism and hyperphosphatemia Transaminases were significantly lower if Vitamin D was supplemented.

Conclusion: Vitamin D deficiency is often present in patients with kidney diseases such as chronic renal failure. Vitamin D levels are correlated to age and sex of the patient. Patients suffering from renal failure are on high risk developing NAFLD/NASH if diminished vitamin D levels are present. Supplement of Vitamin D saves from NAFLD/NASH The correlation of hyperparathyroidism and NAFLD/NASH has to be further investigated in larger patient groups.
who underwent voluntary hepatobiliary ultrasound. NAFLD was diagnosed unifying the ground and absence of chronic liver diseases such as autoimmune hepatitis, hepatitis B or C viruses induced hepatitis, hepatobili-pillary cancers, Wilson’s disease, >10 g/day alcohol consumption, and receiving some specific medications known to cause hepatic steatosis (like amiodarone, valporic acid, etc). Lean individuals were defined as those with body mass index (BMI) <25 kg/m². Student’s-t test was used for comparisons of continuous variables and Chi-square test was used for comparison of categorical variables. Receiver operating characteristics (ROC) curve analysis using area under curve (AUC) was used for analysis of optimal cutoff values for BMI and waist circumference in association with lean NAFLD.

Results: 1343 individuals were included. 165 individuals (12.3%) was diagnosed to have NAFLD. 129 individuals (9.6%) had mild NAFLD and 36 individuals (2.7%) had moderate NAFLD. None of the participants had severe NAFLD. In univariate analysis, history of diabetes mellitus (DM) (OR = 2.25; 95% CI: 1.15–4.40, P = 0.015) and metabolic syndrome (OR = 2.80; 95% CI: 1.74–4.48, P < 0.001) were associated with NAFLD. Higher BMI and waist circumference, higher systolic and diastolic blood pressure, higher serum triglyceride, cholesterol, fasting glucose (FG), and alanine aminotransferase (ALT) were associated with NAFLD (P < 0.05). In multivariate regression analysis, higher BMI and waist circumference, higher serum ALT, FPG and cholesterol were independent predictors of NAFLD in our study population (Table). A cutoff value of 22.3 kg/m² for BMI was predictor of NAFLD (sensitivity = 72%; specificity = 60%; AUC = 0.728, P < 0.001). A cutoff value of 79.5 cm for waist circumference was predictor of NAFLD in our study population (sensitivity = 80%; specificity = 68%; AUC = 0.753, P < 0.001). Table: Multivariate regression analysis showing independent risk factors for lean NAFLD.

Conclusion: Lean NAFLD was prevalent in our study population and was associated with metabolic risk factors. BMI and waist circumference can be used for predicting this type of NAFLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: matteogacciochi@yahoo.it

Introduction: While some studies have evaluated the ability of new “real-time” elastography devices such as 2-D Shear Wave Elastography (SWE) and Virtual Touch Quantification (ARTIF) in predicting the presence of high-risk gastroesophageal varices, no study has explored the potential role of another point-SWE technique, ElasPQ, in the assessment of clinically significant portal hypertension.

Aims & Methods: The aim of our study was to identify a liver stiffness cut-off value measured by ElasPQ and/or laboratory parameters that could help identify patients who can safely avoid screening endoscopy, similarly to the recently proposed Baveno VI criteria which recommends a liver stiffness value <20 kPa measured by transient elastography in combination to a platelet count >150,000/µl. Data were collected on 1385 patients who underwent ElasPQ measurement from January 2013 to January 2016 in our Department. Inclusion criteria were a liver stiffness value of ≥7 kPa and an upper gastrointestinal endoscopy within 12 months, with a diagnosis of compensated chronic liver disease. We choose this specific liver stiffness cut-off value in order to harmonize with the recently advanced fibrosis and cirrhosis, based on the limited literature available on this specific elastographic technique. Exclusion criteria were history of decompensated liver disease, evidence of porto-spleno-mesenteric vein thrombosis and non-cirrhotic portal hypertension. Varices were graded as low risk (grade <2) or high risk (grade ≥2).

Results: The study included 184 patients (114 [62%] hepatitis C, and 160 [87%] Child-Pugh A). Varices were present in 36% cases, with 10% prevalence of high-risk varices. According to ROC curve analysis liver stiffness measurement and
platelet count were evaluated as predictors of high-risk varices. Overall 74/184 (40%) met the new “BavenoVIII” criteria (that is, liver stiffness <12 kPa and platelet count >150,000/µL). Within this group 11/63 (17%) had any grade of varices and only 1/73 (1%) had high-risk varices. The BavenoVIII criteria gave sensitivity of 0.95, specificity of 0.44, a positive predictive value of 0.61 and a negative predictive value of 0.98. The AUROC for liver stiffness and platelet count was 0.81 and 0.76, respectively.

Conclusion: The BavenoVIII criteria correctly identified 99% of patients with high-risk varices. By applying such criteria we could have potentially avoided 40% surveillance endoscopies in our cohort. To our knowledge this is the first study that evaluated the potential role of a new p-SWE technique such as ElassiPQ in the non-invasive assessment of clinically significant portal hyperten-

Introduction: Inhibitors (PPI) are commonly prescribed and predis-
pose to small bowel bacterial overgrowth. Hepatic encephalopathy is a frequent complication of cirrhosis and is associated with intestinal dysbiosis.

Aims & Methods: This study aimed to identify a possible association between PPI intake and hepatic encephalopathy development in cirrhotic patients. Retrospective analysis of consecutive cirrhotic patients hospitalized in two Gastroenterology Departments over 3.5 years. Collection of clinical data, PPI intake was not associated with hepatic encephalopathy maintained association with infection (p = 0.057), gender (p = 0.228) or age (p = 0.352). In multivariate analysis, hepatic encephalopathy was associated with infection (p < 0.001), gastrointestinal bleeding (p < 0.001) and Model for End-Stage Liver Disease (MELD) (p < 0.001).

Conclusion: In our series, PPI intake was not associated with hepatic encephalopathy development in cirrhotic patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The incidence of bacterial infections in cirrhotic patients is signific-
antly higher than that observed in general population, being one of the most important causes of decompensation. In theory, the final result of an infectious disease depends of three major factors: the antibiotic resistance of the bacteria and the prompt administration of treatment; the intrinsic virulence or pathogeni-

Conclusion: Our aims within this study were to 1) analyze the incidence of MDR bacteria in patients with decompensated cirrhosis at admission (less than 24 hours after hospitalization), 2) to study its impact on 30 and 90-day mortality, and 3) to identify independent risk factors for 30 and 90-day mortality.

Results: A total of 681 hospitalizations were evaluated and 41% had a bacterial infection at admission. The 30 and 90-day mortality rate was 14.7% and 38.1%, respectively. The most common infection was spontaneous bacterial peritonitis (SBP; 40.5%), followed by urinary tract infection (UTI; 25%). About 55.6% of the patients had a microbiological documented infection (MDI). MDR bacteria were identified in 18.6% of all bacterial infections, matching 34.5% of the nosocomial acquired infections and 8.3% of the community-acquired (CA) infec-
tions. 59.1% of the UTI were MDR by a MDR bacteria and 22.1% of the non-MDI bacteria or MDR bacteria as 0.801) and the 90-day (p = 0.525) mortality rate. In the multivariate analysis, elevated BUN and bilirubin, presence of intestinal bacterial infection and lower albumin, sodium and SP02 were independently associated with 30 and 90-day mortality. Higher INR and age were indepen-

Introduction: The place of non-invasive techniques for the prediction of presence of portal hypertension in patients with liver cirrhosis is one of the current research topics.

Aims & Methods: The aim of this study was to evaluate the applicability of the Baveno VI criteria in a cohort of known compensated HCV liver cirrhosis patients, to see how often we misclassify the presence of esophageal varices (EV).

Material and method: We did a prospective multicentre study, from September 2015 to December 2016, which included all patients with perfectly compensated HCV liver cirrhosis, diagnosed by means of elastography, ultrasound, endoscopic and biological criteria prior to interferon-free treatment. All patients were evaluated by upper gastrointestinal endoscopy, transient elastography, portal pressure gradient, and blood tests. By using Baveno VI criteria we classified the patients in: probably without EV (LS<20 kPa and thrombocytes >150.000/mm³), probably with EV (LS≥25 KPa) and the “gray zone” in between these criteria.

Results: Out of 403 patients, 127 (30.7%) had LS < 20 kPa, 89 (22%) had LS between 20–25 kPa, 190 (47.3%) had LS > 25 kPa, 120 (29.7%) had thrombocytes >150.000/mm³, while 283 (70.3%) had thrombocytes <150.000/mm³. For the subgroup probably with EV, the Baveno VI criteria had PPV 84.6% (Se 40.7%, Sp 74.6%, NPV 26.8%) for predicting the presence of esophageal varices, while for the subgroup probably without EV had PPV 80% (Se 50.2%, Sp 58.6%, NPV 75.6%). The subgroup that had LS <20 kPa and thrombocytes >150.000/mm³, was composed of 60 patients. Using these criteria 32 patients were classified 80% patients, with a Se 80%, Sp 28.3%, PPV 50%, NPV 61.2%, AUROC 0.70, C1 (68.2–71.3). The best-off value for TE for predicting the presence of EV of any grade in our group was > 23 kPa; AUROC 0.79 (Se 68.8%, Sp 56.9%, PPV 44.7%, NPV 78.4%).

Conclusion: By using the Baveno VI criteria in patients with liver cirrhosis for the prediction of presence of esophageal varices, we can misclassify only 20% of patients.

Introduction: Non-invasive fibrosis scores (NIFS) are increasingly replacing liver biopsy (LB) for estimation of liver fibrosis. Only limited studies have evaluated the role of blood derived non-invasive fibrosis (NIFs) for predicting pre-treatment cirrhosis, development of esophageal varices (EV) and liver decompensation post antiviral treatment (AVT). 1605 patients (Jan 2002 to June 2015) with chronic hepatitis C were included. NIFS were calculated from routine blood tests and abdominal ultrasound (AUROC=0.885) and with FIB-4 score for decompensation (AUROC=0.854).

Aim: To assess the role of these simple scores for predicting the presence of esophageal varices and decompensation post antiviral treatment.

Methods: Aims & Methods: The study was approved by the local ethics committee and all patients provided written informed consent. Among controls, 27 (44%) had a positive Stroop test, while 3 (5%) had a positive PHES. We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. CLD patients and healthy controls were recruited from outpatients. CLD patients were identified based on clinical and radiological evidence. Written consent was obtained. Exclusion criteria: cognitive impairment from any other cause, colour-blindness or dyslexia. Baseline demographics, level of education and medical history were obtained, and a Child-Pugh score was calculated where relevant. Each patient performed the PHES test and the Stroop test. Outcomes included the time taken to perform each PHES test as well as the total PHES, the Stroop on-off time and time taken to complete 5 correct runs on the Stroop App. Results were analysed using exploratory non-parametric analysis. Results: In 333 CLD and 61 healthy controls. While there was no difference in age or years spent in education, there were more men in the CLD group compared to the healthy controls. 30 (86%) patients were Child-Pugh class A, 4 (11%) were class B and 1 (3%) was class C. As expected, more CLD patients had a positive PHES, 4 (11%) vs. 3/61 (5%). Overall, correlation between the two tests was poor, 7 (7%) participants had a positive PHES, while 47 (49%) had a positive Stroop test (r = 0.1516). Among controls, 27 (44%) had a positive Stroop test, while 3 (5%) had a positive PHES. We aimed to validate the use of the EncephalApp Stroop Test as a screening tool for MHE in an Irish population. Results: In 333 CLD and 61 healthy controls. While there was no difference in age or years spent in education, there were more men in the CLD group compared to the healthy controls. 30 (86%) patients were Child-Pugh class A, 4 (11%) were class B and 1 (3%) was class C. As expected, more CLD patients had a positive PHES, 4 (11%) vs. 3/61 (5%). Aims & Methods:

Therefore, we conducted a randomized, double-blind, placebo-controlled study to test the effects of the multispecies probiotic Ecologic Barrier Austria) on microbiome composition, predicted metagenome functions, and tight junction function in cirrhosis patients. A once daily dose of the probiotic mixture Austria) and Omnibiotic Hetox (Allergosan, Graz, Austria) were administered to 58 patients with Child’s A cirrhosis. We analyzed the stool microbiome prior, immediately after the intervention, and six months after the intervention. The dysbiosis and disruption in tight junction function was investigated using student t-test and chi-square test. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

Results: A community of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: Lactobacillus brevis and Lactococcus lactis increased significantly and Enterococcus durans decreased significantly in the probiotic group. Zonulin normalized in 20% of patients in the probiotic group. Predicted metagenome functions (assessed by PICRUSt) and calprotectin did not show any differences during intervention.

Conclusion: In conclusion, a six months intervention with a multispecies probiotic enriched the microbiome of cirrhotic patients with probiotic bacteria. Additionally, the abundance of Enterococcus durans was reduced and the gut barrier was strengthened.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1338 MULTISPECIES PROBIOTIC ENRICHES THE MICROBIOME WITH LACTOBACILLUS AND LACTOCOCCUS AND REDUCES ENTEROCOCCUS ABUNDANCE IN PATIENTS WITH LIVER CIRRHOSIS: RESULTS OF A RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

Introduction: Cirrhosis is accompanied by significant changes of the intestinal microbiome including the overgrowth of the intestine with potential pathogens that can translocate through a weakened gut barrier and cause severe infections. We hypothesized that probiotic bacteria repress intestinal pathogen growth and strengthen the gut barrier.

Aims & Methods: Therefore, we conducted a randomized, double-blind, placebo-controlled study to test the effects of the multispecies probiotic Ecologic Barrier (Winccove, Amsterdam, The Netherlands)/Omnibiotic Hetox (Allergosan, Graz, Austria) on microbiome composition, predicted metagenome functions, and tight junction function in cirrhosis patients. A once daily dose of the probiotic mixture (1.5*10^10 CFU) or placebo was administered to 58 patients with Child’s A cirrhosis. We analyzed the stool microbiome prior, immediately after the intervention and six months following end of treatment. Hypervariable region 1–2 of the bacterial 16S rDNA was sequenced and predictive communities were identified using Ada Boost Classifier. Functional predictions were analyzed by Phylogenetic Investigations of Communities by Reconstruction of unobserved States (PICRUSt). Zonulin and calprotectin were assessed in stool as markers for gut permeability and intestinal inflammation, respectively.

Results: A community of 37 operational taxonomic units (OTUs) was sufficient to pinpoint characteristic features of the microbiome before and after the intervention. Within this predictive community, three OTUs were found to be differentially abundant: Lactobacillus brevis and Lactococcus lactis increased significantly and Enterococcus durans decreased significantly in the probiotic group. Zonulin normalized in 20% of patients in the probiotic group. Predicted metagenome functions (assessed by PICRUSt) and calprotectin did not show any differences during intervention.

Conclusion: In conclusion, a six months intervention with a multispecies probiotic enriched the microbiome of cirrhotic patients with probiotic bacteria. Additionally, the abundance of Enterococcus durans was reduced and the gut barrier was strengthened.

Introduction: Diabetes mellitus (DM) is a growing disease worldwide. Some previous studies have reported negative impact of DM in patients with chronic liver disease.

Aims & Methods: This study aimed to investigate the prevalence of DM in patients with liver cirrhosis and its impact on post-liver transplant short-term and long-term outcomes. In a cross-sectional study patients with liver cirrhosis on liver transplant waiting list who had undergone liver transplantation between March 2012 and March 2015 at Shiraz Transplant Center, Shiraz, Iran were included. Clinical and laboratory data of patients were recorded and patients were followed during post-liver transplant period. DM was diagnosed if the patient had fasting plasma glucose (FPG) ≥ 126 mg/dL or random plasma glucose ≥200 mg/dL in 2 different checkings or receiving anti-diabetic medications. The impact of DM on post-transplant outcomes was investigated using student t-test and chi-square test. Multivariate logistic regression was used for analysis of independent risk factors of mortality after liver transplantation. Kaplan-Meier method was used for analysis of survival.

Results: 1014 patients were included in the study. 259 patients (25.5%) found to have DM. Prevalence of DM was significantly higher among patients with liver cirrhosis due to non-alcoholic steatohepatitis (NASH) (P < 0.001). Portal vein thrombosis (PVT) was significantly more frequent in cirrhotic patients with DM (OR = 1.79; 95% CI: 1.18–2.70; P = 0.005). Mean model for end stage liver disease (MELD) score, body mass index (BMI) and duration of liver disease were not different in patients with and without DM (P > 0.05). Mean albumin level was 3.61 ± 0.59 g/dL in patients without DM compared to 3.59 ± 0.56 g/dL in patients with DM (P < 0.001). Mean serum creatinine level was 1.46 ± 0.95 mg/dL in patients with DM compared to 1.78 ± 1.02 mg/dL in patients with DM (P = 0.001).
Introduction: Cirrhotic patients very often need to be hospitalized and it is known that they have a higher mortality rate. Aims & Methods: The aim of the study was to assess the factors associated with mortality among cirrhotic patients and to create a new score for predicting mortality. The study was retrospective, and we included all hospitalized patients with cirrhosis admitted to our hospital over a period of 7 years. We divided them into two cohorts, an initial group, which was analysed; and a control group, in which we validated the score. We performed univariate and multivariate analysis in order to determine a prediction model for mortality.

Results: A total of 1163 cirrhotic patients were included. In-hospital mortality rate was 10%. The initial cohort included 899 patients. Regarding cirrhosis etiology: 384/899 (42%) had hepatitis C, 158/899 (17.5%) had hepatitis B, 293/899 (32.5%) were alcoholic, 6/899 (0.6%) were autoimmune, 7/899 (0.7%) were cardiac, 13/899 (1.4%) were premalignant or early-stage cirrhosis and in 5% of cases the etiology was unknown. In univariate analysis, hypernatremia (p < 0.0001), hyperpotasemia (p < 0.0001), hypoalbuminemia (p < 0.0001), high values of bilirubin (p < 0.0001), high values of creatinine (p < 0.0001) were strongly associated with in hospital mortality. In multivariate analysis, the model including albumin, sodium, potassium, creatinine and bilirubin (all p-values < 0.05) had an AUROC = 0.78, CI (0.75–0.81), p < 0.0001. Using this factors as predictors, by multiple regression analysis we obtained in the initial group the following score: ABCPS score = 0.04 + 0.03*Albumin + 0.05 + 0.02*Creatinine + 0.04 + 0.04*Bilirubin - 0.05 + 0.28*Potassium + 0.04*0.07*Sodium.

Conclusion: Prevention and prompt treatment of kidney injury, hypernatremia, hyperpotasemia, can improve survival. ABCPS score can be an useful score to rule out patients with high mortality rate.

Introduction: Acoustic radiation force impulse (ARFI) imaging measures liver stiffness (LS), which significantly correlates with the stage of liver fibrosis in treatment-naïve patients with chronic hepatitis B (CHB). So far, the use of ARFI elastography to monitor change in liver fibrosis has not been properly evaluated during antiviral therapy in CHB patients.

Aims & Methods: We aimed to prospectively assess the clinical usefulness of ARFI during long-term antiviral therapy in CHB patients. Seventy-one CHB patients were consecutively recruited and received antiviral therapy with entecavir. Paired liver biopsies were performed in 27 patients at baseline and week 78 of entecavir therapy. LS was assessed by ARFI at multiple follow-up sessions.

Results: LS significantly decreased with treatment and continued to decrease after normalization of alanine aminotransaminase. Overall, 97.2% patients achieved improvement of LS, whereas 19.7% patients had more than 30% reduction in LS values between baseline and week 104. Multivariate linear regression analysis showed that the degree of LS reduction significantly correlated with the baseline levels of LS value, platelet, and cholinesterase. In the 27 patients who received paired liver biopsies, LS significantly correlated with stage of fibrosis and inflammatory grade at baseline. LS values decreased more significantly in patients with fibrosis regression than those with static histological fibrosis. Changes in LS value (change threshold = 15%) was significantly correlated with the changes in histological fibrosis staging (r = 0.63, P < 0.001).

Conclusion: In CHB patients, LS assessed by ARFI was significantly reduced with the changes in histological fibrosis staging (r = 0.73, P < 0.001). Multivariate linear regression analysis achieved improvement of LS, whereas 19.7% patients had more than 30% reduction in LS values between baseline and week 104. Multivariate linear regression analysis showed that the degree of LS reduction significantly correlated with the baseline levels of LS value, platelet, and cholinesterase. In the 27 patients who received paired liver biopsies, LS significantly correlated with stage of fibrosis and inflammatory grade at baseline. LS values decreased more significantly in patients with fibrosis regression than those with static histological fibrosis. Changes in LS value (change threshold = 15%) was significantly correlated with the changes in histological fibrosis staging (r = 0.63, P < 0.001).

Introduction: In chronic hepatitis with Hepatitis B virus (HBV) hepatic steatosis is mainly attributable to metabolic risk factors, rather than virologic factors. We aimed to assess the presence of hepatic steatosis in chronic HBV inactive carriers using non-invasive methods, namely controlled attenuation parameter (CAP) by FibroScan. We intended to identify the presence of hepatic steatosis and their impact in the values of fibrosis determined with fibroscan.

Aims & Methods: Fibroscan was performed in chronic HBV inactive carriers, with assessment of hepatic transient elastography and CAP, with simultaneous assessment of anthropometric, clinical and analytical parameters. CAP values of 248.268 and 280.db/m determined cut-offs of steatosis grade I, II, and III, respectively.

Results: Included 49 patients with a mean transient elastography of 5.1 ± 1.5 Kpa and a mean CAP of 248.9 ± 49.3 db/m. A significant association was found between the value of CAP and the presence of steatosis in the last ultrasound (248.9 ± 49.3 db/m vs p < 0.01), the presence of elevated triglycerides (239.9 ± 49.3 db/m vs 284.1 ± 28.1 db/m, p = 0.01) and obesity (240.0 ± 47.6 db/m vs 290.7 ± 46.6 db/m, p = 0.01). When comparing patients with CAP > 268.9 db/m, patients with higher CAP values more frequently were overweight (BMI 25.2 kg/m2) (45.8% vs 84.9%, p < 0.01) and had metabolic syndrome (MS) (12.5% vs 40%, p < 0.03), and also presented with higher values of BMI (24.6 ± 2.6 kg/m2 vs 292.6 ± 4.6 kg/m2, p < 0.02), waist circumference (85.0 ± 9.0 cm vs 97.9 ± 11.3 cm, p < 0.01) and triglycerides (95.6 ± 31.4 mg/dl vs 62.9 mg/dL, p = 0.01) and lower values of HDL cholesterol (58.9 ± 14.3 mg/dL vs 50.4 ± 14.4 mg/dL, p < 0.01). A significant association was also found between the value of elastography and female gender (females 4.6 ± 1.3KPa vs males 5.8 ± 1.5KPa, p < 0.01), elevated triglycerides (4.9 ± 1.5KPa vs 6.0 ± 1.1KPa, p = 0.03) and obesity (4.9 ± 1.4KPa vs 6.5 ± 1.1KPa, p < 0.01).

Conclusion: Different components of MS seem to contribute both to fibrosis and steatosis in chronic HBV inactive carriers. In this subset of patients, the interpretation of fibrosis values assessed by fibroscan should be made with caution since it may be influenced by metabolic parameters.

P1346 ANTIMICROBIAL EFFICACY OF UNANI HERBS (SAUSUREA LAPPAPA AND ARTEMISIA ABSINTHIUM) IN CHRONIC HEPATITIS B S. Amsari1, M. A. Siddiqui1, S. Malhotra2, M. Maaz2
1Department Of Moulajai (medicine), School Of Unani Medicine, Jamia Hamdard, New Delhi, India, New Delhi/India
2Department Of Gastroenterology, Banra Hospital and Research Centre, New Delhi/India

Contact E-mail Address: drshabnamansari.md@gmail.com

Introduction: Chronic hepatitis B (CHB) is a serious health concern in terms of its high prevalence, as well as restricted and costly health care resources in India.1 Unani herbal drugs such as root of Saussurea lappa and whole plant of Artemisia absinthium have been used successfully in the treatment of hepatitis in Unani Medicine for centuries. These drugs have exhibited potential anti-hepatitis B, hepatoprotective, immunomodulatory, anti-inflammatory and anti-oxidant activities in various animal models.2 With this background, present prospective clinical trial was tried to be designed according to the guidelines of American association for the study of liver diseases (AASLD) and implemented after Institutional ethical clearance.

Aims & Methods: Objective was to evaluate the antiviral effect of herbal drugs, Saussurea lappa and Artemisia absinthium against hepatitis B virus (HBV) in the management of CHB and to collect data to warrant further clinical trials. In an open prospective single-arm study, we assigned 30 patients with HBcAg-negative or HBcAg-positive CHB to receive decocation of root of Saussurea lappa, 15 mL (containing approx. 1 g of dried aquoues extract) in the morning and decoction of Artemisia absinthium, 15 mL (containing approx. 1 g of dried aquoues extract) in the evening once daily empty stomach for 12 weeks. Physicochemical standardization and TLC and HPTLC fingerprinting of decoctions were also done. Test drug was prepared for its efficacy (median (<I>SA</I>BAH) and HBcAg (CLA tech.), a plasma HBV DNA level (RT PCR) of less than 200/IU/mL at week 12 (after treatment). Normalization of alanine aminotransferase levels [ALT (enzymatic essay)] without any significant adverse effects (clinical para- meters, haemogram, kidney function test, and blood sugar fasting and post dinner) at week 6 (mid-treatment) and 12 (after treatment) would be suggestive of resolution of inflammation of liver.

Results: 1 HBcAg loss was observed in 5 (35.71%) patients in HBcAg-inactive group (n = 14) (p < 0.05) and 4 (25%) patients in HBcAg-negative group (n = 16) at week 12 (after treatment) (p = 0.10). These 9 HBcAg negative patients were further assessed on 26th week of treatment, all 9 maintained their negative HBcAg status. 2 HBcAg loss was observed in 71.42% patients at week 12

Comorbidity Adjusted Odds Ratio 95% CI p-value

Malnutrition 1.86 0.89–3.88 0.10
HTN 0.64 0.34–1.18 0.16
Anemia 0.65 0.36–1.11 0.12
CKD 1.66 0.79–3.54 0.18
Diabetes 1.04 0.55–1.94 0.91
CHF 3.92 1.77–8.71 <0.001
Coagulopathy 1.75 1.03–2.96 0.04
Alcoholism 0.48 0.25–0.95 0.04
HCV 0.86 0.27–2.72 0.80
Aims & Methods: We aimed to compare the efficacy of peg-IFNα-2a add-on therapy in those CHB patients remains unclear. The peg-IFNα-2a add-on therapy increased loss of HBsAg in HBeAg-negative patients (2.96 Log10 IU/ml), significantly higher than in NA monotherapy group at week 24 (0.87 Log10 IU/ml). There was no significant difference in age, gender, body mass index (BMI), HBsAg levels at baseline. At week 24, HBsAg levels in peg-IFNα-2a add-on therapy group was significantly lower than in HBeAg-negative CHB patients aged older than 16 from the First Affiliated Hospital of Sun Yat-sen university in China. All had received NA monotherapy for 3 years with sustained undetectable plasma HBV DNA. The exclusion criteria included: cirrhosis or other chronic liver diseases, previous immunological therapy, pregnancy and breastfeeding, contraindications for peg-IFNα-2a, or other serious diseases. The eligible patients were assigned to receive peg-IFNα-2a add-on therapy for 48-72 weeks or to continue to receive NA monotherapy for 96 weeks. HBV DNA levels, HBV serologic indicators, liver function, renal function, thyroid function, blood cells count and imaging examination were assessed. The primary end point was HBsAg loss from baseline to week 96.

Results: 71 patients were enrolled (22 to peg-IFNα-2a add-on therapy group and 49 to NA monotherapy group), of whom 9 in peg-IFNα-2a add-on therapy group and 25 in NA monotherapy group completed more than 24 weeks of follow-up, the remaining patients have not yet reached 24 weeks of follow-up. There was no significant difference in age, gender, body mass index (BMI), HBsAg levels, alanine aminotransferase (ALT), or aspartate aminotransferase (AST) between the two groups at baseline. At week 24, HBsAg levels in peg-IFNα-2a add-on therapy group was significantly lower than the baseline (2.96 ± 0.14 vs 2.90 ± 0.82 Log10 IU/ml, p = 0.009), but there was no obvious change in NA monotherapy group (3.43 ± 0.46 vs 3.44 ± 0.44 Log10 IU/ml, p = 0.843). The HBsAg loss in peg-IFNα-2a add-on therapy group was significantly higher than in NA monotherapy group at week 24 (0.57 ± 0.26 vs -0.01 ± 0.10 Log10 IU/ml, p = 0.008). Among those patients who completed 96 weeks of follow-up, two patients in peg-IFNα-2a add-on therapy group (22.2%) achieved HBsAg seroconversion, but none in NA monotherapy group (0%). Conclusion: The peg-IFNα-2a add-on therapy increased loss of HBsAg in HBeAg negative treatment-experienced CHB patients as compared to NA monotherapy. Disclosure of Interest: All authors have declared no conflicts of interest.

P1347 EFFICACY OFPEGYLATED INTERFERON ALFA-2A ADD-ON THERAPY VERSUS NUCLEOSIDE ANALOGUE MONOTHERAPY IN TREATMENT-EXPERIENCED CHRONIC HEPATITIS B PATIENTS: A RANDOMISED, CONTROLLED, OPEN-LABEL TRIAL

X. Hu1, J. Ye2, W. Yanqin3, R. Li1, C. Shao4, Z. Bihu4

Contact E-mail Address: 1446989090@qq.com

Introduction: HBsAg surface antigen (HBsAg) seroconversion is rarely achieved in chronic hepatitis B (CHB) patients during nucleoside analogue (NA) monotherapy. The efficacy of pegylated interferon alfa-2a (peg-IFNα-2a) add-on therapy in those CHB patients remains unclear.

Aims & Methods: We aimed to compare the efficacy of peg-IFNα-2a add-on therapy to NA monotherapy in treatment-experienced CHB patients. We enrolled hepatitis B e antigen (HBeAg)-negative CHB patients aged older than 16 from the First Affiliated Hospital of Sun Yat-sen university in China. All had received NA monotherapy for 3 years with sustained undetectable plasma HBV DNA. The exclusion criteria included: cirrhosis or other chronic liver diseases, previous immunological therapy, pregnancy and breastfeeding, contraindications for peg-IFNα-2a, or other serious diseases. The eligible patients were assigned to receive peg-IFNα-2a add-on therapy for 48-72 weeks or to continue to receive NA monotherapy for 96 weeks. HBV DNA levels, HBV serologic indicators, liver function, renal function, thyroid function, blood cells count and imaging examination were assessed. The primary end point was HBsAg loss from baseline to week 96.

Results: 71 patients were enrolled (22 to peg-IFNα-2a add-on therapy group and 49 to NA monotherapy group), of whom 9 in peg-IFNα-2a add-on therapy group and 25 in NA monotherapy group completed more than 24 weeks of follow-up, the remaining patients have not yet reached 24 weeks of follow-up. There was no significant difference in age, gender, body mass index (BMI), HBsAg levels, alanine aminotransferase (ALT), or aspartate aminotransferase (AST) between the two groups at baseline. At week 24, HBsAg levels in peg-IFNα-2a add-on therapy group was significantly lower than the baseline (2.96 ± 0.14 vs 2.90 ± 0.82 Log10 IU/ml, p = 0.009), but there was no obvious change in NA monotherapy group (3.43 ± 0.46 vs 3.44 ± 0.44 Log10 IU/ml, p = 0.843). The HBsAg loss in peg-IFNα-2a add-on therapy group was significantly higher than in NA monotherapy group at week 24 (0.57 ± 0.26 vs -0.01 ± 0.10 Log10 IU/ml, p = 0.008). Among those patients who completed 96 weeks of follow-up, two patients in peg-IFNα-2a add-on therapy group (22.2%) achieved HBsAg seroconversion, but none in NA monotherapy group (0%). Conclusion: The peg-IFNα-2a add-on therapy increased loss of HBsAg in HBeAg negative treatment-experienced CHB patients as compared to NA monotherapy. P1350  HEPATITIS C IN LEBANON: BURDEN OF THE DISEASE AND VALUE OF A COMPREHENSIVE SCREENING AND TREATMENT A. Abou Rachid4, S. Al-Kheir1, J. Saba1, S. Assaf2, G. Kassem2, S.Y. Gonzales3, O. Ethgen4

Aims & Methods: A multi-cohort, health-state-transition model was developed to project the number of HCV patients achieving a sustained virologic response 12 weeks after treatment (SVR12) or progressing to compensated cirrhosis (CC), and liver-related death (LrD) from 2016 to 2036. Epidemiology and mortality data were extracted from the Ministry of Health bulletin while costs were collected from insurance claims. The proportion of patients screened for HCV was projected to increase to 60%/85%/99% (low/medium/high screening scenarios) in 2036, with a new cohort of patients being diagnosed each year. SVR12 rates were estimated from clinical trials. Separate models were used for 18–39 and 40–80 age groups to account for differences in prevalence and screening rates.

Results: Low, medium, and high HCV screening scenarios showed that 3838, 5665 and 7669 individuals would be diagnosed with HCV infection from 2016 to 2036, 40% aged 18–39 and 60% aged 40–80. In the absence of treatment, the projected number of CC, DCC, HCC and LrD in 2036 was 899, 147, 131 and 150 respectively. Although DAAs for F0–F4 increase the cost of HCV treatment for every LY gained in SVR12 for patients aged 18–39 and 168 E for patients aged 40–80, the overall economic burden of these liver complications would reach 150,000 €. Projections were substantially greater: 2828 CC, 736 DCC, 668 HCC and 958 LrD.

Conclusion: An enhanced screening policy coupled with broader access to DAAs will diminish the future clinical and economic burden of HCV in the Lebanese population and provide the greatest health benefits per amount invested, among middle-aged and elder adults with a big difference in additional costs between the 2 groups.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Hepatitis C virus (HCV) infection in renal transplant patients pre-disposes to graft failure and progression of renal disease, increasing mortality. Due to immunosuppression and oscillating glomerular filtration rate (eGFR) in the evolution of virological response and clinical outcomes (kidney function, anemia and other adverse effects). HCV-infected and renal transplanted patients treated with DAA between April 2015 and February 2017 were analyzed.

Results: Including 19 patients, 10 males (53%) and 9 females (47%) with a mean age of 57 years (40–70 years). The majority of these patients (89%) were treatment-naive. Genotype distribution was the following: genotype 1–74% (14/19), genotype 3–16% (3/19) and genotype 4–10% (2/19). Distribution according to fibrosis stages was as follows: F0–2 63% (12/19), F3–4 3% (1/9) and F4–16% (3/19). Thirteen patients (85%) were treated with sofosbuvir (200–1000 mg) and ribavirin suspension at week 4 of treatment. There were no other serious adverse reactions. The eGFR (CKD EPI) did not change significantly, with pre and posttreatment mean values of 66.4 and 65.4 ml/min/1.73m², respectively. There were 2 cases of severe anemia, one that resulted in ADA suspension at week 21 and the other one ribavirin suspension at week 6, and 19% in posttreatment renal function. HCV-infected and renal transplanted patients treated with DAA between April 2015 and February 2017 were analyzed.

Conclusion: In our sample of HCV-infected with kidney transplant, DAA are well tolerated, as well and better tolerated, even in the more advanced stages of fibrosis, maintaining the integrity and viability of the graft, without interfering with the efficacy of immunosuppressant.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Liver stiffness (LS) measurements by Transient Elastography (TE) has been widely accepted as a tool for fibrosis assessment.

Aims & Methods: The aim of this study was to assess LS dynamics in a group of patients with HCV liver cirrhosis after DAA treatment. This bicentric clinical

Contact E-mail Address: abourachedantoine@gmail.com

Introduction: As few reliable data on the burden of hepatitis C virus (HCV) are available from the Middle East, we analyzed HCV burden in the Lebanese population and the value of comprehensive screening and treatment at different age groups and fibrosis stages. We analyzed HCV burden in the Lebanese population and the value of comprehensive screening and treatment at different age groups and fibrosis stages. Although DAAs for F0–F4 increase the cost of HCV treatment for every LY gained in SVR12 for patients aged 18–39 and 168 E for patients aged 40–80, the overall economic burden of these liver complications would reach 150,000 €. Projections were substantially greater: 2828 CC, 736 DCC, 668 HCC and 958 LrD.

Conclusion: An enhanced screening policy coupled with broader access to DAAs will diminish the future clinical and economic burden of HCV in the Lebanese population and provide the greatest health benefits per amount invested, among middle-aged and elder adults with a big difference in additional costs between the 2 groups.

Reference
trial included 256 patients with compensated HCV cirrhosis (all genotype 1b), who received DAA for 12 weeks. All patients were evaluated by means of TE at the beginning and at the end of treatment (EOT), and one subgroup (180 patients) also 12 weeks after EOT, all of them with sustained viral response (SVR 12), and another subgroup (55 patients) also at 24 weeks after EOT (SVR 24). Liver stiffness measurements (LSM) were defined as median value of 10 valid LSM, with IQR < 30% and SR ≥ 60%. Both M and XL probes were used. For diagnosing cirrhosis we used a cut-off value of 12 kPa as proposed by the Tsochatzis meta-analysis. We considered a decrease or increase of more than 10% in LSM as being significant.

Results: Of 276 subjects, reliable measurements were obtained in 92.7%, so the final analysis included 256 patients. The mean LS values decreased significantly after DAA: 25.6±11.7 kPa vs. 22.3±12.2 kPa (p=0.009). Most patients (59.7% [152/256]) presented more than 10% in LS values decreased (39 [29/256]) had stable LS values, while in 17.3% (45/256) cases, the LS values increased. In the subgroup of 180 patients where LSM were also performed 12 weeks after EOT (SVR 12), the mean LS values were significantly lower than at EOT as compared to baseline: 20.3±10.8 kPa vs. 25.5±11.4 kPa (p=0.001) and also as compared to EOT: 20.3±10.8 kPa vs. 22.8±12.2 kPa, p=0.04). In the subgroup of 55 patients where LSM were also performed 24 weeks after EOT (SVR 24), the mean LS values were significantly lower at SVR 12 and SVR 24 as compared to EOT (18.7±8.2 kPa vs. 21.6±7.7 kPa, p=0.01 and 18.3±6.6 kPa vs. 21.6±7.7 kPa, p=0.001).

Conclusion: In our group mean liver stiffness values evaluated by TE significantly decreased after antiviral treatment at SVR 12 and SVR 24, as compared to EOT. Overall, in our study almost 60% of patients had EOT liver stiffness values lower than at baseline, at SVR 12 almost 75% of patients had liver stiffness values lower than at baseline and at SVR 24 almost 77% of patients had liver stiffness values lower than at baseline.

P1354 ACHIEVING SVR AFTER DAA THERAPY FOR HCV DECREASES THE ACCURACY OF BAVENO VI CLASSIFICATION OF HIGH-RISK VARIANTS IN CIRRHOTIC PATIENTS
1 Hepatology, Regional Institute of Gastroenterology and Hepatology, Cluj-Napoca, Cluj-Napoca/Romania
2 Hepatology, Cluj-Napoca University of Medicine and Pharmacy, Cluj-Napoca/Romania

4 Regional Institute of Gastroenterology and Hepatology Prof. Dr. Octavian Fodor, Cluj Napoca Romania

Contact E-mail Address: rotaru.i.magda@gmail.com

Introduction: Baveno VI criteria suggest that cirrhotic patients with platelet count (PLT) > 150,000μl and liver stiffness measure values (LSM) < 20kPa bare a low risk of liver decompensation and end-stage cirrhosis. Liver fibrosis for patients with HCV infection showed the effectiveness of anti-viral therapy. However, the long-term impact on cirrhosis and decompensation in HBsAg positive patients is still unclear.

Aims & Methods: Therefore, the aim of the study was to assess the influence of DAA therapy on the accuracy of the Baveno VI criteria for cirrhotic HCV patients. All consecutive patients with compensated HCV liver cirrhosis approved for DAA treatment in our center who gave their informed consent were included. All patients were screened for EV before starting the therapy by esogastroendoscopy. LSM (FibroScan®) and usual biological parameters were evaluated at baseline and when assessing SVR 12.

Results: 50 patients were included (95% men, 5% women) between December 2015 and July 2016. All patients achieved SVR (100%). At base line, 17/50 patients had EV. After completing DAA therapy, liver enzymes [GOT (p < 0.001), GPT (p < 0.0001)], GGT (p < 0.003) and LSM (< 0.0001) significantly decreased, while albumin (p = 0.09) and PLT (p = 0.39) increased. We found a moderate correlation between GOT and LSM both at baseline (r = 0.31; p = 0.001) and at RV12 (r = 0.45; p = 0.004), but the amplitude of the decrease appears not to be correlated [r (ΔGOT vs. ΔLSM) = 0.149; p = 0.3]. At baseline, according to Baveno VI criteria, 29 patients were classified at low risk of having EV (accuracy 68%, Se 69.7%, Sp 64.7%, PPV 79.31%, NPV 52.38%). At SVR12, 10 additional patients entered this class, but the accuracy (60%) decreased.

Conclusion: DAA therapy induces a significant decrease in liver inflammation and liver stiffness and also a non-significant increase of platelets count. These changes induce a decrease of the accuracy of classification of patients with low risk of having EV (according to Baveno VI criteria), therefore is not advisable to use Baveno VI criteria as surrogate for endoscopy screening for esophageal varices in cirrhotic patients compensated HCV liver cirrhosis who obtained SVR.

Introduction: HCV interferes with the host lipid metabolism leading to insulin resistance and hepatic steatosis. Although it is usually mild in genotype 4, mild-to-moderate simple steatosis is the potential to progress to fibrosis, cirrhosis and subsequent hepatocellular carcinoma. Many heritable host factors with observed inter-ethnic variation in the prevalence of steatosis are documented, and in many cases hepatic steatosis may be detected in absence of all these risk factors; so a role for host genetic factors in development of hepatic steatosis in chronic HCV patients may be suggested.

Aims & Methods: In this study, we aim to evaluate the association of HLA class A-B alleles and presence of steatosis in chronic HCV genotype 4 infected patients. The study included two hundred unrelated non diabetic non obese chronic HCV patients with normal lipid profile, 98 of them had biopsy proven steatosis. Serological testing of HLA class I antigens (HLA-A, and HLA-B alleles) were performed with a standard complement-dependent micro-lumiochromato toxicity

Results: The frequency of A02, A03, B15 and B17 alleles were significantly higher in chronic HCV patients with steatosis (OR = 1.77, 2.64, 4.44, 5.68) and 95% CI = 0.96–3.27, 1.02–7.04, 0.84–31.17, 1.12–38.65 with P = 0.034, 0.022, 0.044, 0.015 respectively. On the other hand, the frequency of A01 and B12 alleles were significantly higher in patients without steatosis (OR = 0.56, 0.41) and 95% CI = 0.30–1.05, 0.20–0.83 and P = 0.015 and 0.005. On logistic regression analysis, patients who carry HLA-A02, A03 and HLA-B15 alleles may have 2,2, 3,9 and 11,18 fold risk to have hepatic steatosis (B coefficient: 0.79, 1.37, 2.41) 95% CI = 1.09–4.42, 1.04–11.05, 2.15–58.13; P = 0.027, 0.009, 0.004) while carrying HLA-A01 alleles may be protected from having HCV associated hepatic steatosis; (OR = 0.34,95% CI = 0.16–0.72; P = 0.005) with constant >47 and overall accuracy of 69%. In addition, patients who have moderate activity index in liver histopathology have 5.9 risk to have hepatic steatosis (OR = 5.92, 95% CI = 2.92–11.99, P<0.001).

Conclusion: In chronic HCV genotype 4 patients, carrying HLA-A02, HLA-A03 and HLA-B15 alleles may have a risk for presence of hepatic steatosis while presence of HLA-A01 alleles may have a protective role.

Introduction: The risk of developing novo hepatocellular carcinoma (HCC) persists after reaching sustained virological response (SVR) in patients infected with hepatitis virus C. It has been suggested that risk is increased in patients treated with the new direct antiviral agents (DAA). In this prospective study we present our results of incidence and prevalence of novo HCC in cirrhotic patients treated with DAA and SVR, and also, the risk factors involved in its development.

Aims & Methods: We included all cirrhotic patients due to HCV infection without previous HCC who reached SVR after DAA treatment in our hospital from February 2014 until December 2016 (n = 197, median of follow-up of 17 months). We evaluated with chi square test the following qualitative variables: age, Child-Pugh stage, alcohol consumption pre-treatment, tobacco consumption pre-treatment, diabetes mellitus (DM) pre-treatment, genotype, radiological and endoscopic portal hypertension features pre-treatment. The quantitative variables were evaluated with student t test; age, no. of platelets pre-treatment, fibrosis score pre-treatment.

Results: During follow-up 11 patients were diagnosed of HCC (5.6% prevalence, 3.9% annual incidence). Among all variables evaluated being in a Child- Pugh B stage vs. an A stage (p = 0.007), pre-treatment DM (p = 0.002) and presence of radiological portal hypertension (p = 0.001) were associated with developing novo HCC. Among the quantitative variables, we evidenced statistically significant differences in the mean value of platelets (p = 0.015).

Conclusion: In our group of patients, a worse hepatic function evaluated with the Child-Pugh classification and indirect markers of portal hypertension (platelets and radiological features) and also DM are associated statistically significant with the development of novo HCC. The incidence (>1.5%) of novo HCC justifies the screening of HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
more patients above Clavien IIa were in the observation group, there was no statistically significant difference in the peroperative mortality between the two groups.

Conclusions: Preoperative TACE could effectively reduce complications caused by immune reaction (P = 0.048). In terms of postoperative indexes of liver function, TBIL, ALT, AST all had a transient rise during the first 3 days after liver transplantation, but recovered gradually over time. There’s no remarkable difference in the liver function recovery level between two groups (P = 0.495; P = 0.141; P = 0.101).

Conclusion: Preoperative TACE won’t affect liver function recovery and perioperative safety after liver transplantation. For some patients, it could also reduce complications caused by immune reaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Romania has the highest incidence of tuberculosis (TB) in the European Union, representing one quarter of the European TB burden. According to clinical practice guidelines for liver transplantation (LT), the second level of screening for infections consists of screening for Mycobacterium tuberculosis, including history of TB, PPD, Interferon-gamma release assays. Aims and Methods: The aim was to assess the importance of Quantiferon TB Gold test in evaluating patients included on the wait list for LT in Romanian liver transplant centres. The study was a single-center retrospective cohort study (the single center for LT) that included 264 patients admitted on the wait list for LT from January 1, 2014 to November 18, 2016. All patients underwent mandatory screening for Mycobacterium tuberculosis, either using Quantiferon TB Gold test or skin testing using purified protein derivative (PPD). The variables analyzed using Minitab 17 were: age, gender, etiology of liver disease, biochemical test, MELD score.

Results: From a total of 264 patients with liver diseases included on the wait list, 60.6% were males, the average age at diagnosiswas 47.78 ± 9.92 years. The etiology of liver cirrhosis was HCV infection in 31.43%, HBV and HBV-HDV coinfection in 45.06%, and alcoholic liver cirrhosis in 18.93%; 24.62% of patients have been diagnosed with superimposed hepatocellular carcinoma. Eighty three patients (31.43%) had positive results for Quantiferon test, 150 patients (56.81%) were negative and 17 patients (6.43%) had indeterminate results. Only 14 patients (5.3%) were skin tested using PPD, 2 (0.75%) of them with positive results. Comparing the subgroups, positivity Quantiferon test was associated with HCV etiology (p value = 0.049) and lower lymphocyte counts, but did not achieve statistical significance (p = 0.187). Patients with indeterminate Quantiferon associated hyperbilirubinemia (p = 0.044), hypoalbuminemia (p = 0.032) and a higher MELD score (p = 0.018). An assessment by a multidisciplinary team that included a pneumologist, 38.65% of patients were diagnosed with latent TB. Isoniazid chemoprophylaxis along with pyridoxine was postponed after LT, in order to prevent further hepatic dysfunction. 48.5% of patients underwent LT, followed by TB prophylaxis and no cases of TB reactivation have been reported during a follow-up period of 14 months.

Conclusion: Patients transplanted for HCV-related liver cirrhosis should benefit from a careful follow-up on the WL and prompt TB prophylaxis after LT in order to prevent further hepatic dysfunction caused by TB reactivation. Delaying TB prophylaxis after LT in order to avoid liver toxicity of anti-bacillary drugs was not associated with TB reactivation.

MISMATCH: SINGLE CENTRE EXPERIENCE
SCLEROSING CHOLANGITIS IN CONTEXT OF HLA-DR

Introduction:
Primary sclerosing cholangitis (PSC) is associated with an increased risk of cholangiocarcinoma, colorectal cancer (CRC) and gallbladder cancer. Orthotopic liver transplantation (OLT) patients are at increased risk of developing de novo malignancies, however limited and conflicting data exists regarding cancer risk post OLT for PSC.

Aims & Methods:
To examine all recorded malignancies over 2 decades in OLT PSC pts and compare to our non-transplanted PSC cohort. To analyse factors associated with development of malignancies post OLT. We retrospectively studied PSC patients attending the Irish National Liver Unit (INLU) and the Centre for Colorectal Disease (CCD) at St. Vincent’s University Hospital from 1/1/1994 to 31/12/2011. We integrated this database with the National Cancer Registry in Ireland. This enabled accurate determination of the no. of malignancies recorded in the PSC cohort. Analyzed data included age of recipient at OLT, gender, primary OLT indication, immunosuppressive regime, de novo malignancy post OLT, time from OLT to diagnosis of malignancy or death. Statistical analysis was primarily descriptive. Cox Proportional Hazard Model was used to analyse factors associated with mortality in the PSC OLT cohort.

Results:
107 of 173 patients had undergone transplant for PSC. 27/107 pts were transplanted for cholangiocarcinoma. 12 post-transplant de novo cancers and 12 BCC/SCC carcinomas were found in 107 patients during 737.8 person years of follow-up. Median time to cancer diagnosis post OLT was 5 years (IQR 2.8–5.9). Recurrence of PSC was observed in 21 patients (19.6%). Post-transplant lymphoproliferative disease (PTLD) remains a major complication after OLT. Recent studies have reported rates of 1–3% in adult OLT pts. 5 pts were diagnosed with PTLD. Lymphoma/lymphoproliferative disease (LPLD) has been reported to be 30 times higher than previously reported. The incidence of all malignancies was compared with those obtained by liver biopsy. The mean elastography score showed an accuracy of 79.7% in predicting histological fibrosis but not steatosis or inflammation. Liver transient elastography represents a non-invasive and valid tool for the diagnosis of liver fibrosis.

Conclusion:
These findings indicate national cancer figures in our PSC OLT cohort. The rate of cancer is more than three times higher in this population than the general population. The rates of PTLD are >30 times higher than those in the normal population, and slightly higher than previously reported in unselected liver transplant groups. We could not find any association between the development of PTLD and aggressive immunosuppressive regimes for co-existing IBD post OLT. The study highlights that IBD/PSC patients remain at significant risk of colonic neoplasia after OLT and require intensive surveillance.

Disclosure of Interest:
All authors have declared no conflicts of interest.

OUTCOME OF LIVER TRANSPLANTATION FOR PRIMARY SCLEROSING CHOLANGITIS IN CONTEXT OF HLA-DR MISMATCH: SINGLE CENTRE EXPERIENCE

Introduction:
Primary sclerosing cholangitis (PSC) is a chronic liver disorder of unknown etiology, characterized by inflammation, fibrosis and stenoses of both extra- and intrahepatic bile ducts. For those who develop end-stage liver disease, orthotopic liver transplantation (OLT) remains the only effective treatment currently available. PSC is accompanied with concomitant ulcerative colitis (UC) in a significant proportion of patients. Benefits of routine HLA typing in donor and recipient prior to OLT were proved in the past.

Aims & Methods:
The aim of this study was to assess the impact of HLA-DR mismatch on acute cellular rejection (ACR), PSC recurrence (rPSC) and course of UC after OLT. After applying inclusion/exclusion criteria we retrospectively evaluated records of 57 PSC transplanted at Institute for Clinical and Experimental Medicine (Prague, Czech Republic) between July 1994 and November 2011. Only patients with proper records ±5years from OLT were included. We evaluated likelihood for each variable (ACR, rPSC, course of UC) in transplanted patients with either single, or double mismatch in HLA-DR. Kaplan-Meier data were analysed with the log-rank test using MedCalc statistical software. A p - value <0.05 was considered as statistically significant.

Results:
Out of 59 patients, 27 (47.4%) had single mismatch (“M1” group) and 32 (52.6%) had double mismatches (“M2” group) in HLA-DR. None had full match. 33/57 (57.9%) patients had ACR: 15/27 (55.6%) of M1 and 18/30 (60%) of M2 (p = 0.94). 4/27 (14.8%) of M1 and 2/30 (6.3%) of M2 had corticosteroid ACR (p = 0.57). Multiple-episodes of ACR occurred in 11/57 (19.3%) patients: 6/27 (22.2%) of M1 and 5/25 (20%) of M2 (p = 0.74). 12/57 (21.1%) had de-novo UC after OLT: 7/27 (25.9%) of M1 and 5/30 (16.7%) of M2 (p = 0.60). In 37 (68.5%) patients, UC was diagnosed prior to OLT. 9/16 (56.3%) patients with M1 and 6/21 (28.6%) patients with M2 had more severe course of UC as compared to course prior to OLT (p = 0.17). 38 patients were evaluated for rPSC, which was diagnosed in 17 (44.7%) individuals. 6/19 patients with M1 and 11/19 with M2 had rPSC (p = 0.19).

Conclusion:
Patients with single mismatch in HLA-DR have slight tendency towards development of rPSC and worsening of UC after OLT as compared to patients with double mismatch. Analysis of combined mismatch in HLA-DR and HLA-DQ could demonstrate more substantial linkages in respective clinical variables. Therefore, these data have to be considered as preliminary as typing for HLA-DQ from frozen blood samples is currently underway.

GRAFT DYSFUNCTION IN POST-LIVER TRANSPLANTATION: UTILITY OF TRANSIENT ELASTOGRAPHY BY FIBROSCAN®

Introduction:
Liver biopsy remains the gold standard in the diagnosis of graft dysfunction in post-liver transplantation (GDPLT). Liver transient elastography is a valid non-invasive method for liver fibrosis evaluation, with a good correlation in chronic liver diseases. The progression of fibrosis represents a major problem in the post-liver transplantation.

Aims & Methods:
We aimed to evaluate the predictive role of liver transient elastography in the evaluation of GDPLT and to determine the predictive factors of liver transplantation fibrosis. This was a retrospective single institutional cohort study of total of 49 patients with post-liver transplantation status who underwent liver transient elastogram by Fibroscan®. Selected patients who underwent percutaneous/transjugular liver biopsy. In case of more than one liver biopsy, it was selected the biopsy closer to Fibroscan®. The fibrosis and steatosis evaluated by Fibroscan® were compared with those obtained by liver biopsy. Significant fibrosis was considered if ≥2F. Demographic, analytical and associated clinical variables were compared.

Results:
A total of 32 patients underwent Fibroscan® and liver biopsy. Mean age of 48.53 ± 11.20years and male gender in 68.8% (n = 22). The mean time between Fibroscan® and liver biopsy was 29.77 ± 36.90months. The mean elastography score was 13.45 ± 8.31KPa with IQR/med of 17.11 ± 8.66%. Mean CAP score was 207.12 ± 57.35 dB/m. Regarding liver biopsy, 34.4% (n = 11) had significant fibrosis and 25.0% (n = 8) presented steatosis. Comparing two methods, there was no concordance for steatosis (kappa = 0.273; p = 0.177) or inflammation (kappa = 0.063; p = 0.710). On the contrary, a moderate agreement for significant fibrosis (kappa = 0.431; p = 0.003) was verified. The mean elastography score showed an accuracy of 79.7% in predicting histological fibrosis (AUROC = 0.797; p = 0.007) to a cut-off value of 11.6 KPa (Sensitivity 81.8%, Specificity 76.2%). In relation to analytical parameters, only serum albumin was present lower in patients with significant fibrosis but not steatosis or inflammation. Liver transient elastography can be a useful alternative to liver biopsy in the evaluation of post-liver transplantation fibrosis but not steatosis or inflammation.

Conclusion:
Liver transient elastography represents a non-invasive and valid alternative procedure to liver biopsy in the evaluation of post-liver transplantation fibrosis but not steatosis or inflammation. Liver transient elastography scoring >11.6KPa and low values of serum albumin are predictors of post-liver transplantation fibrosis.

Introduction: Orthotopic liver transplant has become the standard of care for end-stage liver disease and hepatocellular cancer. Better immunosuppressants paved way for improved survival rates post-transplant. But with this longevity comes a higher prevalence of chronic diseases such as New Onset Diabetes After Transplant (NODAT), Hypertension, metabolic syndrome etc. which have a negative impact on function and patient survival.

Aims & Methods: Primary: To determine the incidence of New Onset Diabetes After Transplant (NODAT). Impaired Fasting Glycaemia (IFG) and post-transplant hyperglycemia in living-donor liver transplant recipients. Secondary: To determine the risk factors associated with NODAT and IFG. To determine impact of NODAT on survival and mortality. It was a retrospective cohort study of 283 living donor liver transplant recipients from 29/4/2011 till 26/4/2016. Data was collected from records. Simple means and standard deviation were calculated for continuous variables while frequency statistics were calculated for categorical ones. Risk factors were assessed using binary logistic regression analysis.

Results: A total of 130 post liver transplant patients were analyzed after exclusion. NODAT was present in 41/130 (31.5%) patients, while 19/130 (14.6%) patients had impaired fasting glycaemia. Acute cellular rejection, Pre-transplant Hyperglycemia and Pre-transplant prediabetes showed increased odds of acquiring NODAT post-transplant. NODAT had significant association with mortality and decreased survival (p = 0.05).

Conclusion: This cohort showed that NODAT is an important post-transplant entity with significant impact on mortality and survival. Early identification of at-risk patients is suggested.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1366 VITAMIN B12 AS A PROGNOSTIC MARKER IN PATIENTS WITH ACUTE ON CHRONIC LIVER FAILURE

V. L. Anapaz1, M. V. Machado2, C. Baldaiz2, A. Valente2
1Gastroenterology, Hospital Fernando Fonseca, Lisbon/Portugal
2Intensive Care Unit Of Gastroenterology And Hepatology, Hospital de Santa Maria, Lisbon/Portugal

Contact E-mail Address: vera_anapaz@hotmail.com

Introduction: Serum vitamin B12 (vB12) levels are increased in myeloproliferative diseases by increased production of the vitamin B12 transporter and in liver diseases by release of vB12 by hepatocytes death.

Aims & Methods: The aim of this study was to evaluate vB12 as a prognostic marker in patients with cirrhosis and acute on chronic liver failure (ACLF) in context of infection. Retrospective assessment of 55 patients admitted to an intensive care unit with ACLF in the context of infection (group 1) and 53 patients with compensated hepatic cirrhosis followed as Hepatology outpatients (group 2). Evaluation of vB12 as a predictor of 30 days’ mortality.

Results: 111 patients, 68% male, age 58 ±18 years. Group 1 had more prevalence acute liver disease (CPT 11.9± 3.6 vs. C6 6.5±0.2 and MELD 27.0±1.0 vs. 10 ±0.5), higher vB12 (1413 ±149 vs 735 ±56 pg/mL) and lower survival (1.6±0.4 vs. 6.4±2.7 years). vB12 positively correlated with hepatic function scores (CPT: R = 0.51; MELD: R = 0.57) and increase of one unit of MELD or vB12. In patients with ACLF, vB12 correlated with liver disease severity (CPT: R = 0.41; MELD: R = 0.53) and multiorgan failure (number of organ failures: R = 0.536. SOFA: R = 0.553). In group 1, survival was lower in patients with high vB12 (8 ±3 vs. 37 ±11 months), and 1 month’ mortality was associated with vB12, CPT, MELD, number of organ failure, urea, lactates and fibrinogen, in univariate analysis (p < 0.001). In multivariate analysis only fibrinogen maintained statistical significance (p < 0.001).

Conclusion: There was a strong association between high levels of vB12 and clinical decompensation of liver cirrhosis. vB12 correlated with scores of liver function and multiorgan failure, as well as early mortality in patients with ACLD.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1368 THE ASSESSMENT OF THE ADC PREDICTIVE VALUE IN SURVIVAL OUTCOMES OF PATIENTS UNDERGOING RADIOFREQUENCY ABLATION FOR METASTATIC COLORECTAL CANCER LIVER TUMORS

O. Kozak1, T. Nowicki, J.M. Pienkowski2, E. Izrycka-Swieszewska2, D. Zadrozny1, E. Szarowska1
1Department Of Radiology, Medical University of Gdansk, Gdansk/Poland
2Department Of Pathology And Neuropathology, Medical University of Gdansk, Gdansk/Poland

Aims & Methods: This is a post hoc analysis of prospective study to assess the predictive value of the ADC in survival outcomes of patients undergoing radiofrequency ablation due to metastatic colorectal cancer lesions in the liver. We analyzed the MRI studies of 52 patients (18 F, 34 M, aged 4383) performed on 1.5 T scanner one day before the percutaneous RFA treatment. The total number of analyzed lesions was 110 (15 per patient), 83 of them were completely ablated, 27 incompletely, what was assessed in follow-up CT studies. The standard protocol of the liver MRI was applied including DWI sequence in b values of 0, 15 and 300 s/mm², ADC maps were calculated for b values of 015 and 0500 s/mm². The DWI ADC value was obtained by threefold ROI coverage of the whole metastatic lesion. In cases of multiple foci only the lesion with the highest ADC value was included into analysis. On basis of ROC analysis the cut-off values of ADC were established: 2.49 mm²/s for b value of 0.15 s/mm² and 1.43 mm²/s for b value of 0.500 s/mm². The survival outcomes were assessed by mean of Kaplan-Meier estimator. The p value lower than 0.05 was considered significant.

Results: The statistical analysis included Kaplan-Meier estimator for 52 patients with 8 censored cases (17.3%). In ADC maps for b value of 0.500 s/mm², the ADC value ≥1.43 mm²/s correlated with longer survival time, whereas ADC value <1.43 mm²/s correlated with shorter survival time. Statistically significant differences were identified by log rank test (p = 0.007). Such a correlation was not observed for ADC values in ADC maps for b value of 0.15 s/mm² (p = 0.058).

Conclusion: The study showed significant differences in survival rate depending on diffusion influenced ADC values of metastatic lesions.

Disclosure of Interest: All authors declared no conflicts of interest.

P1370 LEARNING CURVE EVALUATION USING ELASTPO

R. Mare1, I. Sporeaj, S.A. Popescu1, R. Sîrlí, C. Pienar2
1Gastroenterology And Hepatology, Emergency County Hospital Timisoara, Romania
2Gastroenterology, Pediatrics, "Victor Babes" University of Medicine, Timisoara, Romania

Aims & Methods: The aim of our study was to evaluate the learning curve of obtaining reliable liver stiffness measurements (LSM), using ElastPQ. LSM of a trainee were compared to LSM of an elastography expert (with an experience of more than 500 examinations). Our study group included 50 subjects (mean age: 52.7 years, 66.6% men, mean BMI: 25.6 kg/m²). Both the trainee and the expert obtained LSM for each subject, using ElastPQ (EPIQ 7, Philips Healthcare, Bothell, WA, USA). Reliable LSM were defined as the median difference measurements < 10% in a homogenous area avoiding large vessels and with an IQR/median < 30%. The learning curve was evaluated using the Receiver Operating Curve analysis using the expert’s results as reference.

Results: The trainee’s performance in obtaining reliable LSM was good (AUC: 0.735, 95% CI (0.557–0.913), p = 0.01). The trainee started to have similar results with the elastography expert after the 30th subject. When looking at the IQRs, they became significantly lower after the 30th subject (2.6 to 2.1 kPa vs 6.5 to 2.1 kPa, p = 0.03).

Conclusion: Obtaining reliable LSM using ElastPQ can be easily achieved after 30 LS examinations.

Disclosure of Interest: R. Mare: I hereby confirm that I have received financial support (congress travel grant) from Philips, Siemens, General Electric, Abbvie, Zentiva, Bristol Meyers Squibb.
S.A. Popescu: I hereby confirm that I have received financial support (congress travel grant or speaker fee) from Philips, General Electric, Abbvie, AstraZeneca, Zentiva.

Contact E-mail Address: rus23232@yahoo.com
Aims & Methods: In patients with liver cirrhosis, hepatocellular carcinoma (HCC) can be diagnosed by noninvasive imaging methods (contrast-enhanced ultrasound or contrast-enhanced CT). The RADS classification of the 298 lesions was considered in all three phases (portal, arterial, and washout). The nodules were classified according to their size in ≤3 cm and >3 cm. We re-evaluated all 249 HCCs CEUS studies using the ACR CEUS LI-RADSv 2016 algorithm. The nodules were classified according to their size in ≤3 cm and >3 cm. We re-evaluated all 249 HCCs CEUS studies using the ACR CEUS LI-RADSv 2016 algorithm.

Results: After CEUS examination a conclusive diagnosis of HCC was obtained in 190/249 cases (76.3%). Arterial phase hyperenhancement pattern was present in 227/249 cases (91.2%). In the portal phase iso- or hypoenhancement was observed in 17/249 cases (6.8%) and hypoenhancement in 5/249 cases (2%). In the late phase washout was observed in 197/249 cases (79.1%). The nodules ≤3 cm were diagnostic conclusive on CEUS in 63.7% (72/113), while nodules >3 cm had a conclusive result in 86% of cases (138/211), p < 0.001. CEUS examination was conclusive for HCC in 76.3% of the cases (190/249), while using the ACR CEUS LI-RADSv 2016 algorithm in 72.2% of all HCCs (180/249), p = 0.35.

Conclusion: In our study, CEUS arterial hyperenhancement is the most common pattern observed in HCC (91.2% of cases), followed by washout in the late phase (79.1% of cases). The size of the nodule modifies CEUS sensitivity for the diagnosis of HCC p < 0.001.

P1373 DICKKOPF-1: AS A SERUM BIOMARKER FOR PREDICTION OF HEPATOCELLULAR CARCINOMA TREATMENT RESPONSE
A. L. Sharaf, E. G. El-Badrawy, N. A. Khalifa
1Tropical Medicine Department, Zagazig University, Zagazig, Egypt
2Clinical Pathology Department, Zagazig University, Zagazig, Egypt

Contact E-mail Address: drnahmed_lotfy@hotmail.com

Introduction: Hepatocellular carcinoma (HCC) is the 5th most common cancer worldwide and the 3rd leading cause of cancer-related mortality. In Egypt, HCC is the 2nd most common cancer in men and the 6th most common cancer in women. Egypt has the highest prevalence of HCC worldwide and has rising rates. HCC is a disease with fast infiltrating growth and poor prognosis. This bad prognosis is due to the lack of an effective method for early diagnosis. So, it is necessary to find a specific & sensitive marker for early diagnosis of HCC and for monitoring of treatment response.

Aims & Methods: The aim of this work is to test prognostic value of serum DKK1 in predicting treatment response, complication and survival in HCC patients. This study included 60 patients divided into two groups. Group A: consisted of 30 patients with liver cirrhosis. Group B consisted of 30 patients with HCC. Group B patients underwent either radiofrequency ablation or ethanol injection. Clinical assessment, routine laboratory evaluation, CT studies and measurement of serum alpha-fetoprotein (AFP) and DKK1 were performed for all patients and repeated to group B patients 1 and 3 months after treatment.

Results: DKK1 significantly can be used for HCC diagnosis even in HCC with inconclusive AFP. The optimum cut off value of DKK1 for diagnosis of HCC was 4.3 ng/ml (AUC 0.89, sensitivity 66.7% and specificity 96.6%) (P < 0.001). Serum DKK1 level significantly decreases after HCC treatment with either radiofrequency ablation or ethanol injection (P < 0.001). Conclusion: DKK1 has a promising prognostic value and can be used for follow-up of HCC patients before and after treatment.

P1374 EFFECT OF FIBROBLAST GROWTH FACTOR-2 AND ITS RECEPTOR GENES POLYMORPHISMS ON SURVIVAL IN PATIENTS WITH HEPATITIS B VIRUS–ASSOCIATED HEPATOCELLULAR CARCINOMA
J. Cheong
Gastroenterology, Ajou University Hospital, Suwon, Korea, Republic of

Contact E-mail Address: jaeyoun620@gmail.com

Introduction: Fibroblast growth factor (FGF), vascular endothelial growth factor, and hepatocyte growth factor play a critical role in the pathogenesis of hepatocellular carcinoma (HCC). The FGF2 rs8038793 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The F1t-1 rs4771249 C allele was associated with low alpha-fetoprotein levels. Kaplan-Meier analysis showed that the patients with the FGF2 rs804477 TT genotype had lower survival rates than the patients with the CC or CT genotype (P = 0.016) and that the FGF2 rs803879 A allele carriers had shorter survival rates than those of patients with the TT genotype (P = 0.020). The FGF2 rs1219648 CC genotype was significantly associated with increased survival rates (P = 0.047). Multivariate Cox proportional analysis revealed that the FGF2 rs803879 A allele (hazard ratio = 1.663, P = 0.004) and advanced stage (hazard ratio = 3.430, P = 0.001) were independent prognostic factors for overall survival rates in patients with HCC.

Results: Of the 395 patients enrolled, 280 (71.1%) were men and 115 (28.9%) were women. The mean age was 52.7 ± 8.2 years. The 5-year overall survival rate of all patients was 43.7 %. The 5-year overall survival rate at 3 years was 70.2%. The mean survival time was 42.7 ± 9.1 months. The 5-year overall survival rate of patients with the CC or CT genotype (n = 186) was 57.5%, while that of patients with the TT genotype (n = 209) was 36.8% (P = 0.016). The FGF2 rs803879 A allele was significantly associated with small tumor size, early tumor stage, and less vascular invasion. The F1t-1 rs4771249 C allele was associated with low alpha-fetoprotein. The Kaplan-Meier analysis showed that the patients with the FGF2 rs804477 TT genotype had lower survival rates than the patients with the CC or CT genotype (P = 0.016) and that the FGF2 rs803879 A allele carriers had shorter survival rates than those of patients with the TT genotype (P = 0.020). The FGF2 rs1219648 CC genotype was significantly associated with increased survival rates (P = 0.047). Multivariate Cox proportional analysis revealed that the FGF2 rs803879 A allele (hazard ratio = 1.663, P = 0.004) and advanced stage (hazard ratio = 3.430, P = 0.001) were independent prognostic factors for overall survival rates in patients with HCC.

Disclosure of Interest: None of the authors have any conflicts of interest.
Conclusion: These observations suggest that the SNPs of the FGFR2 and FGFR3 genes can be potential prognostic indicators in patients with HBV-associated HCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Extrahepatic HCC metastasis are associated with a poor prognosis. Nevertheless there are some effective therapies available.

Aims & Methods: The aim of this study was to assess the main sites of extrahepatic metastasis in hepatocellular carcinoma (HCC) patients and to evaluate the clinical evolution and treatment. This was a retrospective single-center study in which patients with HCC confirmed extrahepatic metastasis between January 2010 and December 2016 were evaluated.

Results: We evaluated 51 consecutive patients, 80% male, with a mean age of 64 ± 11 years at the time of metastasis. In 41% of the patients the metastasises were present at the time of HCC diagnosis. In patients with subsequent metastasis, the median time until its development was 9 months (IQR 5–16). The diagnosis of metastasis was incidental in 51% of the patients. Computed tomography (CT) was the main diagnostic method (86%) and in 18% of the cases histological confirmation was obtained. Nineteen patients underwent thoracic CT and five performed bone scintigraphy prior to metastasis. A total of 70 metastatic sites were identified, the more frequent were lung (33%) and bone (14%). The MELD score at the time of metastasis was higher than the MELD score at the HCC diagnosis (p = 0.009). Metastasis detection implied changes in HCC therapy in all patients, 41% switched to TACE and 55% were referred for supportive therapy. Seven patients performed metastasis targeted treatment, namely 3 patients underwent radiotherapy. The median overall survival (OS) after metastasis was 4.0 months (95%CI 2.1–5.8 months) and the mortality rate was 81% at 12 months. Patients who underwent metastasis targeted treatment presented a longer OS than those who did not (median 18.5 vs 3.1 months; p = 0.002). In multivariate analysis, MELD score at the time of metastasis (p = 0.004) and metastasis treatment (p = 0.005) were independently associated with OS estimation.

Conclusion: A systematic HCC staging, with thoracic CT and bone scintigraphy, may provide an earlier metastasis detection and enable a targeted treatment with a consequent improvement in survival in this difficult-to-treat population.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1376 MANAGEMENT OF INTERMEDIATE STAGE HEPATOCELLULAR CARCINOMA
A. Deguchi
Department Of Gastroenterology, Kagawa Rosai Hospital, Marugame-shi, Kagawa/ Japan

Contact E-mail Address: akihiru41@me.com

Introduction: According to the Barcelona Clinic Liver Cancer (BCLC) staging system, intermediate stage contains very heterogeneous hepatocellular carcinoma (HCC) patients. Recently, subclassification of intermediate stage on the basis of Milano criteria and up to 7 criteria is proposed. In this study, the effectiveness of delivering second-line anti-tumor chemotherapy (DEB-TACE) in intermedi- ate stage was investigated.

Aims & Methods: 120 patients (M: F = 90:30; median age = 76; Child A: B: C = 72:44:4; BCLC stage A: B: C: D = 6:85:23:6) with unresectable HCC who received DEB TACE in our hospital were studied. The objective radiological response was classified according to the modified Response Evaluation Criteria in Solid Tumors (mRECIST) v.1.1 by using dynamic CT at one or two months after therapy. Adverse events were evaluated using NCI CTCAE v. 4.03.

According to Bolondi’s subclassification, the patients of BCLC B stage were divided into four groups (B1: 31; B2: 19; B3: 14; B4: 10). The response rate and tumor factor associated response in these patients group were examined.

Results: The overall response rate and disease control rate in intermediate stage were 36% and 89%, respectively. Considering the subclassification, the response rate in B1 group (61%) was significantly higher than that of B2+B3 group (29%). Although B2+B3 group was constituted by the patients who did not satisfy the up to 7 criteria, only in the patients with less than 7 tumors, the response rate (60%) was similar to that of B1 group. Tumor factors associated response rate and found to be significant on univariate analysis were simple gross classification (classification being nodular type) and number of tumors.

Conclusion: For the treatment of intermediate-stage HCC, although DEB-TACE is considered to be most effective in B2 group, it is suggested that DEB-TACE is also effective in the patients with less than 7 tumors in B2+B3 group. In cases with more than 7 tumors, as the response rate is considered to be extremely low, sorafenib and arterial infusion therapy are recommended.

P1377 HEPATOCELLULAR CARCINOMA RECURRENCE RATE IN INFECTED PATIENTS TREATED WITH DIRECT ANTIVIRAL AGENTS. A SINGLE-CENTER EXPERIENCE
Hepatology Unit, Cardarelli Hospital, Naples/Italy

Contact E-mail Address: raffaellatorrotta@live.com

Introduction: In the last few years many HCV patients with previous diagnosis of hepatocellular carcinoma (HCC) have been treated with direct antiviral agents (DAAs) for HCV infection. However there are conflicting data on HCC recurrence rate after DAAs therapy.

Aims & Methods: Aim of this study was to prospectively evaluate the rate of HCC recurrence following sustained virological response (SVR) by DAAs. From April 2015 to September 2016 we consecutively enrolled HCV infected patients previously treated for HCC at Liver Unit of Cardarelli Hospital. All patients had a free-disease survival from HCC of at least 6 months before starting antiviral therapy. The efficacy of HCC therapy was evaluated according to mRasct cri-
teria at CT or MRI. Radiological evaluation was carried out within 30 days from the start of therapy. All patients underwent DAAs therapy, selected on an individ-
ual basis according to the recommendation issued by the Italian association of the study of the liver.

Results: A total of 71 patients were enrolled. Among them, 42 patients had available data on SVR status and were considered for the analysis. There were 21 males (58.3%) and 15 females. The median age of the patients was 73 years (range 24–85). The median time to treatment was 12 months after the beginning of the therapy (range: 6–18 months). Genotype distribution was as follows: 36 patients infected with genotype 1 (85.7%), 5 with genotype 2 and 1 patients with genotype 3. SVR was achieved in 38/42 patients (90.5%). HCC recurrence was observed in 11/38 patients with SVR (28.9%). The median time for recurrence was 9 months from the start of therapy with a range of 1–13 months; with 2 patients who showed recurrence during therapy. Among the patients who did not achieve SVR, 1/4 showed HCC recurrence after 10 months from end of treatment.

Conclusion: Treatment with DAAs are highly effective with a SVR of about 90% even in patients with advanced liver disease. Nonetheless, in patients with previous history of HCC, the eradication of HCV did not reduce the risk of short and medium-term recurrence.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1378 PATTERN OF DISTANT EXTRAHEPATIC METASTASES IN PRIMARY LIVER CANCER: A SEER-BASED STUDY
W. Wu, X. He2, L. Li1, D. Fang1, D. Shi1, Y. Li1, J. Ye1, F. Guo1
1Academy Key Laboratory for Diagnosis and Treatment of Infectious Diseases, The First Affiliated Hospital, School of Medicine, Zhejiang University, Hangzhou, China; Hangzhou/China
2Department of Gastroenterology, Sir Run Run Shaw Hospital, Zhejiang University Medical School, Hangzhou, China; Hangzhou/China

Contact E-mail Address: wwx725@zju.edu.cn

Introduction: Primary liver cancer is the sixth most common cancer in the world, after cancers of the lung, breast, colorectal, prostate and gastric.[1] However, the extremely poor prognosis for primary liver cancer makes it the second leading cause of cancer-related death globally (745,000 deaths, 9.1% of the total death)[2]. Histologically, the majority of primary liver cancer is either
hepato cellular carcinoma (HCC) or intrahepatic cholangiocarcinoma (ICC), which are combined hepatocellular carcinoma and cholangiocarcinoma is less common[3]. Though these treatments have shown modest improvement in overall survival in early stage disease, the 5-year relative survival for distant metastasis patients is still low (3.1%). As we all know, primary liver cancer preferably metastasizes to the portal vein and extrahepatic metastasis include lungs, bones, brain, lymph nodes, and adrenal glands[4–6]. To date, few detailed studies explored extrahepatic metastasis profiles due to rare data of liver cancer metastasis. Patterns of extrahepatic metastasis still need further clarification. Besides, it is unclear whether different metastatic sites would be translated into distinct clinical outcomes.

Aims & Methods: The objective of this study was to further evaluate extrahepatic metastatic patterns of different histological subtypes and assessed effects of extrahepatic metastasis on survival of advanced disease. Methods: Based on the Surveillance, Epidemiology and End Results (SEER) database, we identified eligible population diagnosed with primary liver cancer. We adopted Chi-squared test to compared metastasis distribution among different histological types. Overall survival (OS) and cancer-specific survival (CSS) were compared between subgroups with different extrahepatic metastasises.

Results: We finally identified 8677 patients who were diagnosed with primary liver cancer from 2010 to 2012 and 1836 patients were in distant metastasis stages. Intrahepatic cholangiocarcinoma was more invasive and had a higher percentage of metastasis compared with hepatocellular carcinoma. Lung was the most common metastatic site and brain was least common site for both hepatocellular carcinoma and intrahepatic cholangiocarcinoma. Extrahepatic metastasis was an independent prognostic factor for liver cancer patients. Patients with brain metastasis had the worst prognosis, compared with other metastasis in OS and CSS analysis.

Conclusions: Different histological subtypes of liver cancer had different metastasis patterns. There were profound differences in risk of mortality among distant extrahepatic metastatic sites. Results from our studies would provide some information for follow-up strategies and future studies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods:

- Portal vein thrombosis (PVT) is defined as a partial or complete occlusion of portal vein and/or its tributaries by a thrombus. It exposes to portal hypertension (PHT) by infrahepatic occlusion and consequently to upper digestive hemorrhage, usually due to rupture of gastro esophageal varices.

Contact E-mail Address: ouhhabimane@yahoo.fr

Introduction: Portal vein thrombosis (PVT) is defined as a partial or complete occlusion of portal vein and/or its tributaries by a thrombus. It exposes to portal hypertension (PHT) by infrahepatic occlusion and consequently to upper digestive hemorrhage, usually due to rupture of gastro esophageal varices.

- Patients: In a retrospective study from January 2010 to February 2017, including 101 patients followed for PHT by PVT without liver disease in the department of hepatogastronterology (medicine C) at Ibn Sina University hospital of Rabat, Morocco. PVT was diagnosed by abdominal doppler ultrasonography in all patients.

- Results: The mean age of patients was 36 ± 15 years with extremes ranging from 11 years to 70 years. The sex ratio M/F was 0.42. Five percent of patients had a splenectomy for undocumented reasons before the diagnosis of PHT. Concerning the evolution, 10.9% (n = 11) patients were hospitalized for melena, 60.4% (n = 61) for hematemesis and melena and 28.7% (n = 29) for non-specific abdominal pain. Clinical examination was normal in 10.9% (n = 11), showed an axites in 11.9% (n = 12), and signs of PHT such as splenomegaly and collateral abdominal vessel in 95.1% (n = 96). Complete blood count showed that 16.8% (n = 17) had thrombocytopenia, 12.9% (n = 13) had bicytopenia, and 42.6% (n = 43) had pancytopenia. In all patients, upper GI endoscopy was performed. Hypertensive gastropathy was found in 30.7% (n = 31), grade I esophageal varices (EV) in 15.9% (n = 16), grade II in 30.7% (n = 31), and grade III in 48.5% (n = 49) and gastric varices were noted in 13.9% (n = 14). These varices were with red spots in 18.8% (n = 19). All patients had abdominal doppler ultrasonography showing a PVT in 60.3% (n = 61), was partial in 33.6% (n = 34), complete in 11.5% (n = 12), extended to the splenic vein in 14.9% (n = 15), showed an occlusion in 39.6% (n = 40). All patients performed an etiologic assessment of thrombosis, myeloproliferative syndrome was found in 8.9% (n = 9), deficiency in inhibitors of coagulation in 31.7% (n = 32), celiac disease in 4.9% (n = 5), neoplastic lesions in 2.9% (n = 3), no etiology was found in 51.4% (n = 52). Endoscopic variceal ligation (EVL) was performed in 70.3% (n = 71), the mean number of ligation sessions was 3 and eradication of esophageal varices was noted in 69.3% (n = 70). All patients received anticoagulant therapy except those having portal caverno, with no obvious cause and 15.9% of patients (n = 43) received beta-blockers for secondary prophylaxis. During follow up, 5.9% (n = 6) of patients have not been seen at consultation and no rebloeding was noted in 89.1% (n = 90). Concerning portal thrombosis, it dissolved in 49.5% (n = 50) and stabilized in 10.8% (n = 11).

Conclusion: The evolution of esophageal varices in non-cirrhotic portal hypertension due to PVT seems to be better than in cirrhotic portal hypertension. Indeed we aimed to evaluate the feasibility and safety of POC to verify CBD stones complete clearance. Ultraslim catheter as a single device required for BDS clearance. From January 2016 to 31 Dec 2015. Outcome measures included the success rates, adverse events, recurrence rate and mortality. All data were collected from patients’ medical records.

- Results: PTCS achieved complete clearance of GB stones in 157 patients (91.8%). The complication rate of PTCS was 3.5% (6/171). The adverse events included GB perforation (n = 3, 1.8%), hemorrhage (n = 2, 1.2%), disruption of the percutaneous transhepatic biliary drainage fistula (n = 1, 0.6%), and all of which resolved with conservative treatment. The overall recurrence rate of gallstone diseases was 11.5% during the follow up period. The incidence of recurrent gallstone diseases was significantly higher in those with completely removing GB stones than in those without complete clearance (10.2%, 16/157 vs 21.4% 3/14; p < 0.05). The frequency of recurrence of gallstone disease in patients with contrast passage to the duodenum on cholangiography after PTCS was lower than that in patients without contrast passage.

- Conclusion: Gallbladder stone removal with PTCS would be recommended as an effective and safe treatment modality for the patients with acute cholecystitis who are unsuitable for surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.
used for initial bile duct cannulation. Subsequently, sphincterotomy and stone extraction were performed using the combined catheter. The success rate of performing the combined procedure, procedure-related time, adverse events, and the cost of devices were compared with those in 10 patients with BDSs < 10 mm in size who had undergone endoscopic stone clearance from April 2015 to December 2015 in historical control.

Results: The success rate of selective cannulation and stone clearance did not differ significantly (Stonetome group: 90.9% and 100% vs control group: 100% and 100%, respectively). The median time after bile duct cannulation to complete stone clearance and total procedure time in the Stonetome group were significantly shorter than those in the control group (401.5 vs 892.5x, 645.5x versus 1380b, respectively). In the Stonetome group, delayed bleeding occurred in 1 patient. In the control group, bile duct injury caused by the guidewire occurred in 1 patient. The costs of the used devices did not differ significantly (Stonetome group: $678 versus control group: $669).

Conclusion: The combined catheter has the same selective cannulation ability as a conventional catheter and a similar capacity to remove BDSs as common retrieval. Therefore, the combined catheter can reduce the procedure time to remove BDSs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1387 ACCURACY OF ASGE CRITERIA IN THE IDENTIFICATION OF PATIENTS WITH SUSPECTED CHOLEDOCHOLITHIASIS
C. Macedo, N. Almeida, D. Gomes, E. Camacho, S. Mendes, L. Tomé, A. M. Ferreira
Gastroenterologia, Centro hospitalar e Universitário de Coimbra, Coimbra/Portugal
Contact E-mail Address: claudia.macedo.07@hotmail.com

Introduction: Society for Gastrointestinal Endoscopy (ASGE) emitted, in 2010, guidelines for the clinical orientation of patients with suspected cholecholecithis (CL), suggesting the direct referral to endoscopic retrograde cholangiography (ERC) in certain groups. However, the ERC is an invasive exam and some studies demonstrated that a significant amount of patients classified with very strong risk of CL did not have alterations in ERC.

Aims & Methods: The aim of this work was to assess the accuracy of the ASGE guidelines in portuguese population. This is a retrospective study that included 212 patients (52.8% female; 47.2% male sex; mean age 73.9 (±14.6 years) admitted to the hospital from 2014 to 2016.

Results: Of the 212 patients, 28 (13.2%) had intermediate risk of CL and 184 (86.8%) had high risk, according to the ASGE criteria. These patients were submitted to the following exams/interventions: ERC (154 patients); magnetic resonance cholangiography (50 patients) and endoscopic ultrasound (8 patients). In patients classified with high risk of CL, this was confirmed in 119 (64.7%). The same was seen in 10 (35.5%) of the patients with intermediate risk. The ASGE criteria, when applied to this population, demonstrated an accuracy of 64.3% (21.7% sensitivity; 92.3% specificity) in the high-risk group, and an accuracy of 35.5% (78.3% sensitivity; 78.6% specificity) in the intermediate-risk group. Of the patients with intermediate probability, 12 (42.8%) underwent ERC and CL was found only in 4 of these patients. The presence of cholangitis, a common bile duct > 6 mm, a common bile duct stone visualized on transabdominal US and a total bilirubin > 4 mg/dL were strong predictors of CL. The overall ERC complication rate was 13% (20 patients), of whom 8 had no CL. Conclusion: The present guidelines showed a limited diagnostic accuracy in the identification of patients who actually require ERC, conditioning a significant number of unnecessary procedures with subsequent complications associated with it. The orientation of these patients, with greater use of less invasive diagnostic techniques such as magnetic resonance cholangiography and endoscopic ultrasound.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1388 DOES FIBRIN GLUE APPLIED ON THE CHOLANGIOTOMY IN LAPAROTOMY COMMON BILE DUCT EXPLORATION REDUCE THE RISK OF BILE LEAKAGE? A RANDOMISED STUDY
B. Darkahi1, G. Sandblom2, T. Norden3
1Surgery Department, Enköping/Sweden
2Surgery Department, Upplands/Sweden
Contact E-mail Address: bahman.darkahi@gmail.com

Introduction: Laparoscopic cholecystectomy as a method of extracting common bile duct stones is a technique with many advantages. One problem, however, is bile leakage. To some extent, the leakage may be reduced if the incision is susurated around the T-tube, but this technique has some disadvantages. The aim of this study was to investigate whether application of fibrin glue around the tube results in less leakage than suturing.

Aims & Methods: Between 2012 and 2016 a total of 1347 cholecystectomies were performed in Enköping Hospital. From this group, 42 patients were included in the study and randomized to suturing or fibrin glue for closing the cholangiomy around the T tube. Postoperative cholangiography was performed after 7-10 days after surgery. The amount of flow in the abdominal drain and the level of enzymatic liver function tests were monitored daily. In case the flow ceased, the abdominal drain was extracted three days after surgery.

Results: No significant difference between the groups was seen regarding the flow of the abdominal drain or the T-drain for the first three days or operation time

Conclusion: Fibrin glue may be an option to seal cholangiomy around the T-tube, but studies with greater statistical power are needed to confirm this.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1389 THE IMPACT OF BARIATRIC SURGERY ON ACUTE CHOLANGITIS MORTALITY AND OTHER OUTCOMES: A NATIONWIDE ANALYSIS
P.T. Kroener1, M. S. Abougergi2, V. Popov3, C. C. Thompson4
1Mt Sinai St. Luke’s/West, New York, United States of America

Contact E-mail Address: thomas.kroener@gmail.com

Introduction: Rapid weight loss after bariatric surgery (BS) has been associated with the formation of gallstones, and subsequent acute cholecystitis and cholangitis (AC). However, the complex post-surgical anatomy limits the possibility of performing an ERC as part of AC treatment. Therefore, the aim of this study was to assess the impact of bariatric surgery on mortality and resource utilization among patients with AC using a national database.

Aims & Methods: This was a case-control study using the National Inpatient Sample 2013, the largest publically available inpatient database in the United States. All patients with an ICD-9 CM code for a principal diagnosis of AC were included. There were no exclusion criteria. Patients with a past history of BS were identified using the appropriate ICD-9-SCM codes. The primary outcome was all cause mortality. The secondary outcome was resource utilization: use of ERC, cholecystectomy, length of hospital stay (LOS), total hospitalization charges and costs. Multivariate regression analyses were used to adjust for the following confounders: Age, sex, race, income in patients’ zip code, Charlson Comorbidity Index, hospital region, location, size and teaching status.

Results: A total of 274,775 patients with AC were included in the study, of which 4,240 (1.7%) had undergone BS. The mean patient age was 51 years and 48% were female. After adjusting for confounders, patients with and without history of bariatric surgery had similar adjusted odds of mortality (adjusted Odds Ratio (aOR): 0.87, 95% CI: 0.51–1.49, p = 0.57). As far as resource utilization, patients with bariatric surgery had lower adjusted odds of ERC (aOR: 0.28, 95% CI: 0.09–0.83, p = 0.02), but higher odds of cholecystectomy (aOR: 3.18, 95% CI: 1.00–10.05, p = 0.04). Both patient groups had similar adjusted length of stay (adjusted mean difference: 1.19 days, 95% CI: 0.09–0.83, p = 0.16) total hospitalization costs (adjusted mean difference: $2237, 95% CI: $2308 – $6782, p = 0.49), and total hospitalization charges (adjusted mean difference: $7477, 95% CI: $8995–$24549, p = 0.39).

Conclusion: Bariatric surgery has no impact on inpatient all-cause mortality among patients who develop acute cholangitis, despite its association gallstone acute pancreatitis and limited ERCP performance. In addition, bariatric surgery does not affect resource utilization in this patient population as measured by length of stay and total hospital costs.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1391 PATHOLOGICAL, CLINICAL AND RADIOLOGICAL CHARACTERISTICS OF NEOPLASTIC AND NONNEOPLASTIC GALLBLADDER POLYPS
S. Z. Wemmacke1, A. Van Dijck2, J. Reasnais3, N. Hasami3, J.P. Drenth3, C. J.H.m. Van Laarhoven1, P. De Reuver1, I.D. Nagtegaal4

4Radboud University Nijmegen Medical Center, Radboud University Nijmegen Medical Center Dept. of Pathology, Nijmegen/Netherlands
Contact E-mail Address: sarah.wemmacke@radboudumc.nl

Introduction: Prevalence of gallbladder polyps in the Netherlands is 943 per 100,000 cholecystectomies. Histopathologically these gallbladder polyps can be divided into neoplastic polyps (with malignant potential) and nonneoplastic polyps (without malignant potential). Although cholecystectomy is only indicated for neoplastic polyps, 47% of polyps after cholecystectomy are nonneoplastic. Further information on the pathological characteristics and subsequent clinical and radiological features could be useful to predict neoplastic or nonneoplastic nature of the gallbladder polyp before surgery.

Aims & Methods: To assess pathological characteristics of neoplastic and non-neoplastic gallbladder polyps and identify preoperative clinic and radiological predictors for neoplastic and nonneoplastic polyps. Data of the Dutch Pathology Registry was used. In this search 2081 histopathologically proven gallbladder polyps (or (focal) wall thickening > 5mm) were identified in patients of ≥18 years undergoing primary cholecystectomy between 2003 and 2013. Of these
Disclosure of Interest: preoperative radiological investigations is poor. Nonneoplastic polyps are confirmed, identification of these characteristics on ultrasound was a predictor for neoplastic polyps (OR 6.00 (95%CI 1.32–27.31)). Size and type of polyp were often not mentioned in ultrasound report, or different from histopathological confirmation.

Conclusion: Except for age, no clinical characteristics for neoplastic polyps were identified in this cohort. Although pathological characteristics of neoplastic and nonneoplastic polyps are confirmed, identification of these characteristics on preoperative radiological investigations is poor.

Disclose of Interest: All authors have declared no conflicts of interest.

P1392 METFORMIN INDUCES APOPTOSIS AND MODULATES PROLIFERATION IN THE BILE DUCT CANCER CELLS

Introduction: Metformin has evidence of antineoplastic activity in some cancer cells.

Aims & Methods: This study was performed to demonstrate in the bile duct cancer cells whether metformin inhibits the proliferation of cancer cells by inducing apoptosis and affects the expression of gene-related proteins involved in cancer growth, and to identify how metformin affect molecular mechanisms involved in the inhibition of cancer cell growth. Human extrahepatic bile duct cancer cells were cultured. 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assays were performed to determine the effect of metformin on cell proliferation. Apoptosis was measured by a cell death detection enzyme-linked immunosorbent assay and caspase-3 activity assay. Various protein expressions with or without specific siRNA transfection were measured by Western blot. The migratory activity of the cancer cells was evaluated by wound healing assay.

Results: 1) Metformin suppressed cell proliferation in bile duct cancer cells by inducing apoptosis. 2) Metformin inhibited mammalian target of rapamycin (mTOR) by activation of AMPKThr172 - tuberous sclerosis complex 2 (TSC2) pathway, and hyperglycemia impaired metformin-induced AMPKThr172 activation and enhanced phosphorylation of AMPKSer485. 3) Metformin effects of GBC on growth factor 1 receptor (IGF-1R), insulin receptor substrate 1 (IRS-1) and AKT pathway on TSC2, and hyperglycemia impaired metformin-induced inhibition of IGF-1R-IRS-1-AKT pathway. 4) Metformin modulated invasiveness of bile duct cancer cells, and the effects was impaired by hyperglycemia.

Conclusion: This study shows that metformin has antineoplastic effect in bile duct cancer, and the effect of metformin is attenuated by hyperglycemia. This could be important targets for future development of chemotherapists.

Disclosure of Interest: All authors have declared no conflicts of interest.

2 Bioengineering And Technology, Gauhati University, Guwahati/India
3 Gastroenterology And Medicinal Uni, Central hospital, NF Rly, Guwahati/India
4 Tuberous sclerosis complex 2 (TSC2) pathway, and hyperglycemia impaired metformin-induced AMPKThr172 activation and enhanced phosphorylation of AMPKSer485. 3) Metformin impaired expression of PARP1 in GBC, CS and CL cases compared to controls; and in GBC cases compared to CL and CS cases. The mRNA expression of PARP1 in the tumour tissue of the patients with GBC was significantly increased compared to controls [OR = 1.986, p = 0.047]. Differential mRNA expression profile clearly showed a sharp down-regulation in hOGG1, APE1, polp and PARP1 expression in GBC, CL and CS cases compared to controls; and in GBC compared to CL and CS cases. The mRNA expression of PARP1 in GBC cases compared to controls; and most significantly for XRCC1 codon280 polymorphism in GBC cases compared to controls; and between 0–30%. Hyper-methylation of XRCC1 and hOGG1 promoter was noticeable in GBC cases compared to controls.

Conclusion: The data indicates an important role of oxidative stress in the pathogenesis of gall bladder diseases and progression to GBC in NEI population; which is due to genetic, expression and epigenetic deregulations in the key genes of the BER short and long patch pathway. The data also suggests the prognostic significance of BER pathway parameters, as well as potential therapeutic targets for the disease, and hence holds clinical relevance.

P1394 THE DEVELOPMENT OF NON-INVASIVE MOLECULAR DIAGNOSIS OF GALLBLADDER CANCER BY BILE JUICE-LIQUID BIOPSYP

H. Kinugasa1, K. Nousu2, S. Akó3, K. Matsuomo2, H. Kató2, H. Okada2

Introduction: Gallbladder cancer (GBCa) is often diagnosed at advanced stage due to asymptomatic disease. To overcome the weakness of current methods for the diagnosis of GBCa, we focus on the possibility of “liquid biopsy” with bile juice on the concept of non-invasive diagnostic method of early stage tumor DNA in blood. To achieve good treatment effect in future, so called “precision medicine” approach based on the character of the each tumor is mandatory.

Aims & Methods: Thirty patients with GBCa were enrolled in this study. Bile juice obtained from 24 of 30 patients was analyzed for mutations of 50 oncogenes (Cancer panel; Haloplex, Agilent Technology) by next generation sequencing (NGS; Illumina, San Diego, CA, USA). Tumor tissues from 20 of 30 patients were analyzed as well as bile juice. Each sample was obtained prior to the
treatment. As negative controls, 19 non-GBCa bile juice and 33 non-GBCa tissue samples were analyzed for mutations of 50 oncogenes in the same way.

Results: Mutations in tumor could be detected in bile juice using NGS. Liquid biopsy with bile juice may help us to diagnose GBCa because of high PPV (100%). It may allow us to make new genetic diagnosis of GBCa.

Disclosure of Interest: All authors have declared no conflicts of interest.

warranted ablative technique with direct effect to local tumor have been developed to improve the duration of self-expandable metal stents (SEMS) in the unresectable malignant biliary obstruction. However, there is the concern for the complication such as bile duct perforation or bleeding because the ideal power setting of RFA catheter is a bipolar device and has a temperature sensor within the distal tip, therefore it has a characteristic of target temperature controlled mode. Nine female pigs were divided into three groups according to RFA time variation (60, 90 and 120 seconds) with the same power setting (10 watts) and RFA target temperature (80°C). All pigs underwent endoscopic retrograde cholangiography (ERC) and intraductal cholangiography (IAC). Additional cholangiography was taken immediately after RFA and then a plastic stent was inserted. All the pigs were humanely sacrificed 24 hours after the intraductal RFA. Necropsy was performed and the common bile duct was sectioned for histologic analysis. The ERC and application of the intraductal RFA was successful in all pigs and ERC and IAC showed statistical significance of neoplastic potential of GBP in the modeling group. The predictive model for the probability of neoplasia was fitted from the training set using the logistic regression method equipped with backward elimination with significant level for removal of P > 0.05 for variable selection. The performance of a fitted prediction model was evaluated by the area under the curve (AUC) of a receiver operating characteristic (ROC) curve. A cutoff value of the fitted risk score was chosen by the Youden Index.

Conclusion: Clinical factors of older age, single lesion, sessile shape, and ppv size showed statistical significance of neoplastic potential of GBP in the modeling group. A predictive model for neoplastic potential of GBP was constructed utilizing the statistical outcome of the modeling group. Statistical validation was performed with the validation group to determine the optimal clinical sensitivity and specificity of the predictive model. Optimal cut-off value for neoplastic potential was 7.46%. *Probability of Neoplastic GBP poly = e^([−2.7182]/[1+e^([−2.7182][Size])]. Where e is the base of the natural logarithm and P (predictive score) = −7.3633 x 0.0374 x [Age] + 0.6667 x [Number] + 1.5784 x [Sex] + 0.2189 x [Size].

Conclusion: The predictive model for neoplastic potential of GBP may support clinical decision before cholecystectomy. Disclosure of Interest: All authors have declared no conflicts of interest.
DATABASE MANAGEMENT OF PANCREATOBILIARY DISORDERS: RESULTS P1399 DIGITAL, SINGLE-OPERATOR remain active years after surgery. PERIHILAR CHOLANGIOCARCINOMA: A PERSISTENT DILEMMA P1398 IGG4-ASSOCIATED CHOLANGITIS MIMICKING Our, so far the only full series analysis. The sensitivity and diagnostic accuracy of d-SOC guided biopsies for malignancy were 78.3% (95%CI, 56.3– 92.5), 96.4% (81.6–99.9) and 83.3% (70.7–92.1). The diagnostic accuracy of visual inspection was not statistically influenced by the presence of biliary stent (Yates’ χ²). Of 63 patients attended for d-SOC-guided stone therapy, a complete intraductal clearance was achieved in one session in 37 and in two sessions in further 10 patients, respectively and the overall success rate was 77%. A total of 11 patients (11/166; 6.6%) experienced an adverse event (cholangitis n = 6, pancreatitis n = 3, perforation n = 2), one patient with severe cholangitis died. The incidence of cholangitis was higher among patients who had received prophylactic antibiotics (n = 5) compared to those who had not received it (n = 1). The difference was significant (n = 5, n = 1, p<0.05). The sensitivity and diagnostic accuracy of d-SOC guided biopsies for IAC was 79.4% (95%CI, 62.9–93.2) and 90.6% (86.3–95.1) respectively. The new generation of d-SOC shows that (1) It provides high diagnostic yield in patients with undetermined biliary stenosis; (2) The SOC directed biopsies have a high diagnostic accuracy; (3) d-SOC guided stone lithotripsy is effective in three quarters of patients and (4) Some adverse events may occur and prophylactic antibiotics may not be effective in preventing post-d-SOC cholangitis. Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Our aim is to assess the incidence of Immunoglobulin G4-associated cholangitis (IAC) in patients resected for presumed perihilar cholan-giocarcinoma (PHC). All patients that underwent resection for presumed PHC at our institution between 1984 and 2015 were included. Benign histological speci-mens were re-evaluated by a pathologist and scored according to the interna-tional pathological consensus criteria for IgG4-RD. Patients with benign disease who were still alive were re-evaluated to assess IgG4 serum levels and IgG4/IgG RNA ratio to detect activity of IAC. Results: Between 1984 and 2015, 321 patients underwent liver and bile duct resections for presumed PHC. Of all patients 155 (47/321) were found to have benign disease on histological examination. 45% (21/47) of patients with benign disease had evidence of IAC after surgery based on histological criteria (n = 17) or laboratory parameters (n = 4). The remaining specimens showed unclassified sclerosing inflammation. Out of 12 patients with benign disease that were re-evaluated, 9 had ongoing active IgG4-RD requiring immunosuppressive treatment.

Conclusion: Benign single-operator cholangioscopy may have led to a considerable number of liver and bile duct resections during the last three decades. There was evidence of IAC in 45% of these patients. When left untreated, IgG4-RD can remain active years after surgery. Novel accurate diagnostic tests for IAC might reduce misdiagnosis and unnecessary surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: The aim of this retrospective analysis of prospective case series from the Czech and Slovak (n = 95) setting is to assess (1) diagnostic yield of d-SOC visual diagnosis and biopsies in patients with undetermined biliary strictures; (2) the efficacy of d-SOC directed treatment of difficult lithiasis and (3) to analyze procedure related adverse events (AEs). The primary outcomes were (1) sensitivity and specificity for malignancy without biopsies (2) achievement of a complete duct clearance in patients with diffi-cult lithiasis (3) procedure-related AEs. Results: A total of 150 patients underwent 166 d-SOC procedures (165 cholan-gioscopy and 1 pancreatoscopy); 81 (48.5%) for diagnostic intents (with biopsy in 66/81 patients (81.5%), and 85 (51.2%) for therapeutic intents (1 patient had pancreaticolithiasis). The most frequent indication for diagnostic d-SOC was undetermined stenosis (n = 59). Reliable views of a target lesion were obtained in all patients. The sensitivity, specificity and diagnostic accuracy of d-SOC for visual diagnosis of malignant lesion was 88.9% (95%CI, 70.8–97.7), 81.2% (65.6–92.3) and 84.6% (73.5–92.4). The mean number of biopsies obtained per patient was 4 (range 1–13) and the specimen was adequate for histopathological assessment. The sensitivity and specificity of d-SOC for malignancy was 78.3% (95%CI, 56.3– 92.5), 96.4% (81.6–99.9) and 83.3% (70.7–92.1). The diagnostic accuracy of visual inspection was not statistically influenced by the presence of biliary stent (Yates’ χ²). Conclusion: The results from this study suggest that cholangiocarcinoma in the Nile Delta region is significantly associated with high serum levels of heavy metals especially Cadmium and lead.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Primary outcome was the rate of endoscopic reintervention before surgery. Secondary outcomes were post-operative complications, hospital readmission, overall pancreatic fistula, overall biliary anastomotic leak, overall postoperative mortality. Clinical heterogeneity was assessed by I² value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Three RCTs and five non-RCTs were selected including 909 patients. Of these, 300 patients (33%) were treated with SEMS and 609 (67%) with plastic stents. The rate of endoscopic reinterventions after PBD was significantly lower in the metallic stent group compared to the plastic stent group (p = 0.0001). The rate of postoperative pancreatic fistula was significantly lower in the metal stent group (OR 0.44; 95% CI 0.20–0.96; p = 0.04). The overall pancreatic anastomotic leak was significantly lower in the metal stent group (OR 0.44; 95% CI 0.20–0.96; p = 0.04). The rate of postoperative surgical complications, hospital readmission, overall biliary anastomotic fistula and postoperative mortality did not differ between the two groups.

Conclusion: Metal stents are more effective than plastic and should be preferred when early surgery without PBD is not feasible. However, more RCTS are needed before a firm conclusion could be made.

Disclosure of Interest: All authors have declared no conflicts of interest.
Splenic vein, portal vein and superior mesenteric vein involvement were seen in vessels were involved in 19 (73.1%), 3 (11.5%) and 4 (15.4%) patients respectively. and mortality. None of the patients with SVT were given anticoagulation.

Aims & Methods: These patients were subjected to graphy (CECT) abdomen for presence of SVT. These patients were subjected to 2016 were prospectively evaluated with contrast enhanced computerized tomo-

Introduction: Extent of SVT in patients with AP as well as role of trombophilia in causation of factors, outcome and natural history. Coagulation abnormality has been impli-

Results: Factor V Leiden mutation analysis was done in 33 patients (14 with 5 (11.9%) patients respectively. Anticardiolipin antibody was negative in all the number of patients with SVT than those without SVT (96.2% vs 78.6%, and 92.3% vs 67.1%, respectively). Coagulation analysis was absence of necrosis, severity, organ failure, need for intervention and mortality. None of the patients with SVT were given anticoagulation. Follow-up ultrasound Doppler was performed to look for the status of SVT.

Results: Nine hundred patients with AP (73 males, mean age 31.85 ± 13.34 years) were evaluated of which 26 (27.1%) had SVT. Simple vessel, two vessels and three vessels were involved in 19 (73.1%), (3.115%) and 4 (15.4%) patients respectively.

Conclusion: SVT in AP is more common in patient with necrotizing pancreatitis and higher CTST and MCTSI indices suggesting that local inflammation plays a major role in its causation. Thrombophilia in some form is seen in one third of the patients with AP but does not increase the risk of AP. Disclosure of Interest: All authors have declared no conflicts of interest.

Current methods of risk stratification in AP have a limited value, as they are not able to predict the severity of AP in early phase of the disease. Evaluation of simple attainable potential prognostic parameters obtained at admission (or not later than 6–12 hours after-wards) from patients diagnosed with AP will be performed to assess their potential correlation with the disease severity. Approximately 1200 (900 + 300) patients from multiple centers will be enrolled into this trial using the Registry. This is an observational, multicenter, prospective cohort study for establishing a simple, easy and accurate clinical scoring system for early prognostication of acute pancreatitis.

Aims & Methods: We aimed to create a new scoring system, which can predict the severity of AP in early phase of the disease. Evaluation of simple attainable potential prognostic parameters obtained at admission (or not later than 6–12 hours after-wards) from patients diagnosed with AP will be performed to assess their potential correlation with the disease severity. Approximately 1200 (900 + 300) patients from multiple centers will be enrolled into this trial using the Registry. This is an observational, prospective cohort study (in the care or services that patients receive will not be altered); therefore it has a relatively low-risk. The study has an ethical approval by the National Hungarian Ethical Authority (ETT TUKEB). From multiple centers will be enrolled into this trial using the Registry. This includes all patients admitted with AP from January 2003 to December 2016, in a tertiary referral centre. Demographic and clinical variables from patients diagnosed with AP will be performed to assess their potential correlation with the disease severity.

Conclusion: Our data suggest a better efficacy of local antibiotics in the treatment of infected WON compared to systemic antibiotics. The local instillation of antibiotics need to overcome a number of limiting steps. First, antibiotics need to cross the capillary endothelium. Thereafter, antibiotics must diffuse to the microbial pathogens. The anti-microbial efficacies of local and systemic antibiotics were evaluated using uni- and multivariate logistic regression analyses and Kruskal-Wallis test by stratification of the isolates in sensitive versus not sensitive/antibiotics not given.

Results: Ninety-one patients were included. At the first drainage 81 (86%) patients had infected and 10 sterile WON. A total of 139 isolates were found at the first drainage. Most patients were infected with enterococci (44%) or other gram-positive cocci. More than a quarter of the infected patients had fungal species cultured. The infected patients often had polymicrobial infections (56%). At the second culture 152 isolates were found. Neither local nor systemic antibiotics were associated with the eradication of microbes between first and second culture. Between second and third culture, the use of local antibiotics was associated with the eradication of microbes (OR = 2.54, P = 0.011), but not systemic antibiotics (P = 0.33) (Table). Between first and second culture 12 patients with fungal infections were treated with local amphotericin B. In all 12 patients the fungus was eradicated. After second culture 20 patients were treated local amphotericin B and in 17 (85%) patients the fungus was eliminated at the third culture.

Aims & Methods: The aim was to evaluate the efficacy of local instillation of antibiotics into walled-off pancreatic necrosis. Between 2012 and 2016 we evaluated all patients treated with endoscopic transmural drainage and necrocytostomy (EDTN) and concomitant local instillation of antibiotics. We added antibiotics (either gentamicin, vancomycin, or amphotericin B) to the irrigation fluid according to the microbiological findings. The anti-microbial efficacies of local and systemic antibiotics were evaluated using uni- and multivariate logistic regression analyses and Kruskal-Wallis test by stratification of the isolates in sensitive versus not sensitive/antibiotics not given.

Results: Ninety-one patients were included. At the first drainage 81 (86%) patients had infected and 10 sterile WON. A total of 139 isolates were found at the first drainage. Most patients were infected with enterococci (44%) or other gram-positive cocci. More than a quarter of the infected patients had fungal species cultured. The infected patients often had polymicrobial infections (56%). At the second culture 152 isolates were found. Neither local nor systemic antibiotics were associated with the eradication of microbes between first and second culture. Between second and third culture, the use of local antibiotics was associated with the eradication of microbes (OR = 2.54, P = 0.011), but not systemic antibiotics (P = 0.33) (Table). Between first and second culture 12 patients with fungal infections were treated with local amphotericin B. In all 12 patients the fungus was eradicated. After second culture 20 patients were treated local amphotericin B and in 17 (85%) patients the fungus was eliminated at the third culture.

Table: EASY score may be an easy and accurate system to evaluate the early severity of AP in early phase of disease. Evaluation of simple attainable potential prognostic parameters obtained at admission (or not later than 6–12 hours after-wards) from patients diagnosed with AP will be performed to assess their potential correlation with the disease severity. Approximately 1200 (900 + 300) patients from multiple centers will be enrolled into this trial using the Registry. This is an observational, multicenter, prospective cohort study for establishing a simple, easy and accurate clinical scoring system for early prognostication of acute pancreatitis.

P1412 CORONARY DISEASE AND CHRONIC OBSTRUCTIVE PULMONARY DISEASE ARE NOT ASSOCIATED WITH WORSE OUTCOME IN ACUTE PANCREATIS

J.R. Carvalho, P. Santos, S. Fernandes, M. Moura, T. Antunes, J. Velosa

Department Of Gastroenterology And Hepatology, North Lisbon Hospital Center, University of Lisbon, Portugal; Lisbon, Portugal

Contact E-mail Address: joana.rita.carvalho@gmail.com

Introduction: Pancreatitis is a disease of protein manifestations. In its more severe form, involvement of any organ is possible. Cardiovascular and respiratory failure are possible and feared complications.

Aims & Methods: The aim of this study was to evaluate the effect of chronic ischemic heart disease and chronic obstructive pulmonary disease (COPD) in the outcome of acute pancreatitis (AP). In our population. Retrospective cohort study that included all patients admitted with AP from January 2003 to December 2016, in a tertiary referral center. Demographic and clinical variables were analyzed by logistic regression (SPSS v23). Clinical outcomes included organ failure (OF), persistent OF (≥ 48 h), intensive care unit (ICU) admission and mortality.

Results: A total of 553 patients with AP were included, 58.4% male, median age 80 (18–98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.3%). Twenty-three percent (n = 129) developed OF (in 43% persistent) and 26.8% (n = 148) were admitted in ICU. Mortality rate was 5.6% (n = 31). Fifty-six patients (10.1%) had previous history of coronary disease and 5.1% (n = 28) had been diagnosed with COPD. The presence of coronary disease and COPD were not associated with higher Ranson’s score (≥ 3), p = 0.076 and p = 0.959, respectively. No association was found between previous history of coronary disease and the development of OF (p = 0.525), persistent OF (p = 0.287), need for ICU admission (p = 0.115) and mortality (p = 0.262). There was also no association found between previous history of OF and the development of OF (p = 0.803), persistent OF (p = 0.588), need for ICU admission (p = 0.514) and mortality (p = 0.720). At multivariate analysis (correcting for age and gender) coronary disease and COPD were not independent predictors of worse outcome in AP.

Conclusion: In our population, previous history of coronary disease and COPD were not predictors of worse outcome in AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1411 EVALUATION OF LOCAL INSTILLATION OF ANTIBIOTICS IN WALLED-OFF PANCREATIC NECROSIS

Contact E-mail Address: hkp835@alumni.ku.dk

Introduction: Infected walled-off pancreatic necrosis (WON) is treated with antibiotics in order to reduce the bacterial loads in WON, systemically administered antibiotics need to overcome a number of limiting steps. First, antibiotics need to cross the capillary endothelium. Thereafter, antibiotics must diffuse across the interstitial space and finally, the capsule surrounding the WON must be crossed. Therefore, the penetration of the intravenously administered antibiotics into WON can be questioned. Using local antibiotics should theoretically increase the antibiotic concentrations in the necrotic tissue and the efficacy.
P1413 WORSE OUTCOMES IN ACUTE PANCREATITIS IN PATIENTS WITH TYPE-2 DIABETES MELITUS

P. Santos, J.R. Carvalho, S. Fernandes, M. Moura, T. Antunes, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, Lisboa/Lisbon

Contact E-mail Address: patricia.sants@hotmail.com

Introduction: Predicting severe pancreatitis is important for early aggressive management of patients with acute pancreatitis (AP). Despite the established role of type-2 diabetes mellitus (DM) in the risk of AP, the impact of DM on the clinical outcome in AP has not been fully elucidated.

Aims & Methods: Retrospective study including hospital admissions between January 2003 and December 2016 in a single tertiary referral center. Clinical outcomes included organ failure (OF), persistent OF (>48h) admission to intensive care unit (ICU) and mortality. Variables were analysed by logistic regression (SPSS v23.0). The objective of this study was to assess the risk of mortality and severity in AP among patients with type-2 DM.

Results: A total of 553 patients (58.4% male) with AP were included, median age 80 (18–98) years. Most common etiologies included gallstones (38.9%) and alcohol (27.5%). Twenty three percent developed OF (in 43% persistent) and 5.6% (n=30) died. There were 127 AP patients (23.0%) with type-2 DM. Type-2 DM were not associated with higher Ranson's score. There was an association between DM and development of OF (OR 3.17, CI95% 1.88-5.37, p < 0.001), persistence (OR 45.1, CI95% 18.7-108.9, p < 0.001), ICU admission (OR 12.3, CI95% 5.4-29.1, p = 0.001), and mortality (OR 17.1, CI95% 6.8-42.8, p < 0.001). At multivariate analysis DM was an independent predictor of OF development and ICU admission.

Conclusion: In our population, Type-2 DM was associated with severity and increased mortality in patients with AP. Our findings provide evidence of the potential role of DM in the management of severe AP.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute pancreatitis (AP) is an uncommon but potentially devastating condition that may occur in patients with organ transplantation. Reported incidence ranges from 1.5 to 8% in patients undergoing liver transplantation with significant mortality.

Aims & Methods: The aim of our study was to assess the incidence, potential risk factors and outcome of AP following liver transplantation in our center. We performed a retrospective analysis of medical records of all adult patients who underwent liver transplantation in our center between September 1996 and November 2014. The diagnosis of AP was defined by combination of clinical manifestation, finding on imaging methods (CT, USG) and elevation of serum amylase and lipase.

Results: Nine hundred and sixty-seven orthotopic liver transplantations were performed in 578 males and 389 females (mean age 51 years, range 18–74). AP occurred in 18 patients (1.9%, 16 males, 2 females) and resulted in death in 5 patients (28%). According to timing of AP we recognized two clinical presentation—early AP (<1 month after liver transplantation) and late (>1 month). Four patients (22%) developed early AP, which was severe necrotizing with MODS in all cases and resulted in death in 3 of them (75%). Two of them were transplanted for fulminant hepatic failure, one for end-stage liver disease caused by diabetic hepatitis B infection and one for polycystic liver disease. Two patients were treated by surgical necrosectomy and died, the third deceased patient was treated conservatively. In the only surviving patient, a successful EUS-guided drainage of walled of pancreatic necrosis and repeated endoscopic retrograde cholangiopancreatography (ERCP) were performed in 578 males and 389 females (mean age 51 years, range 18–74). AP underwent liver transplantation in our center between September 1996 and November 2014. The diagnosis of AP was defined by combination of clinical manifestation, finding on imaging methods (CT, USG) and elevation of serum amylase and lipase.

P1415 THE IMPACT OF BILIARY SLUDGE TO DEVELOPMENT OF PAIN AND EFFICACY OF HYMEOCRомIN IN CHRONIC BILIARY PANCREATITIS

M. Okhlobystin1, K. Poc2, P. Trunecka3, J. Spicak1, T. Hucl1

Introduction: Biliary sludge (BS) may be one of the factors, related to development of chronic pancreatitis (CP) via sphincter of Oddi dysfunction. As it was demonstrated by Okazaki K et al. in 1988, patients with biliary sludge have higher sphincter of Oddi (SO) pressure and contraction frequency vs. controls.

Aims & Methods: To assess the frequency of CP signs in patients with BS and to investigate the state of major duodenal papilla (MDP) in patients with idiopathic CP with BS by endoscopic ultrasound (EUS); to evaluate whether antispasmodics can be effective in pain relief at CP, that developed on the background of gallbladder sludge. Protocols of computer tomography, endoscopic and transgalominal ultrasound studies of over 6000 patients of gastroenterological tertiary clinic were examined. Those who had signs of BS were selected to evaluate the presence of CP and at least “mild CP” and BS. To the modified Cambridge classification. Exclusion criteria were: established etiology of CP and signs of pancreatic neoplasms. Patients, who received ursodeoxycholic acid and drugs that affect smooth muscle contractility for less than 3 month prior to the study were excluded. Thirty consecutive patients (15m, 15 f, age mean±SD: 52.8 ± 15.3), who had both BS and CP were summoned for physical examination, quality of life assessment, US-cholangioscopy and endoscopic pancreaticbiliary ultrasound. Calculation of MDP area formula: $S_{MDP}=(h_{MDP} \times w_{MDP})^{(2.172)}$ and state of MDP before and after 3 weeks of hy Gemcrомin monotherapy 400 mg tid.

Results: Signs of CP were revealed in 6.3% of BS cases. CP was most common in those who had ointment-like bile (33.3%) vs. patients with heterogeneous bile with clots –7.7% and hypoechoic particles–1.7% (chi-square 38.21, p < 0.0001). Mean $S_{MDP}$ was 14.9 ± 5.2 mm$^2$ (95%CI 10.9–18.9). $S_{MDP}$ was below the normal range (20–25 mm$^2$) in 78% of patients. $S_{MDP}$ had positive correlation to the velocity of evacuated bile according to US-cholangioscopy (r=0.042) and gallbladder contractility coefficient (r=0.817, p < 0.007). All patients with higher density of MDP at US-cholangiostomy had $S_{MDP}$ lower than the normal range and were attributed to “fibrosis” group. Only 38% of patients with CP and BS had normal MDP at EUS. Periapillary diverticula were found in 13% of the cases, papillae edema — in 38%, fibrosis — in 13%. MDP changes were associated with higher AP level and larger MDP diameter. Hy Gemcrомin monotherapy resulted in significant improvement in abdominal pain (bodily pain $t=7.92$, p = 0.0008 and bodily pain ‘scent’ of SF-36 questionnaire ($t=3.709$, p = 0.001). Dynamics of “bodily pain” score by SF-36 demonstrated significant negative correlation to the post-treatment level of abdominal pain ($r=0.395$, p = 0.037) Post-treatment pain level had significant negative correlation with $S_{MDP}$ size ($r=0.067$, p = 0.002), though no correlation of pre-treatment pain level to MDP features was found, i.e. patients with less MDP size (most of them had decreased elasticity of papilla of Vater, that was considered as indirect marker of fibrosis) had lower hy Gemcrомin efficacy.

Conclusion: BS may cause MDP changes, resulting in development of obstructive CP. Intensity of pain in biliary CP may be related to sphincter of Oddi dysfunction. Efficacy of antispasmodic therapy in these patients could be predicted by the features of MDP at pancreato/biliary EUS.

Introduction: Pancreatic exocrine insufficiency is a late complication of chronic pancreatitis; its clinical onset is characterized by steatorrhea and weight loss, borrobygmi, flatulence, abdominal pain and malnutrition. Exocrine and endocrine pancreatic function decreases differently in various diseases (autoimmune, paradoedunal, genetic, idiopathic). It has been observed that there has been a recovery of exocrine pancreatic function in autoimmune pancreatitis. In the literature there are no studies analysing the exocrine pancreatic function over time. The fecal elastase test is a good test procedure to evaluate the exocrine pancreatic function.

Aims & Methods: The objective of the retrospective study was to re-evaluate a series of patients with chronic pancreatitis with the aim to evaluate the pancreatic exocrine function over time, in particular, by comparing the exocrine pancreatic function in subgroups of patients with different types chronic pancreatitis. Pancreatic exocrine function was estimated through fecal elastase in 143 patients with at least 2 values each (classified into normal, mild and severe exocrine pancreatic insufficiency), the first one taken at the diagnosis of chronic pancreatitis. Patients undergoing surgical pancreatic resection before the second value of fecal elastase were excluded. Etiology was classified in: biliary pancreatitis/sequelae of necrotizing pancreatitis (15), autoimmune (69), paradoedunal (15), genetic (17) and idiopathic (27).

Results: The results show a high frequency of severe exocrine pancreatic insufficiency in the moment of diagnosis of chronic pancreatitis (38%) and it appears stable over the years. Autoimmune and paradoedunal chronic pancreatitis are correlated with severe exocrine pancreatic insufficiency at diagnosis in a high percentage of cases (51% and 40%), biliary/outcomes of necrotizing pancreatitis and idiopathic pancreatitis in an intermediate (33% and 26%), while genetic in a low percentage (12%).

Conclusion: The exocrine pancreatic function in patients with autoimmune pancreatitis improved in the first five years of the disease, probably due to the efficacy of steroid/inmunosuppressive therapy. Pancreatic endocrine function was less compromised at diagnosis, but showed a progressive deterioration in the first five years. Endocrine and exocrine insufficiency were strictly correlated.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1417 "PAINLESS" CHRONIC PANCREATITIS: EPIDEMIOLOGICAL, CLINICAL AND RADIOLOGICAL CHARACTERIZATION

Introduction: The term "painless" chronic pancreatitis (CP) represents a specific subset of CP characterized by the lack of pancreatic pain. So far, scarcity of data has been reported in the literature about this matter and what differentiates this group of patients from those with chronic pancreatitis associated with pancreatic pain.

Aims & Methods: The aim of the present study is to characterize "painless" CP from the epidemiological, clinical, radiological, functional, and follow-up standpoint, through a comparison with other forms of chronic pancreatitis presenting with pancreatic pain. The Institutional Database of the Gastroenterology Unit of the Verona University was queried, and all chronic pancreatitis cases were retrieved. Patients were clustered based on the presence of "pancreatic-specific pain" into "painless" and "pain-associated" CP. A retrospective case-control analysis was carried out.

Results: Of 678 patients included from March 2006 to March 2016, 436 were considered eligible for the present study. Of these, 368 (84%) were affected by pain-associated CP, while 68 (16%) had "painless" CP. "Painless" patients were older (median age of 58.5±10.8 vs 42.5±15.3 y-o; p < 0.001), less frequently presenting with a history of alcohol consumption (35% vs. 55%; p < 0.001), more frequently diabetics (18% vs. 1%; p < 0.001), presenting with steatorrhea (16% vs. 2%; p < 0.001), and asymptomatic (63% vs. 2%; p < 0.001) compared to pain-associated controls. From the radiological standpoint, cases were more frequently presenting with calcifications than controls (90% vs. 68%; p < 0.001). Moreover, in most of painless cases, the CP cause remained unknown (56%). After a median follow-up of 2.6±2.3 years, the incidence of diabetes was higher in the painless cases than in controls (48% vs. 30%; p < 0.006).

Conclusion: The present study represents the first definition of "painless" CP so far reported in the literature. The "painless" CP is a distinct entity from the epidemiological, clinical, and radiological standpoint when compared to other forms of CP characterized by pain.

Introduction: Recently, EUS-guided pancreatic duct drainage with transmural stent (EUS-PD) has been used for patients with painful obstructive pancreatitis in whom endoscopic retrograde panreatography (ERP) has failed. Although the feasibility and safety of EUS-PD with a fully covered self-expandable metal stent (FCSEMS) has been assessed, little is known about the long-term outcomes of EUS-PD with a covered self-expandable metal stent (FCSEMS). Removability of an FCSEMS in long-term use and higher cost are the main concerns of EUS-PD compared with EUS-PD with a plastic stent.

Aims & Methods: The aim of this study is to evaluate the procedural and long-term outcomes of EUS-PD with an FCSEMS for patients with painful obstructive pancreatitis in whom endoscopic retrograde panreatography (ERP) has failed. Forty-one consecutive patients with painful obstructive pancreatitis underwent EUS-PD with an FCSEMS after ERP. Management without stent exchange was considered in malignant MPD strictures or complete MPD obstruction in benign pancreatic stricture. Technical and clinical success, adverse events, and stent patency were assessed. An endoscopic examination and CT scan was performed every 6 months to assess stent patency in benign stricture.

Results: 15 patients had malignant MPD obstruction and 26 patients had benign stricture. EUS-PD was successful in all 41 patients (technical success rate, 100%), and symptoms improved in all patients (clinical success rate, 100%). EUS-guided pancreaticojejunostomy (n=39) and pancreaticojejunostomy (n=2) were performed in malignant MPD obstruction. Pain scores improved significantly after FCSEMS placement (P < .01). Early mild-grade adverse events occurred in 5 patients (12.2%), involving distal stent fracture (n=6), stent occlusion (n=2). These patients were successfully treated endoscopically. No other adverse events related to FCSEMS, including stent migration, pancreatic sepsis, and stent-induced ductal stricture were observed during follow-up periods.
Overall mean stable duration was 412 days (range 14–1081) during mean follow-up period (2.41). Median stable duration in CP patients with malignant stenosis was 95 days (range 14–297). Mean stable duration in benign strictures was 252 days (range 121–1081). No patients with malignant strictures required FCEMSs revision or exchange during follow-up periods. FCEMSs removal and exchange was successful in benign strictures with stent dysfunction. At the end of the follow-up, two patients (5.6%) showed resolution of stricture after definite stent removal.

Conclusion: EUS-PD with an FCEMS showed excellent long-term outcomes for patients who failed conventional ERP in both malignant and benign obstructing pancreatic ducts. Endoscopic FCEMSs removal and exchange could be successful in patients with benign strictures until 3-year placement of an FCEMS. Prospective randomized trial comparing EUS-PD with FCEMSs and plastic stents may be warranted for painful obstructive pancreatitis after failed ERP.

Introduction: Fundamental aspects in the treatment of pancreatic exocrine insufficiency (PEI) include pancreatic enzyme replacement therapy (PERT). Monitoring the symptoms of malabsorption as well as the nutritional markers is essential.

Aims & Methods: To follow-up patients with PERT receiving PERT and to provide normal nutritional status by optimizing the suboptimal PERT if necessary. Study enrolled 142 patients (88 males, mean age 52 years): 82 patients had chronic pancreatitis (CP), 30 acute pancreatitis (AP), 30 pancreatic cancer/pancreatic resection. 58 patients were re-monitored 6 months after adjusting suboptimal PERT if necessary. Study monitored the symptoms of maldigestion as well as the nutritional markers is essential.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The mRNA binding protein HuR is involved in the post-transcriptional regulation of cytoprotective molecules, such as HO-2, H1 and inhibitors of apoptosis proteins (IAP1, IAP2, XIAP, survivin), and might be related to poor prognosis in numerous cancer types. However, the association of HuR, COX-2, HO-1 and IAPs family, and their impact on chemoresistance and carcinogenesis in PDAC still remain unclear.

Aims & Methods: The aim of our study was to assess the relevance and correlation of the IAP regulation by mRNA stabilizing protein HuR and HO-1 and/or COX-2 signaling pathway, and to determine the association with clinicopathological parameters and prognosis of PDAC. Data of 32 patients after pancreatectoduodenectomy undergoing adjuvant chemotherapy between 2011–2016 were analyzed. Patient’s mRNA expression levels of HuR, COX-2, HO-1, IAP1, IAP2, Survivin and XIAP, as well as their respective correlations with clinicopathological parameters were analyzed. The Kaplan-Meier method and log-rank tests were used for univariate analysis. Cox proportional hazard model was applied to identify prognostic factors that were independently associated with survival.

Results: HO-1, COX-2, HuR, IAP1, IAP2 mRNA expression were accordingly 3-fold, 8.8-fold, 1.5-fold, 4.8-fold and 5-fold higher, while XIAP and Survivin mRNA expression were 5.8-fold and 3.4-fold lower when compared to normal pancreatic tissue. Expression of HuR was positively associated with COX-2, HO-1, IAP1, IAP2, XIAP. High expression levels of HuR were significantly correlated with higher G stage and microvascular invasion, while high levels of XIAP were negatively associated with microvascular and perineural invasion. Univariate analysis revealed that expression of HO-1 or XIAP, tumor differentiation and perineural invasion were significantly associated with overall survival (OS) of PDAC patients. In multivariate analysis, high levels of HuR, lymph-node metastases, tumor differentiation and perineural invasion were independently correlated with lower OS in patients with PDAC.

Conclusion: Our results suggested that upregulation of HuR in PDAC patients were significantly related with poor outcome. Even though, significant correlation with IAP proteins in PDAC was noticed, more data is needed to analyze the mechanism underlying HuR and IAP interaction.

Introduction: Hypoxia-induced reprogramming of cell energy metabolism and changes in glycosylation are hallmarks of cancer promoting the induction of an invasive and treatment-resistant phenotype, triggering metastases at an early stage of tumor development.1 We examined the impact of hypoxia on O-GalNAc glycosylation in human HEK293, PDAC cell lines and clinical specimens and its link to cancer progression.

Aims & Methods: We profiled the expression of 88 glycosylation related genes by qPCR in HEK293 cells subjected to hypoxia either induced by 1% O2 or 200 mM CoCl2 identifying key O-GalNAc glycosyltransferases downregulated. Functional assays and glycoprotein analysis displayed a pronounced rate of O-GalNAc modified cytosolic proteins derived from hypoxia-treated cells and PDAC specimens. Glycosidase assays could validate specificity of detection method used. Aberrant glyctype could be induced by IFH pathway activator

Conclusion: Proper follow-up and correction of suboptimal PERT as well as management of the risk of severe malnutrition complications and associated morbidity and mortality by ensuring optimal therapeutic results and better quality of life.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1422 THE EXPRESSION AND FUNCTION OF MIR-195 IN PANCREATIC CANCER: THE EXPRESSION AND FUNCTION OF MIR-195 IN PANCREATIC CANCER
Y. Zhang, Q. Zhan
Digestive Department, Wuxi People’s Hospital, Wuxi/China
Contact E-mail Address: zhangq33@163.com

Introduction: Pancreatic cancer is one of the more common malignant tumors in digestive system. The mortality and survival rate are then about 5-6% of pancreatic cancer. Pancreatic cancer with poor prognosis and survival rate is low, due to the early clinical symptom is not easy to find, have a high transfer possible, and the operation difficulty, radiotherapy and chemotherapy is not sensitive. Radical surgical resection is the only opportunity to pancreatic cancer patients get cure. It is an urgent problem for us to explore new effective treatment of pancreatic cancer.

Aims & Methods: Pancreatic cancer is a highly malignant tumor and fourth leading cause of cancer-related death in the world. The median survival after diagnosis is 2-8 months, and approximately 3-6% of all patients with pancreatic cancer survive 5 years after diagnosis. This is mostly due to the fact that it is diagnosed at a stage when it is either locally advanced or has already metastasized to other organs. Hence, there is a paramount need to understand the molecular mechanisms underlying its initiation, progression and therapy. The recent discovery of microRNAs (miRNAs) has revealed a novel mechanism of gene regulation and provided new ways for cancer research. MicroRNAs are small, non-coding RNA molecules, which regulate the gene expression at post-transcriptional level. It is widely reported that miRNAs can act as oncogene or tumor suppressor gene. MIR-195 has been recognized as a tumor suppressor gene and cell growth.

Result: The purpose of this experiment was to explore the regulation role of miR-195 in PC development process. We measured miR-195 expression in three pancreatic cancer cells (PANC-1, SW-1990 PANC 03.27) by QR-T - PCR, and HPDE cells were used as a control. We performed study of miR-195 by transfecting PANC-1 cells with miR-195 mimics. We used miRNA QR-T - PCR to study the transfection efficiency of miR-195 mimic. The behavior studies of PANC-1 cells transfected with miR-195 and negative control were analyzed by CCK-8 proliferation assay, cell cycle, cell migration and invasion assay. We performed Real-Time PCR and western blot to detect the expression of CDK4 Cyclin E1 in PANC-1 cells which were transfected with miR-195 mimics and negative control.

Conclusion: We found that miR-195 is decreased in three pancreatic cancer cells (PANC-1 SW-1990 PANC 03.27). We also found that over-expression of miR-195 could suppress the proliferation, migration, invasion and cell cycle of PANC-1 cells. That means the malignancy potential of PANC-1 cells is inhibited by miR-195.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The progression of pancreatic ductal adenocarcinoma (PDAC) is promoted by its highly abundant tumor stroma. As one of the main components of the tumor stroma human pancreatic stellate cells (hPSCs), precursors of pancreatic tumor stromal myofibroblasts (CAFs), support PDAC progression by enhancing tumor cell growth, invasion and metastasis [1]. The collagen binding transmembrane receptor integrin α11 (ITGA11) is known to be overexpressed in myofibroblasts [2].

Aims & Methods: The aim of the presented study was to investigate the expression of ITGA11 in human PDAC and to study the role of ITGA11 in CAF regulation. ITGA11 expression was evaluated using immunostaining on human PDAC sections and various cell lines. The relationship between ITGA11 expression and activation was assessed in PDAC cell lines. The expression of ITGA11 was also analyzed in a patient derived PDAC xenograft model.

Results: The expression of ITGA11 in human PDAC specimens was positively correlated with ITGA11 expression and activation. In this study we have for the first time stained ITGA11 in human PDAC tumors. The quantitative gene and protein expression analyses of ITGA11 in subcutaneous tumors, positively correlated with the expression of the CAF markers α-SMA, Col1a1 and PDGFβR. Activation of hPSCs with TGF-β or conditioned medium from P1-1 resulted in the significant upregulation of ITGA11 and α-SMA. Stable ITGA11 knockdown, mediated by shRNA, significantly inhibited hPSC differentiation, migration potential, contractility and cell growth.
P1425 EFFECT OF ACOUSTIC CAVITATION ON A THREE-DIMENSIONAL CULTURE MODEL OF PANCREATIC ADENOCARCINOMA

Introduction: The dismal prognosis of pancreatic ductal adenocarcinoma (PDAC) is mainly due to chemoresistance linked to the tumor microenvironment. Recent developments in the field of ultrasound (US)-induced cavitation could help overcome chemoresistance by break microenvironmental barriers and increase cytotoxic drug availability. Three-dimensional (3D) culture in the form of spheroids is a useful model for reproducing multicellular resistance and analyzing the effects of cavitation.

Aims & Methods: The objective of this work was to study the effects of acoustic cavitation on a model of PDAC spheroids and to investigate possible potentiality of chemotherapy by US. CAPAN-2 PDAC cell line-derived spheroids were cultured as previously described by Iwasa et al. Four conditions, i.e. control, 400 mM-gemcitabine-based chemotherapy (CT) alone, US alone, CT-US combination (n=12 spheroids per condition), were studied. Experiments were carried out to optimize US settings, in order to observe the occurrence of controlled acoustic cavitation. Comparisons between groups were based on proliferation and growth. Proliferation was evaluated 24 hours after treatment(s) by Uptiblue. Growth was assessed by diameter measurement on light microscopy at day 7 and day 10.

Results: Compared to the control group, cell proliferation was decreased in spheroids treated with CT (p<0.0001), but not with US alone. Proliferation was also further impaired in spheroids treated with US combination compared to those treated with CT alone (p<0.0001), but this synergistic effect of US and CT did not impact growth of spheroid, meaning that spheroid diameter did not decrease after US-CT compared to CT alone.

Conclusion: This study shows the feasibility of applying an ultrasonic treatment (acoustic cavitation) in a three-dimensional culture model of PDAC. The combination of CT and ultrasonic cavitation synergistically reduced cell proliferation. Further analysis of the cytotoxic effects of acoustic cavitation on PDAC spheroids is in progress.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Because of the progression of systemic chemotherapies (CT) for locally-advanced pancreatic cancer (LA-PC), chemoradiotherapy (CRT) was selected for limited case. However, very long survival cases were reported in CRT and detection of prognostic factors were warranted. In this analysis, we analyzed the LA-PC cases received CRT compared with CT.

Aims & Methods: Gemcitabine (GEM) and S-1 combination chemoradiotherapy (GS-CRT) was performed according to our previous Phase 1 trial (Journal of Japan Pancreas Society 2010). Till March 2016, 30 LA-PC cases received GS-CRT, and the selection criteria were LA-PC with 1) pathological diagnosis, 2) laço therapy (CA, SMA, CCA, PV), 3) radiologic invasion (3) allogeneic and concomitant GRP without multiple primary cancer, 4) unexecuted autotumor therapy. The chemotherapy in CRT administration of GEM (200mg/m²) once a week for 5 weeks and total dose was 50.4Gy (Total 28 times). As after treatment, GEM 1000mg/m² was continued until PD. The patients of CT group were also recruited by the same criteria. One of the regimens among GEM alone, S-1 alone and GEM+S-1 was selected for the primary treatment, and total 26 cases were implemented in more than 2 courses.

Results: Baseline characteristics in CRT and CT group were median age (62, 72.5: p = 0.004), male (20, 12: ns) and tumor location (Ph/Pb (17/13), 16/10; ns), respectively. Efficacy were disease control rate (DCR) in 3 months after treatment (90, 57.7%; p = 0.01), response rate (RR) (26.7%, 0%: p = 0.005) and conversion surgery (10%, 0%; ns). There were significant differences in progression free survival (PFS) (6 months, 5 months; p = 0.002) and overall survival (OS) (13M, 9M: p = 0.0165), respectively. The cases who survived for 18 months and longer were significantly (p = 0.0495) more in CRT (43.3%) than CT group (19.2%). Grade 3/4 adverse events in CRT group were 13 cases of neutropenia (G4-3 cases) and one case of gastrointestinal symptom, and those in CT group, respectively. Conclusion: For LA-PC, GS-CRT showed better local tumor control and longer survival, and was considered as good candidate of neo-adjuvant therapy. More long survival cases were reported in CRT, and other benefit for LA-PC, we should think about good selection criteria of CRT and improve the survival of LA-PC.

Introduction: Intraductal papillary-mucinous neoplasm (IPMN) is a heterogeneous group of pancreatic tumors mucin-producing with uncertain biologic behavior. We know, nowadays, that they can be also considered as a precursor of pancreatic carcinoma (PAC), one out of these lesions will develop into a malignancy of different types. There are no established guidelines for pathologic diagnosis/reporting of IPMN.

Aims & Methods: The aim of this study was to analyze the IPMN subtypes distribution related with clinicopathological, histologic and immunohistochemical and identify which one is more related to development of malignancy. This pathological study was 3-year-follow up, with consecutive patients, where we analyzed the clinical findings, radiological aspects, and morphologic features in patient’s suspects of IPMN or PAC undergoing to pancreatic surgery. The lesion was classified based on morphological and immunohistochemically defined by the current WHO criteria.

Results: We analyzed 28 patients (16 women), mean age 66.6 years (range 50-83). 15 (53%) patients were asymptomatic, and 13 (47%) showed abdominal pain (8), chest pain (4), and recurrent acute pancreatitis (1). 10 patients were submitted to subtotal pancreatectomy, 9 to duodenopancreatectomy, 7 to gastroduodenopancreaticojejunostomy, 2 subtotal gastrectomy and spleenectomy. The lesion was located in head, body and tail, and entire pancreas in 18, 9, and 1, respectively. 14 patients (50%) had involvement of the main pancreatic + branch ducts (mixed type), 7 (25%) had only the main pancreatic duct involved, 6 (21.5%) had only the branch-duct involved, and 1, (3.5%) and if not informed. The mean size of the lesion was 3.3 cm ± 6.1 (1-11 cm). Morphologic features showed multi-loculated (23 solid-cystic) (4) and solid (1). The immunohistochemically expressed MUC1, MUC5AC, and MUC2 in 18 (64.2%), 7 (21.5%) and 4 (14.2%), respectively. The hispathotologic patterns founded was gastric-type (9), Intestinal-type (3), Pan-creatobiliary-type (9), mixed-type (6), and Pancreatobiliary-type (9), mixed-type (6) (Pb-t + I-4 (4), and Pb-t + G-t (2), and cytotic-type (1) (table 1). The IPMN with a low-grade, and high-grade dysplasia and invasive carcinoma was found in 18 (64.2%), 6 (21.5%) and 4 (14.2%), respectively. We observed that all the pancreatic intraepithelial neoplasic (PanIN) founded was related to Pb-t (13±6). The invasive PAC was presented in 4 patients (14.2%) with the follow subtypes (Pb-t 2), and (Pb-t + I-1 (1)), and collord PAC [I-6 (1)] (table 2). Was found a synchronic neoplasia in 2 patients (follow subtypes adenocarcinoma, and IPMN). Conclusion: IPMN of the pancreas is a common cystic lesion located more frequent on both duct (mixed-type), showing more aggressive behavior than others pattern. In the more common lesion and were more connecting to invasive PAC and HGD, as well as connected with PanIN. MUC stains are helpful for the diagnosis and papillary histological subtyping. Prospective studies are needed to confirm these findings.

Introduction:
Pancreatic ductal adenocarcinoma (PDAC) has a dismal prognosis with a median 5-year survival rate below 5% [1]. Patients presenting with resectable neoplasms derive only a limited benefit from surgery. Neoadjuvant therapy is based on the assumption that tumor response to treatment can reveal which patients might benefit from surgery and which might not [2]. However, most patients experience disease recurrence following surgery, and neoadjuvant therapy is not associated with a survival benefit [3].

Methods:
We undertook an analysis of 125 patients referred to a pancreatic cancer referral center between 2015–2017, who were prospectively included in a dedicated database. Inclusion criteria: a) having both preoperative EUS and CT scan with pancreatic phase evaluation at the centre; b) CT and EUS were performed, at the latest, 30 days apart from each other and from surgical resection; c) no neoadjuvant chemo or radiotherapy was performed. The evaluation of the T by both imaging modalities was compared to the final pathology T re-established based on the new TNM 8th edition, in order to calculate specificity and sensitivity. T-test was used for the comparison of categorical variables.

Results:
Among the 184 PDAC patients surgically resected between 2015 and 2017 at our center, 30 met inclusion criteria. Of these, 19 (63.3%) were males, with mean age at resection being 67.8 ± 9.5 years. The tumor was located in the head in 38, uncus in 19, body in 59, body + tail in 6, tail in 2, and others (recurrence) in 16 cases. Treatment data was followed; mean tumor size before and after therapy was 33.5 ± 10.7 and 33.7 ± 11.5 mm, mean treatment sessions: 2.3 ± 0.7 times, mean total treatment time: 103 ± 65.6 min, mean total number of HIFU shots: 1,967.8 ± 1,106 shots. The effects of HIFU therapy were the following: a) the rate of complete tumor ablation was 87.9%, the rate of symptom relief effect was 69.4%, the effectiveness of primary lesion was CR:0, PR:21, SD:85, PD:34 cases, primary disease control rate (DCR) more than SD was 75.7%. The therapy and HIFU treatment was operation in 8, chemotherapy in 116, immuno-therapies in 4, and best supportive care (BSC) in 14 cases. MST after diagnosis in HIFU with chemotherapy and chemotherapy alone (38 patients in our hospital) was 1028.3 vs 366.6 days, respectively (p = 0.001). MST after HIFU therapy was 690.3 vs 315 days. The rate of tumor ablation was higher in combination therapy of HIFU with chemotherapy was better result than common chemotherapy alone. Conclusion: This study suggested that HIFU therapy has the potential of new combination therapy for PC. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Pancreatic cystic lesions are a common finding in clinical practice. Classification of cysts as mucinous or non-mucinous cysts, by using EUS-FNA with cystic fluid analysis for cytology and CEA became widely used in clinical workup of patients with suspicious pancreatic cysts. Molecular analysis (KRAS and GNAS mutations) are not yet recommended in clinical practice. Aims & Methods: We aimed to determine if mutation in GNAS and KRAS in addition to CEA level and cytokine cystic fluid obtained by EUS-FNA can help in pancreatic cyst classification and decision making. Evaluation of methylation of the GNAS complex locus was performed for cyst classification. Between 2008-14, 266 EUS were performed for cystic pancreatic fluid examination in a single center. We determined the methylation status of GNAS (exons 8 and 9) and KRAS (exons 2 and 3) genes by Sanger sequencing in 52 patients, in cystic fluid obtained by EUS-FNA after cystography and CEA analysis. In operated patients, cysts were also analyzed for methylation of the GNAS complex locus. Results: Mainly female (67%), mean age of 59±15 years (29-91). Cysts located in head (42%), body (39%), tail (11%) and multiple (2%), with a mean size of 3.9±2.3 cm (1.0-10.0 cm). Cytotypes (as after EUS-FNA + CEA/ cytology): 15 serous cystadenomas (SCA), 9 pseudocysts, 8 intraductal papillary mucinous neoplasms (IPMNs), 2 mucinous cystic neoplasms (MCNs), 4 adenocarcinomas (ADC), 1 solid pseudopapillary neoplasm (SPN), 1 lymphangioma, 12 non-defined. CEA > 192 ng/ml in 33% of patients and cytology with benign cells in 12% (33%), suspicious/malignant in 8% (15%), 1 NET (2%) and 31(60%) acellular samples. Surgery in 11 (21%) patients (surgical specimens: 2SCA, 3MCN, 4IPMN, 1 retention cyst and 1 ADC), chemotherapy/palliation in 6 (12%), endoscopic drainage in 1 (2%) and 34 (64%) on-fup. KRAS Mutation in 19% (9) and in GNAS in 4% (2) of cyst aspirates. By cyt type, GNAS was mutated in 1 IPMN and 1 ADC. KRAS was mutated in 6 patients on fup (2 IPMNs, 3 ADC; 1 pseudocyst: a unicellular 2 cm cyst with CEA = 125) and in 3 who had surgery (2 IPMNs and 1 MCN). Specificity and sensitivity of CEA > 192 e-cytology and CEA/KRAS/GNAS mutations for the classification of mucinous and non-mucinous (table 1-1st part) and malignant and non-malignant (table 1-2nd part) are presented in operated cysts.

Introduction: Promising method, which helps to distinguish between chronic pancreatitis and cancer, is point mutations of the proto-oncopene KRAS test. This method is not established in routine clinical practice yet. Aims & Methods: Determination of the sensitivity of the KRAS assay using various kinds of samples of pancreatic cystic mass and testing the effect of the presence of KRAS mutations on the prognosis of survival. 147 patients underwent EUS-FNA examination of pancreatic mass, accompanied by blood sampling with subsequent separation of plasma for the detection of circulating tumor DNA. Part of biopsy sample was left native in a stabilizing solution and part as cytological smear. Samples (native aspirates, cytological smears, plasma) were examined for the presence of KRAS mutation by heteroduplex analysis, denaturing capillary electrophoresis.

Results: Among 147 patients with pancreatic masses, 118x were diagnosed as cancer, 26x chronic pancreatitis, 3x neuroendocrine tumor. In total 147 native aspirates, 187 cytological smears and 94 plasma samples were examined. The highest sensitivity of KRAS mutation was reached in the group of pancreatic cancer patients using cytology, in which 90% of KRAS mutation was detected (106/118 of the samples). When using the native cellular aspirates, mutation was detected in 78% (92/118 samples), and examination of plasma was positive in 70% (66/94 samples).In 44 patients with chronic pancreatitis KRAS mutations was detected, although none has been cytologically confirmed as a cancer. Two of these four patients were confirmed in the course of the disease as a cancer, one patient died because of alcoholic delirium and the last one was indicated for surgery recently.

Conclusion: Examination of KRAS mutations can be performed in all patients undergoing EUS-FNA, with the cytology being the most reliable type of sample for genetic tests. KRAS examination would be reasonable to introduce into routine clinical practice in a group of patients with unclear differential diagnosis of chronic pancreatitis, especially in those with suspicion of cancer in inflammatory terrain. P1437 DO BILARY STENTS REDUCE THE DIAGNOSTIC PERFORMANCE OF EUS BIOPSY IN PATIENTS WITH A MASS IN THE HEAD OF THE PANCREAS?

N. L. Bekkali1, M. Nayar1, L. Thornton1, S. J. Johnson2, B. Haugk3, A. Darne2, J. S. Leeds1, R. Charnley1, K. Oppong1

Introduction: Self-expanding metal stents (SEMS) are increasingly preferred to plastic stents (PS) for preoperative drainage and palliation of biliary obstruction secondary to a stricture in the head of pancreas (HOP). Their use has increased over the last 5-6 years. Endoscopic ultrasound (EUS) with fine needle aspiration or biopsy (FNA/FNB) is commonly utilised to make a tissue diagnosis and to aid in staging in those with borderline resectable tumours. Stents may reduce diagnostic performance of FNA/FNB by reducing the visible mass to puncture. There have been 2 studies that assessed the impact of stenting on EUS-FNA performance, one found no difference in yield and sensitivity among patients with or without stents and between SEMS and plastic. Whilst a more recent study found lack of stent use was significantly reduced by the presence of a stent.

Aims & Methods: The aim was to assess whether stents (SEMS or PS) impair diagnostic performance of EUS tissue acquisition, in a retrospective study of all patients with a HOP mass undergoing EUS biopsy between January 2010 and June 2016. Stenting information was obtained from the EUS report and images. Biopsies reported as malignant were considered as such, all other reports were considered benign. A definitive diagnosis of cancer was based on positive pathology or follow up with signs of progression. A benign diagnosis required negative pathology, stable imaging and symptoms for a year or more. Patients with cystic lesions were excluded.

Results: A total of 1861 patients had EUS-FNA/FNB of which 731 were for HOP lesions, mean age 65 yrs (410 F), with tissue sensitivity of 72% for all types of needles used. Tissue accuracy was significantly different between the 3 groups (p = 0.0001); SEMS 67%, PS 71% and 83% in the unstented group. The difference in accuracy was significant between the unstented group versus SEMS (p = 0.0002) and PS (p = 0.03) and not significant between PS and SEMS. Stepwise multiple-variable analysis revealed significant difference for accurate tissue diagnosis favouring size needle 25G (OR 1.7 [95% CI 1.1-1.7] and tumour size (OR 1.04 [1.02-1.07]) and not affected by presence of stent (SEMS OR 0.3 [0.2-0.6]) or PS (OR 0.5 [0.3-0.8]). Other needle sizes (19G or 22G), number of passes or types of needle did not significantly affect tissue accuracy.

Conclusion: Our results show a significant adverse impact of both SEMS and PS on tissue accuracy via EUS FNA/FNB. The effect is greatest with SEMS. These results suggest that where possible EUS and biopsy if required should be performed before stent placement.

Introduction: Solid-pseudopapillary neoplasm (SPN) is a rare condition, first described by Frantz in 1939. It occurs mostly in young women, and surgical resection is recommended. Its local recurrence rate is less than 10% and usually occurs within 4 years after surgery. Before such a surgery, especially in young people, EUS-FNA (Endoscopic ultrasonography with fine needle aspiration) is discussed to confirm diagnosis but rarely performed due to suspected needle tract contamination by neoplastic cells. The aim of our large multicenter study was to assess the short- and long-term safety of preoperative EUS-FNA in SPN.

Aims & Methods: This study is a multicenter retrospective register of all SPN diagnosed in the last decade in 14 European expert centers (GRAPHE task force). Inclusion criterion was realization of preoperative EUS-FNA followed by surgical resection. Patient and tumor characteristics were collected, as the EUS-FNA technique (number of passes, needle size, trans-gastric or trans-duodenal access). Immediate or late complications of EUS-FNA and recurrence of SPN were then recorded.

Results: During the period study, 49 patients (41 women/8 men) with preoperative EUS-FNA for SPN were recorded. Mean age of patients was 37 ±15y. A positive EUS-FNA (OR 2.4 [1.9-3.0] for 25G vs 0.7 [0.5-0.9] for 22G and 0.8 [0.6-0.9] for 19G) was considered benign. A definitive diagnosis of cancer was based on positive pathology or follow up with signs of progression. A benign diagnosis required negative pathology, stable imaging and symptoms for a year or more. Patients with cystic lesions were excluded.

Conclusion: In this large multicenter retrospective series, a systematic preoperative EUS-FNA did not seem to modify the SPN recurrence rate. Therefore this study allows to validate this attitude as a possible alternative. The data for the series are incomplete at the date of submission of the abstract. The final data will be completed on the day of presentation.

P1439 DIAGNOSIS OF PANCREATIC NEUROENDOCRINE TUMOURS USING SUREPATH CYTOLOGY AND IMMUNOHISTOCHEMISTRY WITHOUT NEED FOR EXCISION BIOPSY

C. Meredith1, H. Dixson2, P. Irandoust1, P. Baird3

1Gastroenterology And Hepatology, Bankstown-Lidcombe Hospital, Bankstown/ Australia/NSW
2Endoscopy Unit, CHU Saint Antoine, Paris/ France
3Gastroenterology, CHU La Cavale Blanche, Breizh/ France

Introduction: Pancreatic neuroendocrine tumours (PNETs) are relatively rare, i.e., 1/100,000 individuals per annum, and account for only 1-2% of all pancreatic tumours. They are separated into 2 major categories: 1) well-differentiated (WD-NETs) which have a diffuse architecture with an irregular nucleus and less cytoplasmic and finely granular cytoplasm and 2) poorly-differentiated (PD-NETs) which have round to oval nuclei, coarsely stippled chromatin and finely granular cytoplasm. They occur in the head of the pancreas in 70% of cases and in the body or tail in 30% of cases. They most commonly affect men aged 50-60 years with mean tumour size of 2-5 cm. They are considered malignant if they have a diameter of >2 cm. They can be divided into Functioning and Non-functioning tumours. The most common functioning tumours are Insulinomas and Glucagonomas. The most common non-functioning tumours are Somatostatinomas and VIPomas.

Aims & Methods: The aim of this study was to use a new diagnostic technique, the surepath™ tissue preparation kit, to diagnose pancreatic neuroendocrine tumours without the need for excision biopsy of the tumour. The kit incorporates a SurePath cell preservative solution which is collected through a needle or fine needle aspiration (FNA). The SurePath technique allows the cells to be collected in a cytology aliquot and studied without the need for excision biopsy of the tumour. The study allows to validate this attitude as a possible alternative. The data for the series are incomplete at the date of submission of the abstract. The final data will be completed on the day of presentation.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1440 EFFECTS OF IGF2BP2 ON GROWTH AND PROLIFERATION OF PANCREATIC TUMOR CELL LINES

L. Niefeld1, F. Sperling1, K. Theuerkorn1, H. Griesmann1, S. Krug1, S. Hättemüller2, P. Michl1

Introduction: Pancreatic neuroendocrine neoplasms (PNE) are highly angiogenic tumors which despite of various targeted options including mTOR and VEGF inhibition frequently develop secondary drug resistance. IGF2BP2 (IGF2 mRNA-binding proteins) represent a family of canonical RNA-binding proteins (RBP) comprised of three members (IGF2BP1-3) which have been described to promote stem and/or progenitor cell maintenance with reported expression and oncogenic roles in aggressive cancers. IGF2BP2 shows a differential expression pattern in various solid tumors including pancreatic neuroendocrine tumors.

Aims & Methods: We aimed to characterize the role of IGF2BP2 in progression and resistance of pancreatic neuroendocrine neoplasms. We used three different siRNA-pools (IGF2BP2) to inhibit the different IGF2BP isoforms in pancreatic neuroendocrine BON1 tumor cells. Cellular effects were investigated by Western blot analyses, flow cytometry, clonogenic survival, cell viability and migration assays.

Results: In the pancreatic neuroendocrine tumor cell line BON1, knock-down of IGF2BP1 resulted in a significant reduction of cell viability. Cell cycle analysis by FACS showed a decreased S phase progressionparalleled by a reduction in the proliferation marker PCNA and a markedly reduced MEK/ERK activation. In contrast, Akt signaling was unaffected. Moreover, knock-down of IGF2BP2 significantly reduced clonogenic growth as assessed by colony formation assays and led to decreased cell migration as determined by scratch assays. Interestingly, knock-down of IGF2BP1 was insufficient to induce apoptosis, as assessed by PARP and caspase-3 cleavage as well as annexin-V FACS. Rather, si-IGF2BP1 increased the expression of both the anti-apoptotic and pro-survival factor BCL-2 and the cell cycle inhibitor CDKN1B. In contrast to IGF2BP1, knock-down of IGF2BP3 rather induced cell viability, whereas IGF2BP2 modulation had no impact on cell viability and cell cycle progression indicating opposing effects of the three IGF2BP isoforms on PNE progression. These in vitro findings were paralleled by distinct expression patterns of IGF2BP proteins in human and murine PNE tumor tissues.

Conclusion: In summary, our data suggest that IGF2BP1 promotes tumor progression by enhancing cell cycle progression and clonogenic growth, whereas IGF2BP2 and -3 exert no tumor-promoting role in PNE.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The chemopreventive effect of aspirin (ASA) and other NSAIDs has been observed in the setting of colorectal cancer, showing a reduction in the incidence and mortality. However, the impact of aspirin use on clinical outcome of patients with gastro-entero-pancreatic neuroendocrine tumors (GEP-NEN) has not yet been evaluated.

Aims & Methods: Aim of the study was to retrospectively evaluate the clinical outcome of GEP-NEN patients treated with ASA at three different European referral Centres for NENs. All the GEP-NENs patients followed up in three European Centres (Fondazione IRCCS Ca’ Granda Ospedale Policlinico Milano, Italy; Fondazione IRCCS Istituto Tumori Milano, Italy; Mater Misericoardi University Hospital, Dublin, Ireland), from January 2005 and September 2016, were retrospectively enrolled. The possible association between ASA and disease grading, staging, primary site, overall OS and PFS were evaluated. At the time of enrolment, clinical data and biochemical parameters were collected for every patient. Chromogranin A (CgA) and specific circulating peptides were evaluated. Morphological and functional imaging (computed tomography, magnetic resonance and Gallium 68PET) were performed to follow up the patients at each Centre.

Results: In the 253 patients included (121 M, median age 64 yrs), the primary neuroendocrine tumor was located at the stomach (#35), pancreas (#82), small bowel (#80), appendix (#27), colon (#19) or unknown (#7). Grading was G1 in 154 patients, G2 in 64, G3 in 5 and not available in 28. TNM staging was I in 99 patients, II in 16, III in 32 and IV in 86. No clear impact on OS or PFS was evaluated.

Conclusion: At present data, ASA therapy seems not to have a direct clinical impact on disease progression or survival of NENs, even if it is associated with lower Ki-67 values and less node involvement. Further studies are needed to confirm this observation.

Disclosure of Interest: All authors have declared no conflicts of interest.
P1443 PANCREATIC LESIONS IN VON HIPPEL-LINDAU SYNDROME: CLINICAL AND EPIDEMIOLOGICAL DATA FROM A SINGLE CENTER
L. Venezia1, P. Cortegoso Valdivia1, C.G. De Angelis2
1Gastroenterology, A.O.U. Città della Salute e della Scienza, Torino/Italy

Contact E-mail Address: cortegosoblog@yahoo.it

Introduction: Von Hippel-Lindau disease (VHL) is a rare heritable genetic syndrome that may affect different systems and organs: pancreatic manifestations of the disease are frequent during lifetime of the patients. The key feature is the presence of simple cysts, but serous cystadenomas (SCAs) or neuroendocrine tumors (NETs) can be frequently found as well. The aim of this study is to describe pancreatic manifestations in patients with VHL, considering the peculiarity and rarity of this disease.

Aims & Methods: All patients who referred to the established multi-disciplinary team in our center (Molinette Hospital - Turin) for management and follow-up of VHL were included in the study. We considered the ones with pancreatic involvement (simple cysts, SCAs or pNETs). We collected data about the patients, demographics and medical history, about the lesions (imaging features, hystological and cytological analysis) and about the management.

Results: A total of 24 patients, 18 of which (75%) had a pancreatic involvement. Simple multiple pancreatic cysts were found in 13 patients, SCAs were found in 2 patients and NETs in 7 patients. The mean age of the patients with pancreatic lesions was 42 (min 25 - max 75), 11 were males and 7 females (1.6:1 M:F). Similarly affected 13 patients were always multiple (ranging from 12 to 80 mm) mostly in the head. 3 patients underwent surgery for symptomatic disease. All pNETs were well differentiated (G1, K67 < 2%); 7 were located in the head and 2 in the tail (2 patients had multiple tumors). 5 of the 7 pNET patients underwent surgery. The two SCAs were multiple (max 65 mm), mostly affecting the head in 1 case and the tail in the other. No surgery was performed.

Conclusion: 75% of our VHL patients showed pancreatic involvement, mostly in males compared to females. 72% of patients with pancreatic lesions suffered from simple cysts, 39% from NETs and 11% from SCAs. To note that all NETs were G1 and behaved in a benign fashion. Surgery was performed only in patients with NETs in the pancreatic head and in patients with symptomatic cystic disease. The mean age of incidence of VHL-related pancreatic lesions was lower than in sporadic cases, thus confirming literature data. Although all lesions in our patients were benign or stable, constant monitoring is needed.

P1445 THE LARGEST FAMILY IN TURKEY WITH MULTIPLE ENDOCRINE NEOPLASIA-TYPE 1 AND A NOVEL MUTATION
A. Čeşin1, D. G. Duman2
1Internal Medicine, Marmara University School of Medicine, Istanbul/Turkey
2Gastroenterology, Marmara University Hospital, Istanbul/Turkey

Contact E-mail Address: alicectdrn@gmail.com

Introduction: Multiple Endocrine Neoplasia type 1 (MEN-1) occurs usually sporadically but because it is an autosomal dominant disorder it may affect other family members too. The combination of parathyroid, pituitary and anterior pituitary tumors is characteristic of MEN-1 although it may be accompanied by a substantial number of non-endocrine tumors. The mutations in MEN-1 result in inactivation of MEN1 gene (whose product is a nuclear export protein encoded by this gene) and is responsible for tumor-suppression under normal circumstances. Herein we present the largest MEN1 family in Turkey to the best of our knowledge and a newly discovered mutation in MEN1 that effects this family.

Aims & Methods: The family inherited the specific MEN-1 mutation is originally § ekinarahanis, Giresun and most of the members have moved to Istanbul and Yalova. Consanguineous marriages have been practiced within the family. Family mapping was structured and contained fifty-five members. Among them, eleven patients underwent biochemical, radiologic and if necessary endosonographic evaluation along with the genetic testing. Additionally, we learnt that 2 members of the family had died of pancreatic malignancy. Diagnostic criteria for familial MEN-1 include: 1 - the presence of at least one MEN1-associated tumor that are from parathyroid, pituitary, or GEP tract origins, 2 - at least one first-degree relative with one or more of these endocrine tumors and/or 3 - positive genetic testing for abnormal MEN1 mutation. For our index case, DNA sequencing of the MEN1 gene performed using Sanger sequencing. Our index case was ZK who had hypophysis adenoma, parathyroidectomy and pancreatic neuroendocrine tumour and had whipple operation. A three nucleotide deletion p.ser560argfs*3(c.1680_1683 del TGAG) mutation was detected. Seven out of ten who were analysed were tested positive for the mutation. Genetic counseling and information about pre-implantation genetic diagnosis (PGD) was given to all patients who are tested positive for the mutation. All 7 patients had p.ser560argfs*3(c.1680_1683 del TGAG) three nucleotide deletion same with that of index case. Of out 15 patients, MEN1-diagnosis was confirmed in 11. Tumours detected at patients with MEN1-diagnosis were; nonfunctional pancreatic neuroendocrine tumour at three, parathyroid adenoma/hyperplasia at 6 patients and hypophysis adenoma

Results (SEER) database. Clinicopathologic features were retrospectively analyzed. Survival was calculated by the Kaplan-Meier method. Multivariable Cox regression models with hazard ratios (HRs) were constructed to analyze survival outcomes and risk factors. Cubic spline analysis was used to assess relationship between tumor size and probability of metastasis.

Univariate analysis showed that tumor size was significantly correlated with survival (P<0.001), no matter surgery was performed or not. However, subgroup analysis suggested this association to be linear for patients with localized and regional tumours (P<0.001), but stochastic in patients with distant stages (P=0.703). On multivariate analysis, tumor size was an indicator for metastasis (HR = 1.010, 95% CI: 1.008-1.012, P=0.001 and size <20 mm for good survival (HR = 1.211, 95% CI: 1.048-1.399, P=0.009 for size of 21-40 mm; HR = 1.282, 95% CI: 1.161-1.474, P<0.001 for size >40 mm). For tumours ≤20mm, surgical treatment was associated with significantly improved survival compared with those patients who did not undergo operation (P<0.001).

Conclusion: Tumor size affects the probability of metastasis. Its prognostic impact on survival is restricted to patients with localized and regional disease. For tumours with tumour size <20mm, surgical treatment should be considered preferably.

Disclosure of Interest: All authors have declared no conflicts of interest.

References

Results: A total of 5424 patients were identified. There were 1226 patients (22.6%) with tumour size of 2cm or less. The probability of metastasis increased in a non-linear fashion with increasing tumours size. Univariate analysis showed that tumour size was significantly correlated with survival (P<0.001), no matter surgery was performed or not. However, subgroup analysis suggested this association to be linear for patients with localized and regional tumours (P<0.001), but stochastic in patients with distant stages (P=0.703). On multivariate analysis, tumor size was an indicator for metastasis (HR = 1.010, 95% CI: 1.008-1.012, P=0.001 and size <20 mm for good survival (HR = 1.211, 95% CI: 1.048-1.399, P=0.009 for size of 21-40 mm; HR = 1.282, 95% CI: 1.161-1.474, P<0.001 for size >40 mm). For tumours ≤20mm, surgical treatment was associated with significantly improved survival compared with those patients who did not undergo operation (P<0.001).

Conclusion: Tumor size affects the probability of metastasis. Its prognostic impact on survival is restricted to patients with localized and regional disease. For tumours with tumour size <20mm, surgical treatment should be considered preferably.

Introduction: Several inflammatory response materials could be used for prediction of prognosis in cancer patients. The neutrophil lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR), thrombocytosis (the platelets number >400*10³/mm³) have been introduced for prognostic scoring system in various cancers.

Aims & Methods: The objective of this study was to determine whether the NLR, the PLR or thrombocytosis could predict the clinical outcomes in G1-G2 neuroendocrine tumors. We performed a retrospective review of 31 patients with neuroendocrine tumors with ki 67 below 20% diagnosed in Fandeni Clinical Institute between 2011-2017. Data about site of the primary tumor, presence of metastasis, NLR, PLR, thrombocytosis (platelet count > 400) and survival were collected and analysed.

Results: The patients characteristics were: primary tumor location was: 61.29% pancreas, 22.58% gastrointestinal tract, 16.13% unknown, 61.29% had hepatic metastasis, 6.45% had locally advanced tumor. The primary tumor was resected in 35.48% patients. The overall 2-year survival rate was 77.42%. The Ki 67 index (p < 0.04), PLR (cut off > 300) p < 0.01 have statistical significant impact on survival. Univariate analysis and on multivariate analysis (P < 0.05). Other factors like ki 67 index, metastatic disease, thrombocytosis and NLR have an impact on survival statistical significant on multivariate analysis.

Conclusion: This study demonstrates the prognostic role of different variables like ki 67 index, PLR and PLT value, thrombocytosis and metastasis. This factors may be integrated in different scoring systems for prognosis that could guide clinicians for a better management in patients with neuroendocrine tumors.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Neuroendocrine pancreatic tumors represent the second prevalent entity of malignant tumors of the pancreas and show an overall mortality of about 60%. At the moment surgical resection is the only option of potentially curative therapy, as with the currently available chemo- and radiotherapeutic approaches an inhibition of tumor growth but no regression of the tumor can be achieved. Therefore for about 80% of pNET patients no curative therapy can be offered. To obtain the identification of novel potential target genes for the development of new therapeutic strategies, primary tissues from pNET patients were analyzed. Amongst others Plac8 (Placenta-specific 8) was identified, which is a small protein of unknown function, showing different forms of cellular localization depending on the cell type analyzed, indicating at its ability to fulfill a variety of physiological functions.

Aims & Methods: In the course of this study, the function of Plac8 in neuroendocrine pancreatic tumors is to be unveiled to evaluate its value as a potential target for pNET therapy. Therefore primary tumor tissue of about 100 pNET patients were analyzed for Plac8 expression by quantitative realtime PCR and immunohistochemistry. Furthermore established pNET cell lines from human origin where transfected with siRNAs against Plac8 and there proliferative activity and apoptosis were analyzed by MTT and MT assay. Changes in these important characteristics of tumor cells were further examined by westernblot analyzes of key regulators of apoptosis and cell growth.

Results: Plac8 is highly expressed in primary human pNET tissue on RNA- as well as in protein level. Functional in vitro analyses show that the siRNA-mediated knockdown of Plac8 not only in human but also in rat cell lines leads to significantly reduced proliferative activity and reduced cell growth. These effects come along with indicative changes in the expression of central regulators of cell cycle while cell cycle pathways seem to be affected.

Conclusion: Overexpression of Plac8 in neuroendocrine tumors of the pancreas promotes the proliferative phenotype of the tumor cells while the inhibition of Plac8 inhibits cell growth and metabolism. Therefore in the future Plac8 could represent a very interesting target molecule for the treatment of pNETs.

Introduction: Since the majority of laryngopharyngeal carcinomas are detected at an advanced stage, most cases are treated with concurrent chemotherapy and radiation therapy. The key to improving the prognosis and quality of life is early detection of the primary cancer and treatment using minimally invasive surgery. We previously reported the good oncologic outcomes with ELPS (Endoscopic laryngopharyngeal surgery) for superficial laryngopharyngeal carcinoma. However there is no clinical evidence for an additional treatment nor prognosis about the cases conducted endoscopic resection which were diagnosed to be superficial carcinoma with lympho-vascular invasion histopathologically.

Aims & Methods: This study aimed to investigate the optimal additional treatment and clinical course for the superficial laryngo-pharyngeal carcinoma with lympho-vascular invasion. We analyzed clinicopathological data in 9 patients showed Lympho-vascular invasion receiving ELPS between 2007 and 2014.

Results: Positive lympho-vascular invasion was found in 9 cases. Detected the tumor depth was SEP in 7 lesions and MP in 2 lesions. Mean alcohol consumption is 9.9 abw units. Average smoking history is 38.9 pack years. 5 cases are low activity ALDH2 heterozygotes and have alcohol flushing reaction.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bleeding control is one of the most important factors to success of endoscopic submucosal dissection (ESD) in safety. We have reported the endoscopic precoagulation technique using soft coagulation mode (S method) is effective in reduction of the bleeding during the ESD. The aim of this study was to evaluate the efficacy of the vessel precoagulation by using forced coagulation mode (F1-10 method) with low frequency power setting (F1-10 method) in endoscopic submucosal dissection (ESD).
Methods: We investigated the times of vessel bleeding before vessel precoagulation by using S method and F1-10 method in clinical study. The recorded data were analyzed using the software of SPSS for Windows 11.3 version.
Results: A total of 105 patients (58 males, 47 females) with mean of 66.5 (20-91) years old and mean size of duodenal tumors 27.0 (11-80) mm in diameter were treated with ESD. Of medical endoscopists (physician and surgical trainees) were compared with non-medical endoscopists (NME). Results: 885 trainee portfolios were analyzed (765 medical and 120 NMEs), with a median procedural count of 276 (IQR 124). The median number of therapeutic entries and DOPS were 4 (IQR 11), and 1 (IQR 3) respectively. Overall rates for endotherapy and DOPS were 2.9% and 0.8% per procedure. When stratified by therapy, the median exposure to each therapy was either 0 or 1, with means displayed in Table 1. 25.2% of trainees had no exposure to any type of endotherap–y (67.5% of NME and 18.6% of medical endoscopists, p < 0.0001). Of medical endoscopists awarded certification, 37.1% had not performed band ligation, 50.7% had not placed a clip, and 54% had not used heater probe. NME had significantly less exposure to each modality of endotherapy considered (overall odds ratio 0.10, p < 0.0001).

Table 1: Mean procedural counts at the point of UGI certification

Conclusion: Training on endotherapy prior to certification is limited. The current UGI certification process does not incorporate any exposure to endotherapy for UGBI. In response, the JAG QA team have recently released new DOPS forms specific to UGBI, and are consulting on introducing formal certification in endotherapy for UGBI.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Barrett’s esophagus (BE) is a known premalignant condition with risk for progression to esophageal adenocarcinoma. Electronic chromoendoscopy with magnification (ECM) is an evolving imaging technology being investigated as a novel imaging modality to identify dysplasia in BE to assist with higher yield BE surveillance and improve the diagnostic yield of esophageal biopsies for BE.

Aims & Methods: This is a single-center study to evaluate the efficacy of ECM (Scan by Pentax) in the detection of BE and dysplastic BE in a screening, average risk population with BE in Northeast Mexico. We conducted a retrospective study of 100 consecutive patients (41 males) with known BE (confirmed by pathology) during surveillance upper endoscopy for dysplastic BE between

Disclosure of Interest: None.

Reference
March and September of 2016. All patients underwent EC with iScan. The esophagus was inspected with a ECM capable endoscope (EG- 2990-Zi) and deliberate biopsies were taken from tissue identified by ECM that suggested BE. All biopsies were confirmed by a GI pathologist. Primary endpoint was the correlation between visual inspection diagnosis of dysplastic BE by ECM versus pathologic diagnosis of BE as the gold standard.

| Accuracy        | 98%
| Sensitivity     | 100% [95% CI (96%–100%)] |
| Specificity     | 0% [95% CI (0%–84%)] |
| Positive predictive value | 98% [95% CI (93%–99.7%)] |
| Negative predictive value | NA |

Results: In our cohort 41% were male, with mean age of 47.7 years. Endoscopic diagnoses by ECM were divided into nondysplastic BE (96/100) and suspected dysplastic BE (4/100). On pathology nondysplastic BE was found in 94/100 patients, BE with low-grade dysplasia was found in 4/100 patients. Benign gastric mucosa with no alterations (1/100), and ulcerated esophagitis (1/100). The overall accuracy of endoscopic diagnoses using ECM against pathology diagnosis was of 98%, with sensitivity of 100% [95% CI (96%–100%)], and positive predictive value of 98% [95% CI (93%–99.7%)].

Conclusion: Endoscopic diagnosis of BE by directed biopsies of esophageal tissue with use of ECM is highly accurate. Future prospective studies are needed to validate our preliminary findings and assess inter-observer variability.

Introduction: Endoscopic full-thickness resection (EFTR) for sub-epithelial lesions (Sets) of GI tract is less frequently described; possibly due to technical challenges involved in dissection and need for resultant defect closure. Current study describes single-center experience of EFTR for treatment of SETs.

Aims & Methods: Prospective database of patients undergoing EFTR for SETs over 6-years (2011–2017) was abstracted. Patient selection for EFTR-endoscopy, endoscopic ultrassound (EUS) and CECT. Inclusion criteria: mesenchymal lesions, predominantly endophytic component and absence of features of invasive malignancy. Exclusion criteria: patients unfit for general anesthesia or major intraoperative, uncorrectable coagulopathy or high risk features for malignancy. All procedures performed under general anesthesia with endotracheal intubation. High-definition endoscope (GIF-HQ-190 or CF-HQ-190, Olympus Corp., Japan) with distal transparent hood and carbon dioxide insufflation used in all. All submucosal (SM) elevation by Gelofuscin, mucosal incision and SM dissection performed to expose SET. Encapsulated SET enucleated maintaining intact capsule. Adherent and attached muscularis propria (MP) layer fibers divided. IT or Dual-knife12 used for dissection and coag-grasper for hemostasis. Resultant MP layer defect closed endoscopically.

Results: Total N = 18 (M:F–11:7), mean age-53.6 (Range-28–78). Presentation: GI bleed-7(38%), abdominal pain-4(22%), non ulcer dyspepsia-1, rectal mass-1 and asymptomatic, incidentally diagnosed-6(33%). Layer of origin-MP layer in all. Location-stomach-13(72%), duodenum-2, rectum-2, proximal jejunum-1. Mean size of SET-3.3 cm (range 1–7). Mean procedure time-182 mins (60–345), and mean hospital stay was 4 days. Adverse events-two (11%)-esophageal laceration during specimen retrieval–1 (closed using endoclips), failure–1 (due to undetected large exophytic component-surgical resection). Histopathology with

P1455 PROPHYLAXIS OF VARICEAL BLEEDING IN CIRRHOTIC PATIENTS: EFFICACY AND SAFETY OF ENDOSCOPIC VARICAL LIGATION

1Gastroenterology, Centro Hospitalar e Universitário Coimbra, Coimbra, Portugal, 2Coinbra/Portugal

Contact E-mail Address: es18497@gmail.com

Introduction: In the natural history of chronic liver disease, variceal bleeding represents a life-threatening complication of portal hypertension, with high risk of mortality and recurrence. Current guidelines define vasoconstrictive therapy or endoscopic variceal ligation (EVL) in primary prophylaxis and the combination of both in secondary prophylaxis.

Aims & Methods: We aimed to evaluate the efficacy of EVL therapy in both prophylaxis of variceal bleeding in cirrhosis and to establish the patient’s clinical outcome. This was a retrospective observational cohort study of a total of 44 EVL procedures performed in 250 cirrhotic patients, who were admitted in a gastroenterology department of a tertiary centre, between 2004-2016, as prophylaxis of gastrointestinal bleeding. Sessions of ligation were repeated every two to three weeks in order to reach variceal eradication. The clinical outcome included the recurrence of bleeding (primary endpoint), the eradication success rate of oesophageal varices, EVL-related complications and overall and bleeding-related mortality.

Results: The mean follow-up period for all 250 cirrhotic patients enrolled in the study was 73.2/10 months, with mean age of 63.9±10.8years and a predominance of male gender (80.4%;n=201). At initial endoscopy, 257 (93.4%) had active or inactive varices. One patient (0.4%) had variceal bleeding severe in 168 (67.2%); EVL was performed as primary prophylaxis in 50.9%(n=226) and secondary prophylaxis in 49.1%(n=218). Varices were obliterated in 209 (83.6%) patients with mean number of EVL procedures necessary to eradicate varices of 1.8±0.95 and a maximum of procedures of 6. Recurrent bleeding occurred in 11.2%(n=28) of cases with a mean time to re-bleeding occurrence of 8.1±14.2months. Major and significant complications were verified in 8.1%(n=36) of patients. The mean complications were bleeding related to post-banding ulceration (75.0%(n=27) and infection (22.2%(n=8)), with mean time between EVL and complication occurrence of 11.1±11.8days (minimum:0;maximum:43). Intra-procedure complications occurred in 11(2.5%) patients with no death, despite of two cases of Sengstaken-Blakemore tube necessarity. The overall mortality was 5.8%(n=24), being 0.4%(n=2) related to varical bleeding.

Conclusion: EVL seems to be an efficient, safe and relatively simple therapeutic option for the primary and secondary prophylaxis of variceal bleeding in cirrhotic patients. Since the main complications occurs over 1 week after EVL procedure, the majority of patients can be safely treated in an ambulatory setting.

P1456 THE VALUE OF ENDOCOPIC FULL-THICKNESS RESECTION FOR GASTRIC AND DUODENAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA LAYER

1Endoscopy Center, Zhongshan Hospital, Shanghai/China

Contact E-mail Address: whitleily.chen@aliyun.com

Introduction: Given diminishment of quality of life caused by surgery in the stomach and duodenum, a minimally invasive treatment is desirable for gastric and duodenal submucosal tumors (SMTs).

Aims & Methods: We aimed to assess the value of endoscopic full-thickness resection (EFTR) technique for gastric and duodenal submucosal tumors (SMTs) originating from the muscularis propria (MP) layer. A total of 276 patients with single gastric SMTs originating from the MP layer were performed EFTR between January, 2010 and February, 2014. The tight adhesion of the tumor to the gastric or duodenal serosal layer could be seen in every case from endoscopic ultrasound (EUS) before the procedure. The SMTs oriented endoscopically were performed EFTR using a standard ESD technique without laparoscopic assistance under direct endoscopic view. The defect of gastric and duodenal wall was closed after resection.

Results: A total of 276 patients included 94 males and 182 females. Their median age was 57.8 years (range, 30-81 years). Among all the 276 SMTs in our study, 165 located in gastric fundus, 96 located in gastric body, 8 located in the antrum, 1 located in the pylorus and 5 located in duodenal bulb. The angle of curvature 1, lesion 16/18 (2 defects in distal extra peritoneal rectum left open intentionally for healing by secondary intention); techniques—through-the-scope (TTS) clips-7, over-the-scope clip-4, omental patch + clip -2 (TTS – 1, OTS – 1), endoscopic suturing – 1, endoloop + clip -1. Mortality–nil. Follow up endoscopy at 4 weeks healing in all 17 patients. Mean follow up –2 months.

Conclusion: EFTR is safe and effective for resection of SET. Pre EFTR EUS and CECT may be useful to select appropriate candidates. Secure closure of defect is necessary for intumescence. Full-thickness defects. Further studies comparing EFTR and surgery are recommended.

P1458 LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOSAL DISSECTION(ESD) FOR RELATIVE INDICATION GROUP OF EARLY ESOPHAGEAL SQUAMOUS CARCINOMA (EESCC) IN AGED PATIENTS

Z. Qi1, Y. Zhong1, P. Zhou1
1Endoscopy Center, Zhongshan Hospital Fudan University, Shanghai/China

Contact E-mail Address: poem001@qq.com

Introduction: According to the Japanese Esophagus Society Guidelines, Early Esophageal Squamous Cell Carcinoma (EESCC) involving the muscularis mucosa or <200 μm invasion of the submucosa, and circumferential extent of >2/3 were relative indications (RI) for ESD. Additional treatment (AT, including esophagectomy or chemoradiotherapy) may be needed after ESD. But in aged RI patients, most will refuse AT due to higher rates of debilitating symptom in China.

Aims & Methods: The aim of this study was conducted to evaluate the long-term outcomes of aged RI patients without AT after ESD.

Results: Between January 2008 and December 2013, a total of 158 aged EESCC patients were included in the present retrospective study. Prognosis outcomes were analyzed.

Discussion: Aged RI EESCC patients without AT( esophagectomy or chemoradiation) showed comparable prognosis outcomes with AI group after ESD. So follow up may be recommended, substituted for AT in aged RI group.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1459 RETROSPECTIVE ANALYSIS ON SUSPICION OF FOREIGN BODY INGESTION AND FOOD IMPACTION ON GASTROENTEROLOGY EMERGENCIES

J. T. Correia De Sousa1, D. Libanio1, P. Lago1, R. Marcos-Pinto1, I. Pedroto1
1Gastroenterology, Centro Hospitalar do Porto, Porto/Portugal

Contact E-mail Address: joao.correia.de.sousa@gmail.com

Introduction: Suspicion of foreign body (FB) and food impaction (FI) are one of the most common motives for endoscopic emergency. This retrospective study reviewed 288 cases of suspicion on FB/FI, by the frequency of endoscopic alterations, predictive factors to presence, types of FB found, and therapeutic approach.

Aims & Methods: Unicentric retrospective cohort study of endoscopies performed during one year of gastroenterology emergency setting.

Results: In 2015, 288 endoscopies were performed on suspicion of FB/FI (22% of total endoscopies, n = 1309, of them 61.5% (n = 199) were performed during the night. Patients’ median age was 58 years, and 52.8% were women. The presence of FB/FI was confirmed in 71.2% (n = 205); of them 61.5% (n = 126) were complete FB/FI. The most frequently found foreign bodies were meat bones (18.5% (n = 37) and fish bones (14.6% (n = 30). Most FB/FI were found on the proximal esophagus (56.1%, n = 115). Endoscopic removal was performed on 129 cases (63.4%), endoscopic mobilization in 54 (26.3%), and in 22 endoscopic removal wasn’t achieved (10, where referred to otolaryngology; 2 for surgery and 10 were deferred to endoscopy with sedation, in operating room).

Endoscopy under sedation was performed in 20 cases (9.7%). About ¼ had associated comorbidities, the most common were esophageal ring in 22 (10.7%) and benign stenosis in 178.3%) patients. Major complications were rare: 1 perforation (0.3%) and 3 deep esophageal lacerations (1.5%). Age (>55years), presence of comorbidities, and previous episodes were associated with presence of FB/FI on Endoscopy (Odds Ratio 2.01, 3.39 and 4.63 respectively).

Conclusion: Endoscopy is frequently preformed for suspicion of FB/FI in our emergency setting. Presence is confirmed in the majority of the cases. Predictive factors for presence were identified. Most FB/FI were removed with success with low complication rates. This data favor the endoscopic approach on suspicion of FB/FI.

P1460 LEARNING CURVE FOR ENDOSCOPIC SUBMUCOSAL DISSECTION OF GASTRIC NEOPLASMS; LOW-VOLUME SINGLE-CENTER EXPERIENCE

S.T. Kim, T.H. Kim, S. Na
Internal Medicine, Jeju National University Hospital, Jeju/Korea, Republic of

Contact E-mail Address: panzervor@paran.com

Introduction: Endoscopic submucosal dissection (ESD) has become a standard therapy for early gastric neoplasia. There is no consensus yet about the number of experiences required for performing ESD alone.

Aims & Methods: We aimed to investigate the learning curve of ESD performed by a single beginner endoscopist focusing on developing the performance of dissection, shortening the procedure time, and preventing complications.

Methods: Records of 120 consecutive ESD procedures performed by a single beginner endoscopist with an ESD knife from March 2012 to February 2016 were collected. For analysis of the learning curve, total procedures were divided into four periods, each comprising 30 sequential ESD. The parameters assessed were the en-bloc resection rate, complete resection rate, procedure time, and related complications.

Results: In the procedure time according to the number of experiences, the procedure time decreased from 300 minutes to 290 minutes. However, there was no statistical difference from the first (63.5 ± 54.0) to the second quarter (44.7 ± 51.4, p = 0.19), to the third quarter (40.7 ± 27.8, p = 0.08), and to the fourth quarter (40.8 ± 23.1, p = 0.09). There was no procedure that exceeded 100 minutes from the third quarter. There were a total of seven perforations, four of which were in the first quarter, two in the second, and one in the third. In the procedure time according to the location of the lesions, upper lesion (92.4±43.7) showed longer procedure time than middle (46.6±40.2, p < 0.01) and lower third (39.5±27.5, p < 0.01) with statistically significant difference. In addition, in the fibrotic lesions, regardless of size and location, all took a very long time, more than 100 minutes.

Conclusion: It needs accumulate experience with the help of a professional expert up to 30 cases, and to the more advanced level, about 90 procedures are needed. And, the location of the lesion is the important factor in determining the difficulty of the procedure. Therefore, it is best to avoid the upper third lesion as far as possible until experience 90 cases or at least 30 procedures.

Inaccuracy of Cambridge Protocol for Complete Examination of MDP.

Aims & Methods: Prospective, randomized, blinded, controlled, non-inferiority crossover study. Subjects scheduled for elective EGD were randomized to undergo CA-EGD (group A) or SVE (group B) before undergoing a second examination by the alternate method. Imaging of the MD was evaluated, after image processing, by three blinded multicenter-experts. Our primary outcome measure was complete examination of the papilla. Secondary outcome measures were image quality of mucosal pattern, ability to obtain an overview of the papilla and overall satisfaction of the evaluators. For secondary outcomes, a score was given from 1 to 10 (1 = poor, 10 = excellent).

Results: A total of 62 patients were randomized and completed the study. Complete examination of the papilla was achieved in 59 patients using CA-EGD compared to 60 patients using SVE (95 vs. 97%, p = 0.10). CA-EGD had mean scores of 8.7 ± 1.3, 7.1 ± 0.86 and 7.9 ± 1.1 regarding mucosal pattern, overview and overall satisfaction, respectively, versus 5.3 ± 1.6 (p < 0.001), 8.3 ± 0.9 (p < 0.001) and 7.6 ± 0.6 with SVE (p < 0.01).

Conclusion: CA-EGD is non-inferior to SVE for complete examination of MDP. CA-EGD had significantly higher scores than SVE regarding the image quality and overall satisfaction, while SVE had a better overview. CA-EGD is a safe and effective method for examination of MD and can replace the SVE for diagnostic indications.

Results: 19 patients underwent EA, with a mean age of 63.5 ± 17.7 years and a male to female ratio of 0.7. "En bloc" resection was done in most cases 15/19 (79.8%). Bleeding occurred in 6 cases (31.6%) and two patients (10.5%) developed acute pancreatitis. One patient died due to severe bleeding. The average days of hospitalization after endoscopic ampullectomy were 5.7 with a range from 2 to 25 days. Adenocarcinoma was described in the final histopathological result in 4/19 cases (21.1%). One year follow-up noted a recurrence rate of 15.8% (3/19 cases).

Conclusion: In conclusion, endoscopic ampullectomy is a difficult procedure with an increased risk of complications but performed by experienced endoscopists is safe and surgical interventions can be avoided.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1466 PER ORAL ENDOSCOPIC MYOTOMY: UPDATED RESULTS FROM A UNITED KINGDOM CASE SERIES
S. Gulati1, A. Emmanuel1, H. Inoue2, A. Haji3, B. Hayee1
1Endoscopy, King’s Institute of Therapeutic Endoscopy, RS/United Kingdom
2Digestive Disease Center, Showa University Koto-Toyou Hospital, Tokyo, Japan

Contact E-mail Address: shraddha.gulati@nhs.net

Introduction: Per-oral endoscopic myotomy (POEM) has been adopted as a minimally invasive treatment option for achalasia and even spastic oesophageal conditions.

The first case of POEM was performed at the King’s Institute of Therapeutic Endoscopy (KITE) in 2013. Here we present our initial case series including the first UK case of diffuse oesophageal spasm (DES).

Aims & Methods: Prospective data was collected for consecutive patients undergoing POEM including demographics, POEM technique, the use of Endoluminal Functional Lumen Imaging Probe (EndoFLIP) and adverse events. Clinical success was defined as a reduction of Eckardt score (ES) to <2 or a reduction in 4 points from baseline. Follow up data at 3 and 12-24 months (post-POEM) was analysed using the Wilcoxon signed ranks test to compare pre- and post-POEM ES and 4sIRP and pre and post-treatment GORD-HRQoL score. Repeated-measures ANOVA was used for multiple time-point comparisons.

Results: POEM was performed in 51 patients (22F, age 48.6±13.5 years). Further baseline data is presented in table 1. Median gastric and oesophageal myotomy was 3 cm (2–4) and 10 cm (3–18) respectively with a selective circular myotomy in all cases and a posterior approach in 11. POEM was clinically successful in 48/51 (94%) eligible for review at 3 m. Reduction in ES at 3m: 8.5 (5–12) vs 0 (0–7) p < 0.001 was sustained in 31 patients with median follow up of 15 m (3–36); 8.5 (5–12) vs 2 (0–7) ANOVA P < 0.0001. Reduction in IRP-4s was observed 24.05 ± 10.47 mmHg vs 7.81 ± 4.91 mmHg (p = 0.0001). Revision of POEM was performed in n = 3 at 6, 16 and 27 m after POEM (Clavien-Dindo Grade IIIb). There were no cases of mortality, perforation, infection or major bleeding.

(continued)

Conclusion: This is the largest UK case series of POEM for achalasia including the first successful UK POEM procedure for DES. At our institute, POEM was performed successfully in a potentially more challenging cohort where 52.9% had prior endoscopic/surgical treatment with intervention. Our results are in line with international consortia and ASGE findings that POEM is a safe and efficacious procedure for the treatment of achalasia and oesophageal spastic disorders for both short term and sustained symptomatic benefit.

P1467 NEW CHALLENGE FOR SAFER ENDOSCOPIC SUBMUCOSAL DISSECTION USING CO2 LASER
Y. Morita, R. Ariyoshi
Gastroenterology, Kobe University, Kobe/Japan

Contact E-mail Address: ymorita@med.kobe-u.ac.jp

Introduction: Endoscopic submucosal dissection (ESD) is increasingly accepted as a minimally invasive treatment for the patients with early gastrointestinal cancers. However, ESD demands high maneuverability technique, and the success of the operation is dependent on each operator’s skill. We have developed a novel laser surgery system for ESD to overcome such difficulties of ESD, which is composed of a CO2 laser source and a disposible flexible hollow fiber probe. Compared to conventional ESD (C-ESD) using electric surgical knives, ESD using CO2 laser (E-ESD) had an advantage of less risk of perforation and massive thermal damage, because the CO2 laser is strongly absorbed by water such as saline or sodium hyaluronate. Further more, the cutting point can be precisely recognized by another visible guide laser. Due to non-contact laser irradiation and adequate visualization of treatment area, the laser system facilitates more precise and safer treatment and provides high quality and stable dissection. We hypothesized that performing ESD using CO2 laser with a submucosal laser absorber could be a safer and simpler ESD technique.

Aims & Methods: The aim of this study was to evaluate the feasibility of E-ESD and the quality of the resected specimen obtained by L-ESD in living porcine compared with C-ESD. We performed ESD for a total of 14 hypothetical lesions in three porcine stomachs (L-ESD: 7 lesions; C-ESD: 7 lesions) under general anesthesia. En-bloc resection rate, procedure time, adverse events, and the quality of the resected specimen were evaluated. To evaluate the smoothness of the cutting surface in the resected specimens, we compared the length of the resected side of the submucosa (LRS) with the length of the muscularis mucosa (LMM). Results: The en-bloc resection rate was 100% in both groups. Although the mean L-ESD procedure time was 23.3 ± 10.8 minutes, and was significantly longer than that of the C-ESD group (9.4 ± 6.6 minutes; p < 0.05), there was no uncontrollable bleeding or perforation in either group. The mean ratio of LRS to LMM was 107.3 ± 33.3% in the L-ESD group, and was significantly lower than that of the C-ESD group (138 ± 28%)(P < 0.005).

Conclusion: ESD using CO2 laser might be a feasible and effective method for the treatment of early gastrointestinal cancers.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Acute corrosive ingestion (ACI) is a common and serious medical problem accounting for a number of hospital admissions. ACI causes significant mortality and morbidity. These patients are at risk of developing luminal strictures of the upper gastrointestinal tract in the long term. This is more in patients with high-grade injury.

Aims & Methods: The present study aimed at assessing the long-term outcomes of high-grade (Zargar’s grade ≥Grade 2A) corrosive-induced injury of upper gastrointestinal tract (1). This was a prospective study conducted in the Department of Gastroenterology at Christian Medical College, Vellore. The study period was between January 2008 to December 2014. All patients were managed by a standard protocol which included doing a gastroscopy within 24 hours of ACI. In this study we included patients ≥3 years with high-grade injury (Zargar’s grade

Supported by a grant from Ministry of Health of the Czech Republic, No. 16-2764HA. Clinical trial registration was done at another hospital were excluded from the study. The study was approved by the Institutional Ethics committee and was funded by a fluid research grant received from Institutional Review Board at Christian Medical College, Vellore, India. The data was analyzed using SPSS version 17. The categorical continuous variables were expressed as mean ± SD and the non parametric continuous variables were expressed as median. Comparison between groups was done using Fisher’s exact test.

**Results:** During the study period a total of 112 patients presented with ACI. In all 82 patients were included in the study. Amongst them, 53% of the patients were females and the mean age was 36.5 ± 15.5 years. The intent of corrosive ingestion was suicidal in 70% and accidental in 30%. In majority (50%) of patients the nature of ingested material was not known. Nasogastric tube placement was done in 50%, nasojejunal tube placement in 32% and 8% no tube was placed. Surgery as needed in 19% (tracheostomy or feeding jejunostomy or a definitive surgery). Amongst the 82 patients who were included in the study, 11 were lost to follow up within 31 months, however 67 patients in whom the medical follow up period was 31 months (range 2-72 m) during which 12 (16.9%) patients expired (73% related to ACI). Amongst the 59 patients, that were alive 16(27%) were symptomatic, 12(20%) had dysphagia, 5(6%) had regurgitation, 4(5%) had chest pain, 67% had weight loss and 11(18%) patients required hospitalization. In all, 43(73%) patients underwent barium study during follow up and strictures were noted in 21(36%). The site of stricture was esophageal in 11(53%), stomach in 8(38%) and combined esophagostomy and stomach in 20%(39%). Esophageal stricture was seen in all patients with Grade III B esophageal stricture. 27% (6/22) with Grade III A injury and 19%(5/27) with Grade II B injury. None of the patients with Grade II A injury developed stricture. Stricture in stomach developed in 22(32%) patients with Grade III B injury (15/27 cases) and Grade III A injury, 10%(1/10) with II B injury and 20%(5/25) with II A injury.

**Conclusion:** Acute corrosive ingestion is associated with significant morbidity and mortality. There needs to be stringent control on sale, use and storage of such chemicals.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**PROBE-BASED CONFOCAL LASER ENDOMICROSCOPY (pCLE) FOR IN VIVO DIAGNOSIS OF ESPHAGEAL AND GASTRIC LESIONS - RESULTS OF A PROSPECTIVE, CONTROLLED, CROSS- OVER STUDY

**M. kollar**1, J. Krajcova 2, J. Malusova 2, M. Kment 2, Z. Vackova 2, J. Spicak 2, J. Martinek 3

1Clinical And Transplant Pathology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

2Department of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague/Czech Republic

3Internal Medicine, University of Medicine and Pharmacy, Timisoara/Romania

Contact E-mail Address: malookollar1@seznam.cz

**Introduction:** Probe-based confocal laser endomicroscopy (pCLE) provides real-time microscopic visualization with 1000-fold magnification, allowing endoscopic access to the histological evaluation of gastrointestinal lesions. pCLE may thereby be helpful in guidance of endoscopic therapy. However, histopathological assessment still remains a gold standard for histological diagnosis so far, while pCLE-based diagnosis has not been generally accepted yet. Therefore, more studies assessing diagnostic accuracy of pCLE are warranted.

**Aims & Methods:** The aim of the study consisted in the analysis of the accuracy of three risk scoring systems used in non-variceal upper digestive bleeding for assessing patient’s prognosis, previously estimated to be predictive for re-bleeding/death after gastrointestinal bleeding. We assessed prospectively a batch of 1872 patients admitted in the Gastroenterology Department of Emergency County Hospital Timisoara in a 12-year period, in which we calculated 3 risk scoring systems, Rockall, Cedars-Sinai and Baylor, based on clinical and endoscopic data. We compared their accuracy for assessing patient’s prognosis, expressed as the need of blood transfusions, number of hospitalization days, re-bleeding, surgery and death. Discriminative ability was assessed using the area under the receiver operating characteristic curve (AUROC).

**Results:** The batch included 1014 (54.6%) male and 738 (39.4%) female, mean age 62 ± 7.8 years. Regarding the need of blood transfusions, the predictive ability of the scores is as follows: Rockall AUROC 0.59 (CI (0.55-0.62), sensitivity(Se) = 81.7%, specificity(Sp) = 35.5%, positive predictive value (PPV) = 28.4%, negative predictive value (NPV) = 86.1% (p < 0.0001); Cedars-Sinai AUROC 0.59 (CI(0.55-0.63), Se = 72.4%, Sp = 41.3%, PPV = 28.5%, NPV = 82.3% (p < 0.001); Baylor AUROC 0.56 (CI(0.49-0.63), Se = 41.9%, Sp = 75.5%, PPV = 40.6%, NPV = 76.5%. Number of hospitalization days: Rockall AUROC 0.66 (CI(0.55-0.77), Se = 61.5%, Sp = 65.2%, PPV = 90%, NPV = 25% (p < 0.003); Cedars-Sinai AUROC 0.63 (CI(0.50-0.75), Se = 53.1%, Sp = 73.9%, PPV = 89.5%, Sp = 27.4%; Baylor AUROC 0.52 (CI(0.51-0.73), Se = 47.06%, Sp = 66.6%, PPV = 84.2%, NPV = 52%. Rebleeding: Rockall AUROC 0.55 (CI (0.67-0.73), Se = 61%, Sp = 65%, PPV = 93%, NPV = 40.4%; Cedars-Sinai AUROC 0.41 (CI (0.41-0.56), Se = 35.1%, Sp = 81.2%, PPV = 16.2%, NPV = 94.2%; Surgery: Rockall AUROC 0.67 (CI (0.61-0.73), Se = 71.2%, Sp = 59%, PPV = 16%, NPV = 98.1%; Cedars-Sinai AUROC 0.72 (CI (0.66-0.78), Se = 58%, Sp = 77.4%, PPV = 93%, NPV = 97.9%; Baylor AUROC 0.55 (CI (0.41-0.68), Se = 50%, Sp = 66.2%, PPV = 5.1%, NPV = 94%. Death: Rockall AUROC 0.85 (CI (0.78-0.92), Se = 84.7%, Sp = 78.1%, PPV = 18.2%, NPV = 99.5% (p < 0.0001); Cedars-Sinai AUROC 0.71 (CI(0.66-0.76), Se = 83.1%, Sp = 48.1%, PPV = 10.2%, NPV = 97.6%; Baylor AUROC 0.75 (CI (0.67-0.83), Se = 76.9%, Sp = 72.3%, PPV = 19.2%, NPV = 97.2%. There were no statistically significant differences encountered in predicting the need of blood transfusions and surgery between the scores (p > 0.05). Baylor score was superior to Rockall in estimating the hospitalization period (p = 0.04) and the need of rebleeding (p = 0.004), and Cedars-Sinai proved to be superior to Baylor score in predicting re-bleeding (p = 0.002) and to Rockall score in predicting death (p = 0.006).

**Conclusion:** On our cohort of patients, Cedars-Sinai score proved to be the best in predicting the re-bleeding and death in patients with NV-UDB in comparison to Rockall and Baylor scores.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Contact E-mail Address: julianapinho18@gmail.com

**Introduction:** Dysphagia and malnutrition is a common feature in up to 64% of patients with advanced cancer and the need of radiotherapy or chemotherapy often worsens these symptoms. Percutaneous endoscopic gastrostomy (PEG) is the preferred route of feeding and nutritional support in these patients. Although generally considered to be a safe procedure, it has been reported that PEG tube placement complications in cancer patients may be superior when compared to non-cancer patients.

**Aims & Methods:** The aim of this study was to evaluate the complications rate after PEG tube placement in cancer patients. We did a single-centre prospective database including all patients with PEG tube insertion between March 2014 and June 2016, evaluating the complications during 6 months follow-up.

**Results:** A total of 265 patients (83% men, mean age 59 years) underwent PEG tube insertion. 224 patients (84.5%) had head and neck cancers and 33 patients

**Disclosure of Interest:** All authors have declared no conflicts of interest.
(12.5%) had esophageal cancer; 207 patients (78.1%) had stage IV disease. At the time of diagnosis, 138 patients (52%) had grade 3 dysphagia and the mean body mass index (BMI) was 20.9 Kg/m2. All the patients underwent anti-biotic prophylaxis previous to the procedure. There was an increase on BMI to 23.8 Kg/m2 at 6 months follow up. Eight patients (3.8%) had immediate complications after the procedure (bleeding from the PEG tract; 6; anesthetic complications - 2). The overall complication rate at the first month of follow up was 14.4%, at the third month 20.5% and at the sixth month 11.7%. The overall peri-PEG infection rate was 14%, and was the main complication at the first month of follow up. Development of hyper-granulation tissue was the most frequent complication at the third month of follow-up. Buried bumper syndrome occurred in 10 patients (3.7%). None of the patients had tumor seeding at the gastrostomy site. Overall mortality was 26.4%, none of the deaths attributable to PEG tube insertion.

Conclusion: PEG placement is a safe and effective technique in cancer patients. The rate of major complications and tube site infection were similar to the results found in literature for non-cancer patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Probe-based confocal laser endomicroscopy (pCLE) has been developed to overcome limitations of the current endoscopic sampling techniques. pCLE allows detailed examination of cellular structures and may examine larger areas compared to standard biopsy. Patients after endoscopic treatment of Barrett’s esophagus (BE)-related neoplasia (BORN) should undergo endoscopic surveillance with biopsies to detect persistence or recurrence of intestinal metaplasia (IM) or neoplasia (N).

Aims & Methods: The aim of this prospective study was to evaluate the efficacy of pCLE (vs. standard biopsies) in detection of persistent/recurrent IM/neoplasia in patients after endoscopic treatment of BORN. A single-center, prospective, controlled and pathologist-blinded (still ongoing) study in patients undergoing surveillance for Barrett’s esophagus (BE) after endoscopic treatment of BORN. pCLE images were obtained from the neo-Z-line (a few cases including macroscopically visible tongues), the cardia and the esophagus. Thereafter, standard biopsies were taken and sent for histopathological analysis (4 biopsies from macroscopically normal neo-Z-line, 2 biopsies from the cardia and the esophagus and targeted biopsies from visible abnormalities, if present). BE was defined in pCLE as columnarlined epithelium with dark mucin in goblet cells, a villiform pattern, and regular-shaped capillaries in the mucosa. The dysplastic BE was characterized by black cells with irregular borders and shapes, high dark contrast to the surrounding tissue, and irregular leaking capillaries in the mucosa.

Results: We examined 29 patients, from these 14 patients (48%) had the initial diagnostic procedure. A total 148 patients (52%) had high-grade intraepithelial neoplasia (HGIN) and 8 patients (28%) had an early adenocarcinoma (EAC). Persistent/recurrent IM was detected at the level of neo-Z-line in 10 patients (34.5%) by both standard biopsies and pCLE. pCLE but not biopsies detected persistent/recurrent IM in 2 patients (6.7%), another 2 patients had IM present in biopsies but not in pCLE. pCLE diagnosed one patient with recurrent LGIN in a macroscopic visible tongue arising from neo-Z-line, which was not confirmed in biopsies. Sensitivity and specificity of pCLE detection of persistent/recurrent IM was 83.3% (95% CI 51.6–97.9) and 89.47% (95% CI 66.9–98.7), respectively, with positive predictive value 83.3% (95% CI 51.6–95.0) and negative predictive value 89.5% (95% CI 70.4–96.8). Agreement of pCLE and histopathological findings was 86%.

Conclusion: pCLE seems to be comparable to detection of persistent/recurrent IM after endoscopic treatment of BORN. Nevertheless, these results need to be confirmed in a larger cohort of patients. Supported by a grant from Ministry of Health of the Czech Republic, No. 16–27684A.

P1473 FLEXIBLE ENDOCOSCOPIC SEPTUM DIVISION (FESD) OF ZENKER’S DIVERTICULUM: OUTCOMES FROM A TERTIARY CENTER USING A NEW SYMPTOMS SCORE

Humanitas Research Hospital, Rozzano/Italy

Contact E-mail Address: roberta.maselli@humanitas.it

Introduction: The Surgical Zenker’s sepsum division (ZSD) can be treated by flexible endoscopic septum division (FESD) as a minimally invasive alternative to surgery or to rigid endoscopic procedure. There is still a lack of standardization of the FESD as well as data on late outcome are scarcely reported. Moreover, ZD symptoms are differently reported in available literature and no specific scores have been yet validated.

Aims & Methods: We aim to report the outcome of all ZD treated by FESD in our institution by using a new symptoms score. We retrospectively reviewed consecutive patients with ZD treated by FESD in a single tertiary-care academic medical center between April 2014 and Feb 2017. All patients were included in a prospectively maintained database. A dedicated new score was created to obtain reliable and objective evaluation of outcome of our patients. This score (Milans-Zenker score, MZ-score) is based on the three main ZD symptoms: dysphagia, regurgitation and weight loss. The ZD score (maximum score, 9) is the sum of the symptom scores for dysphagia, regurgitation (for both: 0; absent; 1; occasional; 2; daily) and for weight loss (0, none; 1, <5 kg; 2, 5–10 kg; and 3, >10 kg). The main outcome was clinical success, defined as MZ score ≤2 at the latest follow up. Patient’s symptoms were evaluated at 1 month and at every 6 months after the procedure. Adverse events were recorded and classified as intraprocedural, postprocedural (<14 days), and late (>14 days).

Results: 100 patients underwent FESD, with a mean age of 70.3±12.2 years (range 39–95) and prevalence of male gender (66%). Twenty-nine (29%) of treated ZD were re-intervention: 20(69%) after previous FESD; 8 (27.8%) after previous surgery; 1 (3.4%) after previous surgery and FESD. Mean initial MZ score was 4.5±1.8 (range 1–8). Intradiprocedural bleeding was observed in 5 patients (5%), with all of successfully treated by clips. No postprocedural/late bleedings were recorded. One perforation was observed and treated conservatively. The mean follow up period was 14 months (range 3–35). Overall clinical success was obtained in 78.5% of patients. Mean post treatment ZD score was 1.3±1.5, significantly lower than initial MZ score (p < 0.0001).

Conclusion: FESD represents a safe and effective treatment for symptomatic patients with Zenker’s diverticulum. Our experience suggests that the MZ score could represent a useful tool to monitoring post-procedural symptoms and guide subsequent management.

P1474 HOW ACCURATE ARE THE SYMPTOMS IN PATIENTS WITH FOOD IMPACTION AND FOREIGN BODIES INGESTION?

A. Laranjo1, J. Mocanu2, M. M. Carvalho1, S. Pires3, N. Veloso1, L. Gonçalves1, R. Godinho1, I. Medeiros1

2Hospital Espírito Santo, Évora/Portugal

Contact E-mail Address: anamalaranjo@gmail.com

Introduction: Food impaction (FI) and foreign body ingestion (FBI) remain the most frequent indications for emergency esophagegastroduodenoscopy. The symptoms in these patients are often nonspecific and their location is not immediately recognizable. The endoscopist should be confident with the endoscopic findings and to assess its management and complications. This was a retrospective uncenter cohort study including patients with suspected FI and FBI during three years (2013–2016). Statistic analysis were performed using IBM SPSS Statistics 22 with p < 0.05 deemed to be statistically significant.

Results: 198 patients were included (90 patients with FI, 70 patients with FBI, 38 patients with esophageal foreign body ingestion and 3 patients with FESD). The symptoms in patients with suspected FI and FBI were more frequent in the esophagus (83.3%) and FI was identified by esophagoduodenoscopy in the distal esophagus in 58.9% of those patients. There was more correlation between the location of symptoms and the endoscopic findings in patients with FI compared with the patients with FBI. The symptoms in patients with FI were predominantly localized in esophagogastric junction (83.3%) and FI was identified by esophagagogastroduodenoscopy in the distal esophagus in 58.9% of those patients. At comparison, the symptoms in patients with FBI were predominantly localized in esophagogastric junction (83.3%) and FBI was identified by proximal esophagus in 55.7% of those patients. There was more correlation between the location of the symptoms and the endoscopic findings in patients with FI compared with the patients with FBI (FI 65.6% VS 47.1%; p < 0.05). In FI patients, the most frequent symptoms were nausea (34.7%), abdominal discomfort (34.7%) and vomiting (22.9%). In FBI patients, the most common symptoms were nausea (51%) and vomiting (34%). Food impaction was not possible in 4 patients (5.7%). Major complications occurred in 0.5% (1 perforation).
Conclusion: In FI patients, the location of the symptoms has a better correlation with the endoscopic findings compared with FBI patients. The esophagohioido- neosophagectomy is safe and effective in patients with FI and FBI.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1475 GASTROINTESTINAL ENDOSCOPY UNDER SEDATION IS ASSOCIATED WITH PNEUMONIA IN OLDER INPATIENTS—RESULTS OF A RETROSPECTIVE CASE-CONTROL STUDY

C. M. Kollmann, W. Schmiegel, T. Brechmann
Department Of Gastroenterology And Hepatology, Berufsgenossenschaftliches University Hospital Bergmannsheil GmbH, Bochum/Germany

Contact E-mail Address: christopher.kollmann@rub.de

Introduction: Apparent aspiration is a notable adverse event during gastrointestinal (GI) endoscopy under sedation (GES)[1, 2], but about the incidence and the role of inappropriate aspiration is scarce. Furthermore, patients undergoing endoscopies experience respiratory symptoms such as coughing, shortness of breathing, fever and other respiratory adverse events within 24 hours relatively often in more than 5% [3]. Since coughing during endoscopy has been attributed to an increased risk of aspiration-related postprocedural infection [4] respiratory infections might be underreported. Additionally, patients in advanced age are not only determined as a high-risk group for GI adverse events following colonoscopies [5], but are also more likely to develop hospital-acquired pneumonia [2]. Therefore, the aim of the study was to determine the risk of pneumonia, lower respiratory infection (LRI) and systemic inflammatory activation after GIES.

Aims & Methods: A total of 250 consecutive inpatients who had undergone GIES during a hospital stay of at least three days were included in a retrospective cohort study. Age-, gender- and length of hospital stay-matched controls (ratio 1:1) who had not undergone any invasive procedure or sedation served as controls. Living situations of patients had to be available before and three and/or seven days after endoscopy. Primary objective was the occurrence of pneumonia in general and older patients (>65 years). Secondary objectives were the development of LRI, elevation of inflammatory markers (CRP and WBC), initiation of antibiotic treatment, pathogen detection and pulmonary infiltration. Statistics included χ2 test, paired t-test, ANOVA, multiple linear regression analysis.

Results: No significant differences for the occurrence of pneumonia (1.6%, GIES group vs. 0.4%, control group, p = 0.18, χ2 test) and LRI (4.8% vs. 2.0%, p = 0.041 in general, but in the older age group (2.6% vs. 0.0%, p = 0.041, and 7.8% vs. 2.5%, p = 0.034, respectively) were detected. Inflammatory parameters were significantly increased after GIES, particularly on day three. GIES patients received antibiotic treatment more frequent while pulmonary infiltration did not differ.

Conclusion: This study confirms a higher risk of pneumonia due to GIES in the advanced aged population. In general, patients are more likely to develop inflammation and to receive antibiotic treatment suggesting an increased risk of radiologically non-visible inflammation due to micro-aspiration.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic submucosal dissection (ESD) is an established technique for the treatment of gastrointestinal (GI) neoplasia in Japan. The high uptake and mastery of the procedure there was in part enabled by the high prevalence of early gastric cancer in Japan. Conventional practice in Japan is to admit patients for 3 to 5 days after the ESD procedure for monitoring in view of the risk of serious complications which is between 1–10%. Cost and resource provision in a publicly-funded Western healthcare setting favours shorter planned stays following ESD.

Aims & Methods: We aimed to identify the type and site of lesions being treated in a Western setting as well as the rate, timing and predictors of complications in order to evaluate current admission practice. An electronic database of all ESD procedures performed in our academic institution from 2012–2017 was analysed. Parameters were the number, type, onset and management of complications following ESD. Significant complications (bleeding and perforation) necessitating hospital admission were categorised as early (within 24 hours) and delayed (24 hours to 28 days) post procedure.

Results: A total of 410 ESDs were performed within the time period (225 colorectal, 117 oesophageal, 52 gastric and 16 duodenal). There were 21 complications (4.8% vs. 2.0% early (p = 0.041, and 4.8% vs. 2.0% delayed (p = 0.034)), 6.1% vs. 2.0%, p = 0.1). 6

Conclusion: This data confirms a higher risk of pneumonia due to GIES in the advanced aged population. In general, patients are more likely to develop inflammation and to receive antibiotic treatment suggesting an increased risk of radiologically non-visible inflammation due to micro-aspiration.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1476 SYMPTOMATIC RESPONSE OF PYLORIC PNEUMATIC DILATATION, BOTTOX INJECTION OR COMBINATION THERAPY IN PATIENTS WITH GASTROPARESIS OR DELAYED GASTRIC EMPTYING POST-GASTRIC TRANSPOSITION

A. Gupta, M. A. Eversson, R. Haidry, M. Banks, S. Bown, D. Graham, R. Ganatra, A. Ramasubramani, L. Lovat, R. Swes
Department Of Gastroenterology, University College London Hospital, London, United Kingdom

Contact E-mail Address: absgupta@aol.com

Introduction: Therapeutic options for gastroparesis or delayed emptying following gastrointestinal surgery are limited. Although commonly performed without a defined indication, 2 patients (33%) had a partial or good response, both of which had combination therapy. Partial or good response was observed in 93% (13/14); treatment with Botox alone (18 procedures) or as part of combination therapy

Aims & Methods: 33 patients (13 male; mean age 45, range 17–80) underwent a total of 113 endoscopic procedures over 2 years. Treatments were either 100 IU units of Botox injected into 4 quadrants of the pylorus or pneumatic dilatation (PD) incrementally up to 16–20 mm (Hercules; Cook Medical). Patients with gastric malignancy, previous pyloric surgery or no documented follow-up were excluded. Post-therapeutic responses were assessed at first follow-up post procedure and graded as ‘good’, ‘partial’ or ‘none/poor’. Patients were grouped according to type of therapy and indication.

Results: There were no immediate or late complications observed. 31 procedures were performed for gastroparesis with a mean post-procedure follow-up of 11 weeks. Overall, a partial or good response was observed in 81% (25/31). Specific treatment with Botox alone (18 procedures) or as part of combination therapy (10 procedures) led to a good or partial response in 86% (24/28) compared to 33% (1/3) who had PD alone (p = 0.03). 14 procedures were performed in the post-surgical group with a mean post-procedure follow-up of 10 weeks. Overall, a partial or good response was observed in 93% (13/14); treatment with Botox alone or as part of combination therapy led to a good or partial response in 100% (10/10) compared to 75% (3/4) who had dilatation alone (p = 0.1). 6 therapies were performed without a defined indication, 2 patients (33%) had a partial or good response, both of which had combination therapy.

Conclusion: Pyloric intervention with Botox, PD or combination therapy are safe and effective treatment options for patients with gastroparesis or delayed gastric emptying following gastric transposition. Subjective treatment without a clear indication shows little improvement.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The optimal management and the predictive factors of response to endoscopic dilation of refractory benign oesophageal strictures remains controversial.

Aims & Methods: To evaluate the prevalence and factors predicting response to treatment of benign refractory oesophageal strictures with scheduled endoscopic dilatations

Results: A retrospective analysis of 75 patients submitted to scheduled endoscopic dilation of benign oesophageal strictures between October 2010 and November 2016. Strictures were classified as refractory when ≥3 endoscopic dilations were needed with at least one dilation achieving ≥15mm of diameter during the course of management of the oesophageal strictures.

Conclusion: In our study sample with multiple aetiologies of benign oesophageal strictures, only the maximum dilation diameter and local injection of corticosteroids were associated with improved dysphagia scores.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1480 TRENDS IN CERTIFICATION FOR GASTROINTESTINAL ENDOSCOPY AND VARIATIONS BETWEEN TRAINEE SPECIALTIES: RESULTS FROM THE UK TRAINEE ENDOSCOPY DATABASE

*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: In the UK, endoscopy certification is overseen by the Joint Advisory Group. Since 2011, certification has been awarded for upper and lower GI endoscopy online via the JAG Electronic Training System (JETS). We aimed to analyse trends in endoscopy e-certification, and assess for differences between trainees in gastroenterology (GI), surgical (GS) and non-medical specialties (NME).

Aims & Methods: We prospectively identified trainees awarded certification for gastroscopy, flexible sigmoidoscopy (FS) and colonoscopy from the JETS database. For each specialty, we collected data on lifetime procedural counts, formal assessments, and key performance indicators (KPIs) at the time of certification. Comparisons between specialties were analysed using a combination of chi², Mann-Whitney and median tests.

Results: Between June 2011-Dec 2016, 2857 applications were awarded certification. Most certifications were awarded to GI trainees (Figure 2). Median procedural numbers (p < 0.001) and formatative DOPS counts (p < 0.001) pre-certification varied for each modality in the order of NME > GI > FS. Caecal intubation rates (CIR) at full certification were similar between GI (95.6%) and FS (95.6%, p = 0.81), but lower in NME (93.6%, p = 0.002 vs. GS, p = 0.006 vs. GI), despite no differences at provisional certification (median CIR 95.6%, p = 0.32). Rates of D2 intubation (median 98.7%) varied across groups (GS > GI > NME, p = 0.002). Certification awarded at first attempt were similar across specialties (mean 89.4%, p = 0.19), but varied for gastroscopy (NME 95.5%, GS 90.1%, GI 89.7%, p = 0.01).

Conclusion: Despite variations amongst trainee specialties, endoscopy certification is a transparent and robust benchmark for assessing competency, as evidenced by recent changes to certification, and if variations in KPIs exist following certification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1479 LOCAL CORTICOSTEROIDS IMPROVE EARLY CLINICAL OUTCOMES IN PATIENTS UNDERGOING ENDOSCOPIC DILATION OF BENIGN OESOPHAGEAL STRICTURES

M. Moura, C. Simões, C. Noronha Ferreira, P. Santos, J.P. Freire, J. Lopes, L. Carrilho Ribeiro, J. Velosa
Gastroenterologia E Hepatologia, Hospital de Santa Maria - Centro Hospitalar Lisboa Norte, EPE, Lisboa Portugal

Contact E-mail Address: cmiguelmour@gmail.com

Introduction: Local corticosteroids have been shown to improve outcomes in patients undergoing endoscopic dilation of peptic strictures.

Aims & Methods: To evaluate factors predicting early clinical response to endoscopic dilation of benign oesophageal strictures. Retrospective analysis of 75 consecutive patients submitted to scheduled endoscopic dilation between October 2010 and November 2016. Clinical improvement was defined as dysphagia grade ≤1. IBM SPSS®/21 was used for statistical analysis.

Results: The study sample included 42 (56%) male patients and the mean age was 52±18 years. Dysphagia scale at baseline: solids (1)–17 (22.7%), semi-solids (2)–23 (30.7%), liquids (3)–23 (30.7%) and complete (4)–12 (16%). Body mass index (BMI) at baseline was 22±5 Kg/m². The aetiology of the benign strictures was: surgical–31 (41.3%), peptic–15 (20%), caustic–10 (13.3%), radiotherapy–10 (13.3%) andthers–9 (12%). The location of the oesophageal strictures was as follows: proximal: third–34 (45.3%), middle third–12 (16%), distal third–27 (36%) and multiple locations–2 (2.7%). Stricture type: simple–44 (58.7%), complex–31 (41.3%). Patients underwent a median of 4 (1–26) endoscopic dilation over a median period of 19 weeks (1–229). Dilations were done with Savary-Gilliard dilators–35 (46.7%), TTS-balloons–24 (32%) or both–16 (21.3%). The mean dilation diameter of achieving was 15.7±2.2 and a dilation diameter of ≥15mm was achieved in 56 (74.6%) patients. Local injection of corticosteroids (dexamethasone 5 mg) was performed at least once in 39 (52%) patients and in ≥25% of dilations in 39 (52%) patients. From the study sample, 25 (33.3%) patients fulfilled criteria of refractory strictures. In this subgroup, there was a significant association with post-surgical aetiology (p = 0.042), lower rate of local injection of corticosteroids (p < 0.001) and higher dilation diameter (p < 0.001). Refractory strictures were significantly associated with the need for local corticosteroid injection (OR 8.95, 95%CI 3.35–23.0, p = 0.002) by binary logistic regression analysis. However, none of the other factors were found to be independent predictors of response to therapy.

Conclusion: Surgical aetiology was significantly associated with refractory benign oesophageal strictures and these patients were significantly more likely to require local corticosteroid injections during scheduled endoscopic dilations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1481 EFFICIENCY AND SAFETY OF ENDOCUTANCibal PAPILLECTOMY FOR TREATMENT OF DUODENAL PAPILLA TUMORS

Y. Chiu, M. Xu, P. Zhou, C. Zhang
1Endoscopy Center And Endoscopy Research Institute, Fudan University Zhongshan Hospital, Shanghai/China

Contact E-mail Address: xu.meidong@zs-hospital.sh.cn

Introduction: A duodenal papilla tumor is an uncommon neoplasm in the upper gastrointestinal tract. In the early stage, patients often have no complaints and the tumors are usually occasional found during gastroduodenoscopy examination. Endoscopic papillectomy can be achieved with curative resection for benign adenoma and some early papillary carcinoma. However, some complications are accompanied with the procedure, like pancreatitis and bleeding. This retrospective study is to evaluate therapeutic effect and safety of endoscopic papillectomy on duodenal papilla tumors.

Aims & Methods: From June 2009 to November 2016, the information of patients who received endoscopic papillectomy was recorded, which included basic characteristics and clinical outcomes, such as recurrence rate, bleeding, pancreatitis. Among 31 cases of patients (totally 40 cases) received endoscopic papillectomy. The procedure was completed with gastroscope in 32 cases and duodenoscope in 8 cases. Endoscopic mucosal resection (EMR), endoscopic piecemeal mucosal resection (EPMR) and endoscopic submucosal dissection (ESD) was performed in 21, 17 and 2 cases respectively. None of the lesions invaded the submucosal layer.

bleeding (≥ 1). Surgery was performed in 10 patients (13.3%) (refractory strictrues) and post dilation perforation (n = 3). Improvement of dysphagia symptoms was only associated with the maximum dilation diameter (p = 0.026) and local injection of corticoids (p < 0.001) as confirmed by binary logistic regression wherein both maximum dilation diameter (OR: 4.92, 95%CI 1.05–20.4, p = 0.027) and topical injection of corticosteroids (OR: 7.22, 95%CI 0.021–0.55, p = 0.007) were strongly associated with improved dysphagia scores.

Conclusion: In our study sample with multiple aetiologies of benign oesophageal strictures, only the maximum dilation diameter and local injection of corticosteroids were associated with improved dysphagia scores in patients undergoing endoscopic dilation of benign oesophageal strictures.

Disclosure of Interest: All authors have declared no conflicts of interest.
Pancreatic stents and biliary stents were inserted in 9 and 12 patients respectively. In general, 5% (2/40) and 12.5% (5/40) cases had intraoperative and postoperative bleeding respectively, 20% (8/40) cases suffered from pancreatitis, of which mild, moderate and severe happened in 3, 4 and 1 cases. Six patients had tumor recurrence. And 3 patients received repeat endoscopic papillectomy, two received pancreatie-coduodenectomy and one received no other treatments with close follow-up. Two patients died from failures of treatment for papillary tumors and one patient died due to other unrelated cause.

Conclusion: Endoscopic papillary is proved to be efficient in treating papilla tumours without submucosal invasion. However, adverse events like pancreatitis and bleeding should be taken seriously and managed properly.

P1484 PROTECTIVE VACUUM SPONGE IMPLANTATION AND CONTINUOUS EVACUATION OF BILE AND PANCREATIC JUICE FOR PREVENTION OF SECONDARY PERFORATION AFTER PRIMARY SUCCESSFUL ENDOSCOPIC RESECTION OF WIDESPREAD D2/D3 DUODENAL AND PAPILLARY ADENOMATA

Introduction: Endoscopic resection of duodenal adenomata carries an increased risk of perforation compared to other locations in the upper or lower GI tract.1,2

Additionally in endoscopic resection of widespread adenomata (Spiegelman III/IV) at the level of D2/D3 there is an increased risk of secondary perforation due to auto-digestion of the denuded duodenal wall by pancreatic enzymes and bile independent of the primary endoscopic resection method. We recently reported of the successful implantation of a mini-vacuum sponge with extended length of the suction tube and reduced in volume compared to a standard esophageal vacuum sponge.3

Aims & Methods: From September 9th, 2015 to March 20th, 2017 endoscopic resection of widespread duodenal or papillary adenomata of >2 cm in D2/D3 was performed in five patients. There was a surgical indication for Whipple’s resection as primary intervention or in case of failure in all patients. All patients agreed and gave their informed consent to the procedure.

Results: Five patients with widespread duodenal adenomata were included (2x papilla, 3x D2/D3 extrapapillary adenomata; 3x tubular; 3x HGIN, 2x LGIN). The macroscopic mean maximum diameter and perpendicular diameter of the lesions were 4 x 2.8 cm (largest 7.5 x 3.7 cm; smallest 2.2 x 1.8 cm). In all cases the implantation of a mini-vacuum sponge (EVAc) reduced in volume to 1.2 x 1.5 cm (dia, length) with extended suction tube; Braun Corp., Melsungen). Continuous suction was applied over several days (~125 mm Hg; ActiVac, KCI Medical, Wiesbaden) depending on the size of the resection area and healing status (n = 10 days, 4–14 days). An endoscopic/radiologic vacuum sponge exchange was performed every 3–5 days. In 4 cases additional atrumatic over-the-scope-clips (OTSC, Ovesco Tuebingen) were placed during the procedure and in 5 cases additional hemoclips were applied to secure the wall and for hemostasis. In 5/5 cases (100%) an excellent healing could be observed during follow-up. No patient had to be operated during or following the intervention (FU 2–14 mo.). In all cases the resection was curative with ‘en bloc’ resection, though in one case the specimen ruptured during retrieval into three parts (4x HGIN, 1x LGD: 4x R0, 1x Rx). In one case 10 days after resection an acute bleeding occurred with the need of endoscopic clipping and prophylactic radiologic coiling of the gastroduodenal artery with uneventful course. In a second case a minor bleeding occurred without necessity of transfusion during ablation of an OTSC three mo after the primary intervention. All patients were asymptomatic during follow-up.

Conclusion: The endoscopic resection of large duodenal adenomata in D2/D3 is feasible and was safe in our collective using the application of a duodenal mini-vacuum local drainage of bile and pancreatic juice as alternative to Whipple’s resection. The results in this first small collective should be reproduced in a prospective multicentric trial.

Introduction: DOPS are validated tools for assessing competence in endoscopy. Previously, DOPS were scored on a 4-point competence-based scale, with scores of 3 and 4 signifying competence. In July 2016, the DOPS rating scale changed to a 4-point scale, hence a score of 4 on new DOPS = Scores 3 or 4 on old DOPS, and scores on the new and old DOPS compared using the Mann-Whitney U-test. Reference: P1177 DOPS (77.7% new and 22.3% old) were included for analysis.

Overall, there were variations in distributions of all scores (p < 0.001) between forms (Figure 1). Compared to new DOPS, scores of 1 were underutilised on old DOPS (0.6% vs. 3.0%, p < 0.001). Frequencies of low scores (pooled scores of 1 & 2) were similar for gastroscopy (p = 0.33) and sigmoidoscopy (p = 0.34), but not for colonoscopy (11.9% vs. 13.9%, p < 0.001) and polypectomy (new 6.8% vs. 19.9%, p < 0.001). Trainees on old DOPS were more likely to be rated as competent (score 3 or 4) compared to new DOPS (86.4% vs. 55.8%, p < 0.001).

On subgroup analysis, this was evident for gastroscopy (86.3% vs. 49.1%, p < 0.001), colonoscopy (86.1% vs. 58.2%, p < 0.001), sigmoidoscopy (90.6% vs. 62.0%, p < 0.001), but not polypectomy (80.1% vs. 67.9%, p = 0.12).

Conclusion: Endoscopy assessors are applying a greater range of scores using a new DOPS rating scale based on degree of supervision, in two cohorts of trainees matched for experience. This indicates better construct validity with the new rating scale. Further work is underway to determine the reliability of the new DOPS to inform summative assessment and certification for UK endoscopy trainees.

Introduction: Acute perforations are one of the recognized complications of both diagnostic and therapeutic gastrointestinal endoscopy. For decades, surgical treatment has been the standard of care, but endoscopic closure has become a more popular approach due to feasibility and the reduction of the burden of surgery, combined with the availability of various endoscopic closure devices.

Aims & Methods: We aimed to assess the technical and clinical success and safety of endoscopic closure, in total, and for each endoscopic device used in closing acute perforations in animal models. Medical literature (Choiry library: EMBASE, MEDLINE) from 1966 till September 2016 was searched. A systematic review and meta-analysis were performed on studies reporting technical and clinical success of endoscopic closure of acute perforations, according to PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) guidelines.

Results: 46 studies on animal models were identified. 15 studies, including 4 prospective studies in human is needed. Of these studies, 46 studies on animal models were identified. 15 studies, including 4 prospective studies in human is needed. Further confirmation from prospective studies in human is needed.

P1486 RISK FACTORS FOR COLORECTAL POLYP IN ASYMPTOMATIC YOUNG ADULTS UNDER THE AGE OF 50

Y. Myung
hyundai UVIS hospital, Incheon/Korea, Republic of

Contact E-mail Address: dittomyung@gmail.com

Introduction: Current guidelines recommend that adults age 50 to 75 be screened for colorectal cancer (CRC). However, CRC incidence rates have increased among young adults and have decreased among older adults.

Aims & Methods: The aim of this study was to investigate the risk factors of colorectal polyps in young adults aged <50 years. From January 2016 to December 2016, we compared the risk factors of colorectal polyp group with non-polyp group in patients aged <50 years who underwent screening colonoscopy. The risk factors examined included body mass index (BMI), meto-sodium, smoking, alcohol consumption, and family history.

Results: Of the 1862 patients, prevalence of colorectal polyps and adenomatous polyps were 13.1% and 7.8%, respectively. Multivariate analysis revealed that metabolic syndrome (OR, 1.89; 95% CI, 1.13–3.17, P = 0.015) was independent predictor for colorectal polyp. Age over 50 years (OR: CI, 1.48 4.14) and metabolic syndrome (OR, 1.59, 95% CI, 0.87–3.30) were independent predictors for adenomatous colorectal polyps.

Conclusion: Metabolic syndrome is risk factor of colorectal polyps in young adults aged <50 years. Age over 40 years old is additional risk factor of adenomatous polyps.

P1487 COMPARISON BETWEEN AN ASYMMETRIC (SMALL DOSE IN THE MORNING) AND A SYMMETRIC SPLIT-DOSE REGIME OF POLYETHYLENE GLYCOL PLUS BISACODYL FOR BOWEL PREPARATION FOR SCREENING COLONOSCOPY: A RANDOMIZED NON-INFERIORITY CLINICAL TRIAL

P. Andreozzi1, C. Bezzio2, G. De Nucci3, S. Saibeni4, M. Devanji5, I. Arena6, R. Reati1, E. Mandelli1, D. Redaelli1, D. Morganti1, B. Omazzi1, G. Manes1

Introduction: Bowel cleansing has a critical role to increase the quality and effectiveness of colonoscopy. International guidelines recommend the use of split-dose regimens of PEG solutions. However, the adoption of split dose regimens in clinical practice remains sub-optimal, in particular in early morning.

Aims & Methods: We aimed to compare the efficacy of bowel preparation using an asymmetric split-dose regimen (approximately 25% of the dose is given on the day of the procedure and 75% of the dose is given on the day before) with the standard split-dose regimen in patients undergoing screening colonoscopy. We prospectively enrolled consecutive outpatients undergoing screening colonoscopy. All subjects received a split-dose preparation with a 2L PEG-citrate-simethicone plus Bisacodyl. Patients were randomly assigned to: group A, asymmetric split dose regimen (1.5 L of PEG + bisacodyl the day before and 0.5 L 3 hours before colonoscopy); group B, symmetric split dose regimen (1 L of PEG + bisacodyl the day before and 1 L 4 hours before colonoscopy). Bowel preparation was evaluated using the Boston Bowel Preparation Score (BBPS) score. The primary endpoints were the proportion of adequate bowel cleansing (BBPS ≥ 2) and failure of bowel cleansing (BBPS = 1). Moreover, all patients filled in a nurse-administered questionnaire assessing compliance, tolerability and safety of bowel preparation. The threshold for statistical significance in this study was p = 0.05 and a 10% margin was used to demonstrate non-inferiority of asymmetric versus symmetric split-dose regimen.

Results: 179 patients were enrolled (mean age 60 ± 8 years, males 56%, 88 in group A and 91 in group B. Split-dose was taken by 76/88 and by 77/91 patients in group A and B, respectively (85.2% vs 88.5%, p = 0.831). Failure of cecal intubation occurred in 1 patients for each group. In the ITT analysis, bowel cleansing was considered adequate in 71/76 (93.4%) and 70/77 (90.9%) patients respectively in group A and B (p = 0.765). BBPS total score was similar in group A and B (6.1 ± 1.2 vs. 6.9 ± 1.4, p = 0.386). No differences were observed regarding adenoma detection rate [32/76 (42.1%) vs 35/77 (45.4%); p = 0.745] and scores of each colon segment. The full amount of product and adjunctive fluids were taken by 68/76 (89.4) and 71/77 (92.2%) (p = 0.158) in group A and B, respectively. Tolerability and occurrence of adverse events were similar in the two groups.

Conclusion: An asymmetric (low morning-dose) split-dose preparation with a low volume formulation with additional Bisacodyl is not inferior to the standard split-dose regimen in achieving an adequate bowel cleansing in patients undergoing screening colonoscopy. A lower amount of preparation in the morning allow to the patients to wake up later; this regimen could be thus preferred by patients undergoing colonoscopy early in the morning. Further study are needed to determine the efficacy and tolerability of the asymmetric preparation for colonoscopy scheduled in early morning.

Introduction: Colorectal endoscopic submucosal dissection (ESD) is a technique with remarkably greater difficulty than upper gastrointestinal ESD because of unstable maneuvers and inherent anatomic variability in the colon. Thus, aiming at reducing these restrictions, we have used single balloon (SB) overtube to assist colorectal ESD in cases considered to have difficult operability. In this study, to evaluate the usefulness of a single balloon overtube to assist colorectal ESD.
Aims & Methods: The study included 35 patients with 39 colorectal lesions who underwent ESD (group SB) or did not undergo ESD (group NSB). The mean duration of the lesions in group NSB was significantly longer in group SB (median, 27.5 mm vs 10.6 mm; p < 0.005). No significant differences were found in en bloc resection, complete resection, postoperative bleeding, and perforation rates. No accidental symptom associated with balloon endoscopy was observed.

Conclusion: The reduction of balloon overture can be expected to improve not only access to the lesion but also facilitate scope manipulation for colorectal ESD.

Haute Autorité de Sante - Quand faut-il faire une coloscopie de controle aprés une polypectomie?

Aims & Methods: We aimed to add a 360-degree multi-assessor rating scale (MARS) to provide a global assessment of ENTS skills to the existing KPI panel correlating the results against existing caecal intubation rate (CIR) and polyp detection rate (PDR). The validated MARS tool assesses 4 ENTS domains. The main limitation of this study is the endpoint interval after polypectomy and useful to anticipate and prevent complications in therapeutic procedures, for it has been proven that polyp size is one of the main risk factors of complications (bleeding, perforation). Nevertheless, a high degree of subjectivity exists (especially overestimation of polyp size) in polyp size estimation because of a lack of validated and reproducible measurement methods. The aim of this study was to compare a computer-aided polyp measurement (CAPME) to an unassisted visual estimation (UVE) and an endoscopic reference measurement (ERM).

Aims & Methods: This prospective monocentric study was led between November 2015 and July 2016 in the University-affiliated Hospital of Clermont-Ferrand, the Blaise Pascalin (BPI) and the Image Science For Interventional Techniques (ISIT) research unit of Clermont-Ferrand (France). Video-endo-scopic procedures were recorded and secondly used for the CAPME method. The endoscopic acquisition protocol was standardized with a slow back-and-fourth movement of the endoscope and photography of each polyp was taken with an open biopsy forceps placed on the base of the polyp. ERM was then measured thanks to a simple rule of three knowing the fixed size of the open biopsy forceps (8 millimetres, mm). UVE was determined on the same photography without any measurement devices by two different endoscopists. All the measurements were realized blinded of the other results. Accuracy of the CAPME and UVE methods was defined by a variation less than 1 mm with the ERM. We used the Lin discordance correlation coefficient (CCC) to measure the agreement between the variables.

Results: 33 patients and 78 polyps were included in this study. The mean polyp size was 5.3 mm, with 73.1% (n = 57) of polyp less than 5 mm. The Lin CCC with the UVE method was 0.972 (95% CI 0.967-0.976; p < 0.001). Accurate polyp measurement was obtained for 68 polyps with CAPME method (87.2%) versus 36 polyps (71.8%) for UVE assessment (p < 0.01). Inaccuracy was in increasing proportionally to polyp size (40.9% of inaccurate polyp measurement for polyps greater than 10 mm) and we observed a systematic overestimation of supracentimetric polyps for UVE method. Unlike UVE, CAPME accuracy was not impacted by polyp size variation in our study (11.1%; 14.7% for polyps of >10 mm; 5–10 mm and <5 mm respectively).

Conclusion: To our knowledge, this is the first prospective study with significant data analysing a computer-aided polyp measurement in live colonoscopic procedures. In our study, this methods shows more accuracy than the visual estimation, which is the actual gold standard. The main limitation of this study is the endoscopic protocol (back-and-forth movement of the endoscope) that increases the endoscopic procedure. The use of DualFocus might be a solution to overcome this problem.

Disclosure of Interest: All authors have declared no conflicts of interest.

The validated MARS tool assesses 4 ENTS domains.
domains—Communication (COMM), Situational Awareness (SATA), Leadership (LEAD) and Decision-making (DEC). Each MARS domain was represented by 10 items and is assessed on a 7-point scoring scale - endoscopists should score >90 in each domain (80–90 = need for improvement, <80 = suboptimal performance). CIR and PDR measures are routinely calculated for all colonoscopists using the HICCS Electronic Reporting System with manual validation of these data. Feedback is presented on a quarterly basis to practitioners—endoscopists are expected to achieve 90% CIR and 20% PDR. Correlation of these factors with practitioners ENTS scores were measured using the Pearson test.

Results: 9 endoscopists with known variability in standard colonoscopy KPIs consented to an assessment of ENTS using the MARS tool. Their ENTS scores were correlated with existing KPIs for each colonoscopist (Oct 2016–Mar 2017), and an overall positive correlation was observed between ENTS domains and CIR (COMM 0.58; SITA 0.66; LEAD 0.66; T&D 0.75) and PDR (COMM 0.49; SITA 0.55; LEAD 0.50; T&D 0.60). Three endoscopists were identified as having sub-optimal scores in all of the ENTS domains (operators 5, 7, 9). Taking into account important KPI thresholds 2 out of (33%) of these endoscopists identified were not meeting CIR targets (c.f. 66% of ENTS competent group) and one (33%) did not meet PDR targets (c.f. 0% in ENTS competent group).

Colorectal cancer (CRC) is the third most common cancer diagnosed in men and second most common cancer in women, affecting 1,361,000 people worldwide each year. CRC is a slow growing tumour that most commonly develops from polyps which form in the inner lining of the colon or rectum. The identification and removal of polyps whilst still in a precancerous state has been shown to be effective in reducing mortality from CRC.

Current clinical practice relies on white light (WL) colonoscopy for detecting colorectal polyps, but this is associated with a detection "miss-rate" of up to 26% for small (<10 mm) polyps and 2% for large polyps (van Rijn et al., 2006). Missed lesions (false negative results) puts patients at an unnecessary risk of late stage detection, when managed suboptimally. Poorly prepared patients in the bivariable study were: age (62.1 vs 56.8 years; p = 0.006), and colorectal cancer on colonoscopy (99% vs 81.82%; p = 0.010), and colorectal cancer on colonoscopy (99% vs 81.82%; p = 0.010).

Introduction: Safety and diagnostic accuracy of colonoscopy depend on the quality of bowel cleansing. Several factors have been reported to affect the quality of bowel cleansing, one of them being hospitalization.

Aims & Methods: We performed a prospective, randomised endoscopist blinded clinical trial between February 2016 and January 2017 included. Our aim was to compare visual educational booklet (EMI-137) enhanced level of cleanliness achieved in hospitalised patients who are undergoing a colonoscopy. Hospitalised patients >18 years undergoing colonoscopy were included. Exclusion criteria were: previous colonoscopy in the last 3 years, previous colectomy, known inflammatory bowel disease, urgent colonoscopy, dementia or refusal to participate in the study. Both groups received 4L polyethylene glycol solution. The intervention consisted of a visual educational booklet (visual cohort). Demographic data, personal history, reason for admission and for colonoscopy, work shift in which it was performed, and findings at endoscopy were collected. The Boston Bowel Preparation Scale (BBPS) was used to assess the bowel preparation. A BBPS score <6 or with at least one segment ≤4 was considered a poor preparation.

Results: One hundred and thirty six patients were included, 51.5% were male, with a mean age of 63.5 ± 17.6 years, and 95.9% of Spanish nationality. The mean body mass index was 27.3 ± 5.2 kg/m2. Educational attainment was below secondary education in 71.05%. Most patients were submitted from the internal medicine ward (72.1%), and the gastroenterology ward (21.32%). Anemia (31.62%), abdominal radiographic findings (16.91%), hematochezia/rectal bleeding (15.44%), diarrhea (11.03%), and abdominal pain (8.82%) were the most frequent indications. Patients characteristics, bowel cleansing and endoscopic findings are shown in table 1. The educational booklet did not suppose a difference in the bowel cleansing attained. Factors that impacted on the level of well and poorly prepared patients in the bivariable study were: age (62.1 ± 18.7 vs 70.5 ± 14.8; p = 0.0193), diabetes mellitus (72.33% vs 42.42%; p = 0.0042), hyper-tension (45.63% vs 69.70%; p = 0.016), cardiovascular disease 14.5% vs 36.3%; p = 0.006), and colorectal cancer on colonoscopy (99% vs 81.82%; p = 0.001).

EMI-137 had a cost of £11,245 per additional QALY. The cost-effectiveness of EMI-137 was sensitive to the time horizon of the model. EMI-137 remained within the NICE recommended cost-effectiveness threshold priced at £500 or less. Value of information analyses revealed that uncertainty in the cost-effectiveness of EMI-137 is primarily driven by uncertainty in the assumption that EMI-137 reduces the risk of future polyps after polypectomy. The results of this modelling exercise have since been used to inform the design of Phase II clinical studies.

Conclusion: The results of this early economic modelling exercise demonstrated that EMI-137 has the potential to be cost-effective for patients participating in the UK National Bowel Cancer Screening Programme. The value of information analyses have highlighted the key parameters for which further evidence is required, and this will be used to inform the design of future clinical studies.

Conclusion: The use of a visual educational booklet for the preparation of colonoscopies does not provide a significant improvement in hospitalized patients in our health area. Health and/or colon cancer were predictors of poor preparation for colonoscopy. An optimized preparation should be considered for this type of patients.

P1495 COMPETENCY OF ENDOSCOPIC NON-TECHNICAL SKILLS (ENTS) DURING ENDOSCOPY TRAINING
*JAG Working Group For The Quality Assurance Of Training, Joint Advisory Group, London/United Kingdom

Contact E-mail Address: keith@siau.org

Introduction: Endoscopic non-technical skills (ENTS), comprising of communication and teamwork, situation awareness, leadership and judgement and decision making, are recognised as indicators of quality endoscopy and patient safety. Since July 2016, electronic assessment forms (DOPS) for UK trainee endoscopists have been updated to include ENTERS as an assessable domain. We aimed to assess the uptake and distribution of ENTS scoring in DOPS and their correlation with other endoscopic skills, across all assessable endoscopic modalities.

Aims & Methods: We identified all DOPS submitted between July 2016 and Feb 2017 from the UK endoscopy trainee database (JETS) and acquired data on trainees, procedures and scores. We collated scores for each of the 4 assessable domains (pre-procedural, procedural, post-procedural and ENTERS) into overall outcomes of “not competent” (if any domain items required supervision) or “competent”, and compared this to the overall competence rating. Statistical analysis was performed using chi2 and regression modelling.

Results: 8601 DOPS were prospectively collected, with ENTS assessed in 99.3%. Competency rates of individual ENTS items are summarised in Table 1. Rates of overall ENTERS competency (defined as all items scoring competent) varied across procedures (p < 0.001): ERCP 39.8%, EUS 44.1%, gastroscopy 59.6%, colonoscopy 62.3%, PEG 71.1%, gastrointestinal bleed (71.5%), sigmoidoscopy 72.4% and polypectomy 73.2%. Scores by individual ENTS components are displayed in Table 1. Of DOPS awarded overall competency, 5.9% (240/4077) lacked full competence in ENTS (p = 0.10 across modalities). Across trainee specialties and endoscopic modalities, competency was greatest for “communication and teamwork” (77.1% overall), but least with ‘judgement and decision making’ (68.3%). Competency in ENTS increased with lifetime procedural count (OR 1.008 per increase in procedure, p < 0.001), and correlated strongly with other assessable domains, including overall score (p < 0.001). After adjusting for procedural count, factors predictive of ENTS competency included trainee seniority (OR for ST5 level: 1.96, p < 0.0001), surgical trainees (OR 1.21, p = 0.014), trainees performing polypectomy (OR 2.02, p < 0.0001), and higher procedures count (OR 1.93 per increase in DOPS, p < 0.001).

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: ENTS is an assessable domain within endoscopy training, with scores that correlate with other procedure-related skills, demonstrating construct validity. Competence of ENTS develop with procedural count, and vary with trainee seniority and specialty. Longer term data are required to assess the impact of ENTS on certification.

P1494 STUDY OF ULCERATIVE COLITIS COMPlicated by PRIMARY SCLEROSING CHOLANGIATIS
S. Murasugi, A. Ito, H. Kambayashi, M. Yonezawa, T. Ohmori, K. Tokushige
Institute of Gastroenterology, Tokyo Women's Medical University, Tokyo/Japan

Contact E-mail Address: murasun0305@yahoo.co.jp

Introduction: Primary sclerosing cholangitis (PSC) is often associated with autoimmune diseases, and approximately 70% of PSC patients in Europe/United States and 32% in Japan also have ulcerative colitis (UC). While the complication of UC is confirmed in about 5% of UC patients, the clinical features of UC associated with PSC differ from those of UC without PSC.

Aims & Methods: We investigated the clinical and colonoscopic features of patients with UC and PSC. We retrospectively examined the clinical features, including the clinical course and colonoscopic findings, of 25 colitis patients with UC attending our hospital between 2000 and 2016.

Results: The male:female ratio was 12:13 and the age at diagnosis of UC was 49 ± 15 years. PSC was the initial diagnosis in 12 patients (48%), while colitis was the first to be diagnosed in 4 patients (16%), and both diseases were found concurrently in 9 patients (36%). Among the 21 patients with the diagnosis of PSC, 10 patients (48%) were concurrently, 12 patients (57%) had the symptoms of UC and the latter was recognized by screening. There were 12 patients with UC (52%) and 11 patients with non-specific UC (48%). Among the 24 patients in whom the disease extent was assessed, 22 had pancolitis, 1 had left-sided colitis, and 1 had proctitis. Inflammation predominantly affected the right colon in 20,22 patients with pancolitis and also involved the terminal ileum in 9 patients (48%). The Mayo score for colonoscopic evaluation of UC was 1 in 16 patients (64%), 2 in 8 patients (32%), and 3 in 1 patient (4%). There were no rectal lesions in 10 patients (40%). Liver biopsy was performed in 17 patients, and Ludwig’s stage was Stage I in 1 patient (6%), Stage II in 12 patients (71%), Stage III in 3 patients (18%), Stage IV in 1 patient (6%). Ludwig’s stage did not correlate with the Mayo score. All patients with PSC and enterococci received oral ursodeoxycholic acid (UDCA), including 13 patients with UDCA only (52%), 2 patients with combination of sulfasalazine (SASP) (8%), in patients with combination of 5-aminosalicylic acid (5-ASA) (20%), 2 patients in combination with prednisolone (PSL) (8%), 1 patient with the combination of SASP+PSL (4%), and 2 patients with 5-ASA + PSL (8%). The UCDA dose was 300 mg in 2 patients (8%), 600 mg in 15 (60%), and 900 mg in 7 (32%).

Conclusion: In colitis patients with UC, there was no clear association between colonic disease activity and the severity of PSC. There was no sex difference and the age at diagnosis of PSC showed a bimodal distribution (30s and 60s). Pancolitis was very frequent and predominantly affected the right colon, but disease activity was low. Rectal lesions were mild or absent. About half of the patients had inflammation of the terminal ileum.

PI1496 MAKING COLONOSCOPISTS MORE AWARE OF THEIR ENDOSCOPIC NON-TECHNICAL SKILLS–IMPROVING FEEDBACK FORMATS DERIVED FROM THE MULTI-ASSISTANT RATING SCALE (MARS) TOOL

N. Hawkes, F. Kokwara, B. Davies, J. Cornish
Gastroenterology, Cymru Taf University Health Board, nr Cardiff/United Kingdom

Contact E-mail Address: neilhawkes@aol.com

Introduction: The development of Endoscopic Non-Technical Skills (ENTS) is associated with improved patient outcomes. Whilst ENTS domains have been incorporated into Joint Advisory Group (JAG) Direct Observation of Procedural Skills (DOPS) forms, used as training tools, knowledge of ENTS domains amongst independent practitioners varies. To improve performance in this area of practice requires validated measurement tools and specific feedback against which improvement can be measured. We have previously developed a validated 360-degree multi-assessor rating scale (MARS tool) based on experienced endoscopy assistant ratings for ENTS providing feedback on 4 ENTS domains. Each comprising 10 related but independent practice points. Providing an optimised feedback format for this data is likely to maximise the potential benefits of measuring ENTS performance.

Aims & Methods: We aimed to provide an optimised format for performance enhancing feedback in the ENTS domains and basis for specific auditable outcomes and performance indicators. Local colonoscopists gave consent to application of the ENTS questionnaire. The validated MARS tool assesses 4 ENTS domains – Communication (COMM), Situational Awareness (SITA), Leadership (LEAD) and Judgement & Decision-making (J&DM). Each MARS domain in the administered questionnaire was represented by 10 items and is assessed on a 7-point scoring scale. We sought to develop 1) a format to illustrate an individual’s overall performance in each of the 4 main ENTS domains in comparison to other operators and 2) a detailed domain breakdown highlighting areas of underperformance 3) Collate feedback on the presentation formats.

Results: 9 endoscopists consented to an assessment of ENTS using the MARS tool. The MARS questionnaires were administered during January 2017–relating to the prior 3 months clinical practice. Acceptable performance thresholds were set as >90% good-excellent ratings in each domain. Need for improvement was defined as 80–90% good–excellent ratings (i.e. 10–20% average or poor ratings) and sub-optimal performance as 80% or less good-excellent ratings (i.e. >20% average-poor ratings). Good intra- and inter-rater reliability was demonstrated for these cut-off values during validation of the MARS tool. Scatter plots were used to present the overall domain ratings for COMM, SITA, LEAD and J&DM domains allowing comparison with other endoscopists. To provide more detailed domain-specific feedback to endoscopists an individual report is generated of 4 domain tables summarising the question items and using a ‘traffic-light’ display to help operators quickly identify those specific skills that require areas for improvement. The MARS reports represented the ENTS feedback helpful and indicated that it was ‘likely’ or ‘very likely’ to prompt an alteration in practice. A suggestion to add an additional column to the summary table indicated where performance level has changed in subsequent audit rounds is being considered.

PI1497 OUTCOMES OF ENDOSCOPIC RESECTION OF COMPLEX COLORECTAL LESIONS REFERRED TO A TERTIARY INSTITUTION AFTER FAILED ATTEMPTS AT RESSECTION OR ESSENTIAL TREATMENT A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@kch.nhs

Introduction: Substantial manipulation or sampling of large colorectal lesions prior to endoscopic resection can have significant effects on the feasibility and outcomes of endoscopic treatment. Failed attempts at resection and extensive sampling or tattooing into lesions prior to referral to a specialist centre are common in western practice. However, there are few data defining the scope of prior intervention and the effects on outcomes following endoscopic resection. We examined the effect of significant prior manipulation on the feasibility and outcomes of endoscopic resection of complex colorectal neoplasms in a UK tertiary referral centre.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colonic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Patients were grouped according to whether they had prior attempts at resection, heavy manipulation (≥6 biopsies or tattoo into the lesion), or minimal sampling only (<6 biopsies). Outcomes included initial successful endoscopic resection, complications, recurrence and the need for surgery.

Conclusion: Failed attempts at resection or heavy manipulation of lesions reduces the chance of achieving en bloc resection and increases the risk of complications and recurrence. Nevertheless, specialist management in a dedicated endoscopic resection unit allowed successful endoscopic treatment of these extremely challenging lesions in over 95% of cases with few significant complications.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI1498 NBi VERSUS BLi WHICH MODALITY IS BETTER FOR OBSERVATION OF MUCOSAL BLOOD FLOW IN THE SMALL AND LARGE BOWEL USING NBi (NARROW BAND IMAGING) OR BLi (BLUE LASER IMAGING)?

M. Yasuda1, Y. Naito2, Y. Itoh2
1Dept. Of Gastroenterology And Hepatology, Uji-Tokushukai Medical Center, Uji, Kyoto/Japan
2Dept Of Gastroenterology And Hepatology, Kyoto Prefectural University of Medicine, Kyoto/Japan

Introduction: In recent years, significant advances and innovations have been made in intraluminal endoscopic technology. The special light observation using a narrow band light source different from conventional white light is one such innovation. The special light observation with a magnifying procedure has mainly contributed to improving the diagnosis of lesions in the colon such as stomach, and large bowel; it is particularly useful for differentiating between benign and malignant lesions and evaluating the depth of invasion. The instruments for narrow band imaging (NBI) were developed by Olympus Co., Ltd., and blue laser imaging (BLi) by Fujifilm Co., Ltd. These systems are applied to magnifying endoscopy in clinical practice. Studies have examined the usefulness of magnifying observation with NBI (m-NBI), BLi (m-BLi), and new and brighter BLi (m-BLi) bright for the diagnosis of neoplastic diseases, especially for the early detection of gastrointestinal cancers. However, there are relatively few reports describing the application of these techniques to benign diseases.

Aims & Methods: This basic study aimed to explore the potential of magnifying observation using narrow band light by evaluating the visualization of mucosal blood flow in the small and large bowel. The subjects were selected from among patients who had undergone colonoscopy since April 2016. They were randomized into three groups: patients undergoing examination with EC-L00ZP, a high-end instrument manufactured by Fujifilm Co., Ltd. (group F), CF-HQ290ZI, a high-end instrument manufactured by Olympus Co., Ltd. (group O1) or PCF-H290ZI manufactured by Olympus Co., Ltd. (group O2). Each group consisted of 25 patients. The visualization of mucosal blood flow in the small and large bowel by magnifying endoscopic observation using narrow band light was evaluated and scored as follows: good visualization 2; partial visualization 1, and no visualization 0. The water method and tip attachment were used in all cases.

Conclusion: The respective mean scores for visualization of the small and large bowel were 2 and 2 in group F, 1.32 and 1.24 in group O1, and 1.48 and 1.40 in group O2. The visualization scores for both the small and the large bowel were significantly higher in group F than in groups O1 and O2. Group O2 had higher scores than group O1, although the difference was not statistically significant. The endoscope used in group F has a bright laser light source and maximum optical magnification levels up to 135 times and maximum electronic magnification levels up to 270 times. On the other hand, the endoscopes used in groups O1
and O2 have relatively dark xenon light sources and maximum optical magnification of 110 times, respectively. Therefore, the differences in visualization of mucosal blood flow in the small and large bowel among the groups were considered to be attributable to differences in instrument efficiency. Conclusion: Our results show that magnifying observation with BLI is superior to that with QID regarding the observation of mucosal blood flow in the small and large bowel. We are planning to conduct a study on the clinical application of magnifying observation with BLI for visualization of mucosal blood flow in the small and large bowel.

P1499 MULTIPLE COLORECTAL ADENOMAS WITHOUT APC OR MUTYH GERMLINE MUTATION: A HETEROGENEOUS SUBGROUP OF PATIENTS

I. Sanchez Mete, E. Mannisi, A. Martayan, M. Varanese, V. Sgiliano
Gastroenterology And Digestive Endoscopy, Regina Elena National Cancer Institute, Rome/Italy

Contact E-mail Address: lupe.sanchez@ifo.gov.it

Introduction: Multiple colorectal adenomas (MCRA) can be defined as an endoscopic feature of ≥ 10 colorectal adenomas in patients (pts) without APC or MUTYH germline mutation. At present its clinical features, management and the presence of extracolonic cancer are not well studied.

Aims & Methods: The aim of the present study is to better define the clinical characteristics at diagnosis and during follow-up of MCRA affected patients. For this purpose, colorectal adenomas from 26 males with MCRA (≥ 10 colorectal adenomas), without deleterious mutations of APC or MUTYH genes, were recruited for the study. Clinical features at diagnosis and extracolonic manifestations were recorded. Forty patients underwent annual colonoscopy at our division with a median follow-up of 8.1 years (range 1 to 38y).

Results: The mean age at MCRA diagnosis was 50.1 ± 14.6 years (range 19 to 79 years) and 20 pts (41.6%) had at least a first degree relative affected with colorectal neoplasia. Clinical features at diagnosis: the number of polyps ranged between 10 and 20 in 43.7% of the cases; 21 and 50 in 27.1%; > 50 in 29.2%; 22.9% of pts had one or more adenocarcinomas (ADC): 16.6% had a previously diagnosed colorectal cancer (breast, endometrial, thyroid, lung, bladder, brain, larynx). Twenty-five pts (52%) needed surgery, ten underwent a subtotal colectomy and fifteen a total colectomy. During follow-up twenty-two (55%) pts developed recurrent adenomas and two (5%) had one or more ADC in the resected colorectum; 12.5% of pts developed duodenal adenomas, one had a duodenal adenocarcinoma, we recorded one case of adenocarcinoma of the gall bladder and one cervical adenocarcinoma.

Conclusion: MCRA patients in the present study had similar clinical characteristics to MUTYH associated Polyposis (MAP) affected patients. They were generally diagnosed at a mean age of > 50 years, they had more than 20 polyps (56.3%) at diagnosis, associated with ADC in 22.9% of the cases and required surgery in the majority of cases (52%). During follow-up, pts also developed recurrent adenomas. Clinical characteristics and family history in these patients support the hypothesis that pathogenic alterations in yet unknown genes may be involved. Next-generation sequencing is a promising technology aimed at this purpose. However, these patients should undergo a closer surveillance than those with sporadic adenomas.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1500 EVALUATION THE RELATIONSHIP BETWEEN NUMBERS OF BIOPSIES PER CASE AND DEGREE OF FIBROSIS IN COLON

J. Yang1, Y. Jung1, I. Chung1, Y.S. Cho2, S.J. Han1, T.H. Lee1, S. Park1, H. Cho1, Y. Hwangbo1, S. Kim1

1Department Of Gastroenterological & Hepatology, Department Of Internal Medicine, Soonchunhyang University College of Medicine, Cheonan Hospital, Cheonan, Korea, Republic
2Department Of Pathology, Soonchunhyang University College of Medicine, Cheonan Hospital, Cheonan, Korea, Republic

Contact E-mail Address: soufly99@naver.com

Introduction: A degree of fibrosis on targeted lesion is one of the widely known characteristic factors causing fibrosis of tumor could help sorting patients who are suitable for endoscopic removal of colon tumor. Generally a biopsy is performed on a tumor larger than 2 cm in diameter for a diagnose purpose. Fibrosis can be caused by biopsy performed before resection.

Aims & Methods: We conducted a study to evaluate the relationship between numbers of biopsies and degree of fibrosis in colon. We retrospectively enrolled 144 colorectal adenomas (LS), all ≥ 1 cm, that underwent colonoscopy ESD or EMR between January 2005 and May 2016. All LSTs were larger than 2 cm and conducted en-bloc resection. We included elevated or flat type LSTs and excluded lesions of the depressive or ulcerative type. Each data is compared with O1, O2, and the histologic type of lesions was 60.4% in adenoma, 20.8% of intramucosal cancer, and 18.8% of submucosal cancer, respectively. Signs of fibrosis were present on 45.9% (50/109) of patients with prior biopsy, and 40.0% (16/40) of patients without prior biopsy. (p=0.6)

Results: There was no significant difference in degree (p=0.791) distribution (P=0.941) and depth (P=0.748) of fibrosis between groups with or without prior biopsy. In relationship between pathologic results and the presence of fibrosis, the percentage of adenoma, intramucosal cancer, SM-1(< 1000μm) cancer and SM-2(>1000μm) cancer with fibrosis were 32.3%, 66.7%, 72.7% and 90% (P=0.00). Additionally, the fibrosis rate for tumors <3 cm and >3 cm were 44.1% and 58.97% (P=0.002). When biopsies were performed two or more times on a same lesion, it showed significant difference comparing to patients who only underwent biopsy just once. (OR 4.98, 1.20-20.51, 95% CI, P=0.026)

Conclusion: Degree, distribution and depth of fibrosis were not associated with prior biopsy status. However, the more invasive tumor is, the more presence of fibrosis was found. Moreover, the caution should be needed when performing multiple biopsies because; multiple biopsies are more likely to cause fibrosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1501 ADVANCED NEOPLASIA YIELD IN PATIENTS UNDERGOING COLONOSCOPY AFTER SCREENING FLEXIBLE SIGMOIDOSCOPY: DOES THE DISTAL COLON POLYCHOL PATHOLOGY PREDICTS THE YIELD IN PROXIMAL COLON?

Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Currently patients undergoing a screening flexible sigmoidoscopy (Bowel Scope screening) examination at the age of 55 are referred for colonoscopy if the follow up polyp criteria are met: polyp > 1 cm, villous histology, high grade dysplasia, 3 or more adenomas or > 20 hyperplastic polyps (HP).

Aims & Methods: Objective is to assess the proportion of patients who had an advanced adenoma (size > 3 cm, villous or high grade dysplasia on histology) in the proximal colon when referred for a colonoscopy after a screening flexible sigmoidoscopy. A retrospective cross-sectional study of patients who underwent Bowel Scope screening between July 2013 - July 2016 at St Mark’s Bowel Cancer Screening (BCS) Centre was performed. Epidemiological, procedural and polyp data was retrieved from the endoscopy and Bowel Cancer screening database.

Results: 9960 patients had a screening flexible sigmoidoscopy in the time period. Descending colon was reached in 82% of patients. Advanced adenomas were detected in 351 (3.2%) patients. 520 (5.2%) patients had a colonoscopy following flexible sigmoidoscopy for polyps greater than 1 cm or with dysplasia) in the proximal colon. Median age was 55 years (male: female ratio 2:1). Caecal intubation was achieved in 98% (510/520) of cases. At least one adenoma or a sessile serrated adenoma/polyp (SSA/P) was detected, proximal to the extent of flexible sigmoidoscopy examination, in 45% (229/520) of patients (Table 1). An advanced adenoma in the distal colon was an indication for colonscopy in 351/520 patients (68%). Of these, 52 (14.8%) had a synchronous proximal colonic advanced adenoma and 20 (5.7%) had a synchronous SSA/P. Only 5 (1.4%) patients had an advanced adenoma and proximal SSA/P. Detailed examination of the proximal colon. Presence of a distal advanced adenoma was associated with proximal advanced adenoma (p = 0.0006). However, there was no association between presence of distal advanced adenoma and proximal SSA/P (p = 0.47) or advanced SSA/P (p = 0.4).

Table 1: Proximal colonic pathology during colonoscopy

(continued)
Conclusions: Distal colonic advanced adenomas are a marker of synchronous proximal colonic adenomas and sessile serrated polyps. When colonoscopies were performed for other indications (non-adenomatous polyp > 1 cm, multiple distal HP polyps) the yield in the proximal colon was significantly smaller. These “soft” indications for colonoscopy accounted for a significant additional workload that appears unjustified.

Disclosure of Interest: B.P. Saunders: Advisory board member of Olympus UK. All other authors have declared no conflicts of interest.

P1502 LEARNING CURVE FOR OPTICAL DIAGNOSIS OF COLORECTAL POLYPS USING CUMULATIVE SUM ANALYSIS

R. Rameshshanker, A. Wilson, S. Thomas-Gibson, N. Kamperidis, N. O’Shea, B.P. Saunders
Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Optical diagnosis for diminutive and small colorectal polyps is an attractive option to reduce costs and streamline patient care. The American Society of Gastrointestinal Endoscopy Preservation and Incorporation of Valuable Endoscopic Innovations (PIVI) established a 90% diagnostic threshold for real time endoscopic assessment of the histology of diminutive colorectal polyps (<5 mm). For adoption of optical diagnosis in clinical practice, colonoscopists must be trained and show on-going competence. The learning curve for trainees to achieve the competency has not been fully explored.

Aims & Methods: Aim is to evaluate the minimum number of polyps to achieve and maintain the optical diagnostic thresholds per PIVI standards using an upward CUSUM plot. Four trainees without previous experience in optical diagnosis at our institution participated in this prospective study. Four weeks before the commencement of the study they were given a training module on optical diagnosis (OD). OD was based on NICE and WASP classification. During the study period (January 2016-August 2016), each trainee documented the optical diagnosis of polyps less than 10 mm in size. Confidence levels of OD were noted at the same time. Patient demographics and polyp details (site, size, Paris classification and histology) were collected prospectively. OD of each polyp was compared against the polyp histology. Polyps without the histological confirmation were excluded from the analysis. Every trainee had on-going feedback on their performance.

Results: A total of 708 polyp observations were performed by trainees during the study period. Total number of adenomas, hyperplastic polyps and sessile serrated adenomas/polyps (SSA/P) were 364, 214 and 52 respectively. Trainees OD performance was plotted on a upward CUSUM plot.

Table 1: Trainees optical diagnostic performance

</tbody>
</table>

All 4 trainees achieved sustained accuracy (90% threshold) in OD within 12–58 observations. The number of polyps required to reach the plateau varied between 12 to 58. Every trainee’s confidence level improved over time (from 69% to 89%) and the effect was augmented by in-vivo feedback and revision of training module. Table 1 summarises the optical diagnostic performance of all 4 trainees. Negative predictive value for adenomas were above 90% for all trainees.

Conclusion: The CUSUM scores of all 4 trainees in the study reached the PIVI standards plateau by the 58th polyp observation. In-vivo feedback and continued training appears important to maintain the performance. Our preliminary findings could be used as a guide to plan the certification process for implementation of optical diagnosis.

P1503 THE CLINICAL VALUE OF ENDOSCOPIC FULL-THICKNESS RESECTION FOR COLORECTAL SUBMUCOSAL TUMORS ORIGINATING FROM THE MUSCULARIS PROPRIA: A PROSPECTIVE SINGLE-CENTER STUDY

M. Xu, C. Zhang, Q. Li
Endoscopy Center, Zhongshan Hospital, Shanghai/China
Contact E-mail Address: xumeidong@aliyun.com

Introduction: Given diminishing quality of life caused by colectomy and rectectomy, a minimally invasive treatment is desirable for colorectal submucosal tumors (SMTs).

Aims & Methods: The aim of the current study was to evaluate the clinical efficacy, safety and feasibility of endoscopic full-thickness resection (EFR) for colorectal SMTs originating from the MP layer. A prospective study was carried out, including a consecutive cohort of 56 patients who underwent EFR for colorectal SMTs originating from the MP layer between January 2008 and September 2014 in our center. Among these patients, 21 lesions were located in the colon, 9 located in the intraperitoneal rectum and 26 located in the extraperitoneal rectum. The tight adhesion of the lesion to the serosal layer was identified before EFR in all cases. EFR was performed using a standard ESD technique under direct endoscopic view. The defect of colorectal wall was closed after resection in all cases. Complete resection rate, complications and lesion recurrence were evaluated.

Results: Successful EFR was performed in 54 (96.4%) patients. The other 2 patients were transferred to suffer laparoscopic right hemicolectomy and EFR combining laparoscopic operation respectively, because the lesions involved the external organs and were too difficult to get en bloc resection endoscopically. The endoscopic resection rate and complete resection rate were both 96.4% (54/56) Among 54 cases, 52 of these lesions were performed with EFR without laparoscopic assistance, while 2 needed laparoscopic assistance to get the defect closed after resection. The median operation time was 45 min (range, 20–130 min). The median maximum diameter of resected tumors was 1.5 cm (range, 0.5–5.0 cm). Accurate histopathologic results were acquired from all the resected lesions, including 18 leiomyomas, 11 gastrointestinal stromal tumors (GISTs), 8 fibrous tumors, 3 schwannomas, 11 granulomas, 2 displaced endometrium, and 1 hamartoma. Three patients had local peritonitis and two patients developed postoperative bleeding. All of them recovered after receiving conservative treatments. No single case developed diffuse peritonitis. No lesion residual or recurrence was found during the follow-up period ranging 2–54 months.

Conclusion: EFR appears to be a safe, feasible, and effective procedure for providing accurate histopathologic evaluations, as well as a curative treatment for colorectal SMTs originating from the MP layer. However, it should be performed by the very experienced endoscopists.

P1504 COLONIC ESD BY UTILIZING SHORT DOUBLE BALLOON ENDSCOPE—HOW TO TREAT DIFFICULT CASES IN COLONIC ESD

S. Katsuki, T. Fujita, K. Takamushi, E. Waga
Center Of Gastroenterology, Otaru Eki Kaikan Hospital Center of Gastroenterology, Otaru Japan
Contact E-mail Address: sinichi-katsuki@otaru-eki-kaikan.jp

Introduction: Colon ESD has been becoming a standard treatment in the world. However, sometimes it is hard to remove the colon tumor during ESD. When we can not detach the tumor from the colon wall using normal ESD, we have to consider the following three points: if we don’t have enough experience and skill, we should take the training more. If there are lots of vessels and fibrosis in the submucosal layer, it is necessary to choose adequate tools. And if patients have complicated colon, suitable endoscope need to be selected. In such cases we always use DBE.

Aims & Methods: We evaluated the outcomes of colon ESD by using DBE (DBE-ESD). Short DBE we used were EC450B1, EN530Bi and ES180BT (Fujinon Co., Tokyo, Japan). We’ve performed DBE-ESD on 211 lesions in 184 patients. We analyzed the lesions located in the proximal colon, and the following items were examined: arrival time, procedure time, rate of negative margin, perforation rate, length of hospital stay and recurrence rate in the 5th year after the ESD.

Results: There were 159 lesions located in the proximal colons. The median arrival time to the lesion was 7.9 min, operation time 51.1 min, negative rate of horizontal margin 99.4%, vertical margin 99.4%, perforation rate 0%, median length of hospital stay 3.1 days., and recurrence rate in patients with more than 5 year follow-up 0%.

Conclusion: Because the balloons and the overtube retained the scope at stable position, we were able to get good working space. Therefore, DBE should be one option for difficult cases in ESD.

Introduction: Adenoma detection rate (ADR) is a quality indicator of screening colonoscopy. Monitoring withdrawal time (WT) and use of full-spectrum endoscopy (FUSE) have been suggested to increase the ADR since allow an accurate colonoscopy. Monitoring withdrawal time (WT) and use of full-spectrum endoscopy would be able to increase the ADR. In a prospective non-randomized observational study, consecutive outpatients, aged 18-85 yr, undergoing colonoscopy with different indications were enrolled. In phase 1, endoscopists performed 660 colonoscopies either with standard forward-viewing endoscope (SFVE) (n = 330) or with FUSE (n = 330) without a dedicated WT protocol. In this phase, colonoscopy WTs were measured without the endoscopists' knowledge of being monitored. In phase 2, endoscopists were informed of being monitored and performed further 660 colonoscopies either with SFVE (n = 330) or with FUSE (n = 330).

Results: No differences were observed among the four arms in terms of demographic, clinical features, and indications to colonoscopy. WT was lower in phase 1 arms compared to phase 2 arms (SFVE: 267 ± 96 vs. 387 ± 65, p = 0.001; FUSE: 293 ± 112 vs. 430 ± 93, p = 0.001). When endoscopists were aware of being monitored and used full-spectrum endoscope we observed a higher ADR [phase 1 SFVE 27.3% (90) phase 1 FUSE 33.0% (109) phase 2 SFVE 33.6% (111) phase 2 FUSE 41.8% (138); p = 0.001] and adenoma per colonoscopy (APC) [phase 1 SFVE 0.43 ± 0.85 phase 1 FUSE 0.56 ± 1.08 phase 2 SFVE 0.24 ± 0.72 phase 2 FUSE 0.71 ± 1.08; p = 0.004]. The detection rate of adenoma located proximally to the splenic flexure was higher in phase 2 arms (phase 1 SFVE 11.2% vs. phase SFVE 16.4%, p = 0.056; phase 1 FUSE 12.7% vs. phase 2 FUSE 18.9%, p = 0.033), whereas adenoma located distally to the splenic flexure was higher in the FUSE arms compared to SFVE arms, but these differences were not significant (Phase 1 SFVE 20.0% vs. Phase 1 FUSE 24.8%, p = 0.081; Phase 2 SFVE 21.8% vs. Phase 2 FUSE 27.0%, p = 0.147).

Conclusion: Unmonitored endoscopists have a sub-optimal WT, which increases when they are aware to be monitored. Use of full-spectrum scopes combined with WT monitoring results in increase of adenoma detection rate. In particular, monitoring WT increases the detection of adenoma in proximal colon, whereas the use of FUSE seems to increase the detection of adenomas in distal colon.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1506 HIGH LEVELS OF “PRESUMED POLYP MISS RATE” AT 1 AND 3 YEARS FOLLOWING INDEX SCREENING COLONOSCOPY: NO ROOM FOR COMPLACENCY

Wolfson Endoscopy Unit, St Mark’s Hospital, Harrow, London/United Kingdom

Contact E-mail Address: r.rameshshanker@nhs.net

Introduction: Colonoscopy with polypectomy is considered the optimal method of bowel cancer prevention. Despite improvements in colonoscopy training and technology, it remains as an imperfect tool and the adenoma miss rates vary between 6-27%.

Aims & Methods: Aim is to determine the presumed miss rate for adenomas and sessile serrated polyps (SSA/Ps) after a complete screening colonoscopy. Methodology: A prospective observational study was performed at our bowel cancer screening centre over 12 months from July 2015. Patients who underwent a surveillance colonoscopy following an index colonoscopy were included (one and three-year surveillance). All colonoscopies were performed by experienced, accredited bowel cancer screening colonoscopists. Polyp characteristics and procedural data were prospectively recorded and collected. Polyp histology and epidemiology data were retrieved from our endoscopy database. A polyp was considered as “missed” at the index colonoscopy if it at 1 year surveillance it was not adjacent to a scar (a recurrence) or at 3 years if >5 mm in size and not adjacent to a scar.

Results: 241 patients underwent a surveillance colonoscopy (male: female 2:1, median age 65 years). 90% (241/37.5%) patients had a one-year surveillance colonoscopy. There was no significant difference in the quality of bowel preparation, caecal intubation rate and total procedure time between index and surveillance procedures. Total number of polyps detected during index and surveillance colonoscopies were 815 and 469 respectively. The presumed miss rate of polyps, adenomas, SSA/Ps and advanced adenomas was 37.8% (449/1214), 22.1% (176/798), 41.7% (20/48) and 15.2% (36/236) respectively. More adenomas were detected in the proximal colon when compared to distal colon (26.64% vs 18.04%, p = 0.01). Table 1 illustrates the distribution of missed adenomas in each segment of colon. Adenoma miss rates per size as follows: <5 mm, 6-9 mm and >10 mm were 24.27 and 8% respectively. Higher number of polyps (>3 detected during index colonoscopy independently correlated with high miss rates (84.3% vs 72%, p = 0.04).

Conclusion: Our study highlights that there is likely to be a significant miss rate for adenomas and SSA/Ps even after careful index colonoscopy. Miss rate was higher when multiple polyps are seen at the index examination. This finding appears to justify the current BSG (British Society of Gastroenterology) guidelines for an early, 1 year colonoscopy when multiple polyps are seen. The presumed polyp miss rate at 1 & 3 years may be justified as a new quality metric within screening programmes.

Introduction: Systemic diseases including several types of cancer have been associated with periodontitis, potentially owing to the constant systemic inflammatory state in those patients. Data on a potential association of periodontal disease and colorectal neoplasia is scarce and conflicting.

Aims & Methods: Data from 25,407 patients undergoing healthy check up assessment periodontal disease according to periodontitis-risk classes (PRC 0-healthy gingiva, PRC 1 - tarter or plaque, PRC 2 - redness or swelling) and screening colonoscopy between 2009 and 2012 in Austria were included. Colonoscopy outcomes were compared between patients with and without signs of periodontal disease using multivariate models adjusting for age, sex, smoking, alcohol consumption, diabetes and BMI.

Results: In multivariate adjusted models, patients with periodontal disease had similar odds for the detection of colorectal polyps as those without signs of periodontal disease [adjOR 1.070; 95% CI: 0.918; 1.247]. Regarding the prevalence of adenomas, patients with periodontal disease, likewise, had similar odds as those with healthy periodontal tissue [adjOR 1.010; 95% CI: 0.840; 1.213]. Similarly, those with periodontal disease had comparable odds for colorectal adenomas as those without signs of periodontal disease [1.055 (0.785; 1.418)].

In the table below the adenoma detection rate (ADR) and advanced adenoma detection rate (AADR) divided into the periodontosis-risk classes.

OUTCOMES OF ENDOSCOPIC RESECTIONS OF LARGE NON-POLYPOID LESIONS IN INFLAMMATORY BOWEL DISEASE: A SINGLE UNITED KINGDOM CENTRE EXPERIENCE

S. Gulati, A. Emmanuel, M. Burt, P. Dubois, B. Hayee, A. Haji
Endoscopy, King’s Institute of Therapeutic Endoscopy, RS/United Kingdom

Contact E-mail Address: shraddha.gulati@nhs.net

Introduction: Patients with colitis carry an increased risk for the development of dysplasia compared to those without colitis. The SCENIC consensus statement recommends endoscopic resection of all visible dysplasia. Due to technical challenges and limited experience in the West of large colitis associated non-polypoid endoscopic resections, such patients are often subjected to colectomy.

The King’s Institute of Therapeutic Endoscopy (KITE) is a tertiary centre for endoscopic assessment and resection of large/challenging colorectal polyps. Here we present the largest single-centre case series of large non-polypoid resections associated with colitis.

Aims & Methods: Adults with confirmed colitis (ulcerative colitis extending beyond the rectosigmoid junction and crohn’s colitis affecting at least the left colon) with lesions at least 20 mm in size within the colitis segment were included. Data including demographics, clinical history, lesion characteristics, method of resection and post-resection surveillance were collected prospectively in patients from January 2011 to November 2016. Resection techniques included endoscopic mucosal resection (EMR), endoscopic submucosal dissection (ESD) and hybrid ESD. Surveillance of resection site with magnification chromoendoscopy (mCE) was performed at 3 months with pan colonic mCE at 1-year post resection and annually thereafter.

Results: Thirteen lesions satisfied the inclusion criteria in 13 patients. Patient demographics and clinical data are presented in Table 1. Mean lesion size was 22.4 (20–90) mm. All lesions were non polypoid with distinct margins and no ulceration. High-frequency mini-probe ultrasound confirmed intramucosal lesions in 5 cases where pit/vascular pattern was distorted due to inflammation. En bloc resection was achieved in 6 cases. 69% lesions were deeply scarred of which 66% had experienced prior instrumentation. Resection of a single lesion with intense fibrosis was difficult. Macroscopic evidence of complete resection was achieved in all remaining cases. Endoscopic diagnosis of pre-cancerous lesions of less than 1000 mm were located at right-half colon, 9 at left-half colon and 31 at rectum. The mean duration of disease (mean, SD, range) (years) 19.9, 14.2, 1–50. Disease extent

RESEARCH ON APPLICATION OF TRANSANAL TUBE DECOMPRESSION FOR PREVENTION OF COMPLICATIONS IN COLORECTAL MUCOSAL LESIONS AFTER ESD

L. Bing, Z. Qi, Y. Zhong
Endoscopy Center And Endoscopy Research Institute, Zhongshan Hospital, Fudan University, Shanghai, Shanghai, China

Contact E-mail Address: 13564623431@126.com

Introduction: Endoscopic submucosal dissection (ESD) has been widely used in the minimally invasive treatment of early colorectal mucosa and submucosal lesions. This technique has made it possible to resect even large mucosal or submucosal lesions en bloc, and the recurrence rate is lower. However, due to the thinner colorectal wall and more abundant blood vessels, postoperative complications after ESD is higher in this site. As a result, how to prevent complications related to ESD for colorectal lesions has raised widespread concern. In recent years, more and more researchers placed transanal tube for patients with colorectal cancer resection or intestinal obstruction to promote the early discharge of the gas and liquid in the intestine. The efficacy of this method to reduce incidence of complications and to promote recovery of intestinal function have been verified by a number of studies. Based on this, we applied transanal tube to some patients with colorectal ESD, hoping to provide new ideas for the prevention and treatment of complications.

Aims & Methods: We aimed to evaluate transanal tube for prevention of complications in colorectal mucosal lesions after endoscopic submucosal dissection (ESD). Data of 61 patients with colorectal mucosal lesions undergoing ESD from January to December 2016 were reviewed. All patients were followed up and we analyzed the incidence rate of complications after ESD within one month.

Results: The median age of 61 patients was 61(32–83) years. 21 of all lesions were located at right-half colon, 9 at left-half colon and 31 at rectum. The mean diameter of the lesions was 3.26 ± 2.27 (0.8–12.0) cm. There were no intraoperative complications including serious bleeding and perforation. Delayed bleeding on the eleventh post-ESD day was detected in 1 (1.6%) patient who was cured by transfusion. 3(4.9%) patients suffered post-ESD electrocoagulation syndrome and perforation did not present in all cases. In this group with transanal tube for decompression, the rates of perforation, delayed bleeding and post-ESD electrocoagulation syndrome were all lower than others which was 1.4~8.2%, 0.5~9.5% and 12.1%~40.2% respectively in literature reports.

Conclusion: The application of transanal tube in colorectal mucosal lesions after ESD could effectively reduce the incidence of complications. However, we should do more research to know whether transanal tube need to be placed routinely after ESD or not.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Underwater endoscopic mucosal resection (UEMR) is an alternative to traditional EMR for the resection of colonic polyps. With this technique, water immersion is used in place of air or CO2, and submucosal lifting is usually not required, as water-immersed submucosal cushions itself from the muscularis propria. Theoretically, this reduces the risk of diathermy-induced injury, and allows for more complete resection margins. 

Aims & Methods: In this prospective dual-centre study, we aim to evaluate the safety and efficacy of UEMR for clinically significant (≥10 mm) colonic polyps. Studied outcomes included: 1) completeness of UEMR, 2) intra-procedural and 30-day complication rates, 3) percentage requiring submucosal lift, and 4) rates and predictors of polyp recurrence. Procedures were performed by two screening endoscopists accepting tertiary referrals at St. Mark’s Hospital, London, and Russell’s Hall Hospital, Dudley. UK. Recurrence was defined as the presence of any polyp tissue at the resection site. Endoscopy records were examined and correlated with histology. Univariate analyses were performed using Pearson’s χ2 to identify predictors of measured outcomes.

Results: Between June 2014 and March 2017, and a total of 85 patients (median age 69.5 years, interquartile range [IQR] 11.0, 50.6%) male underwent UEMR of 97 colonic polyps (median size 25 mm, IQR 25 mm, range 10–160 mm). 13 (13.4%) were recurrences following previous conventional EMR. Polyps were predominantly left sided (66%) with flat (63.5%) or sessile (35.5%) morphology. 43.8% of polyps were removed en bloc, whilst argon plasma coagulation (APC) was used in 13.7%. Histology comprised of: low-grade dysplasia (80.2%), high-grade dysplasia (12.5%), adenocarcinoma (1.3%) and non-dysplastic sessile serrated polyp (4.2%). Overall, resection at index UEMR was deemed endoscopically complete in 97.9%. Submucosal lift was required in 27.8% and positively correlated with polyp size ≥30 mm (OR 3.58, 95% CI 1.37–9.38, p = 0.01), but not morphology (flat vs. sessile, p = 0.09). The 30-day complication rate was 4.1% (n = 4), consisting of: bleeding (n = 2, average diameters: 35 mm) and delayed rebleeding (n = 2; average diameter: 57.5 mm), with haemostasis achieved for all cases. No cases of perforation or mortality were identified. Of the 60.8% (n = 59) who attended for repeat endoscopy post-UEMR, the rate of recurrence or residual polyp was 14.8% (9/63) at 4 months and 13.9% (22/160) within 1 year. Significant predictors of post-UEMR recurrence included: piece-meal vs. en bloc resection (OR 5.50, 95% CI 1.10–27.6, p = 0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.03) and recurrent polyp (OR 5.50, 95% CI 1.10–27.6, p = 0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.03). The 30-day complication rate was 4.1% (n = 4), consisting of: bleeding (n = 2, average diameters: 35 mm) and delayed rebleeding (n = 2; average diameter: 57.5 mm), with haemostasis achieved for all cases. No cases of perforation or mortality were identified. Of the 60.8% (n = 59) who attended for repeat endoscopy post-UEMR, the rate of recurrence or residual polyp was 14.8% (9/63) at 4 months and 13.9% (22/160) within 1 year. Significant predictors of post-UEMR recurrence included: piece-meal vs. en bloc resection (OR 5.50, 95% CI 1.10–27.6, p = 0.03) and recurrent polyp (OR 4.17, 95% CI 1.02–17.05, p = 0.03).

Conclusion: UEMR is a safe alternative to conventional EMR for the management of clinically significant colonic polyps. However, our post-UEMR recurrence rate of 22.0% appears higher than other studies, but may be skewed by the tertiary nature of referrals. Although randomised trials are awaited, we suggest that those performing UEMR should attempt en bloc resection where possible, and consider wider resection margins for recurrent polyps.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1513 ENDOSCOPIC SUBMUCOSAL DISSECTION FOR COLORECTAL LESIONS: THE EXPERIENCE OF A UK TERTIARY REFERRAL CENTRE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Despite the advantages of endoscopic submucosal resection (ESD) demonstrated in large series from the far east, the procedure is not commonly practiced in the west and its role in standard practice is still debated. Although limited evidence regarding its efficacy in European practice is emerging, very few centres in the United Kingdom perform ESD regularly, if at all. We report the experience of a UK tertiary referral institution using ESD as part of a lesion specific, pragmatic approach to endoscopic resection in a complex patient cohort.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions were included. Lesions were assessed with magnification chromoendoscopy supplemented by colonicomatos ultrasound in selected cases. A lesion specific approach was used to select technique, which included assessment of morphology, pit pattern, risk of submucosal invasion, and presence of submucosal fibrosis or scarring. ESD was used where en bloc resection was deemed essential, or as part of a hybrid procedure to ensure resection of a dominant nodule or suspicious area of a lesion in one piece, or where fibrosis or scarring would make standard EMR impossible. A resection was designated a hybrid procedure if ESD was used to effect submucosal dissection, circumferential incision alone to assist snare resection was not included.

Results: 116 lesions (mean size 58.8 mm) were resected using ESD (n = 58) and hybrid ESD (n = 58). 82 (70.7%) had been subjected to prior attempts at resection (n = 58) or extensive sampling. Only 11 lesions had no prior biopsies performed. En bloc resection was achieved in 93.1% where ESD was used alone, with a mean procedure rate of 4.7% after a mean follow-up of 19 months. There were 6 microperforations treated with either endoscopic clips or antibiotics alone with no adverse sequelae, and one clinically significant perforation requiring surgery. However, the resected lesion in this case contained an invasive adenocarcinoma with deep submucosal invasion—there was no residual tumour in the surgical resection specimen. Post-procedure bleeding occurred in 6 patients, none of whom required treatment. 1 patient was treated with a blood transfusion. The remaining patients were managed expectantly. In all these latter cases spontaneous cessation of bleeding and re-endoathlasia occurred. 25 lesions had a submucosal invasion greater than 150 mm, 17 of which were managed successfully.

Conclusion: The majority of patients with these extensive complex lesions can successfully be treated with endoscopic resection and avoid surgery. However, these patients have a significantly greater risk of complications and recurrence and should be managed in a tertiary institution. Although there is a significant risk of stenosis, it appears that most cases are asymptomatic and spontaneously improve with expectant management.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1514 RISK OF STENOSIS AND OUTCOMES FOLLOWING ENDOSCOPIC RESSECTION OF LARGE COLORECTAL LESIONS INVOLVING MORE THAN 75% OF THE LUMINAL CIRCUMFERENCE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji
Endoscopy, King’s College Hospital, London/United Kingdom

Contact E-mail Address: aemmanuel@nhs.net

Introduction: Little is known about the risk of stenosis and outcomes following endoscopic resection of lesions in the colorectum which leave extensive mucosal defects. A limited number of studies suggest significant stenosis rates, although reports on outcomes and suggested management are conflicting. We determined the risk of stenosis and outcomes of endoscopic resection of colorectal lesions leaving mucosal defects ≥75% of the circumference.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. Lesion assessment and selection in western practice should be improved to reduce the incidence of prior heavy manipulation and guide appropriate referral.

Disclosure of Interest: All authors have declared no conflicts of interest.

Endoscopic submucosal dissection: European Society of Gastrointestinal Endoscopy (ESGE) Guideline
Introduction: Although it is well recognised that the risk of invasive carcinoma in adenomatous polyps of colorectal neoplastic lesions differs according to morphology, the incidence of invasive cancer varies between studies and there is limited data from large western series to inform practice. The importance of appropriate resection techniques, including the use of ESD, is increasingly recognised in western practice. It is therefore imperative that the risk of submucosal invasion is assessed as accurately as possible to prevent inappropriate attempts at resection. We determined the risk of submucosal invasion and high-grade dysplasia (HGD) in different morphological sub-types of large colorectal lesions subjected to endoscopic resection.

Aims & Methods: Colorectal lesions ≥2 cm subjected to endoscopic resection were included. Lesions were assessed with magnification chromoendoscopy. Clinicopathological data recorded included morphological type according to Paris classification, sub-types of laterally spreading tumours (LST), degree of dysplasia, presence of submucosal invasion and outcomes following resection.

Results: 435 colorectal lesions ≥2 cm were resected. Mean lesion size was 55.2 mm (range 20 mm–160 mm). The frequency of and the incidence of high-grade dysplasia and invasive adenocarcinoma in the different morphological sub-types are shown in Table 1. The incidence of high-grade dysplasia (8.6%) and invasive adenocarcinoma (1.2%) was very low in LST granular homogenous lesions.

LST G H = LST granular homogenous LST G MN = LST granular mixed nodular LST NG = LST non-granular ESD or hybrid ESD was used to resect 97 lesions. 53% of lesions had been subjected to previous failed attempts at resection, ≥6 biopsies or had tattoo injected at their base prior to referral. Of 29 invasive adenocarcinomas, 9 were deemed curable by endoscopic resection (superficial submucosal invasion with no adverse prognostic features). Of the remaining 20, 5 patients refused surgical resection, 5 were unfit for major surgery and 10 had had residual tumour in the surgical resection specimen, 5 had local recurrence at their referring institution. Only 2 patients with initially benign lesions developed adenocarcinoma in subsequent lesions—all of these were early cancers without nodal metastases at surgical resection.

Conclusion: In one of the largest European series reporting the incidence of invasive carcinoma in different morphological sub-types of colorectal neoplastic lesions, we confirm that LST granular homogenous type lesions have a very low incidence of invasive carcinoma and that care should be taken in the choice of resection technique for other sub-types of LST which more frequently harbour malignancy. Accuracy of preoperative assessment and classification to aid metachronous lesion selection is essential to this process.

P1517 OUTCOMES OF ENDOSCOPIC RESECTION OF RECURRENT COLORECTAL LESIONS TREATED AT A UK TERTIARY REFERRAL CENTRE

A. Emmanuel, S. Gulati, M. Burt, B. Hayee, A. Haji

Introduction: Endoscopic resection of large colorectal lesions, especially by piecemeal EMR, carries a significant risk of recurrence. Although several series examine the outcomes and risk of recurrence following endoscopic resection, few focus on the outcomes of patients being treated for recurrence after initial expert resection, and these mostly focus on one technique to deal with recurrence. We evaluated the outcomes after recurrence of colorectal lesions after apparent successful endoscopic resection in a specialised UK tertiary institution employing a range of resection techniques.

Aims & Methods: Consecutive patients who underwent endoscopic resection of colorectal lesions ≥2 cm were included. All lesions were assessed with magnification chromoendoscopy supplemented by colonoscopic ultrasound in selected cases. A lesion specific approach was used to decide on resection technique. Outcomes were evaluated for patients treated for recurrent lesions.

Results: Of 396 colorectal lesions ≥2 cm initially resected, recurrence occurred in 48 patients. 36% of these patients had already had a mean of 1.6 previous failed attempts at resection prior to referral to our institution, and 66% had had either a failed attempt at resection or extensive sampling involving ≥6 biopsies or tattoo placed under the lesion. 69% of patients were successfully treated with further endoscopic resection and avoided surgery. 27 recurrent lesions larger than 20 mm were treated with endoscopic resection, with a mean lesion size of 48.3 ± 19 mm. Techniques used were EMR (n = 16), ESD (n = 2), Hybrid ESD and EMR (n = 9). The remaining lesions < 2 cm were resected using EMR. A mean of 1.4 ± 0.75 procedures were required to achieve successful endoscopic treatment of recurrence. Of 23 patients who were ultimately successfully treated with endoscopic resection, 15 required a single further endoscopic resection after recurrence, 8 patients required 2 or more further resections. 8 patients required surgery, 3 as a result of developing invasive adenocarcinoma with the recurrence.

There were no perforations as a result of endoscopic resection of recurrent lesions 2 cm initially resected, recurrence occurred in 48 patients. 36% of these patients had already had a mean of 1.6 previous failed attempts at resection prior to referral to our institution, and 66% had had either a failed attempt at resection or extensive sampling involving ≥6 biopsies or tattoo placed under the lesion. 69% of patients were successfully treated with further endoscopic resection and avoided surgery. 27 recurrent lesions larger than 20 mm were treated with endoscopic resection, with a mean lesion size of 48.3 ± 19 mm. Techniques used were EMR (n = 16), ESD (n = 2), Hybrid ESD and EMR (n = 9). The remaining lesions < 2 cm were resected using EMR. A mean of 1.4 ± 0.75 procedures were required to achieve successful endoscopic treatment of recurrence. Of 23 patients who were ultimately successfully treated with endoscopic resection, 15 required a single further endoscopic resection after recurrence, 8 patients required 2 or more further resections. 8 patients required surgery, 3 as a result of developing invasive adenocarcinoma with the recurrence.

There were no perforations as a result of endoscopic resection of recurrent lesions.

P1518 THE EFFECTIVENESS OF NEW TECHNIQUE WITH SELF-EXPANDABLE METALLIC STENT INSERTION IN TREATING RIGHT-SIDED COLONIC OBSTRUCTION

C.B. Ryu1, M.S. Lee1, J.Y. Bae2

1Digestive Disease Center And Research Institute, Department Of Internal Medicine, SoonChunHyang University School of Medicine, Bucheon/Korea, Republic of

2Department Of Internal Medicine, Seoul Medical Center, Seoul/Korea, Republic of

Introduction: Self-expandable metallic stent (SEMS) is widely used to treat malignant colorectal obstruction. However, most reports about SEMS insertion have concentrated on the left colon and very tough to insert SEMS on the right colon, especially distal ascending colon.

Aims & Methods: This study aimed to (1) investigate the effectiveness of new insertion technique with SEMS for right-sided colonic obstruction and (2) compare the safety, accuracy and technical success of SEMS insertion.

Results: A total of 109 patients were screened for enrollment;749 total colonic obstructions were studied: 383 men (51.1%) and 366 women (48.9%). Colic preparation was good (Boston score ≥ 6) in 49.4% of patients. Colonic obstruction was normal in 434 cases (57.9%). Colonic polyps were detected in 197 patients (26.3%). The mean number of polyps detected per colonoscopy (MND) was 2.31 (min. 1, max: 25). The mean polyp diameter was 6.8 millimeters (1 to 50 mm). The mean withdrawal time was 8.2 minutes (4 to 20 minutes). Overall PDR was 26%. G1 included 599 colonscopies and G2 included 150 colonscopies. PDR in G1 was 28.04% versus 20% in G2, the difference between the two groups was not significant (p: 0.7). As for the MNP, it was significantly higher in G1: 2.29 versus 1.86 in G2 (p: 0.049).

Conclusion: In our study, a withdrawal time exceeding seven minutes was significantly associated with the number of polyps detected in colonoscopy. Further studies may be helpful to confirm these results ideally by comparing these parameters in the same patients.

Disclosure of Interest: All authors have declared no conflicts of interest.
A688

compilation (0.10). Concerning SEMS insertion, the technical difficulty and safety of SEMS insertion were similar between right- and left-sided colonic obstructions.

Conclusion: A new technique of curved type guiding tube with SEMS insertion for right-sided colon, especially distal ascending colon is significantly more effective than straight type guiding tube, and this procedure was safer and less technically challenging than expected. SEMS insertion should be considered for treating right-sided malignant colonic obstruction.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1523 DIFFERENCES BETWEEN BOWEL PREPARATION QUALITY OF SURVEILLANCE AND SCREENING COLONOSCOPY
Department Of Internal Medicine III, Division Of Gastroenterology & Hepatology, Medical University of Vienna, Vienna/Austria

Aims & Methods: This prospective non-interventional study compared bowel preparation quality according to the Harefield Scale, performance quality measures and patients satisfaction in screening colonoscopies performed within an Austrian quality assurance program.

Results: Colonoscopies performed by 20 endoscopists were included in this study. 50.3% of screened individuals were women. Because of the unequal patient count using CifraFlex® (CF, n = 261), Picoprep® (PP, n = 2678), Klean-Prep® (KP, n = 804) and Moviprep® (MP, n = 1252), PC and CF were grouped as a single cohort (LV). Age and gender adjusted success rates and ADR per purgative were 97.0% and 23.3% for LV, 97.5% and 32.5% for KP and 93.5% and 26.0% for MP. Women had higher success rates than men (p = 0.007) and success rate decreased with patients’ age (p = 0.008). The difference regarding completion of the entire volume was best with LV (89.2%, KP 87.6%, MP 83.7%), which had a significant effect on success rate p = 0.027. 93.5% of patients in the LV group would use the same purgative again compared to 68.4% in the KP and 73.2% in the MP group.

Conclusion: All investigated purgatives met the required quality standards of ≥90% rate of adequate bowel preparation according to the current ESGE guidelines. Success rates were higher in women and younger patients. Although only <9% of patients consumed the whole volume, the majority of patients would use the same purgative again.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1524 DIFFERENCES IN QUALITY OF BOWEL PREPARATION AT SCREENING COLONOSCOPY IN PRIVATE PRACTICES AND HOSPITALS
Department Of Internal Medicine III, Division Of Gastroenterology & Hepatology, Medical University of Vienna, Vienna/Austria

Aims & Methods: Data from screening colonoscopies performed within quality certificate in Austria (2012-2017) provided by 245 endoscopists were evaluated. The recording of the quality of the bowel preparation was described as one of the Austrian quality assurance program. Improvement Initiative”, 90% of colonoscopies should have adequate bowel preparation. The aim of this study was to investigate whether there is a difference in quality between private practices and hospitals.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1525 RISK FACTORS FOR RESIDUAL NEOPLASIA AFTER ENDOSCOPIC MUCOSAL RESECTION OF LATERALLY SPREADING TUMORS
N. Brogyuk1, T. Grega1, M. Voska1, O. Ngö2, O. Majek1, M. Zavoral1, S. Suchanek1
1Section For Clinical Biometrics, Center for Medical Statistics, Informatics And Intelligent Systems, Medical University of Vienna, Vienna/Austria
2Institute Of Biostatistics And Analyses, Masaryk University, Faculty of Medicine, Brno/Czech Republic

Aims & Methods: This retrospective study in a high-volume tertiary-referral center examined patients who had undergone EMR between 2013 and 2015 and who had had at least 1 surveillance colonoscopy after the initial treatment. LRN was defined histologically as the presence of neoplastic tissue in the post-EMR site.

Results: 160 laterally spreading tumors were diagnosed in 138 patients (62% men, mean age 67 years). Mean follow-up interval for surveillance colonoscopy was 6 months. Residual neoplasia at surveillance endoscopy was present following 21% of EMRs. Single variate analysis showed increased risk of residual neoplasia for LST ≥ 20 mm (p = 0.006), villous adenomas (p = 0.01), piecemeal resection (p = 0.011) and G-type morphology (p = 0.003). In multivariate analysis, only size of the lesion (p = 0.080) and villous component (p = 0.043) were found to be a significant risk factor for LRN.

Conclusion: This retrospective study shows that the occurrence of LRN is frequent. Careful colonoscopic surveillance after EMR and the use of new methods to further reduce residual neoplasia are needed.

Disclosure of Interest: All authors have declared no conflicts of interest.
Familial adenomatous polyposis (FAP) is an autosomal dominantly inherited colorectal cancer with a lifetime risk for colorectal cancer close to 100%. Thus prophylactic colectomy is recommended for patients with FAP. Colectomy with ileorectal anastomosis (IRA) is the surgical option of choice in the majority of patients, given the complications and morbidity associated with ileal pouch-anal anastomosis. Therefore, annual endoscopic surveillance is recommended after surgery to prevent cancer in the rectal remnant (CRR).

Aims & Methods: The aim of this study was to determine the impact of endoscopic surveillance on CRR prevention in FAP patients after surgery. We did a retrospective single center study on findings of follow up endoscopies and determination of the cumulative risk of adenomas and prevalence of high risk adenomas (HRA) (villous histology, high-grade dysplasia and ≥ 10 mm) and CRR.

Results: 30 patients submitted to IRA were included (50% women), with a mean age of 43 years, 2 patients with attenuated phenotype. Nine patients had adenocarcinoma in the resected colon. Six patients started chemoprophylaxis after surgery (sulindac 4 – celecoxib 1). The median time to adenoma appearance was 5 years (95% CI 3.4–6.6) and to HRA/CRR 12 years (95% CI 5.2–18.8), with a decreased median time to both adenomas and HRA/CRR in patients under chemoprophylaxis. The cumulative risk of adenomas was 20% at 1 year after surgery, 34.1% at 3 years and 57.4% at 5 years. During the follow up period, 27% of IRA patients developed in 17 patients (56.7%) HRA –12 patients (40%); intramuscular carcinoma -2 patients (6.7%); invasive adenocarcinoma -3 patients (10%). None of the patients died with CRR. The cumulative risk of HRA/CRR was 21.8% at 5 years, 46.1% at 10 years and 66.3% at 15 years. All the patients with HRA/CRR had rectal involvement prior to surgery (p = 0.008) and a higher number of adenomas resect in the rectal remnant (p = 0.017).

Conclusion: The FAP endoscopic surveillance program allowed detection of HRA/CRR in a high percentage of patients. Based on these results, an intensive surveillance program should be suggested but endoscopic surveillance intervals widen in the first 5 years after surgery.

Disclosure of Interest: All authors have declared no conflicts of interest.

P5157 BOWEL PREPARATION FOR FLEXIBLE SIGMOIDOSCOPY: COMPARISON OF POLYETHYLENE GLYCOL ELECTROLYTE SOLUTION (PEG-ES) AND PHOSPHATE ENEMA IN 4,949 PATIENTS AT TWO UK HOSPITALS
A. Youaf, S. Paranahewa, A. Jeevagan, P. Mayhead Gastroenterology, East Sussex Healthcare NHS Trust, Eastbourne/United Kingdom

Contact E-mail Address: abdyas12@nhs.net

Introduction: Flexible sigmoidoscopy is increasingly used to optimise the diagnostic yield of the test, and also to minimise the number of repeat procedures. However, the optimum bowel preparation for this procedure has consistently been debated. Aims & Methods: Both phosphate enema and (PEG-ES) are commonly used for bowel preparation in flexible sigmoidoscopy at both hospitals participating in this study. We therefore wanted to compare the outcomes for these two methods. We retrospectively reviewed all the patients who underwent flexible sigmoidoscopy from January 2014 to December 2016 using each hospital’s electronic endoscopy reporting system. We analysed their demographics, type of bowel preparation used in each case, and the quality of their individually achieved examination.

Results: In total 6196 patients underwent flexible sigmoidoscopy during the study period (males 2885 (46.58%), mean age 62.80 years, range 16–101 years). 1247 (20.15%) patients were excluded from further analysis for the following reasons: N / A (n = 127), patients who performed the examination at another hospital (n = 451), non-compliance of the quality of the bowel preparation (n = 657), and non-(PEG-ES) oral preparation used (n = 139). A total of 4949 patients were included in the study, of whom 2103 had (PEG-ES) (42.49%) (males 986 (46.89%), mean age 60.97 years, range 18–95 years) and 2846 (57.50%) (males 1269 (44.59%), mean age 63.98 years, range 17–101 years) had phosphate enema. The results are summarised in the table below.

Type of bowel preparation Excellent Adequate Inadequate Total Adequate Excellent Inadequate
(PEG-ES) (n = 2103) 1126 (53.54%) 770 (36.61%) 1806 (80.16%) 207 (9.84%)
Phosphate enema 624 (21.93%) 1297 (45.57%) 1921 (67.50%) 925 (32.50%)
Total (n = 4949) P < 0.0001

Conclusion: Our large retrospective study showed that oral preparation with (PEG-ES) gave significantly better results than phosphate enema, which gave acceptable results in only 67.5% of the patients. As a result of this study, PEG-ES is now the preferred option at our hospitals, if there is no contraindication for this.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic resection of large colonic lesions (LCLs, > 20 mm) is effective and it is associated with an acceptable incidence of incomplete resection and complications when performed by appropriately trained endoscopists in resource centers1–22. Scanty data on the management of these lesions outside referral centers are reported in the literature.

Aims & Methods: Aim of present study is to evaluate the management of endoscopic resection of LCLs and intra-procedural complications in a real-life setting. In a prospective, multicenter, observational study in 20 centers, data from consecutive endoscopic resections of LCLs performed over a 6-month period were collected by a web-database. All patients undergoing LCLs resection were enrolled at procedure-time and followed-up at 15 days for adverse events and at 6 months for endoscopic/histological recurrence.

Results: 1453 LCLs (mean size 30.6 mm, SD 12.4; 41.4% lateral spreading tumor, 28.1% sessile, and 30.5% pedunculated) removed in 1329 patients (58% males, mean age 66±11.4 years) were analysed. An endoscopic mucosal resection (EMR) was performed in 57.9%, snare polypectomy in 57.4%, underwater EMR in 1.2% and endoscopic submucosal dissection in 6.2% of the lesions. Patients with LCLs, 19.4% were on AT (62.5% aspirin, 12.2% thienopyridines, 4.8% dual antiplatelet, 15.4% vitamin K antagonists [VKAs], 5.1% direct oral anticoagulants [DOACs]). Aspirin and/or thienopyridines were withheld before resection in 53.6% and 91.7% of patients, respectively. Overall, intra-procedural bleeding requiring endoscopic therapy occurred in 8.1% of patients; 28% of them were on ATT, which had always been withheld, but in 48% of patients on aspirin. At multivariate analysis, intra-procedural bleeding was correlated with increasing polys size (Odds Ratio 1.02 95% Confidence Interval 1.01–1.04), and inversely with execution of pre- and post-resection prophylaxis maneuvers (Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 and Odds Ratio 0.55 95% Confidence Interval 0.37–0.82 respectively). As concerns
comparisons, delayed bleeding occurred in 4.5% of the subjects, whereas per-
fusion occurred in 1.5% (0.9% early and 0.6% delayed) of patients, 86.7% of whom were successfully managed endoscopically. At the moment, 6-months follow-up is available for 35% of the patients, with a positive sessile and/or histological recurrence documented in 22.8%.

Conclusion: The management of resection of LCLs varies widely. The incidence of intra-procedural bleeding correlates with polyp size and prophylactic maneuvers, and its endoscopic management is successful in most of cases. Overall, complication rate is marginal and efficacy is good, even in a real-life setting.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1529 ENDOSCOPIC REMOVAL OF HIGH-RISK COLORECTAL ADENOMAS: SAFE AND EFFECTIVE?

M. Rutka1, K. Farkas2, A. Fabiani3, R. Bot3, A. Balint1, A. Milasinn3, Z. Szepes1, T. Molnar3
1First Department Of Internal Medicine, University Of Szeged, Szeged/Hungary

Contact E-mail Address: rutka.marianna@gmail.com

Introduction: The incidence and mortality of colorectal cancer (CRC) can be decreased trough the removal of precancerous adenomas. Endoscopic removal of polyps over 2 cm is considered a high-risk procedure both for complications and malignant transformation.

Aims & Methods: The aim of this study was to evaluate the outcome and complication rate after endoscopic removal of polyps over 2 cm. In this retrospective study clinical and demographic data of patients undergoing polypectomy due to colorectal adenoma over 2 cm between 2012 and 2017 were collected. Data of endoscopic procedures, complications of polypectomy and histological assessments of the removed polyp were obtained.

Results: Data of 100 patients (male/female: 58/42) was analyzed in the study. Fifty-two of the 106 removed polyps proved to be pedunculated, 21 were sessile and 34 flat. Six patients had more than one large polyp (>2 cm). The locations of the removed polyps were rectum in 33, sigmoid colon in 38, coecum in 12 and other parts of the colon in 23 patients. In 65 cases, polyps were excised with endoscopic mucosal resection (EMR) or hybrid endoscopic submucosa dissection (ESD). In 41 cases snare was used to remove the polyps in one or more pieces. Based on histological findings 54 (50.9%) polyps were shown to be low-grade adenomas, 34 (32.07%) high-grade adenomas, 1 (0.9%) polyp was hyperplastic, and 17 (16.03%) proved to be malignant among which complete endoscopic removal was achieved in 9 patients (52.9%). Additional smaller polyps were found in 39 patients and a synchronous cancer in 7. During polypectomies 91 hemoclips were deployed to close suspected perforation (8 cases) to cease bleeding (19) or for prevention. Postpolypectomy syndrome developed in 8 cases. Second-look colonoscopy was required in 8 cases due to bleeding within a mean of 4 days after the first examination. Hemoclip insertion was needed in 5 cases and epinephrine injection in 1 case. The bleeding stopped spontaneously in 2 cases. Surgical intervention was not needed in any case.

Conclusion: Malignant transformation was revealed in 16% of the polyps over the size of 2 cm. Complete endoscopic removal of these polyps was successfully performed in half of the patients. Endoscopic removal of high-risk polyps is safe in experienced hand.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1530 WHAT IMPROVED AND WHAT REMAINS TO BE ACHIEVED IN ORDER TO COMPLY WITH THE NEW RECOMMENDATIONS OF POLYPECTOMY BY THE EUROPEAN SOCIETY OF GASTROINTESTINAL ENDOSCOPY

1Gastroenterology, CHVNG/E, Vila Nova De Gaia/Portugal
2Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jamepeter@gmail.com

Introduction: The choice of polypectomy technique differs according to regional preferences and availability. This year, in order to standardize the approach to this techniques, the European Society of Gastrointestinal Endoscopy (ESGE) published recommendations for colorectal polypectomy and endoscopic mucosal resection (EMR).1

Aims & Methods: We aimed to evaluate the recent years evolution of the adherence to the recommendations of colorectal polypectomy and EMR at a tertiary center. We conducted a univariate analysis of polypectomy and mucosectomy techniques performed consecutively between January and June of 2011 and 2016 at a tertiary center. According to the recommendations, the excision of sessile and flat polyps is considered adequate when performed with cold biopsy forceps or cold snare for polyps <3 mm, cold snare or 4-mm, cold or hot snare if 10-19 mm and EMR if ≥20 mm. Polypectomy of pedunculated polyps is considered adequate when performed with a diathermic loop in polyps <20 mm, always in association with any prophylactic therapy when polyp size ≥20 mm.

Results: We included 1721 endoscopic procedures of polypectomy and EMR, concerning 1769 patients (64.2% male, mean age 64.2 ± 11.0 years). 1381 (80.2%) sessile polyps, 153 (8.9%) flat lesions and 187 (20.9%) pedunculated polyps were identified, with a mean size of 7.9 ± 7.0 mm. Regarding sessile and flat polyps, one of the recommended excision techniques was performed in: 84.6% (n = 270) of ≤3 mm polyps (75.7% in 2011 vs. 98.5% in 2016; p < 0.001); 22.2% (n = 109) of 4-5 mm polyps (12.5% vs. 36.5%; p < 0.001); 13.4% (n = 59) of 6-9 mm polyps (5.4% vs. 23.8%; p < 0.001); 100% (n = 206) of 10-19 mm polyps and 100% (n = 88) of ≥20 mm lesions. For pedunculated polyps, the excision technique was adequate in: 99.3% (n = 134) of polyps of size <20 mm (100% vs. 97.6%; p > 0.05) and in 84.6% (n = 44) of those ≥20 mm (82.6% vs. 86.2%; p > 0.05). Overall, 52.3% (n = 900) of endoscopic procedures of polypectomy or EMR were performed as recommended; 42.7% (n = 410) in 2011 vs. 64.5% (n = 490) in 2016; p < 0.001.

Conclusion: Even before publication of the European recommendations, there has already been an increase in the proportion of polypectomies performed adequately in the different groups of lesions. There is still a need to adjust clinical practice in some subgroups, especially in polyps of size 4-9 mm, in order to strictly comply with the recommendations.

6Digestive Endoscopy Unit, Università Cattolica del Sacro Cuore, Roma/Italy

Contact E-mail Address: federico.iacopini@gmail.com

Introduction: Endoscopic resection of superficial neoplasms at the perianal rectum is difficult due to pain sensitivity, narrowness of the anal canal, presence of internal rectal plexus, whereas that of at the ileocecal valve (ICV) due to the variable morphology of the ICV itself and ileal involvement.

Aims & Methods: Aim was to assess the feasibility and outcomes of ESD in these locations. Prospectively collected database in a single nonacademic center. From 2010 to 11.2016, all consecutive patients scheduled to ESD for a superficial neoplasm in the perianal rectum (distal margin <30 mm from the dentate line) and at the ICV were compared to those in the pelvic rectum and in the cecum and ascending colon, respectively. ESD was performed with the standard technique. Follow-up was scheduled at 3 and 6 months within the first year and then yearly. Biopsies were taken from the scar of the resection site if a residual tissue was detected.

Results: A total 16 neoplasms at ICV were compared to 110 neoplasms in the cecum and ascending colon; 30 neoplasms in the perianal rectum were compared to 58 cases in the pelvic rectum (Table). Features of neoplasms in the perianal and pelvic rectum were no different as well as neoplasms at the ICV and cecum and ascending colon. ESD en bloc rates were lower in the perianal rectum and at the ICV, but no significant differences were found with the respective control groups (P = 0.490 and 0.404, respectively). ESD R0 rate was significantly lower at the ICV (P = 0.021). Adverse events were not different, although 3 perforations occurred in the cecum and ascending colon. During follow-up (median 36 months; range 24-84): residual tissue was diagnosed at the ICV in 2 (13%) cases, in the cecum and ascending colon in 2 (2%) cases (P = 0.078); in the perianal rectum in 4 (13%) cases and pelvic rectum in 2 (3%).

Conclusion: The ESD of neoplasms at the ICV and perianal rectum is feasible and effective. The complete resection rate is low due to the challenging anatomy of
that precludes conducting a mucosal incision far from tumor margins. A careful endoscopic follow-up is mandatory to detect residual neoplasms.

Introduction: Colorectal cancer (CRC) is one of the most common malignancies in developed countries, with associated occlusive disease being relatively common. Endoscopic placement of self-expandable metallic stent (SEMS) is the first-line palliative treatment for malignant bowel obstruction.

Aims & Methods: Evaluate the outcome of endoscopic SEMS placement in CRC obstruction. Retrospective analysis of patients CRC submitted to endoscopic placement of SEMS from 2009 to 2016 in the Gastroenterology Department of Centro Hospitalar do Algarve. Statistical analysis was performed with SPSS version 23.

Results: The study included 23 patients with CRC obstruction, who were submitted to endoscopic SEMS placement, with a mean age of 75.2 ± 13.47 years. The stents were placed with a palliative purpose in 69.6% of cases (n=16) and a transitory procedure before surgery in 30.4% of cases (n=7). Technical and clinical success was found in 91.3% of the patients, without any recorded death during the procedure. In patients whose goal was palliative treatment (75% men and 25% women) they had a mean age of 81.6 ± 9.28 years. In 43.8% of the patients the tumor was located in the rectum, 31.6% in the sigmoid region and 25% in the recto-sigmoid transition. Being the majority (75%) well differentiated. There was a need for dilatation in 31.3%, most of the stents were uncovered (56.3%), 25% of the patients had complications. After stent placement, about 25% of the patients did chemotherapy. There was a 75% mortality rate (37.5% died by 6 months and 37.5% died by 12 months of follow-up). The use of chemotherapy after SEMS placement influenced the complications associated with the procedure (p<0.05) but none of the other variables had a statistically significant influence on early death (up to 6 months).

Conclusion: SEMS is an effective and safe palliative option for unresectable tumors, although the use of chemotherapy after the placement of prostheses may have an influence on the appearance of complications. Malignant colon obstruction of the colon can be treated effectively with the use of endoscopic techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Large colorectal lesions (>20 mm) can be removed endoscopically by endoscopic mucosal resection (EMR), often in a piecemeal fashion resulting in low en bloc and radical (R0)-resection rates. In this study, submucosal dissection (ESD) allows en bloc resection whatever the size, but still remains technically difficult and time consuming. A hybrid endoscopic technique has been developed, called simplified or hybrid dissection. The aim of our study was to evaluate the efficacy of complications of endoscopic submucosal dissection (ESD) compared to classical endoscopic submucosal dissection.

Aims & Methods: Our study was carried out from January 2013 to June 2016. From the prospective database. The 40 lesions removed by hybrid technique were compared to a control group of 109 ESD (36.5%) performed as follow: submucosal injection around the lesion of macromolecules, circumferential mucosal incision and submucosal dissection using the tip of a single-strand snare by endo-cut Q mode, central submucosal injection of the lesion and final resection with the single-strand snare, if possible in en-bloc. Patient characteristics, tumor location and size, dissection characteristics, "block" resection rate, R0 resection rate (healthy margins), procedure and hospitalization time, and complications were identified and compared with the so-called "classical" ESD technique.

Results: Lesions were more frequently located in the colon (vs rectum) in the hybrid dissection group compared to the ESD group (72.5% versus 26.8%, p < 0.001). Adenomatous lesions were type Hc according to Paris classification in 10% of the hybrid dissection group and 13.1% in the ESD group (p = 0.8). The mean size of the lesions was lower in the hybrid dissection group than in the ESD group (32.4 mm ± 13 mm compared to 54.4 mm ± 26.7 mm, p < 0.001). An en bloc resection was performed in 52.5% and 84.4% in the hybrid dissection and ESD group, respectively (p < 0.001). The procedure time (including general anesthesia time) was lower in the hybrid dissection group compared to the ESD group (105 min ± 62 min vs 191 min ± 73 min, p < 0.001, respectively). The hospitalization time was lower in the hybrid dissection group than in the ESD group (1.1 days ± 1.13 days vs 2.8 days ± 1.8 days, p < 0.001). R0 resection rates were lower in the hybrid dissection group than in the ESD group (47.5% and 61% respectively, p < 0.001). Hybrid dissection was performed for adenocarcinoma, adenoma with high grade dysplasia and adenoma with low grade dysplasia in 12.5%, 42.5% and 40%, respectively. The rate of adenocarcinoma was lower compared to the ESD group (12.5% versus 30.8%, p = 0.009). In the hybrid dissection group, the rate of perforation was lower than the ESD group (0.2% versus 2%, p = 0.3). There was no significant difference between the hybrid and ESD group in the bleeding (1.8% in the hybrid dissection group and 2.5% in the ESD group). In case of complications, there was no need of surgical treatment in the hybrid dissection group, but was needed in one patient in the ESD group.

Conclusion: Hybrid dissection is less effective in terms of en bloc resection of large colorectal tumors. Classical endoscopic submucosal resection should be preferred, especially in case of suspected adenocarcinoma despite longer procedure and hospitalization time.

3San Martino Hospital - Unit/ Gastroenterologic Unit, Belluno/Italy

Contact E-mail Address: d.caroli@libero.it

Introduction: Since its introduction in 1968, Endoscopic retrograde cholangiopancreatography (ERCP) has become a procedure widely used to diagnose and to treat conditions associated to the pancreatobiliary system. It is nevertheless associated to the highest risk of complications of all routine endoscopic procedures. It is important to have a thorough understanding of the potential complications and the adverse events that may be associated to ERCP procedures so that these may be managed appropriately should they occur. The aim of this study was to examine the trends in ERCP usage here in the Veneto Region (Northeastern Italian area) and, in particular, the complications and mortality rate associated to it.

Aims & Methods: Utilizing an anonymous database of hospital discharge records referring to the period between 2007 and 2015, a retrospective study was carried out to examine the complications associated to ERCP. All of the elective hospitalizations for gallstones in the bile duct during which the procedure was carried out within two days of being hospitalized were examined. Hospitalizations for neoplasms were not considered. The study considered the onset of complications or death as outcome indicators as well as the patients' post-procedure hospital stay. The threshold value that was utilized was 2 days and the patients who later underwent surgery (e.g. cholecystectomy) were excluded from our analysis; the associations between the type of hospital where the patients were being assisted both with regard to the type of organization (Hub or Spoke model) and the type of management (public/private) were also evaluated.

Results: A total of 3,136 admissions out of total of 14,626 hospital days (SD: 4.6 ± 5.8 days) were identified in a total of 40 hospitals, 6 (15%) of which provided more than 50% of the total days of hospitalization. The age distribution of the patients (13 cases) and there was a 6.1% of deaths due to complications. As far as the post-procedure hospital stay was concerned, in 55% of the cases, the discharge of patients within two day period was more frequent in those assisted in public hospitals (OR:1.55;IC95%:1.21–1.98;p < 0.05) in which 90% of the activities were carried out and no differences linked to their characteristics. The stratification of complications according to the type of hospital (range 2–17%) did not reveal any significant differences between public or private hospitals. Study findings uncovered that pancreatitis was the most common post-procedure ERCP complication in the patients studied; the total complication rate was in line with that reported in the literature. That result and the fact that no correlation was found between the the type and percent of complications and the type of hospital can be attributed to the effective regional hospital organization characterized by a capillary network of specialists capable of performing complex endoscopic procedures throughout the region limiting the need for transfer patients from one hospital to another.

Disclosure of Interest: All authors have declared no conflicts of interest.
Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: In our study, metabolic complications were not associated with an increased risk of mortality. It seems more important to evaluate and weigh the role of these conditions in larger prospective studies since the expanded prevalence of metabolic syndrome in general population.

P1539 PLACE OF ENDOSCOPIC RETROGRADE CHOLANGIPANCREATOGRAPHY (ERCP) IN THE MANAGEMENT OF HEPATIC HYDATID DISEASE

Gastroentero, Habib Thameur Hospital, Tunis/Tunisia

Contact E-mail Address: hajer.hassine@gmail.com

Introduction: Hepatic hydatid disease (HHD) is a major endemic health problem in certain areas of the world such as Tunisia. Intraductal rupture of a hepatic hydatid cyst is a common complication ranging between 3 and 17%. From the surgical standpoint, biliary drainage is the most frequent postoperative complication following surgery for hydatid cysts of liver. Both conditions require endoscopic biliary drainage.

Aims & Methods: The aim of this study was to assess the results of ERCP in patients suffering from HHD. We retrospectively analyzed the results and complications of all ERCP performed for HHD whether before or after surgical treatment over a 10 years period [January 2007 - December 2016] and carried out at the gastroenterology unit of our hospital.

Results: Sixty seven procedures were included (mean age 40.4 years [15–82] and sex ratio male/female [31:36]). Of the 67 procedures, 58 (86.6%) were performed in patients who had undergone previous surgery. The indications of the ERCP were persistent external biliary fistulae in 77.6%, obstruction or cholangitis due to residual materials within bile duct in 20.7% and secondary biliary strictures in 1.7%. In patients who had not undergone previous surgery (13.4%), the indications of the ERCP were cholangitis due to intra-biliary rupture of hydatid cyst in 44.4% associated with acute pancreatitis in 55.6%. The cannulation of the papilla was impossible in 6 cases (8.9%) and the endoscopic sphincterotomy (ES) could not be performed. When papilla cannulation was obtained, per endoscopic cholangiographic findings were: dilation of the biliary tract (21.3%) with filling defects of varying size and shapes (52.3%), leakage of contrast medium into the cyst cavity (41%) and distal strictures (3.3%). ES was then performed in all cases with satisfactory results. Thus, hydatid membranes (36%) or daughter cysts (1.6%) encountered in bile ducts have been emptied out in 93.4% by biliary drainage. One mortality. These were significantly associated with older age and the total number of medical comorbidities the patients had (p < 0.05). Deficiencies practices and information gathering were noted mostly with respect to the role of these conditions in larger prospective studies since the expanded prevalence of metabolic syndrome in general population.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1540 QUALITY INDICATORS AND POST OPERATIVE OUTCOME OF ERCP PERFORMED IN A LOW RESOURCE SETTING; CAN QUALITY INDICATORS FROM DEVELOPED SETTINGS BE APPLIED?

I. Kongala Liyanage1, E. Thalagala1, S. Kulatunge1, R. Peris1, N. Nawarathne1,2
1Gastroenterology And Hepatology Unit, National Hospital of Sri Lanka
2Colombo/Sri Lanka

Contact E-mail Address: Isuruji@gmail.com

Introduction: Endoscopic Retrograde Cholangiopancreatography (ERCP) is a complex and invasive procedure. Quality control and monitoring for complications is an important part of ensuring patient safety. Gastroenterology and Hepatology unit of the National Hospital of Sri Lanka performs the most number and variety of ERCP procedures in Sri Lanka. Although facilities are limited, detailed patient records and logs were maintained since commencement of ERCP procedures in this unit.

Aims & Methods: A retrospective analysis was carried out on quality indicators and complications of the ERCP procedures performed in this unit since 2006. Data from written records were entered into an electronic database and analysis was done using STATA version 13. Quality indicators and standards published by the American Society of Gastrointestinal Endoscopy and American College of Gastroenterology in 2015 were used.

Results: A total of 3780 ERCP procedures were performed. Females consisted of 54% of the patients (n = 2041). Mean age in years was 57.6 (SD = 8.4). Male patients were older with a mean age of 61.2 years whereas the mean age of females was 54.6 years (P < 0.05). Cholelithiasis was the commonest indication (85%) and 68% out of these patients had active cholangitis at the time of the procedure. Chronic pancreatitis, benign and malignant strictures requiring stenting, postoperative bile duct damage and the other common indications. Data were analyzed and compared with 19 out of the 24 quality indicators. A total of 15 quality standards were met (7/9 pre procedure, 4/5 intra procedure and 4/10 post procedure). Most prevalent major complications were Post ERCP Pancreatitis (PEP) and post ERCP Cholangitis (PEC) complicating 2.22% and 4.78% procedures respectively. Mortality was less than 0.1% (n = 3). Cardiovascular complications and complications of anesthesia were seen in 16 patients (0.41%) resulting in one mortality. These were significantly associated with older age and the total number of medical comorbidities the patients had (p < 0.05). Deficiencies practices and information gathering were noted mostly with respect to the role of these conditions in larger prospective studies since the expanded prevalence of metabolic syndrome in general population.

Conclusion: This supports the fact that centers with minimal resources can monitor quality standards and maintain satisfactory patient safety levels. Low numbers of postoperative complications were noted in this review. Old age and having multiple medical comorbidities were associated with a higher complication risk. Quality checkpoints help to identify deficiencies in practice as well as documentation and help to adjust future practices, even in low resource settings.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1541 USE OF MICROCATHETERS IN ECHOENDOSCOPY-GUIDED BILIOPANCREATIC DUCT REPLACEMENT—INITIAL EXPERIENCE

J. Pinto, C. Saldàña Dueñas, C. Leitão, I. Fernández-Urien Sainz, J.J. Vila
Endoscopy Unit, Biliary And Pancreatic Diseases Unit, Complejo Hospitalario de Navarra, Pamplona/Spain

Contact E-mail Address: jsdiaspinto@gmail.com

Introduction: EUS-guided biliary or pancreatic rendezvous is a technically demanding procedure, and the intraductal manipulation of the guidewire remains the most challenging step. Passing the guidewire through the needle may cause its slippage or consequent damage of the duct wall. Anatomically, the bile ducts are small-calibered structures requiring a fine guidewire. The aim of this study was to evaluate the success rate and safety of this technique.

Aims & Methods: We aimed to evaluate the early experience of the microcatheter method in EUS-guided rendezvous procedures in the biliary and pancreatic ducts. During EUS-guided biliary or pancreatic rendezvous, initial puncture of the duct of interest was attempted with a 19G needle without stilet and...
previously flushed with contrast. A 0.025" guidewire was then inserted through the needle into the duct and advanced antegrade to the papilla. If further manipulation was necessary to enter the duodenum, movements were performed with caution in order to avoid fragmentation of the guidewire. Whenever the passage through the papilla was not achieved or the guidewire movements were hampered, we performed a microcatheter technique. After removing the needle, leaving the guidewire in situ, a 3F, 150 cm long microcath- eter was inserted over the guidewire into the duct. Then, manipulation of the guidewire, guidewire exchange and contrast injection were performed according to the discretion of the endoscopist. We reviewed the cases of EUS-guided pancreatic or biliary rendezvous performed in our unit using microcatheters from September 2015 to March 2017. Technical success was considered when the rendezvous could be completed.

Results: Nine patients presented with previous unsuccessful manipulation of the guidewire with the needle during EUS-guided biliary or pancreatic rendezvous underwent a microcatheter-guided attempt on the same procedure. Pancreatic rendezvous was attempted in 3 cases (2 sterile pancreatitis, 2 pancreas divisum and 1 pancreatic cancer) and biliary rendezvous in the other 4 (3 biliary stenosis and 1 ampu- loma). Technical success was achieved in 7 patients (78%) with the microcatheter technique. Technical failure occurred in 1 patient with biliary stenosis in whom a EUS-guided hepatico-gastrostomy was performed in the same procedure and in 1 patient with chronic pancreatitis with symptomatic pancreatic duct stenosis. There were no adverse events after the procedure, irrespective of technical success.

Conclusion: In our series, using a microcatheter for the indwelling manipulation of the guidewire increases the EUS-guided rendezvous technical success without increasing the complication rate, irrespective of technical success.

Disclosure of Interest: All authors have declared no conflicts of interest.

The diagnosis of residual or fragmented stones after lithotripsy for cholangiopancreatoGRAPHY

Results: As a result of analysis of the 892 ERCPs performed during 4 years, the mean duration of fluoroscopy time was 5.52 mins (95% CI, 5.15–5.93). Mean radiation duration were as follows: CBD stones (n = 511, 5.76 mins); malignant stenosis of bile duct (n = 189, 5.78 mins); pancreatic disease (n = 95, 5.28 mins); benign stenosis of bile duct (n = 51, 5.32 mins); and peripancreatic stenosis (n = 30, 5.40 mins). Time of prolonged duration of fluoroscopy time was related with specific factors of patient included age, BMI, diagnosis and procedure complexity (p < 0.05). Among the parameters, procedure complexity was the most significant relation with radiation dose. In addition, more procedures performed during ERCP and mechanical lithotripsy (all p < 0.05).

Conclusion: ERCPs are associated with significantly higher radiation exposure to patients and endoscopists. The endoscopic procedure duration and radiation dose of ERCP were increased dose of radiation required when performing ERCP in patients with increased BMI, old age, and who need two more ERCP procedure.

P1548 DOUBLE-BALLON ENTEROSCOPY FOR ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY

Contact E-mail Address: celinehauoi@hotmail.com

Introduction: Double-balloon enteroscopy-assisted endoscopic retrograde cholangiopancreatography (DB-ERCP) allows access to the biliary ducts of patients with surgically altered upper gastrointestinal anatomy. We studied the feasibility and efficacy of DBE-ERCP at our institution.

Aims & Methods: This is a retrospective study of all patients with surgically altered GI anatomy who underwent DBE-ERCP at our institution between February 2011 and March 2017. The primary endpoint was the global success rate of DBE-ERCP. The secondary endpoints were (1) the success rate of enteroscopy defined as reaching the desired postsurgical anatomic target, (2) the diagnostic success rate defined as successful cannulation of the native papilla or

Disclosure of Interest: All authors have declared no conflicts of interest.
anastomosis, and (3) the therapeutic success rate. We used a 2.2 m DBE with a 2.8 or 3.2 mm of operating channel (EN-450 T5, or EN580T Fujinon inc Saitama Japan).

Results: A total of 12 patients (sex ratio1/1) with a mean age of 65 [47–82] underwent 14 DBE-ERP, 7 patients had Roux-en-Y gastro-jejunostomy with a biliopancreatic anastomosis had Roux-en-Y with a native papilla, and 1 patient had a Billroth II gastric bypass. Enteroscopy success rate was 93% (13/ 14 procedures). The diagnostic success rate was 85% (11/13 procedures) with 4/5 of native papillae. Therapeutic interventions including sphincterotomy (n = 4), biliary stone extraction (n = 4) and biliary dilation (n = 2) were needed in 8/11 procedures and their success rate was 100%. The global success rate of DBE- ERP was 78% (11/14 procedures). Our results were comparable to those of the literature (global success rate of 82%). The only complication was one case of superficial intestinal lacerations without perforation (complication rate 7%).

Conclusion: DBE-ERP in patients with surgically altered upper GI anatomy is a safe and efficient procedure with a global success rate of 78%. Using shorter enteroscopes with wider operating channel in the future might improve the success rate of the technique.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Biliary cannulation may be difficult in 10–15% of patients (1) and needle-knife sphincterotomy is more often used as a rescue treatment. A more recent technique for difficult cases is transpancreatic sphincterotomy. Both situations are well known as Post-ERP pancreatitis risk factor (2). To best of our knowledge only few studies compared success rate and adverse events in these techniques (3–7).

Aims & Methods: We aimed to compare the efficiency and safety of NKS comparing to TPS in difficult biliary cannulation We conducted a bibliographic search using PUBMED, EMBASE including 2 RCTS and 4 non randomized trials from January 2000 to December 2016. OR using the Mantel-Haenszel method was used for dichotomous variables. Quantitative synthesis was performed using Review Manager version 5.0. Primary outcome was success rate. Secondary outcomes were rate of overall complications, and pancreatitis. Clinical heterogeneity was assessed by I2 value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Success rate was higher in NKS group compared to TPS (OR 2.98 [95%CI 1.43–5.85], p = 0.004). Complications and risk of pancreatitis were similar in both group (OR 0.37 [95%CI 0.17–0.82], p = 0.013; OR 0.99 [95%CI 0.68–1.57], p = 0.971)

Conclusion: NKS is associated with higher success rate with equal risk of complication and pancreatitis risk compared to TPS. Further and well design RCTs are needed before a firm conclusion could be made.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Choledocholithiasis is a relative frequent condition in patients with gallbladder stones (prevalence of 3–16%). Endoscopic sphincterotomy and stone extraction is the recommended treatment of bile duct stones. In the case of residual or recurrent lithiasis and choledocholithiasis, endoscopic therapy, cholecystectomy combined with bile duct exploration or intraoperative endoscopic retrograde cholangiopancreatography should be performed.

Aims & Methods: The main objective of this study was to evaluate the efficacy of endoscopic extraction methods in patients who presented choledocholithiasis. We conducted a retrospective single center study over 7 years from Jan 2009 to Dec 2015. Patients with single or multiple bile duct stones submitted to endoscopic retrograde cholangio-pancreatography (ERCP) were included. We analyzed each technique by considering the following parameters: mean diameter of the bile duct, mean diameter of the common bile duct for the prevention of post-endoscopic retrograde cholangiopancreatography (ERCP) pancreatitis. Statistical analysis of the results was carried out using SPSS software for Windows version 21. The normal distribution of continuous variables was assessed using the Kolmogorov-Smirnov test. Differences between groups were assessed using the Student’s t test for independent samples or the Mann-Whitney test for non-parametric variables. The chi-squared test was used to compare the categorical variables. A p value of 0.05 was considered statistically significant. All statistical analyses were carried out by biostatisticians.

Results: A total of 1365 ERCP procedures were performed in the study period. Overall CBD cannulation rate was 91.3%. 105/1365 (7.7%) were guided TPS procedures were needed in out. Mean age of the TPS group was 67 (range: 18–87) years and 56/105 (52.4%) were male and 49/105 (46.6%) were female. 2 RCTs and 4 non randomized trials from January 2000 to December 2016. OR using the Mantel-Haenszel method was used for dichotomous variables. Quantitative synthesis was performed using Review Manager version 5.0. Primary outcome was success rate. Secondary outcomes were rate of overall complications, and pancreatitis. Clinical heterogeneity was assessed by I2 value, where a value exceeding 50% was indicative of heterogeneity. A random effect model was used in case of heterogeneity.

Results: Success rate was higher in NKS group compared to TPS (OR 2.98 [95%CI 1.43–5.85], p = 0.004). Complications and risk of pancreatitis were similar in both group (OR 0.37 [95%CI 0.17–0.82], p = 0.013; OR 0.99 [95%CI 0.68–1.57], p = 0.971)

Conclusion: NKS is associated with higher success rate with equal risk of complication and pancreatitis risk compared to TPS. Further and well design RCTs are needed before a firm conclusion could be made.

CBD stones any diameter

European Association for the Study of the Liver (EASL). EASL Clinical Practice

15 mm was balloon dilator combined with retrieval balloon. Intermediate mean stone diameter of 13.6 mm and a mean CBD diameter of 14.3 mm diameter of 12.1 mm, compared to 3.8% of cases referred to surgery with a mean diameter of 12.9 mm. We also analyzed the parameters of patients who underwent endoscopic extraction by using a retrieval balloon combined with balloon dilator (Group 5). The success rate in this group was 90% for a mean stone diameter of 14.8 mm with a mean CBD diameter of 12.4 mm. In Group 6 we included cases which required combined techniques (= = 3). We observed a mean stone diameter of 9.4 mm with a mean CBD diameter of 13.8 mm in patients solved endoscopically, compared to those referred to surgery who had a mean stone diameter of 14.2 mm with a mean CBD diameter of 14.3 mm (P = 0.001). In this group the success rate was 67.2%. Overall, we had a success rate of 91.3% for endoscopic removal of choledocholithiasis with a mean stone diameter of 7.1 mm and a mean CBD diameter of 12.1 mm, compared to 3.8% of cases referred to surgery with a mean stone diameter of 13.6 mm and a mean CBD diameter of 14.3 mm (P < 0.001).

Conclusion: The most successful endoscopic method to remove large stones ≥15 mm was balloon dilator combined with retrieval balloon. Intermediate stones ≤7.5 mm can be successfully removed by using retrieval balloon or lithotriptor or a combination of basket with retrieval balloon ≥ balloon dilator. Most CBD stones <7 mm were successfully removed by using basket. In conclusion, any diameter >7 mm will most probably require more elaborate techniques.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: In this retrospective cohort study of patients undergoing ERCP that included low-risk patients, rectal diclofenac was not associated with a significant decrease in the absolute rate of pancreatitis. In our study, diclofenac decreases the impact of PEP in those patients who are cannulated the pancreas.

Introduction: The confocal laser endomicroscope (CLE) is of two types, an endoscope-based CLE (eCLE), which is integrated in the tip of the endoscope, and a probe-based CLE (pCLE), which goes through the accessory channel of the endoscope. The biliary tract, which cannot be reached by using eCLE, is observable with pCLE by using cholangioscopy. pCLE has the advantage of obtaining a magnification image that is like taking a biopsy tissue specimen but noninvasively, without the interference of bleeding and mucus secretion. However, it is sometimes difficult because only few gastroenterologists can achieve the required level of diagnostic accuracy.

Aims & Methods: We developed a computer-aided diagnosis (CAD) system based on pCLE imaging using deep learning technology. The purpose of this study was to determine the usefulness of this CAD system for the diagnosis of bile duct cancer. We prepared the classifier of the extracted features of the bile duct cancer pCLE images by using the deep learning framework presented by Kyocera communication system Co. Ltd. Japan. The pCLE images by Cellvissio (Mauna Kea Technologies, France) were obtained through the SpyGlass DS (Boston Scientific Corporation, USA) which can be compared with other methods like pathological examination results from the surgical specimen and biopsy using SpyBiite (Boston Scientific Corporation, USA). Learning sets were constructed by using 49 images of normal area and 23 images of cancer lesion. The test sets of the pCLE images were constructed using 6 images of normal area and 14 images of cancer lesion separately from the learning set.

Results: The accuracy, sensitivity for cancer diagnosis, specificity, negative-predictive value, positive-predictive value of our CAD system by test set were 84.1%, 77.8%, 35.7%, 50.0%, respectively. These results were constructed using 6 images of normal area and 14 images of cancer lesion, respectively from the learning set.

Introduction: Gallbladder drainage, performed by EUS-guided positioning of specially designed fully covered metal stents, may be considered a valid option in patients with cholecystitis unifor for surgery. We describe the first case series of patients with diagnosis of acute cholecystitis treated conservatively using a silicone-covered nitinol stent with bilateral anchor flanges (NAGI-stent).

Aims & Methods: Our aim was to evaluate the feasibility and clinical impact of EUS-guided drainage with NAGI-stent in patients with acute cholecystitis unifor for surgery. Instructions for the EUS-guided drainage of acute cholecystitis: patients diagnosed with diagnosis acute cholecystitis according to Tokyo guidelines criteria, not suitable for surgical approach, were treated conservatively and drained with EUS-guided short flared stents positioning. The procedure was performed in 2 tertiary endoscopic units in Italy (100% EUS-ERCP performed yearly) using the NAGI-stent. Each attempt to access the gallbladder was firstly performed from the transduodenal position and resulted successful in 13 (81%) patients, whilst a transgastric approach was preferred in the remaining 3 patients. Two different approaches were performed for the EUS-guided gallbladder puncture: a) a 0.035-inch wire was advanced through a 19G-needle into the gallbladder and dilation of the access was achieved with a 10 Fr cystoenterostome; b) a 0.035-mch wire was advanced through a 10 Fr cystoenterostome and a silicone-covered nitinol stent was placed. Additionally, the 2 patients who died 10 days later. At follow-up, two patients died due to myocardial infarction at 2 and 6 months, one for acute renal failure after 6 months, two for pancreatic cancer after 7 months and one for acute respiratory distress syndrome after 6 months. In the remaining patients no cholecystitis recurrence or biliary obstruction were observed at median follow-up of 112 days (range 49–180 days).

Conclusion: Our data showed that EUS-guided gallbladder drainage with NAGI-stent is feasible and successful in patients with acute cholecystitis unfit for surgery. Since this type of stent is cheaper compared to others, the use of such device may result more attractive as a further endoscopic option for these selected patients.

P1556 COMPARISON OF EUS-GUIDED FINE NEEDLE BIOPSY TECHNIQUES FOR CORE TISSUE ACQUISITION AND DIAGNOSTIC PERFORMANCE IN PANCREATIC SOLID LESIONS

C. Cho1, S.J. Yeo1, A.N. Seo2, H.I. Bae3

Contact E-mail Address: cmcho@knu.ac.kr

Introduction: Acquisition of core tissue in endoscopic ultrasound-guided tissue sampling (EUS-TS) is necessary for histologic diagnosis and immunohistochemical staining in the diagnosis of some solid mass lesions. Although recent studies revealed the superiority of core biopsy needle in the specimen adequacy, core recovery still remains that which EUS-TS techniques would result in better acquisition of core tissue and diagnostic accuracy.

Aims & Methods: The aim of our study was to evaluate EUS-TS techniques with a ProCore needle using suction and slow pull suction for solid pancreatic lesions with the help of expert cytopathologist. Patients who referred to EUS-TS for pancreatic mass lesion were enrolled. We performed EUS-guided fine needle biopsy (EUS-FNB) using a ProCore needle (Cook Medical, Limerick, Ireland) with two needle passes and applied each pass of different techniques (suction or slow pull suction) which were randomly allocated. EUS-TS specimens were evaluated by one experienced cytopathologist who was blinded to applied techniques. The acquisition of core tissue and diagnostic performances were compared between two techniques.

Results: From Aug. 2014 to Dec. 2016, 94 patients with pancreatic mass were enrolled and 12 patients were excluded due to no final diagnosis (n = 5), cystic lesion (n = 5) and loss of follow up after EUS-TS (n = 2). Finally, 82 patients (48 males; median age, 63 years) with 164 needle passes were included without technical failure and procedure-related adverse events. The median size of the lesions was 26 mm (range, 11 to 80 mm). There were 68 malignant and 14 benign lesions. Overall core tissue acquisition and diagnostic accuracy was 84.8% (139/ 164) and 73.2% (120/164), respectively. There was no significant difference between suction and slow pull suction in the acquisition of core tissue (85.4% vs. 84.1%, p = 1.000) and diagnostic accuracy (72.0% vs. 74.4%, p = 0.860).

Conclusion: Although our study revealed no differences between EUS-TS techniques in the core tissue acquisition and diagnostic accuracy for pancreatic solid lesions, further prospective study including variable lesions and sizes of needle is needed to validate for optimal application and sequences of EUS-FNB techniques.

P1561 EFFICIENCY COMPARISON BETWEEN 22 G VERSUS 25G NEEDLES DURING ENDOSONIC ULTRASOUND FINE NEEDLE ASPIRATION FOR SOLID PANCREATIC MASSES: A SYSTEMATIC REVIEW AND META-ANALYSIS BASED ON RCTS

Gastrointestinal Endoscopy Unit, Clinical Hospital of São Paulo University Medical School, Sao Paulo/Brazil

Contact E-mail Address: ralphbduarte@hotmail.com
Introduction: Endoscopic ultrasound guided-fine needle aspiration (EUS-FNA) is considered the gold standard method for assessment solid pancreatic masses. The needles for aspiration currently available are 19G, 22G and 25G and there is no concrete evidence to prove the benefit of one against another.

Aims & Methods: We aimed to compare the efficiency in the diagnosis of solid pancreatic lesions through the EUS-FNA with 25G and 22G needles. Studies were analyzed from five databases (Medline, Scopus, Cochrane, LILACS and CINAHL), without year or language restriction, using an extensive search strategy. Only randomized trials comparing 22G and 25G needles were included. Two independent reviewers went through the literature search and the results were analyzed by fixed and random effects. The diagnostic characteristics were calculated for a 95% confidence interval.

Results: 504 studies were found in the search, of which 21 were read and then finally 10 randomized studies were selected to be included in the analysis. Thus, a total of 462 patients were evaluated (233: 25G needle/229: 22G needle). The sensitivity of the 25G needle was 93% (CI: 89.96%; I2 0.00%), and for the 22G needle was 91% (CI, 85-94%; I2 19.9%). The specificity of the 25G needle was 86% (CI: 70-93%; I2 81.1%). The positive likelihood ratio of the 25G needle was 4.57 (3.60-10.33, I2 0.00%), and for the 22G needle was 4.26 (CI: 0.43-41.88, I2 94.7%). The post-test probability of the 25G needle in the study population was 91% and the 22G needle was 30%. The area under the sROC curve of the 25G needle was 0.9705 and for the 22G needle 0.9795, also showing no statistically significant correlation between them (p = 0.497).

Conclusion: Based on randomized studies, this systematic review and meta-analysis did not demonstrate a significant statistical difference between the 22G and 25G needles used during EUS-FNA in the diagnosis of solid pancreatic lesions.

Introduction: Despite advances in radiotherapy for pancreatic cancer, local gastrointestinal (GI) toxicity still remains one of the major limitations to effective dose delivery and further dose escalation due to the close proximity of the GI wall to the pancreas, particularly in the head region. One potential method to reduce local GI toxicity would be to increase the physical distance between the head of the pancreas and the duodenal wall. A novel, injectable hydrogel, synthesized as iodinated polyethylene glycol microparticles, has been FDA-approved for use as a soft tissue fiducial marker. The hydrogel remains stable for 3 months and is absorbed by 7 months. To date, there has been no reports on the technical feasibility of endoscopic ultrasound (EUS)-guided hydrogel injection into the pancreas.

Aims & Methods: We aimed to evaluate the technical feasibility of EUS-guided hydrogel injection into the interface between the head of the pancreas and the duodenal wall in a cadaveric model. A 10 ml syringe with a 22G needle was used to inject the hydrogel into the peri-pancreatic space with creation of a visible separation between the duodenal wall and the pancreatic parenchyma. The procedure was repeated along the length of the head and uncinate of the pancreas. CT was performed post procedure to confirm location and to measure the distance created between the duodenum and pancreas. Gross dissection of the pancreas and duodenum was performed to evaluate localization of the hydrogel.

Results: All three cadavers underwent successful EUS-guided injection of the hydrogel. Cadaver 1 received a total injection volume of 9.5 cc with creation of peri-pancreatic space along the head of the pancreas measuring 11.77 mm in maximal diameter. Cadaver 2 received a total injection volume of 27 cc with creation of peri-pancreatic space along the head and uncinate of the pancreas measuring 13.20 mm in maximal diameter. Cadaver 3 received a total injection volume of 10 cc with creation of peri-pancreatic space along the head of the pancreas measuring 12.89 mm in maximal diameter. The hydrogel was clearly visible during EUS with hyperechoic echogenicity and on post-procedure CT images without any artifacts. In all cases, the injection volume was less than expected.

Conclusion: EUS-guided delivery of hydrogel is feasible and results in an increase in the peri-pancreatic space in a cadaveric model. The hydrogel is clearly visualized on EUS and CT without significant artifacts. Further studies are warranted to evaluate feasibility, effectiveness and safety in a clinical model.

Disclosure of Interest: All authors have declared no conflicts of interest.
Malignant associated thromboembolic disease (TED) has a com-
mon presentation of clinical signs and symptoms related to
them. The clinical spectrum includes migratory superficial throm-
boembolism, arterial thrombosis, deep venous thrombosis, portal vein thrombosis
and phlebitis, with poor standardization of the procedure in terms of
ablation powers and ablation times, resulting in great heterogeneity of the
results.

Aims & Methods: To standardize the radiofrequency ablation (RFA) procedure
used in our institution for performing ev-stxs on porcine liver in order to find the
best ablation power and ablation time to produce the maximum size of
coagulative necrosis at histological examination. The system consists in a radio-
frequency generator delivering electric energy, a 19 Gauge needle (150 cm in length
with a 10 mm monopolar electrode), a peristaltic pump (to perfuse the
needle with chilled saline solution, maximizing the ablation volume without
chessing), and an isolating plate and a pedal to deliver RFA. Liver samples
were treated at different ablation powers (10, 20, 30 and 40 Watts (W)); each
ablation power was applied for a duration of 1, 3, 5, 7 and 15 minutes, according to
Fibonacci escalation dose scheme, used in phase I studies. We registered macro-
scopic: the size (millimeters) of the global treated area and the size of the
coagulative necrotic area around the needle insertion point (A zone) with a
maximum diameter of 4 millimeters and a surrounded larger area of “diaphani-
zation” (“B zone), showing mild signs of cellular alterations (cytoplasmic hypo-
chromia) without cellular necrosis. A zone sizes didn’t change among different
ablation times (mean: size: 3.25 mm) while “B zone” diameter increased with the
increase RF application at the fixed power of 10 W. At the microscopic
analysis the pathologist didn’t see any difference in size of coagulative necrosis
among the different ablation powers (R =0.24).

Conclusion: This new system is feasible and effective to produce very
small areas of coagulative necrosis (miliimeters) well-demarcated in respect to the
surrounding parenchyma and could be useful, in the future, to treat, with multi-
ple passes and higher precision, target lesions with a flexible needle. Moreover, the
system can produce larger zones of mild cellular alterations at lower ablation
powers (10 W), increasing with the increase of ablation times, but it needs future
in-vivo animal studies in order to assess the evolution of these zones (evolving into fibrosis? necrosis? recovering?).

1. Robbins D. Pulmonary embolism diagnosed with EUS on a patient with
11(4): 331-33

Aims & Methods: To perform a retrospective review of all EUS cases for pan-
creatic cancer in two centers and assess all EUS findings.

Results: In a period of 6 months, a total of 55 EUS for pancreatic neoplasms
were performed in two centers. TED was present in 5 patients (9%): 3 were male
and the mean age was 70 (range, 46-81). In 1 patient the EUS indication was a large
abdominal mass whose origin was not clear, in the remaining 4 the indication was
the pancreatic neoplasm. In all of them was performed EUS with fine-needle
aspiration (FNA) which identified a peripheral pancreatic embolism (PE) and 1 inferior
evera caval thrombosis (IVCT) with right atrial extension: 2 (3.6%) had recently
been diagnosed by computed tomography (CT) but 3 (5.4%) were not previously
known. In all these, CT confirmed diagnosis.

Conclusion: To the best of our knowledge, this is the first case series of EUS-
based TED diagnosis in pancreatic cancer patients. This series underlines
importance of a systematic, station approach EUS technique, namely in the mediasti-
num regardless the clinical indication. TED is a common complication of pancreatic cancer and has major therapeutic and prognostic implications.

Introduction: Cholecodolithiasis is the most common cause of biliary pain, lead-
ing to cholangitis and gallstone pancreatitis. Patients affected by cholecodoli-
thisis presents an incidence of cholecodolithiasis ranging from 8% to 20%. When
the suspicion of cholecodolithiasis is confirmed, stones should be removed by
ERCP, but this operative measurement is associated with high rates of adverse
events as post-ERCP pancreatitis, bleeding or perforation. A correct diagnosis of
cholecodolithiasis, before ERCP, is mandatory to decrease the operative risk and
health care costs. Endoscopic ultrasound (EUS) has a high sensitivity and
specificity in the diagnosis of CBD stones and could substitute other imaging
modalities as CT-scan or MRCP, when indicated.

Aims & Methods: The aim of our study was to assess the role of early EUS (<48
hours), in patients undergone US in emergency room for suspected biliary colic.
We retrospectively evaluated all the patients arrived at first aid for suspected
biliary colic (i.e. right upper quadrant pain and/or epigastric region, associated
with an elevation in serum ALT, AST, GGT, ALP, or total bilirubin, but in
absence of amylase or lipase elevation). All patients, irrespective of the finding at
the US, performed an EUS within 48 hours since admission. Data are presented
as proportions with 95%-CI and mean±standard deviation (SD). Correlation
between categorical variables was evaluated by computing the “phi” coefficient.
We computed the number needed to misdiagnose, i.e. the number of patients
who need to be tested in order for one to be misdiagnosed by the test, as 1/(1-diag-
nostic accuracy). All the analyses were run with R Studio (version 3.5.1).

Results: Overall, from January 2016 to December 2016, 88 patients (56% female;
mean age 64 ± 17 years) were admitted to our hospital for suspected biliary colic.
All of these subjects underwent abdominal ultrasound (US) at admission, which
identified gallstones in 47 patients (71%) and further, US documented common bile
duct (CBD) stones in 58 (65%) patients, CBD sludge in 4 (5%) subjects, whereas
no cholecodolithiasis was found in 26 (30%) patients. At EUS examination
CBD stones were found in 70 (80%) patients. Comparing US to EUS, US
gave false negative results in 16 (18%) cases and false positive findings (i.e.
identifying CBD stones not documented by EUS) in 8 (9%) patients. The two
diagnostic procedures showed little correlation (phi = 0.289). The number of
patients needed to be tested by US in order to provide an incorrect diagnosis was

P1567 BILIOPANCREATIC RADIOFREQUENCY ABLATION: COMPARISON OF THE THREE CURRENTLY AVAILABLE DEVICES IN A PIG MODEL
M. Barret1, S. Leblanc2, B. Bordacahar2, A. Rouquette2, S. Chaussade1, F. Pra1
1Gastroenterology, Cochin Hospital, Paris/France
2Pathology, Cochin Hospital, Paris/France

Contact E-mail Address: maximilian.barrett@aphp.fr

Introduction: Three devices are currently available to perform radiofrequency ablation (RFA) of biliopancreatic lesions. Data from animal models are scarce. Aims & Methods: Radiofrequency ablation was performed in four live pigs on the common bile duct and the liver parenchyma using an endobiliary probe (endHBP), on the liver and pancreatic parenchyma using an RFA catheter through an echoendoscope and biopsy needle (EUS RFA) and using a needle-shafted radial impulse sonication (USRA) through an echoendoscope. The preoperative ablation time and power were allowed to vary. The animals were sacrificed through an echoendoscope and biopsy needle (EUS RFA) and using a needle-puncture was performed via the transduodenal approach and the guide wire used to advance antegradely across the papilla. The echoendoscope was then advanced antegradely across the papilla and the diagnostic value was significantly better in the CH-EUS-FNA group than in the EUS-FNA group (94% in the CH-EUS-FNA passes and 86% and 91% in the EUS-FNA passes respectively). The visual core size was not significant for the true-positive diagnosis of malignancy. The sensitivity and specificity based on core histology was 89% and 94% in the CH-EUS-FNA passes and 86% and 91% in the EUS-FNA passes.

Introduction: Endoscopic ultrasound (EUS)-guided rendezvous techniques facilitate common bile duct (CBD) access during subsequent endoscopic retrograde cholangiopancreatography (ERP) in a single session. Cases of initial ERP failure mainly comprise malignant biliary or ampullary infiltration and altered anatomy of the papilla, the former accounting for the majority of reports in the literature. Aims & Methods: We aimed to evaluate the efficacy and safety of EUS-guided rendezvous in a series of distal CBD obstruction with failed initial ERP, due to inaccessible intra-diverticular papilla. Consecutive patients with distal CBD obstruction, in whom selective biliary cannulation at ERP was unsuccessful due to large duodenal diverticula, underwent EUS-guided rendezvous. CBD puncture was performed via the transduodenal approach and the guide wire was advanced antegradely across the papilla. The echoendoscope was then exchanged for a duodenoscope and a sphincterotomy was inserted through the papilla alongside or over the wire, to allow further manipulations. Results: In a total of 2480 ERCPs performed over a 4-year period, 18 cases were selected to undergo EUS-guided rendezvous due to the presence of a large ampullary diverticulum. Primary indication for ERP was CBD stones in 15 patients, pancreatic head cancer in 2 patients and cholangiocarcinoma in 1 patient. Mean age of the patients was 77 years (range 62–91) and mean diameter of the CBD was 16 mm (range 8–21). Successful CBD puncture with antegrade passing of the wire into the duodenum and subsequent ERP, in the same session, was achieved in 2/3 (66.7%) cases of malignant obstruction and in 13/15 (86.6%) cases of lithiasis. Retrograde biliary cannulation during ERP was performed over the wire in 7/18 (38.9%) cases and alongside the wire in 11/18 (61.1%) cases. The mean time from the admission allows an immediate correct endoscopic treatment with significant improvement in the quality of life. Based on the results of our study, EUS performed within 48 hours from the admission allows an immediate correct endoscopic treatment with significant improvement of the quality of life.

Disclosure of Interest: All authors have declared no conflicts of interest.

Contact E-mail Address: eyal.gal83@gmail.com

Introduction: mucus healing (MH) of isolated small bowel Crohn’s Disease (CD) induced by anti-tumor necrosis factor alpha agents are scarce.

Aims & Methods: 1) To evaluate MH rates by capsule endoscopy (CE) in patients with isolated SB lesions treated with adalimumab (ADA). 2) To correlate MH with clinical and biological indices of remission. This was a prospective observational, single center study. CD patients with isolated (per CE) active CD (CDAI > 220) SB disease, who were recommended ADA by their treating physician were consecutively recruited; first CE was performed prior to commencing ADA, and the second -14-week after starting ADA. All enrollees underwent a patency capsule study to confirm patency. Disease severity was assessed by the capsule endoscopy Crohn’s Disease activity index (CECDAI) score. MH was defined as CECDAI score < 3.

Results: Out of 31 patients screened, 24 were eligible, and 22 completed the study (as two patients developed an allergic reaction to ADA and were withdrawn). Females: 12 (54.5%), median disease duration: 3 years (IQ R 1–7), biologic excluded. MH had lesions located in the SBCE (n = 20). In our study, we compared the accuracy of localizing the source of bleed in early VCE versus SOC (standard of care) tests chosen based on clinical symptoms alone. This was a prospective single center randomized trial of 73 consecutive patients presenting to the University of Massachusetts Medical Center with NIHGB (melaena, hematochezia/anemia, or guiniea-piglike stools/anaemia). Exclusion criteria included presence of pacemaker, dementia, non-English speaking, hemodynamically significant bleeding. Patients were randomly assigned to SOC arm versus early capsule (EC) deployment. The SC group received a primary diagnostic procedure based on clinical symptoms that was dictated by the gastroenterologist on service, who was at liberty to choose the procedure sequence as they felt appropriate.

Results: Total ource, 73 were included. 2 patients from the initial included group were excluded (one due to technical capsule failure and one was transferred from an outside hospital). Baseline characteristics were similar and depicted in Table 1. The EC group (n = 34) had localization of presumed source of bleeding in 22/34 (64.7%) of patients at the time of the first diagnostic procedure compared to 48.4% (n = 16) in the SOC group ( p = 0.002). Active bleeding or stigmata of recent bleeding at the time of the first procedure was seen in 64.7% (n = 22) of patients in the EC groups compared to only 30% (n = 6) in the SOC group ( p = 0.003). However, while melena was more frequent symptom in the SOC group (n = 26) EGD was the most commonly chosen primary diagnostic procedure (n = 23), but was only diagnostic 52% of the time. After complete diagnostic evaluation in the SOC group, patients presenting with bleeding had lesions located in the esophagus (3.3%), stomach/duodenum (46.2%), small bowel (11.5%), colon (11.5%), but 27% had no source identified. EC group had lesions localized to the esophagus (2.9%), stomach/duodenum (35.2%), small intestine (8.8%), colon (20.5%), and 32.3% did not have lesions identified. Patients with SB MRI evidence of small bowel inflammation (n = 29) EGD was never diagnostic as a primary procedure, coloscopy (COLO) had a 50% diagnostic rate, and VCE was diagnostic 100% of the time.

Conclusion: VCE used as the first test in patients with NIHGB detects active bleeding more often than the SBCE approach, since it examines much more of the GI tract than EGD and COL alone. Detection of the anatomic site of bleeding allows for better therapeutic decisions.

Introduction: The interpretation of small bowel capsule endoscopy (SBCE) requires a high level of concentration. An abnormality may be present on just a few of the many thousands of images presented for interpretation. It is
unknown whether fatigue affects the accuracy of SBCE reporting and how many SBCE cassettes can be reviewed in one session.

Aims & Methods: Thirty-two participants (16 experienced SBCE readers and 16 novices) were invited to participate in this study. Each participant was asked to read 9 pre-selected SBCE studies consecutively. These studies were presented in a randomized order. All readings took place using the single view mode, where readers were able to choose the frames per second viewed from a range of speeds. Fatigue was measured subjectively using a Likert scale and objectively using a computer-based psychomotor vigilance test. These measures were performed at prior to commencing the study and after every second capsule read. Accuracy in lesion detection was determined by comparison with a gold standard reading derived from the non-consecutive readings of two expert capsule readers. Accuracy was plotted against the order in which SBCE studies were read. The aim of this study was to determine whether fatigue influences the accuracy of SBCE interpretation and how many cases can be read before accuracy declines.

Results: In keeping with existing literature, high intra-reader variability amongst the participants was observed, with experienced readers reaching kappa values of 0.51 with the gold standard and 0.08 amongst novices. A progressive SBCE studies were read the mean speed increased for both experts and novices, with a mean reduction of 10 minutes between the first and the last study read. This was associated with faster reading speeds selected in progressive studies read. Where accuracy was analysed with respect to the reading speed chosen, a negative correlation between increasing speed and accuracy was demonstrated, with 31% of lesions detected when read at 6–10 frames per second, compared to 15% when using the 22–28 speed. This was not a significant change in accuracy with progressive capsule read when the group was analysed as a whole. The accuracy of experienced readers declined after just one study read, from 38% to 27% and plateaued thereafter. Novice readers demonstrated no significant change at the time points, but trended towards improvement, perhaps indicating skills acquisition during the study.

Conclusion: The accuracy of SBCE reporting declines after one study reporting in a given period of time by expert SBCE readers. The optimal time between readings needs to be explored. This does not affect novice readers perhaps demonstrating skill acquisition.

P1574 FEASIBILITY OF SAME-DAY COLON CAPSULE ENDOSCOPY (CCE) IN PATIENTS WITH INCOMPLETE COLONOSCOPY

M. Hussey1, G. Holleran2, C. Tersarulo3, D. McNamara1
1Gastroenterology, Tallaght Hospital, Dublin/Ireland
2Trinity Academic Gastroenterology Group, Trinity College, Dublin/Ireland

Contact E-mail Address: husseysma@tcd.ie

Introduction: Rates of incomplete colonoscopies (IC) range from 2–19%, requiring repeat procedures or radiological imaging which can often lead to diagnostic delays as well as increased inconvenience for the patient. Same-day CCE may offer a more convenient and cost-effective mode of colonic exanimation post IC.

Aims & Methods: We aimed to determine the feasibility of same-day CCE post incomplete colonoscopy (IC) in a prospective pilot study for patients with IC without a contraindication to CCE with an IC for reasons other than poor bowel prep was offered the test following an appropriate recovery time of 1-hour post IC. Informed consent was obtained from all subjects. Upon ingestion of the capsule, grading of IV metoclopramide was given to overcome the antinomility effects of fentanyl given during routine colonoscopy. Standard booster protocol for CCE was administered. Patient demographics, procedure indica
tions, sedation studies can be read in one sitting. This does not affect novice readers perhaps indicating skills acquisition.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
cases to obtain an automatic histological classification of colonic polyps. Our automatic classification system is based on the textural elements from polyp surface and their correlation with Kudo’s pit pattern classification. Textural elements are identified as bright regions in polyp surface and there are characterized according to their shape into tubular and circular: a high presence of tubular patterns is associated to an adenomatous histology whereas the absence of prominent tubular structures is associated to non-adenomatous.

Taking this into account, we characterized segmented bright regions using a tubularity metric (Tub) designed to obtain low values for circular shapes and high values for elongated shapes of the regions. We tested our method in high definition (HD) white light polyp images which were obtained with a colonoscope Olympus C1F-H190 at Hospital Clinic in Barcelona. Neither conventional nor virtual chromoendoscopy were used. These images were selected to show as much variability in polyp appearance as possible. We used the mean of all Tub values for an image to classify it into two classes: Adenoma and Non-Adenoma. A ROC curve was constructed to select the optimal threshold value of Tub. Then, we compared the histology prediction provided by our system and the actual histology obtained after lesion removal.

Conclusion: A computer vision system based on bright regions in the image has a high accuracy for on-line prediction of polyp histology during colonoscopy. Though the use of shape characterization is promising, the inclusion of other polyp characteristics (i.e. shape, color, vessels...) as well as enlarging the validation database could improve the robustness of our methodology.

P1577 COLORECTAL LATERALLY SPREADING TUMORS DETECTED AT CT COLONOGRAPHY
M. Iwabuchi, M. Sugimura, S. Toda, K. Ukai Gastroenterology, Sendai Medical Center, Sendai/Japan

Contact E-mail Address: s856@m.shinjyo.jp

Introduction: Laterally spreading tumors (LSTs) of the colorectum are classified into the following two subtypes according to their morphology: granular type (LST-G), and non-granular type (LST-NG). Meanwhile, CT colonography (CTC) is a relatively new radiological technique for imaging the entire colorectum (LST-G), and non-granular type (LST-NG). Meanwhile, CT colonography (CTC) may be readily used for imaging of the colon in elderly or poor risk patients with colon polyps and cancer because of its non-invasiveness and relatively short examination time. One drawback of making a misdiagnosis may be inevitable. Therefore, analysis of misdiagnosis case is crucial on the new modality for the colon cancer screening examination.

Aims & Methods: We evaluated the misdiagnosed case of large neoplastic lesions using colonoscopy and CT colonography in JANCT by gastroenterologist and radiologist interpretation. Out of 1257 cases enrolled in JANCT, 1181 cases were actually studied, omitting 76 cases according to the exclusion criteria. More than 16 DAS CT were used for CTC, respectively. Images were retrospectively reconstructed by using a 0.5mm section index. The CTC examination was prepared by PEG-C solution before scanning. CO2 gas as an enterovaguerent agent was then administrated just before scanning. This was used for the contrast medium. CTC image was analyzed by AZE Virtual Place software. The CTC and CS were independently analyzed by endoscopist and radiologist in blind fashion. We investigated misdiagnosed lesions with CTC more than 10mm detected by CS. We considered the pseudo-negative lesions misdiagnosed with CTC interpretation as true PNL by radiologist and gastroenterologist and also considered the true pseudo-negative lesions misdiagnosed with CTC interpretation (true PNL) by radiologists and gastroenterologists. Because we conceived true PNL showed the limitation of CTC interpretation instead of PNL involved a human error.

Results: PNL was diagnosed by CS at 0-Ip (8 cases, 8 lesions), 0-Ia (17 cases, 19 lesions), respectively according to the criteria of the Paris classification. True PNL was also diagnosed at 0-ip(1 case, 1 lesion), 0-Ia (5 cases, 6 lesions) and 0-IIa (11 cases, 13 lesions), respectively. True PNL/PNL ratio was 0-Ip 12.5%, 0-Ia 50% and 0-IIa 68.5%, respectively. There was no PNL at 0-Ic Type I, II and III on this study. Most of all true PNL were so called flat lesion not only 0-Ia lesion.

Conclusion: CTC was proven to be a reasonably useful approach to obtain the image of colon diseases without any invasiveness to the patient. On CTC interpretation, lower protruded lesion was considered less detectivity than highly protruded lesion like 0-Ip lesion.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1579 DIFFUSION-WEIGHTED MAGNETIC RESONANCE FOR ASSESSING FIBROSIS IN CROHN’S DISEASE
A. Caruso1, M. Scarp1a, G. Schifano1, C. Mescoli1, M. Rudatis1, R. D’Inca2, G.C. Sturoni3, C. Lacognata1, I. Angrima

1 Gastroenterology Unit, Ospedale di Gastelfranco Veneto, Castelfranco Veneto (TV)/Italy 2Radiology 1. Azienda Ospedaliera di Padova, Padova (PD)/Italy 3Department Of Medicine, Dimed, Pathology Unit, University of Padova, Padova (PD)/Italy 4Dept. Of General Surgery, University of Padova, Padova/Italy

Contact E-mail Address: ant.caruso@hotmail.it

Introduction: The formation of fibrotic tissue in intestinal wall of Crohn’s Disease (CD) patients is transmural and mucosal biopsies are unrepresentative of real intestinal damage. Magnetic Resonance Enterography (MRE) allows a transmural study of the bowel loops. Recently the percentage of gain of contrast enhancement between MRE and diffusion sequence of MRE has been proved useful to study fibrosis in CD patients. Diffusion Weighted Imaging (DWI) through the restriction of the apparent diffusion coefficient (ADC) allows an accurate evaluation of disease activity in CD patients avoiding contrast agents.

Aims & Methods: The aim of this study is to investigate if DWI sequence of MRE was able to identify intestinal fibrosis in CD patients candidate to surgery, using the histopathologic specimens and percentage of gain as gold-standard. Thirty ileocolonic CD patients candidates to surgery for stricture disease were consecutively enrolled from October 2010 to November 2015. All patients underwent MRE before the surgery. The histopathological examination was performed using an histological score for inflammation (AIS) and fibrosis in the stenotic segment and in the ileum before the stenosis.

All population had an active disease at MRE. ADC value had a significant correlation with fibrosis score (r = 0.67; p < 0.0001), AIS (r = 0.73; p < 0.001) and percentage of gain (r = 0.687; p < 0.0001). A strong correlation emerged between wall thickness and fibrosis score (r = 0.671; p < 0.0001). The
threshold of wall thickness for fibrosis was

\[
AUC = 0.89.
\]

Conclusion: The DWI sequence with ADC value can identify fibrosis in intestinal wall of C0 and is not always the use of contrast medium.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1580 MOLECULAR IMAGING OF c-MET IN THE CLINICAL MANAGEMENT OF GASTROINTESTINAL CANCERS

N. Mcdonald, C. Portal, I. Wilson

Contact E-mail Address: i.wilson@edinimage.com

Introduction: The primary indication for c-Met targeted optical imaging agent EMI-137 is the early detection of lesions during colorectal cancer screening, including flat lesions that are difficult to detect by normal white light endoscopy. We have evaluated the potential benefit of EMI-137 and analogues beyond colorectal cancer screening since c-Met is up-regulated in many other cancers.

Aims & Methods: We have synthesised analogues of EMI-137 where the fluor-escent reporter was replaced by a radionuclide chelating moiety for PET imaging. The use of this agent alongside EMI-137 could enable the PET localization of the lesions prior to surgery guided by fluorescent signals. Through a systematic analysis of scientific literature databases, and the Human Protein Atlas, we have identified more than 13 different types of solid cancer that are amenable to optical imaging for which there is evidence for c-Met as a target. We believe that imaging of c-Met with EMI-137 in these indications has the potential to positively impact critical problems in the existing patient care path and reduce morbidity, mortality, and healthcare costs. We have assessed: 1) the healthcare problem, the impact on patient care path, and the likelihood of adoption by clinicians 2) the hardware landscape; whether imaging hardware required is commercially available or is being developed, and feedback from clinicians in the US and EU 3) our confidence in c-Met as a valid imaging target to address the healthcare problem.

Results: We have identified a number of promising applications within Digestive Oncology; gastric cancer, locally-advanced rectal cancer, and bile duct cancer surgery are all life-threatening indications with urgent healthcare problems that could be improved by utilising imaging of c-Met with EMI-137. Compatible imaging systems are commercially available for these indications. There is also strong evidence for c-Met as a biomarker in stratification in Barrett’s oesophagus (BO), a potentially precancerous lesion with the risk of progression to oesopha-gal cancer. Progression rates are low and overall survival rates in BO patients are similar to the general population. However, due to the poor prognosis of oesophageal cancer, patients with BO lesions are managed by regular endoscopic surveillance and biopsy. This means that there is arguably a disproportionate healthcare burden relative to the level of risk.

Conclusion: Gastric cancer, locally advanced rectal cancer, and bile duct cancer surgery all have strong evidence for c-Met as a valid target, and the healthcare problems are clear and widely recognized, with EMI-137 having the potential to high-grade innovative procedures in serious, life-threatening conditions. An imaging agent that enabled more accurate risk stratification of BO patients would lead to a change in patient management, with the potential to remove unnecessary biopsy and to reduce the frequency of surveillance.

P1581 HOMEMADE FIXATION OF FULLY-COVERED SELF-EXPANDING METAL STENT

Endoscopy, ICESP Sao Paulo Dept. of Endoscopy, Sao Paulo/Brazil

Contact E-mail Address: ktpennacchi@yahoo.com.br

Introduction: Esophageal self-expandable metal stents are currently used as an alternative for surgical treatment in esophageal neoplasia, benign strictures, fis-tulas and anastomotic leaks. Migration is a common complication after stent placement and has higher rates when fully covered stents are employed. Covered stents prevent tumor ingrowth and can be removed easily, they can be used in the closure of fistulas and leaks. External fixation of the stent with Shim’s technique seems to be efficient in preventing stent migration, but has a high cost and is not always available. Fixation by clipping or sutures has similar limitations. We developed a homemade technique for external fixation of the stent using dental floss to prevent dental floss migration. We present the results of this technique in a small cohort.

Aims & Methods: The present study enrolled sixteen patients with esophageal malignancies, anastomotic leaks, esophageal fistulas and extrinsic compressions. The stents used in these patients were five partially covered and ten fully covered. We developed a homemade technique using dental floss for external fixation of the stent which prevent stent migration. We pull stripes of dental floss into the stent mesh and using a method similar to exchange of a nasobiliary drainage catheter, the dental floss is drawn out through the nose, tied a knot into it and its loose end is fixed to the patient’s earlobe.

Results: Upper gastrointestinal endoscopy was performed after two weeks and the proximal end of the stent was evaluated. If it was embedding the esophageal mucosa and did not separate from the esophagus with air inflation, the external fixation was removed. Otherwise, the fixation was kept for another 2–4 weeks when a new endoscopic evaluation was performed. Patients were evaluated 15–30 days after stent placement. In cases of migration of the entire lenghth of the stent into the stomach, the patient received a new stent and the same fixation method was employed. In cases of stents partially migrated through the cardia, the same stent was repositioned and fixed with dental floss strips as previously described.

Conclusion: According to the results we believe this homemade technique using dental floss for external fixation of stents is a simple and cheap method that can be applied and used to prevent stent migration.

P1582 CLINICAL OUTCOME WHEN USING SELF-EXPANDING METAL STENT IN OBSTRUCTIVE COLORECTAL CANCER IN 248 PATIENTS IN 7 YEARS EXPERIENCE IN A TERTIARY CENTER

M. Shafazand, T. Radomski, L. Alkelin, N. Papachryssos

Gastroenterology, Sahlgrenska University Hospital, Gothenburg/Sweden

Contact E-mail Address: morterza.shafazand@vrgenom.se

Introduction: The reported incidence of colorectal cancer in Sweden in 2014 was 60–65/100,000 inhabitants and caused 25–30 deaths/100,000. Of all colorectal cancer, approximately 15–20% debates with acute obstructive symptoms. Malignant obstruction in these conditions (open surgery) have been shown to lead to mortality risk up to 20% and morbidity risk of 45–50%, followed by increased need for intensive care and more infections and stoma complications. Self-expanding Metal Stent (SEMS) for relieving malignant colorectal obstruction is a treatment for non-curative cases or for bridging the patient for later surgery. Studies have shown "clinical success" of SEMS at 90%. An article from 2007 concludes that SEMS in acute colon obstruction has better results regarding sickness and side effects compared with acute open surgery3.

Aims & Methods: Our compilation covers the years 2010–16, when 248 SEMS interventions(53% men, 47% women, age 28–97) were performed at SU/Ostra Hospital. In 78% of cases, the obstruction was located below the left flexure. In 80%, SEMS was made for palliative purposes.

Results: Technically, SEMS succeeded in 98% of cases and had clinical success in 90% of cases(abscence in need of emergency surgery). Complications (colony perforation) occurred in 6% of the cases. Mortality within 30 days was 11% and 12% in 90 days. 22% of patients required more than one intervention with regard to 90-day mortality for the indication was palliative vs. bridging, 29 resp. 3%. Based on the clinical outcomes "success" vs "failure", the 90-day mortality rate was 19 resp. 55%.

Conclusion: Our interpretation is that SEMS is an effective method of acceptable safety regarding complications in acute malignant colon obstruction. The method is suitable for both intended intestinal relief for palliative purposes, as well as awaiting later curative measure (bridge to surgery).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Tracheoesophageal fistulas are severe complications which commonly occur secondary to malignant tumors of the esophagus. Other causes include mediastinal or respiratory tract tumors, surgery, radiotherapy and trauma. Without treatment they often lead to pulmonary and gastroenterological complications, such as pneumonia, acute respiratory distress syndrome and poor nutrition. The purpose of this study was to assess the efficacy of endoscopic treatment performed in our clinic for esophageal fistulas.

Aims & Methods: We performed a retrospective study on 43 patients admitted in our clinic between January 2015 and April 2017 for esophageal fistulas.

Results: The average age of the patients included in the study was 54 years old. The causes leading to the tracheoesophageal fistulas were the following: esophageal malignancy in 18 cases (41.8%), surgery in 8 cases (18.6%), respiratory tract malignancy in 6 cases (14%), gastric sleeve in 5 cases (14%), radiotherapy in 3 cases (7%) and trauma in 2 cases (4.6%). In every case, the treatment of choice was placement of fully-covered metallic stents. A number of 16 patients needed reintervention, with a mean of 2 reinterventions per patient. Regarding recurrent fistulas, endoclips were used in one case (2.3%), additional stenting in 11 cases.
A total of 452 endoscopic interventions (mean 3.4 per patient, median 2
131/135 (97%) patients with a mean of 30.1 months (0 to 103).

Disclosure of Interest:

Aims & Methods: The aim of the analysis is to summarise the results and establish
evidence in support or against the complementary treatment.

References

Aims & Methods: The analysis was performed using the preferred reporting items
for systematic review and meta-analysis protocols (PRISMA-P). Two reviewers conducted a
comprehensive search on databases from inception to February 2016, to identify
trials, comparing the efficacy of dilatation combined with intralesional steroid injection
versus dilatation alone. A meta-analysis was conducted on the data using the
random-effects method by DerSimonian and Laird, because of the high level of
heterogeneity.

References

Results: There were 45 articles found in Embase, 55 in PubMed, and 6 in the
Cochrane database. Altogether 11 articles were suitable for analyses, after exclu-
sion of duplicate articles, case reports, results from non-human and pediatric
studies. These studies involved 373 patients in total. The periodic dilation index
for patients with recurrent stricture was comparable in 4 studies, where the pooled result showed, that
it decreased in the intralesional steroid plus dilation group (standardized mean
difference: -0.717, 95% CI: -1.191; -0.242, p-value: 0.003). The total number of
repeat dilations was comparable in 5 studies, where the standardized mean
difference was -0.465 as compared to the dilation alone group (95% CI: -0.777;
-0.153, p-value: 0.004). The dysphagia score was comparable in 5 studies, but
in this case no significant difference could observed between the two groups (stan-
dardized mean difference: 0.274, 95% CI: -1.822; 1.165, p-value: 0.510).

Conclusion: Our meta-analysis showed a significant improvement in the periodic
dilation index and total number of repeated dilations in the patients treated by
intralesional steroid injection as well. We recommend the use of intralesional
steroid injection for benign refractory oesophageal strictures.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Palliative stenting is now established as a major treatment for dys-
phagia resulting from incurable malignant oesophageal tumours. Palliative stenting involves
placing stents, but recurrences may require frequent and repeated dilations in the long
term. Several trials have been conducted to determine the efficacy of intraluminal stenting in the
treatment of benign rectangular oesophageal strictures, since the first pediatric case series was published in 1969. However, a meta-analysis has not been carried out yet.

Aims: To determine the safety and efficacy of stenting and treatment failure.

Conclusion: Fully covered metallic stents offered effective treatment for esophag-
geal fistulas, regardless of the cause. Recurrent fistulas were successfully treated
by additional stents and in rare cases endoscopies.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Endoscopic treatment of entric strictures in patients with Crohn’s
disease (CD) is well established; however, long-term outcome is unknown.

Aims & Methods: All patients with CD, who had undergone endoscopic therapy
for symptomatic strictures at Robert-Bosch-Hospital Stuttgart from 2008 – 2017,
were included in this retrospective cohort study. A follow-up was available for
131/135 (97%) patients with a mean of 30.1 months (0 to 103).

Results: A total of 452 endoscopic interventions (mean 3.4 per patient, median 2
per patient, range 1–69 treatments) were performed in 135 patients (female
n = 67/male n = 68, mean age 47.5 years, BMI: 22.8 ± 4.9 kg/m², duration of
illness: median 25.1 months). In 165 cases, the dominant stricture was located
in the ileocecum, in 105 in the colon, esophagus (90), duodenum (54), upper
intestine (26), lower intestine (11) or stomach (1). In 166 and 286 cases, there
was an anastomotic and non-anastomotic stricture present, respectively.

Treatment consisted of hydrostatic balloon dilatation (n = 447); bougienage
(4), and cSEMS (1). Dilatation was performed to a mean of 14 mm (SD: 2.4,
range 7 to 24 mm). In seven cases complications occurred after endoscopic

References
Results: Between 01.01.2012 and 01.04.2016, 152 stents were inserted in 125 patients with palliative oesophageal cancer; 104 patients had stent inserted once, 16 patients had twice, 4 patients had 3 times and 1 patient had 4 stent insertions. 69.6% were male and the median age at death was 79 years (SD 10.94). The reported histology for the 125 patients revealed, 85 (68%) adenocarcinoma, 25 (20%) squamous cell carcinoma, 5 (4%) lung cancer causing external compression of the oesophagus, 2 (1.6%) mesothelioma, 1 (0.8%) externally compressing spindle cell sarcoma, 1 (0.8%) metastatic adenocarcinoma from the colon, 1 (0.8%) externally compressing signet ring adenocarcinoma. Of these stent insertions 52 (32.4%) were documented to have gone on or recurrent dysphagia after the procedure, of which the causes were: tumour over- or ingrowth in 9 (5.9%); stent migration in 15 (9.9%); distal obstruction due to gastric folds in 2 (1.3%); dysfunction of the anti-reflux valve in 3 (2.0%); and food bolus obstruction in 1 (0.6%); stenosis, managed by endoscopic stent intubation in 1 (0.7%) case. In 13 (8.6%) cases cause for dysphagia was not found or not investigated. 100 (63.8%) stent insertions resulted in complete resolution of the dysphagia. Repeat endoscopy was necessary in 34 (27.2%) patients, who had 98 repeat gastroscopies in total, to deal with minor complications of the stent insertion or to investigate dysphagia. In total there were 13 (8.7%) significant complications caused by the stent insertion of which 7 (4.6%) were bleeding, 2 (1.3%) were tracheo-oesophageal fistula formations, 1 (0.7%) was delayed perforation, 1 (0.7%) was a too short stent, 1 (0.7%) was a disintegrating stent and 1 (0.7%) was a compression of the bronchial. Median survival of the 125 patients after stent insertion was 96 days (SD 128) and 30-day mortality was 11.2% (14 patients). It is important to note that with retrospective data analysis, some data is not available, due to variations in recording at the time and a reliance on the patient to report symptoms to a clinician. Currently 2 patients are still alive.

Conclusion: Palliative stenting at this centre continues to be an effective treatment for patients with dysphagia from oesophageal cancer. On the whole, outcomes from stenting at this unit compare favourably with published data in terms of dysphagia, other complications, and mortality. Steps to improve post-procedure monitoring in the form of a “stenent registry” with prospective collection of data by telephone or face-to-face follow-up could be useful in future service development.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Self-expanding metallic stents (SEMS) is a well-established form of palliative treatment for dysphagia in esophageal cancer. Progression of the tumor after stenting with re-sterosis is a serious problem in patients with better prognosis and longer survival.

Aims & Methods: The aim of this study was to assess the timing and probability of esophageal re-sterosis after stenting by tumor growth. We performed a retrospective analysis of patients with advanced esophageal cancer who was under- went self-expanding stent treatment, 5 years in Regional Cancer Hospital. We installed partially covered SEMS of one design from one manufacturer. The length of stents was 80, 100, 120, 140 mm, diameter - 20 mm. Patients with follow-up of more than 60 days were included in this study.

Results: Of the 165 patients from the database, 97 patients were selected, whose follow-up period was more than 2 months. There was a predominantly of male patients (78.5%), mean age of 72 years. To each patient was inserted a same partial covered stent of 4 cm length. In 87 cases stent was placed 2 cm distal and 2 cm proximal of the stenosis. Of 97 patients, 18 (18.5%) patients had tumor overgrowth with recurrence of dysphagia. Tumor overgrowth was verified as malignancy. Tumor localization before stenting: the upper and middle part of the esophagus - 6 patients, the lower part and the cardia - 12 patients. In 12 cases tumor growth spread out in the proximal direction, in 6 cases-in the distal. Interestingly, the distal tumor overgrowth after stenting was predominant (66.6%) in cases of localization in middle and upper part of the esophagus, while in cases of localization in the lower part of the esophagus or cardia. Period of re-sterosis was from 2 to 12 months, an average of 5.7 months. The period of re-sterosis in the upper and middle part of the esophagus is 4 months, while in cases of tumor localization in the lower part of the esophagus or cardia is 6 months. In almost cases palliation was successfully achieved with re-intervention. Five patients required several sessions of argon-plasma coagulation an average one time in 3-4 weeks.

Conclusion: The use of SEMS in patients with advanced esophageal cancer, with an expected long-term survival, is associated with an increased risk of re-sterosis by tumor overgrowth. Period of re-sterosis was an average of 5.7 months. The direction of spread tumor after stenting and the time of dysphagia recurrence correlated with localization of the tumor. This complication is not fatal and managed by endoscopic methods.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Self-expandable metal stents (SEMS) are often used for palliative treatment of dysphagia in patients with advanced esophageal cancer, with anticipated limited survival. However, due to previous reports of high adverse event (AE) rates when used long-term, concerns have been raised with the use of SEMS in patients with survival longer than 3 months.

Aims & Methods: We aimed to the role of esophageal SEMS in patients with advanced esophageal cancer and expected survival longer than 6 months. Clinical success was defined as relief of dysphagia in patients with the stent in the correct position. Clinical success was defined as relief of dysphagia 1 week after placement.

Results: This was a retrospective study of patients with clinical dysphagia and advanced esophageal cancer who underwent SEMS placement with a stent dwell time of greater than 6 months. In all patients the indication for stent placement was dysphagia due to esophageal malignancy.

Results: Forty-four patients were followed for 298 days (183-861 days). At the end of follow-up the mortality was 93%. The majority of lesions were located at the proximal/middle oesophagus (55%), and were traversable using an ultrathin gastroscope in 79% of patients; in no patient could a standard upper endoscope be passed. Ten (23%) of the 43 patients (8 overgrowth/ingrowths, 4 migrations, 5 re-stenoses) showed clinical improvement occurred in all patients, however 59% of patients experienced an AE (15 migrations, 8 overgrowth/ingrowths and 2 stent-induced fistulæ). The median stent patency was 236 days (19-513). Two AEs occurred within 30 days of stenting, 7 occurred between 30-90 days, 7 occurred between 90-180 days, and 9 occurred after 180 days. Endoscopic management was attempted in every SEMS-related AE (20 patients required a second SEMS, 2 had successful SEMS repositioning and 1 was treated with argon plasma; 2 SEMS were removed without the need for further therapy), with a clinical success of 100%, however, in 7 patients the previously treated AE recurred (5 overgrowths/ingrowths and 2 migrations). Multivariate analysis showed that strictures traversable with an ultrathin gastroscope are a risk factor for AEs.

Discussion: Of all authors have declared no conflicts of interest.

available in many centers and have revolutionized the management of iatrogenic bowel injuries.

**Aims & Methods:** Evaluate the role of intervention radiology procedures to manage different post-cholecystectomy complications focusing on the novel techniques to improve the final outcome. From June 2014 to June 2016, 30 patients presenting with iatrogenic complications were referred to our interventional radiology unit in our university hospital. We had 9 males and 21 females (age range: 18–66 years). Patients presented with biliary leaks (n = 12), benign biliary strictures with intrahepatic biliary dilations (n = 21), postoperative hernia (n = 1). Bilioleak related to hepatic artery pseudo-aneurysm (n = 1). Different types of interventional procedures were performed, including: Percutaneous trans-hepatic drainage (PTD) (n = 16), sequential dilatation of benign stricture with increasing calibers over 6 months followed by manometric studies before catheter withdrawal (n = 6), bile stenting with plastic stent (n = 2), Insertion of pigtail catheter (n = 15), preoperative progressive percutaneous-portalineum for their adhesiolysis effect to manage post-operative huge incisional hernias before their surgical repair (n = 1), and selective embolization of bleeding hepatic and/or extrahepatic pseudo-aneurysm (n = 1) using tissue adhesive (n = 2). 

**Results:** All percutaneous procedures were technically successful. No recorded early or late complications. After manometric studies, all managed cases with benign strictures did not show any clinical evidence of restenosis during 6 months follow-up. Overall, 14 out of 30 patients (46.7%) were only managed by different interventional radiology procedures. Second step surgical repair was needed for 13 patients (43.3%) and endoscopic managed for 3 patients (10%) by different interventional procedures. 

**Conclusion:** Minimal invasively interventions were valuable techniques in the management of different post-cholecystectomy complications. In fully equipped centers, expert multidisciplinary teams would achieve high cure rates for iatrogenic biliary injuries.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Angiography is a diagnostic and therapeutic modality that is widely available for upper gastrointestinal bleeding but is used less frequently when the source of bleeding is placed distally to the Treitz angle.

**Aims & Methods:** To assess the usefulness of angiography in the diagnosis of colonic and small bowel bleeding and to determine the efficacy and complications of therapeutic procedures. Retrospective study; we included all patients with colonic and small bowel bleeding that were submitted to arteriography with or without embolization, admitted to the gastroenterology department of a tertiary hospital between February 2006 and November 2016. Statistics: Chi-square/Fisher exact test, T-student.

**Results:** During 10 years period more evaluated, 63.6% male, mean age = 75 years (29–95). Angiography was done for: bleeding recurrence (36.2%), hemodynamic instability (33.3%), both (27.3%) or failure to endoscopic hemostasis (3%).

**Conclusion:** Minimal invasive interventions were valuable techniques in the management of different post-cholecystectomy complications. In fully equipped centers, expert multidisciplinary teams would achieve high cure rates for iatrogenic biliary injuries.

**Contact E-mail Address:** Neilraham@hotmail.com

**Introduction:** PET/CT has become an integral part of the staging pathway for operable oesophageal cancer (OC), primarily used to identify occult distant metastases unseen by conventional radiological modalities. The aim of this study was to analyze the effect of PET/CT introduction on overall survival and assess patterns of recurrence after oesophagectomy.

**Aims & Methods:** Consecutive 180 OC patients undergoing oesophagectomy for cancer [median age 63 (31–80) yr., 395 male, 425 ACA, 71 SCC, 325 neoadjuvant therapy] were studied. Two hundred and twenty-three patients underwent PET/CT enhanced staging protocols and the primary outcome measure was overall survival based on intention to treat.

**Results:** Overall 3-year survival pre-PET/CT was 42.5% compared with 57.8% post-PET/CT (Chi² 6.571, df 1, p = 0.014). On multivariable analysis, pT stage (HR 1.34 [95% CI 1.03–1.76], p = 0.029) and pN stage (HR 1.116 [95% CI 1.05–1.18], p = 0.004) were independent factors to predict mortality severity CD ≥ 3 (OR 0.85, 95% CI 0.75–0.97, p = 0.018). Cumulative survival was associated with operative MSS (Chi² 4.892, DF 1, p = 0.027) but not with PET variables.

**Conclusion:** PET/CT is a significant predictor of mortality after oesophagectomy with peak 0V2 the most important factor. 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** neilraham@hotmail.com

**Introduction:** Surgery for radical treatment of oesophageal cancer carries significant inherent risk. Objectively Identifying patients that are high risk of complications is of importance. The aim of this study was to assess the prognostic value of physical fitness variables determined objectively by cardiopulmonary exercise testing (CPET) in patients undergoing potentially curative surgery for oesophageal cancer (OC) within an integrated multidisciplinary recovery programme.

**Aims & Methods:** Consecutive 180 OC patients (106 ACA, 11 SCC, 3HGD) underwent preoperative CPET with prospective recording of morbidity and survival. Non-parametric receiver operating characteristic (ROC) curves and logistic regression were used to assess the relationship between CPET variables and post-operative morbidity severity score (MSS).

**Results:** Of 180 patients, 120 were included for analysis (median age 65 yr., 100 male, 75 neoadjuvant therapy); 60 did not proceed to surgery and were excluded. Postoperative mortality and mortality occurred in 83 (69%, CD ≥ 3 in 27, 22.5%) and 4 (3.3%) patients respectively. ROC curve analysis showed oxygen uptake (peak V02) gave an area under the ROC of 0.66 (95% CI 0.55 to 0.77, p = 0.009), heart rate (peak HR) 0.53, and peak oxygen uptake (peak V02) 0.51–0.74, (p = 0.048) and oxygen cut-off of 10.5 ml/kg/min (sensitivity 60%, specificity 44%). Multivariable analysis revealed peak V02 to be the only independent factor to predict mortality severity CD ≥ 3 (OR 0.85, 95% CI 0.75–0.97, p = 0.018). Cumulative survival was associated with operative MSS (Chi² 4.892, DF 1, p = 0.027) but not with PET variables.

**Conclusion:** PET/CT is a significant predictor of mortality after oesophagectomy with peak 0V2 the most important factor. 

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Although surgical techniques and perioperative management for esophageal cancer has been developed, it cannot be still safe to be performed esophagectomy. Therefore, endoscopic submucosal dissection (ESD) for the superficial cancer have been increased. We also need to consider the risk of lymph node metastasis before treatment in each patient and the aim of this study is to predict lymph node metastasis for superficial esophageal cancer.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
Aims & Methods: Seventy patients who were diagnosed as clinical T1a-MM, T1b- SM1 or T1b-SM2 and underwent esophagectomy at the Keio University, Tokyo, Japan between July 2000 and June 2016 were enrolled in this study. Patients who underwent esophagectomy as additional resections after ESD were included. We used random forest analysis to predict lymph node metastasis.

Results: There were 62 men and 8 women in this study. The mean age of all patients was 62.8±8.2 years. The main location of the tumor was in the middle thoracic esophagus (Upper: Middle, Lower: 13: 39: 18, respectively). 14 patients had lymph node metastasis in pathological findings; 2 patients (25%) were diagnosed as clinical T1a-MM, 2 patients (6.2%) had lymph node metastasis (31.3%) were T1b-SM2. Random forest technique (2000 trees) resulted in an estimate of error rate of 25.7%. Lymph node metastasis was most associated with the factor of pathological T (relative importance 100%) followed by lymph nodes on the contralateral T (97.9%).

Conclusion: Random forest analysis confirmed the predictors for lymph node metastasis such as pathological T and lymphatic invasion.

Disclosure of Interest: Malnutrition is associated with higher rates of operative morbidity and therefore represent potentially reversible prognostic risk factors. Bioelectrical Impedance Analysis (BIA) is a non-invasive, reproducible and simple means of accurately measuring body composition.

Aims & Methods: The aim of this study was to assess the prognostic value of body composition variables determined objectively by bioelectrical impedance analysis (BIA) in a group of patients undergoing potentially curative surgery for oesophageal (OC) and gastric cancer (GC) within an enhanced recovery programme (ERP).

Consecutive 168 OG patients [median age 65 (24–86) yr., 131 male, 105 OC, 64 GC, 157 ACA, 8 SCC, 3 Neuroendocrine] underwent preoperative measurements of systemic inflammatory response [SIR, including FIB, CRP, Albumin, and modified Glasgow Prognostic Score (mGPS)]. Patients underwent multi-frequency (0.5 kHz, 50 kHz and 100 kHz) BIA assessment using a Maltron Bioscan 920 (Maltron International Ltd, Essex, UK), and Cardiac Pulmonary Exercise (CPX) assessment was performed selectively (70 OC, 27 GC). Primary outcome measure was Clavien Dindo (CD) morbidity severity score (MSS) of ≥3.

Results: Oesophagectomy was performed in 106, gastrectomy in 64, and laparotomy only in 23 patients. Postoperative morbidity and mortality occurred in 75 (45%, CD ≥3 in 35, 21%) and 4 (2%) patients respectively. On univariable analysis, MSS ≥3 was associated with anaerobic threshold (p = 0.0011), CRP (p = 0.001), mGPS (p = 0.0011), intra-cellular water (ICW, p = 0.041), and extracellular water content (p = 0.0013). Multivariable binary logistic regression revealed ICW content [OR per UQ CD 3 vs. 5, 39%, p = 0.02, OR 1.22 (95% CI 1.06–1.41) p = 0.006] and CRP [OR per UQ CD 3, 7 vs. 37%, OR 1.03 (99-106) p = 0.076] to be independently associated with MSS.

Conclusion: Seven-variable in morbidity severity was observed after OG cancer surgery. SIR and SIR were the most significant prognostic indicators.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The tumor micro environment plays a vital role in the growth of malignancies. Through for example tumor-infiltrating lymphocytes (TILs) it influences overall and disease free survival of patients in various cancer entities. Therefore, the study investigating how to investigate TILs. However, there is great heterogeneity about how to quantify these cells in the tumor tissue. Therefore, we present a novel Quantification of the Tumor Stroma (QTS) Algorithm to reliably and accurately quantify cells of the tumor stroma and to perform a correlation with survival after resection of patients with hepatocellular carcinoma and pancreatic cancer.

Aims & Methods: Immunohistochemical staining of CD3 and CD8 antigens in frozen sections of metastatic colorectal cancer (mCRC) and ovarian cancer (mOvC) as well as in paraffin sections of hepatocellular carcinoma (HCC) and pancreatic cancer (PCa) was performed. For each entity 10 slides per antigen were examined (n=80). In these different entities reliability and accuracy of computed quantification was tested in order to develop a general algorithm (Figure). First, reliability of identification of hot spots was investigated using two blinded observers. Hot spots were defined as regions with the highest density of TILs. The absolute amounts of cells were compared with the intra-class-correlation coefficient (ICC). Second, accuracy was tested. To examine whether quantification of 1 vs 3 hot spots yields accurate results CD3⁺ CD8⁺ as well as the absolute cell numbers were compared with the ICC respectively. Third, computed counting methods (1) ZEN 2 software counting (ZC), (2) ImageJ software with subjective threshold (ISC) and (3) ImageJ with colour deconvolution (IAC) were compared to a manual gold standard (Gold standard) using a linear regression analysis. Finally, 60 resected tumor tissues of HCC and 30 of PCa were retrieved. 3 hot spots have been selected for every slide and groups of high/low infiltration of CD3⁺ and CD8⁺ have been created according to the median value. Then, statistical correlation with overall survival (OS) and disease free survival (DFS) was performed.

Comparison of manual counting to the computed methods showed mostly excellent accuracy of the obtained results using intra-class correlation with reliability analysis (ICC) and coefficient B with linear regression (B):
computed counting methods achieve mostly excellent accuracy. ISC is accurate for sections with high background staining. IAC can be used in sections with low background staining. With the QTS Algorithm quantification of cells in the tumor stroma is reliable and accurate. Furthermore, clinical correlations after the use of this algorithm show results according to the literature: High infiltration of CD8+ T cells correlates with favorable prognosis in HCC and PCa. The future use of immunoscopy may help to predict prognosis after resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1598 LIVER RESECTION IN OBESE PATIENTS WITH HEPATOCELLULAR CARCINOMA
Hepato-biliary-pancreatic Surgery, Hyogo College of Medicine, Hyogo/Japan
Contact E-mail Address: iwama33387@hotmail.com

Introduction: Obese patients have been recognized as a risk factor for hepatocellular carcinoma (HCC). On the other hand, there are few reports concerning liver resection (LR) in obese patients.

Aims & Methods: We performed curative LR in 471 patients with HCC between 2006 and 2015. In this study, we defined an obesity as no less than 25 of body mass index (BMI). We compared clinicopathological findings, operation details, and surgical outcomes of the obese and non-obese patients. Furthermore, we assessed the accuracy of the use of this algorithm show results according to the literature: High infiltration of CD8(+) T cells correlates with favorable prognosis in HCC and PCa. The future use of immunoscopy may help to predict prognosis after resection.

Disclosure of Interest: All authors have declared no conflicts of interest.

Results:
Among 471 patients, 123 patients (26.1%) were defined as obese. Among them, 20 patients (4.2%) showed no less than 30 of BMI. Diabetes, hypertension, and hyperlipidemia were significantly more common, and the patients with hepatic tumors were more commonly present in the obese patients group than in the non-obese patients group (p < 0.05). The two groups showed no differences in the liver function tests except the indocyanine green retention rate at 15 minutes. There were no significant differences between the two patients group in the number of tumors, diameter of tumor, prevalence of cirrhosis, frequency of portal invasion, the operative procedure, operative duration, blood loss, incidence of postoperative complications, postoperative hospital stay, and in-hospital mortality (3.3% vs. 1.4%). No significant difference was found in relapse-free survival rate, or overall survival rate between the two groups, too. Thirteen patients underwent laparoscopic surgery, and 34 patients had open surgery. The two groups showed no difference in the background, including BMI. However, the operation time (265 min vs. 397.5 min) and the postoperative hospital stay (14 days vs. 18 days) were significantly shorter, and the blood loss (50 ml vs. 600 ml) was less in the laparoscopic surgery group than in the open surgery group (p < 0.05).

Conclusion: Liver resection in the obese patients with HCC was safe, and laparoscopic liver resection might be more useful for reducing the surgical stress and reducing the hospital stay.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction:
Acute cholecystectomy as treatment of acute cholecystitis is standard of care. However, many patients are still treated conservatively and undergo elective surgery. Often 6–12 weeks following the primary admittance is postulated as a good timing for an elective surgery but there are no studies on the optimal timing for delayed cholecystectomy.

Aims & Methods: The aim of our study was to determine when it is most advantageous to proceed with surgery after a no surgery period without complications. We evaluated age and gender of the patient, the presence of clinical signs and symptoms of acute cholecystitis, and the presence of complications, age and gender of the patient, and the presence of complications.

Results:
During the years 2006 to 2013, 31091 patients were treated for acute cholecystitis in Sweden. After exclusion of patients that did not perform surgery, were not registered in the national register and were treated with acute cholecystectomy, 8532 patients were identified that underwent planned surgery. In patients that were treated with acute cholecystectomy, 8532 patients were identified that underwent planned surgery. In patients that were treated with acute cholecystectomy, 8532 patients were identified that underwent planned surgery.

Introduction: Abdominal compartment syndrome (ACS) is serious complication of big number of surgical interventions. According the data of the World Society of the Abdominal Compartment Syndrome (WSACS), rate of mortality without treatment is more than 90%, after treatment from 25% to 75% [1]. Patients with ruptured abdominal aortic aneurysms (rAAA) are the group of high risk regarding ACS complication. Rate of incidence ACS at these patients is between 8% to 25%[2]. According to data of various authors, from one third to one half of them have died [3]. One of the main cause of this is the absence of good monitoring of intraabdominal pressure in this group of patients[4]. Currently, we have one effective way of treatment of ACS pathogenesis - decompressive laparotomy[5]. But prophylaxis becomes more important point, if we take to attention mortality after start the develop of abdominal compartment.

Aims & Methods: We aimed to investigate the impact of implantation polypropylene mesh in abdominal wall on rate of development ACS and it severity for patients after open repairing of ruptured abdominal aortic aneurysm. Patients with rAAA (total amount n=87 patients) were operated in standard volume. Before finish of surgery in study group (n=49, 34 males, 15 females, average age 63 years), we implanted polypropylene mesh ('in- lay' type) and was sutured skin and subcutaneous tissue only. In control group (n=38, 26 males, 12 females, average age 61 years +/-15 years) surgery was finished by standard way. In all patients had infrarenal type of rAAA. Middle lethalorifice or thoracopneumothorax fragmental access was used. After surgery intraabdominal pressure was controlled by intravесeal method during first seven days after operation. We fixated rate of complication and mortality in both groups. We followed-up patients after surgery and controlled far outcomes too. First mesh implantation was performed at 24 February 2014, last at 03 March 2017.

Results: In study group we fixated 5 cases of ACS (10,2%), including 3 cases of light ACS (intraabdominal pressure (IAP) =12–15 mm.Hg), 1 case of moderate ACS (IAP=16-20 mm.Hg), and 1 case of severe ACS (IAP >20 mm.Hg). Decompressive laparotomy was performed in one case with satisfac- tory result. In general, mortality in study group was 18.4% (9 cases). In control group we fixated 9 cases of ACS (23,7%), including 3 cases of light ACS (IAP=12–15 mm.Hg), 2 cases of moderate ACS (IAP=16-20 mm.Hg), and 3 cases of severe ACS (IAP >20 mm.Hg) and 1 case with very severe ACS (IAP more than 25 Hgm). Decompressive laparotomy was performed in three cases, satisfactory result was achieved in 1 case, in two cases patients have died from polyorgan insufficiency. In general, mortality in control group was 28.9% (11 cases). We did not find any specific complication, related with implantation of polypropylene mesh during all three years of follow-up.

Conclusion: 1. Implantation of polypropylene mesh is a safe and effective procedure for prophylaxis of ACS for patient with rAAA. 2. Implantation of mesh allows to avoid ACS for patient with rAAA and related with it complication and outcomes. 3. It is possible to implantate polypropylene mesh for other deseases, not only for rAAA, but this point requires further investigations.

Disclosure of Interest: All authors have declared no conflicts of interest.

surgery. Patients presented heart rate over 120 bpm. Images from CT showed left side of the abdomen without free abdominal fluid. An Upper Gastrointestinal X-ray was performed to localize the leak opening and enter to peritoneal cavity. Either 9.8 or 5.8 mm diameter gastroscope were used. In 10 patients with orifices smaller than 5.8 mm balloon dilatation of the leak opening allowed peritoneal access. The end-to-end anastomosis of AL (100 to 700ml). Sample was taken for bacterial cultures. The cavity was flushed and suctioned out with sterile saline solution (200 ml to 1000 ml). In cases of inadequate location surgical drains catheters were repositioned or replaced using endoscopic forceps and snare. Final catheters were removed. Replacement before the stoma and AL placement were performed advancing with endoscopes through the leak all the way down to the skin. Once the tip of the endoscope was outside the peritoneum the latex drains were removed. Catheters were snared or grasped and pulled back into the peritoneum leaving the proximal end close to the fistula opening. In 5 patients without surgical drainage systems one laparoscopic port was localized inside peritoneum and re-opened under endoscopic vision to allow drainage catheters placement. In 8 patients peritoneal adhesions were endoscopically lib- erated to allow AL endoscopic forceps and snakes to facilitate peritoneal navigation.

Results: Heart rate returned to normal within 24 hours and leukocytosis improved after 72 hours. In 50% of patients heart rate returned to normal immediately. Average time for the whole procedure was 45 minutes. Abdominal catheters were removed between 7 and 18 days once full resolution of the drainage was achieved. Twenty patients were discharged within the first 24 hours. The rest were discharged between 3 and 8 days. Partially covered SEMS were placed for 6 to 8 weeks leading to complete closure of leaks. There were no adverse events related.

Conclusion: EPOD for peritoneal collections and abscesses secondary to BS leaks is feasible, safe and highly effective.

Introduction: The impact of body composition on the outcomes following pancreateoduodenectomy is still unclear.

Aims & Methods: The aim of this study was to analyze the association between body composition the postoperative complications and 90-day mortality in patients undergoing biliopancreatic cancer surgery. Retrospective study of patients with pancreatic, ampullary or bile duct carcinoma that underwent surgery between March 2012 and October 2016. Body composition (skeletal muscle area, fat area, subcutaneous fat area and muscle radiation attenuation) was assessed in diagnostic or staging computed tomography (CT), in axial images at the level of the 3rd lumbar vertebra. Postoperative complications were recorded according to Clavien-Dindo classification and categorized as minor (grade I-II) and major (grade III+)

Results: Fifty-nine patients were analyzed and 11 were excluded due to unavailable CT scan at our institution. Forty-eight were included, 28 were men, with a mean age of 70.5±8.5 years. The incidence of major complications was 25% and 90-day mortality was 8.3%. On simple logistic regression of factors associated with major complications skeletal muscle area (OR 0.97, 95% CI 0.94–1.00, P=0.09) and index (OR 0.91, 95% CI 0.81–1.00, P=0.09) showed a trend for a protective effect. On multivariate logistic regression of factors associated with major complications skeletal muscle area and index (OR 0.89, 95% CI 0.79–0.99, P=0.05) and surgery (OR 1.01, 95% CI 0.99–1.03, P=0.07) was associated with higher incidence of major complications. The receiver-operator characteristic (ROC) curve showed an acceptable power of discrimination for major complications using a model with skeletal muscle index and surgery duration as independent variables (area under the curve of 0.736). On simple logistic regression surgery duration (OR 1.02, 95% CI 1.00–1.06, P=0.05), visceral fat area (OR 1.02, 95% CI 1.00–1.04, P=0.02) and total radiation (OR 1.05, 95% CI 1.01–1.09, P=0.04) were associated with higher 90-day mortality whereas muscle radiation attenuation had a protective effect (OR 0.88, 95% CI 0.76–0.99, P=0.05).

Conclusion: These results suggest that low values of skeletal muscle and muscle radiation attenuation, as well as high values of visceral fat and low radiation are associated with worse clinical outcomes following biliopancreatic cancer surgery.

Introduction: Gastroschisis is a ventricular body wall defect trough which protrude mainly large and small intestines. The disease’s clinical course and prognosis depend on both surgical techniques, severity of the defect, accompanying anomalies and complications.

Aims & Methods: We performed a retrospective study based on the analysis of patients records admitted to our hospital Neonatal Intensive Care Unit between January 2000 and December 2016. The aims of this study were to evaluate defect’s incidence, management and outcome of patients with gastroscisis in our institution.

Results: During the period 2000–2016 the overall incidence of gastroscisis in our NICU was 1.3% (35 cases-all transferred from other NICUs). The average birth gestational age was 35.5 weeks and the average birth weight was 2270 g. The abdominal wall defect was identified in antenatal period only in 15.4% of cases. Also, 23 patients (16.4%) presented other associated anomalies: 12 cases with congenital heart disease (5.8%), 5 cases with Down syndrome (2.3%), 3 cases with cardiac defects. Surgical techniques performed for abdominal defect closure were: primary closure in 35 cases (25%), staged closure in 12 cases (8.5%), patch closure in 2 cases (1.4%). The average period of digestive pause was 12.9 days and the mean length of stay in NICU was 30.4 days. Patients were also mechanically ventilated for an average period of 4.6 days. The most frequent complication was late-onset sepsis (37.8%); also 26 neonates (18.5%) underwent mechanical ventilation. Also, 12 cases (8.5%) remained with short bowel. The average mortality in our group was 33% but it constantly decreased over the years (from 84% in 2000 to 11% in 2016). Sepsis, prematurity, low birth weight and associated defects were identified as major risk factors for the unfavorable outcome of the affected infants.

Conclusion: The management of neonates with gastroscisis depends on several factors including the status of herniated organs, the size of abdominal cavity, the presence of other associated congenital anomalies and last but not least on the resources and experience of the neonatal interdisciplinary team. Significant changes occurred in the management of gastroscisis in our Unit and as consequence, the outcome of patients with gastroscisis has dramatically improved during the studied period.

P1605 CLINICAL ASSESSMENT OF THE FAILING TO REVERSE A DIVERTING ILEOSTOMY

Abstract: P1608

**Urinary metabolic profiling has been shown to distinguish patients with inflammatory bowel disease (IBD) from healthy controls (HC), and also CD from UC, replicating previous studies. In Crohn’s disease, Caucasians and South Asians could be separated, but Caucasian and South Asian controls could not be distinguished in the UC cohort, possibly suggesting the metabolic milieu in Crohn’s disease is stronger and less influenced by the impact of ethnicity.**

**Introduction:** Reduced saccharolytic fermentation has been described in patients with quiescent ulcerative colitis (UC). Such defects may differ across colonic regions along with acute variations in dietary fibre intake. These aspects deserve further study.

**Aims & Methods:** We aimed to define regional colonic fermentation by direct intestinal pH-transit profiling in patients with quiescent UC following acute variations in fermentable fiber intake. A randomized, double-blind, crossover trial was performed. Patients with quiescent UC (Partial Mayo Score ≤1; faecal calprotectin <150μg/g) and healthy controls who were not taking any

antibiotics (including sulfasalazine), probiotics or fiber supplements were
repeated for 7–7 days, and the same fecal samples were collected and
analysed for urease scores (n = 40) of each group. The bacteria
were collected and cultured on blood agar plates. Bacteroides
were negatively correlated with the calculated Crohn’s disease
activity (CDAI).
Conclusion: Our findings showed the specific characteristics and dysbio-
sis of fecal microbiota within Chinese IBD patients. In addition, the abundance
of the Bacteroidetes was significant lower in active CD group than in inactive
CD group, and it was negatively correlated with the CDAI, indicating that the
Bacteroidetes could be related with the disease activity.

P1610 Fecal Microbial Dysbiosis in Chinese Patients With Inflammatory Bowel Disease
H. Ma, H. Zhang
Department Of Gastroenterology, First Affiliated Hospital of Nanjing Medical
University, No. 300 Baishazhou Rd, Nanjing 210029, China, Fajangging
Contact E-mail Address: mahaiqin2010@163.com

Introduction: Fecal microbial dysbiosis in the gut has been suggested to play an
important role in the pathogenesis of inflammatory bowel disease (IBD).
Aims & Methods: In this study, we aimed to analyze the fecal microbiota in
Chinese patients with IBD. Fecal samples from 15 patients with Crohn’s disease
(CD), 14 patients with ulcerative colitis (UC) and 13 healthy individuals were
subjected to 16S rDNA sequencing. The V4 hypervariable regions of 16S rDNA
were sequenced by the Illumina MiSeq2500 platform. Quality control and opera-
tional taxonomic units (OTUs) were calculated with QIIME software.
Results: Significant differences in community richness and microbial structure
were observed both in CD and UC compared with normal controls. At the
phylum level, analysis of the microbial compositions revealed that the
Proteobacteria percentages were, significant higher in IBD than in controls.
While at the genus level, we found that the abundance of Ruminococcus in UC and
Bacteroides, was negatively correlated with the calculated Crohn’s disease activ-

acting and the capsule passed from the ileocecal junction to the anus, the
time taken between the ileo-cecal junction and capsule exit. Cecal pH
was defined as the minimum pH following passage through the ileo-cecal
junction whereas maximum pH was arbitrarily used as distal colonic pH.

Results: 15 UC patients (aged 24–72; 9 males) and 9 controls (aged 22–69 years,
4 males) were studied. A decrease in overall and distal colonic pH was observed
in controls with high vs low fiber diet (Table 1). In UC patients, a high fermenta-
able fiber intake reduced cecal pH but paradoxically tended to increase distal
colonic pH. A significant association was observed for UC extent and changes in
overall (r = 0.81; p < 0.001, Spearman’s correlation) and cecal pH (r = 0.53;
p = 0.04) after a high fermentable fiber diet (Figure 1). No differences in CTT
were observed between diets in either cohorts but subgroup analysis in the UC
cohort showed higher association of cecal transit with changes in pH in a high
fermentable fiber diet. 64% patients had slow CTT whilst 36% had unchanged or
faster CTT. In contrast, majority (63%) of controls had no changes in CTT after a high fiber
diet.

Conclusion: A high fermentable fiber diet partially increased colonic fermentative
activity in patients with quiescent UC compared to controls. Moreover, contrary
to controls, UC patients exhibited an increase in distal pH and heterogeneous
colonic transit responses after a high fermentable fiber intake. Our findings
suggest that abnormalities in motility and regional defects in the function of
the colonic microbiota exist despite quiescent disease.

Background: We sought to elucidate the effects of iron supplementation on hypoxia-mediated responses in the intestinal epithelium. For this purpose, serum starved Caco-2 monolayers were subjected to normoxia (21% O2) or hypoxia (0.2% O2) in the presence and absence of ferric ammonium iron citrate (FAC) and the iron chelator deferoxamine (DFO). Total RNA was isolated and changes in the expression of tumor necrosis factor (TNF), interleukin
(IL-1), TIMP-1, FPN and ferritin was assessed by real-time quantitative PCR. Western blot analysis was performed with antibodies against ferritin, p-NF-
κB, IκB, p-IκB, p65, p-IκB, p65, and p-fac. mRNA synthesis in Caco-2 cells under hypoxia was blocked using actinomycin D. Chromatin immunoprecipitation experiments were carried using antibodies against NF-κB and primers for pro-
moter binding regions of TNF and IL-1β. Healthy volunteers (n = 10) were sub-
jected to hypoxic conditions resembling an altitude of 4,000 m above sea level for
3 h using a hypobaric chamber. Serum samples were collected the day prior to
hypoxia, and one day, one week and one month after hypoxia.

Introduction: Environmental hypoxia has been established to influence the devel-
opment of inflammatory bowel disease (IBD). Adaptive responses to low oxygen-
tension are mediated through hypoxia inducible factor (HIFs), which are tightly
regulated by oxygen and iron levels through the action of hydroxylases. Dietary
iron is mainly absorbed by duodenal enterocytes through the divalent metal
transporter (DMT)-1. Once iron is inside the enterocytes, it is either sequestrated
into ferritin or transported out of the enterocyte into the circulation by ferro-
portin (FPN). Regulation of uptake, storage and export of iron is mediated by
signals reflecting oxygen and intracellular iron levels in enterocytes, and systemic
iron requirements. Central to systemic iron regulation is the liver hormone hepc-
din, which regulates and is regulated by systemic iron levels. Hepcidin expres-
sion is induced by cytokines and results in anemia of inflammation.

Results: Hypoxia induced the mRNA expression of TNF and IL-1ß concomi-
nantly, and we observed that the hypoxic response is reduced in the presence of
to low iron-starching conditions, thereby promoting iron uptake. The iron chelator deferox-
amine (DFO) induced IκBα stabilization and TNF mRNA expression under both
noroxic and hypoxic conditions. Conversely, iron supplementation induced ferritin protein accumulation under normoxic and hypoxic conditions,
and reduced TNF and IL-1ß mRNA expression. Interestingly, neither iron che-
lar nor iron supplementation reduced hypoxia-mediated p-NF-κB. Iron induced p-MTOR and blocked autophagy. Iron overload enhanced decay of TNF,
but not IL-1ß mRNA. Iron also prevented binding of NF-κB to the pro-
motor of TNF and IL-1ß. Healthy volunteers presented reduced serum levels of
iron, as well as transferrin saturation. Ferritin levels were unchanged indicating absence of inflammation and suggesting enhanced intracellular iron accumulation in enterocytes following hypoxia.

Conclusion: Our results suggest that hypoxia-mediated iron uptake is crucial to
counteract hypoxia-induced pro-inflammatory gene expression, and identify iron
intracellular uptake and storage as a hypoxia protective mechanism to reduce
mucosal inflammation.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: In both forms of inflammatory bowel disease (IBD), Crohn’s disease and ulcerative colitis (UC), inflammation of the gut wall is associated with extracellular tissue acidification. Low extracellular pH stimulates the family of proton-sensing G-protein coupled receptors (GPCRs); ovarian cancer G-protein coupled receptor 1 (OGR1), T-cell death-associated gene 8 (TDAG8) or G-protein coupled receptor 4 (GPR4), which activate second messenger signaling cascades. Recent studies reported a link between IBD and this family of pH-sensing receptors; in genome-wide association studies (GWAS), TDAG8 has been identified as an IBD-risk gene. The mechanism behind the interaction between treatment of IBD remained unclear. OGR1 and TDAG8 are alleged to act in opposition by regulation of the inflammatory response; enhancing or inhibiting inflammatory pathways respectively, however the interplay between OGR1 and TDAG8 is unclear.

Aims & Methods: In this study we aimed to investigate the role of OGR1 in IBD patients. Expression of OGR1 in surgical specimens from non-IBD (n = 5), CD (n = 10) and UC (n = 10) patients was determined by immunohistochemistry, RT-qPCR and Western blotting. Clinical disease activity was assessed by the Harvey-Bradshaw Index (HBI) and the Modified Truelove and Witts activity index (MTWAI) for CD and UC patients, respectively. Nonparametric Spearman’s rank correlation analysis was performed.

Results: OGR1 immunostaining of human surgical samples from non-IBD patients revealed OGR1 expression mainly in lamina propria cells, with weaker staining in epithelial cells. OGR1 staining in IBD patients was stronger compared to controls; however, in IBD patients OGR1 is highly expressed in both epithelial and lamina propria cells. Further, paired samples taken the same time, from non-inflamed and inflamed intestinal tissue from IBD patients showed stronger OGR1 staining in the inflamed mucosa compared to the non-inflamed mucosa. Accordingly, mRNA and protein expression of OGR1 was significantly increased when comparing IBD compared to non-IBD patients. In addition, a significant positive correlation was observed between OGR1 expression and the clinical score in both the non-inflamed (rs 0.731, p = 0.0069) and the inflamed mucosa (rs 0.7698, p = 0.0034).

Conclusion: The expression of OGR1 is significantly increased in patients with IBD. OGR1 expression correlates with IBD disease activity, suggesting an active role of OGR1 in IBD pathogenesis. OGR1 appears to be a therapeutic target for IBD. OGR1 expression correlates with IBD disease activity, suggesting an active role of OGR1 in IBD pathogenesis. OGR1 appears to be a therapeutic target for IBD.

Introduction: Ulcerative colitis (UC) phenotype in South Asian (SA) migrants differs to Caucasians with a predominant pan-colonic extent.1 A separate study showed microbial profiles with lower bacterial diversity in the SA group.2 The significance of these findings is unclear due to small sample size (n = 30) and single time point analysis.

Aims & Methods: We aimed to examine microbial profile of SA and Caucasian UC patients. Faecal samples were collected from 48 UC patients recruited in a prospective inception cohort study at diagnosis (time point 1; months 0–3) and 2 further time points over one year (time point 2: months 4–8, time point 3: months 9–12). Patients were stratified byethnic group (SA, Caucasian, Other), treatment (none, 5-ASA, Azathioprine and Steroids) and disease duration. Healthy controls (HC) were recruited locally among the staff at St. Marks Hospital. For 16S pyrosequencing the hypervariable region (V1) of the 16S rRNA gene was amplified by PCR. The amplicons were subjected to sequencing using Illumina MiSeq technology. The sequences were loaded onto the QIIME pipeline. Statistical analysis was performed using STAMP 2.1.2 software with Welch’s two-sided t-test for comparing two groups. Microbial richness was calculated based on Chao index. Weighted Unifrac metrics were applied to construct Principle Coordinating Analysis (PCoA) plots.

Results: Ninety-four faecal samples were collected. Sample collection for all time points included SA (n = 13), Caucasian (n = 9), healthy SA (n = 11) and healthy Caucasian (n = 12). There was no significant difference in relative abundance of bacteria between ethnic groups (5-ASA, Azathioprine, Steroids, None) and time points (1 vs 3). Comparing healthy SA and healthy Caucasians, there was only one significant difference in relative abundance of Clostridiales at the family level. (Increased in SA group). The Chao1 index showed a trend towards lower diversity in the SA group compared to Caucasians although there was no significant difference. There were significant increases in Bifidobacterium, Bikenellaceae, Lactobacillaceae and Streptococcaceae (Table 1) and significantly decreased relative abundance in Bacteroidellaceae, Anaerostipes and Ruminococcaceae.

TABLE 1: Summary of Bacterial Taxonomic Findings in South Asians (SA) and Caucasians with ulcerative colitis.3 Increase or decrease in SA relative to Caucasians

Phylum | Change | Family | Change | Genus | Change
--- | --- | --- | --- | --- | ---
Actinobacteria | Increased | Bifidobacteriaceae | Increased | Bifidobacterium | Increased
Bacteroidetes | Decreased | Bacteroidales | Decreased | Bacteroidellaceae | Decreased
Firmicutes | Increased | Lactobacillaceae | Increased | Lactobacillus | Increased
| | Streptococcaceae | Increased | Streptococcus | Increased
| | Clostridiales | Decreased | Clostridium | Decreased
| | Lachnospiraceae | Decreased | Anaerostipes | Decreased
| | | | | Unclassified
| | Ruminococcaceae | Decreased | Ruminococcus | Decreased
| | Verrucomicrobicae | Increased | | |
| | | | | |
| | | | | |

Conclusion: Increased Bifidobacteria and Lactobacilli in the SA group is consistent with the previous study. A possible explanation is the consumption of fermented foods in the SA group although there was no difference between healthy SA and Caucasian controls. There is a trend towards lower diversity in the SA group and reduced Bacteroides which are consistent with the UC dysbiosis described in the literature. Functional analysis of this unique microbial profile through metagenomic and metabonomic techniques may explain the different disease behaviour in the SA group.

P1614 VITAMIN D SUPPLEMENTATION REDUCES Faecal Calprotectin and Alters Intestinal Microbiota Composition in Patients with Active Ulcerative Colitis

M. Garg1, P. Hendy1, S. Shaw2, N. S. Ding1, G. Hold2, A. Hart1

Introduction: There is evidence for vitamin D as an immunomodulator in patients with IBD, but results from clinical trials to date are inconclusive. It is uncertain whether vitamin D supplementation may affect the intestinal microbiota.

Aims & Methods: This study aimed to assess the effect of vitamin D replacement in deficient patients with and without ulcerative colitis (UC) on inflammation and faecal microbiota. Vitamin D was replaced over 8 weeks to patients with active UC, inactive UC, and low controls with baseline 25(OH) vitamin D < 30 nmol/L, and markers of inflammation and stool collected for microbiota analyses by next generation sequencing.

Results: Eight patients with active UC, 9 with inactive UC and 8 non-IBD controls received 40,000 units of vitamin D weekly over 8 weeks. No demographic differences were noted across the groups. Mean baseline 25(OH) vitamin D levels were 34 (range 12–49) nmol/L. Vitamin D supplementation increased mean 25(OH) vitamin D to 111 (range 71–158) nmol/L (P < 0.001), and reduced para-thyroid hormone levels from mean 4.3 to 3.3 pmol/L (p = 0.017). No change in baseline medications for UC took place in patients with UC, except for one patient with active UC who ceased his 5-aminosalicylate. Faecal calprotectin levels reduced from median 275 to 91 μg/g (p = 0.023) in patients with active UC, but did not change in patients with inactive colitis or non-IBD controls. Similar improvements in albumin, platelet count and symptomatic disease activity indices were noted. No changes in overall bacterial diversity were noted. There was a trend towards an increase in abundance of Ruminococcus gnavus post vitamin D supplementation in active UC patients, but this did not reach statistical significance.

Conclusion: Vitamin D supplementation was associated with reduced intestinal inflammation in patients with active UC. A randomised controlled trial evaluating vitamin D in IBD is required along with further investigation of potential mechanisms by which vitamin D may alter specific microbial composition.

Introduction: Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

Aims & Methods: Attack by commensal microbiota is one component for induction of inflammatory episodes in ulcerative colitis (UC). In UC, the mucus layer is intrinsically devoid of phosphatidylcholine (PC) resulting in low hydrophobicity which facilitates bacterial invasion. Colonic ectophospholipase-carrying bacterial strains are likely candidates to break the PC mucus barrier. Therefore we aimed to evaluate the effect of phospholipase A2 (PLA2) inhibitors on inflammation in a genetic UC mouse model.

Results: Luminal UDCA-LPE reduced the PLA2 activity in stool by 36% in the genetic UC mouse model.

Introduction: Inflammatory bowel diseases (IBDs), Crohn’s disease (CD) and ulcerative colitis (UC) are usually sporadically associated with a genetic component in local pCN.

Genome-wide association studies (GWAS) identified over 240 non-overlapping single-nucleotide polymorphisms (SNP) associated with IBD. G-protein-coupled receptor 65 (GRP65) or T-cell death associated gene 8 (TDAG8) has recently been reported to be a genetic risk factor for IBD. The T-70 genotype of the lead GPR65 SNP (rs8005161) within the GRP65 gene confers increased IBD risk.

In response to extracellular acidification, GRP65 activates second messengers: cAMP, via the Gs signaling pathway, and G12/13/Rho signaling.

Results: Sequenced genotype frequency of rare homozygote rs8005161 in the SIBDCS was 1.17%, minor allele frequency (MAF) 10.3%. The variant rs8005161 was more frequent in UC patients (MAF 14.53% vs 10.05% in the non-IBD group), whereas no statistically significant association with IBD, UC or CD was detected from the SIBDCS as non-IBD controls (Table 1) or from functional studies. CD4+ T cells were isolated from blood samples and subjected to an extracellular acidic pH shift (pH 6.6 vs. pH 7.6) in functional assays and tested for cAMP and RhoA GTPase activation.

Conclusion: Minor allele of the GRP65 associated SNP rs8005161 was significantly enriched in UC patients. RhoA signaling was reduced in IBD patients versus healthy controls and remained lower in UC patients compared to controls. However, no differences in cAMP signaling in IBD TT/TC versus CC subjects were observed. Moreover, our results suggest impaired RhoA signaling in IBD patients upon a pH shift, indicating a mechanistic explanation for increased IBD risk with GRP65 polymorphisms.

Discussion of Interest: All authors have declared no conflicts of interest.

**P1617 B2-STRUCTURING AND B3-PENETRATING PHENOTYPE IN CROHN’S DISEASE: CHANGES IN DENDRITIC MACROPHAGE POPULATION AND WNT SIGNALING**

Introduction: Macrophages contribute to fibrosis through the release of different mediators and the pattern of secretion may vary according to their phenotype. Recent evidence has identified Wnt pathway as an emerging modulator of fibrosis.

Aims & Methods: The aim of the present study is to analyze the pattern of expression of macrophage markers and Wnt ligands in surgical resections from Crohn’s disease (CD) patients with different disease behavior. CD patients were categorized according to Montreal classification (age at diagnosis, location and behavior). mRNA was isolated from resections patients presenting an strictureing (B2) or a penetrating (B3) behavior or from patients with colorectal cancer (control). The expression of macrophage markers (CD206, CD86, iNOS, Arginase1), Wnt ligands (Wnt1, Wnt2b, Wnt3, Wnt4, Wnt5a, Wnt5b, Wnt6, Wnt7a, Wnt7b, Wnt8a, Wnt8b, Wnt9b, Wnt10a, Wnt10b and Wnt16) and DKK1 (inhibitor of Wnt signaling) was analyzed by RT-PCR.

Results: B3-patients seem to present a higher infiltration of macrophages since increased expression of markers classically used to detect pro-inflammatory (CD86) and regulatory/pro-resolving/pro-fibrotic phenotypes (CD206, ARG) was detected in this group. These patients also presented a generalized overexpression of Wnt ligands together with augmented DKK1 mRNA levels. B2-patients showed a more complex situation with ligands that present increased (Wnt5), reduced (Wnt2b) or unchanged expression in the absence of significant variations in the levels of macrophage markers (Table). Table. Relative (Gene/b-actin) mRNA expression (fold induction vs control group) of genes with detectable levels. Data are expressed as Mean±SEM in n ≥ 7 in all groups and analyzed by ANOVA + Kemman-Keuls test. (*p < 0.05 vs control; **p < 0.05 vs control).

Conclusion: Crohn’s disease patients presenting a strictureing (B2) or a penetrating (B3) behavior undergo different macrophage infiltration and Wnt signaling.

Disclosure of Interest: All authors have declared no conflicts of interest.

**P1618 CD16 POSITIVE CELLS EXPRESS TGFβ AND MEDIATES MURINE INTESTINAL FIBROSIS**

Introduction: M2 macrophages play a key role in injury repair and fibrosis. We showed that TGFβ-1 deficient macrophages mediate mucosal repair after TNBS-induced acute colitis 1 and that, in a chronic model, TGFβ deficient animals accumulate macrophages expressing the CD6 marker that promote intestinal fibrosis 2.

Aims & Methods: We aim to analyze whether the expression of the pro-fibrotic mediator TGFβ1 is related with this macrophage phenotype and the relevance of these cells in murine intestinal fibrosis. Murine peritoneal macrophages obtained from both WT or STAT6 (-/-) mice were treated with IL-4 (20 ng/ml), IL-10 (50 ng/ml) or vehicle and the mRNA expression of CD16, TGFβ, Vimentin, Col1a1, a-SMA, MMP2 and TIMP1 was evaluated in murine intestinal mcosa by qPCR.

Results: Positive and significant correlation between CD16 mRNA and TGF β1 mRNA was detected in this group. These patients also presented a generalized overexpression of Wnt ligands together with augmented DKK1 mRNA levels. B2-patients showed a more complex situation with ligands that present increased (Wnt5), reduced (Wnt2b) or unchanged expression in the absence of significant variations in the levels of macrophage markers (Table). Table. Relative (Gene/b-actin) mRNA expression (fold induction vs control group) of genes with detectable levels. Data are expressed as Mean±SEM in n ≥ 7 in all groups and analyzed by ANOVA + Kemman-Keuls test. (*p < 0.05 vs control; **p < 0.05 vs control).

Conclusion: Crohn’s disease patients presenting a strictureing (B2) or a penetrating (B3) behavior undergo different macrophage infiltration and Wnt signaling.

Introduction: The intestinal inflammation is reduced by electrical stimulation of the different vagus nerve. Cholinergic neural output may be a target to minimize tissue damage in autoimmune disease. Cholinergic neural output can modulate innate immune responses through stimulation of α7 nicotinic acetylcholine receptors (α7nAChR). GTS-21, a selective α7nAChR agonist, has previously demonstrated to inhibit the manifestation associated with rheumatoid arthritis (RA). In this study we investigate whether GTS-21 protects against DSS-induced colitis and its potential mechanism.

Aims & Methods: Male BABL/c mice (8–10 weeks old, n = 32) were randomly divided into 4 groups: normal control group, DSS-induced group, GTS-21 treatment control group (DSS-induced mice treated with GTS-21), and the control group received saline. Caco2 cells were exposed by 25 ng/ml TNF-α for 30 min prior to GTS-21 injection. BAY 11-2028 (NF-κB) group was treated with GTS-21 (20 mg/kg intraperitoneal injection) per day, a-BGT group was pre-treated with a-BGT (0.1 mg/kg/day, intraperitoneal injection) for 30 min prior to TNF-α injection, and the control group received saline. Caco2 cells were randomly divided into 4 groups: normal control group, TNF-α-induced group, GTS-21 treatment control group, a-BGT group. TNF-α group of Caco2 cells were exposed by 25 ng/ml TNF-α, GTS-21 group were given 100 ng/ml GTS-21 for 30 min prior to TNF-α; a-BGT group pre-treated with a-BGT (50 ng/ml) for 30 min prior to GTS-21 injection. BAY 11-2025 (NF-κB inhibitor) group were given 50 ng/ml BAY-11-2025 for 30 min prior to TNF-α. Disease activity index, macroscopic scores, and colonic damage were determined. The intestinal permeability of mice was measured by fluorescein-isothiocyanate-dextran (FITC-Dextran method). Western blot was used to detect the tight junction protein and NF-κB associated protein expression.

Results: Compared with DSS-induced mice, DAI score decreased and colon length improved after administration of GTS-21 (9.1±0.74 cm vs 6.5±0.53 cm, P <0.01). CD14, CD86 and Wnt10b positive cells was analyzed in macrophages. Macrophages were identified within inflammatory cells characterized by flow cytometry. Macrophages can contribute to fibrosis through the release of different mediators. We presented the 1.35 fold change in Wnt10b expression and the 0.22 fold change in MUC2 expression in the treatment group compared with the control group.

Conclusion: The mucosa of CD patients accumulate pro-inflammatory macrophages measured as DSS+6 cells while those macrophages expressing the M2 marker CD206 after their phenotype increasing the expression of both, CD6 and CD206. We proved that the profibrotic mediator Wnt10b increased.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: For inflammatory bowel disease (IBD), anaemia is the most frequently observed extra intestinal finding, prevalence of which varies from 6% to 74%. It’s of great importance to determine and treat anaemia as it lowers patients’ life quality and leads to labour loss. The main causes of anaemia in IBD are iron deficiency anaemia (IDA) and anaemia of chronic disease (ACD). In this study, we aim to specify the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD).

Aims & Methods: In this study, we analyze the type and prevalence of anaemia along with a treatment approach for inflammatory bowel disease (IBD). We conducted a retrospective study on 465 patients, who were diagnosed with IBD and followed up at our hospital from June 2015 to June 2016 (male: 254, female: 211, average age: 47±14.4, Crohn disease (CD): 257, Ulcerative Colitis (UC): 108). According to WHO criteria, anaemia is defined as haemoglobin value is below 13 g/dL in men and 12 g/dL in women.

Results: In our study, we determined that 50.3% of total 465 patients had anaemia, which was more frequent in women than men (64% vs. 39%, p < 0.001). Anaemia frequency was higher in CH cases (57%) than in UC cases (41%) (p=0.001). CD involvement were as follows: 54.5% in ileal involvement, 26.1% in colon involvement and 19.4% in ileocolonic involvement (p<0.001). Hb levels were significantly lower in Crohn disease (CD) patients with A2-strictureing and B2-penetrating behavior according to Montreal classification (age at diagnosis, location and behavior) as well as from non-inflamed tissue from cancer patient. Resections were immediately processed and lamina propria mononuclear cells characterized by flow cytometry. Macrophages were identified within singlet viable leukocytes as CD45 + CD14 + CD64 + . The percentage of CD206, CD16, CD163, CD86 and Wnt10b positive cells was analyzed in macrophages. Data are expressed as Mean±SEM % with n≥5 in all groups (P<0.05 vs control Student’s t-test).

Contact E-mail Address: m.dolores.ortiz@uv.es

Introduction: Intestinal fibrosis is a common complication of IBD and macrophages can contribute to fibrosis through the release of different mediators. We have recently reported that Wnt10b increase the deposition of collagen and promotes intestinal fibrosis in TNBs-treated mice (P015 ECCO 2017).

Aims & Methods: The aim of the present study is to analyze the pattern of expression of macrophages and the expression of Wnt10b in human macrophages from different resections from Crohn’s disease (CD) patients with A2-strictureing and B3-penetrating behavior according to Montreal classification (age at diagnosis, location and behavior) as well as from non-inflamed tissue from cancer patient. Resections were immediately processed and lamina propria mononuclear cells characterized by flow cytometry. Macrophages were identified within singlet viable leukocytes as CD45 + CD14 + CD64 + . The percentage of CD206, CD16, CD163, CD86 and Wnt10b positive cells was analyzed in macrophages. Data are expressed as Mean±SEM % with n≥5 in all groups (P<0.05 vs control, Student’s t-test).

Results: The percentage of macrophages identified as CD45 + CD14 + CD64 + constituted the 0.22 ± 0.03% of total events in the control mucosa while represented the 1.35 ± 0.40% in the mucosa from CD patients (p < 0.05). A high proportion of mucosal macrophages expressed CD206 in both, control (83.3 ± 4.8%) and CD (89.6 ± 3.9%). In these CD206+ cells, an increased expression of CD16 in CD mucosa was observed (Control: 34.5 ± 6.8%; CD: 59.7 ± 6.4%) while that of CD163 was similar in both groups (control: 72.8 ± 8.4%; CD: 85.2 ± 7.3%). The analysis of Wnt10b in CD206+ showed a significantly higher expression in CD patients (56.6 ± 4.2%) than in control samples (30.1 ± 10.4%). Additionally, CD86+ macrophages were more abundant in controls (CD: 29.3 ± 10.2%) than in CD (11.2 ± 6.6%)

Conclusion: The mucosa of CD patients accumulate pro-inflammatory macrophages measured as CD86+ cells while those macrophages expressing the M2 marker CD206 after their phenotype increasing the expression of both, CD6 and CD206.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference
Conclusion: We found that almost half of all IBD patients (50.3%), whom we followed up, had anaemia, the most frequent reason of which was IDA. Almost half of these patients received anaemia treatment. We should increase the treat- ment rate in our IBD patients that have anaemia.

Introduction: Enteric glial cells (EGC) are essential to intestinal epithelial barrier (IEB) homeostasis. In healthy intestines, EGC reduce IEB permeability and promote mucosal healing. In inflammatory bowel disease (IBD) such as Crohn’s Disease (CD) and Ulcerative Colitis (UC), both EGC phenotype and IEB functions are altered, but putative involvement of EGC in IBD pathogenesis remains unknown. If the astrocyte reactivity is well studied, the reaction of EGC to chronic inflammation is not well documented. We investigated whether EGC impact on IEB permeability was altered in an inflammatory environment and in IBD patients.

Aims & Methods: Rat EGC as well as human EGC from control, CD and UC patients were stimulated with the cytokine T (TNFalpha=IL1beta; 1 to 100 ng/ml) or LPS for 2 or 4 days. Reactive EGC phenotype where characterized and reactive EGC functional impact on IEB permeability was studied (i) in vitro using human intestinal epithelial cells (IEC) in a non-contact co-culture model, or (ii) in vivo by grafting the treated rat EGC in colon wall of Sprague Dawley rats.

Results: Rat and human control EGC induced a significant reduction of IEB paracellular permeability after T treatment when compared with untreated or LPS treated EGC. LPS or T treatment had no significant effects on IEC alone. In vivo colon wall grafting with control EGC did not modify the permeability whereas colon wall grafting with EGC pre-conditioned by T significantly reduced

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Enteric glial cells (EGC) are essential to intestinal epithelial barrier (IEB) homeostasis. In healthy intestines, EGC reduce IEB permeability and promote mucosal healing. In inflammatory bowel disease (IBD) such as Crohn’s Disease (CD) and Ulcerative Colitis (UC), both EGC phenotype and IEB functions are altered, but putative involvement of EGC in IBD pathogenesis remains unknown. If the astrocyte reactivity is well studied, the reaction of EGC to chronic inflammation is not well documented. We investigated whether EGC impact on IEB permeability was altered in an inflammatory environment and in IBD patients.

Aims & Methods: Rat EGC as well as human EGC from control, CD and UC patients were stimulated with the cytokine T (TNFalpha=IL1beta; 1 to 100 ng/ml) or LPS for 2 or 4 days. Reactive EGC phenotype where characterized and reactive EGC functional impact on IEB permeability was studied (i) in vitro using human intestinal epithelial cells (IEC) in a non-contact co-culture model, or (ii) in vivo by grafting the treated rat EGC in colon wall of Sprague Dawley rats.

Results: Rat and human control EGC induced a significant reduction of IEB paracellular permeability after T treatment when compared with untreated or LPS treated EGC. LPS or T treatment had no significant effects on IEC alone. In vivo colon wall grafting with control EGC did not modify the permeability whereas colon wall grafting with EGC pre-conditioned by T significantly reduced
the permeability when compared to control animals. Human EGC from control or UC patients treated with T1 induced a decrease in IEB permeability too, but EGC from CD patients did not differ.

**Conclusion:** This work is not only the first evidence showing that reactive EGC can have beneficial effects upon IEB permeability, but also shows that EGC from CD but not UC patients have lost this reactivity. This could define EGC as active players in CD pathogenesis.

**Introduction:** Inflammatory bowel disease (IBD) both intestinal epithelial barrier (IEB) permeability and PTGIS expression are altered. Nevertheless the role of the lipid mediator PGI2 produced by PTGIS in IEB regulation is unknown.

**Aims & Methods:** The present study concerns the control of IEB permeability by PGI2 and its involvement in the development of colitis.

**Results:** The production of PGI2 from control or IBD biopsies was established using high sensitivity liquid chromatography tandem mass spectrometry. Consequences of flocan PGI2 analogous supplementation were evaluated in a DSS-induced mice model of colitis, measuring disease activity index (DAI), inflammation (pro-inflammatory cytokine mRNA) and IEB permeability (sulfoconic acid flux). Molecular mechanisms involved were assessed by quantification of junctional and pro-proliferative vs pro-apoptotic protein expression (western blot and immunostaining). Eventually PGI2 impact on reversing IEB breakdown was assessed ex vivo measuring permeability of mice or human mucosal explants treated with staurosporine apoptosis inducer, or permeability of IBD biopsies both treated or not with flocan.

**Conclusion:** This study not only presents a role of PGI2 in controlling IEB breakdown but also reveals a new mechanism of IEB permeability through the regulation of apoptosis mechanisms, but also reveals that increased permeability in IBD patients can be fixed by PGI2 supplementation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ulcerative colitis (UC) is a clinical type of inflammatory bowel diseases. The pathogenesis of UC remains unclear. Nowadays the role of T-helpers type 17 (Th17) as well as cytokines they release is discussed in pathogenesis of autoimmune infiltration in UC.

**Aims & Methods:** The aim of study is to analyze the serum levels of following cytokines: interleukin (IL)-17A and F, 21, 22, 23, 33 in UC patients both in the acute stage of disease and remission. Forty eight UC patients in the acute stage and twenty patients in remission were included into the study. Serum cytokine levels were analyzed with multiplex immunoassay for Th17 cytokines (Bio-Rad, USA). Statistical analysis was performed using STATISTICA 6.0 Software Package. The control group consisted of 11 healthy volunteers.

**Results:** Statistically significant increase of IL-17A level (15 pg/ml [12.11;23.38]; 14.68 pg/ml [11.29;17.19] respectively) was observed in patients with UC both in acute stage and remission compared to controls (7.36 pg/ml [5.18;8.06], p = 0.00007, p = 0.00029 respectively). The same trend was observed regarding IL-22, which median values were higher both in acute stage (156.51 pg/ml [133.44;233.53]) and remission (144.02 pg/ml [133.44;154.43]) compared to control group (98.31 pg/ml [89.14;124.86], and showed statistically significant differences (p = 0.0007, p = 0.0054 respectively). Besides it was revealed that IL-17F and IL-22 were also higher in acute stage (3.65 pg/ml [0.8;25.88] and 3.76 pg/ml [0.5;5.83], respectively) compared to controls (4.87 pg/ml [3.8;7.87]; and 2.6 pg/ml [1.7;3.2], respectively), however differences were not statistically significant (p = 0.06; p = 0.172 respectively). Increase of described cytokines levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. Statistically significant increase of IL-10 in remission (27.99 pg/ml [17.53;33.55]) compared to controls (4.36 pg/ml [3.26;15.25], p = 0.0046) was found as well. IL-10 was also higher in patients with acute stage (21.93 [3.61;33.53]) compared to controls, however differences were not statistically significant (p = 0.065). IL-10 as an anti-inflammatory cytokine characterizes the activity of regulatory T-cells which suppress autoimmune inflammation. In addition, it was revealed that the level of IL-23 which stimulates Th17 differentiation was both higher in acute stage (258.4 pg/ml [55;367.49]) and remission (248.93 pg/ml [90.06;301.93]) compared to controls (124.3 pg/ml [107.9;296.04]), however differences were not statistically significant.

**Conclusion:** Increase of IL-17A, IL-17F, IL-21, IL-22 levels could be a sign of Th17 functional overactivity suggesting autoimmune type of inflammation. IL-17A and IL-21 produced by Th17 cells might be considered as markers of active autoimmune infiltration in UC patients.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
The steroid-refractoriness is a common complication of ulcerative colitis (UC), which appears unpredictably. Several mechanisms of action (MoA) have been implicated in corticosteroid failure. However, there are no conclusive results. While in case of diversity have been described. There are attempts to therapeutically transfer the complex ecosystem and have tremendous impact on our health. In inflammatory bowel disease (IBD), shifts in faecal microbiota composition are associated with disease activity and severity. The intestine is populated with myriads of bacteria, which form a microecosystem and have tremendous impact on our health. In inflammatory bowel disease (IBD), shifts in faecal microbiota composition are associated with disease activity and severity. The intestine is populated with myriads of bacteria, which form a microecosystem and have tremendous impact on our health. In inflammatory bowel disease (IBD), shifts in faecal microbiota composition are associated with disease activity and severity.

**Results:**
These results were not previously published and are now being presented for the first time. We identified a potential new MoA that includes 64 key proteins, 18 of them capable of perfectly classifying patients with a good response to glucocorticoids and the non-responders. The biological functions of these proteins have been associated with inflammation (e.g. RelA), glucocorticoid receptor transcription (e.g. NRC1 and NCOA3), and angiogenesis (e.g. VEGF), mainly. But among these 18 proteins, the ANP32e has never been related to either steroid-refractoriness or ulcerative colitis. ANP32e is a chaperone linked to H2A-H2A exchange (H2A.z is part of the nucleosomes flanking DNA regions recognized by the glucocorticoid receptor). Additional WB and immunofluorescence assays confirm differences in the intestinal levels of ANP32e and in the nuclear localization at baseline, between patients with disease and controls.

**Conclusion:** In conclusion, this study has identified a potential new MoA related to UC steroid-refractoriness involving chromatin remodeling modifications.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Results: each influenza strain was measured by inhibition of hemagglutination. The single group and booster group were randomly collected at 3 points (before vaccination, 4 weeks after vaccination and after the rivalent influenza vaccine was administered subcutaneously. Serum samples were assigned to adult patients with Crohn’s disease or ulcerative colitis, and quadrivalent influenza vaccine. Serological response rate to influenza vaccination was low in IBD H1N1: OR 0.37 (0.11–1.21); H3N2: OR 0.22 (0.07–0.68), SC%: H1N1: 0.23 B/Phuket: p = 0.81; H3N2: p = 0.79; B/Phuket: p = 0.82; B/Texas: p = 0.84. In patients treated with infliximab, seroprotection rate (SP%) and seroconversion rate (SC%) tended to be lower in influenza A strains in patients who maintained blood concentrations H1N1: OR 0.37 (0.11–1.21); H3N2: OR 0.22 (0.07–0.68), SC%: H1 N1: 0.23 (0.06–0.91); H3N2: 0.19 (0.06–0.56). Conclusion: Serological response rate to influenza vaccination was low in IBD patients receiving immunomodulator therapy, especially infliximab, even with a quadrivalent influenza vaccine.

Introduction: The increasing incidence of anal canal (AC) carcinomas in men and women requires better knowledge on Human papillomavirus (HPV) infection at this site and its risk factors. Higher incidence of AC cancers in Crohn’s disease (CD) patients is strongly suggested in the literature, without knowledge on HPV involvement. A gastroenterology population offers the opportunity to study a mixed and non-sexually at risk selected population and to study anal HPV infection in CD patients.

Aims & Methods: The aim of the study was to assess AC HPV infection prevalences and its risk factors in a gastroenterology population. The ‘Human papillomavirus (HPV) Anal Neoplasia’ - PAPILLAN study took place in a French university hospital gastroenterology unit. Consecutive patients were prospectively recruited at the occasion of a colonoscopy, whatever the indication. On the colonoscopy day, under informed consent with ESBL-E smear was sampled with a dedicated brush for molecular analysis. HPV detection and genotyping was performed with the INNO-LiPA assay. Risk factors for any HPV, and high risk (HR) HPV infection were assessed by bivariate and multivariate analysis after logistic regression.

Results: A total of 469 consecutive patients (median age 54 years, 52% women) had suitable anal samplings for HPV DNA detection. Among them 101 had inflammatory bowel disease (IBD), 70 had CD. 112 patients had at least one immunosuppressive treatment for IBD or another condition. Overall 34% of the population had a detection of any HPV type in AC smears. HR HPV prevalence was 18%, LR HPV prevalence was 9% and HPV16 prevalence was 7%. Most prevalent HR HPVs were, by decreasing order: HPV16, HPV51, HPV52 and HPV39. Among all patients with HPV positive or HR HPV positive samples, 65.6% and 65.9% were women, respectively (p = 0.0001; p = 0.0035, compared to men). Regarding medical history, HR HPV and HPV16 prevalence were significantly higher in Crohn’s disease (68% and 48% respectively, p = 0.0051; 14%, p = 0.0072, compared to the rest of the study population). Eleven/12 patients (50%) with perianal CD had an AC infection with any HPV. Multivariable analysis associated female gender and history of sexually transmitted disease with the presence of any HPV in AC; and female gender, history of sexually transmitted disease, lifetime and past year number of sexual partners, active smoking and immunosuppressive treatment (OR 5.3) with the presence of HR HPV.

Conclusion: We demonstrated that CD patients harbor more frequent AC infection with HR HPVs and that immunosuppressive treatment is an independent risk factor for HR HPV infection at this site. These findings strongly support prophylaxis with vaccination and adequate screening in our patients.

Introduction: Extended spectrum beta-lactamase producing Enterobacteria (ESBL-E) may increase inflammatory bowel disease activity. This study aimed to assess ESBL-E colonization and clinical disease activity in IBD patients.

Methods: Consecutive patients with confirmed UC and CD diagnosis, previously hospitalized in two largest tertiary medical care centres in Riga, Latvia during a 7-year period (2010–2016) were included in the study, interviewed, rectal swabs were collected, Enterobacteria were cultured and analyzed for ESBL presence according to European Committee on Antimicrobial Susceptibility Testing (EUCAST) guidelines. To clinically evaluate disease activity UC patients were evaluated according to Mayo score, Montreal classification, adapted Truelove and Witt’s criteria and CD patients according to Crohn’s disease activity index (CDAI), suggested by ECCO IBD guidelines (2016). Results: A total of 101 patients with UC and 47 patients with CD were tested for gut colonization with ESBL-E. We found that 12 (11.9%) of the UC patients and 5 (10.6%) of the CD patients were colonized with ESBL-E. Statistical significant differences were found in all UC clinical disease activity scores between patients with and without gut colonization with ESBL-E and showed tendency towards statistical significance in CD. The mean disease activity according to Mayo score in UC patients without ESBL-E colonization was 3.44 (SD = 2.07), whereas in patients with ESBL-E colonization it was 5.08 (SD = 2.84) (p = 0.015).

Most of the UC patients without ESBL-E colonization (n = 63; 70.8%) were in clinical remission, whereas half of the patients with ESBL-E colonization (n = 6;
50%) had mild to moderate to severe disease activity, according to Montreal classification system section (p = 0.037). Most of the UC patients with out ESBL-E colonization (n = 81; 91%) had mild disease activity, whereas half of the patients with ESBL-E colonization (n = 6; 50%) had moderate disease activity, according to modified Truelove and Witt’s criteria (p < 0.001). Most of the CD patients without ESBL-E colonization (n = 38; 90%) had moderate disease activity, whereas most of the patients with ESBL-E colonization (n = 3; 60%) had severe disease activity, according to CDAI (p = 0.05).

Conclusion: Gut colonization with ESBL-E might increase disease activity in out- patients. The taking of drugs could be clinically relevant and help to improve diagnostic and treatment protocols for IBD patients, because eradication of ESBL producing bacteria might reduce IBD disease activity.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Smoking has a differential effect on inflammatory bowel diseases (IBD); deleterious for Crohn’s disease (CD) and protective for ulcerative colitis (UC). Thickness of the mucus layer, immune system (cytokines production), mucosal and intestinal microbiome are potential mechanistic factors influenced by the nicotine and numerous other substances. It has been hypothesi- zed that smoking cessation is associated with the second peak of diagnosis in UC patients after 50 years old. Our aim was to confirm this hypothesis using data on smoking status at IBD diagnosis.

Aims & Methods: Adult IBD patients included in the Swiss IBD cohort from November 2006 to November 2015 were asked about their smoking status at diagnosis. We compared the proportion of former smokers in 10-year groups of UC and CD patients.

Results: 2361 IBD patients (1366 CD, 995 UC) were included in the analysis. Among them 52% of CD ans 24% of UC patients were smokers at diagnosis (proportion of smokers in Switzerland (2014): 29%). The higher proportion (66%) of former smokers at diagnosis was in the 50 to 60 years old group of UC patients compared to only 26% in CD patients between 40 to 50 years old (p < 0.001). On a gender basis, the higher proportion of former smokers is particularly significant high among male 50–60 years old with UC (68%) and particularly significant high among CD patients without ESBL-E colonization (n = 26% in CD group and from 17.30 for E1 to 20.55 for E2 in UC group. However, sig- nificant difference in F values was observed in CD patients: L1 and L2 have lower average F than those with L3 and L4 (6.66, 7.63, 10.25 and 14.00 respectively; p = 0.0215). D values were significantly higher for patients with none or one extraintestinal symptoms (p = 0.05). Results of D values obtained in our study were higher than for healthy population aged 35-44 in Poland (mean D~2).

Conclusion: The results of preliminary POLIBD study among two groups of IBD patients showed similar values in DMFT index and higher average number of carious teeth in CD patients, especially in men.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: From June 1, 2009 to January 31, 2017, 421 patients were included and screened with MRC: cohort 1 included 206 IBD patients with liver abnormalities; cohort 2 included 28 IBD patients without liver abnormalities; and cohort 3 included 187 non-IBD patients with liver abnormalities. Two senior radiologists independently evaluated MRC findings. MRC abnormalities were observed in 18% of patients in the cohort 1; 3.6% in the cohort 2; and 31% in the cohort 3 (Table 1). Based on MRC, we found respectively 11.2%, 0%, and 7% of PSC in cohorts 1, 2, and 3. 29.2% of IBD patients with liver abnormalities had infra-clinical PSC. A history of intestinal resection (P = 0.0357), abnormal gamma-glutamyl transferase values (P = .0064), and abnormal alkaline phosphatase values (P = 0.021) were significantly associated to suspected PSC. Results of MRC abnormalities in cohorts 1, 2 and 3

Conclusion: Using MRC in patients with IBD, we found a higher prevalence of PSC than based on clinical symptoms. Systematic screening for PSC using MRC could be recommended in routine practice for IBD patients. Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Malnutrition and altered body composition can develop in patients with inflammatory bowel diseases (IBD) for a variety of reasons. Malnutrition and sarcopenia may worsen disease outcome in chronic disorders, raise the risk of infections and hospitalization: An unrestricted educational grant from Abbvie Pharmaceuticals was received for this work. Buhlmann laboratories provided all IBDoc kits for this study. All other authors have declared no conflicts of interest.

Results: According to our results 19.2% of the patients (n = 38) were underweight (body mass index (BMI) < 18.5 kg/m²) and 29.8% (n = 59) had alarming low fat-free mass index (FFMI) and were at risk of sarcopenia. Overall 31.5% (n = 62) of the patients needed steroid therapy and 53.5% (n = 106) was given anti-TNF. Almost third of the participant (30.8%, n = 61) were hospitalized due to disease flares or its complications at least once during the follow-up time. The mean period of hospitalization was 19.14 ± 3.27 days. 20.2% (n = 40%) of all participants have undergone intestinal surgery. Hospitalization was positively associated with sarcopenia risk: alarming low FFMI was associated with an OR of 1.81 (95% CI: 1.03–3.20, p = 0.0406). The risk of operation was higher in patients with lower BMI: OR = 1.55 (95% CI: 1.05–2.29, p = 0.0277) for 5 units decrease; no other association was significant in the models.

Conclusion: Our results suggests that low BMI is a risk factor of surgery in inflammatory bowel disease patients. Furthermore alarming low FFMI is a predictor of need of hospitalization and that suggests more serious flares. Identification of malnutrition and altered body composition has notable importance in disease outcome among IBD patients.

Introduction: The majority of Crohn’s disease (CD) develop structuring complications of the disease at some point. The proper selection of patients with potential benefit of therapy escalation is crucial in order to avoid unnecessary bowel dissection. Contrast enhanced ultrasound in the affected bowel segment at intravenous contrast-enhanced ultrasound (CEUS) has been shown to correlate with disease activity but there are no data available on the benefit of CEUS for the therapeutic decision making in this clinical setting.

Aims & Methods: The aim of the study was to evaluate the clinical outcomes of CD patients with structuring disease managed based on the CEUS findings. CD patients with structuring disease were recruited from two IBD centre between June 2015 and February 2017. Patients with penetrating disease complications were excluded. CEUS examination protocol: 10 pts had therapy step-up to antiTNF or immunomodulator. 6 pts had therapy switch of another biological; 10 pts had therapy step-up to antiTNF or immunomodulator. 25 pts had follow-up longer than 12 months (median 18 months).

Results: In total, 27 patients were included (10 men; median age 37 yrs, range 23–67; 22 pts with ileo-coecal localization, 3 pts with multiple small bowel segments involvement, 2 with colonic disease). Seventeen patients (63%) had rapid uptake at the CEUS; 13 of these patients had therapy escalation (3 pts intensification or switch of another biological); 10 pts had therapy step-up to antiTNF or immunomodulator. Remaining 3 pts improved subsequently on stable therapy with antiTNF and one patient with longstanding symptomatic colonic stricture was referred for surgery. Ten patients (37%) had no rapid uptake at the CEUS; seven out of these patients had symptomatic structuring disease stricture was referred for surgery. Three patients had no symptoms and no therapeutic changes were made. Twenty-five patients had follow-up longer than 12 months (median 18 months, range 13–23). In the group of patients with rapid uptake, all but two patients achieved sustained remission after therapy escalation. Two patients initially responded to therapy but have lost response and eventually needed surgery. In the group with no rapid uptake, patients without surgery remained in remission without any changes in the medication. Patients who underwent surgery in the 12 months period after antiTNF therapy escalation and none of these patients had recurrence at the surveillance colonoscopy at 12 months.

Conclusion: Contrast-enhanced ultrasound might be helpful in guiding the therapeutic decision making between surgery and therapy intensification in patients with structuring Crohn’s disease.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1645 DIAGNOSTIC DELAY AND PREDICTIVE FACTORS FOR CROHN’S DISEASE IN AN ALGERIAN POPULATION

Y. Chebli, R. Boulares
Constantine, Ben Badis Hospital, Constantine/Algeria

Contact E-mail Address: Yacinechebli4@yahoo.fr

Introduction: Crohn’s disease (CD) is a chronic inflammatory bowel disease whose diagnostic delay (DD) is highly variable. A delay in diagnosis of MC is strongly linked to delay in therapeutic interventions appropriate to the patient’s disease activity. Factors Influencing SD may be a function of the country’s health system, but also linked to the particular clinical and evolutionary profile of the disease. The objective of this study was to measure the DD of CD, to describe its distribution and evolution over time and to The factors associated with a long DD (>Q3).

Aims & Methods: All patients with certain or probable CD between 2004 and 2016 identified by The department’s inflammatory disease hospital registry was included. The socio-demographic characteristics collected included: the patient’s personal area at the time of diagnosis in urban, rural or semi-urban, distant from the nearest hospital (CH). Clinical symptoms and phenotype of CD to diagnosis according to the Montreal classification were collected.

Results: Among 247 patients with CD; 90 had a median SD of 03 months. A DD >7 months was considered a diagnostic delay observed in most patients is 157. In univariate and multivariate analysis at diagnosis, the female sex (54.25%), young age (37.24%), absence of enemas (27%), presence of extra-digestive manifestations (25.91%) and Isolated lesions (L1) (34%) and penetrating phenotype (B3) (22.67%) were associated with anopenial lesions (27.12%). Diagnostic delay. Socio-demographic characteristics were not associated with delayed diagnosis.

Conclusion: This study shows that most of the patients, 63.56% have a diagnostic delay significantly associated with the female sex, The young age, the absence of enemas, The presence of extra-digestive manifestations and Isolated lesions (L1). Socio-demographic variables or reflective of access to care were found to influence.

Disclosure of Interest: All authors have declared no conflicts of interest.

Reference

Aims & Methods: We intend to know the incidence of tuberculosis in IBD patients under anti-TNFα therapy in a single tertiary referral centre, analyzing the tuberculosis screening methods and demographic characteristics. IBD patients treated with anti-TNFα therapy between January 2000 and December 2016 were retrospectively analyzed.

Results: During this period 166 patients received anti-TNFα therapy. Before anti-TNFα treatment, screening for LT was performed through medical history, chest X-ray, tuberculin skin test (TST) and/or IGRA. Forty-two patients (25%) had positive screening and received tuberculosis prophylaxis prior to anti-TNFα therapy. Seventeen patients (4.2%) developed tuberculosis while under anti-TNFα treatment (four women, mean age 44 ± 7 years and mean IBD duration 10 ± 8 years). Six of them had a negative LT screening (methods: TST and 2 IGRA) and one patient had positive TST screening, been treated with isoniazid before starting anti-TNFα therapy. During screening three patients were under immune-suppressive and one under corticosteroid therapy. In the IGRA negative screening patients, the diagnosis of tuberculosis occurred within the 10 weeks after starting anti-TNFα. There were five cases of miliary tuberculosis and two of pulmonary disease. Despite difficult diagnosis, all patients were treated successfully, six of whom needed hospitalization.

Conclusion: In our centre the incidence of tuberculosis in IBD patients under anti-TNFα therapy was 4.2% and most of them presenting with a severe disease pattern. The therapeutic regime of tuberculosis was effective and no mortality was recorded. All this patient had a previously negative screening, two of them with IGRA, been considered a high specificity and specificity screening method. Therefore, a surveillance strategy for IBD patients with anti-TNFα therapy is needed.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The MedCrohn study was designed to evaluate the level of agreement between the Harvey Bradshaw Index (HBI) translated into a patient-based questionnaire completed through a mobile app, and the original HBI questionnaire assessed by the clinician (considered as reference).

Aims & Methods: Patients completed the HBI score through a mobile app designed for both Android and iPhone devices and thereafter (<48 h later), the questionnaire was completed onsite by the gastroenterologist who was blinded for the patients’ responses. We assessed agreement between HBI scores of the clinician and patient on the total sum score and per item. HBI score <5 was considered as inactive disease.

Results: 135 participants studied in the project and completed the HBI trough a mobile app (mean age: 36.3 ± 8 years, 58% women). The proportion of agreement between clinician and patient assessment, both evaluating CD as active or in remission was 91.1%. Only in 12 cases (11%), the patient classified CD as active whereas the physician evaluated it as inactive. No active cases remained undetected by the patient evaluation. Sensitivity, specificity, positive and negative predictive values are shown in Table. The highest agreement was seen for the questions: “abdominal mass” and “general well-being” whereas “number of liquid stools per day” was the item with the lowest agreement.

Patient Rate Clinician Assessment Clinician Assessment Total
Active 26 12 38
Remission 0 97 97
Total 26 109 135

Sensitivity (%) Specificity (%) PPV(%) NPV (%) Agreement
100 89 68 100 91.1% CI(95%)

Conclusion: The HBI score self-administered by the patient through a mobile app resulted in a high percentage of agreement with the gastroenterologist evaluation, and high negative predictive value for disease activity. Results of the MedCrohn study encourage the use of this mobile app and gives some hints on its conditions of use as a support for the involvement of patients in the management of their disease. Future studies will help to define its precise role in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

3Pathology, Jeroen Bosch Hospital, ’s-Hertogenbosch/Netherlands

Contact E-mail Address: pim.kranenburg@radboudumc.nl

Introduction: Histological remission (HR) has become an important treatment target in ulcerative colitis (UC). However, limited data exist on reliability of histological scoring in daily practice, when it comes to assess minor histological abnormalities. We investigated the reproducibility and reliability of UC histological scores in colonic biopsies assessed as HR by a general pathologist in daily practice. Next, we investigated correlations between the initial histological assessment and the expert review by expert gastrointestinal (GI)-pathologists.

Aims & Methods: We performed a retrospective single-centre study in a tertiary IBD referral centre. Colonic biopsies of UC patients with mucosal healing (MH) throughout the examined colon were included. All biopsies were re-assessed by three blinded GI-pathologists using three histological scoring indexes (Geboes score (GS), Riley score (RS), Harpaz-D’Haetga Index (HGI)) and a global visual scale (GVS). We evaluated inter- and intraobserver variation and correlations between scores and initial histological assessment using Cronbach’s alpha and Spearman’s rho analysis.

Results: We included 270 biopsies from 94 UC patients. The interobserver concordance for all histological indexes was substantial to almost perfect (GS 0.84; RS 0.91, HGI 0.61GVS 0.74). The correlation between the RS and GS was almost perfect (R = 0.86), but no correlation was found between the primary histological assessment and the GS (0.00), the RS (<0.01), the HGI (0.03) and the GVS (~0.04) as scored by expert GI-pathologists.

Conclusion: Available histological scores for UC are reliable with strong mutual correlations in case of limited histological abnormalities. However, the discrepancies in case of minor histological abnormalities might impact on daily practice. Future studies will help to define its precise role in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1649 EVALUATION OF MODIFIED MAYO ENDOSCOPIC SCORE AND ULTRACOLONIC STOPEUCCROP: IMPACT ONNCE ADOPTURE ULCERATIVE COLITIS EXTENSION, IN THE PREDICTION OF RELAPSE
1Gastroenterology, CH/NG/E, Vila Nova De Gaia/Portugal
2Gastroenterology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova De Gaia/Portugal

Contact E-mail Address: jaimepereirarodrigues@gmail.com

Introduction: Current endoscopic activity scores for Ulcerative Colitis (UC) do not take into account the extent of mucosal inflammation. Recently, two endoscopic scores that combine the assessment of severity and disease extension were developed, the Modified Mayo Endoscopic Score (MMES1) and Degree of Ulcerative Colitis Burden of Luminal Inflammation (DUBLIN).2

Aims & Methods: We aimed to evaluate the relation of the scores with disease activity and as predictive factors of clinical relapse. Patients with UC in clinical remission (partial Mayo score [pMS] ≤1) who underwent colonoscopy between January/2010 and December/2013 were included. MMES and DUBLIN scores were calculated. Analytical and histological activity (defined by Geboes score ≥3.1 and Nancy score ≤2.4) as well as predictive factors of relapse and relapse-free time were evaluated. Relapse was defined as pMS ≥2, therapy to induce remission, hospitalization and/or colectomy.

Results: 82 patients were selected. 51.2% (n=42) female, mean age 49.4 ± 13.7 years. MMES ranged between 0–138 and DUBLIN between 0–9. MMES and DUBLIN scores presented good correlation (r=0.945, p<0.001). MMES was higher in patients with histological activity defined by Nancy (3.7 ± 4.0 vs. 0.8 ± 1.5; p<0.001) and Geboes (4.0 ± 4.2 vs. 1.3 ± 2.4; p=0.005). DUBLIN was also higher in patients with histological activity defined by Nancy (1.9 ± 2.1 vs. 0.5 ± 0.8; p=0.001) and Geboes (2.0 ± 2.3 vs. 0.7 ± 1.2; p=0.000). There was no significant correlation between both scores and analytical activity. Relapse occurred in 36.6% (n=30) of patients, with a cumulative risk of 9.8, 18.4, 25.9, 31.5 and 42.0% at 12, 24, 36, 48 and 60 months, respectively. Mayo Endoscopic Subscore (MES) (p<0.001), MMES (p<0.001), DUBLIN (p<0.001) presented a significant association with relapse. In multivariate analyses, MES (OR=2.32; p<0.001), MMES (OR=1.19; p<0.001) and DUBLIN (OR=1.36; p<0.001) were predictive of relapse independently from histology. Areas under the ROC curve were: 0.71 (MMES), 0.75 (DUBLIN), 0.74 (DUBLIN, p=0.001) for prediction of relapse, with MMES significantly higher than MES by a difference of 0.037 (0.002-0.072); p=0.03.

Conclusion: MMES and DUBLIN scores correlate with each other and with histological activity and are independent predictors of relapse. MMES was superior to MES in the prediction of relapse.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Magnetic resonance enterography (MRE) is an imaging technique recommended to determine and confirm the extension and activity of Crohn’s disease (CD) in the small bowel and discriminate penetrating disease and complications. MRE diagnosis allows to optimize medical treatment in IBD patients.

Aims & Methods: The aim of this study is to evaluate the impact of MRE on medical decision making in IBD patients and determine the maintenance of this new treatment along the time. Consecutive MRE studies performed in patients with confirmed or suspected Crohn’s disease between January 2011 and August 2014 of 2015. Medical charts were retrospectively reviewed. MRE indication, demographic and IBD data were collected at time of MRE. Three months after MRE, medical decision (conservative approach with maintenance therapy, significant change in medical therapy or surgery) was assessed. After twelve months of follow-up, the treatment decided after MRE was reviewed.

Results: A total of 474 MRE studies were performed and indications for MRE were: assessment of small bowel involvement in 40 (8.3%) patients with indeter- minate colitis (IC) and 20 (4.2%) with suspected IBD patients or evaluation of severity and extension of the disease in 414 (87.5%) CD patients (232 F; mean age 37 ± 13 years). Only 4 patients with suspected-IBD (4/20.20%) had involvement of small bowel on MRE confirming the CD diagnosis. Twenty-one patients with IC (21/40.52%) changed the diagnosis to CD. In 199/474 (40.5%) MRE determined a change on medical decision and 140 (70.3%) patients modified maintenance treatment because of MRE findings. Of them, 127 (63.8%) underwent “set-up” treatment by prescribing immunosuppressants (IS) (n=45), anti-TNF agents (n=22), anti-TNF escalation (n=8), adding IS to anti-TNF agents (n=9) and changing anti-TNF agents (n=5). In addition, 13 (9.2%) patients underwent “top-down” therapy due to stop IS (n=7), anti-TNF (n=3) or anti-TNF de-escalation (n=3). Surgery was indicated in 62 (62/ 199;31.1%) patients after MRE. After one year of follow-up, the medical decision was maintained in 65.4% (288/440) of patients.

Conclusion: RE is a very helpful tool for the medical management of CD patients. MRE provides major information to optimize treatment in the long-term of patients with active CD.

Discussion of Interest: All authors have declared no conflicts of interest.

Introduction: The aetiology of Crohn’s disease (CD) and ulcerative colitis (UC) is not known. Recent data suggest a different cytokine profile between CD and UC.

Aims & Methods: The aim of this study was to analyse the expression of mRNA of proinflammatory, regulatory anti-inflammatory cytokines, chemokines and their ligands (IL-6, IL-8, IL-10, IL-23, TNFα, CCR1, CCR2, CCR5, CCL2, CCL5), and transcription factor FoxP3 in the inflamed and non-inflamed intestinal biopsy samples of mucosa in IBD patients. We performed a cross-sectional study. The cohort consisted of 87 consecutive IBD patients (47 CD and 40 UC) who underwent colonoscopy at the IBDC centre of University Hospital Bratislava. We biopsied inflamed and non-inflamed mucosa from ileum, colon and ileocolonic and ileocecal valve areas. In each specimen we measured IL-6, IL-8, IL-10, TNFα, CCR1, CCR2, CCR5, CCL2, CCL5, and FoxP3 mRNA levels.

Results: We found a different cytokine profile between CD and UC patients. The expression of cytokines in inflamed and non-inflamed mucosa separately for CD and UC patients.

Conclusion: This was a significant difference in the mRNA cytokine profiles between CD and UC patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1654 THE RELATIONSHIP OF NEUTROPHILIC AND ENDOTHELIAL ACTIVITY MARKERS WITH THE DISEASE ACTIVITY IN INFAMMATORY BOWEL DISEASE

Introduction: Endothelial cell activation (ACTIVITY) and neutrophil activation (ACTIVATION) may be involved in development and progression of IBD. The relationship between these markers and disease activity, and their levels at different stages of IBD disease is not well known.

Aims & Methods: Eighty-six UC, 63 CD, 36 non-IBD (screening, irritable bowel syndrome) and 52 healthy controls who were followed up in Gastroenterology Department of Sisli Hamdiye Etfal Education and Research Hospital between years 2015–2016 were enrolled. Patients were evaluated by endoscopic (Rachmilewitz index for UC, simple endoscopic score for CD (SES-CD) for CD) clinical (colitis activity index (CCI)) for UC and CD activity index (CDAI) for CD), and pathologic activity scores and immunohistochemical staining.

Results: There were no differences between UC and CD patients in terms of serum endoglin and NGAL levels. NGAL and endoglin levels were significantly higher in endoscopically active UC group (n=59) (135.0 ± 28.9 ng/mL and 71.9 ± 13.6 pg/mL) compared to inactive UC (n=27) (119.7 ± 26.3 ng/mL and 476.9 ± 134.2 pg/mL), to non-IBD (115.8 ± 27.2 ng/mL and 460.6 ± 103.2 pg/mL) and to controls (16.7 ± 31.7 ng/mL and 457.2 ± 141.1 pg/mL). Although there were limited number of inactive CD patients (n=11), serum NGAL and endoglin levels were significantly higher in endoscopically active CD group (n=52) (135.0 ± 28.9 ng/mL and 555.6 ± 133.6 pg/mL) compared to inactive CD (115.2 ± 35.9 ng/mL and 458.7 ± 132.8 pg/mL), to non-IBD and to controls (Figure). Stricking and fluctuating CD groups had significantly higher endoglin levels compared to inactive CD (p < 0.001) and p = 0.001). NGAL levels were significantly increasing with the increasing disease extention in UC and CD (p = 0.012 and p < 0.001). While the clinical activity subgroups were evaluated, there were significant difference in UC and CD patients in terms of endoglin levels but not NGAL levels (Endoglin: r = 0.443, p = 0.001; NGAL: r = 0.274, p = 0.011; r = 0.409, p = 0.001). The immunohistochemical staining index of endoglin showed positive correlation with the immunohistochemical staining of vascular endothelial growth factor (VEGF) (UC r = 0.486, p < 0.001; CD r = 0.383, p = 0.002). The immunohistochemical staining index of endoglin in the colonic mucosa was correlated with the serum levels of endoglin in both UC and CD patients (UC r = 0.641, p < 0.001; CD r = 0.437, p < 0.001).

Conclusion: The present study highlights significant associations between endoglin and NGAL and IBD presence and activity, and demonstrates elevated serum and colonic endoglin levels in patients with active IBD as a novel finding.

Introduction: Although thiopurine-induced myelotoxicity and hepatotoxicity rarely occur during maintenance thiopurine therapy for inflammatory bowel disease (IBD), current guidelines advise laboratory monitoring every 3 months. This study was performed to assess the current laboratory monitoring regime in thiopurine maintenance therapy with regards to consequences of myelotoxicity and hepatotoxicity.

Aims & Methods: In this multicenter cohort study, we evaluated adult IBD patients with quiescent disease who were on maintenance thiopurine therapy between 2000–2016. Data collection started after 12 consecutive months of thiopurine treatment. The primary outcome was therapy adjustment, i.e. therapy cessation or dose reduction, due to myelotoxicity (leukocyte count <4.0 10^9/ l, platelet count <150 10^9/ l, and/or hepatotoxicity (alkaline phosphatase (AP), gamma-glutamyltransferase (y-GT), alanine aminotransferase (ALT) and/or aspartate aminotransferase (AST) above the upper limit of normal (ULN)). The secondary outcomes were prevalence of myelotoxicity and hepatotoxicity and additional diagnostic procedures due to this toxicity.

Results: This study included 223 IBD patients (55% female, 64% with Crohn’s disease, mean age at diagnosis 27.2 years (SD 11.5)). Median follow-up was 3.2 years (IQR 1.9–4.7). The mean monitoring frequency was 3.3 assessments per treatment year (SD 1.8). Toxicity was observed in 44/2402 laboratory assessments (18.5%) in 120 patients. In total, 20 (0.8%) therapy adjustments were performed and 25 laboratory assessments (1.0%) led to additional diagnostic procedures. Myelotoxicity, observed in 244 assessments, led to 11 dose reductions and in 3 patients therapy was stopped. For hepatotoxicity, observed in 201 assessments, 2 dose reductions were performed and in 4 patients therapy was stopped. Ninety percent of observed toxicity were mild leukopenia (leukocyte count <3.0–4.0) or mild hepatotoxicity (<2 ULN), primarily in the first years of treatment. Dose adjustments were more often associated with moderate leukopenia (leukocyte count <3.0) than with mild leukopenia (p < 0.01). In total, 2 complications were recorded, 1 patient was hospitalized because of pancytopenia and received red blood cell transfusion, and 1 patient was treated for a CMV infection. Both patients presented with symptoms in clinic with preceding normal laboratory values. No mortality due to thiopurine-induced toxicity was observed.

Conclusion: Although mild toxicity is common during maintenance thiopurine therapy, adjustments based on laboratory assessments are rare. Therefore, a less intensive regime to monitor thiopurine-induced toxicity should be considered.

P1656 ULTRASOUND ELASTICITY IMAGING PREDICTS THERAPEUTIC OUTCOMES IN PATIENTS WITH CROHN’S DISEASE TREATED WITH ANTI-TUMOR NECROSIS FACTOR ANTIBODIES

Aims & Methods: The aim of this explorative study was to assess the ability of UEI to predict therapeutic outcome in active CD patients treated with anti-TNF antibodies. 30 patients with ileal or ileocolonic CD (20 males, age 38.8 ± 14.5) initiating anti-TNF treatment were enrolled in the study. All patients completed the induction phase and underwent scheduled maintenance therapy with anti-TNF for 16.1 ± 8.5 months. Patients underwent bowel ultrasound and UEI at baseline and 14 weeks after initiation of anti-TNF therapy. Bowel wall stiffness at UEI was quantified by calculating the strain ratio (SR) between the bowel wall and the surrounding mesenteric tissue. Receiver operating characteristic curve analysis was used to identify the best SR cut off able to predict surgery/bowel obstruction.

Results: Five patients (16.6%) underwent surgery or hospitalization for bowel obstruction during the follow up. Frequency of CD-related surgeries or hospitalizations was significantly greater in patients with SR ≥ 2 at baseline than in patients with SR < 2 (p = 0.02). A significant reduction in bowel thickness was observed after 14 weeks of anti-TNF treatment (from 5.8 ± 1.5 mm to 5.1 ± 1.7 mm, p = 0.005), while SR values remained unaltered (1.5 vs 1.3, p = 0.5). A significant inverse correlation was observed between values of strain ratio at baseline and thickness variations following anti-TNF therapy (p = 0.007). Eight out of 30 patients (27%) achieved transmural healing at 14 weeks. Baseline SR was significantly lower in patients with transmural healing than in patients not achieving this endpoint (1.06 ± 0.16 vs 1.67 ± 0.17, p < 0.05).

Conclusion: This explorative study shows that UEI is able to predict therapeutic outcomes, including CD-related surgeries and transmural healing, in patients with Crohn’s disease treated with anti-TNF therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Disclosure of Interest: There were no significant superioriry of FICE, in dysplasia screening. Conclusion: There were no significant differences in the clinical characteristics of UC and FICE at the study, showing that FICE can be a useful tool for detecting diminutive polyps, and evaluating surface patterns without magnification. In clinical remission in patients with UC, FICE can have a role in the assessment of the severity of inflammation. For this purpose, more clinical trials are needed. Our study was the first to find that FICE in UC. Channels 2 and 9 are the best image channels of FICE in UC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1658 EVALUATION OF COLONIC STOMA WITH FLEXIBLE SPECTRAL IMAGING COLOR ENHANCEMENT (FICE) IN PATIENTS WITH LONG TERM ULCERATIVE COLITIS DURING DYSPLASIA SCREENING
1Gastroenterology, Dokuz Eylül University Hospital, Izmir/Turkey

Contact E-mail Address: sedozdinc@yahoo.com

Introduction: Ulcerative colitis (UC) associated colorectal cancer risk (CRC) is related to the age, gender and duration of disease. The risk of CRC increases with the duration of the disease (1). Current guidelines recommend beginning the surveillance colonoscopy after eight to ten years of disease; random biopsies should be obtained from 4 quadrants of every 10 cm of colon (2). Digital subtraction colonography (DSC) can be used for evaluation of the mucosal and vascular structure. However, there were no significant differences between channels 2 and 9.

Conclusion: The association was found between CRP and dysbiosis in CD patients (P = 0.02), while for UC and symptomatic non-IBD patients. No association was found between FICE and dysplasia severity in UC patients, and in combination with elevated levels of FCal and/or FICE in UC patients. In the healthy controls, increasing dysplasia severity yielded higher abundance of FCol and or FICE in UC patients. Disease activity: No association was found between FICE and dysplasia screening.

Results: All controls had normal mucosa and vessel pattern. Dysplasia was suspected in 5% of UC patients. In normal controls, polyps and polyps images acquired by FICE, were evaluated by ten endoscopists and statistical analysis was performed. Results: A total of 18 patients, by evaluating 123 colonic segments, 1831 images were reviewed. Normal mucosa was found in 10 patients (55.55%). Dysplasia was found in 7 (38.88%) of the 18 patients. In the remaining patient with UC, FICE was performed to evaluate the mucosal pattern and vascular structure. However, there were no significant differences between channels 2 and 9.
P1660 SIMPLIFIED MR ENTEROCOLONOGRAPHY CLASSIFICATION BASED ON ENDOSCOPIC FINDINGS FOR ACTIVITY ASSESSMENT OF CROHN’S DISEASE
T. Fujii1, Y. Kitazume2, K. Takenaka1, M. Kinumara1, E. Saito1, K. Matsuoka1, M. Nagahori1, K. Ohtsuka1, M. Wanatabe1
1Gastroenterology And Hepatology,Tokyo Medical and Dental University,Tokyo/Japan
2Radiology, Tokyo Medical And Dental University, Tokyo/Japan

Introduction: Crohn’s disease (CD) is a lifelong inflammatory bowel disease. Evaluating the extent and severity of the disease is critical to determine appropriate therapeutic strategies in patients with Crohn’s disease. MR imaging is one of the most recommended technique for detection of large and small bowel lesions in Crohn’s disease. One of the main tasks of clinical activity is the assessment of its clinical ability of the 3-point MR enterocolonography (MREC) classification for assessing CD activity based on endoscopic findings.

Aims & Methods: A total of 120 patients (70 for derivation cohort and 50 for validation cohort) with CD was enrolled and underwent MREC and ileocolonoscopy or balloon-assisted enteroscopy (BAE). MREC was evaluated for each bowel segment: rectum, sigmoid, descending, transverse, ascending colon, terminal, proximal ileum, and jejunum, according to the consensus of two observers in the derivation phase, and independently by three observers in the validation phase, using a 5-point MREC classification based on a lexicon of MR findings. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients.

Results: BAE was performed in 49 (70%) and 37 (74%) patients in the derivation and validation cohorts. The AUCs of MREC classification were 89.0% in the derivation phase and 88.5, 81.0, and 77.3% for three observers in the validation phase. The AUCs of MREC classification were statistically non-inferior to those of MaRIA (p < 0.001). The cross-validation accuracy was 81.9% in the derivation and 81.3% in the validation phase. The MREC classification showed good reproducibility.

Conclusion: For clinical use, radiological reporting systems should be simple and provide appropriate levels of accuracy and reproducibility. The 5-point MREC classification meets these requirements, and is useful for evaluating CD activity in the large and small bowel segments.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1661 RISK FACTORS FOR METABOLIC SYNDROME AND ITS COMPONENTS IN INFLAMMATORY BOWEL DISEASE
Department Of Medicine And Ageing Sciences And Center For Excellence On Ageing And Translational Medicine (cest-met), "G. D'Annunzio" University and Foundation, Chieti/Italy

Contact E-mail Address: efk78@gmail.com

Introduction: Metabolic syndrome (MetS) is a combination of biochemical and anthropometric disturbances and a recognized risk factor for cardiovascular disease. A higher prevalence of this condition has been previously reported in IBD patients, correlating to age as in the general population.

Aims & Methods: The aim of this study was to assess the effect of individual disease activity-related putative risk factors for MetS in a group of IBD patients, as well as any protective effects of treatment on MetS or its components. Consecutive IBD patients and age- and sex-matched controls were included as well as any protective effects of treatment on MetS or its components. MetS was diagnosed according to the “harmonized” 3 criteria among elevated waist circumference, anthropometric disturbances and a recognized risk factor for cardiovascular disease. The conventional MR score, or MaRIA, was evaluated simultaneously. Areas under the receiver operating characteristic curves (AUCs) were obtained to assess the accuracy of discriminating deep ulcers. Inter-observer reproducibility was assessed using weighted Kappa coefficients.

Results: 51 patients were included, 30 (58.8%) of them female, with a mean age 34.3 ± 14.5 years. Twelve patients (23.5%) required medical rescue therapy. No patient underwent colectomy. The presence of deep ulcers and a shorter evolution of the disease were associated with a lack of response to intravenous corticosteroids. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), p = 0.028, 2.8 ± 3.5 (g/dL), p = 0.005, respectively. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), p = 0.028, 2.8 ± 3.5 (g/dL), p = 0.005, respectively. The CRP/albumin ratio was also higher in unresponsive patients, medical rescue therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve (AUC).

Conclusion: A high value of CRP/albumin ratio was significantly associated with the likelihood of response to intravenous corticosteroids, at the 3rd day of treatment. This index may also better risk stratification on admission, of patients with acute severe ulcerative colitis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1662 C-REACTIVE PROTEIN/ALBUMIN RATIO IS A GOOD PREDICTOR OF RESPONSE TO INTRAVENOUS CORTICOSTEROIDS IN ACUTE SEVERE ULCERATIVE COLITIS

Introduction: Patients with acute severe ulcerative colitis (ASUC) have a high risk of rescue medical therapy or colectomy. Recently, the C-reactive protein (CRP)/albumin ratio at the 3rd day of treatment, with intravenous corticosteroids, has been shown to be a predictor of early colectomy in patients with ASUC.

Aims & Methods: To evaluate the accuracy of CRP/albumin ratio on admission, to predict response to intravenous corticosteroids in patients with ASUC. Retrospective assessment of systematically hospitalized patients with first episode of ASUC, who required intravenous corticosteroids. Demographic, clinical, laboratory and endoscopic variables were evaluated on admission. The response to intravenous corticosteroids (ASUC 3 was based on clinical cure. In unresponsive patients, rescue medical therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve (AUC).

Results: 51 patients were included, 30 (58.8%) of them female, with a mean age 34.3 ± 14.5 years. Twelve patients (23.5%) required medical rescue therapy. No patient underwent colectomy. The presence of deep ulcers and a shorter evolution of the disease were associated with a lack of response to intravenous corticosteroids. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), p = 0.028, 2.8 ± 3.5 (g/dL), p = 0.005, respectively. Patients with no response to intravenous corticosteroids had higher CRP admission values and lower albumin values, compared to patients with response, 111 vs 67.5 (mg/L), p = 0.028, 2.8 ± 3.5 (g/dL), p = 0.005, respectively. The CRP/albumin ratio was also higher in unresponsive patients, medical rescue therapy with infliximab or cyclosporine has been instituted. The accuracy of CRP/albumin ratio in predicting non-response to intravenous corticosteroids was assessed by the area under the ROC curve (AUC).

Conclusion: A high value of CRP/albumin ratio was significantly associated with the likelihood of response to intravenous corticosteroids, at the 3rd day of treatment. This index may also better risk stratification on admission, of patients with acute severe ulcerative colitis.

3Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal

Contact E-mail Address: jsr_roseira@hotmail.com

Introduction: The MCV flow study confirmed the association of AMCV ≥ 7fl at week 26-28 of Azathioprine monotherapy (mAza) with favourable outcomes in a homogeneous IBD population.

Aims & Methods: For this work, our aims were to evaluate the need for step-up therapy in those under mAza with AMCV < 7 and to identify predictors of combined deep remission outcomes (DeepRem), at the same timepoint, for the patients who subsequently began combination therapy with Anti-TNF (AzaExperienced + Anti-TNF). Evaluation of patients under mAza with AMCV < 7 at key timepoint week 26-28 treatment, included for The MCV flow study. Demographic characterization and severity of pre-treatment disease was evaluated (Montreal classification, previous surgery status, Mayo score and Crohn’s disease activity index [CDAI]). AMCV’s association with DeepRem (Steroid-free clinical remission (CDAI ≤ 150, Mayo ≤ 2) + mucosal healing (MH) + C-reactive protein (CRP) < 10) and need for biological therapy at the end of week 26 of DeepRem in an independent predictor in patients who subsequently started combination therapy. Statistical: Chi-square test; Binary logistic regression.

Results: A total of 106 IBD patients were evaluated [56.6% men, mean age 39 ± 15.2 years, 58 ad, 14% operated] at week 26-28 of mAza. Identified strong association between an average AMCV ≤ 7 (n = 70; 66%) with DeepRem (p < 0.05), while a ΔAMCV ≤ 7 was associated with biological therapy need (p < 0.05). 45 patients were later started with Anti-TNF therapy
(Aza + Infliximab 46.7%; Aza + Adalimumab 53.3%) and only 44% achieved DeepRem at the key-timepoint. A Cronh’s A3L2B3 + phenotype (p = 0.045), steroid therapy in the last year (p = 0.009) and ΔVGM < 7 (p = 0.036) were identified as the variables that best explained the difficulty reaching DeepRem.

**Conclusion:** This study confirms the prognostic value of ΔVGM in our popula- tion. ΔVGM ≤ 7 was associated with DeepRem and ΔVGM < 7 was found to be associated with biological therapy need. However, even after starting Anti-TNF, ΔVGM < 7 was identified as a predictor of the difficulty reaching DeepRem.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**FCAL PROTECTIN PREDICTS SHORT-TERM RELAPSE IN INFLAMMATORY BOWEL DISEASE PATIENTS IN DEEP REMISSION**

R. Nakov1, V. Nakov1, V. Gerova1, L. Tankova1, T. Kundurzhiev2, R. Vladimirov1

1Gastroenterology, Clinic of Gastroenterology, 2Tsartsa Joanna - ISUL University Hospital, Medical University - Sofia, Sofia/Bulgaria

**Introduction:** Most inflammatory bowel disease (IBD) patients with clinically successful treatment seem to have some degree of residual mucosal inflammation. Elevated fecal calprotectin (FC) concentrations can be found despite clinical remission and may indicate relapse risk in asymptomatic IBD.

**Aims & Methods:** The aim of this prospective study was to evaluate whether elevated FC values can predict short-term clinical and/or endoscopic relapse. We enrolled 60 IBD patients (30 ulcerative colitis - UC, 30 Cronh’s disease - CD) who were in clinical and endoscopic remission. FC was measured using a quantitative immunochromatographic point-of-care test (Quantum Blue® Calprotectin, Bühmann Laboratories AG, Switzerland). Patients were followed-up by FC examination and clinical activity assessment every second month until relapse or up to 24 months. Ileocolonoscopy was performed at inclusion and at the time of clinical remission.

**Results:** During the follow-up 36 (60%) relapsed and 24 (40%) remained in remission. The mean time to relapse in all patients was 13.9 (range 2-20) months. Surprisingly, mean FC levels was seen 2 months (p < 0.001) before endoscopic relapse. ROC analysis indicated that a cut-off of 90 μg/g (OR 24, 95% CI = 5-117, p < 0.001) in mean FC values 2 months before relapse could predict relapse in UC patients with 83.3% sensitivity and 82.9% specificity. For CD patients a cut-off of 155 μg/g (OR 193, 95% CI = 22-1682, p < 0.001) could predict relapse within two months with 91.7% sensitivity and 94.6% specificity. Constantly normal FC values during the follow-up were predictive for deep remission.

**Conclusion:** It is seen that FC elevates two months before clinical and/or endoscopic relapse. FC is a suitable marker for predicting relapse and building a follow-up strategy for IBD patients in clinical practice.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1665 **

**GLYCEMIC CONTROL AND INSULIN RESISTANCE IN PATIENT WITH INFLAMMATORY BOWEL DISEASE - PRELIMINARY RESULTS FROM THE POLIBUD STUDY**

R. Filip1, J. Sztembisa, P. Kielå1, A. Rybak1

1Gastroenterology, Clinic of Gastroenterology, 2Department Of Social Medicine And Health Management, Section Of Biostatistical, Medical University, Sofia, Sofia/Bulgaria

**Introduction:** Hyperglycemia associated with critical illness - also called stress hyperglycemia - has high prevalence of severe ill patients. It is connected with many factors, including increased cortisol level, catecholamines uptake, glucagon production, gluconeogenesis, insulin resistance and inflammatory markers. It is not considered as an adaptive response anymore, but as an altered hyperglycemia is associated with poor outcomes and significantly increases mortality rates. That is why stress hyperglycemia and insulin resistance may be a marker of severe illness.

**Aims & Methods:** We analysed the data (glycemia, insulin level, HOMA IR level, C-reactive protein level, HbA1C) of 62 aged patients and older (20 women and 42 men, 32.26 +/- 13.8 years of age) with IBD hospitalized in our clinic from 2016 to 2017. 16 patient were with Ulcerative Colitis (UC) and 48 patients with Crohn’s Disease.

**Conclusion:** The analysis of the patients with Ulcerative Colitis showed that only one of the patients had hyperglycemia within the range of 140-200 mg/ml (the patient had type 2 DM) but interestingly 37.5% of the patients had fasting hyperglycemia over 100 mg. Over 85% of these patient were submitted to our clinic with the exacerbation of the disease and had abnormal level of C-reactive protein, cal-protectin (>1800) and fasting insulin level over 10 IU/ml. The analysis of the group of patients with Cronh’s Disease showed different results which may be connected with different metabolic profile of these patients. Most of the patients with fasting hyperglycemia (only 12.5%) had elevated C-reactive protein level but not fasting insulin level - it was within normal range. The highest level of the fasting insulin (over 10 IU/ml) in this group was observed in 3 patients who had to undergo immediate surgical treatment - two of them because of the bowel obstruction and one of them because of the perforation.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**THE ROLE OF MR IMAGING IN ASSESSMENT OF LENMANN INDEX IN THE COURSE OF CROHN’S DISEASE**

J.M. Plenkowska, O. Kozak, T. Nowicki, E. Szurowska

**Introduction:** Crohn’s disease (CD) is a progressive, chronic and destructive inflammatory bowel process which, during its course, can lead to complications such as strictures and penetrating lesions (fistulas and abscesses), which may consequently require operative treatment. In some patients, bowel damage is present at the moment of diagnosis. The aim of the study is to assess the initial Lennam Index (LI), which comprehensively evaluates the entire gastrointestinal tract damage in patients with newly diagnosed Crohn’s disease.

**Aims & Methods:** In 209 patients with clinical suspicions of Crohn’s disease MR imaging with fast spin-echo T2 and contrast-enhanced T1 sequences was performed. In 151 patients with confirmed active/chronic CD the Lennam Index has been calculated on the basis of radiological and clinical information for initial assessment of cumulative digestive tissue damage. To create the Lennam Index the gastrointestinal tract was divided into 4 organs: upper digestive tract, small bowel, colon, rectum and anus. Each organ was divided into segments (3 for the upper digestive tract, 6 for the colon/rectum and 1 for anus). Strictures and penetrating lesions were assessed at each segment on 4-degree scale (0–3) according to the severity of lesions.

**Results:** Based on the findings of the initial radiological examination, active inflammation process was found in 76 patients and chronic process in 75 patients. The baseline study demonstrated such complications as strictures in 14 patients, fistulas in 15 and abscesses in 4 patients. For all patients the LI was calculated. The obtained values were within the range from 0 to 22.

**Conclusion:** Over the years, the progression of Crohn’s disease leads to an increase in the value of Lennam Index, therefore, it seems that the evaluation of the first, baseline stage is high in following control MR examinations will allow for a more complete assessment of patients in terms of progressive bowel damage and modification of the therapeutic process.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**OPTICAL CHARACTERIZATION OF LESIONS IN IBD COLITIS: A SYSTEMATIC REVIEW AND META-ANALYSIS**

R. Lord1, N. Burr2, N. Mohammed3, V. Subramanian3

1Gastroenterology, Endoscopy Research fellow/Gastroenterology registrar, research, Leeds/United Kingdom
2Gastroenterology, Leeds Institute for Biomedical and Clinical Sciences, Leeds/ United Kingdom
3Gastroenterology, Leeds Teaching Hospitals NHS Trust, Leeds/United Kingdom

**Introduction:** Optical imaging is being increasingly advocated for characterization of polyps during colonoscopy. The accuracy of these techniques during surveil- lance colonoscopy in colon inflammatory bowel disease (IBD-C) is unclear and with variable results reported. We aimed to perform a systematic review and meta-analysis of the diagnostic accuracy of optical imaging techniques including blue light imaging and virtual colonoscopy, magnification endoscopy and confocal laser endomicroscopy.

**Aims & Methods:** We searched Medline and Embase for relevant papers. Full articles or abstracts were eligible when characterization performance of dye- based colonoscopy (DCE), virtual colonoscopy (VCV) (narrow-band imaging [NBI], i-scan, Fujinon intelligent colonoscopy [FICE]), magnification endoscopy and confocal laser endomicroscopy (CLE) had been com- pared with histopathology, as the reference standard. Enough information had to be gathered to permit data extraction and meta-analysis.

Introduction: Microscopic colitis (MC) is a clinical syndrome of severe watery diarrhoea with few or no endoscopic abnormalities. The incidence of MC is reportedly similar to that of other inflammatory bowel diseases. The need for histological confirmation of MC frequently guides reimbursement health policies. With the advent of high-definition (HD) colonoscopes, the incidence of distinct endoscopic findings reported in MC has risen. This has the potential to improve diagnosis times, increase cost-effectiveness of MC management and diminish the workload and costs of busy modern endoscopy units.

Aims & Methods: Publications on distinct endoscopic findings in MC available until 31st March 2017 were searched systematically (electronic and manual) in PubMed. The following search terms/descriptors were used: collagenous colitis(CC) OR lymphocytic colitis(LC) AND endoscopy, colonoscopy findings, findings, findings, findings.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: It is well recognized that patients with inflammatory bowel disease (IBD) are at risk for nonalcoholic fatty liver disease (NAFLD). Our aim was to evaluate the prevalence and to quantify hepatic steatosis in IBD patients by using the controlled attenuation parameter (CAP).

Aims & Methods: We prospectively recruited all IBD patients presenting for a disease flare or follow-up visit in our clinic, during a 18 month period. Patients were considered to have initial clinical criteria more than 20 g/day and those with coexisting viral hepatitis were excluded from analysis. Clinical characteristics and laboratory data were recorded. Hepatic steatosis was evaluated by conventional ultrasound, hepatic steatosis index (HIS) and transient elastography with CAP (Fibroscan, Echosens, Paris). Significant steatosis (S ≥ 1) was defined for a CAP value over 236 [1], and the cut-off of HSI for detecting NAFLD was set at ≥ 36 [2].

Results: Altogether 62 IBD patients (35 ulcerative colitis, UC and 27 Crohn’s disease, CD), mean age 45 ± 15 years, 50% female, were included in the analysis. The two groups (UC, CD) were similar regarding disease activity (remission/flare-48.5%14.4% in the UC group, 55.6%44.4% in the CD group), BMI (24.1 and 24.3), and HBD (mild: 21 and 21.1), and mean vitamin gen 498 and 513 mg/dl). UC patients had higher mean cholesterol values (205.9 vs. 196.4 mg/dl) and 11% of them were diabetic (compared to none in the CD group). Mean CAP was higher in CD compared to UC–246 vs. 225 dB/m, while UC patients had higher mean concentration (205.9 vs. 176.4 mg/dl) and 11% of them were diabetic (compared to none in the CD group). UC patients had higher mean cholesterol values (205.9 vs. 196.4 mg/dl) and 11% of them were diabetic (compared to none in the CD group).

Conclusion: In our cohort, about one in three IBD patients had fatty liver disease, as quantified by CAP. Diagnostic performance of CAP was better than conventional ultrasound and HSI in detecting fatty liver in IBD patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Irritable Bowel Syndrome (IBS) is a common gastrointestinal disorder that affects around 11% of global population. Despite the high prevalence of IBS, the cause of this disorder remains unknown and the criteria used to diagnose IBS are still unclear. In recent years, disturbances in the intestinal microbiota have been associated to the pathophysiology of IBS. Recently, two accurate Faecalibacterium prausnitzii (Fpra) and Escherichia coli (Eco) have been shown to discriminate between Inflammatory Bowel disease (IBD) and Healthy subjects (H). Therefore, the purpose of this study was to verify the capability of Fpra and Eco abundances to distinguish among healthy subjects (H), IBS, and IBD patients, in order to create a non-invasive system of diagnostic support for IBS patients.

Aims & Methods: A cohort consisting of 33 H and 14 IBS was enrolled. IBS patients were separated by subtypes: IBS with constipation (C-IBS), IBS with diarrhea (D-IBS) and alternating IBS (A-IBS). Rome IV criteria were used to diagnose IBS patients. Moreover, 29 ulcerative colitis (UC) and 15 Crohn’s disease (CD) patients were also included. All subjects were recruited by the Gastroenterology Services of the Hospital Universitari Dr. Josep Trueta (Girona, Spain) and Hospital Universitari de Bellvitge (Hospitalitat del Llobregat, Spain). Fpra total and Eco abundances were quantified by qPCR.

Results: We found lower abundance values of Fpra in IBS patients when compared with H (P=0.005). In contrast, Eco abundance was higher in IBS patients, although the differences observed were not significant (P=0.221). When comparing among subtypes of IBS (C-IBS, D-IBS, and A-IBS) no significant differences were observed, although Fpra abundance was lower in C-IBS. We also used Fpra in combination with Eco as a complementary indicator of dysbiosis (Ratio Fpra/Eco). This ratio allows a good discrimination between H and IBS (FPR=0.04). When it comes to discrimination between IBS and IBD patients, significant differences were observed in Fpra/Eco ratio between UC and IBS patients (P=0.008), but not between IBS and CD patients (P=0.775). Concerning disorders different to IBS, significant differences were also observed between healthy and CD (P > 0.001), between H and UC (P = 0.037), and between CD and UC (P = 0.027).

Conclusion: Fpra abundance is a good biomarker to discriminate between healthy subjects and IBS patients. The use of Fpra/Eco ratio allows to distinguish IBS from H and UC patients. In contrast, none of the used biomarkers was able to differentiate IBS and CD patients. These results show that IBS and CD patients share similar dysbiosis parameters opening the need of further study to stabilised any eventual pathogenic link.

Disclosure of Interest: All authors have declared no conflicts of interest.
In patients with inflammatory bowel diseases (IBDs), comprising Crohn’s disease (CD) and Ulcerative colitis (UC), a patient-tailored therapy is an urgent need that requires accurate monitoring of the intestinal disease activity. We demonstrated recently, that the expression of microRNA (miR)-320a follows the disease activity in murine colitis models1. In this prospective study we evaluated the potential of miR-320a as a biomarker to monitor disease activity in IBD patients as well as its potential to distinguish UC/CD from infectious colitis.

Aims & Methods: The miR-320a was measured by qRT-PCR analysis in peripheral blood samples from 36 CD and 34 UC patients with acute flare of disease (n = 51) and in remission (n = 37) as well as in healthy control patients (n = 20) and in patients with infectious colitis (n = 9). Disease activity was assessed clinically applying the Crohn's disease activity index (CDAI) and the partial Mayo score, respectively, to assess UC patients as well as the simple endoscopic score Crohn’s disease (SES-CD) and the endoscopic Mayo score (eMayo) to score endoscopic disease activity.

Results: Both in CD and in UC patients, miR-320a expression in remission was significantly increased as compared to healthy controls (49 ± 8.7 ± 17 vs. 17 ± 3; both p < 0.001) but distinctly lower as in in CD/UC patients with acute flare (1718 ± 488; p = 0.006; 513 ± 107, p = 0.001). In UC patients with clinical acute flare (CDAI > 220), miR-320a expression level were significantly increased as compared to CD patients in clinical remission (CDAI < 15; 267 ± 6.37 vs. 57 ± 0.9; p < 0.001) and showed a strong correlation with endoscopic disease activity (r = 0.70). Similarly, in UC patients, miR-320a also revealed a significant increase in patients with low (pMayo 3–4), moderate (pMayo 5–6) and severe clinical disease activity (pMayo > 6) as compared to UC patients in remission (259 ± 47; 281 ± 26; 1090.2 ± 24 vs.76 ± 13, all p < 0.001). Furthermore, we detected a significantly enhanced miR-320a expression with increasing endoscopic disease activity (eMayo 1: 99 ± 14 vs. eMayo 2: 301 ± 30, p = 0.006; eMayo 3: 775 ± 245; p = 0.02). Most importantly, miR-320a expression in CD and UC patients with acute flare of disease was significantly increased as compared to patients with infectious colitis (53 ± 12, p < 0.001).

Conclusion: The miR-320a expression in peripheral blood from IBD patients follows the disease activity and may distinguish between CD and infectious colitis. Therefore, miR-320a might serve as biomarker to non-invasively assess the disease activity in IBD patients.

P1675 COST EFFECTIVENESS OF IBDOC FAECAL CALPROTECTIN AS A SURROGATE MARKER OF MUCOSAL HEALING POST INDUCTION OF BIOLOGICAL AGENTS IN INFLAMMATORY BOWEL DISEASE

Dept. Of Gastroenterology, Mercy University Hospital, Cork/Ireland

Contact E-mail Address: jafaralsafi@hotmail.com

Introduction: Traditionally in our unit all IBD patients started on anti-TNF therapy are followed up at 3 months at the clinic and we aim to do a colonoscopy at 6 months to assess for mucosal healing. Recently we have started using a relatively new technology, called IBDoc, which allows testing the faecal calprotectin at home using a smartphone application and the results are automatically updated in our database.

Aims & Methods: We aimed to evaluate the cost effectiveness of using IBDoc faecal calprotectin post induction of biological agents. The data was collected retrospectively from our IBDoc data base. All patients that were commenced on anti-TNF therapy for IBD and trained in using IBDoc at home were included. IBDoc faecal calprotectin was tested at 3 and 6 month post induction of biological agents.

Results: Total number included in the study was 131 patients. 40% had normal calprotectin at 3 month saving 53 follow up clinic visits (cost of clinical visit 128 euro), and 75% had a normal faecal calprotectin at 6 months saving 40 routine colonoscopy (cost of colonoscopy 337 euro). 78 patients had a raised faecal calprotectin at 3 month, of which 28% had a normal faecal calprotectin at 6 months saving 22 follow-up colonoscopy. In total 53 clinical visits and 62 colonoscopies were avoided.

Conclusion: This study demonstrate a significant cost effectiveness of using IBDoc faecal calprotectin post induction of anti-TNF therapy, as well as reducing the waiting time for both clinic visits and colonoscopies.

Introduction: The intraclass correlation coefficients were 0.81 (p = 0.001) and 0.79 (p = 0.01) respectively. Those measured by established ELISA (Promonitor level: mean 4.67, median 4.37; Quantum Blue level: mean 4.57, median 4.17) showed a good correlation (r2 = 0.56). A Bland-Altman analysis showed a bias of 1.88% confirming the overall excellent correlation of the two methods. The results for each method were stratified according to a commonly accepted therapeutic range (3–18 μg/ml). The Quantum Blue assay had a high (r2 = 0.89) and significant (p < 0.001) correlation with the Quantum Blue® assay. A Bland-Altman analysis showed a bias of 1.88% confirming the overall excellent correlation of the two methods. The results for each method were stratified according to a commonly accepted therapeutic range (3–7 μg/ml lower: 3 and higher than 7) with a high agreement. We estimated a simplified score to convert the “point-of-care” level into “Promonitor” level and facilitate dose management: “Nivel de Promonitor = 0.793 + 0.615*Nivel QB”.

Results: A total of 135 serum samples from patients with CD and UC. IFX concentration in serum samples were determined using a well established IFX-specific ELISA assay (Promonitor®) and the test assay Quantum Blue®. According to the manufacturer, the lower and upper limits of quantification are: In the Quantum Blue assay 0.035 μg/ml and 20 μg/ml respectively. In the Promonitor assay 0.035 μg/ml and 14 μg/ml respectively. All statistics were carried out using the statistical programs IBM SPSS statistics 21 and Epidat version 4.2.

P1679 THE ADDITION OF AN IMMUNOSUPPRESSANT IS AN EFFECTIVE OPTIMIZATION STRATEGY AFTER LOSS OF RESPONSE TO ANTI-TNF ALPHA MONOTHERAPY IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE: A TWO-YEAR STUDY
F.S. Macaluso1, C. Sapienza2, M. Ventimiglia1, S. Renna1, G. Rizzuto1, R. Orlando1, M. Di Pisa1, M. Alfonsi1, E. Orlando1, M. Cottone1, A. Orlando1

Introduction: In patients with inflammatory bowel disease (IBD) the addition of an immunosuppressant (IM) after loss of response to anti-TNF alpha monother-apy is regarded as an emerging strategy of therapeutic optimization. However, few clinical data have been reported to date.

Aims & Methods: The aim of this study was to evaluate efficacy and tolerability of the “add-on” combination therapy in patients with IBD. All consecutive patients with loss of response to anti-TNF alpha monotherapy despite an intensive dose optimization who added an IM from October 2014 to October 2016 were entered in a prospectively maintained database. The steroid-free remission and the clinical response, this latter defined as a clinical improvement (reduction of Harvey-Bradshaw Index ≥ 3) for Crohn’s disease and of Mayo Partial Score ≥ 2 for ulcerative colitis compared with baseline) with a concomitant reduction of steroid dosage compared with baseline and discontinuation within twelve weeks, were set as clinical endpoints.

Results: Among 630 patients treated with biologics during the study period, 46 (33 Crohn’s disease and 13 ulcerative colitis) were included (table 1). A total of 31 patients (67.4%) were treated with an intravenous anti-TNFα (infliximab, as originator product or biosimilar), while 15 (32.6%) with a subcutaneous anti-TNFα agent (10 adalimumab and 5 golimumab). The mean doses of thiopurines used in combination therapy were below those regarded as therapeutic in IBD, methotrexate was mostly employed at a dose of 15mg/week, and all patients treated with mycophenolate mofetil were able to tolerate the target dose of 1500mg/day. The mean duration of follow-up was 12.8±7.3 months. Twenty-one patients (45.7%) remained on combination therapy at the end of follow-up: 15 (32.6%) maintained a steroid-free remission, and 6 patients (13.0%) achieved a clinical response. In patients who experienced a treatment success, median value of C-reactive protein decreased from the baseline to the end of follow-up (13.2 vs. 3.0, p = 0.01; normal values < 5 mg/L). Adverse events leading to treatment discontinuation were reported in 8 out of 46 patients (17.4%).
Introduction: Many studies have demonstrated that in patients with inflammatory bowel disease (IBD) and particularly patients with Crohn's disease (CD) an increased frequency of Extra-Intestinal Manifestations (EIMs) is observed. The presence of EIMs is associated with a more severe degree of luminal disease and lower response to conventional therapy (i.e. immunosuppressants). Drug trough levels are associated with biological drug response, while the role of Anti-dru Agent Antibodies (AAA) is still debated. Moreover, the predicting factors associated with AAA development have not been thoroughly studied yet. To the best of our knowledge, there are no studies correlating the presence of EIM and AAA development.

Aims & Methods: The aim of our prospective study was to identify an association between the presence of EIM and the development of AAA in CD patients treated with biological therapy. We prospectively enrolled 60 CD patients (32 males, mean age 46y, range 21–72) treated either with adalimumab (ADA n=39, 66.6%; IFX n=21, 33.4%) with a median follow-up of 80 (range 14–206) weeks. Blood samples were drawn at standardized time points assessed using an homogenous mobility shift assay (HMSA; Prometheus Lab, San Diego, United States).

Results: ADA were detected in 27 (45.5%) patients and IFX in 15 (45.5%) patients. It has proved to be more frequent in subjects treated with IFX rather than those in therapy with ADA (n=14, 66.6% vs 13, 33.3%, P=0.017). EIM were observed in 26 (43.3%) patients, without any significant difference between ADA and IFX patients (n=17, 51.5% vs n=9, 42.9%, P=0.1). We found that ADA treated patients with EIM were more likely to develop AAA (n=9, 52.9% versus n=4, 18.2%, P=0.039) while no statistically significant association between EIM and AAA development was observed in IFX treated patients (n=5, 55.5% versus n=9, 75%, P=0.64).

Conclusion: We found that ADA-treated patients with EIM tend to develop more frequently AAA. Assuming that the presence of AAA reduces the effectiveness of biological therapy, the presence of EIM may be considered a predictive factor for loss of response to biological therapy with anti-tumor necrosis factor alpha drugs.

Introduction: Usteukinumab (UST) has been shown to be effective in refractory Crohn’s disease (CD) in phase III trials. The aim of the present study was to prospectively evaluate the association between UST trough levels and anti-ustekinumab antibodies, with the response and induction to maintenance UST treatment in CD patients.

Aims & Methods: We performed a prospective study including all CD patients refractory to anti-TNF who received subcutaneous UST from September 2015 to November 2016 in the tertiary French referral center of Gastroenterology in CHRU Lille hospital in Lille. During induction patients received 90mg of SC UST at week 0, 4 and 12. During the maintenance phase patients received 90mg of SC UST every 8 weeks that could be optimized by shortening injection interval to every 4 weeks in case of loss of response. Clinical response was defined by decreased Harvey Bradshaw Index (HBI) by 3 points, clinical remission by HBI < 5, loss of response by new increase of HBI. UST trough levels and antibodies were dosed at 12 weeks, and at a single time-point for patients who had received more than 3 months of UST. The results of dosage were obtained by enzyme-Linked ImmunoSorbent Assay technique. We evaluated the correlation between clinical and biological response and remission to UST, and UST through levels and antibodies concentrations. Differences between independent groups were traced with the use of Mann-Whitney exact test.

Results: Forty-eight patients with active disease received at least three UST injections. At time of ustekinumab introduction 77% of patients received concomitant immunosuppressant and 42% received corticosteroids. At the end of the induction phase (week 12) clinical response was observed in 57% patients. There was no significant difference in mean UST trough levels in patients who responded to UST induction (median 1160 ng/ml; IQR: 603–1644) as compared to patients who did not respond (median 1556 ng/ml; IQR: 494–2758, p = 0.24). Forty-three (90%) patients received at least 4 injections of UST, with 12 patients who were optimized at the time of dosages. Clinical response was observed in 30/43 (70%) patients. Median UST concentration in clinical responder was 1359 ng/ml (IQR: 554–2086) and 2392 ng/ml in non-responder (IQR: 1496–3494), with no significant difference between the two groups of patients (p = 0.20). UST antibodies were undetectable for the 48 patients.

Conclusion: We confirmed that UST treatment is effective in the majority of CD patients refractory to anti-TNF agents. Median trough levels to UST are not correlated to response and remission to UST induction and maintenance treatment, with no antibodies developed against UST.

Introduction: The monitoring of appropriateness, costs, and clinical outcomes of biological therapy in inflammatory bowel disease (IBD) is a relevant need.

Aims & Methods: We aimed to evaluate all these issues in Sicily through a web-based network of all prescribing centers. The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is composed by a super Hub coordinator centre and five Hub plus ten Spoke centres. From January 2013, all IBD patients starting a biological agent (incident cases) or already on treatment (prevailing cases) were entered in a web based software. Herein we report data of incident cases about the efficacy of biological therapy after twelve weeks and one year of treatment.

As clinical endpoint, we set remission (corresponding to a Mayo Partial Score ≤2 for CD, and to a Harvey-Bradshaw Index ≤5 for UC), and response (reduction of Harvey-Bradshaw Index ≥5 for CD and Mayo Partial Score ≥5 for UC compared with baseline).

Results: From January 2013 to January 2017, 1578 patients were included. Incident cases were 1151 (808 Crohn’s disease [CD], 333 ulcerative colitis [UC]), and 427 prevalent cases. A total of 1407 treatments were reported. In one line of therapy, a total of 1407 treatments were reported. CD: there was a higher proportion of patients naïve to biological therapy after twelve weeks and one year of treatment. UC: no significant difference in efficacy was observed between IFX originator and biosimilars. Several factors were identified as predictor of response - independently of the drug employed - at multivariable logistic regression analysis (table 1).

Conclusion: In one of the largest “real-life” series of IBD patients on biological therapy reported to date, ADA in CD had a higher success compared to IFX at both 12 and 52 weeks; however, this results could be influenced by the preference of ADA as first-line anti-TNF drug in CD. IFX in UC was superior to GOL and ADA at 52 weeks; once again, this result could be influenced by the preference of IFX as first-line anti-TNF agent in UC; no difference was found between GOL and ADA in UC. Being naïve to biologics is a relevant predictor of response in both CD and UC at any time point. No significant difference in efficacy was observed between IFX originator and biosimilars.

Contact E-mail Address: andreas.munch@regionstergotland.se

Introduction: Microscopic colitis (MC) is a common cause of chronic watery diarrhoea which is effectively treated with budesonide. However, in rare cases patients are refractory to budesonide leading to a severely deteriorated quality of life. Data on treatment options for budesonide refractory MC patients are sparse. We retrospectively evaluated the outcome of MC patients who have received biological therapy at our centre.

Aims & Methods: All patients with MC treated with biological therapy at the Department of Gastroenterology, University hospital Linköping, Sweden were selected and the outcome recorded. Patients were investigated according to sex, age, disease subtype, clinical remission (defined as < mean 3 and 0 watery stools/day/week), clinical response (defined as 50% reduction of mean stool frequency/day/week), side effects and long-term outcome.

Results: 14 patients (10 women) with mean age at diagnosis of 49 years (range 19–76), thereof 12 with collagenous colitis and 2 with lymphocytic colitis were investigated. All 14 patients had received anti-TNF agents (11 adalimumab (ADA), 3 infliximab (IFX)). ADA was given as induction treatment (160-80-40 mg) and IFX 5 mg/kg at week 0, 2 and 6. Six patients achieved clinical remission. Of these, 2 patients maintained clinical remission for several years after induction treatment, 2 patients are on maintenance treatment with 40 mg ADA/eow, one patient on 400 mg INF every 8 weeks and one patient had loss of response and did not gain clinical remission despite the use of a third anti-TNF agent (certolizumab). Four patients had a clinical response but stopped treatment due to side effects (vomiting, anxiety, fatigue and eczema—all reversible). Four patients had no effect on anti-TNF despite the fact that 2 patient had even tested both anti-TNF agents. Of these 4 patients who failed anti-TNF, 3 patients received treatment with vedolizumab (300 mg week 0, 2 and 6) without effect. One patient had further treatment with rituximab (1000 mg twice) and another patient tested ustekinumab (390 mg once); both did not achieve any clinical improvement.

Conclusion: Budesonide refractory MC patients can achieve clinical remission or response on anti-TNF agents. In the cases that failed anti-TNF, further treatment with vedolizumab (n = 3), rituximab (n = 1) and ustekinumab (n = 1) did not improve the clinical condition. Prospective studies with long duration are needed to evaluate the efficacy of various biological treatments in budesonide refractory MC.

Introduction: Recent studies have shown that FODMAPs (Fermentable Oligosaccharides, Disaccharides, Monosaccharides, and Polyols)-free diet is effective in subjects with Irritable Bowel Syndrome (IBS). Patients with Inflammatory Bowel Diseases (IBD), and celiac disease (CD) can experience functional gastrointestinal symptoms unrelated to inflammation, but data about the use of low FODMAPs diet in these settings is still scarce.

Aims & Methods: To evaluate the usefulness of a low FODMAPs diet on patients with IBS, non-active IBD, and CD on strict gluten-free diet (GFD), we performed a dietetic interventional prospective study evaluating the effect of a low FODMAPs diet on patients affected by IBS, CD following at least a 1-year GFD therapy, and IBD who had been experiencing gastrointestinal symptoms without signs of active inflammation. Each subject was put on a low FODMAPs diet after being evaluated by filling out questionnaires concerning on quality of life and symptoms experienced (IBS-SSS and SF-36), and was re-evaluated twice, first after 1 month and second after 3 months.

Results: 127 subjects were enrolled: 56 with IBS, 30 with IBD and 41 with CD. The analysis of the IBS-SSS survey showed that abdominal symptoms improved after 1 month of low FODMAPs diet in all subjects, with statistically significant difference within each group at T0 (average score in IBS: 293 ± 137 SD, average score in IBD: 206 ± 86 SD, average score in CD: 222 ± 65 SD, p < 0.001). Furthermore, by analysing the SF-36 questionnaire, while we did not observe any significant difference between the three groups in terms of response to diet (p = NS), we observed a clinical improvement from T0 to T3, after the start of the diet, for most of the questionnaire’s domains.

Conclusion: A low FODMAPs diet could be a valid option to counter abdominal symptoms in patients with IBS, non-active IBD or CD on GFD, and, thus improve their quality of life and social relations.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1688 EFFICACY OF VEDOLIZUMAB ON INTESTINAL AND ARTICULAR SYMPTOMS: REAL-LIFE DATA FROM THE SICILIAN NETWORK FOR INFLAMMATORY BOWEL DISEASE (SN-IBD)

Introduction: Vedolizumab (VDZ) is a new biologic agent approved for the treatment of adult patients with moderately to severely active ulcerative colitis (UC) and Crohn’s disease (CD).

Aims & Methods: The Sicilian Network for Inflammatory Bowel Disease (SN-IBD) is composed by all Sicilian centres prescribing biologics. These centres continuously enter in a web based software all real life data about pre-scriptions and outcomes of biological therapy in patients with inflammatory bowel disease (IBD). Herein we report data on efficacy of VDZ on intestinal and articular symptoms after 10 and 24 weeks of treatment. As clinical end-point, we set steroid-free remission (corresponding to a Mayo Partial Score < 2 for UC, and to a Harvey-Bradshaw Index < 5 for CD), and clinical response (reduction of Harvey-Bradshaw Index ≥3 for CD and Mayo Partial Score ≥2 for UC compared with baseline with a concomitant reduction of steroid dosage at week 10, and complete discontinuation at week 24).

Results: From July 2016 to April 2017, 163 patients (84 with CD and 79 with UC) were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 79 (48.5%). Out of 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%). Out of 71 patients were included (table 1). At week 10, a steroid-free remission was obtained in 71 patients (43.6%), while a clinical response in 37 (22.7%).

Conclusion: In this large cohort of Sicilian IBD patients, VDZ showed good efficacy after 10 and 24 weeks of treatment, particularly in those with a shorter duration of disease and a limited inflammatory burden. A subset of patients reported improvement also on articular symptoms, probably as a consequence of the concomitant control of gut inflammation.

Disclosure of Interest: F.S. Macaluso: Lecture grants from MSD and Takeda Pharmaceuticals; lecture grants from AbbVie, MSD, Takeda Pharmaceuticals, Zambon. M. Cottone: financial support for the organization of a second level Master degree in inflammatory bowel disease from AbbVie, MSD, Takeda Pharmaceuticals, Zambon. S. Renna: advisory board member for AbbVie and MSD; lecture grants from AbbVie, MSD, Takeda Pharmaceuticals, Zambon. All other authors have declared no conflicts of interest.

All three groups, while we did not observe any significant difference between the three groups, in terms of response to diet (p = NS), we observed a clinical improvement from T0 to T3, after the start of the diet, for most of the questionnaire’s domains.

Conclusion: A low FODMAPs diet could be a valid option to counter abdominal symptoms in patients with IBS, non-active IBD or CD on GFD, and, thus improve their quality of life and social relations.

Disclosure of Interest: All authors have declared no conflicts of interest.

**Introduction:** Combined immune suppression of anti-tumour necrosis factor (antiTNF) biologicals and thiopurines is superior to respective monotherapies in remission induction and maintenance of response in inflammatory bowel disease due to additive or synergistic mechanisms. The clinical benefit of mutually positive pharmacokinetic effect of thiopurines on antiTNF levels and vice versa, has been suggested for this synergistic effect, reduced dose of thiopurines might be sufficient but the data supporting this hypothesis are still limited.

**Aims & Methods:** The aim of the study was to assess the differences of infliximab trough levels according to the dose of concomitantly used thiopurines. All IBD patients treated with infliximab (Remicade®) in two IBD centres between November 2015 and April 2017 were eligible. Infliximab trough levels were routinely measured in all patients with maintenance infliximab therapy using commercially available ELISA kit (Ridiscreen®, R-Biopharm). All patients in remission with stable dose regimen of 5mg/kg every 8 weeks at the time of the first infliximab trough level measurements were evaluated prospectively from the medical records. The differences in the proportion of patients with adequate trough levels (3–12 μg/mL) between patients on infliximab monotherapy, reduced (below 2 mg/kg) azathioprine (AZA) dose vs. full (2 to 2.5 mg/kg) AZA dose were assessed statistically.

Results: Out of a total of 214 IBD patients treated with infliximab, there were 154 patients with maintenance infliximab therapy using combined AZA and infliximab. All other authors have declared no conflicts of interest.

**Introduction:** The primary drugs used for treatment of inflammatory bowel disease (IBD) treatment have some adverse effects and often are ineffective, so the need for more potent and more reliable medications is clear. A significant role at all the stages of the inflammatory process is attributed to reactive oxygen species, therefore the use of antioxidants is a promising direction of the IBD therapy.

**Aims & Methods:** C60 fullerene are the effective free radicals scavengers [1], therefore the evaluation of possible protective properties of water-soluble pristine C60 fullerene using the simulation of acute ulcerative colitis (UC) in rats was aimed to be discovered. The pristine C60 fullerene aqueous colloid solution (C60FAS; initial concentration 0.15 mg/ml) was prepared according to the protocols developed before [2]. UC was simulated by acetic acid intracolonic instillation. C60FAS was intraperitoneally or intrarectally applied at dose of 0.5 mg/kg C60 daily for 2 times after UC induction. The colon injury was estimated semi-quantitatively on macro- and light microscopy levels using 10- and 14- grade score respectively, and the grade of total injury (GTTi) was calculated, percentile abnormality of colon epithelium was estimated by phenol red dye daily excretion. The states of the colon, liver, pancreas and spleen were assessed by histological (hematoxylin-eosin staining) and biochemical (plasma blood liver enzymes activity) methods, quantitative blood indices were calculated and leukograms were analyzed.

**Results:** Colon wall edema, hyperemia and hemorrhage on bowel internal surface, ulcer(s) of different size, epithelium desquamation and inflammatory features manifested by submucous lymphoid and histiocytic infiltration and extravasation appeared under UC conditions equal to 12 (GTTi 3). C60FAS correction of UC condition was equal to 12 (GTTi 0). Racemi360405@med.shimane-u.ac.jp

**P1691 EARLY CLINICAL REMISSION BY WEEK 2 PREDICTS GOOD SHORT- AND LONG-TERM EFFICACY OF TACROLIMUS THERAPY IN PATIENTS WITH MODERATE TO SEVERE STEROID-REFRACTORY ULCERATIVE COLITIS**

Gastroenterology And Hepatology, Shimane University School of Medicine, Izumo,Japan

Contact E-mail Address: si360405@med.shimane-u.ac.jp

**Introduction:** Tacrolimus, a calcineurin inhibitor, has been shown to be safe and effective when used as salvage therapy for steroid-refractory ulcerative colitis (UC). Its pharmacological effect has been reported to be dependent on trough level in blood, though little is known regarding predictive factors in relation to the clinical efficacy of tacrolimus in UC patients.

**Aims & Methods:** The aim of this study was to identify factors related to prediction of short- and long-time efficacy of tacrolimus for UC. We retrospectively reviewed the medical records of patients with moderate to severe steroid-refractory UC who were treated with tacrolimus as induction therapy at Shimane University Hospital between January 2010 and March 2016. Oral tacrolimus was administered at a whole-blood trough level of 10–15 ng/mL to induce remission and then 5–10 ng/mL to maintain remission. Following tacrolimus therapy for 3 months, patients in clinical remission were given azathioprine for maintenance at an appropriate dosage. Using the Rachmilewitz clinical activity index (CAI), clinical remission was defined as a score of ≤4. Predictive factors associated with short- and long-term tacrolimus efficacy were analyzed by evaluating various clinical parameters.

**Results:** Thirty-six patients received oral tacrolimus for induction, of whom 22 (61.1%) and 27 (75%) experienced clinical remission at 2 and 12 weeks, respectively, after starting therapy. In patients showing short-term efficacy, the clinical remission rate at 2 weeks was significantly associated with CAI at 2AI (p < 0.001 for both comparisons, infliximab trough levels in blood, though little is known regarding predictive factors in relation to the clinical efficacy of tacrolimus in UC patients. Use of tacrolimus therapy for 3 months, patients in clinical remission were given azathioprine for maintenance at an appropriate dosage. Using the Rachmilewitz clinical activity index (CAI), clinical remission was defined as a score of ≤4. Predictive factors associated with short- and long-term tacrolimus efficacy were analyzed by evaluating various clinical parameters.

**Conclusion:** Tacrolimus induction therapy was effective for patients with moderate to severe steroid-refractory UC. Our results clearly indicate that clinical remission achievement at 2 weeks is useful for predicting both short- and long-term outcome in UC patients treated with that therapy.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
P1692 INFLIXIMAB (IFX) IN MODERATE TO SEVERE ULCERATIVE COLITIS (UC): COMPARISON BETWEEN SCHEDULED TREATMENT STRATEGY AND BRIDGE STRATEGY

A.M. Sambuelli1, A. H. Gill2, S. M. Negreria3, M. I. Bellicoso1, S. Goncalves1, S.P. Huernos1, P.R. Tirado1, P. Chaverro1, A. Cabanne2

Introduction: UC is a potentially severe disease that carries an increased risk of complications and colectomy. Immunosuppressant and biological therapies are relevant tools for complex patients. The ACCENT study showed that in Crohn’s disease (CD), scheduled IFX infusions vs. episodic are associated with greater efficacy. The historical difficulties of economic access in IBD and the lack of a standard IBD treatment plan led to the development of a bridge strategy. This strategy (p=0.007), strong ‘cyclical’ timeline (ß 1.33 (95% CI 0.33–2.34), p=0.019), more ’consequences’ (ß 2.00 (95% CI 0.60–3.42), p=0.006), stronger ‘emotional representations’ (ß 1.58 (95% CI 0.08–3.08), p=0.039) and a low ‘coherence’ (ß –1.29 (95% CI –2.45–(0.14)), p=0.029). In addition, the coping strategies increased ‘diverting attention’ (ß 1.34 (95% CI 0.26–2.66), p=0.047) and increased ’consideration’ (ß 1.18 (95% CI 0.10–2.27), p=0.033), as well as the illness outcomes low physical (ß –7.22 (95% CI –9.68–4.77), p<0.001) and mental (ß –3.10 (95% CI –5.99–(0.23), p=0.035) health and increased activity impairment (ß 0.15 (95% CI 0.07–0.23), p<0.001) were related with the shift of biological drug compared with the scheduled strategy ‘pacing’ (p=0.003) was found in IFX patients with arthropathies compared with baseline scores.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CT-P13, the first biosimilar monoclonal antibody to infliximab (IFX) has previously been confirmed to be efficacious in inducing mucosal healing in ulcerative colitis (UC) patients.

Aims & Methods: The aim of this study was to evaluate the efficacy of CT-P13 therapy in maintaining mucosal healing in UC. Patients diagnosed with UC, who were administered CT-P13 from June 2014 at 4 Hungarian and one Czech IBD Centre were prospectively enrolled. Sigmoidoscopy was performed at week 14 and week 54 to assess mucosal healing. Mucosal healing was defined as Mayo endoscopic subscore of 0 or 1. Complete mucosal healing was defined as Mayo endoscopic subscore of 0. CT-P13 trough levels, antibody positivity, serum inflammatory markers as CRP level, fecal calprotectin at weeks 14 and 54, concomitant steroid and azathioprine therapy at the time of mucosal healing and at weeks 14 and 54, previous use of anti TNF drug and the need of dose intensification as possible predictive factors for mucosal healing at week 54 were evaluated. Results: Seventy-five UC patients were included in the study of which 74 patients completed the induction therapy and 54 patients had already completed the 54 week treatment period. Mucosal healing was shown in 55.4% of the patients at week 14 and 61.7% at week 54 (p=0.033). Complete mucosal healing was patient in 24.3% at week 14, but in 54% at week 54. The proportion values of CRP (p=0.017), leukocytes (p<0.001), thrombocytes (p<0.001), and albumin (p=0.002) showed significant difference at baseline and week 54. Mean trough level of CT-P13 was 5.02 µg/ml and 4.4µg/ml at week 14 and 54. Serum antibody positivity was assessed in 7.7% at 26.2% of patients at week 14 and 54, respectively. Dose escalation was necessary in one third of patients. None of the patients need surgery who completed week 54, however 4 subjects who stopped CT-P13 therapy after induction regimen required colectomy.

Conclusion: Suffering from IBD patients in IBD is strongly associated with different Illness perceptions, coping strategies and illness outcomes and changes of these factors over time. As a gastroenterologist, addressing the maladaptive illness perceptions, coping strategies and related poor illness outcomes in these patients may provide an important opportunity to target for behavioral interventions including cognitive behavioural therapy (CBT) or physical exercise.

Disclosure of Interest: All authors have declared no conflicts of interest.
of non-serious infections, 8% (95% CI 6–10%) for serious AEs and 7% (95% CI 3–13%) for VDZ-treated patients was 21% (95% CI 14–32%); 10% (95% CI 6–16%) for week 8 (response p = 0.02; remission: ADA vs GOL p = 0.027). At week 16 only IFX seems to be more effective than GOL in inducing clinical response (p = 0.048) but not remission. No significant difference among the three drugs was observed in patients naïve to anti-TNFs. Treatment was discontinued in 2 patient in IFX group and in 6 patients in GOL group and in 6 patients with ADA because of persistent disease activity.

Conclusion: This single-center study shows that IFX is more effective than GOL both in the induction (8 weeks) and in the maintenance of response (16 weeks). ADA is more effective than GOL in inducing remission at 8 weeks but no significant difference is observed in the medium-term. However, GOL was used mainly as a second or third-line. In naïve patients, efficacy among anti-TNFs is comparable. Our results may help clinicians in the choice of an anti-TNF in UC. It should be preferred in steroid-resistant patients to get a faster response, ADA and GOL should be the first options in steroid-dependent patients naïve to anti-TNFs.

Disclosure of Interest: All authors have declared no conflicts of interest.

*Includes paradoxical skin manifestations, acute generalised exanthematous pustulosis, dry skin, erythema nodosum, palmar erythema. †Includes spontaneous nausea. ‡Includes liver test abnormalities (transient transaminisits), drug-induced liver injury (not specified). ††Includes severe musculoskeletal syndrome, exacerbation of pre-existing enteropathic arthritis †‡Includes pneumonia, lower respiratory tract infections, respiratory tract infection (not specified)

Conclusion: Pooled analysis of AE rates across multiple studies support the favourable, long-term benefit–risk profile of VDZ in real-world clinical practice, with low rates of infusion-related reactions, serious infections and malignancies reported, and no identification of new safety signals. These results are consistent with integrated safety data reported for VDZ in six clinical trials (>4000 patient-years), despite the selection of complex patients failing previous anti-TNF biologic therapies. Limitations of incidental reporting in real-world studies include potential underestimates of AE rates and the reporting of AEs not regularly observed in clinical trials; for example, due to the variability in medication use and sub-optimal screening of prior infections.

Introduction: Although many biologics (Bs) have been approved for the treatment of refractory moderate-to-severe Ulcerative Colitis (UC) in patients who have responded inadequately to conventional therapy, the selection of Bs is controversial due to the lack of head-to-head trials. Indirect economic comparisons of these costly drugs are available from National Healthcare perspectives that are not consistent over time.

Aims & Methods: The objective is to evaluate cost-utility of Bs for the treatment of refractory moderate-to-severe UC both in and the Lombardy Region. A Markov model (considering 3 transition states: remission, clinical response, relapse) was constructed using the software R and Markovchain-package to evaluate incremental cost-utility ratios (ICUR) of adalimumab (ADA), infliximab (IFX), infliximab biosimilar (IFX-B), golimumab (GOL) and vedolizumab (VED) treatments of patients over a 10-year time horizon from the perspective of the Italian (N) and Lombardy Region (R) healthcare system. Clinical parameters were derived from clinical trials. Costs (actualised by 1.5%) were obtained from the National database and Regional public tender. Utility was expressed as QALY (Quality Adjusted Life Years).

Results: Costs per treatment were different from N and R perspective (ADA −55%; IFX −16.7%; IFX-B −29.6%; GOL −9.6%; VED −10%). Direct healthcare costs (treatment cost, visits, lab tests, hospital admissions) were calculated over 10 years of treatment per patient: ADA (N: €114,227, R: €96,314, −40.2%), IFX (N: €130,955, R: €103,081, −22.5%), IFX-B (N: €110,438, R: €78,852, −28.6%), GOL (N: €118,602, R: €96,922, −18.3%), VED (N: €113,852, R: €102,932, −9.6%) with associated QALY respectively of 6.68, 6.66, 6.66, 7.02. From a N perspective, IFX-B was dominating compared to all other treatments. The ICUR of VED/IFX-B was €9843 for 10 years of treatment ($102,932, −9.6%) and $9843 for 10 years of treatment ($118,602, −9.6%). From a R perspective, ADA was dominating compared to all other treatments. The ICUR of ADA/VED was €101,818 for 10 years of treatment ($107,840, −80%)

Conclusion: National and Regional cost-utility analyses produced different results. As Regional price discounts can occur, local analysis is needed to estimate the economic impact of therapies to ensure optimal choice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Dysplasia is considered as the precursor of colitis-associated cancer in the long standing ulcerative colitis (UC). Although endoscopic submucosal dissection (ESD) has been suggested as an endoscopic resection technique for non-polypoid dysplasia, only a few studies investigated the feasibility of ESD as a dissection (ESD) has been suggested as an endoscopic resection technique for dysplasia diagnosed by the surveillance biopsy specimens taken during ESD. Metachronous or recurrent dysplasia was identified in 2 of 9 patients who underwent follow-up colonoscopy after ESD (median follow-up period of 12.3 months, range 9.2-19.2 months). One developed metachronous LGD at 18 months after ESD and the other developed both metachronous and recurrent LGDs at 8 months after ESD.

Conclusion: According to our ESD series for dysplasia, ESD seems to be feasible for the endoscopic resection of UC-associated dysplasia. However, meticulous surveillance colonoscopy is mandatory to monitor local recurrence and metachronous dysplasia. Non-lifting sign and surface ulceration are highly suggestive of invasive colitic cancer.

Introduction: Biological therapies are effective treatments for inflammatory bowel disease (IBD) but represent an important economic burden to the healthcare system. Adherence surveillance is necessary to optimize the efficacy of treatment and its costs. This issue has been evaluated just in a few studies.

Aims & Methods: We aim to describe the adherence to infliximab in patients with IBD and identify causes and factors associated with poor adherence. We identified all IBD patients treated with infliximab in a single center since 2009. Fulfillment of the prescribed schedule was assessed for every single infliximab infusion. For every patient, we grouped infusions in “courses of treatment” defined as the administration of infliximab at the same dose and schedule for a minimum of six months. Therefore, restarting the treatment after a holiday of more than 4 months, or changing the interval of doses were considered as a new course of treatment. We defined “infusion well administered” when it was done within seven days before or after the date prescribed.

Results: We included a total of 147 courses of treatment, administered to 100 patients. Seventy-four per cent of courses were Crohn disease patients, and 25% in ulcerative colitis patients. In 89% of courses combo therapy with immunosuppressants was used. The prescribed regimens were: every 8 weeks (76.2%), every 4 weeks (26%), every 6 weeks (7.5%), every 4 weeks (5.4%), every 12 weeks (2.7%) or every 4 weeks (2%). The mean duration of the courses was 23 months (range 6-103). Only 69 out of 1174 infusions (4%), were not properly administered. The reported causes for that included: 36 “unknown” (52%), 18 “change requested by patient” (26%), 15 “due to logistic reasons” (21%) and 4 “other” (5%). 107 course (73%) of the infusions were well administered; in 143 (97%)>80% of infusions were well administered and only 4 courses (2.7%) had less than 80% of adherence. In more than an half of the infusions the cause could not be identified, for that reason analysis of predictive factors could not be performed.

Conclusion: The adherence to the scheduled infliximab regimen was very high and it would contribute to maintain the drug efficacy. The reasons for changing the date of administration should be indicated in the clinical history to identify associated factors and minimize the lack of adherence.

P1700 TNF-EXPRESSION OF MONOCYTES IS A PREDICTIVE MARKER FOR RESPONSE TO ANTI-TNF TREATMENT IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE

D. Lissner, B. Jessen, E. Sonnenberg, F. Schmidt, A. Kuehl, B. Siggmond

Department For Gastroenterology, Infectious Diseases And Rheumatology, Charité-Universitätsmedizin Berlin, Campus Benjamin Franklin, Berlin/Germany

Contact E-mail Address: domata.lissner@charite.de

Introduction: One-third of all patients with inflammatory bowel diseases (IBD) do not respond to initial treatment with the anti-TNF-antibody Infliximab. Thus, predictive markers for response to anti-TNF-treatment are required.

Methods: The study was designed to investigate the expression levels of TNF produced by peripheral blood mononuclear cells (PBMCs) can predict response to anti-TNF-treatment. Fourteen patients with proven Crohn’s disease (CD) or ulcerative colitis (UC) without treatment with biologics in the past six months were included prior to first Infliximab infusion. Disease activity was measured by the use of Harvey-Bradsaw-Index (HBI) or partial Mayo Score, C-reactive protein (CRP) and ultrasound (Limberg Score). TNF-expression of LPS-stimulated PBMCs was measured by ELISA before treatment. Additionally PBMCs'
intracellular TNF-expression was analysed by flow cytometry. According to a cut-off value patients were divided into low-producers and high-producers. Primary endpoint was clinical response, secondary endpoints were decrease in CRP and Limberg Score. Clinical response was defined as a decline in Score of ≥2 (HBI) or ≥5 (partial Mayo Score). A HBI <5 or a partial Mayo-Score <2 was defined as remission. Results were analysed using the Fisher’s exact test. Results: Nine patients reached the endpoint at week 6 and were available for further analysis (5 patients with CD, 4 patients with UC). The median TNF-expression was defined as remission. Results were analysed using the Fisher’s exact test.

Conclusion: Quantification of TNF-expression in PBMCs and the resulting classification in low- and high-producers could be a potential predictive marker for response to anti-TNF-treatment in IBD patients.

P1702 VEDOLIZUMAB TROUGH LEVELS PREDICT CLINICAL OUTCOMES IN INFLAMMATORY BOWEL DISEASE
L. Guidi1, D. Pugliese1, T. Panici Tonucci2, B. Tolosso2, C. Felice1, A. Papa1, I. De Vitiis1, E. Gremese2, A. Gasbarrini2, G.L. Rapaccini1, A. Armuzzi1
1Internal Medicine And Gastroenterology IBD Unit Unipi, Piroli 4, 00184 Rome, Italy; 2Internal Medicine And Gastroenterology IBD Unit University of Turku, Turku, Finland
22. Statistics was performed by Mann-Whitney test, Spearman’s rho, receiver operating characteristic (ROC) curve analysis.

Results: We included 50 patients (mean age 45.5 ± 3.6 years) with Crohn’s disease (CD, n = 28) and Ulcerative colitis (UC, n = 22). 44 (88%) IBD patients had previous anti-TNFα therapy. Baseline median HBI was 8 (5–16) and median pMayo was 6 (5–7). Median VTL (interquartile range, IQR) at weeks 6, 10 and 14 were 38.6 (20.3–53.5), 25.4 (13.4–45.6) and 17.7 (10.1–33.7) μg/ml, respectively. VTL measured at week 6 were significantly higher in clinical responders as compared to non-responders: median (IQR) 48.1 (32.5–55.8) vs 32.8 (19.7–44.3) μg/ml, p < 0.001. Week 6 VTL were also higher in CRP responders (<5 mg/l): median (IQR) 48.1 (32.5–55.8) vs 32.8 (19.7–44.3) μg/ml, p < 0.001. Week 6 VTL were inversely correlated with CRP (r = −0.39, p = 0.006). By ROC curve analysis a cut-off of 44.3 μg/ml was defined for clinical response at week 6 (AUC 0.677, sensitivity 61.9%, specificity 79.3%, p = 0.002). Week 6 VTL were significantly higher in patients in clinical remission at their last follow-up (median week) compared to non-remitters: median (IQR) 55.8 (46.6–64.1) vs 33.3 (25.9–40.4) μg/ml, p = 0.0005. The ROC curve analysis identified a cut-off of 44.3 μg/ml (AUC 0.813 sensitivity 88.9%, specificity 73.2%, p = 0.0006). Week 14 VTL were also significantly higher in patients in clinical remission at 22 weeks compared to non-remitters: median (IQR) 38.3 (20.5–49.8) vs 13.4 (8.4–20.6) μg/ml, p < 0.0005. The cut-off identified by ROC curve analysis for this outcome was 16.4 μg/ml (AUC 0.820 sensitivity 100% specificity 63%, p = 0.0019). AVA were detected in 2% of patients at week 6, 5.9% at week 10 and 4.5% at week 14 and were not correlated with clinical response.

Conclusion: These preliminary data suggest that obtaining a VTL of 44.3 μg/ml after the first 2 Vedolizumab infusions is correlated with early clinical and biological (CRP) response and with clinical remission at a mean follow-up of 20 weeks. Week 14 VTL are correlated with clinical remission at week 22 and the identified cut off is 16.4 μg/ml. Immunogenicity of Vedolizumab is low in these patients.

Disclosure of Interest: L. Guidi: Lecture fees by AbbVie, Merck, Takeda, Mundipharma, Zambon
B. Siegmund: Britta Siegmund received a research grant from Pfizer, served as consultant for Janssen, MSD, Abbvie, Takeda, Hospira and received lecture fees from Abbvie, Falk, Ferring, MSD, Merck, Takeda; all money went to the institution. All other authors have declared no conflicts of interest.
Results: In the context of ~77,382 patient-years of VDZ exposure and a total of 36 acute VDZ-related flares, 35 (13.3%) occurred in the VDZ database: 20 (57.1%) were non-serious and no serious events were reported. 15 of 15 patients with pre-existing viral hepatitis (B = 5, C = 10) reported flares due to VDZ. Of these, 14 (93.3%) patients presented with acute viral flare or acute viral hepatitis. The second group included 8 patients with concomitant anti-TNF therapy. Of these, 7 (87.5%) reported flares due to VDZ. Events were more common in patients with hepatitis B (9/15 patients) were more common than in patients with hepatitis C (4/8 patients). Adverse events included: 14 events related to VDZ (B = 7, C = 7). The most common events included infections (B = 5, C = 4), dyspepsia (B = 2, C = 1), and febrile conditions (B = 1, C = 1). The remaining events included: 1 event due to concomitant anti-TNF therapy (B = 1, C = 0). Of these, 14/15 patients had a history of viral hepatitis (B = 7, C = 7). Of these, 13/15 patients reported flares due to VDZ. Two events were reported in patients with hepatitis C: one patient was a smoker who reported hepatic neoplasms; the other patient had a history of skin cancer, cholecystectomy, bladder tumour removal and right radical orchidectomy. Both events resulted in VDZ discontinuation. Of events with a reported outcome, 22/26 (84.6%) were resolved or resolved at the time of reporting and 4/26 (15.4%) were unresolved; NR n = 25. VDZ treatment was continued in 10/26 (74.6%) patients and discontinued in 4/26 (14.6%) patients; NR n = 1.

Conclusion: In the post-marketing setting, there was no evidence of increased risk of virus reactivation in patients with hepatitis B or hepatitis C receiving VDZ. Liver-related events were reported in two patients with hepatitis C—two patients who were smokers. The other patient had a history of skin cancer, cholecystectomy, bladder tumour removal and right radical orchidectomy. Both events resulted in VDZ discontinuation. Of events with a reported outcome, 22/26 (84.6%) were resolved or resolved at the time of reporting and 4/26 (15.4%) were unresolved; NR n = 25. VDZ treatment was continued in 10/26 (74.6%) patients and discontinued in 4/26 (14.6%) patients; NR n = 1.

Introduction: Adherence to 5-ASA is equivalent to medication intake. For patients with UC, adherence is defined as the percentage of prescribed 5-ASA that is taken. However, adherence to medication is a complex phenomenon and the use of 5-ASA in UC is associated with many factors such as patient characteristics, disease, and treatment. The aim of this study was to analyze adherence to 5-ASA in UC patients.

Methods: This was a retrospective study of all 5-ASA prescriptions recorded in the Hospital de la Santa Creu i Sant Pau (Barcelona, Spain) between 2014 and 2017. All patients were included if they were receiving 5-ASA for at least 1 year. The percentage of adherence was calculated using the number of pills taken divided by the number of pills prescribed. Adherence was considered as 80% or more. The predictor variables were age, sex, disease activity, and the presence of comorbidities. The main outcomes were the percentage of adherence and the percentage of patients who were adherent. The results were analyzed using descriptive statistics and logistic regression analysis. The significance level was set at p<0.05.

Results: A total of 200 patients were included in the study. The mean age was 46 years, 60% were women, and 65% had a proctitis. The percentage of adherence was 80.5%, and 60% of patients were adherent. The variables that were associated with adherence were gender (female vs. male: OR 1.84, 95% CI 1.10–3.08, p=0.02), age (older vs. younger: OR 1.66, 95% CI 1.01–2.69, p=0.04), and the presence of comorbidities (has vs. no: OR 2.12, 95% CI 1.23–3.64, p=0.007).

Conclusion: Adherence to 5-ASA in UC patients is high. However, adherence is associated with several factors, and the use of 5-ASA in UC is a complex phenomenon. Further research is needed to identify strategies to improve adherence to 5-ASA in UC patients.
P1706 DEVELOPMENT AND FEASIBILITY OF A WEB-BASED REGISTRY FOR MULTICENTRE SURVEILLANCE OF EFFECTIVENESS AND SAFETY OF NOVEL IBD-DRUGS IN THE NETHERLANDS

Introduction: Randomized controlled trials provide efficacy data of novel IBD drugs. The majority of patients included in these trials however, especially for novel biologics, are highly selected patients from referral centres and are included in a variety of countries with very different health care systems. Inclusion criteria and follow-up protocols are strict and do not reflect routine care. Long-term country specific effectiveness and safety data for novel drugs are therefore warranted. Development and implementation of a novel protocol and electronic case reporting registry for every new compound is however time consuming and expensive. Therefore, the Initiative on Crohn and Colitis (ICC) aimed to develop a web-based registry suitable for capturing, managing, and reporting data for all drugs and all IBD phenotypes in everyday practice in all centres.

Aims & Methods: We aim to test the feasibility of the web-based registry in patients starting vedolizumab. With a structured iterative process with IBD-specialist from the ICC, case report forms and lab-evaluation forms were developed to assess key elements of disease activity, safety and a PROM. Furthermore the ICC decided on a uniform follow-up protocol reflecting everyday practise. A web-based registry for capturing, managing and reporting follow-up data of IBD patients starting a new drug was developed (ICC-case series). The registry automatically reminds the treating physician or nurse prior to novel follow-up visits. Feasibility of the ICC-case series was assessed in 6 centres in the Netherlands in patients who started vedolizumab. To test data extraction and follow-up protocols are strict and do not reflect routine care. Long-term country specific effectiveness and safety data for novel drugs are therefore warranted. Development and implementation of a novel protocol and electronic case reporting registry for every new compound is however time consuming and expensive. Therefore, the Initiative on Crohn and Colitis (ICC) aimed to develop a web-based registry suitable for capturing, managing, and reporting data for all drugs and all IBD phenotypes in everyday practice in all centres.

Conclusion: The ICC developed a uniform web-based registry to study post-marketing safety and effectiveness of novel IBD-drugs. A feasibility study with 230 patients starting vedolizumab showed successful data-capture, managing, and reporting with the ICC-case series in 6 centres. Table 1 shows clear differences between baseline characteristics of real-life Dutch patients and patients in the GEMINI studies underlying the importance of country specific post-marketing data.

Contact E-mail Address: claudio.cassieri@libero.it

Introduction: Azathioprine (AZA) and thiopurine are widely used for induction and maintenance of remission in patients steroid-resistant or dependent with inflammatory bowel disease (IBD). The treatment must be withdrawn in 5–30% of patients due to the occurrence of adverse events.

Aims & Methods: Aim of this study has been to investigate its efficacy and safety in maintaining steroid-free remission in steroid dependent IBD patients six year after the institution of treatment. Data from consecutive IBD outpatients referred in our Institution, between 1985-2015, were reviewed and all patients treated with AZA were included in this retrospective study. AZA was administered at the recommended dose of 2–2.5 mg/kg. Blood chemistry was analysed before administration of the drug, every 10–15 days for the first 3 months and then every 1–2 months following the institution of treatment.

Results: Out of 2722 consecutive IBD outpatients visited in the index period, AZA was prescribed to 415 patients, 227 (54.7%) were affected by Crohn’s disease (CD) and 188 (45.3%) by ulcerative colitis (UC). One hundred and fifty-eight patients with a follow-up <72 months were excluded from the study. Two hundred and fifty-seven patients were evaluated, 143 (55.6%) with CD and 114 (44.4%) with UC. One hundred and forty-two (55.2%) were male...
and 115 (44.8%) female (average age of 35.68 ± 12.22 SD years, range 14–74 y.). Six years after the institution of treatment, 130 (50.6%) patients still were in steroid-free remission (85 CD vs 45 UC, 59.5% and 39.5%, respectively, p = 0.0017), 71 (27.6%) had a relapse requiring retreatment with steroids (29 CD vs 24 UC, 20.3% and 36.6%, respectively, p = 0.0048), 56 (21.8%) discontinued the treatment due to side effects (29 CD vs 27 UC, 20.2% and 23.7%, respectively). Loss of response from 1st to 6th year of follow-up was low, about 20%

**Conclusion:** Six years after the onset of treatment 56% of patients did not require further steroid courses. After the first year loss of response was low in five subsequent years. In the present series the maintenance of steroid-free remission was significantly higher in CD than in UC patients. The occurrence of side effects leading to the withdrawal of AZA treatment has been low.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1708 CLINICAL EFFICACY AND SAFETY OF ANTI-TNF THERAPY IN INFLAMMATORY BOWEL DISEASE IN THE ELDERLY: A UK TERTIARY REFERRAL CENTRE EXPERIENCE**

J. Digby-Bell
Dept. Of Gastroenterology, St. Thomas’ Hospital, London/United Kingdom

**Contact E-mail Address:** jdigbybell@doctors.org.uk

**Introduction:** Many patients, especially the elderly or those with comorbidities, are excluded from clinical drug trials and little real-life data exists on the safety and efficacy of anti-TNF.

**Aims & Methods:** We aimed to compare the clinical efficacy and safety of anti-TNF therapy in patients over 60 years in a tertiary IBD centre in London, UK. We interrogated our IBD databases from January 2009 to November 2015 and performed retrospective data analysis until end of follow up in April 2017. Data was collected on demographics, endoscopy, calprotectin, CRP, clinical scores, serious infections, malignancy, drug levels and anti-drug antibodies. Patients with an age of >60 when starting anti-TNF therapy were identified and <60 comparators were selected at random in a 2:1 ratio. Primary endpoints: week 14 and week 54 steroid-free clinical remission (Harvey Bradshaw Index < 5 or Simple Colitis Activity index < 3) Secondary endpoint: proportion of patients remaining on anti-TNF at the end of follow up

**Results:** See table.

**Conclusion:** Only a small number of >260 patients started anti-TNF (29 out of greater than 650). This may reflect our local population or that clinicians favour anti-TNF therapies in this older group. Overall there was similar clinical efficacy at weeks 14 and 54 of anti-TNF therapy between the ‘young’ and ‘old’ groups. There was a higher discontinuation rate after 1 year of therapy in the older group (p=0.043). There were more adverse events in the older group (7/29) including 3 new cancer diagnoses compared with the younger group (3/58). 4 patients had detectable anti-drug antibodies in the older group despite 2 of them having therapeutic thiopurine suggesting that the elderly may have more immunogenicity than the young. Further studies with more patients across multiple sites are required to clarify safety and efficacy in the elderly.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1709 TACROLIMUS IN REFRACTORY ULCERATIVE COLITIS–12 MONTH OUTCOME IN A SINGLE-CENTRE UK DISTRICT HOSPITAL**

N. Jayasooriya, L. Everson, S. Mann
Gastroenterology, Barnet and Chase Farm Hospital, Royal Free Trust NHS, Barnet/United Kingdom

**Contact E-mail Address:** nishani.jayasooriya@nhs.net

**Introduction:** Rescue therapy is required for patients with moderate - severe ulcerative colitis (UC) who have failed to respond to steroids and thiopurines. Anti-Tumour Necrosis Factor Agents (Anti-TNFs) are widely used before considering a colectomy. Calcineurin inhibitors such as ciclosporin and Tacrolimus may be considered as alternatives to biologics. There have been some case series in assessing the use of Tacrolimus in such patients although the United Kingdom experience is limited. (1, 2)

**Aims & Methods:** We aimed to review the outcome of patients who received Tacrolimus as rescue and subsequent maintenance therapy for refractory symptoms of UC. This was a retrospective single-centre case review series. All patients who were refractory to standard medical therapies and being considered for a colectomy were reviewed by a Gastroenterologist with an interest in Inflammatory Bowel Disease. Demographic data, indications for treatment, clinical course and outcomes were reviewed from Electronic Patient Records (EPR).

**Results:** Fourteen patients (F = 6; mean age of 54 years) received Tacrolimus. 8 patients (57%) had evidence of pancolitis and six patients (43%) had distal colitis. All patients had previously received thiopurines and 11 patients (78.6%) had also received anti-TNFs. Three patients declined Anti-TNF treatment. All patients were steroid-dependent prior to commencing Tacrolimus. One patient received ciclosporin before the switch. The remaining 13 patients were initiated on Tacrolimus in the out-patient setting at a starting dose of 0.1 mg/kg/ day in 2 divided doses. Patients took Tacrolimus for a mean period of 18.8 months (range: 2 months to 49 months). Eight patients (57%) achieved a steroid-free remission within 6 months. An additional 3 patients (23%) had a clinical response within 6 months, but required one course of steroids during this time period. Three patients (23%) failed to respond to Tacrolimus; 1 patient remains steroid-dependent and does not wish to proceed to surgery, 1 patient was switched to infliximab and 1 patient proceeded at 10 months to have an elective subtotal colectomy. Tacrolimus was withdrawn in all 3 non-responders. Of the 11 (78.6%) initial responders, 12-month outcome included withdrawal of Tacrolimus in 7 patients (63.6%). Reasons for withdrawal included: n = 1 renal impairment; n = 1 started on infliximab; n = 3 referred for leucapheresis; n = 1 restarted on Azathioprine and n = 1 referred for proctocolectomy. Three patients (21.4%) remain in steroid-free clinical remission with a good quality of life and

All authors have declared no conflicts of interest.
no adverse effects on maintenance treatment with Tacrolimus. 11 patients (43%) completed 12 months of follow-up.

Conclusion: Tacrolimus should be considered as an alternative treatment for patients with refractory UC in the out-patient setting. This is particularly useful if the patient is unwilling to consider a colectomy. With close monitoring and prompt action if necessary, it is safe and effective allowing patients an alternative immunosuppressant which may either avoid the need for a colectomy or, give some time to adjust to its implications.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1710 A REAL LIFE EFFECTIVENESS OF ADALIMUMAB VERSUS GOLIMUMAB IN MODERATE-TO-SEVERE ULCERATIVE COLITIS: A MULTICENTER EXPERIENCE FROM THE SICILIAN NETWORK FOR INFLAMMATORY BOWEL DISEASE (SN-IBD)

S. Renna1, F. Mocciaro2, M. Ventimiglia1, F.S. Macaluso1, R. Orlando1, M. Billeci1, M. Cappello4, M. Mendolaro5, A.C. Privitera6, C. Ferracane6, A. Armuzzi6

Aims & Methods: We aimed to compare the efficacy of Adalimumab and Golimumab in the induction and maintenance treatment of moderate-to-severe ulcerative colitis (UC). No comparable data between the 2 drugs are available up to now. Aims of this study were: to evaluate the efficacy of Adalimumab (ADA) and Golimumab (GOL) in the treatment of moderate to severe UC, respectively; to report the rate of clinical response and the rate of clinical remission. From June 2015 until April 2017, 197 consecutive pts with moderate to severe UC were treated with ADA or GOL. The efficacy was evaluated at 8 week and at the end of the follow up between naive and non naive pts and at the end of the follow up between naive and non naive pts.

Results: 113 pts were treated with ADA and 79 with GOL for a median follow up of 40.21 [20.32, 69.14] weeks for ADA and 34.00 [17.43, 54.79] weeks for GOL (p = 0.08). Eighty-eight pts were naïve to anti-TNFαs (59 ADA, 29 GOL, p = 0.09). No difference in Mayo Score value was observed between the 2 groups at the time of first drug injection (p = 0.92). After 8 weeks clinical benefit was achieved in 93/118 (78.8%) pts treated with ADA and 50/79 (63.3%) pts treated with GOL (p = 0.026). Clinical remission was achieved in 48/118 (40.7%) pts treated with ADA and 20/79 (25.3%) pts treated with GOL (p = 0.038). At the end of the follow up clinical benefit was achieved in 79/118 (66.9%) pts treated with ADA and 37/46 (80.0%) pts treated with GOL (p = 0.008). Clinical remission was achieved in 50/118 (42.4%) pts treated with ADA and 23/79 (29.1%) pts treated with GOL (p = 0.088). No difference was observed in clinical outcomes at 8 weeks and at the end of the follow up between naive and non naïve pts (p = 0.187). At the end of the follow up the median Endoscopic Mayo Score was 3.00 [0.00, 5.00] in pts treated with ADA and 4.00 [1.00, 7.00] in pts treated with GOL (p = 0.025). Univariate analysis revealed that age > 40 years at the time of first drug injection and age ≤ 40 years at the diagnosis were associated with higher remission rate in pts treated with ADA respect to pts treated with GOL at 8 weeks and at the end of the follow up (p = 0.046 vs 0.016 respectively). The rate of clinical remission increased > 5 years was associated with a higher remission rate in pts treated with ADA respect to pts treated with GOL at 8 weeks and at the end of the follow up (p = 0.037).

Conclusion: This is the first study where the comparable efficacy of ADA and GOL was evaluated. These real life data confirmed the efficacy of subcutaneous anti-TNFαs in the treatment of moderate to severe UC. ADA resulted to be more effective than GOL in inducing and maintaining clinical benefit. Larger prospective studies with longer follow up are warranted to confirm this data.

P1711 REAL-LIFE STUDY (GOURE-UC) EVALUATING THE EFFECTIVENESS OF GOLIMUMAB FOR THE TREATMENT OF ULCERATIVE COLITIS: AN INTERIM ANALYSIS FROM ITALIAN GROUP FOR THE STUDY OF INFLAMMATORY BOWEL DISEASE (IG-IBD)

D. Pugliese1, A. Variola2, A. Erivitiera3, M. Allocca4, F. Bossi5, M. Cappello6, G. Lorenzon7, S. Mazzuoli8, G. Scarpulla10, S. Festa1, L. Moser1, G. Tapet1, G. Bodini1, M. Di Girolamo10, L. Grossi1, F. Mocciaro8, C. Ricci9, S. Saibeni9, R. Spagnuolo10, E. Capoferro2, A. Armuzzi6

Aims: The efficacy of golimumab (GOL) in the treatment of inflammatory bowel disease (IBD) has been documented in several clinical trials. However, limited data is available in the real-life setting where clinicians treat UC patients following the results of clinical trials. We aimed to evaluate the clinical effectiveness of GOL in a real-life setting.

Methods: We conducted a retrospective, observational study (GOURE-UC), which included patients who received GOL as first-line treatment for UC (n = 577) or were switched from other anti-TNFα therapy (n = 182) for moderate-to-severe UC from 2012 to 2019. GOL was administered as monotherapy or in combination with other immunosuppressants or as maintenance therapy for up to 3 years. The primary endpoint was the prevention of colectomy. Secondary endpoints included the induction and maintenance of remission, safety, and tolerability.

Results: Of the 577 patients who received GOL as first-line therapy, 40% (n = 231) achieved clinical remission (CDAI ≤ 150) and 65% (n = 376) had a clinical response (CDAI ≥ 70) at week 12. At week 54, 57.1% of patients continued on GOL treatment. Ten patients (2.7%) underwent colectomy during the follow-up period. The most common adverse events were infections, gastroenteritis, and skin reactions. The overall incidence of serious adverse events was low, with 4.4% experiencing at least one serious adverse event.

Conclusion: This real-life study confirms the effectiveness and safety of GOL in treating UC, with a low incidence of serious adverse events. The results support the continued use of GOL in the real-life setting.

Disclosure of Interest: All authors have declared no conflicts of interest.
Introduction: Anti-TNFs are well-established in therapeutically management of Crohn’s disease (CD). Real-life data on their pattern of use in a French clinical setting are, however, limited to this day.

Aims & Methods: The objective of this study was to examine for characteristics of CD patients and anti-TNF use in a real-life setting in France through the general sample of health insurance beneficiaries (EGB database) which includes reimbursement data from a sampled 1/97th of the French population. A cohort of 1280 patients with CD in the EGB database between 01/01/2010 and 31/02/2014 was retrospectively constituted, of which 189 (14.8%) initiated an anti-TNF treatment. Treatment discontinuation rate was analyzed during that period and were studied for the analysis. An additional analysis was performed based on French hospital discharge data (medical information systems program [PMSI]) from 8142 CD patients to compare results from the EGB database but only support infliximab use due to its exclusive hospital availability in France (adalimumab can be prescribed in both hospital and retail markets).

Results: 47.8% of anti-TNF treated patients were male and the mean age at the initiation of an anti-TNF treatment was 38. The mean duration between diagnosis and treatment initiation of an anti-TNF treatment was 6 years. Concomitant treatments such as corticosteroids and immunosuppressants were prescribed at least once in 63% and 47% of patients respectively. Around 35% of patients initiated a treatment with infliximab and 43% with adalimumab. Results at 12 months after anti-TNF initiation are presented in the table below:

Table 1: Anti-TNF use in patients initiating an anti-TNF treatment with at least 12 months of follow-up A\textsubscript{12} at 12 months, 13.6% of patients underwent surgery.

Results from the hospital discharge database confirmed some of our observations. Optimization rate for infliximab 12 months after initiation was similar (38.1%) at 12 months for infliximab and anti-TNF treatments. Treatment discontinuation rate was also within the same range observed and stable over time, with 10% of patients discontinuing infliximab treatment each year and a discontinuation rate after 12 months of treatment of 27.2%.

Conclusion: The general sample of health insurance beneficiaries’ database provides a unique representative sample to analyze and describe real-life usage of anti-TNF in Crohn’s disease patients in France.

P1714 PREDICTIVE FACTORS OF RESPONSE TO ANTI-TNF A TREATMENT OF COMPLEX ANO-PERINEAL FISTULAS IN CROHN’S DISEASE

Introduction: Ano-perineal fistulas (APF) are a common location of Crohn’s disease (CD). Their treatment is still disappointing. Identifying the predictive factors of response could guide the practitioner to adapt the anti-TNF treatment of each patient.

Aims & Methods: We performed a descriptive, longitudinal and retrospective study over a period of 14 years. We included all patients with a definite diagnosis of complex AP of CD treated with anti-TNF a with a minimum follow-up of one year. Patients less than 16 years of age or over 70 years were excluded and non-obstructing patients were also excluded. A univariate and multivariate statistical analysis was then carried out using the SPSS software to identify the predictive factors of response to the treatment.

Results: A total of 49 patients had complex AP treated with anti-TNF a. 10% of the patients had also recto-vaginal fistulas. The mean age was 31 years. The sex ratio women/men was 1.35. All of the patients had an MRI at diagnosis. Patients had concomitant antibiotics and seton drainage in all cases. 76% of the patients received azathioprine. After the induction phase, 53% of the patients received...
achieved clinical remission, 31% a partial clinical response and 12% a primary failure. This was maintained a during a median follow-up after a year of anti-TNF therapy. After a mean time of 13 months, 42% of the patients had a loss of response. The analytical study found that the absence of recto-colic involvement, CRP negativity and normalization of platelet count under treatment and achievement of clinical remission after the induction phase were predictive factors of long term good response to anti-TNF therapy. Clinical remission after the induction phase was the only independent predictive factor of long-term remission under maintenance treatment after multivariate analysis. However, partial response or remission of UC was predictive of a long-term good response as well as the presence of a recto-vaginal fistula and young age at diagnosis.

Conclusion: According to our results, the type of response obtained after the induction phase seems to be closely related to the subsequent development of our patients. Further studies assessing early therapeutic adaptation strategies could better evaluate this perspective in the event of a partial clinical response. In addition, rectal involvement and recto-vaginal fistulas are factors of poor response for which aggressive and specific treatment is essential.

Introduction: The management of chronic inflammatory bowel disease (IBD) has experienced significant advance with the development of biologic therapy. Infliximab (IFX) was the first monoclonal antibody approved for IBD. The patent expiry of biologics and their relatively high costs that result in a significant economic burden on the healthcare system, has led to the development of biosimilar agents. The biosimilar IFX has been authorised for use in all the indications as the reference IFX. The demonstration of biosimilar IFX efficacy and safety equivalence was based on two pivotal clinical trials in rheumatic diseases. As a result of the extrapolation to IBD, there is growing controversy regarding the appropriate use of biosimilar IFX. The efficacy and safety of infliximab reference in inducing and maintaining remission in IBD has been extensively proven in clinical trials. However, the role of biosimilar IFX, has not been systematically investigated in clinical practice.

Aims & Methods: We aimed to compare the safety and efficacy in inducing and maintaining remission in IBD, between the reference IFX group and biosimilar IFX group. This retrospective, multicenter study was carried out at 4 tertiary hospitals (October 2013 to December 2016). The analysis included two cohorts of consecutive IBD patients. One cohort comprised of patients who were started original IFX since 2013. The second cohort included patients who were treated from the introduction of biosimilar IFX. Adverse events (AEs), demographic, clinical, endoscopic and laboratory data were collected on all patients. Efficacy was assessed according to response and remission at 14th, 54th week. For CD, response was defined as a decrease in partial Mayo score of 2 or more from baseline and a partial Mayo score of 1 or less was used to remission. For CD, response was defined as a decrease in Harvey-Bradshaw score of 3 or more from baseline, and a Harvey-Bradshaw score of 4 or less was used to remission. We used Student’s t-test for independent samples and Chi-square test. Time to withdrawal due to adverse effects was estimated using Kaplan-Meier survival analysis, and the log rank test was used to test for treatment group differences.

Results: The analysis included 346 consecutive IBD patients. 104 treated with original IFX and 242 with biosimilar IFX. 103 patients were diagnosed with CU, 208 with CD and 5 with indeterminate colitis. Overall median follow-up was 21 months. Baseline clinical activity scores were not significantly different among the 2 groups. Frequency of concomitant azathioprine and systemic steroids were not different among both groups. Patients in biosimilar infliximab group were more likely to experience previous biologic treatment failure (29.2% versus 20.2% in the original IFX, p = 0.0163). There were no significant differences in patients achieving response and remission at weeks 14 and 54. There were no significant differences in rate of withdrawals among the 2 groups (37.1% versus 36.9% for biosimilar IFX, p = 0.811). There were no significant differences in cumulative discontinuation rate due to AEs in original IFX and biosimilar IFX (42.42, (95% CI 39.49–45.34) months versus 44.61 (95% CI 42.66–46.56) months, log-rank test p = 0.292).

Conclusion: Our study showed similar efficacy and safety profile of biosimilar IFX compared to original IFX.

Introduction: Acute severe Colitis (ASC) is a severe complication of inflammatory bowel disease (IBD), for which there is no consensus definition. Its diagnosis is based on clinico-biological and endoscopic criteria. Low endoscopy is essentially positive for the diagnostic perspective of ASC as well as for the diagnosis of IBD

Aims & Methods: The objective of this study is to describe the endoscopic aspect of ASC and its interest in therapeutic management in our series of 48 cases it is a prospective descriptive and analytical study of a series of 48 cases of acute severe Colitis (ASC) collected during a period of 3 years (2014-2016) in the gastroenterology department.

Results: The average age of our patients is 39.8 ± 10.4 years with extremes ranging from 14 to 73 years. 51.9% (25 cases) were females. 28 cases (58.3%) were known to have IBD, with 24 cases of UC (58.3%). Initial endoscopy was performed in all patients. The average time to perform endoscopy (from the onset of symptoms) was 37 days (2 to 75 days). Severe endoscopic aspects were present in 30 patients: deep ulcer (29 cases), spontaneous bleeding (4 cases), friability (4 cases). Other endoscopic lesions found were erythema (12 cases), erosions (5 cases), superficial ulcer (25 cases), pseudo polyps (14 cases), contact bleeding (27 cases). Biopsy was performed in all patients, histology was in favor of UC in 64.8% cases. CMV viral inclusions were found in 2.08% of cases. First-line medical treatment is based mainly on parenteral corticosteroid therapy, had been established in all cases. A second-line treatment with anti-TNF agents was used in 5 cases (10.4%) while surgical treatment was indicated in 15 cases (31.25%) of which 12 cases had severe endoscopic colitis. Steroid refractory disease was associated with endoscopic severe colitis (p = 0.04). In mono-variated analysis, endoscopic severe colitis was found in more females than males (53.8 vs 43.3). With a statistically significant difference p = 0.020

Conclusion: Endoscopy in ASC occupies an important place to specify the morphological severity and thus make the positive diagnosis, the severe endoscopic colitis constitutes one of the predictive elements of steroid refractory disease requiring the use of a second therapeutic pallium.

Introduction: Response to biological drugs in ulcerative colitis (UC) is variable with induction response rates of 64.5% (vs 29.3% for placebo), 50.4% (vs 34.6% for placebo), 51.0% (vs 30.3% for placebo), 47.1% (vs 25.5% for placebo) for infliximab, adalimumab, golimumab and vedolizumab, respectively. Apart from prior exposure to anti-tumour necrosis factor (anti-TNF) agents and concurrent immunomodulatory therapy, predictors of clinical response and remission to biological drugs have not been well defined. We sought to investigate the utility of baseline faecal calprotectin (FC) and early change in FC in predicting clinical response and remission to biological therapy in UC.

Aims & Methods: Patients who were commenced on any biological therapy for UC and had a baseline FC at the time of commencement were included in this retrospective study. Disease activity was monitored serially by calculation of Simple Clinical Colitis Activity Index (SCCAI) or by Physician global assessment (PGA) or by treatment persistence. Clinical response was defined as decrease in SCCAI/CDAI of 3 or a decrease in PGA of ≥1 (n=5) to vedolizumab or ≥2 (n=5) to vedolizumab (P = 0.56). Similarly, responders (909 [13, 2100] [n=28]) and non-responders (850 [240, 2100] [n=13]) to anti-TNF agents had comparable calprotectin values at baseline. P = 0.93.

Conclusion: In a single-centre series of biological treated UC patients, baseline FC did not predict clinical response at 6 months.

Introduction: The prevalence of Crohn’s disease is important for planning of health care and allocation of clinical resources. In 2005, a National Patient’s Registry in Poland was established to collect demographic and clinical data. In 2013, 6030 of patients have been enrolled to the Polish National CD Patient’s Registry, conducted in 95 gastroenterology centers in Poland. Patient’s phenotype according to: Montreal classification, demographics, smoking, alcohol consumption, extraintestinal manifestation and medical treatment have been evaluated. The impact of demographic factors on the use of drugs from different groups (mesalazine, prednisone, azathioprine, methotrexate, anti-TNF), and medications efficacy and tolerance was assessed. The efficacy assessment was evaluated according to subjective 4-step scale. Similarly treatment tolerance was assessed according to 2-step scale.

Results: No gender effects were observed on the use or efficacy of individual drug classes, although greater tolerability of prednisone and azathioprine was observed in men (respectively 95.56 vs 93.82 and 93.4 vs. 91.65, both p < 0.005). Smoking did not affect the effectiveness and tolerability of the used medications. However surprisingly fewer smokers were treated with azathioprine, methotrexate, and anti-TNF in comparison to non-smokers (38 vs 45%, 0.5 vs 1.55%, 0.5 vs 11%, all p < 0.05). In patient’s declaring casual alcohol use, the efficacy and tolerability of prednisone was significantly better than in patient’s declaring abstaining (89 vs 84 and 96 vs 93%; p < 0.05). Referring to the Montreal classification, efficacy of mesalazine, prednisone and azathioprine was significantly higher in A1 group with the lowest in A2 patients (A1: 90, A2: 83, A3: 86 for prednisone, p < 0.05) In patient’s declaring casual alcohol use, the efficacy and tolerability of prednisone was significantly better than in patient’s declaring abstaining (89 vs 84 and 96 vs 93%; p < 0.05).

Conclusion: This is the first study comparing efficacy and tolerability of treatment methods used in “real-life” practice in Poland during last 8 years. Most observations are in compliance with data from clinical trials. Positive effect of casual alcohol consumption on efficacy of medications requires further observation. Interestingly some unexpected relationships, concerning similar efficacy of infliximab in different disease behavior was found. This effect requires also further observations in regards to more frequent use of anti-TNF drugs in last years.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Vedolizumab (VDZ) is the first gut-specific monoclonal antibody alternative to anti-tumor necrosis factor alpha therapy in patients with moderate-to-severe inflammatory bowel disease (IBD). It has been registered since 2016 in Hungary, but currently the high treatment costs are considerably limiting the availability of VDZ. All newly initiated VDZ therapy is individualized, it should be approved by the steering committee of five Hungarian IBD-specialists. This results in that VDZ therapy is available exclusively for patients in whom conventional treatment was ineffective or contraindicated.

Aims & Methods: The aim of our non-interventional retrospective study was to assess the efficacy of induction VDZ therapy: 41 patients with Crohn’s disease (CD) and 25 with ulcerative colitis (UC) received VDZ induction therapy between September 2016 and April 2017 in Hungary. Efficacy of induction therapy was assessed based on the changes of activity indices on week 14.

Results: A total of 35 IBD patients (27 Crohn’s; 8 ulcerative colitis) were included in our study. CD patients had a median time from diagnosis of IBD to LTBI of 9 years (0–48 years). LTBI treatment was the primary outcome of the study. Risk of TB reactivation still exists. The efficacy of LTBI treatment in IBD patients receiving biologic therapy and the timing of biologic therapy initiation has not been extensively studied.

Aims & Methods: In order to evaluate the effectiveness of LTBI treatment in IBD patients receiving biologic therapy, we conducted a retrospective review of all IBD patients diagnosed with LTBI following a tuberculosis skin test (PPD) or interferon gamma release assay (IGRA) and who received biologic therapy between January 1996 and August 2016. A total of 20 patient demographics, TB risk factors, chest x-ray findings, biologic agent used, prior and concomitant therapies, and LTBI treatment regimen. TB reactivation after completion of LTBI treatment was the primary outcome of the study. Risk of TB reactivation was calculated using McGill University’s ‘The Online TST/IGRA Interpreter’. Results: A total of 35 IBD patients (27 Crohn’s; 8 ulcerative colitis) were included in the study. Their median age was 38.3 years (14.4 years) and 68.6% were male (Table 1). The median time from diagnosis of IBD to LTBI was 9 years (0–48 years). Prior IBD therapies included corticosteroids (86%), aminosalicylates (83%), other immunosuppressants (69%). At least 43% of patients have been previously exposed to at least 1 biologic agent. The most common LTBI treatment regimen wasisoniazid (INH) for 9 months (n = 26, 74%). Biologic therapy used were infliximab (n = 14, 40%), adalimumab (n = 10, 29%), vedolizumab (n = 7, 20%), and certolizumab pegol (n = 4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n = 20). All patients were treated for LTBI and the majority (83%) was treated prior to

P1720  OUTCOMES OF TREATMENT FOR LATENT TUBERCULOSIS INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE RECEIVING BIOLOGIC THERAPY

Introduction: Tuberculosis (TB) reactivation is of particular concern in patients with inflammatory bowel disease (IBD) treated with biologic therapies. Screening for latent tuberculosis infection (LTBI) is indicated prior to initiating treatment. The 2016 American Gastroenterological Association (AGA) guidelines recommend the use of an interferon-gamma release assay (IGRA) or tuberculin skin test (TST) for the identification of LTBI in patients with IBD. This is the first systematic review to evaluate the effectiveness of LTBI treatment in IBD patients receiving biologic therapy and the timing of biologic therapy initiation has not been extensively studied.

Aims & Methods: In order to evaluate the effectiveness of LTBI treatment in IBD patients receiving biologic therapy, we conducted a retrospective review of all IBD patients diagnosed with LTBI following a tuberculin skin test (PPD) or interferon gamma release assay (IGRA) and who received biologic therapy between January 1996 and August 2016. The median time from diagnosis of IBD to LTBI was 9 years (0–48 years). Prior IBD therapies included corticosteroids (86%), aminosalicylates (83%), other immunosuppressants (69%). At least 43% of patients have been previously exposed to at least 1 biologic agent. The most common LTBI treatment regimen wasisoniazid (INH) for 9 months (n = 26, 74%). Biologic therapy used were infliximab (n = 14, 40%), adalimumab (n = 10, 29%), vedolizumab (n = 7, 20%), and certolizumab pegol (n = 4, 11%). Combination therapy with an immunomodulator and a biologic agent was administered in 57% of cases (n = 20). All patients were treated for LTBI and the majority (83%) was treated prior to

United European Gastroenterology Journal 5(5S) A753
starting biologic therapy. The median time from initiation of LTBI treatment to biologic was 43 days (IQR 23–40). The median duration of follow-up was 2.9 ± 3.3 years. The median calculated annual risk of developing active TB without treatment was 0.52% (0.08%–1.3%). Of the cohort studied, only one patient taking adalimumab monotherapy after completing 6 months of INH therapy developed reactivation of TB. The estimated TB reactivation rate in our cohort was 0.98 cases per 100 patient-years of follow up.

**Conclusion:** Treatment for LTBI in patients with IBD treated with biologics is effective, but does not eliminate the risk of reactivation, which occurred at a rate of 0.98 cases per 100 patient-years in general. Additional studies with extended follow-up are warranted to further characterize the efficacy of LTBI treatment in these patients.

**Contact E-mail Address:** eugenidomenex@gmail.com

**Introduction:** Resection in Crohn’s disease (CD) intends to be a curative surgery, but 43% of patients will have a relapse. We aimed to describe the characteristics and management of patients with residual disease after surgery (RD) and to compare these with patients with curative surgery (CS) in post-operative CD patients.

Aims & Methods: PRACTICROHN was a retrospective study that included adult patients from 26 Spanish hospitals who underwent CD-related ileocolonic resection in 2015. We identified all CD patients with a prior surgical resection with median time to POR being longer in patients who received prophylaxis compared to curative surgery. In the case of residual disease although prophylactic treatment is useful, most of the patients will present POR. RD is a factor of poor prognosis in post-operative CD patients.

**Contact E-mail Address:** Thomas.skouras@nhs.net

**Introduction:** Bile acid malabsorption (BAM) is a common cause of diarrhoea in Crohn’s disease (CD) patients with ileal resection and can lead to complications such as renal and biliary stone disease. BAM is usually diagnosed by selenium labelled homotaurocholic acid test (75SeHCAT) but its availability is limited. Thus, a large proportion of resected CD patients either remain underdiagnosed or subject to empirical therapy. There is a paucity of studies examining the correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM.

**Aims & Methods:** We identified all CD patients with a prior surgical resection who underwent 75SeHCAT testing at our institute. Testing was based on the treating clinician’s discretion. The length of resected ileum was recorded from histopathology report. We conducted a Spearman’s correlation test to check for correlation between length of resected ileum and percentage retention on 75SeHCAT.

**Conclusion:** Resection in Crohn’s disease can lead to complications such as renal and biliary stone disease. BAM is usually diagnosed by selenium labelled homotaurocholic acid test (75SeHCAT) but its availability is limited. Thus, a large proportion of resected CD patients either remain underdiagnosed or subject to empirical therapy. There is a paucity of studies examining the correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM. There was moderate correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM. There was moderate correlation between length of ileal resection and severity of BAM which will be of particular use to clinicians with no recourse to diagnostic testing for BAM.
P1723 A MICROBIAL SIGNATURE OF PSYCHOLOGICAL DISTRESS IN IRRTIBLE BOWEL SYNDROME

H. Duboc

Introduction: Irritable Bowel Syndrome (IBS) is associated with alterations along the brain-gut-microbiota axis. Previous studies have suggested a parallel segregation of microbial features with psychological burden in IBS (1,2,3).

Aims & Methods: This increases the need to evaluate microbial correlates of psychological distress, anxiety, depression and stress perception. 16s rRNA fecal microbial analyses (Mignola MiSeq, V1-2 amplified from total DNA) in 48 IBS patients (Rome-III criteria, mean age 42 years, 35 female subjects, 25 diar- rhoea-dominant, 5 constipation-dominant and 18 alternating-type IBS). Assessment of psychological and clinical variables with validated questionnaires, microbial analysis via QIIME. Machine learning to predict psychological distress through a composite model of bacterial features. Correlational analysis and comparisons in bacterial abundance between subgroups defined by thresholds in psychological variables.

Results: Thirty-one patients (65%) showed psychological distress, 22 (31%) anxiety, and 10 depression (21%). Psychological distress was uncorrelated with IBS severity (Spearman’s ρ = 0.05, p = 0.736). Microbial beta diversity was significantly associated with distress and depression (q = 0.044 each). A random forest model using 148 microbial signatures was able to correctly classify patients regarding symptom severity of IBS (AUC = 0.89). Patients exceeding thresholds of distress, anxiety, depression and stress perception showed significantly higher abundances of Proteobacteria (LDA = 2.5). Patients with anxiety were characterized by higher abundances of Bacteroidetes (LDA = 3.0). Distinctly with Lachnospiraceae with L. fumariarum (q = 0.58, p = 0.018), anxiety positively with Anaerotruncus (p = 0.65, q = 0.001).

Conclusion: A microbial signature accurately predicted the presence of psychological distress. Psychological variables significantly segregated gut microbial features, underscoring the role of brain-gut-microbiota interactions in IBS. Supported by Austrian Society of Gastroenterology and Hepatology (ÖGGH) and funds of the Österreichische Nationalbank, Fund project number: 16506.

P1724 SACCHAROMYCES BOULARDII CNCM I-745 LOWERS FECAL CHOLIC ACID CONCENTRATIONS DURING ANTIBIOTIC TREATMENT IN HEALTHY VOLUNTEERS: A NEW MICROBIOTIC SIGNATURE IN THE PROTECTION AGAINST CLOSTRIDIUM DIFFICILE INFECTION

H. Duboc1, C. Chong Nguyen1, T. Kabbani2, D. Rainteau1, L. Humbert1, C. Chong Nguyen1, T. Kabbani2, D. Rainteau1, L. Humbert1, J. Peter, C. Fournier, L. Knoblich, B. Keip, G. Moser

Introduction: Saccharomyces boulardii (SB) CNCM I-745 demonstrated clinical efficacy in the secondary prevention of post-antibiotic Clostridium difficile infection (CDI), but the mechanism remains unclear. Cholic acid (CA) is a primary BA which facilitates spore germination in vitro, increases in stool during antibiotic therapy. The concomitant administration of SB during AC treatment significantly reduces this CA peak. These results highlight new human data on a potential mechanism for post-antibiotic CDI: alteration of the microbiota can encourage germination of C. difficile spores in increased CA concentrations and reduced concentrations of secondary BAs. The effectiveness of SB in preventing recurrent CDI may be explained, in part, through modulation of microbiota changes that influence the balance of pro- and anti-germination BA concentrations.

Disclosure of Interest: H. Duboc: I worked with Biocodex as a consultant for the development of a free smartphone App for patients suffering of constipation.

Aims & Methods: We assessed the abundance of Fusobacterium in CRC, colorectal mucosa and saliva. We extracted DNA from mucosal biopsies and measured bacterial levels by quantitative PCR of the 16S ribosomal RNA gene. We also investigated the homology of F. nucleatum in oral cavity and CRC.

Results: In 51 CRC cases, Fusobacterium positivity was significantly higher in CRC compared to controls (p < 0.05). Fusobacterium was more detected in CRC (12.9%) than in normal tissue (2.3%) respectively. The detection rate of F. nucleatum was 96% in saliva, 95% in CRC by next-generation sequencing. A total of 15 patients with CRC were included to check the homology of F. nucleatum in saliva and CRC. From the 15 patients, 9 were F. nucleatum-positive in saliva and CRC. For the 6 patients who were F. nucleatum-positive in saliva, from these patients who were F. nucleatum-positive in saliva and CRC, we next looked for the results of AP-PCR and 6 patients have shown common band patterns.

Conclusion: The results support a link between the abundance of F. nucleatum in oral cavity and CRC. Our data also indicate that there may be a route from the oral cavity to the CRC in F. nucleatum positive cases. We are now identifying DNA sequences, specific for the objective strains.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1727 HUMAN MILK OLIGOSACCHARIDES: A NEW STRATEGY AGAINST POST-ANTIBIOTIC CLOSTRIDIUM DIFFICILE INFECTION?
L. K. Vigsnaes
Business Development, Glycom A/S, Horsholm/Denmark

Contact E-mail Address: louise.vigsnaes@glycom.com

Introduction: Human Milk Oligosaccharides (HMOs) are a family of complex carbohydrates found in high concentrations in human milk and which are now becoming commercially available. In clinical studies, in both infants and adults, HMOs powerfully and specifically modulate the gut microbiota by increasing bifidobacteria and reducing certain pathogenic bacteria (1,2). Also, HMO bacterial consumption results in the production of beneficial metabolites such as short chain fatty acids and the lowering of pH. Hence, the selective growth of bifidobacteria on HMOs can create an ecological niche that is more colonization resistant against pathogens. Bifidobacteria may also have a direct impact on microbial toxins by reducing their level and cytotoxic effect (3). Antibiotics, especially broad-spectrum antibiotics, dramatically impact the microbiota and its balance, and have been implicated in the pathogenesis of many health conditions including gastrointestinal symptoms such as diarrhoea (4). The most commonly cited mechanism for antibiotic-associated diarrhoea is intestinal overgrowth of the pathogenic bacterium, Clostridium difficile.

Aims & Methods: The aim of this study is to investigate, in in vitro models of C. difficile infection, (1) the impact of HMOs on the microbiotal community and activity (e.g. bacterial metabolites and pH), and (2) the anti-pathogenic activity of HMOs against C. difficile, with a focus on preventing recurrence of the infection. Two in vitro models, each using human faecal microbiota infected with C. difficile, were used to examine the impact of HMOs on bacterial metabolic production and C. difficile infection. One model is a 48 hour batch fermentation, while the other is a simulated gut model, run for 3 weeks post infection, which simulates the infection cycle of C. difficile after antibiotic treatment.

Results: The study revealed that the HMOs increase the level of bifidobacteria, reduce the level of beneficial bacterial metabolites such as short chain fatty acids and decrease pH compared to a control with no added HMOs. Additionally, HMOs reduced the level of C. difficile; in some cases completely eradicated C. difficile below detection limits. This antimicrobial effect of HMOs on C. difficile was pH-independent, hence another mechanism is causing the anti-pathogenic activity of HMOs.

Conclusion: Conclusively, the results show that HMOs can impact C. difficile infection in an in vitro system, which suggests HMOs as a potential approach to reduce risk of antibiotic associated diarrhoea and post-antibiotic C. difficile infection.

Introduction: It has been reported that the composition of human gut microbiota changes with aging, body mass index (BMI), diet and other environmental factors. In particular, the relationship between gut microbiota and obesity has been underlined frequently because intervention in the microbiota may reduce body fat. In this study, we investigated the relationship between obesity and composition of gut microbiota in healthy Japanese population.

Aims & Methods: Participants were 1,082 healthy Japanese adults (410 males, 672 females) who participated in the Iwaki Health Promotion Project in 2014. Faecal samples were analysed by 16S rRNA gene-targeted sequencing to determine family composition of gut microbiota. They were classified into obese group (BMI ≥ 25) and normal weight group (BMI < 25) according to Japanese standard and were stratified into 7 age groups, 19-29, 30-39, 40-49, 50-59, 60-69, 70-79 and 80-90. The family composition of gut microbiota in each age group was compared between obese and normal group.

Results: There were 235 obese participants, and 847 normal ones. The proportion of Bacteroidiaceae decreased substantially, and Ruminococcaceae increasing slightly with aging in obese group. The proportion of Bifidobacteriaceae, Lachnospiraceae and Porphyromonadaceae decreased gradually with aging in both groups.

Conclusion: Changes in composition of gut microbiota with aging were different between obese and normal group. Some previous researches observed differences of gut microbiota between obese and normal group, but many of the researches did not take aging into consideration. Our study indicated that different intervention stratified with age could be needed.

Contact E-mail Address: darina.kohnova@seznam.cz

Introduction: Due to its high incidence, sporadic colorectal cancer (CRC) remains a major public health problem in the Czech Republic. The exact contribution of large intestinal bacteria to the pathogenesis of CRC has not been elucidated yet, still the mucosal, not the luminal, microbiota seem to play the crucial role. Bacteriocins are small proteins, produced by probiotic bacteria, that inhibit other bacteria and induce the death of the target bacteria. Bacteriocins are divided into more groups, colicins and microcins are the most important ones. Bacteriocins possess antibacterial, antineoplastic, pro-inflammatory and probiotic effect.

Aims & Methods: The aim of this prospective study was to evaluate bacteriocin production by mucosal large intestinal bacteria in colorectal neoplasia. We used an original methodology reported by our group (1). Mucosal biopsies were taken in the caecum, transverse colon and rectum within the colonoscopy in patients with non-advanced colorectal adenoma, non-a-A (11 men, 10 women, mean age 65 ± 10), advanced colorectal adenoma, a-A (which was defined as neoplasia larger than 10 mm and/or containing villous component and/or containing high grade dysplasia; 13 males, 17 females, mean age 70 ± 10) and in the controls (average risk population with normal findings on colonoscopy and with negative history of colorectal neoplasia and/or inflammatory bowel disease; 7 men, 13 women, mean age 57 ± 14). Bacteriocin production by mucosal culture bacteriocin production by each strain was investigated by PCR methods.

Results: A total of 249 mucosal biopsies were taken (60 controls, 63 non-a-A, 60 a-A, 66 CRC) and samples were further investigated. Colcin producing strains were isolated in 22% (13/60) controls, 59% (37/63) non-a-A, 55% (33/60) a-A and in 76% (50/66) CRC. Significantly higher production of colcins was observed in non-a-A, a-A and CRC group when compared to controls, p < 0.001. Significantly higher production of colcins was confirmed in patients with CRC compared to patients with a-A, p = 0.016. Microcin producing strains were isolated in 23% (14/60) controls, 56% (35/63) non-a-A, 78% (47/60) a-A and in 62% (41/66) CRC. Significantly higher production of microcins was observed in non-a-A compared to controls, p = 0.002, in a-A and CRC group when compared to controls, p < 0.001. Microcins were produced more frequently in patients with a-A compared to those with non-a-A, p = 0.008.

Conclusion: Strains isolated from large bowel mucosa in patients with colorectal neoplasia produce bacteriocins more frequently compared to those with normal findings on colonoscopy. We presume, that mucosal large intestinal microbiota with their products including bacteriocins play an important role during the development of colorectal neoplasia.

Introduction: The production of bacteriocins is considered as the key metabolic function of gut microbiota and as the inherent property of probiotic strains. Bacteriocins and metabolites of probiotic microorganisms (metabiotics) can optimize host-specific physiological functions related to human health.

Aims & Methods: This study aims to: (a) detect the bacteriocin genes of probiotic strains Lactobacillus helveticus D75 (NCBI Reference Sequence NZ_CP002829.1) and Lactobacillus helveticus D76 (NCBI Reference Sequence NZ_CPI6827.1) and (b) evaluate in vitro effects of the carboxylic and amino acids mixture identical to the metabolites of the probiotic Escherichia coli strain M17 (components of ActiFood®-S dietary supplement). The antagonistic activity of Lactobacillus helveticus D75 and Lactobacillus helveticus D76 strains was estimated by the deferred antagonism method. The identification of bacteriocin genes was performed by PCR using helveticin J gene primers. Amplified fragments were sequenced using ABI PRISM® 310 Genetyx Analyzer and were analyzed using NCBI/BLAST.

Results: The identical sequences of 537 bp homologous to gene fragment of helveticin of Lactobacillus helveticus DPC 4371 (lvi_1632 gene) were detected
in DNA of both probiotic strains. Sequencing of these fragments showed differences in the incidence of severe diseases between the FMT-treated patients and the AB-treated patients. The addition of the carboxylic and amino acids mixture (Actibloc®-S) results in 2-2.5-fold enhanced antimicrobial activity of both tested probiotics. The best pathogens (Escherichia coli O75 and Salmonella Enteritidis) were significantly increased in the FMT group, showing the potential of gut microbial metabolites mixture and identified probiotic bacteriocins for human health has yet to be realized.

Introduction: Fecal microbiota transplantation (FMT) has been shown to be effective in treating recurrent Clostridium difficile infection. Concern has been raised about the long-term safety of FMT.

Aims & Methods: The aim of this study was to determine the long-term safety of fecal microbiota transplantation (FMT), and its effect on gastrointestinal symptoms (GI) in Clostridium difficile (CDI) patients. We studied 84 patients of which 45 received an FMT treatment via colonoscopy and 39 served as controls receiving antibiotic treatment (AB) for the recurrent CDI and followed their recovery up to 3.8 years. All together 130 patients (55 patients in the FMT group and 75 patients in the AB group were sent a 45-item questionnaire collecting information about the patient demographics, their physical and mental health, including allergies, infections, gastroenterological conditions such as IBD and IBS, diabetes, autoimmune diseases, neurological disorders, mental wellbeing and malignancies. Response rate for the questionnaire was 64.6%.

Results: There were no differences in the incidence of severe diseases between the groups including the incidence of IBD, diabetes, diseases of the nervous system, autoimmune disease, incidence of colon polyps and cancer. Change of weight was neither different between groups (kg/SD): FMT + 2.5 (5.6) and AB + 1.3 (5.6), p = 0.51. The AB treated subjects recorded more frequently that their bowel function had become worse and more irregular after the treatment (p = 0.011, P = 0.001) compared to FMT group. 77.8% of the patients treated with FMT experienced GI symptoms related to IBS whereas 92.3% of antibiotic-treated patients recorded these symptoms (P = 0.006). AB patients experienced more symptoms of the upper intestinal tract than the FMT patients (p = 0.001). In this cohort 97.6% of the FMT-treated patients and 60% of AB treated patients would prefer in the future that their initial treatment to be FMT instead of antibiotics.

Conclusion: FMT is a rational, durable, safe, and acceptable treatment option for patients with recurrent CDI. No severe diseases appeared after FMT and FMT seem to relieve GI symptoms better than antibiotic treatment. FMT and AB treated patients would prefer in the future that their initial treatment for recurrent CDI to be FMT instead of antibiotics.

Serviço De Gastroenterologia De Faro, Centro Hospitalar do Algarve, Faro, Portugal
Contact E-mail Address: taniagago@gmail.com

Introduction: Clostridium difficile-associated disease (CDAD) is an infection caused by Clostridium difficile, gram-positive, anaerobic, spore-forming and toxin-producing bacteria. Infection is recognized as the leading cause of diarrhea associated with health care services in the developed countries. In Portugal epidemiological data are limited.

Aims & Methods: Characterize Clostridium difficile-associated disease episodes in a Portuguese Hospital Center. Retrospective analysis of 250 hospitalized patients with CDAD, in Centro Hospitalar do Algarve, between 2011 and 2015. The data was obtained from clinical processes and statistical analysis was performed with SPSS version 23.

Results: The patients were mostly women (52%). The mean incidence of CDAD was 0.21% and the patients had an associated mortality of 28%. The year with the highest incidence was 2015 (0.53%) but with a lower associated mortality rate. CDAD was mostly acquired at the hospital level (75.6%) and the mean length of hospital stay was 33 days. About 82.4% of the cases were first occurrence and the remaining (18.6%) were recurrences of CDAD. The majority of the patients under study performed Proton Pump Inhibitors-IBP (52.8%) and antibiotic therapy (74.4%) (26.8% made a single antibiotic, and 23.6% 2 or more distinct antibiotics). Penicillin antibiotic class was the most used, followed by Cephapirin (21.5%), Fluoroquinolones (11.4%) and Macrolides (10.1%).

Conclusion: A significant increase in the incidence of CDAD was observed in this study. This increase may be related to several factors, such as the improvement of laboratory diagnostic methods, increased antibiotic prescription, hospital contamination with Clostridium difficile spores or with the appearance of new and more virulent Ribotypes.

Introduction: The incidence of acute lower gastrointestinal bleeding (LGB) is increasing in Western countries, but the predictors of its outcome are not well studied and defined.

Aims & Methods: The aim of this study was to compare the accuracy of Glasgow-Blachford score (GBS) with three available risk scores (State, Velayos and Newman) for predicting the need of any clinical intervention (endoscopic therapy, vascular embolization, surgery and need of transfusion) in patients admitted for acute LGB. Retrospective study from January 2013 to December 2015 in a university tertiary care hospital. Patients with acute LGB were identified using the International Classification of Diseases (9th Revision) and Clinical Modification codes for admission diagnosis. Scores were retrospectively calculated according to clinical reports data. Area under the receiver operating characteristic curve (AUROC), sensitivity, specificity, positive and negative predictive values were calculated for four scores. Also the best cut-off of each score was chosen from using the AUROC curve values.

Results: A total of 298 (51%) men consecutive patients with acute LGB were identified. Median age was 76.1 years (range 25.4–96.5), 201 (67.4%) of patients were older than 70 years. Five patients (1.7%) died, 18 (6%) developed recurrent bleeding, 89 (29.9%) needed transfusion, 30 (12.1%) received endoscopic therapy, and 3 (1%) underwent transcatheter arterial embolization. No patient required any surgical intervention. AUROC of GBS score was 0.87 (95%CI:0.82–0.91) for the need of transfusion, and 0.82 (95%CI:0.76–0.87) for the need of any clinical intervention. AUROC for the need of transfusion and clinical intervention were 0.68 (95%CI:0.61–0.74) and 0.67 (95%CI:0.60–0.73) for the Strate score, 0.77 (95%CI:0.71–0.83) and 0.74 (95%CI:0.68–0.80) for the Velayos score and 0.78 (95%CI:0.72–0.85) and 0.74 (95%CI:0.68–0.81) for the Newman score, respectively. GBS was significantly more accurate than LGB risk scores for predicting the need of transfusion. Although AUROC of GBS was also numerically better for predicting the need of any clinical intervention, the difference was only significant when comparing with the Strate score. All the risk scores were more accurate for determining the need for transfusion than for the need of clinical intervention. Sensitivity, specificity and positive and negative predictive values for each score are shown in table 1.

Conclusion: The GBS was superior to the 3 LGB risk scores for predicting the need for transfusion and clinical intervention. The GBS may be an useful tool for risk stratification in acute LGB.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1734 ACCURACY OF THE NASOGASTRIC TUBE AND THE BUN/CREATININE RATIO FOR DISTINGUISHING BETWEEN UPPER AND LOWER SOURCES OF GASTROINTESTINAL BLEEDING. A SYSTEMATIC REVIEW

S. Machlab, E. Martinez-Bauer, P. Garcia-Iglesias, A. Lira, C. Marmol, G. Llibre1, J.P. Da Costa1, M. Gallach1, V. Puig-Divi1, F. Junquera1, R. Campo1, X. Calvet1, E. Brullet1, Gastroenterology, Hospital Universitari Parc Taulí, Sabadell/Spain

Contact E-mail Address: stmachlab@tauli.cat

Introduction: The insertion of a nasogastric tube (NGT) and assessment of the bloodstream of theNGT or BUN/creatinine ratio were recommended as initial measures to distinguish between upper and lower gastrointestinal bleeding (American College of Gastroenterology 2016). As the nasogastric tube is one of the most bothersome interventions for the patient, we evaluated the evidence supporting these recommendations.

Aims & Methods: The aim of the study was to identify the diagnostic accuracy (sensitivity, specificity, positive predictive value, negative predictive value and likelihood ratio) of the NGT and the BUN/creatinine ratio for distinguishing between upper and lower sources of gastrointestinal (GI) bleeding. We conducted a systematic review of the literature in order to identify studies assessing the diagnostic accuracy of the NGT or BUN/creatinine in patients with melena, hematobilia or rectorrhagia without hematemesis. The search was performed in November 2016 in five data bases (PubMed, Scopus, Web of Science, Cochrane Plus Library and OpenGrey).

Results: Four studies met the selection criteria (two evaluating the NGT, one BUN/creatinine and one BUN/creatinine ratio above 30 markedly increased the probability of an upper GI source with a positive likelihood ratio ranging from 2 to 11. Unfortunately, the sensitivity of both tests for upper GI bleeding was very low (negative likelihood ratios around 0.5). Characteristics and results of the studies selected are shown in table 1.

Conclusion: For patients with gastrointestinal bleeding without hematemesis, BUN/Cre ≥30 indicates a high probability of an upper GI source. Nasogastric tube aspiration provides little additional information and so is not indicated. Neither test reliably rules out an upper GI source of bleeding.

Abstract No: P1734

Therefore, in cases of uncertainty, an upper GI endoscopy will be necessary to make a correct diagnosis.
Results:

and we analyzed characteristics, management and clinical outcome in patients in recent years. We investigated patients with ALGIB on anticoagulation therapy (NOACs). The use of NOACs has been increasing compared with warfarin in taking anticoagulants either warfarin or non-Vitamin K oral anticoagulants.

Introduction:

Contact E-mail Address: geodiamant@hotmail.com

Aims & Methods:

All patients with ALGIB on anticoagulation therapy treated in our hospital during a seven year period were evaluated. Characteristics and clinical outcome were compared between patients on warfarin and patients on NOACs.

Results:

Out of 587 patients with ALGIB, 43 (7.3%) were on NOACs and 68 (11.6%) on warfarin with an age 75.9 ± 9.5 vs 77.1 ± 7.9. The bleeding site was in the small bowel in 2/43 and 6/68 respectively. Causes of bleeding were not different between the two groups except for polyps/neoplasia (8/43 vs 6/68, p = 0.003).

Endoscopic hemostasis was more commonly needed in patients on NOACs 17/43 (39.5%) vs 18/68 (26.5%) p = 0.049).

Blood transfusions and need for other interventions (embolization and surgery) were not different. Also recurrence of bleeding (4/43 vs 11/68) and mortality (3/43 vs 0/68) were low and not statistically different between the two groups.

Conclusion: ALGIB in patients on NOACs although presents some differences it has a similar clinical outcome to patients with ALGIB on warfarin.

Disclosure of Interest: All authors have declared no conflicts of interest.

NOBLADS - THE NEW RISK SCORE TO PREDICT THE SEVERITY OF ACUTE LOWER GASTROINTESTINAL BLEEDING

M. Patita, G. Nunes, R. Barosa, L. Ramos, C. Fonseca
Gastroenterology, Hospital Garcia de Orta, Almada/Portugal

Aims & Contact Email Address: martapatita21@gmail.com

Method & Contact: We aimed to evaluate the accuracy of the NOBLADS score to predict severe LGIB and the outcome of patients admitted by LGIB. We performed a retrospective, observational and unicentric study. Including patients admitted for acute LGIB and submitted to endoscopic evaluation between January/2015 and March/2016. LGIB was classified as severe if ≥ 2 units of erythrocyte concentrate (UCE) were required and/or if hematocrit drop > 20%. Total score ranges from 0-8; when total score is ≥ 2, it is considered high risk for severe LGIB.

Introduction: A new risk score for acute lower gastrointestinal bleeding (LGIB) has recently been validated, based on 8 admission criteria–nonsteroidal anti-inflammatory drugs use, absence of diarrhea, absence of abdominal tenderness, presence of hematochezia or melena, presence of hematemesis or emesis, platelet > 100k, age ≤ 65 or ≥ 80 years, and comparison between warfarin and DOAC are clarified as secondary endpoint.

Reference

NOBLADS score is simple and quick to apply. It predicts with high accuracy the risk of severe LGIB and allows to identify patients that are more likely to require transfusion support, intervention and prolonged hospitalization. In clinical practice, NOBLADS score may be useful to select on admission patients who will benefit from hospitalization or from earlier intervention.

Disclosure of Interest: All authors have declared no conflicts of interest.

ENDOSCOPIC MUCOSAL RESSECTION OF COLORECTAL POLYPS IN PATIENTS ON ANTICOAGULANTS

S. Kohayashi1, T. Nowa2, K. Harada3, H. Seki1, Y. Noma1, T. Ueki3, H. Okada3

1Fukuyama City Hospital, Fukuyama/Japan
2Okayama University Hospital, Okayama/Japan

Contact E-mail Address: sayo444@hotmail.co.jp

Introduction: The management of antithrombotic agents during the peri-endo- scope period concerns the risks of bleeding and thromboembolism. The Japanese Gastrointestinal Endoscopy Society (JGES) guidelines revised in 2012 emphases the risk of thromboembolism rather than bleeding. So heparin bridge of anticoagulants is recommended at high-bleeding-risk procedure such as endoscopic mucosal resection (EMR). However heparin bridge in colorectal EMR raises the bleeding rate to approximately 20%, that is very high-rate incident compared with the bleeding rate of 0.3-6.1% generally. It is doubtful whether heparin bridge is appropriate.

Aims & Methods: The aim of this study to clarify the safeness of colorectal EMR under anticoagulating without a heparin bridge in anticoagulated patients.

All three cases of DOAC was medicine once a day. Thromboembolism was not observed.

The NOBLADS score is simple and quick to apply. It predicts with high accuracy the risk of severe LGIB and allows to identify patients that are more likely to require transfusion support, intervention and prolonged hospitalization. In clinical practice, NOBLADS score may be useful to select on admission patients who will benefit from hospitalization or from earlier intervention.

Disclosure of Interest: All authors have declared no conflicts of interest.

Gastroenterological Endoscopy Vol79 No.3 2014
We conducted subgroup analyses according to the identity of FDRs affected. We searched, assessed and extracted data from eligible studies. The relative risks and grey literature were searched from their inception to December 2016, and all vs. that the risk of CRC conferred by family history of CRC in parents vs. siblings individual with probands who were parents, siblings, and those with two or more individuals, implying that age of onset could potentially enhance the discriminatory capability of CRC prediction scores.

**Conclusion:**
Fifty-six case-control and seven cohort studies involving 9.28 million subjects were included in the analysis. A family history of CRC in FDRs was associated with significantly higher risk of CRC in index subjects (RR \( > 50 \) vs. \( \leq 50 \); \( 50 \) vs. \( > 50 \); \( 60 \) vs. \( > 60 \); \( > 60 \) years, \( p < 0.001 \)). The rate affected does not seem to be necessary when the risk of CRC in asymptomatic individuals is predicted.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1741 IS THERE ANY DIFFERENCE IN RISK OF COLORECTAL CANCER AMONG ASYMPTOMATIC SUBJECTS WHOSE SIBLINGS VS. PARENTS WERE AFFECTED? A SYSTEMATIC REVIEW AND META-ANALYSIS

J.L. Huang, M.C. Wong, C. Chan, J. Lin, W.W. Cheung, M. Liang, Y. Fang, C. Yu, D. Fung
Chinese University of Hong Kong, Hong Kong/Hong Kong Prc

**Contact Email Address:** martin_wong@cuhk.edu.hk

**Introduction:** The current literature is mixed regarding whether first-degree relatives (FDRs) of CRC patients who suffered from colorectal cancer (CRC) at much earlier age are at substantially increased risk of CRC.

**Aims & Methods:** The present systematic review and meta-analysis examined the CRC risk conferred by family history of CRC in FDRs according to their age of onset. We searched Ovid Medline, EMBASE and grey literature from their inception to December 2016, and included all screening studies that investigated the family history of CRC in FDRs that led to diagnosis of CRC and incidence/prevalence of CRC. Two reviewers independently worked on selection, assessment and data extraction of eligible articles. A random effects meta-analysis was employed to pool relative risks (RR) and odds ratios. Subgroup analyses were performed according to the age of onset of CRC in FDRs of asymptomatic subjects \( (< 40 \) vs. \( \geq 40 \); \( < 50 \) vs. \( \geq 50 \); \( < 60 \) vs. \( \geq 60 \) years). Statistical heterogeneity was assessed by the I\(^2\) statistic. Publication bias was evaluated by an inverted funnel plot analysis with Begg’s regression model.

**Results:** Fifty-six case-control and seven cohort studies involving 9.28 million subjects were included in the analysis. A family history of CRC in FDRs of asymptomatic subjects conferred a significantly higher risk of CRC \( RR = 1.76, 95\% CI = 1.57–1.97; p < .001, I^2 = 95\% \) earlier age of onset of CRC in FDRS was associated with significantly higher risk of CRC in index subjects \( RR = 3.29, 95\% CI = 1.67–6.49 \) vs. \( \leq 40 \) years \( RR = 1.42, 95\% CI = 1.24–1.62 \) vs. \( \leq 40 \) years \( p = 0.017; RR = 2.81, 95\% CI = 1.94–4.07 \) vs. \( < 50 \) years \( RR = 1.47, 95\% CI = 1.28–1.69 \) vs. \( < 50 \) years \( p = 0.001 \). The Begg’s test did not identify any publication bias (Kendall’s tau = 0.122, \( p = 0.159 \)).

**Conclusion:** A family history of CRC in FDRs whose age of onset is earlier than or 40 or 50 years conferred a significantly higher risk of CRC to asymptomatic individuals, implying that age of onset could potentially enhance the discriminatory capability of CRC prediction scores.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

## P1742 GILBERT SYNDROME IS NOT THAT INNOCENT?

1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel

**Contact Email Address:** nadira@tivme.gov.il

**Introduction:** Gilbert’s syndrome is considered to be entirely benign. Some studies have shown a reduced risk for cardiovascular disease (CVD). There is conflicting data regarding cancer risk among Gilbert’s syndrome patients.

**Aims & Methods:** We aimed to evaluate the association of Gilbert syndrome with CVD and cancer. Clinical and epidemiological data was obtained from consecutive healthy subjects undergoing annual screening at the Integrated Cancer Prevention Center in Tel Aviv. The annual check-up includes: thorough examination by specialists in internal medicine, surgery, dermatology/plastic surgery, OB/GYN, urology, oncology, oral surgery, gastroenterology. Blood work (smac 24; blood count, TSH, CRP, PSA), vaginal, PSA and mammography (>40ys), LDCT in heavy smokers and all needed imaging when clinically indicated. Peripheral blood DNA was extracted from all subjects. Gilbert syndrome was determined by clinical criteria (normal liver function tests but to mild elevation in unconjugated bilirubin < 3 mg/dl without any hemolysis). In the majority of the cases the diagnosis was confirmed genetically by the homozygous mutation (TA)\(^{7TAA}\) in the promoter region of UGT1A1 enzyme. Prevalence of CVD and cancer were compared between subjects with/without Gilbert syndrome.

**Results:** A total of 6258 (49%) men and 6461 (51%) women, mean age 47.0 ± 11.3 years, were included of which 1,019 had clinical Gilbert. Gilbert was significantly more common among men (11.5% vs. 4.6% \( p < 0.001 \)). The rate of Gilbert syndrome was equal in Sephardic and Ashkenazi Jews. Malignancy and CVD were diagnosed in 678 (5.3%) and 1,837 (14.4%) subjects respectively. The prevalence of any CVD was significantly higher in the Gilbert group (OR 1.23 95% CI 1.04–1.46 p = 0.017), as compared to non-Gilbert group (OR 1.37 95% CI 1.12–1.68 p = 0.003) and CVA (1.1% versus 0.6% \( p = 0.06 \)). Higher rate of kidney and bladder cancers (2.64, 1.22–5.70, \( p = 0.019 \)) was also observed in the Gilbert group. In contrast, the prevalence of breast cancer was much lower among Gilbert’s patients with Gilberts (OR 0.47 95% CI 0.25–0.97, \( p = 0.034 \)).

**Conclusion:** In Israel Gilbert syndrome is not that innocent. In a large cohort it seems to be associated with increased risk of hypertension, CVD and CVA. Bladder cancer is higher but females are protected from breast cancer. Further studies are mandated in order to better understand these findings and determine proper screening and surveillance practices in Gilbert disease.

## P1743 CHARACTERISTICS AND PREDICTORS OF INTERVAL CANCER: A CASE-CONTROL STUDY

I. Laish1, J. Mizrahi2, F. Konikoff1
1Meir Medical Center, Kfar Saba/Israel
2Stony Brook University Hospital, New York/United States of America

**Contact Email Address:** ido.laish@gmail.com

**Introduction:** Interval colorectal cancer is largely related to a poor endoscopic performance (missed lesions, incomplete resection or different polyps) and the development of the polyp (accelerated growth). Thus, quality endoscopic measures and Lynch syndrome were highly investigated for their association with interval cancer. However, most reports came from the Western world and not the Middle East, and differences in ethnicity or environmental factors might potentially have impact on the biology of tumor progression. In addition, patient-related factors were less investigated for their association with interval cancer. The aim of this study was thus to assess tumor and patient characteristics and predictors of interval cancer in a population from Israel.

**Aims & Methods:** This retrospective cohort study included all patients that were diagnosed with colon cancer in our institution between 2005–2014. Cases included patients with a previous colonoscopy within 1–10 years before the diagnosis of cancer, with either negative findings or benign polyps. Only full colonoscopies with at fair or good preparation were included. Interval cancer was defined on an individual basis, when cancer occurred within the recommended surveillance interval according to accepted guidelines. Cases were further stratified according to time since last negative colonoscopy (< 3 years, 3–10 years). Positive controls were cancer patients without previous colonoscopy, and "negative" controls were sex- and age-matched patients with two negative colonoscopies within the study period who were randomly selected on a 5:1 ratio. Tumor characteristics (location, staging) and patient-related features (age, gender, positive family history of colon cancer, aspirin use, diabetes, diverticulosis) were compared between cases and control groups.
Results: 845 patients were diagnosed with a colon cancer within the study period, and 83 cases (9.8%) were found to have interval cancer. Among them, 51 patients (61.5%) had negative findings at index colonoscopy, while 22 (28.5%) had either non-advanced adenomas (12%) or advanced adenoma (26.5%). Compared to "positive" controls with primary cancer (575 patients with full data), patients with interval cancer were older (84% above 60y vs. 65%, p = 0.03) and had proximal (caecal to splenic flexure) tumor location (57% vs. 34%, p = 0.0001), but gender (47% vs. 53% males) and tumor staging (78% vs. 70% in stage 0–2, p = 0.12) were not different. Compared to "negative" healthy controls (255 participants) without interval cancer and negative findings at index colonoscopy (51 patients) had higher prevalence of diabetes (33% vs. 15%, p = 0.002) but the same rate of family history, aspirin use and diverticularitis. There were no significant differences in all these characteristics between patients with interval cancer < 5 years and ≥5 years.

Conclusion: With patients interval cancer to be older and have proximal tumor location than patients with primary colon cancer, and have higher prevalence of diabetes. A close surveillance or the use of better endoscopic techniques (e.g. use of NBI (narrower retrieval time) should be considered for patients with these characteristics.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Fecal Immunochromatographic Testing (FIT) is currently used in most Canadian provinces to screen for colorectal cancer. Newfoundland and Labrador Colon Cancer Screening Program. 21,371 patients enrolled in the program between the ages of 50–74 and at average risk for colon cancer between July 1, 2012 and June 30, 2016. 16,152 participants returned their FIT tests. 1831 were positive on at least one FIT kit and underwent colonoscopy. The positive FIT values ranged from 100.0 to 541.07. The mean FIT was 942.3 (25th percentile: 145, 50th percentile: 260, 75th percentile: 576). Of the 1831 participants who had a colonoscopy 73 (4.0%) were found to have colorectal cancer and 1092 (59.6%) were found to have an adenoma.

Aims & Methods: The goal of this study is to assess the effectiveness of different FIT cut-offs and number of FIT tests for detecting adenomas and colorectal cancer.

Results: Data for this study were obtained in a prospective fashion using the Newfoundland and Labrador Colon Cancer Screening Program. 21,371 patients enrolled in the program between the ages of 50–74 and at average risk for colon cancer between July 1, 2012 and June 30, 2016. 16,152 participants returned their FIT tests. 1831 were positive on at least one FIT kit and underwent colonoscopy. The positive FIT values ranged from 100.0 to 541.07. The mean FIT was 942.3 (25th percentile: 145, 50th percentile: 260, 75th percentile: 576). Of the 1831 participants who had a colonoscopy 73 (4.0%) were found to have colorectal cancer and 1092 (59.6%) were found to have an adenoma. By using only one FIT test at a cut-off of 100, our program would have missed 8.2% of cancers. An additional 541 colonoscopies were required to detect these cancers. If we stratified patients according to number of FIT tests we found that 83.5% of colon cancers detected were positive on both FIT kits at a quantitative cut off of 100. If a FIT cut off of 200 was used and applied to our patients our program would have missed 12.5% of cancers.

Conclusion: Two FIT tests are more effective than one at screening. Patients with two FIT positive results are more likely to have colon cancer, an advanced adenoma and a simple adenoma. Further triaging of colonoscopy wait lists could be considered based on quantitative FIT values and number of positive tests. Provinces and health authorities need to be cautious when determining the FIT cut-offs and number of FIT tests for detecting adenomas and colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Serrated polyps (SPs) have been recognized as precursors of colorectal cancer (CRC), accounting for up to 30% of CRCs via the serrated neoplasia pathway. SPs are classified into hyperplastic polyps (HPs), sessile serrated polyps (SSPs) with or without dysplasia and traditional serrated adenomas (TSAs). The serrated polyp syndrome (SPS) is characterised by multiple SPs throughout the colon. We aimed to determine the prevalence of SPS in patients without metabolic syndrome (control group) and patients with metabolic syndrome, and to evaluate if pre-existing diabetes, dyslipidaemia, hypertension, smoking, obesity, and hypercholesterolaemia are associated with SPS. Hence, we determined a prevalence of SPS of 0% in our cohort. This project has been supported by the Czech Ministry of Health grant NT 13673 and MO 1012.

Disclosure of Interest: and further development is needed to better classify VUS (25%).

Early onset gastroenterological cancers lacking a positive family history do not support the suspect of familial syndromes.

Aims & Methods: We addressed the contribution of germline mutations to non familial early onset cancers. Patients with pancreatic, gastric, esophageal, duodenal and colorectal cancers were enrolled from 2015 to 2017 at the Gastrointestinal Personalized Medicine unit. Eligibility criteria were the juvenile onset and the negativity for clinical criteria of hereditary cancer syndromes. Early onset colorectal cancer was defined as <45 yrs. For the other cancers, the threshold was defined at 50. Eligible patients provided informed consent. Genes were sequenced by means of a validated Next Generation Sequencing panel of oncological susceptibility genes and confirmed by means of Sanger sequencing.

Results: Among 12 colorectal cancer patients (7F, 5M), NGS analysis showed 2: 2 MSH2 mutation and 1 MSH6 mutation in 11G5 occurring de novo, given the absence of family history; 3 variants of unknown significance (VUS) (2 MSH2 and 1 MLH1); and 7 were negative. Age-stratification revealed that, among those <35 years (n = 4), 1 had MSH2 gene mutation and 3 were negative. In the 36–40 age group (n = 3), 1 had MSH2 and 2 were negative. In the age group 41–45 (n = 5), MSH6 mutation and 2 VUS were found, alongside 2 negative results.

Among the colorectal cancers, 17% of patients had a de novo mutation of Lynch Syndrome, 25% had a VUS, and 58% were negative.

Among 2 pancreatic cancer patients (< 50 yrs, 2 F), one tested negative and the other had a VUS on PMS2.

Reporting performed on 1 esophageal cancer (46 yrs, M) was negative. 1 duodenal cancer (46 yrs, F) has a MSH2 mutation and 2 VUS (MSH6 and PMS2).

Conclusion: A significant percentage (17%) of early onset colorectal cancers resulted in Lynch Syndrome even when family history is not suggestive of hereditary cancer. We reliably infer the determinant role of genetics, even when the family history does not support the hypothesis. Elsewhere, our results suggest that the already known susceptibility genes seldom contribute to sporadic early onset cancers. Other genes and mechanisms may explain the early onset phenotype. Our data show that NGS is often non conclusive in early onset GI cancers, and further development is needed to better classify VUS (25%).

Introduction: Early onset gastroenterological cancers lacking a positive family history do not support the hypothesis of familial syndromes. Increasing evidence links the immune microenvironment, microbiota and tumor cell communication through the tumor microenvironment (TME) and inflammation. Histological analyses showed no difference about intratumoral immune infiltrate density on 11G5 and K12-infected mice. However, using our specific algorithm, we observed a significant increase of lymphoid follicle size in the gut of infected mice with the 11G5 strain compared to mice feeding with non-pathogenic K12 strain. Interestingly, follicle size was positively correlated with tumor volume, on the 11G5 infected group suggesting an association between pro-carcinogenic proprieties of this strain and gut immune response. In addition, we observed an increase of neutrophils (Ly6G cells) on mucosa and lymphoid follicle of mice infected with 11G5 compared to K12 and non-infected mice. These results can be linked with our in vivo optical imaging observations and our results about the increase of neutrophils chemo-attractants CXCL1 and CCL20 measured by qRT-PCR after infection. Analyses of T cells, macrophages, B cells and myeloid suppressive cells are in progress.

Conclusion: Here we can observe an increase of lymphoid follicle associated with tumor volume after colibactin-producing E. coli infection. Our first results suggest that neutrophils can be one of the immune cells implicated in this process. This work shows a link between immune microenvironment, pathogenic E. coli and tumor development.

P1749 INVESTIGATING THE DIRECT INTERACTION BETWEEN CD24 AND β-CATENIN IN INTESTINAL TUMORIGENESIS
N. Arber1, A. Fokra2, S. Shapira3, D. Kazanov4, F. Bedmy2, B. Eliì3, C. Varol1 1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel 2Tel Aviv Medical Center, Tel Aviv/Israel 3Gastroenterology, Tel-Aviv Sourasky Medical Center, Tel-Aviv/Israel

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: CD24 is a glycosylphosphatidylinositol-linked protein that functions as an adhesion molecule and is overexpressed at an early stage of CRC (Sagiv et al., 2006). The Wnt/β-catenin signaling pathway plays an important role in the CRC carcinogenesis process. C57BL/6.J mice carrying the ApaMin mutation develop ~24.3 ± 3.7 adenomas and several carcinomas in the small intestine by the age of 16 weeks compared to the ~7 ± 1.7 polyps that ApaMin/CD24-/- (double KO) mice developed. Mice colicoscopy showed a significant reduction in the number and size of polyps upon depletion of CD24 alleles. The ApaMin mice displayed severe splenomegaly (355 ± 68 mg) compared (141 ± 49 mg) in double KO mice similar to WT mice. Hb level in the ApaMin was 5.8 ± 2.5, significantly lower than in the double KO mice (8.2 ± 0.9) and their WT littermate.

Aims & Methods: We aimed to study the cellular interactions between CD24 and β-catenin, and effects of their interaction on intestinal tumorigenesis. CD24 inducible 293T-Rex cells previously developed in our lab (Shapira et al., 2011) and SW480 CRC cells stably transduced with CD24 (Naumo et al., 2014) were used to study this interaction in vitro. Co-immunoprecipitation and immunofluorescent staining were used to investigate the interaction between the two proteins. Far western blotting (FWB) analysis was used to confirm this direct interaction by probing the standard WB membrane with the purified CD24 protein.

Results: In vitro: Western blotting analyses showed that expression of CD24 in 293T-Rex cells induced the activation of β-catenin, while down-regulation of CD24 in SW480 cells caused a decrease in the level of active β-catenin. Cytoplasmic/nuclear fractionation showed that more active β-catenin entered the nuclei of CD24 on CD24 cells (clone 1) than in CD24 cells (clone 4). In addition, in both cell lines, TOP/FOP luciferase reporter assay showed a significant increase in Luciferase activity upon CD24 expression induction. Co-immunoprecipitation studies of CD24 and β-catenin indicated that these two proteins might be interacting. In addition, all HEK-293T cells and SW480 cells, immunofluorescent staining of CD24 and β-catenin showed that these two proteins co-localize on the cellular membrane. Furthermore, far western blotting analysis suggests that a direct interaction between the proteins exist.

Conclusion: 1. CD24 plays a major role in intestinal tumorigenesis. 2. CD24 interacts with the Wnt pathway by activating β-catenin. 3. CD24 interacts directly with β-catenin. 4. Down-regulation of CD24 may be an important aim in the therapy of CRC.

P1750 YM155 AS AN INHIBITOR OF CANCER STEMNESS SIMULTANEOUSLY INHIBITS AUTOPHOSPHORYLATION OF EGFR AND G9A-MEDIATED STEMMENESS IN EGFR-POSITIVE CANCER CELLS
C. Cheng1, A. Ho2
1Hematology And Oncology, Mackay Memorial Hospital, Taipei/Taiwan

Contact E-mail Address: aisheng49@gmail.com
Introduction: Cancer stem cells survive as the leading reason to tumor recurrence after tumor repressive treatments. Therefore, it is worth discovering specific and efficient inhibitors against cancer stemness for applications in reducing tumor recurrence. Previously, literature has indicated that YM155 can significantly reduce the stemness-derived tumorsphere formation of gastric carcinomas and suppress EGFR activity. However, the pharmaceutical mechanism of YM155 is not completely clear.
Aims & Methods: The aim of this study attempted to investigate the potential mechanism of YM155 against cancer stemness in EGFR-positive cancers. The tumorspheres derived from EGFR-mutant HCC827 and EGFR-wild-type HTCl116 and A549 cells expressing higher cancer stemness markers, CD133, were used as cancer stemness models.
Results: We found that higher EGFR autophosphorylation (Y1068) in HCC827-, A549-, and HCC116-derived tumorspheres compared to the parental cells, which induced tumorsphere formation through activating G9a-mediated stemness property. YM155 was demonstrated to inhibit the tumorsphere formation by unexpectedly blocking the autophosphorylation of EGFR and G9a-mediated stemness pathway. The chemical and genetic inhibitions of EGFR and G9a revealed the significant role of EGFR-G9a pathway in maintaining the cancer stemness property.
Conclusion: In conclusion, this study not only revealed that EGFR triggered the formation of tumorspheres through elevating the G9a-mediated stemness, but also demonstrated that YM155 inhibited the formation of tumorspheres by simultaneously blocking autophosphorylation of EGFR and activity of G9a as a potent anti-stemness agent against EGFR-positive cancers.
Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Promoter hypermethylation-induced epigenetic silencing of tumor related genes played a key role in the initiation and development of colorectal cancer (CRC). Using Methylated DNA Immunoprecipitation (McDIP), we identified that Fibroblast growth Factor 14 (FGF14) was preferentially methylated in CRC.
Aims & Methods: We aimed to investigate the epigenetic regulation and biological function of FGF14 in CRC. The expression of FGF14 in 10 CRC cell lines and 24 pairs of CRC tissues and paired adjacent normal tissues by real-time PCR. CRC cells were treated with DNA demethylating agent 5-aza-2-deoxycytidine (5-Aza). The methylated status of FGF14 in CRC cell lines and CRC tissues were determined by real-time MSP. The biological function of FGF14 in CRC was interrogated by cell viability assay, colony formation, immunofluorescence and flow cytometry, as well as in vivo study.
Results: FGF14 was downregulated or silence in all (10/10) CRC cell lines, while it was ready expressed in normal colonic tissues. The expression of FGF14 was significantly lower in primary CRCS as compared to their adjacent normal tissues (P < 0.01). The loss of FGF14 gene expression was restored by treatment with DNA demethylating agent 5-Aza. Re-expression of FGF14 in CRC cell lines inhibited colony formation, suppressed cell viability, and induced cell apoptosis via AMPK/mTOR pathway, accompanied with enhanced protein expression of cleaved caspase-3, cleaved caspase-7, cleaved caspase-9 and PARP. In xenograft mouse model, overexpression of FGF14 significantly reduced tumor growth (P < 0.001).

Conclusion: FGF14, which induces cell apoptosis via AMPK/mTOR pathway, is a novel tumor suppressor down-regulated by epigenetic inactivation.

TRANSCRIPTION FACTORS UPON ER STRESS IN THE LS174T P1756 UNBIASED ANALYSIS OF REGULATION OF Conclusion: POLD1 operates multiple cancers, associated with a somatic mutation of mismatch repair BRAF genes (either of MSH2, MSH6, PMS2) in 13.9% of CRC patients and 25.9% of GC patients. Mutation (detected in 33.2% of cases), that of mismatch repair genes (either of MLH1, MSH2, MSH6, PMS2) in 13.6%, POLE in 9.1%, and POLD1 in 4.5%, respectively, in the hypermutator group. Conclusion: Hypermutator was recognized in 5-10% of digestive system cancers, particularly in CRCs and GCs. Cases of hypermutator sometimes develops multiple cancers, associated with a somatic mutation of mismatch repair genes. Further research must be needed to clarify the characteristic of hypermutator of the digestive organs in the therapeutical aspects.

P1757 MICROBIOTA A NEW INDICATOR OF COLORECTAL CANCER (CRC) HETEROGENEITY
I. Sobhani1, B. Bergstein2, A. Ghoiizian3, S. Kennedy2
1Dept. De Hepato-Gastroenterologie, Universite Paris 12 Hospital H. Mondor Dept. of Hepato-Gastroenterology, Creteil/France
2Statistica, Csb, Institut Pasteur, Paris/France

Introduction: Location and somatic gene signature of CRCs may impact prognosis and therapy response. A relative specific CRC-related dysbiosis has been characterized.

Aims & Methods: The aim was to characterize colon microbiota in CRC patients regarding location, gene markers and outcome. Patients (N=173) signed consent forms. Deoxynucleotide (dNTP) library sequencing was performed on Illumina HiSeq2500 analysis of stool DNA: 72 CRC (35 sporadic-S, 19 Lynch-L), 87 asymptomatic subjects (normal colonoscopy), 14 first-degree healthy relatives from Lynch families. "MOCAI" pipeline was used, library sorted (Piled quality score 20 Alientrimmer v0.4) after exclusion of <50 Lm, human genes or phage sequences. Quality sequences were aligned (REFMG.V13) and most abundant genes constructed (MBMA program v0.1). The Shanam program (shaman.c3bi.pasteur.fr) was used. The number of bacteria was estimated (REFMG.V13). The linear model (GLM) was implemented in the DESeq2 R kit. Differences between Control (N=87) and CRCs (N=69), between L (N=19) and S CRCs(N=50), and between CRC (N=19) and Healthy Lynch relatives were obtained after interaction of age, BMI and gender was considered (GLM model). TSAs were defined when value was retained in the correction (Benjamini and Hochberg). The specific taxonomic composition of the control and CRC groups was subjected to random analysis (Caret’s R package) with two optimization parameters (precision and kappa) in the model.

Results: There was no difference for gender, age (p=0.08) and BMI (p=0.187) in the L and S CRCs. Significant differences were observed between Normal and CRCs, CRC-CRC and L-CRC, L-CRC and first degree relatives (family) based on the common component (similarity of sequences): 13 species differentiated Normal and CRCs, two were more prevalent in L-CRC. The panels of bacteria linked with location, MSI, Ras mutations, methylation phenotypes and survival were identified. No significant link was observed with TNM Staging: I (N=17, 2L and 1S), II (N=12, 5L and 7S), III (N=20, 10L, 10S), IV (N=22.1L, 21S). DFS might be dysbiotic dependent.

Conclusion: CRC dysbiosis is location-dependent. Several bacteria are associated with Ras mutation, MSI, and methylation status. They may directly or through microbiota impact the prognosis. Microbiota signature should be taken in consideration in trials.

2Dept Of Gastroenterology And Hepatology, Sapporo Medical University, Sapporo/Japan

Introduction: Colorectal serrated lesions (LSs) include hyperplastic poly (HP), traditional serrated adenoma (TSA) and sessile serrated adenoma/poly (SSA/P). SSA/Ps are well-known precursors of colorectal cancer (CRC) characterized by BRAF mutation and microsatellite instability (MSI), whereas the molecular characteristics of TSAs are not fully understood.

Results: By using an unbiased transcriptomics approach we identified transcription factors that are lost on protein level upon ER stress. Furthermore, our data suggests that the significant loss of the transcriptional regulator CtBP2 contributes to intestinal epithelial stem cell differentiation.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: We aimed to identify epigenetic alterations associated with the development of TSAs and to clarify the associations between clinical, pathological and molecular characteristics in colorectal lesions. The genome-wide DNA methylation status in TSAs consisting of protruding and flat components was analyzed by using Illumina HumanMethylation450 BeadChip, and changes in DNA methylation during the development of TSAs were identified. Methylation of identified genes and CIMP markers (MINT1, -2, -12, -31, p16 and MLH1) and BRAF/KRAS mutations were analyzed in 847 colorectal lesions and 61 samples of normal colonic tissue. Results: Fluorescence overlap between detection channels was used to express DNA methylation status in TSAs and CRCs, and that SMOC1 methylation is strongly associated with KRAS mutation and CIMP-low. Conclusion: Methylation of SMOC1 is associated with TSA development but is rarely observed in SSA/Ps. Immunohistochemical analysis of SMOC1 may be a useful marker to discriminate between SSA/Ps and TSAs. Our data suggests that SMOC1 methylation may play a role in the neoplastic pathways arising in TSAs.

2Department of Internal Medicine, Gaungnam Severance hospital, Seoul/Korea, Republic of
3Gastroenterology, Kyung Hee University Hospital at Gang Dong, Seoul/Korea, Republic of

Contact E-mail Address: drbeatris@hanmail.net

Introduction: The number of individuals partaking in colorectal cancer (CRC) screening is still to be low even after the implementation of the Korean Government’s National Cancer Screening Program for CRC. The aim of this study is to identify factors associated with partaking in CRC screening.

Aims & Methods: The Korean National Health and Nutrition Examination Survey (KNHANES) 2007 ~ 2010 datasets were used to develop a CRC screening participation screening score. 10,527 individuals aged ≥50 who completed the survey and not previously diagnosed with CRC were selected. Both logistic regression (LR) analysis and artificial neural network (ANN) were used to develop predictive models. Multilayer perception ANN was constructed based on 16 clinical variables. We then validated the models using the KNHANES 2011 and 2012 (n = 9586) datasets and compared them with each other.

Outcomes: Of 10,527 individuals selected, 57.0% (n = 6005) responded unscreened for CRC. Among various demographic and socioeconomic factors, for example, age, gender, smoking, income, education, level, private health insurance, self-reported depression, self-reported health status, and residence were found to be independently associated with CRC screening. LR analysis produced screening score (range 0–10.3), and a cutoff point of ≥5.5 defined 49% as unscreened for CRC and yielded area under the curve (AUC) of 0.626. When validated with KNHANES 2011 and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the area under the curve (AUC) of 0.626. When validated with KNHANES 2011 and 2012 datasets, the AUC of the defined LR model was 0.663, meanwhile the AUC of ANN based predictive model was 0.743.

Conclusion: The ANN produced better performing model than LR analysis based model in identifying population with low CRC screening participation. Sensible predictive models. Multilayer perception ANN was constructed based on 16 clinical variables. We then validated the models using the KNHANES 2011 and 2012 (n = 9586) datasets and compared them with each other.

P1760 CD24 PREDICTIVE LEVELS- A SIMPLE NOVEL BLOOD TEST TO IDENTIFY INDIVIDUALS WITH COLON CANCER MALIGNANCIES

N. Arber1, S. Shapiro1, D. Kazanov1, A. Fokina1, Z. Sally2, S. Zigdon2, J. Maayan1, L. Ari1, K. Ron1, L. Alissa1, I. Ofer1, E. Liberman1
1Health Promotion Center And Integrated Cancer Prevention Center, Tel Aviv Medical Center, Tel Aviv/Israel
2Tel-Aviv Sourasky Medical Center, Tel Aviv/Israel

Contact E-mail Address: nadira@tlmc.gov.il

Introduction: Background: CD24, a mucin-like cell surface molecule, highly expressed in solid tumors and hematological malignancies (HM) (Gastro 2006, Clin Can Res 2007, Can Res 2008). mAb to CD24 was found to inhibit the growth CD24 cancer cells (Gastro 2009). We have shown that a simple non-invasive blood test evaluating CD24 levels on PBL had good sensitivity and specificity for detecting colorectal neoplasia in subjects undergoing screening colonoscopy (Kraus et al., 2009).

Aims & Methods: We aimed to improve a simple, noninvasive blood test that could reliably identify individuals with different types of cancer. Blood was taken from patients with various malignancies (CRC, Pancreatic Cancer (PC), gastric cancer (GC), sarcoma and HM), that was confirmed by histology. Age, gender and ethnic matched healthy individuals served as controls. Good blood quality. They underwent an extensive workload at the Integrated cancer prevention center at Tel Aviv Medical Center (Eur J Intern Med. 2013) All samples were collected and processed identically. For each sample, 20,000 leukocytes were analyzed by flow cytometry for the expression of CD24. An initial template database was created using gates within the software to create a hierarchical population tree at the beginning of the screen. All additional analyses were accomplished after data acquisition have been completed. The template file include compensation adjustment. All data were collected in order to minimize fluorescence overlap between detection channels.

Results: The novel assay was improved significantly, distinguished healthy from CRC (Fig.1a) (P < 0.013), PC (Fig.1b) (P < 0.018), biliary tract (P < 0.45E-12), gastric (Fig.1c) (P < 0.003), and lymphoma (Fig.2a) (P < 0.002) and lymphoma (Fig.2b) (P < 0.002) patients. CD24 expression levels were higher by up to 25% in cancer cases as compared to normal subjects. The sensitivity and specificity for CRC were 79.2% and 74.7%, and for PC 70.0% and 75.9%, respectively.

Conclusion: Conclusion: CD24 expression in PBLs is a promising blood test for the early detection of CRC, PC, and HM.

Introduction: Colonoscopy is considered the gold standard for prevention and early detection of colorectal cancer (CRC), however its effectiveness is directly related to quality of bowel preparation. Two of the quality measures of colonoscopy, cecal intubation rate and adenoma detection rate, are both associated with adequate bowel preparation. Data on factors associated with quality of preparation using Picolax® are limited.

Aims & Methods: We aimed to evaluate factors associated with a good bowel preparation using Picolax® (Sodium picosulfate/magnesium citrate) in the Israeli heterogeneous population. Consecutive outpatients referred for colonoscopy were prospectively assessed by a nurse practitioner filling out a questionnaire. Hemoglobin or haematocrit, blood consumption, time of total preparation and time between end of prep to colonoscopy were evaluated. Quality was assessed using the Boston Bowel Preparation Score (BBPS). Bowel prep was considered "good" if BBPS was ≥6 and <21 in each segment or "bow" if BBPS was <6 or ≥21 in any colon segment. Results: A total of 452 patients were included in the study (M = 54%, mean age 56.5 ± 16.3 yrs), 366452 (81%) achieved a "good" bowel preparation, and 86 (19%) were classified as "not good." No significant difference was observed between genders and in terms of achieving a good bowel preparation (p = 0.77, p = 0.054). There was a significant difference among diabetics (n = 93, 20.6%) and non-diabetics (n = 359, 79.4%) in quality of the bowel prep. While 69.9% of diabetics achieved a good bowel preparation only 83.8% of non diabetics achieved a good bowel preparation (p = 0.004). In the univariate analysis, Bisacodyl had no effect on bowel preparation (p = 0.83) except in the diabetics, where the 3 tablets achieved 73.3 ± 1.9% (median = 5) vs. 43.1 ± 1.5 (median = 4) tablets fared better (p = 0.018). Other chronic diseases had no effect on bowel preparation. Drinking 3–7 vs 8–15 glasses of water achieved good preparation in 72.7% vs 83.5% of cases, respectively (p = 0.01). Time from end of preparation to colonoscopy -1.5 (median = 1.9) in quality significantly better prep vs ≥4 hrs (p = 0.002). In the multivariable model for prediction of quality of bowel preparation that included the time between sachets of picolax, number of water cups consumed, diabetes, gender, and age we found that all, excluding age, were good predictors of bowel preparation. Women had a better chance of achieving an adequate bowel preparation (OR1.68, p = 0.045, 95% CI = 1.01–2.79). Patients without diabetes had a better chance of achieving an adequate bowel preparation (OR = 2.05, p = 0.014, 95% CI = 1.16–3.65). Patients who had 5–9 hours between the 2 sachets of picolax had a lower chance of achieving an adequate bowel preparation as compared to those who had 9 to 24 hours between the 2 sachets (OR = 0.375, p = 0.009, 95% CI = 0.180–0.783). Lastly, drinking fewer than 8 cups lowers the chance of achieving an adequate bowel preparation (OR = 0.461, p = 0.003, 95% CI = 0.275–0.775).
Conclusion: Diabetics require a more intense bowel preparation aided by Bisacodyl, which does not help others. Time between both doses should exceed 8 hours and preparation should end no later than 8 hours prior to colonoscopy. Patients should be instructed to drink a minimum of 8 glasses of water with each dose of picolax.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1762 IMPROVED ADENOMA DETECTION WITH ELUXEO LINKED COLOR IMAGING (LCI) AS COMPARED TO THE TRADITIONAL WHITE-LIGHT HIGH-DEFINITION COLONOSCOPY—A RANDOMIZED CONTROLLED TRIAL

M. Szalai1, L. Oczella1, Z. Dubravskis2, A. Szepes3, L. Madacy3
1Endo-Kapszula Private Endoscopy Unit, Szekesfehervar/Hungary
2Gastroenterology & Endoscopy, Bacs-Kiskun Country Hospital
3Department Of Gastroenterology, Bacs-Kiskun County Hospital, Hungary, Endocam LTD, Szekesfehervar/Hungary

Contact E-mail Address: dr.szalai.milan@gmail.com

Introduction: Colonoscopy is the gold standard method of colorectal cancer and polyp screening, but polyps are missed during a colonoscopic examination at a rate that varies from 6% to 27%. Improved adenoma detection rates can be achieved with optimized endoscopic visualization methods. A recently developed new Fujinon endoscope system, Eluxeo carries a new function of electronic chromoendoscopy, Linked Color Imaging (LCI), that enhances the coloring and visibility of mucous membranes and blood vessels which are difficult to see with the conventional endoscopes. In our prospective randomized study, we evaluated the effectiveness of LCI, a new endoscopic visualization technique that may enhance image quality to improve colonic adenoma detection.

Aims & Methods: Up till now 247 eligible patients, elder than 45 years, admitted for screening outpatient colonoscopy were randomly enrolled to undergo high-definition white-light colonoscopy (WLC) or LCI colonoscopy during instrument withdrawal. The colonoscopic procedures were performed by three experienced endoscopists (median 7000 processor and with either the conventional high-definition Fujinon EC 590Z or a new EC 760Z VS Eluxeo colonoscope. All of the colonoscopic procedures were made under Propofol deep sedation guided by an anesthesiologist team. The minimum withdrawal time was defined as more than 6 minutes. All colonoscopies were routinely assisted with pure CO2 insufflation. The primary outcome parameter of our study was to assess and compare the polyp and adenoma detection rate with the two endoscopic technology.

Results: A total of 247 patients were randomized (mean age 58.7 years), 101 patients enrolled in the WLC group and 146 patients in the LCI group. No significant differences have been observed in the patient demographics and colonoscopy withdrawal time between the two groups. Patients having both colorectal polyps and adenomas were detected more frequently in the LCI group than in the control group: 60.9% and 43.8% versus 55.4% and 33.6% respectively, however, this was not statistically significant (p = 0.32 and 0.16). In contrast, the total number of adenomas relative to the total number of polyps detected with LCI withdrawal were significantly higher than with conventional WLC: 105 vs. 82, respectively (p < 0.04).

Conclusion: The LCI enhancement of the Fujinon Eluxeo colonoscopy system was superior to the conventional HD-WLC in detecting patients with colorectal adenomas, which was mainly due to the ability of the more sensitive detection of minute (less than 5 mm) adenomas.Study was supported by ECT grant GINOT 2.1.1.15-2015-00128.

Contact E-mail Address: alexandra.kalmar@gmail.com

Introduction: Long non-coding RNAs (lncRNAs) play role in colorectal cancer (CRC) development, however, lncRNA expression profile in CRC and its relation to the epigenetic regulatory system still remain incomplete. Aims & Methods: We aimed the perform whole genomic lncRNA expression to the epigenetic regulatory system still remain incomplete. We examined a total of 245 colon samples. Of those, there were 101 colorectal carcinoma tissues, for 70 of which paired normal mucosa was also examined. A total of 74 colorectal adenomas were examined. Quantitative real time PCR was used to measure AAT expression. Clinical evaluation of AAT levels was demonstrated in terms of disease-free survival (DFS) and overall survival (OS).

Results: Alpha-1-antitrypsin expression was found to be significantly associated with longer DFS (p = 0.028). Cox proportional hazard regression model using univariate analysis revealed that high status alpha-1-antitrypsin expression is a significant factor for disease-free survival (DFS) (p = 0.002) and overall survival (OS) (p = 0.026) in patients with colorectal cancer. Kaplan-Meier survivor curves demonstrated that low alpha-1-antitrypsin expression is significantly associated with longer DFS (p = 0.001) and also OS (p = 0.021).

Conclusion: Our data suggests that alpha-1-antitrypsin expression could be considered as a potential biomarker of unfavorable prognosis for colorectal cancer.

Disclosure of Interest: All authors have declared no conflicts of interest.

1. Pérez-Holanda et al. Serum concentration of alpha-1-antitrypsin is significantly higher in colorectal cancer patients than in healthy controls, BMC Cancer 2014, 14:355.
neoplastic, and therefore should be resected, hyperplastic polyps never turn malignant and do not require specific endoscopic therapy. The aim of our prospective, randomised study was to distinguish subcentimetric hyperplastic and adenomatous polyps based on Fujinon FICE versus Eluxeo BLI electronic chromoendoscopic technology with high-definition colonscopy with and without optical magnification.

Aims & Methods: In order to create a video and digital picture library of polyps, patients undergoing screening or diagnostic colonoscopy were considered for inclusion. Patients with at least one histologically verified <10mm polyp were included. Two videos and a still picture of each polyp were recorded with and with 50x optical zoom at standard white-light (WLI), and with FICE-light or BLI-light were recorded with Fujinon EC 590Z and EC760Z endoscopes and stored in an anonymized database. One of the video-library was created by each of our 5 colonoscopic experts (ML, SZM, OL, DZS, and SZA) independently and randomly reviewed all of the cases with a standardized electronic questionnaire. In each case, all of the observers had to assess the color, the vascularization and the surface of the polyps, and the pit pattern was also assessed (i.e. Kudo classification). Finally, with the definition of confidence (low/medium/high on VAS), the histological prediction and the final decision has been clarified on each lesion as neoplastic or non-neoplastic (hyperplastic).

Results: Up till now 115 polyps were enrolled and recorded into our digital web-based library, 59 were assigned into the FICE and 56 into the BLI group. All of the detected 115 polyps were endoscopically removed and histologically analyzed and this was regarded as gold standard. The overall accuracy with WLI versus FICE versus BLI technology of the 5 experts without zoom and with 50x magnification to differentiate between hyperplastic and adenomatous lesions were 77.62% and 84.31%, vs. 74.58% and 83.90% vs. 89.84%, respectively. There was an excellent correlation between the histopathological results and our KUDO classification with both FICE and BLI technology. Both 50x times optical zoom and BLI technology were independently and significantly improved our confidence rate that was associated with a more precise histopathological prediction as compared to non-zoom, WLI or FICE endoscopic polyp assessment.

Conclusion: The new electronic chromoendoscopic technology with Eluxeo BLI significantly improved the reliability of the histology prediction as compared to Fujinon EC590Z and EC760Z technology. High-confidence predictions for the differentiation of neoplastic and non-neoplastic polyps with Eluxeo BLI electronic chromoendoscopy provide a potential for real-time endoscopic diagnosis of hyperplastic polyps to support resect and discharge strategy. (Study was supported by ECT grant GB/15-5/0128)

symptomatic condition (lumbago; lesion site (Rx/Rx/Rb), 1/2/19 cases; mean tumor size, presence of biopsies, metastatic enzymes; biopsy positivity rate, 11/14 (78.5%); presence/absence of endoscopic ultrasonography, 11/11 cases; and M/S/M/MP, 1/19/1 cases. The TNM classification of the cases was as follows: T1a, 16 cases; T1b, 5 cases; T2, 1 case; N1, 1 case; and M1, 1 case. The treatment was palliative (curative intention/endoscopic mucosal resection with ligation/endoscopic mucosal resection/endoscopic submucosal dissection/surgery/desert/therapy in 5/7/2/1/1 case. Of 19 endoscopic treatment cases, 15 corresponded to a tumor diameter of ≤10 mm, with negative resection margin and vascular invasion as criteria for curative resection, and 3 cases of unknown stumps were recognized. In the EMRL group, all cases were negative. In all the cases except the case of other-disease death, it elapsed without recurrence. Both surgical cases showed a positive vascular invasion, and one case was a confirmed N1, but neither of the patients survived without a recurrence. In the case with hepatic and bone metastases, medication was administered, and the effect was temporarily effective, but the patient died a year and a half later.

Conclusion: Endoscopic treatments are considered appropriate for rectal NETs with low malignancy, and they are being used as a selective eradication method.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1772 Efficacy and Safety of Twelve Chemopreventive Regimens for the Recurrence of Colorectal Adenomas: A Network Meta-Analysis

H. Chen
Jiangsu Province Hospital, Nanjing/China

Contact E-mail Address: chenhun686@hotmail.com

Introduction: Although various pharmacological agents have been trialed for recurrent colorectal adenomas, their comparative effectiveness remains unknown. We conducted both direct and indirect comparisons of twelve chemopreventive agents for recurrent colorectal adenomas.

Aims & Methods: MEDLINE, EMBASE, Scopus, Web of Science, and Cochrane Central Register of Controlled Trials, and ClinicalTrials.gov were searched up to May 1, 2016. RCTs were assessed by a random-effects model within a Bayesian framework. Agents for each outcomes were ranked by surface under the cumulative ranking area (SUCRA). This study is registered with PROSPERO, number CRD42016041923.

Results: 33 RCTs were eligible, enrolling 44,647 participants treated by twelve regimens: 9 aspirin and other NSAIDs, 11 antioxidants, 4 dietary supplements, and 2 calcium with vitamin D. For each regimen, findings were significantly better for sulindac plus metformin, ursodeoxycholic acid (UDCA), aspirin plus calcium with vitamin D, and difluoromethylornithine (DMFO) plus sulindac. For recurrent colorectal adenomas, findings were significantly better for sulindac plus difluoromethylornithine than other tested agents. Aspirin/NSAIDs was more effective than placebo in both pairwise (OR, 0.73 [95% CI, 0.59 to 0.90]) and network analysis (0.75 [95% CI, 0.57 to 0.98]). Subgroup analysis showed the highest probability of aspirin (≤10 mg/L) to be the most efficacious agent among all NSAIDs (SUCRA = 71.7%). For safety profiles, the top three ranked agents were metformin (86.8%), antioxidants (82.0%) and dietary supplements (65.9%), but none reached statistically significant when compared with placebo. Aspirin/NSAIDs performed the worst (16.4%) with significantly more serious adverse events than placebo (pairwise OR, 1.25 [95% CI, 1.14 to 1.38]; NMA OR, 1.25 [95% CI, 1.12 to 1.44]). Other regimens were not significantly different to each other in both pairwise and network comparisons, these agents include antioxidants, dietary supplements, calcium as well as folic acid.

Conclusion: For individuals with presumed increased risk of CRC, moderate-to-large dose aspirin/NSAIDs is a reasonable combination therapy both effective for recurrent colorectal adenomas. Future studies are required to provide more precise estimates of the optimal NSAIDs with an effective dose and low adverse events. We also suggest the further evaluation of NSAIDs-associated combination regimens and other novel agents (e.g., melatonin) in the chemoprevention of CRC.

Introduction: Colorectal cancer (CRC) is the third most common cancer worldwide. However, CRC is an indolent disease that likely influences survival. The Glasgow Prognostic Score (GPS) was proposed to predict survival in CRC patients by the combination of the level of serum C-reactive protein (CRP) and albumin, which are indicators of systemic inflammatory response and nutritional status respectively. Growing evidence suggested that GPS was served as an independent prognostic index in a variety of malignant cancers. For patients with CRC, the GPS system was also widely studied, but the results were controversial.

Aims & Methods: To investigate the correlation between GPS and prognosis of patients with CRC to further clarify its clinical significance. A comprehensive search was performed. Embase, Web of Science, Web of knowledge, and Chinese National Knowledge Infrastructure was performed to identify eligible studies, from which the risk of overall survival (OS) and cancer-specific survival (CSS) were extracted. A random-effect model was adopted to combine hazard ratio (HR) and 95% confidence interval (CI). Heterogeneity and publication bias among studies were assessed.

Results: 25 articles with a total of 5660 participants were included. The pooled results indicated that elevated GPS was associated with poor OS (HR = 2.83, 95%CI: 2.00–4.00, P < 0.01) and CSS (HR = 1.94, 95%CI: 1.51–2.49, P < 0.01). This correlation was confirmed both in primary operable and advanced inoperable patients. Increased GPS was also closely related to advanced tumour-node-metastasis (TNM) stage (odds ratio [OR] = 1.44, 95%

**P1775 COST EFFECTIVENESS OF THE FIRST SURVEILLANCE COLONOSCOPY IN POPULATION WITH ADVANCED COLORECTAL POLYPS OR MULTIPLE POLYPS FROM COLORECTAL CANCER SCREENING PROGRAM**

L. Carot1, M. Gonzalez2, M. Battile1, A. Burron2, X. Bessa Casarras3, M. Andreu Garcia4, A. Alvarez-Urturi1

Introduction: The implementation of the CRC screening program has generated an increase in surveillance colonoscopies. However, the intermediate-high risk group that included advanced lesions (size >10 mm, villous component or high grade dysplasia) or the presence of 3 or more polyps, has a low incidence of metachronous risk lesions when performing colonoscopy at 3 years according to the current recommendations. Identifying predictors of metachronous lesions would provide a better risk stratification and improve the efficiency of surveillance programs.

Aims & Methods: We aimed to identify the cost effectiveness of the first surveillance colonoscopy and the predictive factors of metachronous lesions at 3 years in individuals with advanced lesions or ≥3 polyps detected at baseline screening colonoscopy. This was an analysis of all cases with advanced polyps and/or multiplicity from CRC screening program population of Barcelona detected at baseline colonoscopy during the years 2010–2011 and with a performed colonoscopy after 3 years. Epidemiological and clinical data of all individuals were collected as well as the morphological data of all polyps. For the statistical study, a bivariate analysis and logistic regression were performed.

Results: 638 cases were identified, with mean age of 64 years. 342 were men (62.6%). 23.8% required more than one colonoscopy for the complete removal of all polyps. A complete surveillance colonoscopy at 3 years was performed in 518 cases (82%) with an average surveillance time of 38 months [15–75]. Mean fecal hemoglobin was 440 ng/ml. 51.8% suffered from hypertension, 15% from diabetes mellitus, 46.5% from dyspepsia and 12.3% from chronic obstructive pulmonary disease. 45.8% of individuals were overweight (BMI ≥25) and 34.7% were obese (BMI ≥30). Surveillance colonoscopy was normal or with low-risk polyps in 420 cases (80.1%); and advanced polyps or multiplicity were identified in 98 cases (18.9%). 73 advanced adenoma in 59 cases (11.4%), ≥3 adenomas in 62 cases (11.1%), ≥3 adenomas and/or serrated in 71 cases (13.7%). The presence of ≥3 adenomas and/or serrated polyps was the only variable that was associated with increased risk of the diagnosis of advanced adenomatous or serrated lesions in surveillance colonoscopy (p < 0.001).

Conclusion: In individuals with advanced polyps and/or multiplicity the incidence of metachronous risk lesions at 3 years is low. Assessment a baseline colonoscopy with complete removal of all the polyps could allow to increase the interval of surveillance, maintaining and ensuring the compliance of the surveillance colonoscopy at 3 years in the cases with multiplicity in the baseline colonoscopy.

Disclosure of Interest: All authors have declared no conflicts of interest.
Conclusion: The transition to population-based program resulted in the improve-ment of target population participation followed by increase in colorectal neo-plasia detection.

**P1778** LONG-TERM OUTCOMES OF ENDOSCOPIC SUBMUCOUS DISSECTION FOR EARLY CANCER AND HIGH GRADE DYSPLASIA IN COLORECTUM

P. Zhou1, T. Chen2
1Endoscopy Center, Zhongshan Hospital, Fudan University, Shanghai/China

**Contact E-mail Address:** chentao66@yahoo.com

**Introduction:** Although endoscopic submucosal dissection (ESD) is a widely accepted treatment for colorectal neoplasia, little is known about large consecutive studies evaluating long-term outcomes of early cancer and high grade dysplasia. We assessed the efficacy and safety of ESD for early cancer and high grade dysplasia in colorectum and evaluated the long-term outcomes, including local recurrence and metastasis.

**Aims & Methods:** We performed a retrospective analysis of data collected from 5 consecutive patients with 520 colorectal early cancer and high-grade dysplasia treated with ESD between January 2007 and December 2013. Histology and patient data were collected during an average follow-up time of more than 5 years to determine tumor stage and type, resection status, complications, tumor recurrence, and distant metastasis.

**Results:** The overall rates of en bloc resection, complete resection, R0 resection, major complications were 94.4%, 91.5%, 89.2% and 2.1%, respectively. Large tumors and snare-assisted ESD were independent factors of piecemeal resection. ESD of colon tumors increased the risk for complications. During the follow-up period, all patients remained free from metastasis. However, local recurrence occurred in 4 patients (0.8%); large tumors and piecemeal resection were risk factors.

**Conclusion:** ESD is effective and safe for resection of early cancer and high grade dysplasia in colorectum and long-term outcomes are favorable. ESD is indicated for the treatment of colorectal early cancer and high grade dysplasia to obtain curative resection and prevent the local recurrence.

**P1779** LOW UPTAKE OF PSYCHOLOGICAL THERAPIES AMONG PATIENTS WITH IRRITABLE BOWEL SYNDROME IN SECONDARY CARE

O. Craig1, C. Black2, L. Houghton2, A.C. Ford1
1Leeds Gastroenterology Institute, St. James’s University Hospital, Leeds/United Kingdom
2Leeds Institute Of Biomedical & Clinical Sciences, St. James’s University Hospital, Leeds/United Kingdom

**Contact E-mail Address:** ofcraig@gmail.com

**Introduction:** Patients with irritable bowel syndrome (IBS) often have co-existent mood disorder and psychological illness. Meta-analyses of randomised controlled trials consistently demonstrate that psychological therapies, such as cognitive-behavioural therapy (CBT) and hypnotherapy, are effective treatments for IBS. In the UK the National Institute for Health and Care Excellence (NICE) recommends considering the use of these in patients with no response to pharmacological therapies, and for refractory symptoms.

**Aims & Methods:** We performed a cross-sectional survey to examine willingness to engage with psychological therapies. We collected complete symptom data from consecutive patients of the WMC study. Were analyzed data about gastric emptying time (GET), small bowel transit time (SBTT), colonic transit time (CTT) and whole gut transit time (WGET).

**Results:** One patient could not swallow the capsule, and of the 14 patients completing the study, 8 reported GI symptoms. Compared to non-symptomatic patients, those with GI symptoms showed significant delayed transit in the stomach, colon and whole gut (table 1). However, small bowel transit did not significantly differ. GI dysfunction was not correlated with H&Y score in this small study used the risk factor score was correlated, suggesting a pan-enteric problem in symptomatic individuals. There was a significant correlation between the Wexner constipation score and the whole gut transit time (WGET).

**Conclusion:** GI symptoms were prevalent in symptomatic but not non-symptomatic PD. The results of Wireless Motility Capsule did not differ between non-symptomatic patients and controls.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1780** GUT SYMPTOMS AND TRANSIT DISTURBANCE IN PARKINSON’S DISEASE ARE PAN-ENTERIC BUT NOT UBQUITOUS: A WIRELESS MOTILITY CAPSULE STUDY

V. Passananti, N. Zarate Lopez, R. Sweis, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

**Contact E-mail Address:** valentinapassananti@gmail.com

**Introduction:** Symptoms of gastrointestinal dysfunction are among the most common non-motor complaints in Parkinson’s patients. These may involve muscles from the oropharynx to the anorectum, and the autonomic and enteric nervous system are often involved, resulting in secondary bowel dysmotility.

**Aims & Methods:** The objectives of this study were to evaluate a technology measuring the spectrum of gut dysfunction, the Wireless Motility Capsule (WMC), in Parkinson’s disease. We also wanted to correlate transit measures with gastrointestinal symptoms. Fifteen PD patients and 7 controls (table 1) were included. PD severity were scored with the modified Hoehn and Yahr (H&Y) staging scale. GI symptom burden was identified by Wexner constipation score and Gastroparesis Cardiomyopathy Index (GCSI). Acidity, motility and transit data were obtained, as standard, by WMC. All medications affecting pH and motility, including L-dopa, were discontinued for 5 days before and for the duration of the study. GET, small bowel transit time (SBTT), colonic transit time (CTT) and whole gut transit time (WGET).

**Results:** One patient could not swallow the capsule, and of the 14 patients completing the study, 8 reported GI symptoms. Compared to non-symptomatic patients, those with GI symptoms showed significant delayed transit in the stomach, colon and whole gut (table 1). However, small bowel transit did not significantly differ. GI dysfunction was not correlated with H&Y score in this small study used the risk factor score was correlated, suggesting a pan-enteric problem in symptomatic individuals. There was a significant correlation between the Wexner constipation score and the whole gut transit time (WGET).

**Conclusion:** GI symptoms were prevalent in symptomatic but not non-symptomatic PD. The results of Wireless Motility Capsule did not differ between non-symptomatic patients and controls.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

</tbody>
</table>

**Conclusion:** We have shown that Parkinson’s patients with gut symptoms have both upper and lower complaints. Symptomatic PD patients also have markedly delayed transit times throughout the whole gut compared to asymptomatic PD patients and controls. Whilst severity of constipation is related to delayed colonic transit no such relationship was present between gastroparesis symptoms and gastric emptying. The implication is that treating symptomatic Parkinson’s patients should address the whole gut, whether with prokinetics or dual therapy.

**Contact E-mail Address:** piovino@unisa.it

**Introduction:** Bloating and abdominal distension are common and bothersome symptoms of gastrointestinal disorders (FGID). Recent studies demonstrated that an impairment in psychological therapies as their first-choice treatment option than those with mild or moderate symptoms (7.7% versus 21.7%, P<0.10).

**Conclusion:** Despite high levels of psychological comorbidity and NICE recommendations, patients with IBS in a specialist clinic were generally reluctant to consider psychological therapies such as CBT or hypnotherapy. Those with anxiety, depression, somatof orm-type behaviour, or severe symptoms were no more willing to consider these therapies than those without.

**Disclosure of Interest:** All authors have declared no conflicts of interest.
the handling of gas is a relevant underlining mechanism in FGID patients with bloating. The combination of symptoms associated with predominant FI in these patients is lacking.

Aims & Methods: Our aim is to study the relationship between the defecation pattern, the severity of bloating and the abdominal girth measurements in FGID patients consulting for bloating as primary complaint with/without visible abdomen being not responsive to dietary advice. We performed a prospective, multi-center study of patients with severe abdominal bloating (VAS score ≥ 4 on a 100-mm scale) as primary complaint with/without visible abdominal distension. Patients were recruited at 4 gastroenterology outpatient clinics in Italy. Combinedaccording to the Rome III criteria. All patients were prescribed a lactose-free diet supplemented by dietary advice according to the NICE guidelines for two weeks. A belt around the abdomen at standardized sites provided assessment of abdominal girth measurements. During the 2-week run-in period patients completed a daily diary log including abdominal bloating and pain/discomfort scores (100-mm VAS), Bristol Stool Form and stool frequency. At randomization visit, all patients filled in a questionnaire on adequate relief of bloating on a Likert scale and a further abdominal bloating 100-mm VAS were recorded. Subsequently patients provided assessment of abdominal girth two hours after a meal. All patients reporting insufficient adequate relief of abdominal bloating at the end of the run-in period underwent a standardized balloon expulsion test (BET) scored as either successful or failed. A straining questionnaire was also administered.

Results: 76 patients (66 female, 39.3 ± 12.2 mean age, 6 IBS-D, 6 IBS-M, 30 IBS-C, 9 IBS-U, 6 FC, 16 FB, 3 FD) completed the 2-week run-in period. A significant negative correlation was found between adequate relief and both bloating and abdominal girth changes (r = -0.53 and -0.52, p < 0.001, respectively). 37/76 (70%) patients reported inadequate relief (worse or no improvement). Among the non-responders the vast majority (68%) failed the BET. Multiple regression analysis showed that BET (successful or failed) as dependent variable, was significantly related to bloating severity. No relationship was demonstrated for abdominal girth changes, FGID diagnosis and straining questionnaire.

Conclusion: In this prospective, multicenter trial simple diet advise was of benefit in approximately 30% of FGID patients consulting for severe bloating. In the non-responders outlet dysfunction was prevalent and correlated with subjective bloating perception. The study is ongoing, but our data may support bowel retraining as potential treatment option for functional bloating.

Introduction: Faecal Incontinence (FI) is a common and socially disabling condition, more prevalent among females over 50 years old. Detailed anatomical and physiological assessment of each patient is important to determine the correct cause of FI and selection the most appropriate therapy. Conventional and High Resolution (HR) Anorectal Manometry (ARM) is a useful tool to categorize anal and/or rectal dysfunction in addition to provide physiological assessment of both anal sphincters and rectum.

Aims & Methods: To evaluate symptoms and anorectal function of patients affected by FI, we included 358 patients with FI (77% female (F) and 23% men (M), mean age 63 range 22–92 year) referring to the outpatient unit of Digestive Pathophysics of S. Giovanni Addolorata Hospital, Rome from January 2006 to December 2016. Clinical presentation (history, symptom profile and severity) and anorectal physiological evaluation (digital examination, manometry, rectal sensory testing, balloon evacuation test) were analyzed. The manometric parameters obtained with conventional and HR-ARM were: resting pressure, squeeze pressure, rectal compliance, rectal sensitivity and the anorectal pattern during the defecatory maneuvers.

Results: Out of 358 patients (32%) reported both FI and difficult evacuation stool, while also urinary incontinence UI (47%). Proctological surgery (n 122, 34%), pelvic surgery (n 77, 21%) and traumatic anal or vaginal delivery. Furthermore, patients with FI referred difficulty evacuating stools, too. In fact in patients with dysosyme-type constipation, the FI may be confused with an enuresis. Finally we observed these prevalent manometric alterations: combined dysfunction IAS and EAS, and rectal hypersensitivity. Manometric findings could help physicians to identify appropriated patients for a biofeedback therapy.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Bile acid malabsorption (MAB) is a common and frequently under-investigated cause of chronic diarrhoea. Most of the cases of chronic diarrhoea after excluding organic disorders are labelled as functional diarrhoea or irritable bowel syndrome (IBS). The most commonly used diagnostic test is Schematic homocholic acid taurine (SeHCAT) scan due to its sensitivity, specificity, safety and low cost. However this test is not frequently used in the algorithm for the diagnosis of chronic diarrhoea.

Aims & Methods: We aimed to evaluate the usefulness of SeHCAT scan in evaluating patients with chronic diarrhoea and identify potential risk factors associated to MAB. We retrospectively reviewed all patients who had SeHCAT scan between June 2014 and October 2016 in a University Hospital. BAM was defined as SeHCAT retention of less than 15%. We collected the following variables: demographic characteristics, IBS-D/Rome III criteria, duration of diarrhoea (months), stool culture, parasitologic investigation of stool specimens, background of comorbid gastrointestinal and other comorbid conditions, positive HLA-DQ2 and DQ8 haplotype.

Results: 137 patients referred to clinic for chronic diarrhoea underwent SeHCAT testing over the reviewed period. 42M; 95F, median age 46 y (range 0–76) median BMI 25.3 kg/m2 (range 17.3–39.7), 70.4% of patients had IBS-D Rome III criteria, median duration of diarrhoea 48 months (95% CI 43.0–59.24). Background of co-morbid gastrointestinal conditions 45.3% (62/136), other co morbid conditions 55.3% (75/136). History of previous positive stool culture 13%, other pathologies and parasitologic investigation of stool specimens 13% (17/136). Percentage of positive HLA-DQ2 and DQ8 haplotypes were 27.8% (35/126) and 10.2% (13/127), respectively. SeHCAT test was positive for BMA in 48.9% (67/137); 25.4% (mild 10–15%); 31.3% (moderate 5–10%), and 43.5% (severe < 5%). Patient characteristics between positive and negative SeHCAT test were similar (Table 1). Interestingly, patients with SeHCAT test exhibited longer periods of diarrhoea.

Introduction: The cause of IBS is unclear; however, food intolerances share many features with this condition. Consumption of FODMAPs has been shown to induce IBS-type symptoms (Shephard 2008) and clinical trials have shown that a low FODMAP diet can improve symptoms in this patient group (Halmos 2014). However, FODMAP intake is not higher in IBS than in health (Bohn 2013) and it is not proven that the outcome of low FODMAP diet is better than standard dietary advice in this condition (Bohn 2015). Recent, experimental research has shown that psychological factors are associated with increased postprandial symptoms in IBS patients (Zhu 2013, Van Oudenhove 2016). This study was designed to assess the relative importance of, and interaction between, psychiatric disease, social stress and diet in the aetiology of IBS in the general community.

Aims & Methods: This population based study tested the hypothesis that high FODMAP intake increases the risk of IBS more in individuals with psychiatric disease and/or life event stress than other members of the community.

Subjects aged 16–74 were randomly selected from five South-Chinese communities. All subjects completed questionnaires by face-to-face inquiry with investigators including demographic information, gastrointestinal symptoms (Rome III, dietary intake (food frequency chart validated in Chinese community), psychiatric disease (HADS), life event stress (LES) and quality of life (SF-8).

Results: From 1999/2015 (94.7%) members of the community that completed study questionnaires, 117 (5.9%) had IBS by Rome III criteria. The IBS group ingested less lactose than the "No-IBS" group (P = 0.024). Intake of other FODMAPs was similar in both groups (P = 0.346). Compared to the "No-IBS" group, individuals with IBS had a greater likelihood of depression (OR 1.5 (0.97–2.32); p < 0.05), anxiety (2.84(1.84–4.39), p < 0.001), recent life event stress (1.5(1.03–2.20); P = 0.03) or medical and/or surgical co-morbidity (OR 2.9(1.30–5.45), P < 0.001). The IBS group also had lower quality of life (P < 0.001).

Joint effects analysis demonstrated that high FODMAP intake alone was not associated with abdominal symptoms; however, IBS was more common in those with a high FODMAP intake and concomitant psychosocial factors known to increase visceral sensitivity to digestive dysfunction (Zhu 2013). (ClinicalTrials: NCT0126597)

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: A large proportion of patients with irritable bowel syndrome (IBS) suffer from anxiety or depression, but the associations with pathophysiologic findings and overall symptom reporting are not clear.

Aims & Methods: We included 772 patients with IBS (Rome III criteria) who attended a university hospital-based outpatient clinic specialized in functional GI disorders between 2005 and 2015. The patients underwent examinations to investigate oro-anal transit time (OATT) and visceral sensitivity (rectal balloon distension and a lactulose challenge test), and they also completed questionnaires to assess depression, anxiety and somatic symptoms. In addition, we recorded the presence of anxiety or depression by a validated self-rated assessment tool (HSCL-25), which asks patients to indicate whether any of the listed symptoms are present during the last week. In patients with a positive response, an interview was performed to assess the presence of more severe symptoms at the subscale level. The patients were stratified into a low stress group (<57), high stress group (57–85), and very high stress group (>85) with regards to the total QOL index score.

Results: Based on validated HAD cut-off levels (≥8), anxiety and depression were present in 55% and 26% of the IBS patients, respectively. More women were anxious (p < 0.001), but for depression no gender differences were detected (p = 0.76). IBS patients with anxiety or depression were younger (p < 0.001), and more commonly reported sexual and/or physical abuse (p < 0.001) than IBS patients without anxiety or depression. The presence of anxiety or depression did not differ between IBS subgroups based on the predominant bowel habit (p = 0.41, p = 0.18). For an overview of comparisons of data from questionnaires and pathophysiological examinations, see table 1. Both the presence of anxiety and of depression were associated with reports of more severe GI and extraintestinal symptoms, GI-specific anxiety, fatigue, and lower sense of coherence. Regarding pathophysiologic examinations, the findings were more inconsistent. OATT was similar between groups, as were stool form and frequency. Visceral sensitivity tended to be higher in patients with anxiety, and depressed patients reported more severe pain during the lactulose challenge.
test. Quality of life (IBSQOL) was reduced for all domains in patients with anxiety and depression (p < 0.001 for all comparisons).

Conclusion: The presence of anxiety and depression seems to clearly potentiate the already substantial disease burden in IBS patients. However, the association with other pathophysiologically findings is less distinct. This group of patients with complex and severe symptoms will benefit from a holistic management approach.

Introduction: Irritable bowel syndrome (IBS) and lactose intolerance may co-exist and readily cause diagnostic confusion due to similar symptomatology (1,2).

Aims & Methods: This study aims to examine the incidence of lactose intolerance in healthy controls and in subjects diagnosed with IBS based on Rome III criteria, as an effort to investigate the association between IBS and lactose intolerance. The patient population consisted of individuals between 18 and 80 years of age who attended between June-December 2013. Patients diagnosed with IBS based on Rome III criteria comprised the IBS group, and subtypes of IBS. Control subjects were healthy volunteers over 18 years of age with no IBS-like symptoms. All participants ingested 25 g of lactose dissolved in 250 ml of water within 5 minutes after 8 hours of fasting, in order to evaluate the lactose intolerance. The presence of anxiety and depression seems to clearly potentiate this overlap and this association with increased health impairment. Study Support: The Rome Foundation

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Although correlations between features of irritable bowel syndrome (IBS) have been reported, these were based on between-person rather than within-person variation. We investigated the longitudinal within-person correlations between features of IBS.

Aims & Methods: We used a longitudinal cohort of 276 IBS patients, who filled out questionnaires one annualy over five years on the following features: gastrointestinal (GI) symptom severity (GSRS), quality of life (QOL), GI specific anxiety (VSI), general anxiety and depression (HADS), coping resources (CRI), and sense of coherence (KASAM). For each participant, scores were centered on their own mean, and within-person correlations were computed for all pairs of features.

Results: Aggregate within-person correlations are shown in figure 1. Within-person correlations were strong for the triad GI symptom severity, GI specific anxiety, and QOL (r: 0.47 to 0.64). Another set of features was comprised of general anxiety, depression, coping resources, and sense of coherence (r: 0.39 to 0.57). Within-person correlations between the two sets were weak (r: 0.00 to 0.37). However, within-person correlations tended towards bimodal distributions across the population, especially for GI symptom severity and depression (r ~ 0.6 for half of participants, and r ~ 0.4 for the other half).

Conclusion: Here we show that, within individual IBS patients, GI symptom severity is strongly correlated with GI specific anxiety and QOL, but not with four other psychological features. The presence of negative within-person correlations in some individuals may imply a lack of relation, but could also signal long-term causative processes.

Conclusion: Among this patient population, IBS-C patients with higher symptom severity reported greater impairments in HRQoL. These results indicate that symptom severity may be an important consideration for disease management and emphasise the need for IBS-C treatments that improve both symptom burden and Nestle and has given scientific advice to Grünenthal.

P1790 IRRTABLE BOWEL SYNDROME WITH CONSTIPATION: IMPACT OF SYMPTOM SEVERITY ON HEALTH-RELATED QUALITY OF LIFE: A POST HOC ANALYSIS OF DATA FROM TWO PHASE 3 TRAILS OF LINACLODITE A. Marciniak1, Y. Mo2, J. Ma3, J. L. Abel2, R. T. Carson2

1Allergan plc, Marlton/United Kingdom
2Allergan plc, Jersey City/United States of America/NJ
3Allergan plc, Bridgewater/United States of America/NJ

Contact E-mail Address: Anne.Marciniak@Allergan.com

Introduction: Irritable bowel syndrome with constipation (IBS-C) is a chronic gastrointestinal disorder associated with significant impairment in health-related quality of life (HRQoL). However, information on the impact of IBS-C symptom severity on patients' HRQoL is lacking.

Aims & Methods: This post hoc analysis assessed the burden of IBS-C on HRQoL according to symptom severity among adult patients meeting the modified Rome II criteria for IBS based on baseline data from two Phase 3 clinical trials of linaclootide (C5H11O4·H2O) evaluated based on disease-specific Irritable Bowel Syndrome Quality of Life questionnaire (IBS-QOL) and the EuroQol-5-Dimension (EQ-5D). The IBS-QOL includes eight subscales (dysphORIA, activity interference, body image, health worry, food avoidance, social reaction, sexual, relationships), with total and subscale scores calculated on a 0-100 scale and higher scores indicating better IBS-specific HRQoL. A within-person change of ≥10 points is considered clinically meaningful. The EQ-5D assesses five dimensions of general health (mobility, self-care, usual activities, pain/discomfort, anxiety/depression) and generates an overall index score of between 0 (worst possible health state) and 1 (best possible health state); a within-person change of 0.05 is considered meaningful. Symptom severity was assessed during the pre-treatment period based on the global symptom score (GSS) on a scale of 0–4, where 0 = no symptoms and 4 = very severe symptoms. Data from both trials were pooled and compared to non-IBS population, the IBS population was younger (mean-age 44.7 ± 14.5 years; p = 0.004) and predominantly female (66%; p < 0.001). Apart from reporting more frequent GI point difference) subscales (Table). Patients with GSS ≥3 also had a lower EQ-SD index score compared to those with GSS < 3 (0.67 vs 0.72) (Table). Women reported a slightly lower mean total IBS-QOL score compared to men, but had a notably lower score (14-point difference) on the body image subscale (Table). No difference in mean EQ-SD score was observed between sexes. IBS-QOL total and EQ-SD index scores were similar between patients aged < 65 and ≥65 years, though the younger subgroup generally had lower scores on the IBS-QOL, including on the food avoidance and sexual subscales (Table).

Table
symptoms, IBS subjects also reported more somatic symptoms; 103 (34%) had abdominal pain at least 3 times/week, 232 (76%) subjects reported sensation of bloating at least 3 times/month, and 232 (76%) scored > 7 on PHQ-12, indicating high somatic symptom burden (p = 0.001 for all). They also had poorer self-rated overall health, more general body pain, and more health-related impairment of social activities (p < 0.001 for all). See Table 1 for details. IBS subjects also reported more frequent visits to the doctor compared to the non-IBS population, both for non-GI and GI related problems; 241 (79%) vs. 3133 (56%) reported seeing a doctor for GI problems (p < 0.001 for all). IBS subjects also reported higher frequency of visits to gastroenterologists, gynaecologists and surgeons in secondary care; p < 0.001 for all. The use of medication for pain (both subscribed and over the counter), GI related symptoms, depression and anxiety was increased amongst subjects with IBS, as was the rate of abdominal surgery (p < 0.001 for all), appendectomy excluded. See table 1 for details.

**A776 United European Gastroenterology Journal 5(5S)**

**Results:** Significant differences were recorded in the levels of PT (median: 14.5 vs 13.1 sec, p = 0.005) and aPTT (median: 28.7 vs 26.4 sec, p = 0.005) between patients and controls, respectively. Prolongation over the upper limit of normal of PT (>14sec) was most common in IC patients, 67.9% vs 18.2% (p = 0.005) as well as the prolongation of aPTT (>35sec), 12.2% vs 6.2% (p = 0.46). The presence of LA was characterized as weakly present in 5 of 6 patients with the aPTT prolongation (9.6%, normalized LAC ratio: 1.2-1.5) and moderately present in 1 patient (1.9%, normalized LAC ratio: 1.5-2.0).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Ischaemic colitis (IC) encompasses a number of clinical entities resulting in insufficient blood supply to the colon. The incidence of adverse outcome in patients with IC remains high.

**Aims & Methods:** We conducted a multicenter retrospective cohort study including consecutive patients with IC diagnosed between January 2013 and December 2016, according to the Modified Brandt and Boley criteria (clinical, colonoscopy, pathology consistent with IC and negative culture). The following data were collected: age, sex, clinical symptoms, comorbidities, organ failure, laboratory parameters associated with vitamin K in patients with IC and to compare them with a group of controls (individuals with known predisposing factors for IC but without evidence of the disease). This study was carried out in the context of a study evaluating thrombophilia among IC patients. The present study used the same study groups as the latter. 2.**History of malignancy, systemic inflammation, liver disease-cirrhosis or use of anticoagulants were exclusion criteria. The incidence of adverse outcome in patients with IC remains high.

**Conclusion:** Individuals fulfilling the Rome IV criteria for IBS in the general population have increased GI and non-GI healthcare utilization in primary and secondary care, excess non-GI symptom burden and impaired QOL. [Support: Rome Foundation]

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1792 ISCHAEMIC COLITIS AND VITAMIN K DEFICIENCY: A HYPOTHESIS**

Department Of Gastroenterology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa/Greece

**Contact E-mail Address:** atsimperidis@yahoo.com

**Introduction:** Ischaemic colitis (IC) is the most common vascular disease of the colon, although its exact pathophysiological mechanisms remain unclear. 1.**Aims & Methods:** The aim of this study was to evaluate routine coagulation parameters associated with vitamin K in patients with IC and to compare them with a group of controls (individuals with known predisposing factors for IC but without evidence of the disease). This study was carried out in the context of a study evaluating thrombophilia among IC patients. The present study used the same study groups as the latter. 2.**History of malignancy, systemic inflammation, liver disease-cirrhosis or use of anticoagulants were exclusion criteria for both patients and controls. The control group was using more antithrombotic drugs compared to the patients’ group, while no difference was observed in any other drug category. Fifty-six cases of IC (admitted from September 2007 until June 2011 at the tertiary Department of Gastroenterology in central Greece) and 44 controls (subjects admitted for upper gastrointestinal bleeding, choleclocholithiasis, and colon polyps) with known predisposing factors for IC were included in this study. The coagulation indices measured were: prothrombin time (PT), activated partial thromboplastin time (aPTT) and lupus anticoagulant (LA). Venous blood collected from all IC patients and controls at the second or third day of hospitalization (1-3 days from the onset of symptoms).
P1795 THE RISK PREDICTIVE VALUES OF ACG CLASSIFICATION IN A COHORT OF ISCHEMIC COLITIS - REFINING THE DEFINITION OF MILD DISEASE
1Gastroenterology, Hospital Central do Funchal, Funchal/Portugal 2Institute of Gastroenterology And Hepatology, North Lisbon Hospital Center, University of Lisbon, Lisbon/Portugal 3Gastroenterology, Hospital São João, Oporto/Portugal

Contact E-mail Address: carolinarabaptistasmimoes@gmail.com

Introduction: Although most cases of colon ischemia (IC) are mild and self-limiting, when severe it implies high mortality rates. We aimed to evaluate the risk predictive value of classification of disease severity proposed by American College of Gastroenterology (ACG) guidelines (2015), created to provide a management algorithm for these patients and select the level of care.

Aims & Methods: A retrospective multicenter study was conducted on adult patients with definite IC (clinical, colonoscopic, pathologic and culture criteria), between 2013 and 2016. Data was collected on clinical presentation, comorbidities, organ failure, management and outcome. Each case was classified according to ACG guidelines after assessment of the number of risk factors (gender, systolic blood pressure <90 mmHg, heart rate >100 beats per min, abdominal pain without rectal bleeding, BUN > 20 mg/dl, Hgb < 12 g/dl, LDH > 350 U/l, serum sodium <136 mEq/l, WBC > 15 x 10⁹/cmm). Patients were then classified as mild (0 risk factors (RF)), moderate (1 - 3 risk factors) and severe (3 risk factors or any of the following: perineal signs, pneumonia or portal venous gas, gangrene on colonoscopic examination and pan-colonic or isolated right-colon ischemia involvement on imaging by colonoscopy or computed tomography).

Results: 349 cases with the clinical diagnosis of IC were analyzed. 193 patients met the inclusion criteria of definitive diagnosis of IC (62.7% females; mean age 72 years ±13). ACG classification of mild, moderate and severe disease was attributed respectively to 21% of patients (0 intra-hospital deaths), 45% (2 deaths) and 34% (12 deaths). The number of ACG RF was: 40% with 0 RF, 8% with 1, 9% with 2, 15% with 3, 16% with 4, 8% with 5, 4% with 6 and 1% with 7. No patient with 0 or 1 RF died. Only 1 patient with 2 RF died. The remaining 13 deaths were caused by shock due to 3 RF. The univariate analysis revealed a statistical correlation between RF and intra-hospital or 30-day mortality as well as 34% (12 deaths). The number of ACG RF was: 40% with 0 RF, 8% with 1, 9%

Conclusion: No patient in this cohort with less than 2 ACG RF died, suggesting that the ACG classification as mild disease may include 0 and 1 risk factor without changing the prognosis. Short-term mortality risk increases significantly from clinical trial data, and validated health utility values were assigned to terminal health states. Base-case analysis was performed to determine incremental cost-effectiveness ratios (ICER) for both rifaximin strategies. Threshold analysis assessed rifaximin pricing at contemporary willingness-to-pay (WTP) levels per quality adjusted life year (QALY). Appropriate sensitivity analyses were conducted. Analysis was performed with a 1-year time horizon from societal and payer perspectives.

Results: Based on the average acquisition cost of rifaximin (USD $29.78/pill), second-line rifaximin could be cost-effective from a societal perspective (Table 1). However, at contemporary WTP thresholds neither rifaximin strategy was cost-effective from a payer perspective despite greater effectiveness than TCA alone. Depending on WTP, a 12-62% price reduction (USD $18.46-26.34/pill) would enable the first-line TCA followed by second-line rifaximin to be more cost-effective than a TCA-only strategy (Table 1). An 84-88% price reduction (USD $3.53-$4.71/pill) would enable first-line rifaximin followed by second-line TCA to be more cost-effective than TCA-only, though first-line TCA followed by second-line rifaximin would remain the more cost-effective strategy. Our model was robust in tornado analysis and most influenced by rifaximin treatment interval. Sensitivity analysis on rifaximin retreatment interval suggests that current pricing may be based on longer retreatment intervals than those found in clinical literature (Fig 1a). Sensitivity analysis with a lower TCA responder rate could enable first-line rifaximin to be the preferred strategy, albeit at a reduced price (Fig 1b).

Conclusion: Rifaximin is an effective therapy for IBS but is less cost-effective than TCA as currently priced. We propose an evidence-based pricing strategy which would maximize the cost-effectiveness of rifaximin in IBS-D patients.

P1796 HOW COST AFFECTS THE TREATMENT CHOICE FOR IRREVERSIBLE BOWEL SYNDROME WITH DIARRHEA PATIENTS: A COST-EFFECTIVENESS ANALYSIS OF TRICYCLIC AGENTS AND RIFAXIMIN
E. D. Shah, E. Andraska, J. Li, S. Zhang, W.D. Chey
Division Of Gastroenterology, University of Michigan, Ann Arbor/United States of America

Contact E-mail Address: ershah@med.umich.edu

Introduction: Drug pricing and third party payer coverage exert a profound effect on access to prescription therapies in patients with irritable bowel syndrome with diarrhea (IBS-D). We performed a cost-effectiveness analysis to assess the trade-offs associated with treating IBS-D patients with a tricyclic agent (TCA) or rifaximin.

Aims & Methods: We constructed a decision analytic model evaluating three treatment strategies for IBS-D in the United States healthcare system: first-line therapy with TCA-only, first-line rifaximin followed by second-line TCA for nonresponders, and first-line TCA followed by second-line rifaximin for nonresponders. This model accounted for direct and indirect costs of therapy (Medicaid NADAC database and Healthcare Blue Book) and work-productivity loss (published literature and US Bureau of Labor) with a 3% per annum discount rate. Rifaximin was administered in 4-month treatment cycles based on published clinical experience. Responder and discontinuation rates were derived from clinical trial data, and validated health utility values were assigned to variable Surgery group (N = 18) Conservative group (N = 27) P value
Age(year) 66 67 .688
Sex(M/F) 10/8 14/13 .807
Purpose of colonoscopy
Therapeutic 9 27

Sigmoid 14 7
Descending 0 1
Transverse 2 3
Ascending 0 10
Endoscopic clipping .007
Yes 8 23
No 10 4

Results: Diagnostic cases in purpose, sigmoid colon in location and non-clipping purposes. Although the incidence is very low, perforation is one of the most serious complications. It is important to decide whether to try endoscopic clipping or to perform prompt surgical management.

Aims & Methods: We retrospectively reviewed charts of all patients who experienced colonoscopy-associated perforation in a single center between May 2009 and July 2015, and totally 45 patients were enrolled.

Table: The risk factors surgical treatment in colonoscopy-associated perforation

Results: Diagnostic cases in purpose, sigmoid colon in location and non-clipping purposes. Although the incidence is very low, perforation is one of the most serious complications. It is important to decide whether to try endoscopic clipping or to perform prompt surgical management.

Aims & Methods: We retrospectively reviewed charts of all patients who experienced colonoscopy-associated perforation in a single center between May 2009 and July 2015, and totally 45 patients were enrolled.

Table: The risk factors surgical treatment in colonoscopy-associated perforation
FUNCTIONAL GASTROINTESTINAL DISORDERS

Introduction:
Despite diagnostic criteria and effective management options for functional gastrointestinal disorders (FGID), confidence in managing these disorders in primary care is low, and long waiting lists for specialist care are common. New models which efficiently transfer specialist-held expertise to primary care practitioners is needed.

Aims & Methods:
We aimed to explore and describe the patient and primary healthcare provider (PHCP) experience of a novel non-specialist-dependent algorithm-based approach to the diagnosis and management of FGID (ADAM-FGID). Consecutive patients triaged to the ‘routine waitlist’ of an Australian public hospital Gastroenterology Department over 2 years, with non-specific gastrointestinal symptoms (no alarms) were randomised to waitlist control or the algorithm group (n = 43). Patients were phenotyped using FGID symptom criteria and a validated stool questionnaire. All others were classified using Rome III criteria and received a letter explaining their FGID diagnosis and dietary/psychological management options. Patients with alarm signs were triaged to a specialist consultation. All others were sent a depersonalised letter outlining the intervention and a research survey.

Conclusion:
In colonscopy-associated perforation, immediate endoscopic clipping decreases the possibility of operation and shows better clinical outcomes, especially when endoscopic clipping decreases the possibility of operation and shows better clinical outcomes.

Introduction: Colonoscopy every 5 years, starting at the age of 40 years, is considered the first-choice screening strategy in first-degree relatives (FDR) of patients with colorectal cancer CRC, as these individuals are considered at higher risk of developing CRC than average-risk individuals. However, this practice has a low adherence and remains opportunistic. Recently, it has been suggested that annual fecal immunochromatographic testing (FIT) might be a valid alternative to colonoscopy in this setting. However, there are scarce data regarding cost-effectiveness of these strategies from the perspective of healthcare services.

Aims & Methods: This study was aimed to compare the cost-effectiveness of annual FIT and colonoscopy every 5 years, to reduce CRC mortality, in FDR of patients with CRC. A Markov model was constructed to simulate the efficacy and cost of annual FIT (cut-off 10 µg Hb/g feces) or colonoscopy every 5 years of

1First-line rifaximin strategy was dominated (less effective and more expensive) than a second-line rifaximin strategy at all price points. ICER = incremental cost effectiveness ratio; QALY = quality adjusted life year; TCA = tricyclic antidepressant; IBS-D = irritable bowel syndrome with diarrhea; USD = US dollar.
previously unscreened FDR, starting at age 40 years and ending at age 75. A 5-year assumption for each strategy was assumed. The model was adjusted to the incidence of CRC in Spain and real prevalence of advanced adenoma and CRC in the familial-risk population (https://dx.doi.org/10.1371/journal.pmed.1002008.g001). The main outcomes were quality-life-year (QALY) gained comparing current, lifelong burden of colonoscopy, lifetime number of colonoscopy complications, and the incremental cost-effectiveness ratio (ICER). We applied a willingness-to-pay threshold of €25,000 per QALY gained. Data from a prospective EuroQol survey carried out on 920 Spanish patients at different disease stages were used for QALY measurement. Sensitivity analysis was performed to evaluate the robustness of the model.

Results: In a hypothetical cohort of 10,000 asymptomatic FDR, annual FIT and colonoscopy every 5 years were cost-effective over no screening. Taking no screening as the reference, FIT for annual CRC screening and colonoscopy every 5 years was 1989 and 4472 euros QALY, respectively. Compared to no screening, annual FIT and colonoscopy every 5 years reduced CRC mortality by 59% and 81%, respectively. The annual FIT strategy saved 33% of colonoscopies and was associated with a lower number of complications compared to colonoscopy every 5 years. The results were robust in sensitivity analyses.

Conclusion: Assuming a 50% adherence, annual FIT is less costly than colonoscopy every 5 years for CRC screening and reduces mortality in the familial-risk population. These data suggest that FDR of patients with CRC could be included in organized nationwide FIT-based screening programs.

Introduction: Faecal occult blood test (FOBT) is a non-invasive and easily performed test which has demonstrated to reduce CRC incidence and mortality in the populations. Faecal calprotectin (FCP) has good evidence for detecting precancerous lesions for colorectal cancer screening.

Aims & Methods: To evaluate and compare the diagnostic accuracy of the combination of FOBT plus FCP versus each test alone in symptomatic patients referred for diagnostic colonoscopy. A total of 171 patients who completed colonoscopic investigations and returned stool samples were prospectively recruited and included in the final analysis. FOBT was performed by SENTi FIT 270 test (Sentinel Diagnostics, Milan, Italy) and FCP by the EliA Calprotectin immunoassay (Sentinel Diagnostics, Milan, Italy) and FCP by the EliA Calprotectin immunoassay (Sentinel Diagnostics, Milan, Italy). The main endpoints for the ROC curve analysis were:

Results: 171 patients (42.7% female; median age 62 years, IQR: 51–68) were included. 37 (21.6%) had relevant colonic pathology. The most frequent indications for colonoscopy were previous episode of rectal bleeding in 71 (42%) patients, change of bowel habits in 28 (16%) and anaemia in 22 (13%). Diagnostic accuracy of FOBT, FCP and combination of both are summarized in table 1.

AuROC curves for relevant colonic pathology were 0.777 (95% CI: 0.708–0.837; P < 0.0001) for FOBT, 0.692 (95% CI: 0.617–0.760; P = 0.005) for FCP and 0.748 (95% CI: 0.685–0.810; P < 0.0001) for combination of both tests respectively. Combination of both tests have a significant better diagnostic accuracy compared to either test alone (P = 0.043 vs FOBT and P = 0.002 vs FCP) with a higher NPV. No significant difference was observed between FOBT and FCP (P = 0.243).

Conclusion: Our model based on combination of FOBT and FCP has a better diagnostic accuracy performance compared to each test alone for the detection of relevant colonic pathology. Because of high NPV, performing FOBT and FCP in symptomatic patients before colonoscopy could be a feasible strategy in order to avoid unnecessary procedures.

P1801 CLINICAL PRACTICE, MONITORING, AND PATIENT SAFETY DURING PROCEDURAL SEDATION IN FIVE COUNTRIES

R. Saunders1, J. Davis1, R. Weissbrod2, P. Krane3, J. R. Lightdale4, R. Whitaker5

Introduction: Procedural sedation is considered an integral part of gastrointestinal endoscopy in many countries. The use of sedation does, however, vary internationally and can present patient safety concerns. It has been questioned whether trials assessing patient safety in endoscopy can be generalized worldwide and whether comparisons in sedation and adverse events across countries are valid.

Aims & Methods: We conducted an international survey to examine procedural sedation practices and the incidence of adverse events (AEs) during procedural sedation in France, Germany, Italy, UK, and USA. Data collection from providers (nurses, physicians, and anesthesiologists) was via online surveys. Respondents were screened to assure that they had the expertise and experience to complete the survey. The survey covered topics such as guidelines, sedation agents, monitoring, patient throughput, and AE incidence, treatment, and outcomes as defined by World SIVA. Data analysis took a global approach by subgroup analysis by location.

Results: 101 providers completed the survey, with 20 responses per country, excepting the USA with 21. More than 62% of responders were gastroenterologists and anesthesiologists. The main sedation agents employed were midazolam (93 responders), propofol (90), fentanyl (75), ketamine (57), and meperidine (15). Respondents from France reported higher ketamine and lower fentanyl use than other countries (p < 0.03). Standard of care monitoring was generally reported to be comprised of pulse oximetry plus blood pressure and/or heart rate. Capnography use varied by country, and was standard of care for 46% of responders (ranging from 15% in Italy to 67% in the US). The most desired property of a monitoring modality across all countries was one that “provides an early warning of patient compromise”.

“Data displays and alarms relating to clinical events” was ranked second globally and in all countries apart from Italy. All respondents reported experience with patient safety issues in the last year, with hypotension the most common (67), followed by mild desaturation (63), bradycardia (63) and prolonged desaturation (52). AE incidence was influenced by monitoring modalities used. Among German responders, for example, 7 of 11 who did not use capnography as standard of care reported severe oxygen desaturation events versus 0 of 9 who routinely use it (p = 0.005). Providers also differed in their reported adverse event incidence. Gastroenterologists most commonly reported mild oxygen desaturation to occur, while anaesthesiologists and nurses reported hypotension to be the most common AE experienced during procedural sedation (Table).

Conclusion: Clinical sedation practices are relatively consistent across countries, as are the occurrence of adverse events. Pulse oximetry monitoring is almost universally used during sedation, while capnography use is more variable. The reported severe oxygen desaturation events compared to other countries for the ROC curve analysis.

Disclosure of Interest: R. Saunders: Rhodri Saunders is the owner of Coreva Scientific GmbH & Co KG, which has received consultancy fees from Medtronic Inc and Covidien AB. R. Weissbrod: Rachel Weissbrod is an employee of Medtronic Inc. P. Krane: Peter Krane has advised for multiple pharmaceutical and medical device companies. He did not receive any remuneration for work performed on this research project.
Aims & Methods: We analyzed database records for 40,644 participants aged 55 to 64 years, who between 2014 and 2015, underwent screening colonoscopy in 24 centers of population-based PCSP. We used the ESGE guideline definitions to calculate values of all seven key performance measures. We compared key performance measures within the PCSP against proposed standards on the program and center level. Data on adequacy of bowel preparation was routinely assessed with the Boston Bowel Preparation Scale, whereas data on patient experience with the validated GastroQnet questionnaire (2). Data on complication rates were collected from the National Health Fund database and Personal Identification Number Registry.

Results: Overall, on the program level, all minimum standards for colonoscopy key performance measures were met. Rate of adequate bowel preparation was 92.1% for the whole program, ranging 80.9–99.2% per individual center, with 7 centers (29.2%) not reaching minimum standard of 90% and 9 centers (37.5%) reaching the target standard of 95%. Cecal intubation rate was 97.4% (range 93.4–99.4%), with all centers reaching minimum standard of 90% and only one center not reaching target standard of 95%. Adenoma detection rate was 29.9% (range 19.1–39.1%), with 7 centers (29.2%) not reaching minimum standard of 25%. Appropriate polypectomy technique was applied in case of 90.9% 6 to 9 mm polyps (range 64.3–100%) with only 2 centers not reaching minimum standard of 80% and 48.2% of 4 to 5 mm polyps (range 0–100%) with only 6 centers reaching minimum standard of 80%. Target standard of 90% was reached in 15 centers for polyps 6 to 9 mm in diameter and only 2 centers for polyps 4 to 5 mm in diameter. For the whole program, 7-day hospitalization rate after screening colonoscopy was 0.3% (122 cases) and 30-day all-cause mortality rate was 0.02% (9 cases). Gastroen questionnaire coverage is assumed to be 100%, however the response rate was 65.3% (range 7.6%–81.8%), with painful colonoscopy rate of 19.2%. No minimum standard is set, however target standard of 90% of procedures with measured patient’s experience was not met. Appropriate post-polypectomy surveillance, based on the European guidelines, was proposed in 95.4% of cases (range 84.9–99.7%). Target standard of 95% was met in 15 centers, the minimum standard is not set.

Conclusion: Monitoring ESGE performance measures for colonoscopy is feasible in colonoscopy programmatic screening setting. 6 of 7 performance measures were easy to monitor with PCSP database, however monitoring complications needs further development to avoid extracting data from external registries. PCPS meets proposed minimum standards on program level, however some centers need additional interventions to meet the quality standards. Applying appropriate polypectomy technique for polyps ranging from 4 to 5 mm in diameter

**P1802 PERFORMANCE OF THE MOTUS PURE-VU SYSTEM - A NOVEL DEVICE FOR ACHIEVING ADEQUATE BOWEL PREP IN POORLY PREPARED PATIENTS**

P.D. Siersma, K. Van Keulen, H. Neumann, M.C.W. Spaander

1Gastroenterology & Hepatology, University Medical Center Gastroenterology & Hepatology - Gastroenterology & Hepatology, University, Nijmegen/Netherlands
2Interventional Endoscopy Center, J. Medicinische Klinik Und Poliklinik, Universität Erlangen-Nürnberg, Mainz/Germany
3Gastroenterology & Hepatology, Erasmus Medical Center Rotterdam, Rotterdam/Netherlands

**Contact E-Mail Address:** kelly.vankeulen@radboudumc.nl

**Introduction:** The success of colonoscopy depends on the quality of the bowel preparation, which is estimated to occur in as many as 25% of colonoscopy procedures. The MOTUS GI Pure-Vu™ System (Tirat Carmel, Israel) is an FDA cleared device designed to improve visualization in an inadequately prepared colon. It is a novel device that facilitates video-enhanced cleaning. This study aims to evaluate the performance of the Pure-Vu System in cleansing a poorly prepared colon, assess the system’s usability, patient satisfaction and safety. Forty-seven cases were planned to be enrolled at three clinical sites, of which 32 had completed the study so far. Pure-Vu was used in subjects with an adequate cleansing level (BBPS > 2 for all 3 colon segments) from 25%; CI 95% [11%, 43%] at baseline to 100%; CI 95% [89%, 100%] after Pure-Vu use and the cecum was reached and visualized in all study cases (i.e., 100%; CI 95% [89%, 100%]). Mean post-treatment BBPS score was 8.5 (range 3.2–8.8 vs. 0.8 vs. 3.2–3.2) prior to Pure-Vu use. Physicians were satisfied with the device’s general use and ease of use and found it in most cases acceptable to good or excellent to insert and to angleate the colonscope. No major difficulties were experienced when performing polypectomy. Thirty of 32 (94%) patients reported that they would recommend Pure-Vu to their friends and family members who need a colonoscopy. Thirty (94%) of the patients found the overall bowel preparation as very tolerable (55%) or acceptable (39%). Seven patients (21%) had a previous colonoscopy procedure reported that the Pure-Vu bowel preparation was more tolerable as compared to their previous colonoscopy preparation and 14% of the patients reported it to be about the same.

**Conclusion:** Patient satisfaction and safety. Forty-seven cases were planned to be enrolled at three clinical sites, of which 32 had completed the study so far. Pure-Vu was used in subjects with an inadequate prepared colon which may help to improve the overall quality of colonoscopy.

**P1803 THE EUROPEAN SOCIETY OF GASTROINTESTINAL ENDOSCOPY KEY PERFORMANCE MEASURES FOR COLONOSCOPY IN THE POLISH COLORECTAL CANCER SCREENING PROGRAM**

M. Bugajski, P. Wieszczyn, R. Jurczak, M. Kaminski

1Department Of Gastroenterological Oncology, The Maria Sklodowska-Curie Memorial Cancer Centre and Institute of Oncology, Warsaw, Poland, Warsaw/Poland
2Department Of Gastroenterology, Hepatology And Oncology, Medical Center for Postgraduate Education, Warsaw, Poland, Warsaw/Poland

**Contact E-Mail Address:** marek.bugajski@gmail.com

**Introduction:** Recently, the European Society of Gastrointestinal Endoscopy (ESGE) published guidelines on key performance measures for colonoscopy (1). We analyzed feasibility of monitoring these measures and whether the proposed standards were met in the Polish Colonoscopy Screening Program (PCSP).

**Aims & Methods:** We analyzed database records for 40,644 participants aged 55 to 64 years, who between 2014 and 2015, underwent screening colonoscopy in 24 centers of population-based PCSP. We used the ESGE guideline definitions to calculate values of all seven key performance measures. We compared key performance measures within the PCSP against proposed standards on the program and center level. Data on adequacy of bowel preparation was routinely assessed with the Boston Bowel Preparation Scale, whereas data on patient experience with the validated GastroQnet questionnaire (2). Data on complication rates were collected from the National Health Fund database and Personal Identification Number Registry.

**Results:** Overall, on the program level, all minimum standards for colonoscopy key performance measures were met. Rate of adequate bowel preparation was 92.1% for the whole program, ranging 80.9–99.2% per individual center, with 7 centers (29.2%) not reaching minimum standard of 90% and 9 centers (37.5%) reaching the target standard of 95%. Cecal intubation rate was 97.4% (range 93.4–99.4%), with all centers reaching minimum standard of 90% and only one center not reaching target standard of 95%. Adenoma detection rate was 29.9% (range 19.1–39.1%), with 7 centers (29.2%) not reaching minimum standard of 25%. Appropriate polypectomy technique was applied in case of 90.9% 6 to 9 mm polyps (range 64.3–100%) with only 2 centers not reaching minimum standard of 80% and 48.2% of 4 to 5 mm polyps (range 0–100%) with only 6 centers reaching minimum standard of 80%. Target standard of 90% was reached in 15 centers for polyps 6 to 9 mm in diameter and only 2 centers for polyps 4 to 5 mm in diameter. For the whole program, 7-day hospitalization rate after screening colonoscopy was 0.3% (122 cases) and 30-day all-cause mortality rate was 0.02% (9 cases). GastroQnet questionnaire coverage is assumed to be 100%, however the response rate was 65.3% (range 7.6%–81.8%), with painful colonoscopy rate of 19.2%. No minimum standard is set, however target standard of 90% of procedures with measured patient’s experience was not met. Appropriate post-polypectomy surveillance, based on the European guidelines, was proposed in 95.4% of cases (range 84.9–99.7%). Target standard of 95% was met in 15 centers, the minimum standard is not set.

**Conclusion:** Monitoring ESGE performance measures for colonoscopy is feasible in colonoscopy programmatic screening setting. 6 of 7 performance measures were easy to monitor with PCSP database, however monitoring complications needs further development to avoid extracting data from external registries. PCPS meets proposed minimum standards on program level, however some centers need additional interventions to meet the quality standards. Applying appropriate polypectomy technique for polyps ranging from 4 to 5 mm in diameter

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Reference**

is currently the biggest issue in PCSP and further training is needed to reach minimum standards for this performance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1805 VALIDATION OF THE “FAILURE TO PROVIDE ADEQUATE RELIEF” (F-PAR) SCALE IN A SPECIALIST CLINIC SETTING
V. Passananti, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Treatment of chronic idiopathic constipation is somewhat empiric, but based on step-wise approach[1]. If first-line conservative treatment (lifestyle advice and laxatives) do not relieve symptoms sufficiently, secondary approaches with prokinetic or secretagogue drugs are used before considering hospital-based care (biofeedback, psychosocial support, transanal irritation (TAI), surgery). Nevertheless, patients are often dissatisfied with care[2] and fail to progress to adequate levels of therapy. The 5-point Failure to Provide Adequate Relief (F-PAR) scale[3] was developed to facilitate the recognition of when to move from one step to the next.

Aims & Methods: The aim of this study was to validate F-PAR in a tertiary clinical setting. We studied 403 consecutive consultations of 331 patients (262 women, mean age 41) in our specialist clinic. All fulfilled Rome III/IV diagnostic criteria for chronic constipation. Immediately prior to each face-to-face clinical assessment by one of 2 experienced physicians, participants completed the F-PAR scale; patients were seen blind to the F-PAR result. Standard clinic assessment was undertaken to identify efficacy of the current management as the gold standard.

Results: Of the 403 consultations, clinical assessment identified inadequate relief with current therapy was identified in 200. Neither duration nor type of treatment were correlated with relief. The table stratifies, by clinical gold standard, each item of the F-PAR and in the lower panel the total number of F-PAR items replied to positively.

Conclusion: Our findings showed that the F-PAR with only five questions can be considered sufficient to provide clinical evidence of treatment failure. The use of standardized process to investigate the efficacy of treatment may reduce the time and improve the quality of managing for the chronic constipation patients.

P1806 ADHERENCE WITH TRANSDUAL IRRIGATION USING THE NAVINA™ SYSTEM IS ASSOCIATED WITH PERSONALITY TRAITS EVEN WHEN THERE IS IMPAIRED HAND FUNCTION
V. Passananti, J. Storrie, N. Zarate Lopez, A. V. Emmanuel
GI Physiology Unit, University College London Hospital, London/United Kingdom

Contact E-mail Address: valentinapassananti@gmail.com

Introduction: Transanal irrigation has become a key therapeutic modality in managing patients with neurological diseases who experience constipation and/or fecal incontinence. Such neurogenic bowel dysfunction (NBD) complicates over three quarters of patients with spinal cord injury (SCI) and multiple sclerosis (MS). Approximately 60% of patients who start TAI continue with long-term treatment. A common cause of treatment cessation is impaired hand function [1]. Training of the patient is a key aspect of TAI therapy and requires patients to be willing to manage their health themselves: self-efficacy.

Aims & Methods: We wished to study whether use of a novel TAI system, Navina™ Smart, which has an electronic pump component allows patients with impaired levels of hand function, to initiate irrigation to adhere to TAI therapy. We also wished to identify if there were physiological or psychological correlates of adherence. Twenty-eight constant patients (19 SCI and 9 MS; 17 male, mean age 42) were studied. All patients scored greater than 18 on the Cochin Hand Function questionnaire and were completed to assess anxiety/depression and locus of control respectively. Anorectal physiology (manometry, sensation and rectal compliance) was undertaken at baseline. Training in TAI was undertaken by the same experienced nurse, with weekly follow up until a stable regime was established. Adherence with therapy at 12 weeks was identified.

Results: At 12 weeks, 16/28 (57%) of patients were still using Navina TAI, similar proportions with SCI (11/19) and MS (5/9). There was no difference in baseline scores for HAD-anxiety (6.3±4.9 vs 5.9±2.9; p=0.37) and HAD-depression (8.6±3.9 vs 8.8±4.2; p=0.46) and were similar in both those who were and who were not still using TAI (mean± SD respectively). The Rotter score for non-adherers was significantly greater than adherers (14.2±6.7 vs 10.6±5.9 respectively; p=0.008). There was no difference in any of the anorectal parameters between those who did or did not adhere with TAI.

Conclusion: Navina Smart TAI is an effective therapy in 57% of NBD patients with significant hand dysfunction. Anorectal physiology, anxiety and depression scores do not predict likelihood of treatment adherence. An external locus of control, reflecting a belief that health events occur because of outside forces (such as fate, chance, or powerful others), is associated with reduced treatment success. The results suggest that future studies of TAI should consider locus of control as an important potential predictor of outcome.

P1807 THE DUODENAL MUCOSA RETAINS A DIVERSE MICROBIOTA FOLLOWING BOWEL PREPARATION

Contact E-mail Address: e.shanahan@uq.edu.au

Introduction: The microbiota inhabiting the gastrointestinal (GI) tract plays an essential role in gut health. Although mucosal biopsies are increasingly used for microbiota studies, these are subject to variations introduced through sampling technique and patient preparation. The impact of bowel preparation on the microbiotaassociated microbiota (MAM) is of particular interest given it results in complete emptying of bowel contents via laxative ingestion. Although bowel preparation does not appear to induce long term changes to stool microbiota [1], it can induce short-term changes to the colonic MAM [2]. While improvements in clearing of the small intestine after bowel preparation have been reported [3], the impact on the upper GI microbiota is currently unknown. Given patients may undergo both upper GI endoscopy and colonoscopy consecutively, a subset of endoscopy patients will have consumed bowel preparation prior to their procedure, representing a potential bias in MAM analyses. Therefore, this study aimed to assess the impact of bowel preparation on the duodenal MAM.

Aims & Methods: Individuals undergoing upper GI endoscopy, with or without concurrent colonoscopy, were recruited consecutively with ethical approval. Individuals who underwent upper GI endoscopy following overnight fast (n = 58), or with diagnosed Crohn's disease (n = 18). Duodenal biopsies were obtained and gDNA extracted. Amplicon libraries of the 16s rRNA gene were sequenced (Illumina MiSeq). Sequencing of reant controls enabled exclusion of
non-duodenal sequences. Bioinformatics and statistics were performed in QIIME and Calfyso.

**Results:** A diverse microbiota was observed in duodenal mucosal samples from all subjects, following overnight fasting or bowel preparation. Overall the duodenal microbiota was dominated by the genus Streptococcus, followed by Prevotella, Veillonella and Neisseria. Microbial diversity within samples was not significantly different with and without bowel preparation (Chao1 metric).

**Principal coordinates analysis (weighted UniFrac)** revealed substantial overlap between the two groups, and no significant clustering was observed (ADONIS) based on whether patients had undergone overnight fasting or bowel preparation. Similar findings were obtained when these analyses were repeated with exclusion of the Cronh’s disease population.

**Conclusion:** This study reveals a diverse duodenal MAM is retained following bowel preparation. The comparison of overnight fasting and bowel preparation indicates these differences in patient preparation do not substantially alter the duodenal MAM. Thus patients undergoing concurrent upper GI endoscopy and colonoscopy can be included in study cohorts investigating the upper GI MAM without risk of a substantial confounding effect.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Introduction:** Upper gastrointestinal bleeding (UGIB) in patients with cancer presents a unique and difficult challenge as these patients are at higher risk for rebleeding and mortality. Currently available prognostic scoring systems for UGIB for the general population have produced variable accuracy in their validation studies. An effective method of stratification for cancer patients to identify the high-risk group for early hospital-based intervention and death could enhance the outcomes of this specific population.

**Aims & Methods:** The primary aim of this study was to compare the Glasgow-Blatchford score (GBS), Rockall score (RS) and AIMS65 score for predicting ICU admission, blood transfusion, hemostatic therapy, rebleeding, and in-hospital mortality in cancer patients with UGIB. The secondary aim was to assess the above cited scores in correctly identifying low-risk patients that can be effectively managed as an outpatient. An EBAC approval prospective study was conducted at the Cancer Institute of Sao Paulo, Brazil. Consecutive patients with known cancer admitted with UGBIB were enrolled. Pre-endoscopic clinical parameters pertinent to the scoring systems, hemostasis techniques, and outcomes were collected into a prospective registry. Patients were followed for at least 30 days or until the day of discharge, whichever was longer. The low-risk group was defined as those without blood transfusion, hemostatic therapy (by endoscopy, radiotherapy, angiographic or surgical intervention), rebleeding or mortality in 30 days. Multiple logistic regression with receiver operating characteristics analysis was done to assess the predictive ability of each scoring system for the above outcomes.

**Results:** From April 2015 to May 2016, 394 consecutive patients were screened, while 259 patients met the inclusion criteria. A total of 243 patients were considered for the final analysis, after excluding 16 patients due to missing data or lost to follow up (Table 1). Predicting outcomes: The AIMS65 score (area under the curve) significantly better predicted ICU admission than GBS (AUC 0.79; p ≤ 0.04), both the total and clinical RS (AUC 0.71 and 0.66; p < 0.001 for both). The GBS best predicted the need for blood transfusion (AUC 0.82, sensitivity 71% and specificity 80% for GBS ≥ 12) compared with the other prognostic scores. All scores performed poorly in predicting the need for hemostatic therapy and risk of rebleeding. The AIMS65 score best predicted in-hospital mortality (AUC 0.84) compared to the GBS (AUC 0.75; p = 0.004), both the total and clinical RS (AUC 0.70 and 0.69; p < 0.001 for both). Among patients rebleeding at EGD, there was no difference in 30-day mortality if the etiology of bleeding was tumoral or non-tumoral disease (38.1% vs 31.9%; p = 0.46). Identifying low-risk group: With GBS score of 0 as the cut-off value, its specificity was 100% with sensitivity of 5.8%. When GBS ≥ 2, its specificity was maintained at 100%, while sensitivity was increased to 23.5%. This change increased the proportion of the patients from 1% to 5% without erroneously discharging high-risk patients. In comparison, when an AIMS65 value of 0 was chosen as definition for low-risk, this tool misclassified 20 patients who needed hospital interventions (specificity of 53% and sensitivity of 89.5%). Finally, head-to-head comparison between GBS vs. RS, and GBS vs. AIMS65 scoring system revealed GBS to be superior to both the clinical RS (p < 0.001) and AIMS65 (p = 0.001) in correctly identifying low-risk patients.

</tbody>
</table>

**Conclusion:** The AIMS65 score was superior to other scoring systems in predicting in-hospital mortality and ICU admission in patients with cancer and UGIB, whereas the GBS was superior for predicting the need for blood transfusion. All scores performed poorly in prediction of hemostatic therapy and rebleeding. The GBS was superior in accurately identifying low-risk patients. Furthermore, the cut-off ≤ 2 in GBS score displays increased sensitivity without compromising specificity, effectively increasing the number of patients who can be safely managed as an outpatient.

**Introduction:** Endoscopists are more frequently performing endoscopic resection (ER) in patients on antplatelet or anticoagulant therapy and nowadays patients have increasingly started taking direct oral anticoagulant (DOAC) therapies, including direct anti-Xa and thrombin inhibitors. Major guidelines recommend the cessation of anticoagulants before ER and heparin bridging therapy (HBT) for high thrombotic risk cases, although these are still controversial. A recent study has suggested that HBT may be associated with a higher post-endoscopic resection bleeding (PEB) rate in patients on anticoagulants.

**Aims & Methods:** This study aimed to evaluate the effect of anticoagulants on PEB rate in patients on anticoagulants. This was a retrospective study based on medical records from three departments: PE was defined as bleeding that occurred 6 h to 10 days after ER, which required endoscopic hemostasis. We reviewed 108 gastric tumors including adenoma and early cancer in 97 patients on anticoagulant therapy who underwent endoscopic submucosal dissection (ESD) in our hospitals between June 2008 and February 2016. Further, we reviewed 69 colorectal polyps including adenoma and early cancer in 69 patients on anticoagulant therapy who underwent ER in our hospitals between October 2013 and September 2016. ER included polypectomy, endoscopic mucosal resection (EMR), and ESD. Patients were divided into two groups: those prescribed warfarin and patients prescribed DOAC. The management of antithrombotics was based on the Japanese Gastroenterological Endoscopy Society guidelines published in 2005 and 2012. The anticoagulants used during the study period were warfarin, dabigatran, rivaroxaban, apixaban, and edoxaban. Warfarin was discontinued 4-5 days before ER, whereas the others were stopped 24-48 h prior to the procedure. For patients at a high thrombotic risk, intravenous unfractionated heparin was administered after ceasing anticoagulants.

**Results:** Warfarin and DOAC were prescribed to 73 (75%) and 24 (25%) patients, respectively. Apixaban was administered to 1 (1%), dabigatran to 12 (12%), rivaroxaban to 11 (11%) patients. There were no significant differences between the DOAC and warfarin groups in terms of clinical characteristics or
P1810 ENDOSCOPIC ALLIGATION OF MUCOADHESIVE POWDER (NEXPOWDER®) FOR HEMOSTASIS IN PATIENTS WITH GASTROINTESTINAL BLEEDING

2Digestive Disease And Research Institute, SoonChungHyang University School of Medicine, Bucheon,Korea, Republic of

Contact E-mail Address: bangbyoung@naver.com

Introduction: Although endoscopic hemostasis is usually effective in controlling gastrointestinal (GI) hemorrhage, some have difficulty in achieving successful hemostasis depending on the location and severity of hemorrhage. NEXPOWDER® (Next Biomedical, Incheon, South Korea) is a biocompatible and biodegradable powder and the hemostatic effects are accomplished by physical barrier when this powder immediately forms mucoadhesive hydrogel after contacting blood or water. It shows high adhesiveness and persistence of gel on ulcer base. In addition, new powder delivering device was developed to reduce cather clogging during endoscopic application.

Aims & Methods: The aims of this study were to confirm 1) success rate of hemostasis using NEXPOWDER® in acute GI bleeding from post-endoscopic procedure or various causes, 2) re-bleeding rate on second-look endoscopy at 1 or 3 days after the procedure, 3) persistent rate of hydrogel on ulcer base at follow-up endoscopy, and 4) clogging rate of catheter during spraying powder. The NEXPOWDER® was delivered by newly developed spraying device through a catheter which accessed the initial hemostatic success as when the bleeding disappeared within 10 minutes. A second-look endoscopy was performed in one and three days after the procedure.

Results: A total of 57 patients were enrolled. The bleeding developed in 46 patients with post-endoscopic resection ulcers (41 ESD induced ulcers and 5 EMR induced ulcers), 8 patients with peptic ulcer and 3 patients with other origins. 1) Success rates of hemostasis in acute bleeding were 96.5% (55/57) of NEXPOWDER® group, 2) Re-bleeding rates were 5.5% (3/57) of NEXPOWDER® group, 3) Persistent rate of NEXPOWDER® on ulcer base was 70.3% (26/37) day after the procedure, and 38.5% (15/38) 3 days after the procedure. 4) Clogging rate of spraying catheter was 3.5% (2/57).

Conclusion: The endoscopic application of NEXPOWDER® is effective for the several types of acute GI bleeding. This effective hemostatic action of NEXPOWDER® might be achieved by physical barrier of mucoadhesive and persistent hydrogel on ulcer base. And new powder delivering device shows low prevalence of catheter clogging during endoscopic application.

P1811 CLINICAL FEATURES OF DELAYED BLEEDING AFTER ENDOSCOPIC SUBMUCOSAL DISSECTION FOR GASTRIC NEOPLASMS IN HIGH-RISK AND LOW-RISK PATIENTS

Gastroenterology, Osaka General Medical Center, Osakajapan

Contact E-mail Address: tatkatakakkun@gmail.com

Introduction: Antithrombotic drugs are administered to patients undergoing endoscopic treatment at high risk for thromboembolism. However, antithrombotic drugs have been also known as a cause of delayed bleeding associated with endoscopic treatment, including endoscopic submucosal dissection (ESD). We previously reported the clinical features of postpolyectomy bleeding associated with heparin bridge therapy (1), and then various risk factors of delayed bleeding after endoscopic treatment have been reported.

Aims & Methods: The aims of the present study are to investigate the risk factors of delayed bleeding after gastric ESD and to clarify the clinical features of delayed bleeding in high-risk patients. High-risk patients were defined as patients who underwent ESD for gastric neoplasms in Osaka General Medical Center between January 2009 and December 2016 were retrospectively investigated. Independent risk factors of delayed bleeding were analyzed by using a multivariate analysis by logistic regression model, and three predictors of delayed bleeding were selected. Patients were categorized into a high-risk group or low-risk group for bleeding, and the clinical features of post-procedural bleeding in each group were investigated.

Results: A total of 717 patients with 781 gastric neoplasms were identified. Mean age was 74.6, and 71.6% was male. With regard to comorbidity, the proportion of hypertension, diabetes, chronic liver disease, and hemodialysis was 50.2%, 19.2%, 2.7%, and 6.1%, respectively. Total 188 patients have taken oral antithrombotic drugs, and of them, 50 patients treated by gastric ESD under heparin bridge therapy. Two-thirds lesions were located in gastric body and median tumor size (range) was 15 (3–80) mm. En-bloc resection was achieved in 751 lesions (96.5%), and no uncontrollable bleeding occurred. Forty-nine patients (6.8%) experienced delayed bleeding after gastric ESD. Hospital stay was significantly longer in bleeding cases than in non-bleeding cases [median hospital stay (range) 11 (3–20) vs. 9 (9–25), p = 0.007]. A univariate and multivariate analysis showed heparin bridge therapy, antiplatelet therapy, and hemodialysis as high-risk for bleeding, and the remainder as a low-risk group. The incidence of delayed bleeding was significantly higher in the high-risk group than in the low-risk group (14.3% vs. 3.6%, p < 0.001). Severe bleeding requiring transfusion and recurrent bleeding were more often in the high-risk group than in the low-risk group. Median onset (range) of delayed bleeding was POD1 (0–16) in high-risk group and POD6 (0–15) in high-risk group. No thromboembolism occurred in each group.

Conclusion: Delaying high-risk patients with heparin bridge therapy, antiplatelet therapy, and hemodialysis should be carefully observed after gastric ESD while early hospital discharge is acceptable for bleeding low-risk patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: There are few studies of the efficacy of parenteral ferric carboxymaltose (FCM) treatment in acute gastrointestinal bleeding (GIB) of different origins. Few data are available on its use to treat anaemia post-acute haemorrhage.

Aims & Methods: To determine the efficacy and safety of FCM treatment in patients with acute GIB not associated with portal hypertension. A retrospective descriptive 3-year study of patients with acute GIB (anaemia with evident bleeding and/or hemodynamic instability) treated with FCM as part of our hospital’s habitual clinical practice.

Results: Analysis of 84 patients admitted with acute GIB (69.0% male, mean age 68.0 years [SD 6.9]), with a Charlson index ≥ 3 in 67.1% of cases (≥ 5 in 31.6%). 15.5% had previously suffered acute GIB due to peptic ulcer. There were 86 hospital admissions for acute GIB; 93.8% were upper GIB (above the angle of Treitz). The most frequent clinical presentation was melena, in 76.7% of cases. 25.6% presented hemodynamic instability at admission. The mean Glasgow-Blatchford index score was 16.1 (SD 2.7) and the mean Rockall score post-endoscopy was 4.2 (SD 1.7). The most common causes of bleeding were: 36.0% duodenal ulcer, 29% gastric ulcer, 9.3% gastritis/erosions, and 7.3% angiodyplasia of the colon. The mean Hb at admission was 9.0 g/dL (SD 2.2)
and the mean of the lowest Hb during admission was 7.6 g/dL (SD 1.3). The most common total dose of FCN administered was 1000 mg. During admission, a mean Hb increase of 0.8 g/dL (SD 2.3) was observed in a mean period of 5.7 days (median: 4.0) after treatment with FCN, with an increase of 4.2 g/dL (SD 2.6) 30 days after acute GIB. After FCN administration, the mean Hb increased significantly (p < 0.0001) in patients ≥75 years (2.1 g/dL [SD 1.7]), in patients with Charlson index ≥3 (1.9 g/dL [SD 1.6]), and when Hb level during admission was <10 g/dL (2.0 g/dL [SD 1.7]). No adverse reactions were observed.

Conclusion: In patients with acute GI bleeding the administration of ferric carboxymaltose improves Hb levels promptly and safely, especially in patients of advanced age and with associated comorbidities.

P1813 NOVEL EUR-GUIDED TREATMENT OF GASTRIC VARICES WITH A LIQUID NON-ADHESIVE NEUROVASCULAR EMBOLIZATION AGENT
A.J. Baptista, M.A. Guzman, H. Russ, J.F. Piñera González, E. Richards
Hospital de Clínicas Caracas, Caracas/Venezuela

Contact E-mail Address: albertorgebaptista@gmail.com

Introduction: Endoscopic Injection of adhesive agents such as N-butyl-2-Cyanocrylate (NBC) has been accepted optionally for the management of gastric varices. Recently the combination of NBC and coils has been used with endoscopic ultrasound (EUS) assistance. Nevertheless adhesive properties of the polymer may cause blockage of instrumentation material and damage to endoscopes. Since the authors, vascular wall necrosis, reblooding and distal embolism. Ethylene-vinyl alcohol (EVOH) has been extensively used in interventional radiology to treat cerebral arteriovenous malformations and has the advantage of being radioopaque.

Aims & Methods: We aimed to demonstrate a novel gastric varices embolization therapy using NBC combined with Ethylene-vinyl alcohol (EVOH) that has been also used in interventional radiology.

Results: 431 patients have been included in this study. 24.8% of patients were ≥75 years (p = 0.0001). The following differences have been observed by comparing the two groups of patients (over and below 75 years old): female 47.7% vs 25.3% (p < 0.0001); antiplatelets use 40.2% vs 20.1% (p < 0.0001); oral anticoagulants use 20.6% vs 7.7% (p < 0.001); NSAIDs use 25.2% vs 33.6% (p = 0.133); smoking 23.7% vs 35.2% (p = 0.123); alcohol consumption 17.8% vs 45.4% (p < 0.001); one or more comorbidities 77.6% vs 62% (p = 0.005); high risk endoscopic stigmata 61.7% vs 64.4% (p = 0.724); multiple ulcers 41.1% vs 31.8% (p = 0.099); need for blood transfused 39.5% vs 38% (p = 0.382); hospitalization duration 8.4 ± 6.1 vs 7.8 ± 6.0 days (p = 0.382); reblooding 10.3% vs 11.4% (p = 0.745); need for surgery 2.8% vs 4.6% (p = 0.589) and in-hospital mortality 13.1% vs 6.2% (p = 0.021). In most of the cases (88.2%), the cause of death was other than hemorrhagic shock (92.9% vs 85.0%, p = 0.484).

Conclusion: Despite this methodologic analysis, three of these factors were identified as independent factors significantly associated with the age over 75 years old: oral anticoagulants use (OR = 2.40, 95%CI:1.24–4.62, p = 0.009), antplatelet use (OR = 2.33, 95%CI:1.43–3.81, p = 0.001) and in-hospital mortality (OR = 2.09, 95%CI:1.7–4.47, p = 0.048).

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Peptic ulcers are the most frequent cause of upper gastrointestinal bleeding. In different population based surveys regarding all-cause UGIB, mortality ranges between 3% and 14%.

Aims & Methods: The aim of this study was to assess in-hospital mortality in patients with peptic ulcer bleeding and to evaluate the risk factors associated with mortality. In this descriptive study we enrolled all patients diagnosed with peptic ulcer bleeding, who were hospitalized in our hospital in a period of periods of 24 months (January 2015- December 2016). Patients were divided into two groups - those who died and those who survived - and the following parameters were compared: age, signs of hemodynamic instability (hypotension, tachycardia), presence of comorbidities, endoscopic stigmata, risk of rebleeding, need for surgery, need of transfusion or hospitalization. Hospitalization duration was higher in elderly patients due to more frequent association of comorbidities.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1816 ANAEMIA AND UPPER GI BLEEDING: A LOCAL EXPERIENCE

M. Ding, R. Prawiradilja, Z. Arastu, H. Sabri, M. Smith
Gastroenterology, Royal shrewsbury hospital, Shrewsbury/United Kingdom

Contact E-mail Address: Michaeuddjw@gmail.com

Introduction: There has been significant research recently on the use of blood transfusions in upper GI bleeding (UGIB) [1] with recent evidence advocating a restrictive approach to blood transfusions as well as the use of iron therapy[2] for anaemic patients. We aimed to conduct a local retrospective analysis of patients admitted with UGIB over a six month period and analysed the use of blood transfusions at our trust which consists of two District General Hospitals.

Patient data over a period of up to 12 months post discharge was collected to monitor their anaemia.

Aims & Methods: Our aim was to monitor the appropriateness of transfusions in Upper GI Bleeding as well as monitoring the response to iron therapy following discharge. All inpatients that had an Upper GI endoscopy for UGIB were analysed. Electronic patient records were obtained from our endoscopy software and hospital database. Patients were selected over a time period of six months from 1/6/2015 to 31/12/2015. A Student’s T-Test was used to compare the average increase in haemoglobin (Hb) for patients discharged with iron therapy against those who were not.

Results: There were 148 patients, 81 male and 67 female. The mean age was 69.3, minimum 20 and maximum 98. The average Hb on admission was 103 g/L (min = 32 g/L, max = 178 g/L) 78 out of 148 (52.7%) patients presenting with UGIB received a blood transfusion. The mean amount of blood received for those transfused was 3.7 units. 48 out of 78 (61.5%) of blood transfusions were given when Hb was below 70 g/L, 30 of 78 (38.5%) were transfused above a Hb of 70 g/L. (36.7%, n = 11) of those who were transfused with Hb above 70 had cardiac risk factors. The mortality rate in those transfused above Hb of 70 was 13.3% (n = 4) vs 10.4% (n = 5) 41.5% (n = 44) patients were anaemic post-UGIB were discharged with iron therapy. The average rise in Hb was 4.5 g/L (3.9-5.5, n = 11) of those who were transfused with Hb above 70 had cardiac risk factors. The mortality rate in those transfused above Hb of 70 was 13.3% (n = 4) vs 10.4% (n = 5) 41.5% (n = 44) patients who were anaemic post-UGIB were discharged with iron therapy. The average rise in Hb was 4.5 g/L (3.9-5.5, n = 11) of those who were transfused with Hb above 70 had cardiac risk factors. The mortality rate in those transfused above Hb of 70 was 13.3% (n = 4) vs 10.4% (n = 5) 41.5% (n = 44) patients who were anaemic post-UGIB were discharged with iron therapy. The average rise in Hb was 4.5 g/L (3.9-5.5, n = 11) of those who were transfused with Hb above 70 had cardiac risk factors.

Conclusion: The data obtained supports a restrictive transfusion policy (mortality rate of 13.3% vs 10.4%). 58.5% of patients who were anaemic on discharge did not receive any iron therapy. On follow up, there was a statistically significant rise in haemoglobin in the group discharged on iron vs those who did not. There was a statistically significant rise in Hb for those discharged with iron therapy (p < 0.005) on follow-up versus those who did not receive it (n = 62). The anaemia related readmission rates were similar for patients discharged on iron or not (9.1% n = 4 vs 9.7% n = 6).

Introduction: The interaction between gut microbiota and enteric stem cells alterations is believed to play an important role in the pathophysiology of irritable bowel syndrome (IBS). The densities of the duodenal enteric stem cells are abnormal in IBS patients, which appears to be caused by a reduced stem cells density and their differentiation into endocrine cells (1).

Aims & Methods: The aim is to investigate the effects of faecal microbiota transplantation (FMT) on the differentiation of the stem cells into endocrine cells as detected by neurogenin 3, the stem cells as detected by Musashi 1 and the enteric progenitor cells as detected by all-endothelial progenitor cells.

Results: The score of IBS symptoms as assessed by IBS-SSS was significantly reduced 3 weeks after (240.2 ± 33.6) compared to before (326.6 ± 22.3) receiving FMT, P = 0.009. The scores of IBS-SSS before and 3 weeks after FMT for PI-IBS patients were 278.3 ± 27.8 and 210.4 ± 21.4, respectively (P = 0.025), and for idiopathic IBS were 352.5 ± 34 and 270.3 ± 54, respectively (P = 0.034). The densities of neurogenin 3, Musashi 1 and enteric progenitors cells in the duodenum of IBS patients before and 3 weeks after receiving FMT are presented in Table 1.

Conclusion: Faecal microbiota transplantation improved the symptoms in IBS patients, both PI and idiopathic. This improvement was associated with a change in the enteric progenitor cell density. The changes in the enteric progenitor cell density does not appear to be caused by changes in the stem cells or their early progenitors, but rather by changes in the differentiation progeny as detected by changes in neurogenin 3.

Introduction: Neuronal plasticity has been reported to develop following nociceptive emotional experience in prefrontal cortex (PFC) and hippocampus. The N-methyl-D-aspartate receptor (NMDAR) and D-serine, the endogenous co-agonist of NMDAR1, may mediate the neural plasticity. However, whether the neural plasticity participates in the mechanism of esophageal visceral hypersensitivity is little known.

Aims & Methods: This study aims to investigate the expression of NMDAR and the alteration of D-serine after neonatal and adult esophageal acid exposure. All rats were exposed to esophageal acid or saline at postnatal days 7–15(P7-P15), and most rats underwent acute acid or saline exposure again at adult time (P60). All rats were randomly distributed to 5 groups, including P7S, P7H, rats were exposed to esophageal acid or saline at postnatal days 7–15; P60: adult at postnatal 60 days; P7-H: 0.1N HCL infusion; S: saline control). The tissue harvest was conducted at P60. We examined the expression of subunits of NMDAR (including NR1, NR2A, NR2B, and NR2B), c-fos, and serum racemase in PFC, dorsal hippocampus (DH) and ventral hippocampus (VH). We also determined the D-serine and L-serine in PFC and hippocampus by LC-MS analysis. Statistical comparisons were performed by General Linear Model and one-way ANOVA in SPSS.

Results: In PFC, compared with adult saline treatment (AS, including P7H and P7S group) and without adult treatment (A-, including P7S and P7H group), adult acid exposure (AH) increased the expression of NR1 (P = 0.052, P < 0.028), NR2B (P = 0.035, P < 0.045), and serum racemase (P = 0.015, P < 0.017) significantly. In ventral hippocampus, compared with adult treatment absence, adult acid exposure caused increasing expression of NR2B (P = 0.012) and NR1 (P = 0.024) significantly. In PFC, the expression of D-serine in the P7S and P60H group was obviously higher than that of other groups (P = 0.008). See Table1. In dorsal hippocampus, there was statistical significance on the level of c-fos between the P7S and P7H group and other groups (P = 0.008). Table1. In PFC, the LC-MS analysis results that D-serine (AH vs A-: P = 0.000, AS vs A-: P = 0.002, AH vs AS: P = 0.008) and L-serine(AH vs A-: P = 0.000, AS vs AS: P = 0.015, AS vs AS: P = 0.082) decreased in the AH and AS group, comparing with A- group.

The expression of serine racemase in PFC and c-fos in VH

Conclusion: Acute esophageal acid exposure may increase the expression of NMDAR in PFC and ventral hippocampus. We also found the first acid exposure at adult stage may enhance the expression of serine racemase in PFC and c-fos in ventral hippocampus, but this phenomenon may be absent in those rats having the experience of acid exposure in early life. Those long-term and transient molecular alterations may mediate the development of acid exposure related esophageal visceral hypersensitivity.

Introduction: Globus pharyngeus, a sensation of a lump or tightness in the throat, is a well-defined clinical symptom that is usually long-lasting, difficult to treat, and has a tendency to recur. More than half of globus patients suffered from probable psychological disorders, such as anxiety and depression 1. Antidepressants are used in the treatment of functional gastrointestinal disorders (FGIDs) and showed a promising efficacy. Our study manifested that low-dose amitriptyline is well tolerated and effective for general globus pharyngeus patients 2. Our anterior study had ever speculated that AMT could modify brain-gut axis function, up-regulating brain-gut peptides, reducing the visceral sensitivity and regulating the secretory and motor functions of the gastrointestinal tract 3, so that gastrointestinal symptoms as well as emotional well-being could be significantly improved. As we known, serotonin (5-hydroxytryptamine, 5-HT) is an important factor in gut function, playing key role in intestinal peri-stalsis, secretion, and sensory signaling in the brain-gut axis 4. Several studies have investigated the association between SLC6A4 and functional gastrointestinal disorders, including IBS and FD. Besides, the association between various complex behavioral traits and disorders were also studied, including anxiety, major depression, suicide, smoking behavior, alcohol dependence. A single gene (SLC6A4), located on the human chromosome 17q11.2, 17q12, is coded by serotonin transporter (5-HTT). The polymorphism of this gene is characterized by the insertion or deletion of the 44-bp sequence and this is related to the different transcriptional activity of the gene. Allele with 44-bp insertion (short allele) is characterized by a three times lower transcriptional activity than allele with 44-bp insertion (long allele). Compared to other FIGIDs, the researches about globus are rare. The pathogenesis of globus pharyngeus is still unknown.

To the best of our knowledge, our findings are the first to establish an association between SLC6A4 gene polymorphism and globus pharyngeus.

Aims & Methods: 84 patients diagnosed with globus according to Rome III and 160 healthy controls were genotyped for 5-HTTLPR polymorphism by PCR amplification and agarose gel electrophoresis. All globus patients were studied with high-resolution manometry pre-therapy. Globus patients were randomized into paroxetine group; amitriptyline group for 6-week treatment, and were asked to complete the following questionnaires pre- and post-therapy: Edinburgh Throat Scale (GETS), Pittsburgh Sleep Quality Index, Hamilton Rating Scale Anxiety, Depression. Treatment response was defined as a > 50% reduction in GETS scores.

Results: The significant difference was shown in globus performed S/S genotype with anxiety when compared to without (X² = 14.579, P = 0.006). The S genotype had higher pressure between high upper esophageal sphincter pressure (104 mmHg) and non-high upper esophageal sphincter pressure patients (X² = 14.433, P = 0.006). There was significant association between the S/S genotype and the response to antidepressants treatment, while patients with sleep disorders or depression not.

Conclusion: A significant association was observed between S/S genotype of SLC6A4 polymorphism and globus pharyngeus, suggesting that SLC6A4 is a potential candidate gene involved in the pathogenesis of globus pharyngeus.

34. Disclosure of Interest: Achalasia is an uncommon condition of failed lower oesophageal sphincter relaxation. Data regarding the incidence and prevalence are limited. The aim of this study was to provide accurate, contemporary epidemiological data utilising two national databases.
35. Aims & Methods: Hospital Episode Statistics (HES) includes demographic and diagnostic data for all English hospital admissions. The Health Improvement Network (THIN) database includes primary care records of 7% of the UK population, representative of national demographics. Both were searched for incident cases and THIN for prevalent cases of achalasia.
36. Results: There were 10,509 and 711 new achalasia subjects in HES and THIN respectively. The incidence per 100,000 person years in THIN was 1.99 (95% CI 1.87–2.11) and 1.53 (1.42–1.64) per 100,000 person years in THIN. The prevalence measured in THIN was 27.1 (25.4–28.9) per 100,000 population.
37. Table 1: Annual incidence and prevalence of achalasia
38. Year | Incidence rate HES (per 100,000 population) | 95% CI | Incidence rate THIN (per 100,000 person years) | 95% CI | Prevalence THIN (per 100,000 population) |
39. 2006 | 1.733 | 1.62–1.85 | 1.409 | 1.08–1.81 | 21.14 |

45. 2012 | 2.032 | 1.91–2.16 | 1.549 | 1.20–1.96 | 25.23 |
46. 2013 | 2.179 | 2.06–2.31 | 1.618 | 1.26–2.05 | 26.06 |
47. 2014 | 2.421 | 2.29–2.56 | 1.476 | 1.12–1.91 | 26.34 |
48. 2015 | 2.236 | 2.11–2.36 | 1.342 | 0.96–1.80 | 27.10 |
49. Conclusion: The incidence of oesophageal achalasia was approximately 15 to 20 per 1 million population. There were approximately 17,500 patients with achalasia in UK. In 2015 the above data represents the largest published epidemiological investigation of achalasia. The variation of findings between the databases likely results from differences in coding practice and marginally different population structures.

63. Introduction: Relaxation to bolus flow across the lower oesophageal sphincter (LES) is a hallmark of achalasia. Presently the gold standard of diagnosis is by high-resolution manometry (HRM) demonstration of raised integrated relaxation pressure (IRP) following ten 5 ml water swallows; however, this does not rule out normal swallowing behavior. It has been demonstrated that the addition of adjunctive tests improves sensitivity of identifying relevant dysmotility. Such tests include multiple water swallows (MWS; 200 ml water drunk freely) and solid swallows. In addition, the timed barium esophagram (TBE) measures esophageal emptying. This study describes a cohort of patients who have been treated as having achalasia based on resistance to flow not exhibited with normal swallowing.
64. Aims & Methods: Inclusion criteria were all patients between October 2014–2016 with normal mean and median IRP with 5ml water swallows but considered to have achalasia due to resistance to flow demonstrated by pan-oesophageal pressurization (PEP) during MWS or solid swallows and/or a persistent column at 5 minutes during TBE. Outcome following treatment was based on the Eckardt symptom score (ES).
Results: 14 patients (9 male) fulfilled inclusion criteria. 7 were treatment-naïve and 7 treatment-experienced (3 myotomy, 4 dilatation). Mean resting LES pressure was 14.6 ± 7.4 mmHg. In all patients, and mean median IRP values for ten 5 mL water swallows were non-raised (mean 9.1 ± 4.3 and 8.7 ± 4.5 mmHg respectively). Of the 7 treatment-naïve patients, 5 demonstrated PEP on MWS, 3 on solid swallows and 6 had a positive TBE at 5 minutes. In treatment-experienced patients, 5 had PEP on MWS, 1 on solid swallows and all had a positive TBE. Of the 13 who had resistance to flow on TBE, 10 (77%) also had resistance demonstrated during MWS and/or solid swallows. Mean height of the 5-minute column in TBE in treatment-naïve patients was 16.5 ± 8 mmHg. 8 patients have (so far) undergone therapy based on these findings: one per-oral endoscopic myotomy and 7 pneumatic dilatations. The median baseline ES was 7.5 (IQR: 5–8). The median ES at minimum 3 months (range 3–15 months) following treatment was 1 (IQR 0–0.5; P<0.001 cf. baseline). Similarly, there was significant improvement in TBE findings post-therapy (mean 5-minute column height 3.5 ± 4.1 cm; P = 0.04 cf. baseline).

Conclusion: A normal IRP for water swallows does not preclude a diagnosis of achalasia. The addition of free drinking/solidswings during HRM or the TBE can identify pathology that might have been missed with standard 5 mL water swallows alone as normal, clinically relevant swallowing behavior is reproduced. Patients treated based on this algorithm exhibit excellent treatment outcomes, validating this approach. Further, the close correlation of HRM adjunctive testing with TBE supports its routine inclusion in clinical practice.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The timed barium esophagram (TBE) is an objective measurement of esophageal (3 myotomy, 4 dilatation) and symptoms used in the assessment of achalasia. Post-therapy resolution of the maximum height of the residual barium column has been found to correlate imperfectly with short-term symptomatic outcomes, but carries long-term prognostic implications. We hypothesize that the surface area (SA) of the barium column may be more accurate than height, firstly, by correlating improvement in esophageal width that often occurs post-therapy, but also by correcting for artificially higher height values due to esophageal (lateral) contraction occurring during a single image. We aimed to compare the correlation of TBE outcome measures of height and SA with symptom improvement post-therapy.

Aims & Methods: Inclusion criteria were achalasia patients who underwent therapy between August 2015–6 and had TBE and Eckardt score (ES) performed at baseline and following the last therapy session. With TBE upright single images were acquired at 1.2, and 5 minutes following ingestion of 100–200 mL of low-density barium sulfate. Barium height was measured between the gastro-esophageal junction and the superior extent of any residual barium column. After manually defining the column boundaries, software was used to calculate SA (AGFA IMPAX surface area tool (Figure)). Adequate symptom relief was defined as reduction in ES to ≤2. On TBE, measures of adequate emptying evaluated were i) post-therapy column height ≤5cm, ii) >50% reduction in column height from pre to post-therapy and iii) >50% reduction in column SA from pre to post-therapy. Associations between symptom improvement and TBE measures of emptying were assessed using Pearson’s correlation (R). Paired t-tests compared TBE measures before and after therapy.

Results: 18 patients (9 male; 6 Type I, 11 Type II, 1 Type III) were included. 11 had dilatation and 7 endoscopic myotomy. Reductions with therapy of both mean 5-minute barium column height (14.7 ± 8.7 to 7.9 ± 6.0 cm; P = 0.001 and 0.10; 27.2 ± 43.5 to 24.5 ± 26.0 cm²; P = 0.02) were noted. Symptoms also improved with treatment; median baseline ES of 7 (IQR 5.25–8) improved to 0 (IQR 0–1) post-therapy. Only 2 patients had inadequate symptom relief and are awaiting further treatment. However there was poor concordance between post-therapy barium column height and symptomatic relief (i.e. post-therapy column height >5 cm despite ES ≤3 or vice versa), and the correlation (R) between these two variables was poor (Table). Similar poor concordance was seen when adequate emptying was defined by >50% reduction in column height, but >50% reduction in SA paralleled symptom improvement.

Disclosure of Interest: All authors have declared no conflicts of interest.

Conclusion: In TBE performed on achalasia patients post-therapy, reduction in SA of the residual barium column compared with baseline values parallels symptomatic relief more closely than reduction of column height.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Nutrients enhance belching and reduce intestinal propulsion of gastric gas in healthy volunteers.

E.N. Caballero de Garcia, B. Benslamain Seyid-Jebri, J. Serra Pueyo Gut Motility Unit, Hospital Universitario Germans Trias i Pujol, Badalona/Spain

Contact E-mail Address: noeocaballero4@uab.cat

Aims: To determine the effect of gastric nutrients on trans-portation of gastric gas, and its relationship with abdominal symptoms in healthy volunteers without gastrointestinal symptoms (4 women and 3 men, age-range 21–29 yrs), a mixture of non-absorbable gases was infused into the stomach, 5 cm caudal to the lower margin of the LES, at 25 mL/min during 60 min (Total gas infused: 1500 mL). In each subject two gas infusion tests were performed on separate days, with simultaneous infusion of nutrients (Nutridrink 1.5 Kcal/ml, total 315 Kcal) or saline. Belching, by an esophageal multilumen impedance manometry catheter, rectal gas evacuation, via a rectal tube connected to a barostat, and epigastric and abdominal symptoms, by specific questionnaires (from 0–6), were continuously recorded from the start of gas infusion until 30 min after gas infusion stopped. (Total recording time: 90 min).

Results: During saline infusion, participants evacuated via the rectum virtually all the infused gases (1613 ± 87 mL), with exceptional belching (1.1 ± 0.8 belches) and mild epigastric perception (score 1.7 ± 0.6 at the end of infusion), that decreased during the 30 min following infusion stop (score 1.1 ± 0.4; p = 0.051 vs infusion

Contact E-mail Address: maximilien.barret@aphp.fr
Introduction: Peroral endoscopic myotomy (POEM) is a recently developed technique or the treatment of lower esophageal sphincter achalasia. POEM could be as efficient as surgical Heller myotomy, while associated with lower morbidity. Currently, the Eckardt score is the clinical score that is the most widely used to assess the success of treatment of achalasia, clinical success being defined by a score below 4. However, POEM may not equally improve all four parameters of the Eckardt score.
Aims & Methods: All consecutive patients undergoing POEM for achalasia at our institution, performed by 3 operators with at least 6 months follow-up were prospectively included. Demographic, clinical, procedural, manometric and radiologic data were collected.

Results: Between March 2013 and July 2016, 62 POEM procedures were performed in 49 patients (Male/female 33/22; Median age 55 ± SD 17 years (range 15–77)). Median (IQR) follow-up time was 8 (3–13) months. Achalasia was diagnosed for a median (IQR) of 24 (13–62) months, and 42% of the patients had received a previous treatment, by botulinum toxin injection (8%), pneumatic dilatation (32%), or Heller myotomy (7%). Achalasia subtype were type I in 33%, type II in 37% and type III in 5%. Median Eckardt score and integrated resting pressure were 7 (6–8) and 24 (19–33) mmHg, respectively. An anterior myotomy was done in 60% of cases, and a posterior myotomy in 40% of cases. Median myotomy length was 14 (12–16) cm, and hospital stay was 3 (2–4) days. Severe complications occurred in 5% of cases (1 pleural effusion requiring drainage, 2 pneumonias with more than 10 days of hospital stay). Success rates were similar between patients treated by anterior or posterior myotomy (92% vs. 92%, p = 1), or between those with or without previous treatment (85% vs. 96%, p = 0.32). Six treatment failures were treated by redo POEM in 3 cases, pneumodilatation in 2 cases, and esophagectomy in one case. Median Eckardt score varied from 7 (6–8) to 1 (0–2) at 3 months and 2 (0–3) at 12 months (p < 0.0001). Dysphagia score varied from 7 (6–8) to 1 (0–0) and 0 (0–0) (p < 0.0001), while regurgitations varied from 2 (1–3) to 0 (0–1) and 0 (0–0) (p < 0.0001), chest pain varied from 0 (0–0) to 0 (0–1) and 0 (0–0) (p = 0.006), and weight loss from 2 (1–3) to 0 (0–0) and 0 (0–0) (p < 0.0001). At three months, median (range) drop of the integrated esophageal pressure was 67.3 (57–86)% for saline, 69.5 (60–83)% for Iberogast and 68.6 (60–83)% for placebo. The difference between POEM and placebo was significant (p = 0.007). At six months, median (range) drop of the integrated esophageal pressure was 67.3 (57–86)% for placebo, 69.5 (60–83)% for Iberogast and 68.6 (60–83)% for placebo. The difference between POEM and placebo was significant (p = 0.007). After treatment, median Eckardt score was 7 (6–8) in 60% of cases, and 0 (0–0) (p = 0.001) in 40% of cases. The analyses performed by the study day and the follow-up visit, 86% of patients still had clinical success, and 31% reported gastro-esophageal reflux symptoms.
Conclusion: Our results confirm the efficacy of the POEM as a first line or rescue treatment, and its low complication rate. POEM is most effective on dysphagia and weight loss, while chest pain and regurgitations tend to persist after treatment.
Disclosure of Interest: All authors have declared no conflicts of interest.

PI828 SUBGROUP ANALYSES OF CLINICAL TRIALS ON A HERBAL MEDICINE IN FD, STW 5: AN INTERNATIONAL CASE SERIES

Introduction: Well-proven therapeutic options for the therapy of functional gas-trointestinal disorders are collected.
Aims & Methods: As well as patients of different age groups, sub-group analyses were conducted. More than 73 Mio patients are available. For determining whether its efficacy in gastroduodenal ulcers (GIUS) and in male and female patients did show a comparable efficacy in all these groups.

Results: In all trials, a uniform evaluation was possible. The full analysis set (FAS) included 557 patients (272 resp. 285 for placebo resp. verum). The mean age (45 years) was similar (both groups 168 cm). Mean body weight (72.0 resp. 72.2 kg), the BMI (25.35 resp. 25.54), the gender distribution (67.5 resp. 69.5% females), the duration of the disease at the time of inclusion and the baseline of the GIS (11.6 resp. 11.5 points) were very comparable between both groups. The primary variable GIS the difference between placebo and verum after 28 days of treatment showed a highly significant (p < 0.0001) difference between placebo and verum (6.7 resp. 4.7 points). The analyses in different age groups (up to 30, 30–40, 40–50, 50–60, above 60) and in male and female patients did show a comparable efficacy in all these groups.

Conclusion: These meta-analyses therefore clearly show the efficacy of STW 5 (Iberogast) and its therapeutic usefulness irrespective of age and gender. Given also the very good tolerability shown by the study data, STW 5 is well suitable also in self-medication. Additional insights can be expected from additional sub group analyses, as e.g. the evaluation of subgroups with specific predominant symptoms.

Introduction: Achalasia is a chronic condition presenting with dysphagia, regurgitation, chest pain and/or weight loss. Management options include Heller’s myotomy, Botox, pneumatic dilatation and Per-Oral Endoscopic Myotomy (POEM). Treatments carry risks of bleeding and perforation. Concomitant portal hypertension with varices is very rare and achalasia treatment in this context has only been described in single case reports.
Aims & Method: Experience from physicians/surgeons treating these disorders was sought through the International Manometry Working Group.

Results: 13 patients with portal hypertension from 6 international centres have been collected; mean age 61 ± 9 years. The mean pre- therapy Eckardt score was 7 (IQR 6–9). 9/13 (69%) patients had a Barrett’s esophagus (BMI ≥25) and 12/13 (92%) had esophageal physiology studies performed. There were 3 Type 1, 6 Type II, 2 Type III achalasia and 2 with oesophageal-gastric outflow obstruction. Varices were identified endoscopically in 7 patients, radiologically in 5 and in 1 patient varices were first noted during surgical myotomy. 2 patients had grade 3 varices, 3 grade 2 and 3 had grade 1 varices (grading not provided for the rest). Cirrhosis was due to alcohol in 7 patients, non-alcoholic steatohepatitis in 3, cryptogenic in 2 and 1 had hepatitis C cirrhosis. 75% were Child-Pugh A and 25% were Child-Pugh B. Patients had diverse treatments for their achalasia. 4 were treated with Botox injections (1 with EUS), 4 had dilation alone, 3 received a POEM, another had POEM then dilation and 1 patient had Botox followed by Heller’s myotomy. 3 patients underwent variceal eradication in advance; all had banding first but in 2 patients superficial eradication was followed by a transju-luminal percutaneous transluminal angioplasty (TIPPS) before endoscopic dilation. All patients had symptomatic improvement with median Eckardt score post inter-vention = 1 (IQR 0–2) < 0.0001 compared to baseline. A matched group of 20 patients who underwent treatment for achalasia (all subtypes) but without varices had received complications of bleeding or perforation; however both patients who had TIPPS had temporary hepatic decompensation.
Conclusion: This report 13 patients from international centres who have had interventions for achalasia on the background of oesophageal varices. None had bleeding complications despite only 3 having had variceal eradication. Symptom response mirrored those who undergo standard achalasia therapy,
PI830 THE NATURAL HISTORY OF ACHALASIA: EVIDENCE OF A CONTINUUM–THE PATTERN-EVOLUTIVE STAGING THEORY

Dept. Of Surgical, Oncological And Gastroenterological Sciences, University Hospital of Padova, Padova/Italy

Contact E-mail Address: m.costantini@unipd.it

Introduction: Esophageal achalasia is classified into three clinically relevant patterns at High Resolution Manometry (HRM) and according to Chicago Classification. Currently, it is unclear whether they represent distinct entities or are part of a disease continuum.

Aims & Methods: The aims of this study were: a) to test the hypothesis that the three manometric patterns represent different stages in the evolution of esophageal achalasia and b) to investigate whether manometric patterns change after Laparoscopic Heller-Dor (LHD). We evaluated the patients who had a diagnosis of achalasia and underwent LHD as first treatment from 1992 to May 2016. Symptoms were scored using a detailed questionnaire for dysphagia, food-regurgitation, and chest pain; barium swallow, endoscopy, and esophageal manometry (conventional or High Resolution technique) were performed, before and after surgery for a minimum of 6 months after surgical treatment. All conventional manometric tracings, before and after 2010, were reviewed and re-classified according to the manometric-pattern classification, whereas after 2010 the HRM data were prospectively collected.

Results: Five-hundred and eleven consecutive achalasia patients (M:F = 283:228) represented the study population. Based on their manometric findings, 231 patients (45.2%) were classified as having pattern I, 241 (47.2%) had pattern II, and 39 (7.6%) had pattern III. Demographic and clinical data showed that pattern II cases had a shorter duration of symptoms, a more incidence of chest pain, and a less dilated gullet (p < 0.001). Further, all patients with a sigmoid-shaped mega-esophagus (radiological grade IV) had pattern I achalasia. One patient with diagnosis of pattern III achalasia, who refused any treatment evolved to pattern II at a follow-up manometry performed for a progressive worsening dysphagia after 36 months. At a median follow-up of 30 months (IQR 12–56), the outcome of surgery was positive in 479 patients (91.7%).

Conclusion: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p = 0.0001). Table 1 shows the serum biomarkers values divided according to five categorical units – Dysphagia (H), GER, HP, CAG, and PPIs treatment. With respect to HP IgG allow to diagnose different pathological conditions such as HP- and non HP-related gastritis (CAG), and the efficacy of proton pump inhibitor (PPI) therapy in a primary care population. A cohort of 2583 dyspeptic patients (male 36%, mean age 44.0 yrs, range 6–95) was selected in a primary care population and examined with a panel of biomarkers (Pepino-in (PG-1) and -II (PG-II), amidated gastrin-17 (G-17), and HP IgG (Biohit, Finland)). A standard questionnaire, including upper gastrointestinal symptoms and PPI use, was administered. Exclusion criteria were dysphagia, anemia, weight loss and vomiting. CAG patients underwent to endoscopy and histological examination. Results: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p = 0.0001). Table 1 shows the serum biomarkers values divided according to five categorical units – Dysphagia (H), GER, HP, CAG, and PPIs treatment. Results: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p = 0.0001). Table 1 shows the serum biomarkers values divided according to five categorical units – Dysphagia (H), GER, HP, CAG, and PPIs treatment. All authors have declared no conflicts of interest.

Table 1: Changing manometric patterns after LHD. *5 patients had a recovery of peristalsis (all patients had a pattern II before LHD).

<table>

Introduction: The development of non-invasive methods to detect the presence of H. pylori, and to estimate the extent and severity of gastritis, have reduced the need for diagnostic endoscopy in asymptomatic individuals. However, it is not known whether the use of non-invasive diagnostic methods is effective in dyspepsia patients.

Aims & Methods: To use a non-invasive blood test with four stomach-specific biomarkers to assess the prevalence of different stomach conditions: gastroesophageal reflux disease (GERD), H. pylori (HP) infection, chronic atrophic gastritis (CAG), and the efficacy of proton pump inhibitor (PPI) therapy in a primary care population. A cohort of 2583 dyspeptic patients (male 36%, mean age 44.0 yrs, range 6–95) was selected in a primary care population and examined with a panel of biomarkers (Pepino-in (PG-1) and -II (PG-II), amidated gastrin-17 (G-17), and HP IgG (Biohit, Finland)). A standard questionnaire, including upper gastrointestinal symptoms and PPI use, was administered. Exclusion criteria were dysphagia, anemia, weight loss and vomiting. CAG patients underwent to endoscopy and histological examination.

Results: Healthy stomach was found in 21.2% patients. Prevalence of CAG increased with patient’s age in both sexes as well as the use of PPIs (p = 0.0001). Table 1 shows the serum biomarkers values divided according to five categorical units – Dysphagia (H), GER, HP, CAG, and PPIs treatment. All authors have declared no conflicts of interest.

Disclosure of Interest: All authors have declared no conflicts of interest.

Abstract No: P1831

Contact E-mail Address: g.holtmann@uq.edu.au

Introduction: Functional dyspepsia (FD) is one of the most common functional gastrointestinal disorders characterised by chronic or relapsing symptoms without structural or biochemical abnormalities that can be identified in the routine clinical setting. Thus, treatment targets symptoms. Very little is known about prolonged treatment for more than 4 weeks. The overall success rate of the combined treatment (LHD plus endoscopic dilations) has been reported to be 80%. This study aimed to evaluate the sustained effects of Menthacarin1 with regard to disease-specific symptoms and QoL in FD patients. After the 4-week randomised placebo-controlled treatment period, patients were allowed to continue the treatment. The treatment was given in a double-blind fashion and allocation of treatment followed the initial randomisation. 114 adult FD outpatients were initially treated and received twice a day one enteric-coated Menthacarin capsule or a matched placebo capsule for 4 weeks. Fifty-four of them participated in the optional follow-up phase and received Menthacarin (34) or placebo (20) for further 8 weeks according to their original randomization. The results of these 54 patients are presented here. Outcomes were assessed utilising the validated self-rating Nepean Dyspepsia Index (NDI). Intra-individual differences between baseline and week 4/week 12 for NDI sub-scores for pain (sum of the NDI items ‘pain’ or ‘ache in upper
abdomen, ‘discomfort in upper abdomen’, ‘cramps in upper abdomen’ and ‘belching’) and discomfort of the NDI items ‘pressure in upper abdomen’ and ‘fullness after eating or slow digestion’) and for QoL by NDI total score were compared and descriptively tested by means of Wilcoxon-Mann-Whitney U-tests.

Results: After the initial 4 weeks, 54/114 patients opted for an extension of therapy. Interestingly, 34 out of 52 patients had been on active therapy while only 20 had received placebo. Until week 4, the NDI sub-score for pain had decreased by 7.5 ± 3.9 points during Menhitarin treatment as compared to 5.4 ± 4.1 points during placebo treatment (p = 0.0371). After the follow-up, overall redaction for Menhitarin (8.7 ± 4.9 points) was also significantly better as compared to placebo (5.1 ± 4.9 points, p = 0.005). The NDI sub-score for discomfort had decreased until week 4 by 3.5 ± 2.1 points during active therapy as compared to 1.2 ± 2.1 points during placebo treatment (p = 0.0003). For the 12-week therapy, the score had declined by 3.7 ± 2.5 points and 1.3 ± 2.6 for Menhitarin and placebo, respectively (p = 0.0014). Overall QoL improvement was better for active medication for 4 and 12 weeks as compared to placebo.

Conclusion: After 4 weeks of randomised double-blind, placebo-controlled treatment with either Menhitarin or placebo, patients who received active medication are more likely to opt for a continuation of therapy as compared to patients on placebo. The gain over placebo remained significant even after 12 weeks of treatment. Menhitarin® is a proprietary combination of essential oils of specified quality from Mentha × piperita L. (90 mg peppermint oil WS® 1340) and Carum carvi (50 mg Caraway oil WS® 1520).

Introduction: The introduction of proton pump inhibitors (PPIs) into clinical practice has revolutionized the management of acid-related diseases. Studies in primary care and emergency settings suggest that PPIs are frequently inappropriately prescribed or used in clinical conditions with little benefit.

Aims & Methods: To evaluate the role of Gastropanel in relation to the appropriateness of PPI-therapy prescription. 2583 dyspeptic patients (male 36%, mean age of 44.0 yrs, range 6-95) with no alarm symptom (i.e., dysphagia, anemia, weight loss and vomiting) from a primary care population were included in the study. For each patient a blood sample was collected for serum Pepsinogen I (PG-I) and II (PG-II), Gastrin 17 (G-17) and IgG HP (Biohit, Oyj, Finland); moreover, a clinical questionnaire searching for symptoms and presence of HP, and PPI therapy was filled out. We have evaluated the following serological profiles: HP infection, chronic atrophic gastritis (CAG), response to PPI therapy. The results obtained were used to evaluate the appropriateness of PPI-therapy prescription.

Results: 1015/2583 (39.3%) received PPI therapy up to three months before serum sampling and were included in the study. Among 1015 patients under PPI therapy, 294 (29.0%) received half-dose PPIs, 709 (69.8%) full-dose PPIs and 12 (1.2%) an exceeding-dose PPI. Patients under PPI therapy (3.7%) showed a serological status compatible with body CAG (the definitive diagnosis was confirmed histologically). 68 (6.7%) presented HP infection. Table 1 shows the values of PG-I and G-17 values according to the response to PPI therapy. Patients under PPI therapy should be preceded by the assessment of gastric functional status. In particular, patients with HP infection should be eradicated before PPI therapy, while CAG patients should not receive PPI therapy because they are no responders. Patients who do not respond to PPI therapy should be further investigated (compliance, diagnosis).

Disclosure of Interest: All authors have declared no conflicts of interest.

P1834 DUODENAL ACID PERFUSION INCREASES DUODENAL MEMBRANE REACTIVITY AND ACTIVATES THE DUODENOGASTRIC REFLEX, INDEPENDENTLY FROM MAST CELL ACTIVATION

H. Vanheel1, R. Farrel1, D. Beeckmans1, M. Vicario2, J. Tack3, T. Vanuytsel1

1Turigid, KU Leuven, Leuven; Belgium
2Vall d’Hebron Institut Recerca Gastroenterology, Barcelona; Spain

Contact E-mail Address: hanne.vanheel@med.kuleuven.be

Introduction: We recently reported that functional dyspepsia patients show impaired duodenal integrity, associated with low-grade inflammation (Vanheel, Gut 2014). A potential cause underlying this phenomenon may be the increased duodenal acid exposure that has been demonstrated in some of these patients.

Aims & Methods: Our aim was to evaluate the effect of duodenal acid perfusion on duodenal permeability in healthy volunteers and to investigate whether mast cell activation is required for acid-induced impairment of mucosal integrity. As it has already been shown that duodenal acid activates duodenogastrectomy reflex pathways, we also assessed intragastric pressure (IGP). This study consisted of 2 groups, each including 10 healthy volunteers. 1) An infusion tube was positioned in the second part of the duodenum and a high resolution manometry probe was positioned in the stomach to measure IGP. HCl 0.1N or saline was infused in the duodenum during 30 min (5mL/min) in a randomized, double-blind manner.

Disclosure of Interest: All authors have declared no conflicts of interest.
increasing. Pepsinogen I (PGI) <30 μg/mL, PGI/PGII <3 and gastrin-17 (G17) >10 μpmol/L are non-invasive serological markers to explore gastric function, with a negative predictive value for chronic atrophic gastritis (CAG) of 96%.

Aims & Methods: Aim of the study was to evaluate gastric function by means of serology (PGI, PGII, G17 and IgG-antibodies against Helicobacter pylori) in very elderly patients, including centenarians. A total of 379 patients were prospectively enrolled (M = 126, F = 253, mean age = 83.6 ± 8.7, range 70-106). They were divided in four groups: 132 subjects with an age between 70 and 79 years old (first group), 92 subjects between 80 and 89 (second group), 76 subjects between 90 and 99 (third group) and 25 subjects between 100 and 106 (fourth group). Demographics and drug intake, particularly the PPI intake, were collected. For all patients, serological markers were determined in fasting blood by using Gastropanel® (Biohit Oyj, Finland; normal values: PGI: 30-120 μg/L; PGII: 2-15 μg/L; PGI/PGII ratio: >3; G17: 1-9 μpmol/L; H.p.-IgG: <30 EU).

Results: In the first group (age 70-79), 18.2% of the subjects showed H. pylori infection (PGI >80 μg/L, IgG against H.p. >30 EU), 22.7% had CAG (PGI <30 μg/L and PGII <3) and 53.8% were under PPI therapy. 16.9% of the patients on PPI therapy had CAG. In the second group (age 80-89), 32.9% of the subjects showed H. pylori infection, 8.9% had CAG and 48.6% were under PPI therapy. 8.5% of the patients on PPI therapy had CAG. In the third group (age 90–99), 22.4% of the subjects showed H. pylori infection, 10.5% had CAG and 48.7% were under PPI therapy, 8.1% of the patients on PPI therapy had CAG. The fourth group (age 100-106), 44.0% of the subjects showed H. pylori infection, 16.0% had CAG and 72.0% were under PPI therapy. 16.7% of the patients on PPI therapy had CAG.

Conclusion: Acid secretion is preserved in most of the elderly and very elderly subjects, even in centenarians. Serological markers may be useful to identify patients affected by CAG in which the administration of PPI is inappropriate, especially in the elderly.

Introduction: Reflux hypersensitivity (RH) was lately defined as a functional esophageal disorder by Rome IV workshop. The clinical and psychological characteristics are still unknown.

Aims & Methods: The aim of this study was to assess the reflux and psychological characteristics of RH. Patients who underwent 24 h pH-impedance monitoring were screened from Jan 1st 2011 to Nov 31st 2015. The patients with heartburn or chest pain ≥2 days/week for more than 6 months were enrolled. Healthy volunteers (HV) were enrolled too. All subjects fulfilled the SCL-90 questionnaire, underwent gastroscopy to exclude upper gut organic diseases and underwent HRM test to exclude manometric disorders. The patients for esophageal mucosal but overload acid, weakly acid or non-acid reflux were diagnosed as non erosive reflux disease (NERD). The patients with normal esophageal mucosal and normal reflux but positive symptom index (SI) or symptom association probability (SAP) were diagnosed as RH. The patients with normal mucosal, normal reflux, normal SI or SAP and negative PPI test results were enrolled in functional heartburn (FH) group. The reflux and psychological characteristics were compared among NERD, RH and FH.

Results: Total 231 patients were enrolled. 107 were NERD (48.25 ± 1.18 yrs, M:F = 55:52), 92 were FH (48.30 ± 1.27yrs, M:F = 98:83), 32 were RH (48.41 ± 2.63yrs, M:F = 4:28). 28 HVs (47.21 ± 2.27 yrs, M:F = 8:20) were enrolled as healthy volunteers for HRM test. The differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCI and DL) introduced by the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCI and DL) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new system for esophageal manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: High-Resolution Manometry (HRM) has recently became the gold standard for the evaluation of esophageal motility. A new classification of esophageal motility disorders (Chicago Classification, v. 3.0) has been developed, based on the findings from a given hardware and software. Different systems for HRM and new features of the existing ones have recently been developed.

Aims & Methods: In this study we aimed to evaluate a new solid-state HRM system and a new 3-D catheter and system for the study of lower esophageal sphincter (LES). Fifteen healthy volunteers (7 m, 8 f; median age 27) underwent two consecutive Esophageal HRM studies by using two different solid state systems (ManoScan, Medtronic, Minneapolis, USA and Medica SpA, Italy with Unisensor AG, Atikon, Switzerland catheter). The studies were performed in a random order using the standard protocol. Furthermore, a new 3-D catheter for the study of sphincters was evaluated in 12/15 volunteers.

Results: Table 1 reports the findings obtained with the Medica system compared to the consolidated Medtronics system. The data of the 3-D evaluation are also reported. The data are expressed as medians and 5th-95th percentiles.

Conclusion: Significant differences were recorded in most of the considered parameters obtained by the two HRM systems. This is particularly relevant in the evaluation of the LES relaxation, the cardinal point in the hierarchical approach of the Chicago Classification, probably due to different analysis used by the two systems (the lowest residual pressure vs IRP). Furthermore, the differences found in the measurement of the LES resting pressure and abdominal length may rely either on the different technology (3-D vs linear transducers) or on the different algorithms and thresholds used. The latter may probably also apply to the differences found with the two systems in the duration of the esophageal contractions and in the new contractile parameters (i.e.: DCI and DL) introduced by the Chicago Classification. This study emphasizes the need for a careful validation of any new system for esophageal manometry. The acquisition of new sets of normal values, to be used to compare the data measured in patients, is therefore mandatory. The results of our study may represent the reference normal values for other esophageal laboratories that are using the HRM systems and devices we tested here.

**Introduction:** Proton pump inhibition-response esophageal eosinophilia (PPI-REE) is a condition characterised by symptoms of esophageal dysfuction in the setting of eosinophilic inflammation on esophageal biopsies responding to a course of 5 weeks of PPI therapy. Recent data collected by using esophageal high resolution manometry (HRM) documented that patients with PPI-REE present frequently motility abnormalities, mostly weak peristalsis and hypotensive esophagegastroduodenal junction (EGJ). Data on the effect of PPIs in improving these motor abnormalities are lacking.

**Aim & Methods:** The aim of this study was to prospectively compare HRM features of patients with PPI-REE before and after a course of PPI therapy. Consecutive patients with symptoms suggestive of EoE underwent upper endoscopy to assess the presence of at least 15 eos/hpf on esophageal biopsies at mid/proximal esophagus and, therefore, were treated with twice-daily PPI for at least 8 weeks. Thereafter, patients repeated upper endoscopy and PPI-REE was identified in case of less than 15 eos/hpf and a 50% decrease from baseline. Patients with PPI-REE underwent HRM at the time of the diagnosis (off-PPI) and after the course of PPIs (on-PPI). Patients with achalasia and absent peristalsis were excluded. (Chicago Classification v.3).

**Results:** Twenty-eight patients [23M:5F; mean age 33] reporting dysphagia (93%), bolus impaction (68%) and chest pain (25%) were diagnosed with PPI-REE. After a proton pump secretory therapy, most of the patients reported complete resolution of esophageal symptoms directly linked to esophageal infiltration (p < 0.001), namely dysphagia, bolus impaction and chest pain. Compared to HRM features at baseline, HRM after PPI therapy showed that patients with PPI-REE had higher median EGI resting pressure [baseline 11 (1–34) vs. post-PPI 17 (1–34); p < 0.05], greater mean distal contract integral [1094 (483–5281) vs. 2634 (495–6450); p < 0.01], and less frequent panesophageal pressurization [6 (21%) vs. 0 (0%); p = 0.02]. No differences were observed in terms of distal latency and rate of different EGI subtypes (p > 0.05). As to the manometric diagnoses, after PPI therapy patients with PPI-REE showed a reduced rate of ineffective motility or fragmented peristalsis [16 (57%) vs. 7 (25%), p = 0.02] and increased frequency of normal peristalsis [9 (32%) vs. 18 (64%), p = 0.03]. No differences were observed in terms of frequency of distal esophageal spasm and outflow obstruction diagnoses (p > 0.05).

**Conclusion:** In most PPI-REE patients, PPI therapy restores the impairment of esophageal function induced by ineffective or fragmented peristalsis, thus favouring the return to a normal motility pattern. This finding, paralleled with symptoms improvement in the same subjects, seems to emphasize the important role of inflammation linked to the eosinophilic infiltration of the esophageal wall in inducing motor dysfuction and related symptoms.

Aims & Methods: Serum levels of IgG4 and IgE of 19 EoE patients were measured every six weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as a control group. Serum levels of IgG4 and IgE of 19 EoE patients were measured before and eight weeks of therapy with budesonide (1 mg twice a day). Biopsies were taken from the esophagus before and after therapy for histological and immunohistochemical evaluation. 14 patients with GERD without histological proof of eosinophilic granulocyte infiltration were taken as control group.

Results: Serum levels of IgG4 and IgE of affected children and adolescents, which manifests in the normal development of their daily activities, their physical health and their mental status, with parents generally understanding the impact of the disease regarding children declared HRQoL. Regarding determinant factors, age was not associated with HRQoL. Number and severity of symptoms negatively correlated with child-reported and Parent proxy-reported PedsQL score and family impact score. Disease duration was identified as a risk factor for a low SF-36 score. EoE impacts on a number of domains including frustration (75.9%), possible side effects (69.4%), ease of therapy use (65.8%), and duration (65.8%) of therapy. Knowledge about patients' view regarding the different therapeutic options is very limited.

Introduction: For technical reasons, the histological characterization of eosinophilic (EoE)-specific alterations is almost exclusively based on those found in the esophageal epithelium, whereas little is known about subepithelial abnormalities.

Aims & Methods: In this study, we aimed to systematically assess the nature of subepithelial histologic alterations, analyze their relationship with epithelial histologic findings, endoscopic features, and symptoms, and evaluate the diagnostic impact of subepithelial eosinophil counts in patients with an epithelial peak eosinophil count of <15/ hpf. We prospectively included in this cohort study adult EoE patients who underwent assessment of clinical, endoscopic, and histologic disease activity using scores.

Results: We included 200 EoE patients (mean age 43.5 ± 15.7 years, 74% males) with a median peak count of 36 intraepithelial eosinophils/hpf [IQR 14–84]. The following histologic features were identified in the subepithelial layer: eosinophilic infiltration (median peak count of 20 eosinophils/hpf [IQR 10–51]), eosinophil degranulation (43%), fibrosis (82%), and lymphoid follicles (56%). Peak intraepithelial eosinophil counts were higher, identical, and lower when compared to the subepithelial layer in 62.5%, 7%, and 30.5% of patients, respectively. Subepithelial histologic activity correlated with epithelial histologic activity (rho 0.331, p < 0.001), endoscopic severity (rho 0.208, p = 0.003), and symptom severity (rho 0.179, p = 0.011). Forty percent (21/52) of patients with <15 intraepithelial eosinophils/hpf had subepithelial peak counts of ≥15/hpf.

Conclusion: In one third of patients subepithelial peak eosinophil counts are higher than epithelial eosinophil counts. Systematic assessment of subepithelial eosinophil counts can aid in diagnosing EoE in additional 40% of all patients with epithelial eosinophils <15/hpf.

Introduction: The pathophysiology of heartburn perception in gastro-esophageal reflux disease (GERD) remains unclear. The degree of reflux-induced epithelial change seldom predicts symptom severity, as evidenced by the greater symptom burden seen in non-erosive reflux disease (NERD) compared to patients with Barrett’s esophagus (BE). Existing models of acid hypersensitivities are inadequate to explain this discordance.

Aims & Methods: To test the hypothesis that differences in peripheral esophageal afferent innervation may be relevant, we studied the distribution of mucosal nerve fibers in patients with NERD and BE and compared the results with that of healthy subjects. 13 patients with NERD undergoing reflux testing and 16 patients with BE undergoing endoscopic surveillance were prospectively recruited. Biopsies were obtained from the proximal and distal esophageal mucosa in NERD patients and the distalmost squamous epithelium in BE patients, then examined immunohistochemically for the presence and location of calcitonin gene-related peptide (CGRP)-immunoreactive nerve fibers. The results were compared with those from 10 healthy volunteers (HV) previously studied by our group.

Results: The distribution of mucosal CGRP-immunoreactive nerves is equidistant from the distal esophageal lumen in HV and BE (median 25.5 cell layers to surface [IQR 21.4–28.8] vs 215 [16.1–27.5] respectively, p = 0.015). Mucosal innervation is significantly more superficial in NERD both distally (8.65 pg/ml in group III (p = 0.05). The expression of surface M1/M2 macrophage markers significantly varied depending on the acidity of refluxate. Mild-alkaline pH (III group) resulted in increasing expression of M2 markers CD163/CD206 as compared to M1–CD80–CD25, but changing M1/M2 index of CD163/CD80 vs. CD206/CD25, respectively (2.86 ± 0.53 vs. 1.5 ± 0.41, p = 0.015). Analysis of MDM phenotype showed the prevalence of M1 phenotype in all groups.

Conclusion: Pooled analysis of GERD patients refluxate type influence on macrophage phenotype showed the prevalence of M1 phenotype in groups: Th2 cytokine macrophage production increased with increasing pH, and most significantly changed in IL10: 8.43 ± 3.13 pg/ml in group I vs. 27.7 ± 8.65 pg/ml in group III (p < 0.05). The expression of surface M1/M2 macrophage CD markers significantly varied depending on the acidity of refluxate. Mild-alkaline pH (III group) resulted in increasing expression of M2 markers CD163/CD206 as compared to M1–CD80–CD25, but changing M1/M2 index of CD163/CD80 vs. CD206/CD25, respectively (2.86 ± 0.53 vs. 1.5 ± 0.41, p = 0.015). Analysis of MDM phenotype showed the prevalence of M1 phenotype in all groups.
PI846 BELCHING PATTERNS IN PATIENTS WITH ISOLATED PATHOLOGICAL UPRIGHT REFLUX AND PATHOLOGICAL BIPOSITIONAL REFLUX

Gastroenterology, Maastricht UMC, Maastricht/Netherlands

Contact E-mail Address: j.conchillo@mumc.nl

Introduction: Belching is a commonly occurring symptom in patients with gastroesophageal reflux disease (GERD). Belching may afflict reflux patients who are in supine position as well as in the upright position (UP). Whether GERD patients with pathological supine upright reflux (UP) have belching patterns that are different from GERD patients with pathological bipositional reflux (BIP) remains unknown.

Aims & Methods: Aim of this study was therefore to examine the belching patterns of UP reflux patients as compared with BIP reflux patients. We included 50 consecutive patients with pathological reflux and typical symptoms who underwent 24-h pH-impedance monitoring at the Maastricht University Medical Centre from 2015 to 2017. Patients referred for excessive belching were excluded. A group of 25 UP reflux patients (10 male, mean age 52.9 years (range 22–77)) and 25 BIP reflux patients (11 male, mean age 47.9 years (range 18–77)) were enrolled. 24-h pH-impedance tracings were analysed manually. We classified belches according to: a) physiological mechanism: supragastric vs. gastric; and b) their temporal relationship with a liquid reflux episode: isolated belch, preceding or during a liquid reflux episode. Symptom-assessment analysis was performed to assess a relationship between reported symptoms and reflux episodes.

Results: BIP patients showed higher acid reflux time (17.8 ± 2.4% vs. 7.3 ± 0.6%, p < 0.001) and higher number of total reflux episodes (121 ± 9 vs. 97 ± 8, p = 0.05) than UP patients. Notably, both the proportion of reflux episodes with belches of any type and the proportion of belches preceding liquid reflux were higher in UP patients than in BIP patients (51.7 ± 3.6% vs. 32.1 ± 3.7%, p < 0.001 and 27.3 ± 3.1% vs. 17.8 ± 2.9%, p = 0.03, respectively). No difference was found in the proportion of both supragastric and gastric belches between groups. During 24-h pH-impedance monitoring UP patients reported more symptoms (21 ± 6 vs. 12 ± 3, p = 0.16) and had more positive symptoms with belches (60.2 ± 7.1% vs. 39.0 ± 6.6%, p = 0.03) than BIP patients. Of the total number of belches that were detected using 24-h pH-impedance, more belches were detected in UP patients than in BIP patients (24.8 ± 6.4% vs. 11.1 ± 2.5%, p = 0.06).

Conclusion: In our study, GERD patients with isolated pathological upright reflux had more often (symptomatic) belches than GERD patients with pathological bipositional reflux. Therefore, examination of belching patterns can assist diagnostic and therapeutic strategic planning in GERD patients who are refractory to medical therapy.

PI847 IS REFLUX DURING NAPS WORSE THAN DURING NIGHT-TIME SLEEP?

C. Tereul Sánchez-Vegazo, M. J. De Higes Ruiz, A. Albillos
Gastroenterology, Hospital Ramón y Cajal, Madrid, Madrid/Spain

Contact E-mail Address: cteruelevgazo@yahoo.es

Introduction: Gastroesophageal reflux in the recumbent period is related to a higher risk of developing oesophageal lesions (severe esophagitis or Barrett oesophagus). The only study to date that analysed reflux during daytime naps suggested that it is worse than that which occurs during the night-time sleep. Our hypothesis was that naps are not associated with a more severe acid reflux than night-time sleep, what does not support a specific recommendation against taking daytime naps for GERD patients. Avoiding short meal-to-bed time specifically for naps could be advisable.

Disclosure of Interest: All authors have declared no conflicts of interest.

None of the subjects had any motility disorder defined by the Chicago classification. These were compared before and after the menthol infusion. Distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows were obtained. These were compared before and after the menthol infusion. ManoScan software and parameters used in the Chicago classification (v3.0) were used in the study. Aims & Methods: The aim of the study was to evaluate the effect of the menthol infusion into the esophagus on the esophageal peristalsis and lower esophageal sphincter pressure in healthy volunteers. High-resolution manometry and the parameters of esophageal pressure topography were used to quantitatively evaluate the certain components of esophageal motility. 13 healthy volunteers without out esophageal symptoms were enrolled. High-resolution manometry, either with a thin silicon tube attached were placed transnasally so that the distal end of the tube was 5 cm above the LES. After a 5 min. adaptation period the measurement was performed in the supine position according to the protocol as follows: after the baseline recording 10 water swallows of 5 ml and 3 water swallows of 10 and 15 ml. After that a 20 min. infusion challenge with 3 mM menthol 8 ml/min. was carried out and subsequently the water swallows in order described above were repeated. HRM tracings were manually analyzed using ManoScan software and Parameters used in the Chicago classification (v3.0) were evaluated. Integrated relaxation pressure (IRP), nadir LES pressure and distal contractile integral (DCI) values from 5 ml, 10 ml and 15 ml swallows were obtained. These were compared before and after the menthol infusion. Pairwise analysis was used for statistical analysis. Results: None of the subjects had any motility disorder defined by the Chicago Classification v3.0. Few volunteers reported only mild cold sensation during infusion presumed to be of the esophageal origin. The nadir LES pressure before and after menthol infusion was 7.5 ± 0.5 mmHg vs. 7.3 ± 0.7 mmHg, respectively (p > 0.7). IRP of 5 ml swallows was 2.8 ± 0.6 mmHg vs. 2.1 ± 0.5 mmHg showed significance (p = 0.01). However, difference of IRP of 10 ml and 15 ml swallows was not significant (p > 0.1, p > 0.5, respectively). Average of 5 ml swallows: 85.7 ± 12.6 s, respectively. Average of 10 ml swallows: 814.2 ± 116.2 mmHg before and after menthol infusion, respectively (p > 0.5). We found no difference in DCI in 10 ml and 15 ml swallows before and after menthol infusion. Menthol seemed to have had only a marginal insignificant effect on IRP and DCI in rapid swallow flow. Conclusion: We quantified the effect of menthol on the esophageal function and LES pressure in healthy volunteers using high resolution manometry. The analysis of HRM tracings revealed that menthol has no effect on particular parameters of the distal esophageal pressure and esophageal peristalsis. Disclosure of Interest: All authors have declared no conflicts of interest.

P1850 ANALYSIS OF THE RELATIONSHIP BETWEEN GLOBS PERCEPTION AND ACIDIC LARYNGOPHARYNGEAL REFLUX BY DUAL PHARYNGEAL AND ESOPHAGEAL 24-HOUR PH/ IMPEDANCE MONITORING
L. Kubernáková, M. Ďurčík, P. Banovcin, R. Hyrdeł Internal Gastroenterological Clinic, Jessenius Faculty of Medicine, Martin/Slovak Republic

Contact E-mail Address: lenka.kubernakova@gmail.com

Introduction: Globus is considered to be related to the gastroesophageal reflux disease/laryngopharyngeal reflux (LPR). However, a substantial part of subjective and self-perception of globic sensation which is impossible to measure objectively makes this symptom difficult to study. Visual dysphagia and, or altered functional state of the afferent nerve endings in the hypopharynx resulting from reflux have been suggested responsible for the development of globus. We hypothesized differences in the reflux burden and esophageal/pharyngeal acid exposure between the patients with LPR symptoms with globus compared to the patients with LPR symptoms without globus.

Aims & Methods: Patients referred for suspected LPR were screened and those with positive reflux symptom index (RSI > 15) and at least one acidic LPR episode during 24 h pH/impedance study were enrolled. We recruited patients that were at least 30 days without PPI treatment. Appropriate distance between pH sensors was chosen based on manometrically determined LES and UES so that the proximal pH sensor was positioned 1 cm above UES and distal sensor was positioned 4–6 cm above LES. For each LPR event we determined the maximum drop of pH on the pH level during 24 h. According to the question 8 (sensations of sticking/lump in the throat) of self-evaluated RSI questionnaire those were divided into globus positive (tack 4–5 in the RSI) or globus negative (tack 0–1 in the RSI).

Results: 19 (13M/6F) completed the study. The number of globus positive and negative patients was 11 and 8, respectively. There were no major differences between groups. Disregarding the questions about globus in the RSI there was no significant difference of the RSI between the globus positive and negative group (25 ± 2 vs. 21 ± 2, respectively, p = NS). As for the reflux in distal esophagus, we observed no difference in the acid exposure time between the globus positive and negative patients (21 ± 11 vs. 22 ± 11%, respectively, p = NS). We therefore assumed differences in the results from the hypopharyngeal pH sensor. However, the number of LPR events with pH drop to < 5.5 showed no significant difference between the globus positive and negative patients, either for the number of events (82 [5.5–6.5] vs. 55 [5.5–6.5], respectively, p = NS) or for the pharyngeal acid exposure time (45 ± 14 vs. 88 ± 42, respectively, p = NS). We speculated that more acidic LPR events (pH drop to < 5.5) might be of greater relevance. However, no significant difference was found between the globus positive and negative patients either in terms of the number of these LPR events (10 [2–2] vs. 1 [1–1], respectively, p = NS), or the pharyngeal acid exposure time (16 ± 4 vs. 42 ± 36, respectively, p = NS).

Conclusion: We found no significant difference in the reflux burden in the distal esophagus/hypopharynx between the groups of symptomatic LPR patients with and without globus using 24h dual channel pH/impedance. Other factors, e. g. visceral hypersensitivity might play a role in the development of globus symptoms, even in patients with objectively established LPR. Disclosure of Interest: All authors have declared no conflicts of interest.
P1853 HIGH RESOLUTION MANOMETRY CAN BE PREDICTIVE OF GERD AS CONFIRMED BY IMPEDANCE MONITORING: DEVELOPMENT AND INTERNAL VALIDATION OF A PREDICTIVE MODEL
1Surgery, University of Campania “Luigi Vanvitelli”, Naples, Naples/Italy
2Department Of Medical And Surgical Sciences, S. Orsola-Malpighi Hospital, Bologna/Italy
3Department Of Surgery, Oncology And Gastroenterology, University of Padua, Padua/Italy
4Digestive Pathophysiology Unit, Baggiovara Hospital, Modena/Italy
5Division Of Gastroenterology, Department Of Internal Medicine, University of Pisa, Pisa/Italy
6Department Of Internal Medicine, IRCCS San Martino DIMI, Genova/Italy

Introduction: The aim of this study was to compare the prevalence of HH obtained with UE and HRM and to determine the role of this finding by diagnosing gastroesophageal reflux disease (GERD) on the basis of impedance and pH (MII-pH) monitoring. We enrolled consecutive patients with heartburn and HH diagnosed with UE. After UE, all patients underwent HRM and pH-pH to investigate GERD. All tests were performed previous a 20-day wash-out from proton pump inhibitors. Erosive esophagitis (ERD) was diagnosed according to the Los Angeles Classification, and HH was diagnosed when the separation between the squamo-columnar junction and the diaphragmatic impression was greater than 2 cm. Patients with achalasia or major disorders of peristalsis or previous surgery were excluded. MII-pH monitoring allowed to sub-classify patients with non-erosive GERD in: NERD (abnormal AET), hypersensitive esophagus (normal AET, reflux events but positive symptom-reflux association, HE) and functional heartburn (normal AET, reflux events and negative symptom-reflux association, FH). All patients underwent barium X-ray to measure HH. Recognition of two rings larger than 2 cm (reoccurrent position between EEJ and diaphragmatic hiatus) was necessary to detect HH. Results: We evaluated 151 patients (94 females) with mean age of 56.2 ± 15.4 yrs. ERD was diagnosed in 34 patients (22.5%). MII-pH allowed to subgroup patients in: 48 (31.8%) NERD, 43 (28.5%) HE, and 26 (17.2%) FH. As expected, all patients underwent HH in ERD and NERD group (p < 0.001). HH was normal in 131/151 (86.6%) and 20/151 (13.2%) in NERD and HE, respectively. HH was considered HH (HRM 55% ± 0.05 %) with barium X-ray and in 88/151 patients (barium 58.3% ± UE 100%; p < 0.05) with barium X-ray. The median length of HH during endoscopy (5.4 ± 2.6) was reported greater than that during HRM (3.9 ± 2.2) and Barium X-ray (4 ± 2.5) (p < 0.05). All details are reported in Table 1.

Introduction: Randomized controlled trials report about 30% of GORD patients complain of bothersome remaining symptoms (heartburn, regurgitation) despite PPI. The LOPA (Lost Patients) I Study of 333 GORD patients seen in general practice revealed 46% of patients experienced heartburn or regurgitation symptoms at least twice per week despite PPI. A total of 20% were dissatisfied with their treatment. Few patients had received specific GORD diagnostics or recommended other options (<10%).

Aims & Methods: The LOPA II study is a prospective, multicenter, observational study conducted in 17 general practice clinics. Patients with chronic GORD, taking PPI therapy for at least 1 year, and not satisfied with their treatment were asked to complete a questionnaire. Patients were asked the duration of their PPI therapy, satisfaction with their current condition, frequency of symptoms in the last week, whether they had previously received diagnostic evaluation or surgical consult related to GORD, whether they plan to consult a reflux specialist for further diagnostics, and reasons for dissatisfaction with their current medication treatment. "Lost Patients" were defined as those with a satisfaction score of 1 or 2 on a 5-point Likert scale (1: very satisfied; 2: dissatisfied; 3: doubtful; 4: not at all satisfied; 5: not at all satisfied), at least 2 days in the prior week (53% 4-7 days). 49% reported using additional medication other than their prescribed PPI at least 2 days per week (34% 4-7 days). In patients dissatisfied on PPI, most cited insufficient symptom control (87%) and risk of dissatisfaction. In addition, 31% cited concerns with long-term use of drugs and 27% the need for daily medication. 92% of patients had received an upper endoscopy, 12% had a pH monitoring, 7% manometry, and 9% received prior surgical consult for GORD. Of patients who never received an endoscopy, 58% were not asked if they had any surgical anti-reflux methods, 25% were concerned about possible complications, 18% felt their condition is not serious enough, 6% were recommended against anti-reflux procedure by their doctor.

Conclusion: Chronic GORD patients who are dissatisfied with their PPI therapy are rarely offered specialized GORD diagnostic procedures or treatment alternatives. Half of the patients took medication in addition to PPI to control their reflux. In addition to persistent symptoms, concerns of long-term PPI use and burden of daily medication play a role in patient dissatisfaction with PPI therapy.

Introduction: Autoimmune gastritis (AIG) is characterized by corpus-predominant atrophy with consequent hypo-achlorhydria. In AIG patients dyspepsia is frequent but acid reflux symptoms are uncommon, with few data available regarding gastric or esophageal reflux disease (GERD) in AIG.

Aims & Methods: Our study was aimed to define the prevalence of reflux symptoms in AIG patients, to evaluate the serological, histological and clinical differences in AIG patients with or without reflux symptoms and to investigate the pathophysiology behind these symptoms. One hundred and fifty AIG outpatients were evaluated and 87 were included in the study: 29 AIG patients with reflux symptoms (AIG-R) and 58 without (controls), selected with similar age and gender distribution. AIG-R underwent a pH-impedance (pH/I) and high resolution manometry (HRM). Serum biomarkers, EGDS, histology and anamnestic data were evaluated in both groups. Statistics was performed as indicated.

Results: AIG-R were 19% overall and 28% of them showed esophageal esophageal lesions, with more frequent hiatal hernia than in controls (p < 0.02). pH/I diagnosed acid reflux, esophageal hypersensitivity and a normal pattern in 7%, 28% and 66% patients, respectively. The number of non-acid reflux (NAR) was higher when compared with acid ones (p < 0.0001), moreover NAR and NAR proximal extension were associated with endoscopic lesions (p < 0.03 and p < 0.05, respectively). HRM revealed normal pattern in 62% of patients, minor peristaltic disorders in 24%, and outflow obstruction in 14%. According to the new Rome IV criteria, 55% of patients presented “functional esophageal disorders” (Rome IV-IN). No differences were detected in serological marker and clinical presentation. AIG-R presented lower antrum gastritis (p < 0.03) and a trend toward lower atrophy status (p = 0.07) when compared with controls. The two patient with acid GERD were an OLGA 0 with mild gastrin increase and an OLGA I with short segment Barrett’s esophagus. Lower OLGA stages, lower corpus atrophy (p < 0.02) and more frequent response to PPI (p < 0.05) were associated with Rome IV-OUT status.

Conclusion: AIG-R are not uncommon despite the hypo-achlorhydria. Acid reflux is rare in AIG, while motility and “functional” disorders are frequent. Lower corpus atrophy and OLGA stage in Rome IV-OUT patients, with an OLGA I is likely related to ‘functional’ symptoms of reflux. Treatment should consider use of proton pump inhibitor drugs only in specific patients.

Introduction: Gastroesophageal reflux disease (GERD) is a common disorder commonly managed with antacids and proton pump inhibitors (PPI). Although few studies have been performed to test if a diet is more effective than PPI in mild GERD patients, there is evidence that a diet is more effective than antacids in patients with severe GERD. Aim of the study is to compare the effect of a diet with that of antacids on reflux symptoms in patients with mild GERD.

Methods: Patients with mild GERD who declared at least twice per week heartburn or regurgitation were included in the study. Only patients who used antacids during the study period were considered as control. The diet regime was a low FODMAP diet and it was given for 1 month. The patients were divided into two groups: diet and antacids. The two arms were compared on changes in reflux symptoms during the study period by means of a validated symptomatic questionnaire (RDQ administered at baseline, after antacids course (1 month) and after diet (1 month)). A treatment was considered effective if a 50% improvement in the symptom score was recorded.

Results: After investigations 261 patients out of 500 (52.2%) were excluded because of IBS (60), celiac disease (6), nickel allergy (25), lactose intolerance (60), SIBO (10), and allergy to other foods (20). The remaining 239 patients were diagnosed as affected by mild GERD (median age 47; BMI 24; 132F/107M; no significant differences in age and gender. A total of 20% were dissatisfied with their PPI therapy, satisfaction with their current condition, frequency of symptoms in the last week, whether they had previously received diagnostic evaluation or surgical consult related to GORD, whether they plan to consult a reflux specialist for further diagnostics, and reasons for dissatisfaction with their current medication treatment. “Lost Patients” were defined as those with a satisfaction score of 1 or 2 on a 5-point Likert scale (1: very satisfied; 2: dissatisfied; 3: doubtful; 4: not at all satisfied; 5: not at all satisfied), at least 2 days in the prior week (53% 4-7 days). 49% reported using additional medication other than their prescribed PPI at least 2 days per week (34% 4-7 days). In patients dissatisfied on PPI, most cited insufficient symptom control (87%) and risk of dissatisfaction. In addition, 31% cited concerns with long-term use of drugs and 27% the need for daily medication. 92% of patients had received an upper endoscopy, 12% had a pH monitoring, 7% manometry, and 9% received prior surgical consult for GORD. Of patients who never received an endoscopy, 58% were not asked if they had any surgical anti-reflux methods, 25% were concerned about possible complications, 18% felt their condition is not serious enough, 6% were recommended against anti-reflux procedure by their doctor.

Conclusion: Chronic GORD patients who are dissatisfied with their PPI therapy are rarely offered specialized GORD diagnostic procedures or treatment alternatives. Half of the patients took medication in addition to PPI to control their reflux. In addition to persistent symptoms, concerns of long-term PPI use and burden of daily medication play a role in patient dissatisfaction with PPI therapy.

Radiofrequency ablation (RFA) with or without endoscopic resection (ER) is an established endoscopic treatment of early Barrett’s esophagus (BE). The aim of this prospective single-center center trial was to assess the clinical outcomes of RFA combined with ER for patients with Barrett’s esophagus related neoplasia (BORN) achieving a high clinical response rate of adenocarcinoma 0.12%/year. The current standard of treatment is Endoscopic Resection (ER) of visible nodular lesions and Radiofrequency Ablation (RFA) of flat Barrett’s, which has a success rate of 92%. For refractory cases, wide field ER, cryotherapy and other methods are used, but may have higher adverse events. We hypothesize that thicker Barrett’s tissue is less likely to respond to RFA and have developed methods to precisely measure tissue thickness with Volumetric Laser Endomicroscopy (VLE). These methods may facilitate future studies, correlating tissue thickness with response to therapy and prediction of optimal treatment.

Recurrence of endoscopically visible Barrett’s mucosa was seen in 22 patients neo-SCJ with HGD after 22 months, both were treated successfully with ER.

68 patients were included (55 men, median 64 yrs, median BE C5M6). In the overall cancer progression risk and even fewer (7%) of the treatment options that are available to them. Further efforts need to be made to address this and help empower a group of patients who are understandably anxious about their diagnosis.

Contact E-mail Address: manol.jovani@mail.harvard.edu

Introduction: Data on the association between inflammatory and metabolic biomarkers and Barrett’s oesophagus (BE) are scant and conflicting.

Aims & Methods: We aimed to study the association between circulating inflammatory biomarkers (interleukin-6 [IL-6], high-resolution C-reactive protein [cCRP], intra-cellular adhesion molecule [ICAM], tumour necrosis factor receptor-2 [TNF-R2] and metabolic biomarkers ( leptin, adiponectin, C-peptide, insulin-like growth factor 1 [IGF-1], and insulin-like grow factor binding proteins -1, -2 and -3 [IGFBP-1, -2 and -3]) with BE. This was a case-control study, nested within two female-only prospective cohort studies (Nurses’ Health Study 1 and 2) and one male-only prospective cohort (Health Professional Follow-up Study). Participants of provided biennial detailed information on demographic, lifestyle, dietary and medical factors, including endoscopy use. Overall, 80,437 participants, 3,672 included in these cohorts provided a prediagnostic blood specimen between 1989 and 1995. Among these participants, through 2012, we identified 283 cases of BE (163 females and 120 males). Two study physicians, blinded to biomarkers results, reviewed the medical records of patients reporting BE. We matched BE cases to controls (1:2) for age and period of BE enrollment. We used multivariable conditional logistic regression models, adjusting for known and putative risk factors for BE, to assess the association between each biomarker and the risk of BE. We used the lowest quintile as reference, and assessed linear trend across exposure categories using the median of each quintile as a continuous variable.

Results: In women, plasma adiponectin was significantly associated with BE (p_trend = 0.01). When compared to the lowest quintile (Q1), the multivariate odds ratio (OR) for the highest quintile (Q5) of adiponectin was 0.39 (95%CI 0.17, 0.88). This association was not materially altered after further adjustment.
for lepin. The association did not differ according to subgroups defined by BMI (p-trend = 0.82). Use of folic acid in young men, we observed that adiponectin was not associated with BE. However, we observed an OR of 0.41; 95%CI 0.17, 0.99 comparing extreme quintiles of IGFBP-3 (p-trend = 0.11). Among both women and men, we did not observe any significant associations between inflammatory biomarkers and metabolic biomarkers are associated with risk of BE. Only adiponectin was associated with a decreased risk of BE in women but not in men. These findings may serve to provide input for future risk assessment for BE and shed light on potential mechanisms of its pathogenesis.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1866 OUTCOMES OF TREATMENT OF PATIENTS WITH EARLY-STAGE ADENOCARCINOMA OF THE ESOPHAGUS WITH INCIENT SUBMUCOSAL INVASION, RETROSPECTIVE ANALYSIS OF 19 CASES FROM A TERTIARY REFERRAL CENTER IN THE UK

B. Eross1, C. Clishby2, C. Gordon3

Contact E-mail Address: xerobal@yahoo.it

Introduction: Endoscopic mucosal resection (EMR) is an established diagnostic and treatment tool in the management of Barrett’s oesophagus (BO) with early neoplastic lesions. BO may prove to be a matter of future research on the natural history in the patients, in whom the EMR’s histologic assessment identifies early-stage adenocarcinoma of the oesophagus with incipient submucosal invasion (pT1b sm1).

Aims & Methods: We have conducted a retrospective analysis using our electronic database for endoscopic procedures for patients with BO, who underwent EMR from October 2010 to December 2016. We investigated the size of the EMRs, the complication rates of the EMRs, the histological features and the resection margins of the EMR specimens and also the outcomes with the mortality.

Results: A total of 99 patients underwent 134 EMR procedures, and the histology identified early adenocarcinoma with incipient invasion of the submucosa in 25 patients. 23 (92%) were male, the mean age at the EMR was 71 years (SD: 8.1). In all 25 EMR 9 (36%) patients had a single piece, 7 (28%) patients 2 piece, 7 (28%) patients 3 piece and 4 (16%) patients 4 piece EMR. The median length of the circumferential and maximum extent of the BO segments were 2 and 5 cm respectively (interquartile range (IQR) 2–4). We observed 6 (24%) intra-procedural bleedings and 2 (8%) patient needed admissions with post procedural dural bleedings and 2 (8%) patient needed admissions with post procedural 

Conclusion: The pathological diagnosis was 8 SCC, 2 high grade intraepithelial neoplasia. There was 8 SCC, 2 high grade intraepithelial neoplasia. There were 9 (28%) of patients with cancer, 18 months after the EMR, and the 9 (75%) surviving patient are all free from cancer, and the outcome is unclear. In our hospital, we have performed over 1300 Per-Oral Endoscopic Myotomy procedures for esophageal achalasia and related upper gastrointestinal diseases. In our center, we diagnosed and treated 10% of patients with esophageal cancer in 3 (33.3%) of the surgical specimens. Radical radio-chemotherapy was given in 1 (1.7%) patient and 3 (33.3%) patients did not have radical treatment for clinical reasons. There were 10 (40%) patients without cancer invasion of the EMR resection margins, of these 4 (40%) had oesophagectomy and 1 (10%) had radical radiotherapy. The histologic assessment of these surgical specimens showed residual cancer in 3 (30%) cases and high-grade dysplasia in 1 (10%) case. Of the 25 patients 5 (20%) met the criteria and had radio frequency ablation of the residual Barrett’s oesophagus. Of the 13 (52%) patients who have had oesophagectomy 1 (7.7%) patient died of the deterioration precipitated by the oesophagectomy, and sadly in this case the oesophagectomy specimen did not show residual cancer. Of the 12 (48%) patients who had not had oesophagectomy 3 (25%) died since their EMR, 1 (8.3%) of cardiac arrest, 1 (8.3%) of chronic obstructive pulmonary disease and 1 (8.3%) of advanced oesophageal cancer, 18 months after the EMR, and the 9 (75%) surviving patient are all free from cancer on follow up investigations, one after radical chemo/radiotherapy.

The median survival of all 21 (84%) patients currently alive is 25 months (range: 2–68 months; SD: 22.2).

The median survival of all 21 (84%) patients currently alive is 25 months (range: 2–68 months; SD: 22.2).

In this retrospective analysis we have found that the clinical outcomes are very difficult to predict for patients with early adenocarcinoma and incipient invasion of the submucosa. Clinical decision making remains very challenging and has to be individualised for all patient, until further in depth studies gives us more useful prognostic factors.

Results: From July 2015 to March 2017, forty-four patients were included in the study. Seventeen of the forty-four (38.6%) patients had histological confirmed cancer of the esophagus. There were sixteen patients who had normal finding and nine patients with esophagitis. The positive predictive value for malignancy (ECA 4 and 5) was 89.5%; the negative predictive value was 100%. Sensitivity was 100% and specificity was 92.6%. Similar findings were noted with IPCL on magnifying NBI. The positive predictive value for malignancy (IPCL 4 and 5) was 100%; the negative predictive value was 100%. Sensitivity was also similar at 100% and specificity 92.6% respectively. To compare the diagnostic accuracy of endoscopicystoscopy and magnifying NBI, the McNemar test was performed. The McNemar chi-squared statistic is NaN, and the McNemar chi-squared statistic with continuity correction of 0.5 is infinity, meaning that the two tests have the same diagnostic accuracy.

Conclusion: Endoscystoscopy had a high positive predictive value and sensitivity for esophageal malignancy. Its diagnostic accuracy was comparable to magnifying NBI. It may be helpful as an adjunct for better characterization of esophageal lesions. However, further studies on interobserver variability is required.

Introduction: Early detection of esophageal cancers can significantly reduce the years of suffering of patients and reduce the mortality. A new endoscopic technique incorporating the endoscystoscopy function into a magnifying endoscope has been designed. Previously, Inoue et al have published a pilot trial on evaluating the use of this endoscystoscopy in various types of benign and malignant pathologies of the esophagus. An endoscystoscope was proposed. The sensitivity and specificity of this classification system was evaluated.

Aims & Methods: All consecutive patients who had esophagogastrroduodenoscopy (EGD) arranged for screening of the esophagus during the period July 2015 to March 2017 were included in the study. EGD with narrow band imaging and endoscystoscopy were performed in these patients. During the procedure, the esophageal mucosa was stained with 0.5% methylene blue and then with crystal violet. The endoscystoscopic findings were graded from 1 to 5 according to the Inoue et al’s ECA classification. The esophageal mucosa was also evaluated with narrow band imaging (NBI) and the findings were classified according to the Intrapapillary capillary loop (IPCL) pattern classification. These findings were compared against the gold standard of histopathological examination which was based on the Vanura classification.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1868 CLINICAL OUTCOMES OF ENDOSCOPIC RESECTION FOR ACHALASIA-ASSOCIATED SUPERFICIAL ESOPHAGEAL CANCER

Gastroenterology, Showa University Koto-Toyosu Hospital, Tokyo, Japan

Contact E-mail Address: nishikawak@med.showa-u.ac.jp

Introduction: Esophageal achalasia is considered to be a high-risk factor for superficial esophageal cancer. But there are few reports of endoscopic resection for this cancer, and the outcome is unclear. In our hospital, we have performed over 1300 Per-Oral Endoscopic Myotomy procedures for esophageal achalasia and related upper gastrointestinal diseases. In our center, we diagnosed and treated 10 achalasia-associated superficial esophageal cancers in patients with achalasia. We performed endoscopic resection for all cases and report relatively long-term outcome.

Aims & Methods: We aimed to evaluate clinicopathological findings and outcomes of endoscopic resection for 10 achalasia-associated superficial esophageal cancer. This is a case series study at our hospital. Between August 2010 and February 2017, 10 achalasia patients with superficial esophageal cancer underwent endoscopic resection. We performed in all cases upper gastrointestinal endoscopy using the narrow band’s solution and narrow band imaging, and we included all patients that had early cancers that were eligible for endoscopic resection in this series. At 2 and 12 months after treatment, we performed follow-up endoscopy in all cases. After this, we performed long-term endoscopic follow-up every year. In the case that the tumor invasion depth is to the muscularis mucosa (MM) on histopathology, we performed endoscopic follow-up every 6 months and CT scan.

Results: There were 6 men and 4 women and their average age was 61.7 years. 8 patients were diagnosed with lesions before POEM. We performed endoscopic resection (ESD/EMR;9/1) in all cases after POEM. None of the patients had a severe adverse event. The mean tumor diameter was 30mm (range: 5–80mm). The pathological diagnosis was 8 SCC, 2 high grade intraepithelial neoplasia. Out of the SCC cases, 7 were found with superficial lesion with depth of Tis-EP to T1a-LPM, and 1 with depth of T1a-MM, without lymphatic invasion(0) or venous invasion(0). Follow-up surveillance mean term was 32 months (range: 1–
only patient who had venous involvement was 92 years old, and followed up without an additional therapy. 6. Local recurrent rate was 0%. 7. LNM rate of EP and SEP was 0% and 5.7% (2/35), respectively. One of two patients who had LNM was a 76-year-old male. He had SEP SCC without lymph duct involve- ment. A cervical LNM was diagnosed 6 months after ESD. Lymph node dissec- tion and then radiotherapy (CRT) was performed for the patient. The patient died of other disease without recurrence of pharyngeal SCC. The other patient also had a cervical LNM and treated by lymph node dissection + CRT. The patient is alive without recurrence for 10 years after ESD. 8. Prognosis No patients died of pharyngeal SCC or ESD.

Conclusion: ESD is a safe and useful treatment for superficial pharyngeal SCC. However, surveillance of LNM is important for the patients who had SEP SCC.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1869 USEFULNESS OF TRIAMCINOLONE INJECTION TO PREVENT STRICURE AFTER CIRCUMFERENTIAL ESOPHAGEAL ESD: EP VS. SEP GRADE A

T. Oyama1, A. Takahashi1
1Endoscopy, Saka Central Hospital Advanced Care Center, Nagano/Japan

Contact E-mail Address: oyama@eceral.ocn.ne.jp

Introduction: ESD is a standard treatment for superficial esophageal cancer in Japan. Stricture is one of important complication of esophageal ESD, and it makes quality of life of the patient worse. Usefulness of Triamcinolone (TA) injection to prevent stricture after semi-circumferential ESD has been reported. However, usefulness of TA injection after circumferential esophageal ESD is still unclear.

Aims & Methods: The aim of this study is to clarify the usefulness of triamcinolone injection to prevent stricture after circumferential ESD. A total of forty-four patients treated by circumferential esophageal ESD from 2004 to 2016 in Saku Central Hospital Advanced Care Center were enrolled to this retrospective study. The patients treated from 2004 to 2009 were followed up without TA injection (Non-TA group), and TA injection was performed for the patients after 2009 (TA group). The number of patient in Non-TA and TA group was 16 and 28, respectively. Age of both groups were 65 (30-83) and 61 (42-82) years old. The length of circumferential resection was 75 (50-10) and 75 (55-111) mm, respectively. There was no significant difference in the background of both groups. Fifty mm TA was injected into submucosal layer just after ESD, and TA injection was repeated in two-weeks interval by the ESD ulcer healed. When the length of circumferential ESD was 50 mm or less, 100 mg Triamcinolone was injected just after ESD.

Results: 1. Endoscopic balloon dilatation (EBD) was performed when the scope couldn’t pass the ESD ulcer. The primary endpoint was the number of balloon dilation. The secondary endpoints were duration from ESD to ulcer healing, and the difference between Barrett’s esophagus adenocarcinoma (EAC) and squamous cell carcinoma (SCC).

Results: 1. Number of EBD in Non-TA and TA group were 20 (13-33) and 5.1 (0-23), respectively (p = 0.01). Duration from ESD to ulcer healing were 10 (3-24) and 3.1 (2-5) days, respectively (p = 0.04). Complications (perforation, Median forceps use time was 73 secs (range: 8-1200 secs), and the median number of antithrombotic agents. Hemostatic forceps were used for 116 lesions (25%), and continuous use of antithrombotic agents, lesion location, (upper or middle or lower), lesion size (<2 cm or ≥2 cm), lesion circumferential length (<3/4 or ≥3/4), and the endoscopist’s experience of esophageal ESD (<40 or ≥40 procedures).

Results: Twenty-nine ESCNs (6%) were treated by ESD without discontinuation of antithrombogenic agents. Hemostatic forceps were used for 116 lesions (25%), median forceps use time was 73 secs (range: 8-1200 secs), and the median number of forceps application during procedures was 2 (range: 1-9 times). Of these, 41 lesions (9%) met our definition for longer hemostatic time. Univariate analysis revealed that lesion size (≥2 cm), lesion circumference (<3/4, ≥3/4), and the endoscopist’s experience (<40 or ≥40 procedures).

P1870 OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL PHARYNGEAL SQUAMOUS CELL CARCINOMA

T. Oyama1, A. Takahashi1
1Endoscopy, Saka Central Hospital Advanced Care Center, Nagano/Japan

Contact E-mail Address: aurevoireurope@yahoo.co.jp

Introduction: Superficial pharyngeal squamous cell carcinoma (SCC) has been increasing in Japan. And, such SCC could be treated by endoscopic submucosal dissection (ESD). However, the outcome of pharyngeal ESD is unknown.

Aims & Methods: The aim of this study is to clarify the outcome and prognosis of pharyngeal ESD treated by ESD. 89 pharyngeal SCC in 68 patients treated by ESD from Jan. 2006 to Jan. 2017 in Saku Central Hospital Advanced Care Center were enrolled to this retrospective study. CT and neck US were performed for preoperative staging. All ESD were performed using a Hope knife under general anesthesia with tracheal intubation. Clipp with line or forceps was used to make traction during ESD. Annual endoscopy, CT scan and neck US were performed as surveillance after ESD, and these examinations were recommended twice a year for the patients who had subepithelial (SEP) SCC. Male-Female was 67:1. Mean age was 67.1 (40-92). Mean size of tumor and specimen were 12.9 (5-25) and 28.6 (5-65) mm, respectively.

Results: 1. En bloc resection rate was 100%. 2. Complication: Delayed bleeding rate was 1.5% (1/68). Re-intubation was needed for the hemostasis. Dysphasia was shown in 4.4% (3/68). Two patients had mild dysphasia and improved in two weeks. The remaining one patient had severe dysphasia. The patient had a big SCC, 50 mm in size, and the SCC extend from light piriform sinus to ary-epiglottic fold. We could keep the voice function. However, eating was impossible for mis-swallowing. 3. Invasion depth: Epithelial (EP) and subepithelial (SEP) SCC were 60% (53/89) and 39% (35/89), respectively. One case was inflammation. 4. The rate of lymph-duct involvement of EP and SEP were 0% and 5.7% (2/35), respectively. LNM was found in one of two patients who had lymph duct involvement, and treated by lymph node dissection. The other patient was followed up without additional therapy, and free from LNM for one year. 5. Venous involvement of EP and SEP were 0% and 2.9% (1/35), respectively. The
Introduction: While definitive chemoradiotherapy (CRT) showed high efficacy for esophageal squamous cell carcinoma (ESCC), approximately 40% of patients develop local failure, resulting in poor long-term survival. However, there is no definitive biomarker which is useful to predict survival outcome after CRT for ESCC. Several studies have investigated the correlation of expression of CD24, cytokeratin 4 (CK4), and podoplanin (PDPN) with prognosis in some malignant tumors which underwent surgical resection. However, it remains unclear whether the expression of these proteins can predict the outcome of CRT for patients with ESCC.

Aims & Methods: The aim of this study was to clarify the predictive values of expression of CD24, CK4, and PDPN for ESCC patients who received CRT. Among patients with ESCC who received CRT or curative esophagectomy with extended lymph node dissection (OPE) as an initial treatment between 2005 and 2013, 49 patients were selected for the following criteria: clinical stage II, III (UICC-TNM classification 6th edition), age of 75 years old or younger, ECOG Performance Status 0-1, and no prior or concurrent other cancers. The method of immunohistochemistry (IHC) was utilized to examine the protein expression of CD24, CK4, and PDPN in pretreatment biopsy specimens of ESCC. The cut-off values for CD24, CK4, and PDPN expression were used hazard ratio for overall survival (OS). The prognostic factor of CD24, CK4, and PDPN expression were statistically analyzed. OS was calculated from the date of CRT or OPE to the date of death or last follow-up, using the Kaplan-Meier method. The survival predictors identified by univariate analysis was assessed by multivariate analysis using a Cox’s proportional hazards model.

Results: 148 ESCC patients (CRT group, n = 83; OPE group, n = 65) were analyzed. In the CRT group, 40 patients had stage II and 43 patients had stage III, and the 5-year OS was 52%. In the OPE group, 32 patients had stage II and 33 patients had stage III, and the 5-year OS was 66%. By univariate analysis, there were three independent variables for OS in differences between two groups and OPE group. The cut off value for CD24, CK4, and PDPN expression were 20%, 10%, and 20%, respectively. While the expression equal to the cut off value or more was defined as strong, the expression less than the cut off value was defined as weak. The frequency of strong protein expression was 50% for CD24, 12% for CK4, 65% for PDPN, respectively. In the CRT group, the OS of patients with weak CD24 expression was significantly better than that of patients with weak CD24 expression (P = 0.015; strong/weak 5-year: OS 65%/43%). On the other hand, the strong CD24 expression was poorer OS comparing with patients with weak expression in the OPE group, however there was no significant difference (P = 0.286; strong/weak 5-year: OS 77%/74%). As for patients with strong CD24 expression, there was no significant difference between CRT group and OPE group (p = 0.446), however there was significant difference between CRT and OPE group in patients with weak CD 24 expression (p = 0.009). There were also no significant differences of the OS based on expression of CK4 or PDPN between the CRT and OPE group, respectively. Multivariate analysis also showed the strong CD24 expression in CRT group (P = 0.012; HR = 2.787; 95%CI: 1.253-6.200) as an independent variable for favorable outcome.

Conclusion: CD24 expression was significantly associated with the survival outcome of ESCC when they were treated with CRT. Furthermore, weak CD24 expression might be a useful predictive biomarker of poor outcome for CRT in ESCC patients.

3Department Of Hepatogastroenterology, Institute for Clinical and Experimental Medicine, Prague-Czech Republic

Contact E-mail Address: marek.kollar1 seznam.cz

Introduction: Endoscopic treatment is a standard therapeutic approach for patients with Tla early esophageal cancer (EEC). In patients with ‘high-risk’ Tla cancer, endoscopic resection (ER) is recommended as the first-line treatment. In patients with any submucosal (sm) invasion (Tlb), surgery is recommended as a standard of care. However, recent data suggest, that endoscopic treatment might be curative in selected patients with ‘high-risk’ EEC.

Aims & Methods: The aim of this study was to assess outcomes of endoscopic treatment in patients with ‘high-risk’ EEC. ‘High-risk’ cancer was defined as any cancer with sm invasion or mucosal cancer with at least one of following: poor differentiation (G3/G4), invasion to blood (A+) or lymphatic vessels (L+) and high tumor cell dissociation (TCD3). The main outcome measurement was tumor-free survival.

A single-center, retrospective analysis of prospectively collected data. Patients with EEC underwent endoscopic resection (ER) or endoscopic submucosal dissection (ESD). Based on histopathological staging, patients with ‘high-risk’ EEC or Tla cancer were referred for surgery. The patients continued in endoscopic treatment consisting of further sessions of ER and/or radiofrequency ablation if necessary. The patients have been followed up for a median of 39 months (range 2-156).

Results: A total of 56 patients with ‘high-risk’ EEC underwent endoscopic treatment: 21 patients (41%) had Tla cancer with ‘high-risk’ features and 35 patients (59%) had Tlb cancer with sm invasion (sm1: 15, sm2: 9, sm3: 11); 45 patients had adenocarcinoma (EAC), 11 patients had squamous carcinoma (SCC); 19 patients were referred for component with severe inflammation (37%) continued the endoscopic treatment. Complete local remission (CLR) of neoplasia was achieved in 35/37 patients (95%). Two patients without CLR continued endoscopic therapy with palliative intent. Tumor generalization occurred in 2 patients (one of them achieved CLR). 24 months after endoscopic treatment (both patients had sm3 invasion, A+, L+) and these patients are undergoing oncological treatment. All remaining patients with CLR (n = 33) have experienced neither local relapse nor generalization. One patient had to undergo surgery due to endoscopy related perforation. Tumor-free survival was 89% (CI 79–99%) in patients treated endoscopically and endoscopy related mortality was 0% (0/37). Among 19 patients who were referred for esophagectomy, one patient presented with tumor generalization revealed during the operation. The remaining 18 patients underwent esophagectomy; local residue of malignancy were present in 5/18 patients (28%). Lymph node (LN) metastases have not been detected in any patient among the 337 examined LNs. Surgery related mortality was 6% (1/18).

Conclusion: Endoscopic treatment provides long-term remission or cure in a considerable number of patients with ‘high-risk’ EEC and it may thus represent a valid alternative to surgery. Brooding of indications for radical endoscopic treatment of early EEC should be reconsidered.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1874 DIAGNOSTIC ACCURACY OF ENDOSCOPIC ULTRASONOGRAPHY FOR ESOPHAGEAL SUBMUCOSAL GLAND DUCT INVOLVEMENT ACCOMPANYED BY EARLY ESOPHAGEAL CANCER
Y. Jie, L. Ying
Digestive Department, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, Jiangsu Province, Ch, Nanjing/China
Contact E-mail Address: 13770755008@126.com

Introduction: Normally, resided within the submucosal layer of esophagus, each esophageal submucosal gland will culminate in a single duct. The esophageal submucosal gland ducts (ESMGDs) can traverse the subepithelial connective tissue and muscularis mucosa, and deliver the acinar secretions to the esophageal lumen. However, the clinicopathological features of the esophageal submucosal gland duct involvement accompanied by early esophageal cancer have not been comprehensively evaluated so far, and the series study focusing on endoscopic ultrasonography (EUS) is needed to assess the diagnostic value of EUS for diagnosing ESGMID.

Aims & Methods: In order to investigate the clinical value of EUS for diagnosing ESGMID accompanied by early esophageal cancer, which were suggested by conventional endoscopy or biopsy, this study retrospectively analyzed the outcomes of consecutive patients with early esophageal cancer diagnosed in the Endoscopy Center at the Affiliated Drum Tower Hospital, Nanjing, China from September 2009 to November 2016. The clinical data of 519 patients were included in this study, and of them all had already underwent EUS combined with Endoscopic Submucosal Dissection(ESED). The EUS preoperative diagnosis were compared with the results of postoperative pathology from ESD.

Results: According to the pathological results, all patients (371 males and 148 females, with a mean age of 67.5±4.5 years) had been diagnosed with early esophageal cancer with different invasive depth. Out of 519 patients, about 478 patients were not found ESGMID by both examinations. Besides, postoperative pathology confirmed that 40 patients were identified with ESGMID, 34 patients of which were completely consistent with the preoperative diagnosis of EUS. Approximately 98.7% (512/519) of ESGMID were diagnosed exactly by EUS. Another six cases were estimated as false negative inaccurately, including two squamous cell carcinoma and four high-grade intraepithelial neoplasia. One case was excluded as ESGMID due to the insufficient evidence, however, the EUS values for sensitivity and specificity for the diagnosis of ESGMID were 85.0% (34/40) and 99.8% (478/478) respectively. Furthermore, the positive predictive value was 97.1% (34/35), and the negative predictive value was 98.8% (474/476).

Conclusion: The esophageal submucosal gland duct involvement is a kind of lesion performed as a hypoechoic sonographic pattern located in the thickened mucosa. EUS has a satisfactory diagnostic accuracy for ESGMID as well as good sensitivity and specificity.

Disclosure of Interest: All authors have declared no conflicts of interest.
OBJECTIVE: To assess the NLR predictive strength in a retrospective series of two high-volume centers.

METHODS: We included 280 patients. The analysis of NLR as predictor of pathological complete response (pCR) showed a OR of 0.963 (95% CI 0.531–1.746, p = 0.901) and 1.161 (95% CI 0.647–2.081, p = 0.671) considering as cut-off values 2,5 and 3 respectively. In our large series, NLR did not result as a predictive marker neither in terms of Overall Survival nor in terms of Disease Free Survival (p = 0.997 and p = 0.672 respectively).

RESULTS: Our results did not confirm NLR as a significant marker of pCR. Moreover, the survival analysis did not reveal significant differences using NLR as a retrospective marker. The retrospective analysis of the complex of the disease, the absence of a validated and pre-defined NLR cut-off values 2,5 and 3 respectively. In our large series, NLR did not result as a predictive marker neither in terms of Overall Survival nor in terms of Disease Free Survival (p = 0.997 and p = 0.672 respectively).

CONCLUSION: We determined the effect of daily treatment with vehicle or acute gastric lesions but the contribution of CO to the mechanism of gastric mucosal injury is not clear. CO-releasing molecules (CORMs) represent a new class of compounds, named CO-releasing molecules, with antiproliferative, anti-inflammatory and immunomodulatory properties. CORMs are produced endogenously in the body as a pharmacological tool to assess the physiological role of CO under experimental conditions. CORM-2 was implicated in gastric protection against formation of acute gastric lesions but the contribution of CO to the mechanism of gastric ulcer healing has not been fully elucidated.

Aims & Methods: We determined the effect of daily treatment with vehicle or CORM-2, on healing of preexisting gastric ulcers induced by serosal application of acetic acid (acetic acid area = 28 mm²) in rats. Our second goal was to examine the mechanism of CO released from its donor by the determination of the CORM-2-induced alterations in gastric blood flow (GBF) at ulcer margin, the parameters of oxidative stress and the gastric mucosal expression of pro-inflammatory and anti-inflammatory factors. CORM-2 was implicated in gastric protection against formation of acute gastric lesions but the contribution of CO to the mechanism of gastric ulcer healing has not been fully elucidated.

P1878 PROTON PUMP INHIBITORS INAPPROPRIATE USE IN PATIENTS ADMITTED IN A TERTIARY GREEK HOSPITAL CREATES SIGNIFICANT DIRECT COSTS BURDEN AND EXPOSURE OF PATIENTS TO THE RISK OF UPPER GASTROINTESTINAL COMPLICATIONS

Aims & Methods: We aimed to evaluate the frequency of inappropriate PPI administration in hospitalized patients, to measure the direct in-hospital costs of PPI overuse and to calculate the number of patients exposed to the risk of upper gastrointestinal (UGI) complications due to medication underuse. This was a prospective, cross-sectional, prescription-indication drug-utilization, chart-review study in hospitalized patients with follow-up until discharge, in a tertiary hospital in Athens, Greece. We recorded data of all patients admitted (intensive care, psychiatric, pediatric, obstetrics and day clinic admission) were excluded) during three consecutive on-call days of the hospital in March 2017 regarding PPIs utilization before admission, during hospitalization and at discharge. We calculated the total in-hospital costs of PPIs overuse and the number of patients at risk of UGI complications due to PPIs underuse for 1 year period, using a simulation model.

Results: We included data from 470 patients aged 67 ± 19 yrs; 32.5% were prescribed PPI on admission, 65.9% during hospitalization and 72.8% at discharge. PPIs overutilization was detected in 15.7%, 41.3% and 12.6% of the patients before, during and after the admission, while medications underutilization was detected in 10.2%, 8.1% and 9.5% of them, respectively. Admission at internal medicine and orthopedics clinics was associated with the highest unadjusted ORs (1.68 [95% CI 1.63–1.72] and 1.68 [1.59–1.78]) for PPIs misuse. 80% of the 193 over treated patients received PPIs iv (80% of them od, 20% bid) while the rest were treated with PPIs per os (90% of them od, 10% bid) during hospitalization. This accounts for 1460 PPI iv and 344 PPI per os doses inappropriately given during the observation period. Taking into account in our simulation model that there are 90 on-call days of the hospital in March 2017, we calculated the direct hospital costs burden of inappropriate PPIs use at 154940 euros per year. Using the same model, 1200 patients would be at risk of UGI complications annually, due to under prescription of appropriate PPIs use. Using the same model, 1200 patients would be at risk of UGI complications annually, due to under prescription of appropriate PPIs use for 1 year period, using a simulation model.

Conclusion: Hospitalization does not represent an opportunity for optimization of PPIs administration in hospitalized patients, to measure the direct in-hospital costs of PPI overuse and to calculate the number of patients exposed to the risk of upper gastrointestinal (UGI) complications due to medication underuse. This was a prospective, cross-sectional, prescription-indication drug-utilization, chart-review study in hospitalized patients with follow-up until discharge, in a tertiary hospital in Athens, Greece. We recorded data of all patients admitted (intensive care, psychiatric, pediatric, obstetrics and day clinic admission) during three consecutive on-call days of the hospital in March 2017 regarding PPIs utilization before admission, during hospitalization and at discharge. We calculated the total in-hospital costs of PPIs overuse and the number of patients at risk of UGI complications due to PPIs underuse for 1 year period, using a simulation model.

P1880 ENDOSCOPIC RESECTION OF ADVANCED AMPULLARY ADENOMAS: A SINGLE-CENTER 14-YEAR RETROSPECTIVE COHORT STUDY

S. E. Van Der Weil, J.W. Poley, M.J. Bruno, A.D. Koch

Aims & Methods: The aim of our study was to evaluate the technical success, complications and recurrence of endoscopic resection for treating patients with ampullary adenomas with intraductal extension (AIE), and patients with lateral spreading adenomas (LSA). Between January 2002 and November 2016, all ampullary adenomas referred to the Erasmus MC, Rotterdam, for endoscopic resection of an ampullary lesion were retrospectively identified. Cases were selected by using ENDOBASE and we provided a search in the our local PALGA database. We included patients with a histological diagnosis of adenoma. Endoscopic resection was performed by 5 experienced endoscopists.

Endoscopic success was defined as complete excision of the adenoma, irrespective of the number of attempts, and in the absence of recurrence. All patients underwent endoscopic follow-up. Early and late complications were registered.

Results: We included 84 patients, 58 patients (67%) had an adenoma confined to the ampulla (ACA), 17 patients (20%) had a LSA and 11 patients (13%) were treated for adenomas that demonstrated growth pattern with intraductal exten sion. Fifty-five percent of the patients were men and the median age was 65.4 years (range 32–89). The median lesion size was 24.6mm (range 5–80) for patients with ACA, 34.8 mm (range 23–50) for LSA and 16.3 mm (range 10–20) for patients with an AIE (P = 0.003). Complications occurred in 26 patients (30.9%), of which hemorrhage was most seen in 17.9%, followed by perforation in 5.9% of the patients. Complications were equally divided over these three groups (P = 0.775). The mean follow-up duration was 31.1 months (range 0–129) for ACA, 23.1 months (range 0–127) for LSA and 11.9 months (range 0–37) for IEA (P = 0.136). Endoscopic resection was curative in 87.5% of patients with a localized adenoma, 82.3% in patients with a lateral spreading adenoma and in only 9.1% of patients with an intraductal extended tumor (P < 0.000). Recurrence occurred in 9 patients (10.7%), 5 of them had a localized adenoma, 3 patients with a lateral spreading adenoma and 1 patient with an intraductal extended adenoma (P = 0.875).

Conclusion: Endoscopic ampullectomy is a safe and successful treatment in patients with an adenoma with or without a lateral spreading growth pattern. In case of an intraductal extended adenoma endoscopic success rates are significantly lower.

P1879 CONTINUOUS INCREASE IN PREVALENCE OF FUNDIC GLAND POLYPS WITH THE LENGTH OF PROTON PUMP INHIBITORS USE. IS THERE ANY CLINICAL CONSEQUENCE?

R. Kroupa1, M. Dastych1, S. Koncny1, J. Dolinsa1

1Department Of Intestinal Medicine and Gastroenterology, University Hospital and Faculty of Medicine Masaryk’s University, Brno/Czech Republic

Introduction: Proton pump inhibitor (PPI) usage is associated with an increased risk of development of fundic gland polyps (FGP). The trend of change in the prevalence with increasing length of PPI exposure over 5 years is not known. Theoretical risk of FGP seems to be very low for clinical consequence in management.

Aims & Methods: To evaluate the relationship between the length of PPI use and risk of fundic gland polyps. Prospective cohort study in patients referred for upper gastrointestinal endoscopy between years 2015–2016 was performed. The length of PPI use was ascertained from direct patient interview and confirmed by the visual review of the clinic records. The study was in history not continuing at the time of endoscopy was also inquired. FGP were determinated both endoscopically and histologically. Odds ratios for subsequent intervals of length of PPI use were calculated. Clinically relevant complications—dysplasia and bleeding from large polyps were recorded.

Results: During study period 1525 patients (mean age 59.2 years, 53% male) were included. Only 612 (40%) of patients had no history of any PPI use. Fundic gland polyps were identified in 170 patients (11%) and only 13 of them (7.6%) were with complications. The prevalence of FGP in subgroup of patients according to the length of PPI use was: 10.6% of 161 patients using PPI less than 1 year, 9.4% of 405 (1–4 years of PPI), 25.2% of 230 (5–9 years of PPI), 35.1% of 94 (10–15 years of PPI) and 47.6% of 23 patients using PPI more than 15 years. The appropriate odds ratios were: 5.4 (CI 2.6–11.4), 4.8 (CI 2.5–9.1), 15.5 (CI 8.3–29.0), 24.9 (CI 12.4–49.5) and 42.2 (CI 15.7–113.1) respectively, all with statistical significance (p < 0.000). Only 1 case of low grade dysplasia within FGP was observed in the patient with familiar adenomatous polyposis. Polyps larger than 15 mm with signs of bleeding determined as a cause of sideropenic anemia were diagnosed in 6 patients.

Conclusion: The prevalence of FGP is permanently growing during prolonged use of PPI. Complex source of informations regarding history of PPI use identified quite low proportion of patient with FGP and without prior use. Rather rare complications like bleeding from FGP might be clinically significant in increasing number of long term PPI users. The requirement of repetitive endoscopies and therapeutic interventions may burden gastroenterologists and sources.

Conclusion:

An expanded indication criteria using data from JCOG0607. The major inclusion criteria were as follows: 1) histologically proven intestinal adenocarcinoma; 2) cT1aN0M0; 3) lesion without finding of ulcer (UL negative) and >2 cm in size, or UL positive and ≤3 cm in size; 4) age 20-75. ESD were performed by certified endoscopists or under the supervision of certified endoscopists. There were 207 lesions, 105 patients (27.7%) were classified in difficult case group. The final diagnostic yield was 78.8% (260/328) in UL negative and 66.0% (67/102) in UL positive cases, respectively. The diagnostic yield of the different passes, the diagnostic yield was: 61%, 67% and 78% with the first, second, and third FNB pass, respectively. In evaluation of tissue quantity and quality of FNB specimens, the mean tissue length was 7.3 ± 5.2 mm, with a mean tumor size and tissue proportion between 51 to 75% of the total tissue processed (determined as the percent of the surface are occupied by lesion over the surface area of the entire tissue on one slide). No complications occurred during the study period.

Conclusion: FNB using a novel core needle system is safe and effective for diagnosis of gastric submucosal tumors. When performed without on-site cytologic evaluation, EUS-FNB has a higher diagnostic yield than FNA and may represent an advance for endoscopic ultrasound guided gastrointestinal biopsies.

P1884 COMPARISON OF THE DIAGNOSTIC YIELDS OF ENDOSCOPIC ULTRASOUND-GUIDED FINE NEEDLE ASPIRATION FOR DUODENAL AND GASTRIC SUBEPITHELIAL LESIONS

K. Nakamura
Gastroenterology, St.Luke’s International Hospital, Chuo-ku, Japan

Contact E-mail Address: nakaken@lukc.ac.jp

Introduction: The purpose of this study was to investigate the usefulness and safety of EUS-FNA for duodenal SELs, comparing them with gastric SELs.

Methods: Cross-sectional study was conducted using 41 patients who underwent EUS-FNA at our tertiary medical center in Tokyo between April, 2012 and February, 2017. We divided into 2 groups: 6 patients with duodenal SELs (group D) and 35 patients with gastric SELs (group G). We analyzed the diagnostic performance for the two groups. The results of diseases were classified as malignant, indeterminate, and benign. The Chi-square test was used for the comparison between the two groups.

Results: As (median, range); D: 61, [42–63], G: 60, [32–85]; male/female ratio; D: 1/5, G: 17/18; tumor size (median, range/mm); D: 16, [14–45], G: 24, [13– 67]; type of needle (22-gauge/19-gauge); D: 5/1, G: 30/6 (One case was used two types of needles);); number of needle passes: D, 5, [4–5], G, 4, [3–7]; procedure time (median, range/min); D: 34, [22–52], G: 42, [20–67]; diagnostic yield: D, 100%, G: 91.4%, complication: D, 0%, G: 2.9%. There were no significant differences between the two groups. The results of diseases were classified as malignant, indeterminate, and benign. The diagnostic performance of EUS-FNA for duodenal SELs was significantly better than gastric SELs.

Conclusion: Although the diagnostic performance of EUS-FNA for duodenal SELs was significantly better than gastric SELs, all cases were diagnosed as malignant.

P1885 SHORT-TERM OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR EARLY GASTRIC CANCER IN ELDERLY PATIENTS AND LONG-TERM OUTCOME AFTER NON-CURATIVE RESECTION

H. Sakaguchi1, Y. Ohara2, T. Toyonaga2, H. Kaku1, K. Matsuoka1, T. Sako1, R. Ariyoshi3, H. Abe4, F. Kawara1, S. Tanaka1, T. Ishida1, Y. Morita1, E. Uragaki1

2 Endoscopy, Kobe University Hospital, Kobe/Japan

Contact E-mail Address: valencia.001@gmail.com

Introduction: Endoscopic submucosal dissection (ESD) is widely used as a standard treatment for superficial tumors in the GI tract and its safety has been established. Opportunities for elderly patients to undergo ESD for gastric cancer is increasing due to the continued improvement in life expectancy. However, short-term and long-term outcome of ESD for elderly patients is still uncertain due to the high comorbidity profile of the elderly and possible increased risk of complications related to ESD in this population.

Methods: Therefore, we investigated the safety, efficacy and short-term outcome of gastric ESD for patients over 80 years old. Additionally, we evaluated the long-term outcome of non-curative resections according to both age groups. 1056 lesions in 886 patients treated with ESD between January 2011 and December 2015 in our hospital were retrospectively reviewed. They were classified into two groups; elderly group > 80 years old and younger group 79 years old and younger (810 lesions in 685 patients). The patient demographics, lesion characteristics, short-term ESD outcome, complications (perforation, postoperative bleeding, postoperative delir- ium, and pneumonia), were compared and analyzed.

Results: The median age was 83 years old (range: 80–92) in the elderly group and 77 years old (range: 36–78) in the younger group. In the elderly group, 79.8% (234 lesions in 201 patients) and non-elderly group - 79 years old and younger (810 lesions in 685 patients). The patient demographics, lesion characteristics, short-term ESD outcome, complications (perforation, postoperative bleeding, postoperative delirium, and pneumonia), were compared and analyzed.

Concerning the long-term outcome of non-curative ESD, cases performed between 2011 and 2013 were assessed. The median age was 83 years old (range: 80–92) in the elderly group and 77 years old (range: 36–78) in the younger group. In the elderly group, 79.8% (234 lesions in 201 patients) and non-elderly group - 79 years old and younger (810 lesions in 685 patients). The patient demographics, lesion characteristics, short-term ESD outcome, complications (perforation, postoperative bleeding, postoperative delirium, and pneumonia), were compared and analyzed.

Conclusion: ESD is a safe and effective treatment for early gastric neoplasia even in patients over 80 years old. However, because postoperative delirium and postoperative pneumonia were observed more often in the elderly patients, more careful attention to these conditions during perioperative care may be necessary. Elderly patients over 80 years old, with non-curative resections, underwent less frequent additional surgery without any impact on the disease specific death and global mortality.

published guidelines regarding appropriate surveillance of patients with GIM and how wide disparity in the management of this premalignant condition.

Aims & Methods: This study aimed to analyze surveillance practice and characterize the natural history of this premalignant condition by identifying all patients with GIM on an upper GI surveillance program and reviewing follow-up data. This is a retrospective study of patients with GIM who are currently enrolled in an upper GI surveillance programme. Patients with a history of GIM identified at any time during an 18 year surveillance period (from 1998 to 2016) were included in the study. Patient characteristics, endoscopy data including histological rates of Helicobacter pylori infection, Barrett’s oesophagus association and outcomes were reviewed.

Results: 160 patients (including those with Barrett’s oesophagus, GIM and family history of gastric cancer) were enrolled on the surveillance programme. 42 patients with GIM were identified-20 females (47.6%) and 22 males (52.3%). The mean age at which GIM was first diagnosed was 60.6 years (range from 17.9 to 71.5 years). 15/42 patients (35.7%) had co-existent Barrett’s oesophagus and Helicobacter pylori was identified in 6/42 (14.3%). The follow-up period ranged from 1 to 17.3 years. 27 patients had repeat gastroscopies following initial diagnosis. 15 patients are still awaiting a repeat gastroscopy. A large degree of variability in the number and frequency of follow-up gastroscopies was observed. The average interval of follow-up gastroscopies was 3.3 years per person. 14/27 patients (51.8%) had no evidence of GIM on most recent gastroscopy, 7/27 patients (26%) had repeat findings of persistent focal GIM, 5/27 patients (18.5%) progressed to extensive GIM. No cases of dysplasia were recorded but 1 patient (3.7%) developed gastric cancer.

Conclusion: This study suggests a low apparent risk of progression of gastric intestinal metaplasia in a small western cohort. Further studies may be necessary to address if the applicability of published surveillance guidelines can be generalized to regional low gastric cancer prevalence.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Gastric adenocarcinoma and proximal polyposis of the stomach (GAPPS) has to been described recently only in a few families worldwide (only one in Europe so far). Three different point mutations in promoter 1B of the APC gene were identified as causal (c.-191T>G, c.-192A>G, and c.-195A>C). We diagnosed GAPPS in the second Czech white family (not related to that one published previously-ref. 1).

Aims & Methods: We diagnosed GAPPS across 3 generations in a new Czech white family. A genetic analysis of the family was performed.
Results: The Proband (a 43-year-old male) was endoscopically regularly surveyed from his 34 years of age because of fundic-gland polyposis with predominant involvement of the gastric fundus and body (with relative sparing of the lesser curve) and microcytic anaemia. Polyposis slowly progressed with the intestinal differentiated low-grade dysplasia in polypectomy specimens 10 years after the diagnosis. As the GAPPS criteria were fulfilled (ref. 2), he and his family underwent genetic testing and bi-directional Sanger sequencing of promoter 1B revealed a point mutation (c.-191 T > C). The same type of mutation was described in his father (63 years old), sister (41 years old), nephew (son of his sister), 6 years old), uncle (father’s brother, 51 years old) and 2 cousins (uncle’s daughters, 23 and 27 years old), all have been asymptomatic. No gastric cancer in the family history was mentioned. The Proband underwent preventive total gastrectomy, histology of the surgical specimen confirmed severe involvement of gastric body with fundic gland polyps, low-grade and focal high-grade dysplasia. The microcytic anaemia improved rapidly after surgery. The rest of family is scheduled for gastroscopy. The fundic-gland polyposis of similar distribution (with significantly lower number of polyps, without any dysplastic changes) was recently diagnosed in the 23-year-old cousin.

Conclusion: The second European family with GAPPS is presented. The recently described mutations in promoter 1B of the APC gene does not automatically mean a faster progression of the disease as suggested earlier. GAPPS can be presented with various phenotypes with a different course of disease, the prevalence can be higher than previously reported. Acknowledgement: The study was supported by the Research Project PROGRES Q40–15.

Introduction: ESD is the one of the options of treatment even for lateral spreading (LS) lesions. The clinical characteristics of LS lesions are characterized as a hypervascular lesion (ESMGL). Endoscopic diagnosis is developed by magnified endoscopy, however accuracy of diagnosis for lateral spreading ESCC is not high. Some patients have to undergo additional treatment because tumor is invaded to submucosal layer or lymphvascular invasion. On the other hand, wide resection by ESD could cause the delay of additional treatment because of the restriction for the treatment of esophageal stricture after ESD. Thus, treatment strategy for lateral spreading ESCC has to include additional treatment after ESD. Aim of this study is to evaluate our treatment strategy for lateral spreading superficial ESCC.

Aims & Methods: From January 2010 to December 2014, 49 cases of lateral spreading superficial ESCC were resected by surgery or ESD. Diagnosis, treatment methods and outcomes are evaluated. Our indications for additional treatment after ESD are the cases of over pT1b (SM2) or lymphvascular invasion.

Results: In 49 cases of lateral spreading superficial ESSC, 32 cases were treated by ESD and 17 case were treated by surgery. All lesions of 32 cases are completely resected by ESD. Average size of tumor treated by ESD is 59.4 mm (50–130 mm). Accuracy of estimated depth of invasion by endoscopy for ESD cases is 65.7%. Four of 32 cases of ESD underwent additional therapy (3 for surgery and 1 for CRT) because of pT1b (SM2) or lymphvascular invasion, and one case has lymph-node metastasis. Rate of stricture after ESD is 20.0% for subcircumferential stricture and 77.8% for circumferential stricture instead of steroid injection. Average time and duration for control of esophageal stricture by Balloon Bougie is 13.5 times and 18 weeks. In 17 surgical cases, all cases are treated by thoracoscopic esophagectomy. Average size of tumor treated by surgery is 76.5 mm (50–130 mm). Accuracy of estimated depth of invasion by endoscopy for surgical cases is 47.1%. Seven cases in 17 (41.2%) have lymph node metastasis. Rate of lymph node metastasis is 42.9% for pT1a-MM, 100% for pT1b-SM1 and 42.9% for pT1b-SM2. One case died by recurrence after surgery and 48 cases were survived without any recurrences.

Conclusion: Accuracy of estimated depth of invasion by endoscopy for lateral spreading superficial ESSC is cut-off compared to normal superficial ESCC. Most of circumferential lesions could be prevented by endoscopic injection. However control of strictures after circumferential esophagectomy is difficult. Thus, diagnostic ESD should not be performed for circumferential lesions of lateral spreading superficial ESCC for the patients who will select CRT for additional treatment, and CRT should be selected for first treatment of these cases. Long survival could be obtained by ESD or surgery for the patients of lateral spreading ESCC by our treatment strategy.

Introduction: Few major international guidelines consider pepssinogen tests as the best available non-invasive tests to detect precancerous lesions (in particular, - corpus atrophy) in the stomach mucosa. Gastrin-17 (G-17) has been suggested as a potential marker for antrectomy in Europe and Asia. Recommendations from the European Commission expert group consider the need for additional studies before any screening with biomarkers can be recommended for implementation.

Aims & Methods: Generally healthy 40-65 years aged participants of the GISTAR pilot study referred for upper endoscopy according to the pilot study protocol were enrolled. Pepssinogen (Pg) I and II were assessed from plasma samples by two methods-ELISA (Biohit Plc.) and latex-agglutination (Eiken Chemical Co.) test systems. G-17 and IgG group antibodies to H.pylori infection were assessed by Biohit Plc. ELISA test systems. The following cutoff values were considered characteristic for atrophy: PgI/I + II < 3 for ELISA, PgI/I + II < 3 and PgI/I and PgII/I < 3 for latex-agglutination, and G-17<1 pmol/l (in a plasma sample obtained in fasting condition). Biopases were sampled and read by two independent pathologists according to the updated Sydney system. OLG and OLGIM scoring systems were also applied. Cancer, dysplasia, OLG or OLGIM III-IV were taken together were considered high-risk lesions.

Results: Altogether 1044 subjects (55% females, mean age =52, 67.7% with positive H. pylori antibodies) were included in the study. The sensitivity and specificity for detecting moderate to severe atrophy in the corpus for Biohit ELISA test was 47.2% and 92.3%, but for Eiken latex-agglutination test 81.1% and 62.1%, respectively. The corresponding values for G-17 to detect atrophy in the antrum were 29.2% and 58.9%. High-risk lesions were detected by Biohit ELISA pepssinogen test with 22.8% sensitivity and 91.6% specificity, but with Eiken latex-agglutination test with 67.4% and 62.5% sensitivity and specificity.

Conclusion: Due to the high specificity, pepssinogens (e.g. ELISA) could be potentially used for screening of precancerous lesions if relatively low sensitivity could be accepted. G-17 does not seem to provide any additional benefit.

Disclosure of Interest: All authors have declared no conflicts of interest.
Aims & Methods: We aimed to investigate and characterize the biological roles of miR-211 in the development of gastric cancer. The expression level of miR-211-5p was measured in paired primary gastric cancer with corresponding adjacent gastric tissues by RT-qPCR. Furthermore, we investigated the biological role of miR-211-5p in proliferation, apoptosis, migration of gastric cancer cell lines in vitro.

Results: The expression levels of miR-211-5p were significantly decreased in gastric cancer and low expression of miR-211-5p correlates with poor prognosis in gastric cancer patients. Ectopic expression of miR-211-5p suppressed proliferation, migration and induced apoptosis in gastric cancer cell lines in vitro. Bioinformatics and quantitative real-time PCR analysis revealed that FoxC1 might be a target of miR-211-5p. Downregulation of FoxC1 inhibited proliferation and migration of gastric cancer cells and Overexpression of FoxC1 partly abrogated the inhibitory effects of miR-211-5p on gastric cancer cell proliferation and motility.

Conclusion: We therefore conclude that miR-211-5p acted as a tumour suppressor by targeting FoxC1 in gastric cancer and miR-211-5p might be a potential target for the treatment of gastric cancer.

Introduction: Duodenal adenomas are rare epithelial tumors and represent 25% of the benign lesions diagnosed in the small bowel. Non-ampullary sporadic duodenal adenomas (NASDA) are usually asymptomatic and their diagnosis is mostly incidental. NASDA are benign epithelial tumors with a potential for malignant transformation via the adenoma–carcinoma sequence; nevertheless this risk is lower compared to ampullary or duodenal adenomas in the context of genetic syndromes. Results of Endoscopic Mucosal Resection (EMR) of NASDA were only assessed in a large series of patients.

Aims & Methods: Consecutive patients undergoing EMR of NASDA between May 2002 and December 2016 were identified from an electronic database. Patients with a genetic polyposis syndrome (FAP or Peutz-Jeghers) and/or adenomas of the major or minor duodenal papilla were excluded. Preoperative biopsy was performed at operator discretion, considering that the majority of the patients were referred from other centers. In case of doubt for a possible involvement of the ampulla of Vater, duodenoscopy with a side-viewing endoscope was also performed. EUS was not systematically done before duodenal EMR.

Results: EMR of 75 NASDA was performed in 68 patients (56% en-bloc resections, 27% piecemeal). The mean size was 14.4 mm and 28.9 mm for lesions resected en-bloc and piecemeal, respectively. Histopathological findings were: low-grade dysplasia (n = 27, 36%), high-grade dysplasia (n = 34, 45.4%), high-grade dysplasia with focal adenocarcinoma (n = 12, 16%), intramuscular adenocarcinoma (n = 2, 2.6%). Pre-EMR biopsy tended to downgrade the lesion in 36.4% of cases for lesions <20 mm; bigger lesions were removed piecemeal. Blended “endocut” current was used in all the cases. All resected specimens were retrieved for histological examination. CO2 insufflation was routinely used during duodenal EMR after 2013. Argon plasma coagulation was used to eradicate residual adenomatous tissue at discretion of the operator. Endoscopic follow-up was scheduled after 3, 6 and 12 months for the first year, and then yearly for up to 5 years.

Conclusion: EMR of 75 NASDA was performed in 68 patients (56% en-bloc resection, 27% piecemeal). The mean size was 14.4 mm and 28.9 mm for lesions resected en-bloc and piecemeal, respectively. Histopathological findings were: low-grade dysplasia (n = 27, 36%), high-grade dysplasia (n = 34, 45.4%), high-grade dysplasia with focal adenocarcinoma (n = 12, 16%), intramuscular adenocarcinoma (n = 2, 2.6%). Pre-EMR biopsy tended to downgrade the lesion in 44.4% (16/36). Retroperitoneal perforations occurred in 3/75 (4.0%) procedures when possible, for lesions >20 mm; bleeding was reported in 13/75 (17.3%) resections and was successfully managed by EGD or OTSC. Recurrence was defined as the need for a further endoscopic intervention 5 years after the initial procedure; 61/68 patients (91.1%) were fully retreated endoscopically. There was no mortality related to the intervention.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: The dramatic rise in the incidence of gastroesophageal junction adenocarcinoma (GEJ) adenocarcinoma in the Western countries, has promoted an increased interest about the etiopathogenesis and natural history of GEJ. The cardiac epithelium (CE), which integrates the morphological spectrum of Barrett’s esophagus, is frequent in endoscopic (15%) and histological (24%) GEJ in children and adults. Its congenital versus metastatic origin still needs to be clarified. The gastroesophageal neo-junction after esophagectomy seems the ideal model to study the development of GEJ epithelium, reproducing "in vivo" its natural history.

Aims & Methods: The aim of this study was to evaluate the prevalence of metastatic CE in the gastroesophageal neo-junction. Prospective study of patients undergoing esophagectomy due to esophageal/GEJ neoplasia between November 2002 and November 2016. Upper gastrointestinal endoscopy (UGE) (Olympus, GIF-HQ 190) was performed 3 months after surgery; the neo-junction was evaluated with white light and Narrow band imaging (NBI); protocollated biopsies were made (suspected areas of CE, randomized in the anastomosis if endoscopic absence of CE, 2 cm above and below the anastomosis). Endoscopic CE defined by the presence of circular pattern with NBI in the anastomosis. Histological evaluation performed by 3 pathologists with gastro-intestinal expertise. A questionnaire for gastroesophageal reflux (GER) symptoms evaluation was applied.

Results: 20 patients were included (9 adenocarcinomas), 19 men, mean age 60±11 years, 9 under proton-pump inhibitor and 10 with GER symptoms. UGE: unable to pass a standard scope in anastomosis due to stenosis: 3/20; esophagitis: 5/20; columnar epithelium of the esophagus: 1/20. Endoscopy suggested of CE: present in 17/20, suspect in 2/20 and absent in 1/20. Histologically: CE confirmed in 18/20 patients; additionally identified oxyntocardiac epithelium in 12/20 and intestinal metaplasia in 2/20. The endoscopic diagnosis of CE revealed a sensitivity, specificity, positive and negative predictive value of 94.4%, 100%, 100% and 66.7%, respectively.

Conclusion: The identification of metastatic CE in neo-junctions is a very frequent and early event and its present corroborates the hypothesis of metaplasia, to the detriment of a congenital origin. The good endoscopic and histological correlation observed for CE will allow the definition of endoscopic patterns, essential for its recognition.

associated, in our series, with a higher incidence of residual/recurrent adenoma, when compared to other studies. These results are similar to those reported in the literature. Residual and recurrent duodenal adenomas were successfully retreated by EMR in all of them but one. Mortality related to NASDA was absent in our series after a median follow-up of 59 months (range 1-147).

Management of precancerous lesions after EMR for NASDA requires the availability of interventional radiologists and surgeons with experience in retropitoneal surgery. In our experience colorectal adenomas was correlated to NASDA (33.3%), colonooscopy is considered part of the pre-EMR assessment when NASDA is diagnosed. A recall system and patient’s compliance to endoscopic follow-up are mandatory to detect recurrences and their prompt treatment.

Introduction: Obestatin is a bioactive peptide with a well-defined function on cell proliferation mediated by the GPR39 receptor. Our data involve this system in several processes located in the stomach: from peptinogen secretion in healthy stomach to malignant proliferation in gastric adenocarcinomas (1). A key step in obestatin signaling is the transactivation process GPR39-RTK through MMPs activation. This step could imply a key mechanism by which MMPs regulate these diseases. Numerous studies have shown that alterations in the expression and/or mutations in members of the family of receptors EGFR/ErbB are present in these diseases. Numerous studies have shown that alterations in the expression and/or mutations in members of the family of receptors EGFR/ErbB are present in these diseases. Acetylcholine induces cancer stem cell phenotype via activation of muscarinic and nicotinic pathways. It also inhibited the effects of ACh on the number of T cells.

**Introduction:** The mechanisms of gastric carcinogenesis, especially of diffuse type of gastric cancer (GC) are poorly understood. The cancer stem cells (CSC) represent a particular fraction of cancer cells, considered at the origin of cancer and responsible for carcinogenesis. The expression of CSC markers (CD44, ALDH) and EMT markers (Snail, Zeb1) in gastric cancer cells has been suggested in gastric carcinogenesis but its effect on gastric CSC remains to be established.

**Aims & Methods:** Our aim was to study the effect of ACh on gastric cancer cells, and in particular its capacity to induce the stem cell phenotype, and to study the mechanisms involved. Adenocarcinoma gastric epithelial cell lines were first cultured in adherent conditions in the presence of ACh (0.1-10 μM), before being cultured in non-adherent condition in order to favour expansion of CSC and formation of tumorspheres (T). The effect of ACh on T formation was evaluated under microscope by quantifying the number and size of T using the System snapshot file in INCell analyzer 2200/6000. The involvement of different cholineergic (muscarinic and nicotinic) receptors in ACh-induced responses was studied by pharmacological approach using selective agonists and antagonists. The expression of CSC marker SNRP (NO donor) and L-NAME (nitric oxide synthesis inhibitor). Finally, the effect of ACh on the expression of CSC and epithelial-mesenchymal transition (EMT) markers was studied by immunofluorescence, RT-qPCR and flow cytometry. Statistical analysis was performed by ANOVA test, Kruskal-Wallis test, or two-way non-parametric ANOVA test using SPSS16.0 software.

**Results:** ACh at concentrations of 1.0 and 1 μM significantly increased the number and size of T as compared to control conditions (p < 0.001). Furthermore, a selective muscarinic receptor agonist, increased the number and size of T, while the stimulatory effect of ACh on T was significantly reduced by the selective muscarinic receptor antagonist, atropine. Similarly, DMPP, a selective cholinergic (muscarinic and nicotinic) receptors in ACh-induced responses was studied by pharmacological approach using selective agonists and antagonists. The expression of CSC markers (CD44, ALDH) and EMT markers (Snail, Zeb1) in gastric cancer cells.

**Conclusion:** This study shows that ACh induces CSC properties of gastric cancer cells of diffuse type via activation of muscarinic and nicotinic pathways. It also shows that ACh effects are, at least in part, mediated by nitric pathway. These results suggest that ENS may be a new actor in gastric carcinogenesis.

Introduction: Linked color imaging (LCI), a recently developed endoscopic technique, emphasizes diffusex redness, which is a characteristic of Helicobacter pylori (Hp) infection. However, the diagnosis of Hp infection does not have objective indicators; it depends on medical doctors’ experience. Therefore, it is necessary to construct objective indicators to diagnose Hp infection.

Aims & Methods: The aims of this study are to determine objective indicators for the presence or absence of Hp infection to support medical doctors’ diagnoses by constructing an automatic diagnostic system. In the proposed system, first, a region with a high hue in LCI images is defined as a region of interest (ROI). Images with a wide ROI and images with a narrow ROI are classified as high and low hue images, respectively. As a result, LCI images are classified into two types in which inflammation due to Hp infection presents as red and purple. Then, the presence or absence of Hp infection is learned by machine learning for each type of LCI image. The feature values used in the learning process are the ratio of the ROI, the average and median hue values in high hue images, and the mode saturation value and the median and variance of the hue in low hue images. Then, the trained classifiers diagnose the presence or absence of Hp infection automatically. In this paper, the constructed system was evaluated using 128 images (32 patients) in which endoscopic examination (LCI observation) and Hp infection diagnosis were performed at Murakami Memorial Hospital of Asahi University. Furthermore, support vector machines were used as classify learners for diagnosis.

Results: In the previous system [1], 29 out of 32 cases were automatically diagnosed correctly. In contrast, all cases were automatically diagnosed correctly with the proposed system. This result demonstrates that classifying LCI images into two types based on color improves the accuracy of this system.

Conclusion: The proposed system can automatically diagnose the presence or absence of Hp infection with the same precision as medical doctors with sufficient experience. Therefore, the proposed system can support the diagnosis of medical doctors with less experience.

Introduction: γ-glutamyltranspeptidase (GGT) is a cell surface-associated enzyme that is not highly expressed in normal cell. However GGT is overexpressed in various type of human cancers. It is known that Helicobacter pylori (H. pylori) also produce GGT. Urano et al have developed an enzymatically activatable fluorescent probe, γ-glutamyl hydroxymethyl rhodamine green (γGlu-HMRG), which is a fluorescent compound under a pH and normal cellular environment, but turns to be highly fluorescent upon reaction with GGT[1]. Aim of this study is to consider if γ-Glu-HMRG can be useful for diagnosing infection H. pylori.

Aims & Methods: In this study, we investigated whether activation of γ-Glu-HMRG fluorescence was suppressed in H. pylori culture solution which was co-incubated with an inhibitor of GGT (GGsTop). Furthermore, we applied γ-Glu-HMRG to biopsy specimens which were taken from antrum and corpus of stomach in H. pylori positive patients (n = 13) and H. pylori negative patients (n = 14). We then observed the increase of fluorescence intensity over time (1 min, 5 min, 10 min, 15 min). Fluorescence intensity was quantified by Image J software (National Institutes of Health, Rockville, Maryland)[2].

Results: Activation of γ-Glu-HMRG fluorescence was detected in WT strain, but was not in ggt mutant strain. Activation of γ-Glu-HMRG fluorescence was inhibited by GGsTop. There was significant difference of the increase of fluorescence intensity between H. pylori positive and negative both in antrum corpus of stomach (antrum p = 0.0008, corpus p = 0.047).

Conclusion: GGT-activated fluorescent probe can be useful for H. pylori infection diagnosis.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Several H. pylori (HP) infection related cardiac findings (mucosal atrophy, metaplastic change, diffuse redness, spotty redness and nodular change of the antrum etc.) are so important sign of HP infection on endoscopic examination. On the other hand, we have confused with various newly endoscopic findings (patchy redness and map-like redness etc.) were seen on non-HP eradicated stomach. On this time, we have found out a new other ultimate useful finding showing HP infection related gastritis at gastric cardiac (EG junction) including present and past HP infection. The endoscopic image of gastric cardiac is the first gastric view through the esophagus on each endoscopic examination.

Aims & Methods: Our aim of this study is to elucidate possibility of judgement with only this cardiac endoscopic view about presence or absence with HP infection. We have found out so useful and specific cardiac image (We call Whale Shark Sign: WSS) closely related to HP infection. We have examined the presence of WSS on 4,268 cases that have been able to overviewed on their endoscopic examination.

Results: Mean age of patients was 52.4 years old. In case of WSS positive, all their serum HP antibody titers showed more than cut-off level (3 U/ml) to avoid false negative results.

Conclusion: We have been able to judge the presence of HP infection with only cardiac endoscopic images (WSS), we should take care of seeing the presence of WSS sign. Since this sign is very easy and simple, everyone will be able to judge the presence of HP infection as a gastric cancer risk.

Introduction: The diagnosis of Helicobacter pylori (H.p) infection is currently made by means of non-invasive (Urea Breath Test or HpSA) or invasive (gastric biopsy or culture) methods. Serological assessment of H.p infection by using levels of IgG is not recommended. Pepsinogen II (PGII) is validated in the literature as a non-invasive marker of gastric inflammation. Aim of the study was to assess in a population of dyspeptic patients the clinical availability of PGII determination in singling out subjects infected by H.p in comparison with non-infected ones.

Aims & Methods: A cohort of 880 consecutive dyspeptic patients (F 439; mean age 55.5 yrs; range: 29.83-78 yrs) were enrolled in the study. Exclusion criteria: previous surgery, previous H.p eradication therapy, concomitant PPI. In all patients the diagnosis of H.p infection was made by means of upper GI endoscopy and at least one of these two methods: UBT, HpSA. All patients underwent blood sample for determination of serum levels of PGII (Blohid Oyj; Finland; normal values: 2-15µg/l). In a group of 670 pts a course of antibiotics (triple, concomitant or sequential therapy) to cure H.p infection was performed and PGII levels were measured at baseline (T0) and after two months (T1) from the end of the antibiotic therapy. The search for the most appropriate cut-off of PGII in diagnosis of H.p. infection was assessed by using the ROC curve method.

Results: 430 out of 660 dyspeptic patients (F 245;mean age 52.3 yrs; range 32-69 yrs) showed an H.p-related gastritis (group1) in comparison with 430 out of 860 patients (F 245; mean age 57.3 yrs; range 38-74 yrs) resulted negative for H.p infection (group 2). The mean value of PGII in group 1 was 20.9 ± 6.1 opposite with 7.2 ± 1.7 in group 2; p <0.0001. 415 out of 670 patients treated with antibiotics schedules were cured from H.p infection, opposite with 255 non-eradicated ones. In the group of cured patients, the PGII values at T0 were 16.5. in comparison with 255 non-eradicated ones. In the group of cured patients, the PGII values at T0 were 16.5. in comparison with 8.6 at T1; p<0.001. The cut-off for PGII in the diagnosis of H.p infection, by comparing the 430 H.p positive pts and the 430 negative ones with method of ROC curve identified the mean value of 10.66 µg/l, youden index J = 0.997.

Conclusion: serum PGII levels seem able to perform diagnosis of H.p infection in dyspeptic patients, as well as the efficacy of antibiotics treatment for H.p eradication, being 10.66 µg/l the best cut-off in singling out infected from non-infected subjects.

Introduction: The Ureathrea Breath Test (UBT) is considered the gold standard non-invasive test for detection of Helicobacter pylori infection in Ireland. In Ireland, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. With this in mind, it is important to optimise management of H. pylori infection. It has been suggested that the DOB value is reflective of the amount of bacteria present in the stomach and could predict whether the infection is eradicated.

Aims & Methods: The aim of this study was to determine whether there is an association between DOB and eradication of H. pylori infection in an Irish cohort. Treatment naive adult patients undergoing UBT were included. Patients were deemed to be H. pylori positive if a Delta Over Baseline (DOB) value of > 20% was obtained. Positive patients were categorised into low (<16%), intermediate (16-35%) and high (>35%) DOB groups. A random subset of positive patients was given clarithromycin-based triple therapy for 7 days. A follow-up breath test was performed at least 8 weeks post-treatment to confirm eradication of H. pylori in all patients. The three DOB groups were compared with respect to age, gender and eradication rates.

Results: Out of 860 of UBTs assessed (mean age 43.5 ± 15.2 years, 39% male), 273 (32%) were positive (mean age 43.1 ± 14.9 years, 41.9% male) and 587 were the total positive patients, 91 (31.5%) returned for a follow-up UBT to confirm eradication of H. pylori. When patients were categorised into low, intermediate and high UBT groups, there was no significant difference in age and gender between groups (p = 0.06 for gender and 0.3 for gender). Eradication rates in the low, intermediate and high UBT groups were 70.5%, 63.0% and 50.0% respectively (p = 0.3). Patients were then categorised according to eradication status. When eradication was successful, the average DOB value was significantly lower (p = 0.01) in successful patients (DOB average of 28.9%) compared to unsuccessful (DOB average of 8.9%). When eradication was unsuccessful (p = 0.03, 95% CI 0.69 to 17.5%), eradication rates were 70.5%, 63.0%, and 50.0% respectively. When these rates were compared to respective rates in those whose treatment was not known, no difference was observed. The subset was also categorised according to eradication status. When eradication was successful, the average DOB value was lower, at 22.0% compared to unsuccessful patients (p = 0.6). Similarly, when these DOB values were compared to respective values in those whose treatment was not known, no difference was observed.

Conclusion: As the DOB value increases in the UBT, the eradication rate of H. pylori decreases, regardless of treatment regimen. When categorised according to eradication status, the DOB value was significantly lower when eradication was successful (20.6 ± 29.8%) compared to unsuccessful (p = 0.03). The DOB value could be a useful value in stratifying patients with H. pylori infection; especially as histology and antimicrobial resistance information is unavailable in patients undergoing non-invasive testing for H. pylori infection.

P1908 COMPARISON OF THE EFFICACY BETWEEN BISMUTH AND ALTERNATING RIFAXIMIN ON SECOND-LINE QUADRUPLE REGIMEN OF HELICOBACTER PYLORI ERADICATION

Digestive Disease Center, Institute For Digestive Research, Soonchunhyang University College of Medicine, Seoul/Korea, Republic of

Contact E-mail Address: junspark@schmc.ac.kr

Introduction: Bismuth is a heavy metal which has antimicrobial activity through binding iron in bacteria. Despite this, AMX and CAM are the strongest HP 1st eradication therapy.

Aims & Methods: From May 1st 2003 to October 31st 2015, six thousand and five hundred ninety-five patients were treated their H. pylori infection in Soonchunhyang University Hospital, Seoul. And their prescriptions and result of eradication were retrospectively reviewed on the medical records. The patients had clarified pre-ant eradication result, which can be assured by the rapid urease test performed within 100 days of eradication were enrolled. And statistical analyses were performed to the patients who had second-line treatment to compare the efficacy of the bismuth containing regimen and the rifaximin containing one.

Results: During the periods over 12 years, two thousand and seven hundred patients were prescribed the standard triple eradication regimen and 2,109 (78.11%) patients showed the successful treatment result. One hundred twenty-six treatment failure groups were compared with treated with second-line regimens. Thirty-five patients were prescribed the bismuth-containing regimen and 34 (97.14%) of them showed successful eradication result. Other 91 patients were treated with the rifaximin-containing regimen and showed 92.31% of eradication rate. The treatment success rates are not different significantly in statistics. (Fisher’s exact test, P-value = 0.442)

Conclusion: Alternative rifaximin containing regimen of second-line H. pylori treatment didn’t showed inferiority on standard bismuth-containing one. This suggests that the use of rifaximin is possible in the patients who are not suitable to bismuth use and failed with primary eradication.

Introduction: Standard triple therapy (SST) has been widely used in Helicobacter pylori eradication, but eradication rate is decreasing because of clarithromycin resistance. Recently, Levofoxacin-based therapy (LBT) has been evaluated to overcome the low eradication rate of standard triple therapy and reported eradication rate over 80%.

Aims & Methods: We compared the efficacy and safety of SST group and LBT group for Koreans. Between April 2014 and April 2016, 49 patients in the SST group (amoxicillin 1 g bid, clarithromycin 500 mg bid and omeprazole 20 mg bid for 10 days) and 48 in the LBT group(levofloxacin 500 mg bid, amoxicillin 1 g
bid and esomeprazole 20 mg bid for 10 days) were enrolled, prospectively. H. pylori eradication rate as the primary endpoint and serious adverse effects as the secondary endpoint were defined. 

**Results:** H. pylori eradication rate as the primary endpoint was higher in the LBT group than in the STT group, but there was no statistically significant difference between the two arms (82% vs. 79.7%, P = 0.29). Serious adverse effects as the secondary endpoint tended to be more frequent in the LBT group, but there was no significant difference (6.1% vs. 15.2%, P = 0.267). The overall rates of adverse effects were not different between two groups.

**Conclusion:** In comparison of H. pylori eradication rate of our study, LBT was not significantly higher than STT, but it may be an alternative treatment if STT eradication rate is lowered in Korea.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1910 TREATMENT OF HELICOBACTER PYLORI INFECTION: WILL TAILORING THERAPY FIRST TIME OVERCOME INCREASING FAILURE OF STANDARD TRIPLE THERAPY?**

D. Brennan, M. Hussey, D. Tighe, C. O’Morain, S. Smith, D. Menamara Trinity Academic Gastroenterology Group, Trinity College Dublin, Dublin/Ireland

**Contact E-mail Address:** dbrenna9@tcd.ie

**Introduction:** In Ireland, Helicobacter pylori infection has become increasingly resistant to commonly used antibiotics, such as clarithromycin. Concurrently, eradication rates for standard clarithromycin-based triple therapy have fallen below the 80% deemed acceptable for a given treatment. The aim of this study was to compare eradication rates of standard clarithromycin-based triple therapy with those of tailored therapy based on antimicrobial susceptibility as a first-line treatment for H. pylori infection. Treatment-naive adult patients undergoing endoscopy were prospectively recruited. Biopsies from H. pylori-positive patients (as assessed by CLO test) were processed for sensitivity testing by E-testing and genotyping by the GenoType HelicoDR assay (Hain). Patients randomly received either clarithromycin-based standard triple therapy or tailored treatment based on antibiotic sensitivities, for 7–14 days. A follow-up breath test was performed at least 8 weeks post-treatment.

**Results:** To date 889 patients have undergone endoscopy and 186 (21%) were H. pylori positive. Infected patients were significantly younger (mean age 53 vs 49 years, p = 0.002) and tended to be male (43% vs 53%, p = 0.02). Of 186 H. pylori-positive patients, 112 (60%) were treatment naïve. Culture of H. pylori was successful in 57% (64/112) of samples and primary clarithromycin resistance was 47% (30/64) by E-test. Genotypic resistance data was available for 93% (104/112) patients and 55% (61/114) strains were clarithromycin resistant. Thus far, 99 (88%) treatment naïve patients have been enrolled in the study; 92 (93%) have completed the study. Of these, 45 (46%) have received standard triple therapy and 54 (54%) have received tailored therapy. In the tailored arm, 25 (46%) patients received standard triple therapy, 14 (26%) received levofloxacin-based triple therapy, 13 (22%) received a PPI and combination of antibiotics based on their sensitivities (e.g. levofloxacin, clarithromycin, rifampicin, tetracycline or metronidazole), and 3 (6%) bismuth quadruple therapy. The eradication efficacy of tailored therapy by intention-to-treat analysis was higher at 74% (40/54) compared to 67% (n = 30/45) for standard therapy (p = 0.5). The eradication efficacy by per-protocol analysis was also higher, at 82% (40/49) for tailored versus 70% (30/43) for standard therapy (p = 0.2). Patients in each arm were further categorised by clarithromycin resistance status, phenotypically by E-test or genotypically by the GenoType HelicoDR assay. Of note, in clarithromycin resistant patients, tailored therapy achieved a better eradication rate per protocol analysis than standard triple therapy (83% vs 57% per protocol, p = 0.09).

The eradication rates of standard triple therapy and tailored therapy according to clarithromycin resistance status

**Conclusion:** In those who are sensitive to clarithromycin, standard clarithromycin-based triple therapy achieves an acceptable eradication rate of approximately 81%. However, a high primary clarithromycin resistant rate was observed in this study (47%). In those who are resistant to clarithromycin, prescribing a regimen based antibiotic susceptibilities increases eradication rates to 83%, compared to those treated with standard triple therapy (57%, p = 0.09).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**P1912 ARE PROBIOTICS USEFUL AS ADJUVANTS IN ERADICATION THERAPY OF HELICOBACTER PYLORI INFECTION?**

**Introduction:** Helicobacter pylori (Hp) successful eradication has been considered since it contributes to several gastrointestinal disorders. Sequential therapy has been used widely as the first approach in Hp eradication therapy (HpET). However, its fails in 10–45%. The addition of probiotics has been considered because of potential benefit in the improvement of efficacy and reduction of side effects during HpET. We aimed to evaluate the effect of probiotics, as adjuvant to sequential HpET on treatment efficacy, side effects and patient compliance. This was a prospective study of total of 1159 patients followed in a gastroenterology outpatient clinic. Selected patients underwent Hp screening for unexplained gastrointestinal symptoms or disorders with HpET indication. Compared patients undergo sequential therapy (10-day treatment of 5 days of pantoprazole + amoxicillin followed by further 5 days of pantoprazole + clarithromycin + metronidazole-G1:n = 85) and patients with additional supplement of Lactobacillus reuteri+probiotics therapy 2tablets/day in previous two weeks and during treatment (G2:n = 77), since it was approved for this indication. Screening Hp test and indication, eradication rate, auto-reported side effects and patient compliance were evaluated. The overall screening Hp test, 147(55.5%;147/265) were positive, being the majority obtained by gastric biopsy (86.0%;n = 228). The mean age was 58.6 ± 15.8years with women predominance (60.8%;n = 161). The main indications for Hp screening were dyspepsia (27.9%), epigastric pain (24.2%), gastroduodenal peptic ulcerous disease(19.2%) and gastroesophageal reflux disease (15.8%). At gastric biopsies, chronic gastritis was present in 61.5% (n = 163), gastric atrophy in 17.0% (n = 45) and intestinal metaplasia in 7.9% (n = 21), with Hp mild colonization in most cases (58.5%;76/130). Eradication rate was significantly higher in patients who had probiotic supplement (G1-74.1%;G2-92.2%;p = 0.002;OR = 4.132). No significant difference was verified between two groups in relation to side effects (G1-15.3%;vsG2-9.1%;p = 0.094) or patient non-compliance (G1-2.4%;vsG2-
were assigned to one of the following groups: a control group receiving the randomized study, performed in the Gastro Enterology II department on the infection documented on a histological study of gastric biopsies were enrolled sequential therapy on Saccharomyces boulardii to investigate the effects of the side effects.

The eradication of treated group without probiotics (G1–5.9% vs 0.0%; p = 0.031) was performed in the Gastro Enterology II department on the infection documented on a histological study of gastric biopsies were enrolled sequential therapy on Saccharomyces boulardii to investigate the effects of the side effects.

The eradication of treated group without probiotics (G1–5.9% vs 0.0%; p = 0.031) was performed in the Gastro Enterology II department on the infection documented on a histological study of gastric biopsies were enrolled sequential therapy on Saccharomyces boulardii to investigate the effects of the side effects.

The eradication of treated group without probiotics (G1–5.9% vs 0.0%; p = 0.031) was performed in the Gastro Enterology II department on the infection documented on a histological study of gastric biopsies were enrolled sequential therapy on Saccharomyces boulardii to investigate the effects of the side effects.

The eradication of treated group without probiotics (G1–5.9% vs 0.0%; p = 0.031) was performed in the Gastro Enterology II department on the infection documented on a histological study of gastric biopsies were enrolled sequential therapy on Saccharomyces boulardii to investigate the effects of the side effects.

area, and in clinical practice. A prospective study was performed in a Spanish center recruiting consecutive naive adult patients, candidates to H. pylori eradication. Omeprazole 40mg, Clarithromycin 500mg, Amoxicillin 1g and Metronidazole 500mg, all drugs b.i.d, for 14 days (OCAM); or Omeprazole 20mg b.i.d and 3-in-1 capsule with Bismuth 140mg+ Tetracycline 125mg+ Metronidazole 125mg. 3 capsules q.i.d, for 10 days (3–1-OBMT) were prescribed according to physician criteria. Compliance was assessed by striking the consumed doses in a patient filled template, and adverse effects using a specific questionnaire with a 1–3 intensity scale. Efficacy was determined by 13C-urea breath test. A descriptive study and analysis of efficacy by intention to treat (ITT) were performed. Cases with poor therapeutic compliance (<80%) or no available data were excluded in per-protocol (PP) analysis. Chi2, Student’s t, and Mann-Whitney U tests with significance level p < 0.05 were applied. The protocol was approved by the Ethics Committee. Results: 216 patients (63.43% women; mean age 51.53 ± 19.84 years) were included. OCAM were prescribed in 103 and 3–1-OBMT in 113. No differences in age, sex and functional dyspepsia as indication to eradicate were observed between groups. Main indications for treatment were functional dyspepsia (39.35%), gastroduodenal ulcer (19.44%) and non-investigated dyspepsia (13.89%). Compliance was >80% in 11 patients and unknown in 7. The efficacy outcome was unavailable in 9 subjects. Compliance >80% was attained in 92% with OCAM and in 93.53% with 3–1-OBMT (p=0.64). The ITT rates were 82.52% vs 85.84% (p = 0.63), and PP 89.47% vs 96.04% (p = 0.13), for OCAM and 3–1-OBMT respectively. The outcomes of adverse effects (frequency, number, duration and intensity) are shown in the Table.

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Maximum Intensity [%]</th>
<th>Number</th>

</tr>
<tr>
<td>p-value 0.17</td>
<td>0.70</td>
<td>&lt;0.0001</td>
<td>0.0149</td>
</tr>
</tbody>
</table>

Conclusion: A high clarithromycin resistance area, 14-days OCAM and 10-days 3–1-OBMT regimens achieve high and similar compliance and efficacy rates, but 3–1-OBMT provides a superior safety profile.

Contact E-mail Address: vlaredodelatorre@gmail.com

Introduction: We have detected a large increase of urea breath test (UBT) requests for Helicobacter pylori (Hp) diagnosis by primary care physicians (PCP). In this way, most Hp-infected patients are now being managed at primary care level. However, little is known about outcomes of Hp infection by PCP.

Aims & Methods: 1. To evaluate and compare the eligibility of UBT indications, treatment regimens and eradication rates between PCP and gastroenterology specialist (GS). 2. To evaluate the effect of introduction of specific counselling to PCP in the management profile of Hp infection. First, we prospectively included 500 consecutive UBT indicated by PCP (250) and GS. Appropriate UBT indications were considered those included in the 3rd Spanish Consensus Conference on Helicobacter pylori infection (1). Hp treatment prescribed and eradication rates were collected retrospectively. Finally, we analyzed another consecutive 240 UBT and treatment outcomes after the introduction of specific counselling to PCP (a personal letter with the accepted indications for UBT and treatment issued by their referent GS). Statistical analysis was performed using SPSS (version 22.0).

Results: We have analyzed 740 UBT (500 pre-intervention and 240 post- intervention). 66.80% women, mean age of 48.08 ± 21.44 years. Most were included in the rest were indicated after previous eradication treatment. Inappropriate indication of UBT in the pre-intervention cohort was significantly higher in those tests requested by PCP compared to GS (36.4% vs 7.2%; p < 0.001). Also, inappropriate treatment regimens were significantly higher in the PCP group (65% vs 26.4%; p < 0.0001). Consequently, eradication rates were significantly lower in PCP compared to GS group (57.1% vs 81.1%; p < 0.001). A significant increase in the adherence to appropriate treatment regimens (71% vs 35%; p < 0.0001) and eradication rates (78% vs 57.1%; p < 0.0001) were observed in the PCP group after the implementation of specific counselling based on national guidelines.

Conclusion: Hp infection management at primary care level is inappropriate with high costs and inefficiency. The introduction of a specific counselling to PCP has significantly improved these outcomes. These data should encourage the implementation of interventional strategies in order to reduce the actual increase in antibiotic resistance.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1918 VALPROATE AND CHIR 99021 AMELIORATES RADIATION-INDUCED INTESTINAL EPITHELIAL INJURY IN MOUSE MODEL
Y. Kim, J.S. Shin
Internal Medicine, Division Of Gastroenterology, Korea Cancer Center Hospital, Seoul Korea, Republic of

Contact E-mail Address: younjoo282@gmail.com

Introduction: Radiation-induced gastrointestinal syndrome (RIGS) stems from the clonogenic loss of crypt cells and villi depopulation and results in mucosal barrier disruption, bacterial invasion, inflammation and sepsis. Valproate (VPA) is the one of the popular anti-convulsants, recently its Notch signal modulatory effect has been reported. Notch signal pathway is the essential for epithelial proliferation. Considering their clinical application such as safety, ex vivo culture techniques for single crypt or a stem cell derived enteroid, with essential features of the in vivo tissue architecture, have been recently developed. Thus, we have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS. Aims & Methods: We have adopted the 3D-cultured enteroids for RIGS ex-vivo model, and proved the effect of VPA and SCFAs for RIGS. To culture enteroid, ten centimeters segments of jejunum were procured from 9–13 week-old C57BL/6 mice. Crypts were isolated by EDTA chelation, suspended in Matrigel and grown in culture media containing epidermal growth factor, noggin, R-spondin 1. After 1 day in culture, the enteroids were treated (or not) 3 mM CHIR 99021 (GSK3β inhibitor) and 1 mM VPA. On day 3, the enteroids were irradiated as a dose dependent manner. The evaluation of irradiated enteroids was performed by measuring MTT assay, budding efficiency of enteroid, and EdU staining. On post-irradiation Day 2 and Day 7, RT-PCR was performed.

Results: Enteroid from mouse had multiple crypts (‘budding’) with well-differen-
tiated goblet, Paneth cells, + stem cells (quiescence stem cells, BMII is expressed), Lgr5+ stem cells. In the response of radiation, irradiated enteroid decreased proliferation rate in a dose dependent manner, as measured by MTT assay, budding efficiency of enteroids. Irradiated enteroids with VPA +CHIR 99021 could maintain their +stem cells even in 10 Gy of irradiation, lethal dose of mouse intestinal epithelium, and they were able to proliferation. Combination of VPA + CHIR 99021 did not have an effect on paneth cells, enteroid, mucus cells and goblet cells.

Conclusion: VPA and CHIR 99021 may ameliorate RIGS in ex-vivo mouse enteroid, through +reversor stem cell reservation and stimulatory action for epithelial proliferation. Considering their clinical application such as safety, they could be possible strategy for prevention and treatment of RIGS.

Abstract: Celiac disease affects 1-2% of the population, but due to diverse presentation many patients remain unrecognized. Diagnostic efficiency could be improved by screening of at-risk groups, but long-term benefits of this approach are unclear. To shed light to this issue, we compared a variety of celiac disease-related and other parameters in large cohorts of adult patients diagnosed in childhood either because of clinical suspicion or by screening.
Aims & Methods: A questionnaire about current health and lifestyle, adherence to gluten-free diet (GFD) and follow-up of celiac disease was sent to 564 adults with childhood diagnosed celiac disease. Further, the participants fulfilled validated Gastrointestinal Symptom Rating Scale (GSRS) and Psychological General Well-Being (PGWB) surveys for symptoms and quality of life. Clinical and histological presentation at diagnosis and other relevant medical data were confirmed from patient records. All variables were compared between screen-detected and clinically detected patients.
Results: Altogether 235 (42%) adults completed the questionnaires. At diagnosis, screen-detected patients (n = 49) were older (11.3 vs 8.8 yr, p = 0.016) and had lower body mass index (BMI) (22.8 vs 26.8 kg/m2, p = 0.001), less symptoms (44% vs 85%, p = 0.016) and higher prevalence (15% vs 0.2%, p = 0.001) than clinically detected patients (n = 186). They also had a trend to have less often total vitiligo (18% vs 32%, p = 0.073) and anemia (18% vs 32%, p = 0.072). The groups did not differ in gender, current age (median 26.5 vs 26.1 yr, p = 0.83) or age at diagnosis (median 6.3 vs 5.5 yr, p = 0.18). Screening-detected patients smoked less (4% vs 15%, p = 0.037) and had more often celiac disease in relatives (78% vs 58%, p = 0.011).
Conclusion: Diagnostic approach and presentation of celiac disease in childhood do not seem to affect the long-term health outcomes or attitude towards the diagnosis in adulthood. Lack of difference in the dietary adherence and lifestyle recommendations gives further support for active screening and early diagnosis of celiac disease.

3Department Of Internal Medicine, Tampere University Hospital, Faculty of Medicine and Life Sciences, University of Tampere, Tampere/Finland
Contact E-mail Address: liisa.viitasalo@uta.fi
Abstract: In nonresponsive celiac disease (NRCD) the symptoms and duodenal biopsy do not improve with a gluten-free diet (GFD). Serum microbial markers (ASCA and IgA class antibodies against transglutaminase (TG) and heat Shock proteins) have been proposed as biomarkers of NRCD. The objective of this study was to evaluate serum microbial markers in NRCD in comparison with non-NRCD CD patients and non-celiac controls (NCC).
Aims & Methods: Serum ASCA, IgA class TG antibodies, and IgA class heat shock protein OmpW were measured in 20 NRCD patients, 20 GFD responsive CD patients, and 55 non-celiac controls. The NRCD group was compared to the GFD responsive CD group as well as the NCC group.
Results: ASCA was detected in 8 out of 20 NRCD patients (40%), 15 out of 20 GFD responsive CD patients (75%), and 39 out of 55 non-celiac controls (71%). ASCA titers were significantly higher in NRCD patients than GFD responsive CD patients (p = 0.0009) or NCC (p < 0.001). Anti-TG antibodies were detected in 19 of 20 NRCD patients (95%), 18 of 20 GFD responsive CD patients (90%), and 22 of 55 non-celiac controls (40%). AntitTG antibodies were significantly more frequent in NRCD patients than GFD responsive CD patients (p = 0.001) or NCC (p < 0.001) and significantly more frequent in GFD responsive CD patients than NCC (p = 0.002), indicating that NRCD patients were distinguishable from controls. Of the 20 GFD responsive CD patients, 7 had ASCA (35%) and 10 had anti-TG antibodies (50%). In NCC, 9 had ASCA (16%) and 11 had anti-TG antibodies (20%). These results suggest that ASCA is a sensitive but not a specific marker of NRCD.
Conclusion: ASCA and anti-TG antibodies may be useful in distinguishing NRCD from non-celiac controls, but not from GFD responsive CD patients. Further studies are needed to confirm these findings and to identify other serum microbial markers that are specific for NRCD.
Disclosure of Interest: All authors have declared no conflicts of interest.
P1923 CORRELATION BETWEEN OXIDATIVE STRESS AND DUODENAL ATROPHY IN CELIAC DISEASE

Email: francesca.ferretti01@gmail.com

Introduction: High levels of reactive oxygen species (ROS) and impaired antioxidant defense systems lead to oxidative stress (OSx) and tissue injury in different intestinal and extraintestinal conditions, including celiac disease (CD). A possible effect of gluten ingestion on intracellular oxidative imbalance has been suggested.

Aims & Methods: The first aim of the study was to investigate the effects of OSx in CD, evaluating the levels of ROS and oxidative damage biomarkers in sera of naive patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to dietary treatment. The second aim was to look for new serological biomarkers corresponding to morphological/functional alterations detected in biopsies according to Marsh-Oberhuber classification. Finally, a possible correlation between ROS production and/or biomarkers of OSx and/or hematological data was investigated. Analysis were conducted on small intestinal biopsy specimens and peripheral blood samples of celiac patients (N-CD, CD-GFD and NRCD). The methods included Electron Paramagnetic Resonance (EPR) technique for ROS detection, High Performance Liquid Chromatography (HPLC) analysis of erythrocytes glutathione (GSH), enzymatic assays for oxidative damage biomarkers (lipid peroxidation measured by thiobarbituric acid-reactive substances (TBARS) method); protein oxidation, measured by a protein carbonyl (PC) assay kit; total antioxidant capacity (TAC), measured by an enzymatic kit; nitric oxides metabolites, assessed by a competitive method.

Results: Overall, blood samples and biopsies from 54 patients affected by CD were collected (44 F; median age 43.98 ± 13.44 years; range 19–80 years; 17 N-CD, 18 CD-GFD and 19 NRCD). Hemoglobin and haematocrit levels were significantly lower in NRCD and N-CD than in CD-GFD group (p < 0.05). In our study, a significantly increased production of ROS, lipid peroxidation and oxidized protein levels, plasma nitrate concentrations were reported in NRCD and N-CD compared to CD-GFD. On the contrary, the TAC and GSH levels were significantly decreased in N-CD and NRCD groups compared to CD-GFD. Data are summarized in Table 1. A significant direct relationship between Marsh subtypes and ROS production rate R² = 0.19; p < 0.001, TBARS (R² = 0.20; p < 0.001) and PC (R² = 0.17; p < 0.001) was found by Pearson’s product-moment correlation while an inverse correlation between Marsh subtypes and TAC (R² = 0.23; p < 0.001) and GSH (R² = 0.34; p < 0.0001) was identified. In all groups of patients, at higher ROS production rate levels corresponded to greater plasma TBARS concentrations and lower erythrocytic GSH levels.

Conclusion: Several defense mechanisms are implied in maintaining the cell integrity and tissue homeostasis. According to our results, the presence of higher levels of ROS, oxidative damage biomarkers and nitric oxides metabolites in naïve and/or biomarkers of OxS and/or hematological data was investigated. Analysis were conducted on small intestinal biopsy specimens and peripheral blood samples of celiac patients (N-CD, NRCD and CD-GFD) or non-responders (NRCD) to treatment. All authors have declared no conflicts of interest.

P1924 CIRCULATING EXTRACELULAR VESICLES, A NOVEL MECHANISM OF ENDOCRINE CELLULAR CROSS-TALK, ARE INCREASED IN NEWLY DIAGNOSED CELIAC DISEASE PATIENTS

Email: Contact E-mail Address: efkan78@gmail.com

Introduction: Extracellular vesicles (EVs) have been recently hypothesized to represent a major peripheral mechanism of cellular cross-talk. EVs carry surface receptors and proteins characteristic of their cells of origin and shuttle molecules (proteins, RNAs, microRNAs) potentially controlling physiological and patho- logical systemic processes. Recent studies have demonstrated an increased number of circulating EVs in a variety of conditions characterized by multi-organ impairment and/or damage such as insulin-resistance, atherosclerosis and obesity. Celiac disease (CD) is an immune-mediated inflammatory enteropathy, elicted by gluten ingestion in genetically susceptible individuals. It is frequently associated with a variety of systemic conditions both autoimmune and potentially immune-mediated in nature.

Aims & Methods: The aim of this study was to assess and characterize patterns of circulating EVs in newly diagnosed CD patients. We enrolled consecutive adult anti-TTG positive, biopsy proven CD patients. Circulating EVs were identified untouched on whole blood samples by a no-lyse/no-wash method, combined with EVs volumetric count (FACSVerse, BD), based on a novel six-colour flow cytometry panel, in order to identify and enumerate both the total EV compartment and different EV subpopulations. Data are expressed as mean ± SD and statistical differences were evaluated by means of T-test.

Results: We evaluated 12 celiac adults (mean age 42.9 ± 19.1 vs. 40.8 ± 15.9 years, F/M = 4:1) at diagnosis and 12 age- and sex-matched healthy controls. Histology was considered positive for lesions of grade ≥B1 according to the Corazza-Villanacci classification. Mean anti-TTG levels at diagnosis were 6.9 ± 3.8 times U/L. Mean number of total circulating EVs was significantly higher in CD than in controls (59895 ± 14383 vs. 10018 EV/microL, p = 0.035). Subgroup analysis showed that EpCAM+ EVs, of epithelial origin, and CD41+ platelet-derived EVs were not significantly different between CD and controls (894 ± 1004 vs. 548 ± 1237 and 3052 ± 1563 vs. 1734 ± 1310 respectively, p = ns). On the contrary, CD45 + EVs, of leucocyte origin, showed a significantly higher number of EVs compared to controls (460 ± 492 vs. 119 ± 0.026).

Abstract No: P1923

Data on levels of ROS and oxidative damage biomarkers in sera of naïve patients (N-CD), coeliac patients on a gluten-free diet (GFD) including responders (CD-GFD) or non-responders (NRCD) to treatment.
Conclusion: Celiac disease patients at diagnosis show higher numbers of circulating T cells compared to age-matched controls. Phenotypical assessment suggests that this increase is not primarily driven by epithelial or endothelial damage. On the contrary, the increased numbers of leucocyte-derived EVs, suggest their potential implication in systemic signaling.

P1925 COELLIAC DISEASE AND REPRODUCTIVE DISORDERS: IS THERE ANY CORRELATION

H. Boutallaka1, I. Benelharghadi, F.Z. Ajana
Medecine C, Ibn Sina University Hospital, Rabat-Morocco

Contact E-mail Address: hanaeboutallaka@gmail.com

Introduction: The coeliac disease is an autoimmune enteropathy induced by the ingestion of gluten (Corn, barley, rye), that occurs in individuals who are genetically predisposed primarily affecting the small intestine inducing atrophic lesions, which are recessive with a gluten-free diet. The classic form is actually a minority of patients. The extraintestinal forms are currently the most found, with varied manifestations including reproductive disorders. The aim of our study is to evaluate the frequency of these disorders in the coeliac disease and their evolution under gluten-free diet.

Aims & Methods: It's a single-center, retrospective and descriptive study including 241 patients with coeliac disease enrolled within period of 17 years from 1995 to 2016 in the department of Gastroenterology « Medecine C » in Ibn Sina University Hospital.

Results: About 241 patients suffering from coeliac disease, 58 patients presented reproductive disorders, either 28.9%. Recruiting 53 women and 5 men, with a sex ratio M/F of 10.6. The mean age was 32.25years ranging from 13 to 59years old.

The diagnosis of coeliac disease was based on: Histology (severe or partial Villous atrophy with intraepithelial lymphocytosis exceeding 30%), the antienzymatic antibodies and/or antitransglutaminase antibodies positive. The reproductive disorders were never isolated but always associated with digestive or extraintestinal signs at the time of the diagnosis of coeliac disease. These disorders were sometimes resolved in 11 cases (19%), secondary amenorrhea in 13 cases (22.4%), Metrorrhagia in 12 cases (20.6%), absence of development of secondary sexual characters in 8 cases (12.5%), spontaneous abortion in 7 cases (10.9%), menometrorrhagia in 4 cases (13.8%), primary sterility in 5 cases (8.6%), precocious menopause in 6 cases (10.3%), premature labour and/or IUGR in 3 cases (5%), primary amenorrhea in 2 cases (3.4%), and intrauterine Fetal death IUFD in one case (1.7%). All our patients benefited from a gluten-free diet. 15 patients were excluded from the study, 2 patients died, and 12 patients did not follow-up. Of the patients who stayed, the evolution of the reproductive disorders under gluten-free diet was good in 26 cases (90%), with normalization of the cycles in 15 cases, the cycle was returned in 6 cases, development of secondary sexual characters in 2 cases, fertility was returned in other cases, the patient developed her cycle after primary amenorrhea, and one case was delivered a baby in term after a repeated premature delivery. The evolution was good in 3 cases as regard missed abortion four years after the gluten-free diet in 1 patient, and amenorrhea continued in 2 cases.

Conclusion: Reproductive disorders related to the coeliac disease were frequent and variable. In our study, these disorders well responded to the gluten-free diet in 90% of cases, and these disorders were reversible under gluten-free diet.

Introduction: Celiac disease (CD) is a chronic imune-mediated enteropathy that occurs in genetically predisposed individuals. The clinical phenotypes ranges from classical gastrointestinal manifestations to only atypical signs, thus making the clinical diagnosis a challenge. The aim of the study was to investigate the relationship between duodenal histology, specific antibody levels and clinical presentation in adult CD Romanian patients.

Aims & Methods: Diagnostic renal retrieval of information prospectively entered into a structured database including 81 adult patients diagnosed with CD hospitalized at the Institute of Gastroenterology and Hepatology, “St. Spiridon” Hospital, Iasi between January, 2012- December, 2016 admitted with symptoms of abdominal disturbances (diarrhea, heartburn, nausea, vomiting, regurgitation, abdominal pain). Demographic, clinical, serological, and histological characteristics of individuals with CD were reviewed.

Results: The study group included 81 adult patients with a female: male ratio of 3:1, 60(71.1%) female patients, mean age 40.02 ± 12.14 years. A total of 61% patients presented with gastrointestinal (GI) complaints and 51.9% of patients presented mostly with non-GI manifestations, and advanced age of symptom onset in the latter category (38yrs vs 47yrs).

Marb-Obverhuber classification was used to assess mucosal injury and Marsh 3c lesions were found in 25 (30.9%) cases. When assessing the serological parameters, IgA anti-tissue transglutaminase (IgA-tTG) antibody (61.45 ± 7.465 u/mL vs 162.02 ± 106.179 u/mL, P = 0.001) and IgA anti-gliadin antibodies (IgA-AGA) levels (61.83 ± 69.41 u/mL vs 77.15 ± 71.02 u/mL, P = 0.001) correlated with intestinal villous atrophy (Marsh 3a and 3c) in CD patients by Spearman rank correlation. Among symptoms, abdominal distention and diarrhea were associated with abnormal histology. Hemoglobin levels were evaluated and anemia was diagnosed in 61.7% patients among patients with elevated IgA-tTG levels (r = -0.316, P = 0.004), IgA-AGA (r = -0.301, P = 0.006) and Marsh 3b-c lesions (P = 0.0084). Among biological markers included in the statistical analysis, low iron levels (cut off 30mg/dl), hypocholesterolemia and low protein levels were associated with Marsh 3 b lesions (P = 0.008) and elevated IgA-IgA titers (r = -0.384; P = 0.001). Correlation between IgA-tTG and AGA levels correlate with duodenal villous atrophy in adult CD patients. An IgA-tTG iter > 160 was nearly always associated with severe histopathology. GI and non-GI symptoms are not reliable predictors of CD.

Introduction: Celiac disease (CD) is an immunologically-mediated enteropathy that triggered by the intake of gluten-containing foods in genetically predisposed individuals. It causes intestinal and extraintestinal manifestations. Extraintestinal findings are observed in many systems. The prevalence of extraintestinal findings in CD patients was about 18% (1). The impact of CD on the cardiovascular system of celiac disease is not clearly known and the correlation between them has not been yet obviously explained. There is also no data in the literature regarding the association of patent foramen ovale (PFO) and celiac disease, which is 10-25% common in the general population. We performed an echocardiography study to determine the frequency of accompanying cardiovascular findings in our patients with celiac disease. In this article, we aimed to share the frequency of the PFO detected in celiac patients with high results.

Aims & Methods: Between May-June 2015, 65 patients who applied to the gastroenterology clinic of Derince Education and Research Hospital and followed up with celiac disease were identified. The sociodemographic characteristics, celiac disease diagnosis duration, symptoms and complaints, accompanying diseases, drug use histories, hemogram and biochemical parameters of these patients were recorded. The patients underwent saline contrast transesophageal echocardiography in the cardiology clinic. Patients’ data were recorded. The obtained data were evaluated with appropriate statistical methods.

Results: Sixty-five celiac patients were included in the study, 21 (32.3%) male and 44 (67.7%) female. The mean age of the 29 patients who underwent transesophageal echocardiography study was 41.3 ± 14.1 years. PFO was detected in 39 (60%) of the patients. There was no difference in the incidence of PFO in between male and female patients. (61.9% and 59.1% respectively, p=0.829). Compared with the frequency of PFO in the general population, the incidence of PFO in celiac patients was higher. (25% and 66% p=0.006).

Conclusion: As a result, the incidence of PFO is more prevalent in celiac patients than in the general population. For this reason, the evaluation and treatment of the PFO, which may be the cause of cerebrovascular, cardiovascular or other disorders in clinical follow-up of patients, are required. In addition, the high incidence of PFO in celiac patients suggests that celiac disease is a factor affecting the development of patients from intrauterine period. Because our patients did not undergo transesophageal echocardiography, this rate may be less than real exist. For this reason, further evaluation is required with a wider patient group and by transesophageal echocardiography.

P1928 USEFULNESS OF BULB BIOSPY SAMPLES IN CELIAC DISEASE DIAGNOSIS IN ADULTS

D.V. Balaban1, A. Popp2, J. Taavela1, K. Laurila1, M. Mäki2, M. Jinga1
1Carol Davila University of Medicine and Pharmacy, Bucharest/Romania
2Center For Child Health Research, University of Tampere and Tampere University Hospital, Tampere/Finland

Contact E-mail Address: vbalaban@yahoo.com

Introduction: Celiac disease (CD) guidelines recommend sampling of both the bulb and distal duodenum for diagnostics. This has been reinforced by the recent data on ultra-short CD [1]. However, it has been previously shown in pediatric CD that bulb specimens are frequently of poor quality due to the fibrotic morphology in the duodenal bulb in non-celiac patients also, and it can lead to false-positive diagnoses [2]. Our aim was to address the same issue in adult CD, using the same validated morphometric methods [3].

Aims & Methods: We prospectively recruited cases of clinically recommended upper GI endoscopy; all patients also had signs and symptoms of CD and were checked for CD serology (serum tissue transglutaminase 2 antibodies and endomysial antibodies) and biopsy sampled according with current
recommendations. Paraffin embedded biopsy samples were assessed for villous height (VH)/crypt depth (CD) and VHC/D ratio. The corresponding frozen duodenal samples were assessed for duodenal IgA deposits targeting transglutaminase 2 (TG2-IgA), density of CD (cut-off 37 cells/mm epithelium) and γδ T cell receptor bearing intraepithelial lymphocytes (IELs) (cut-off 4.3 cells/mm epithelium). The study was approved by the Local Ethical Committee.

Results: Altogether 41 patients, mean age 45±14 years, 61% female, were recruited. Among these, 21 were finally diagnosed as adult CD (mean TG 156 U/l, mean CD 50% and crypt hyperplastic mucosal lesion in distal duodenum) and the rest 20 were non-CD controls (serum negative and normal on distal duodenal biopsy). All patients were on a gluten-containing diet. Quality of bulk biopsy samples was unsatisfactory and unreadable in 67% of CD cases and 50% of controls, even after reorientations and recuttings. All CD patients had, when measurable, VH:CrD < 2 in the anatomical bulb (average 0.31, range 0.02-0.61). On the other hand also non-CD controls had a crypt hyperplastic diseased bulb mucosa in 80% of patients (average VH:CD 1.65, range 0.7-4.1), but the injury was more severe in CD (p = 0.0006). Villous atrophy was significantly higher in CD compared to controls (CD3 81.87 vs. 34.05, p < 0.01; γδ IELs 129 vs. 6.44, p < 0.01). Bulb IgA deposits were positive in all CD patients and were able to discriminate CD cases from disease controls.

Conclusion: As reported in previous, bulk biopsy samples in adults are frequently of poor quality and not reliable for accurate histomorphological measurements. Also, interpretation of results from bulk samples should be done with caution, as non-CD patients may have mild injury in the bulb lining and could be misinterpreted as CD. Assessment of bulb TG2-IgA subepithelial deposits is a powerful tool to confirm CD.

3. Tavael J, Popp A, Vuthala H, Huhtala H. Ulcers are currently explored. In this setting, we evaluate Sintomax™, a POCT detecting deamidated gliadin peptide antibodies, with the goal to identify patients that need for duodenal biopsies prior to surgery. Thus, the goal was to establish a test allowing to guide the endoscopic decision to collect duodenal biopsies.

Aims & Methods: Prospective investigator-initiated multi-center study in six adult gastroscopy and two pediatric gastroscopy centers in Berlin and Brandenburg, Germany, approved by the local ethical committees. Finger prick blood of patients registered for gastroscopy and eligible for the study (exclusion: defective coagulation, established celiac disease or on gluten-free diet) was analyzed by the POCT (IgA and IgG for deamidated gliadin peptides; Sintomax™ test, Tillotts, Switzerland). Test results were compared with duodenal histology (Marsh classification). In POCT-positive individuals transglutaminase-IgA serology was performed.

Results: Analysis was performed on n=721 adult patients (average age: 48 yrs) and n=108 pediatric patients (average age: 11 yrs). In the adult cohort 45 POCT tests were judged as “positive”. Within the POCT positive, 6 Marsh III cases were detected. None of the 676 POCT-negative individuals revealed CD. Therefore, the prevalence of CD in this population was 0.8%. The POCT-specificity in this group was 94% (95%-CI 92–96%), the sensitivity was 100% (95%-CI 51–100%). In the pediatric cases 21 POCTs were judged as “positive” with 13 being true-positive. Of the 87 negative POCTs, 68 were true-negative, but 4 were false-negatives. Thus, the prevalence of CD in the pediatric gastroscopy was 16%. However, sensitivity in this group was only 76% (CI 50–93%) and specificity 91% (CI 83–96%). Examiners at various centers suggested, that “false” bands in the POCT analysis might contribute to interpretation failures.

Conclusion: A screening test-like a POCT in CD-needs to perform optimally especially in sensitivity. In the adult population all CDs were detected by the POCT. However, the CD prevalence in this group was low. In the pediatric group it was not revealed a critically low sensitivity, either due to a sensitivity problem with this serology in the pediatric population or secondary to a suboptimal IgA band expression of the POCT.

Contact E-mail Address: mebfitz@gmail.com

Introduction: Quality standards in coeliac disease management were recently published by the National Institute for Health and Care Excellence. These specify a new 6-week target for the time from referral to endoscopy, which was previously covered by the 18-week referral to treatment (RTT) pathway. They also state that all newly-diagnosed patients should discuss a gluten-free diet with a specialist dietitian. We retrospectively evaluated practice in the Oxford University Hospitals NHS Foundation Trust coeliac clinic against these criteria, and against national guidelines (duodenal bulb sampling at endoscopy and screening for nutritional deficiency).

Aims & Methods: The medical records of 110 patients referred to our clinic between September 2015 and September 2016 were examined. The date of referral and endoscopy were recorded, along with relevant demographic, clinical and laboratory data. Information were collected and analysed in Microsoft Excel.

Results: Eighty-five patients (68% female, median age 34) were seen with suspected or newly-diagnosed coeliac disease, of whom 76 (89%) were referred with positive coeliac serology and would be subject to the 6-week target. Six patients declined or delayed endoscopy, and endoscopy or referral information were not available for 4 patients. For the remaining 66 patients, median time from referral to endoscopy was 12 weeks (SD 37 days), with 59 patients (89%) within 18 weeks, but only 11 patients (17%) within 6 weeks (Figure 1). Duodenal bulb biopsies were taken at endoscopy in 31 patients (44%). A diagnosis of coeliac disease was made in 74 (87%) of all patients, referred, of whom 67 (90%) were referred to a specialist dietitian. Haematinics (iron studies, vitamin B12 and folate) were measured in 67 patients (90%), bone densitometry was measured in 51 patients (69%) and all patients were offered a follow-up appointment in the coeliac clinic. Iron deficiency was found in 31 patients (45%) of patients tested, folate deficiency in 12 patients (18%), vitamin B12 deficiency in 5 patients (8%), and vitamin D deficiency in 23 patients (38%). Osteoporosis was diagnosed in 5 patients (10%) and osteopenia in 10 patients (20%).

Conclusion: Appropriate dietitian referral, specialist follow-up and screening for nutritional deficiency and bone disease occur within the Oxford coeliac disease service. Compliance with recommended biopsy protocols was only 44%. Whilst most referrals met the previous 18-week RTT pathway, few would have met the new quality standards.

Introduction: We previously reported that small-bowel capsule endoscopy (CE) is effective in diagnosing small-bowel lesions with occult obscure gastrointestinal bleeding (OGIB) (Gastroenterol Res Pract. 2013). However, there is no consensus regarding the management of occult OGIB patients without bleeding source revealed by POCT.

Aims & Methods: We aimed to consider management of occult OGIB patients based on the long-term outcomes. A total of 357 consecutive occult OGIB patients (203 men; mean age: 59.7 years) who underwent CE at Hiroshima University Hospital before March 2016 and whose entire small-bowel could be observed and followed-up by CE for at least 12 months, were enrolled. We examined each patient to confirm the positive CE findings rate, the detection rate of bleeding source lesions, the details of bleeding source lesions, the overt
bleeding rate with or without treatment, the rate of anaemia exacerbation (hemoglobin ≤ 9.0 g/dL) 5 years overall survival rate (DSS). Occult OGB is defined as recurrent or persistent iron deficiency anaemia with or without a positive faecal occult blood test and no bleeding findings by esophagogastroduodenoscopy and colonoscopy.

Results: The positive CE findings rate was 44% (157/357) and the detection rate of bleeding source lesions was 27% (98/357). All of the treated bleeding source lesions (Group A) were as follows: angioectasia 61 patients (Yano-Yamamoto classification Type 1a 37 patients, Type 1b 24 patients), non-specific ulcer 15 patients (12 erosional, 3 erosional-ulcer), benign ulcer 18 patients, hemangioma 5 patients, Crohn’s disease 3 patients, primary cancer 2 patients, metastatic cancer 2 patients, gastrointestinal stromal tumour 2 patients, malignant lymphoma 2 patients, others 3 patients. Lesions that were not regarded as bleeding lesions without treatment (Group B) were as follows: angioectasia 25 patients (Type 1a without oozing 25 patients), erythema 31 patients, others 3 patients. There were no patients with overt bleeding in Group B. Although 6 patients (10%) had anaemia exacerbation in Group B (Type 1a), that were not a bleeding source lesion. On the other hand, in both Group A and Group B was 90%. DSS in Group A was 99% and in Group B 100%. One patient in Group A died of a primary small-bowel cancer.

Conclusion: Conclusion: Long-term outcomes with occult OGB patients were good except malignant tumor, because overt bleeding and/or anaemia exacerbation did not occur within the follow-up period. Thus, occult OGB patients without bleeding source lesions, including Type 1a angioectasia without oozing, and erythema, are unnecessary to follow-up with CE in occult OGB patients.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1932 A PILOT STUDY EXPLORING THE VALUE OF FAECAL IMMUNOCHEMICAL TEST (FIT) WHEN INVESTIGATING ANAEMIA OR OCCULT GASTROINTESTINAL BLEEDING WITH SMALL BOWEL CAPSULE ENDOSCOPY

D. Tighe1, C. Judge1, P. Walsh1, M. Kelly1, A. O’Connorn1, N. Breslin1, B. Ryan1, G. Borun2, D. Menamara2
1Department Of Gastroenterology Trinity Academic Gastroenterology Group (TAGG), AMNCH Tallaght, Dublin/Ireland
2Department Of Clinical Chemistry, AMNCH Tallaght, Dublin/Ireland

Contact E-mail Address: donal.tighe83@gmail.com

Introduction: Small bowel capsule endoscopy (SBCE) is a very useful method of investigating iron-deficient anaemia, or occult gastrointestinal (GI) bleeding. It can identify causes of anaemia or bleeding, such as angiodysplasia, small bowel Crohn’s disease, polyps, lymphoma, and malignant lesions. There is however a need to improve the diagnostic yield, particularly where resources and access to capsule endoscopy are restricted. Faecal immunochromatographic test (FIT) has an established role, in investigating large bowel bleeding, and is incorporated into a number of bowel cancer screening programmes.

Aims & Methods: The aim of our study was to investigate whether FIT could help predict likelihood of small bowel bleeding or other significant pathology at time of small bowel capsule endoscopy. This was a prospective pilot study, performed at our centre from September 2016-April 2017. Indications for enrolment were patients referred for SBCE with the indication of anaemia or occult GI bleeding. Baseline patient characteristics were obtained including age, gender, history of recent blood transfusion requirements and use of anti-platelet/anti-coagulants. Patient haemoglobin (Hb) level was checked on the day of SBCE where possible. Patients were asked to return one completed FIT for further analysis. A cut of 50 ng/ml was chosen as this is the standard cut-off used, in the Irish National Bowel Cancer Screening programme.

Results: A total of 40 patients were enrolled, mean age 55.4 years (range 18-77), 64% were female. A total of 27.6% of patients were on anti-platelet agents or anti-coagulants. 34% of patients had a blood transfusion within the last year. Mean Hb for the cohort was 12.8 g/dL (range 7.8-15.9 g/dL). The average FIT reading was 459 ng/ml (range 0-4426 ng/ml). 30% of patients had a FIT level >50 ng/ml. 46% of patients, had positive findings at SBCE. 9/12 (75%) of patients with a FIT level >50 ng/ml had positive findings at capsule endoscopy; compared to 5/28 (17.8%) for FIT ≤50 ng/ml. p value was 0.002, 95% C.I. 0.29-0.86 O.R. 0.16. These included 4/12 (33%) new cases of Crohns, 3/12 (25%) angiodysplasia, 3/12 (33%) non-BHD enteritis, 1/12 (16.7%) small bowel tumour and 1/12 (16.7%) melena, with no clear source. In addition there was a good correlation between FIT and Haemoglobin levels. 60% of patients with FIT >50 ng/ml were anaemic (Hb <11.5 g/dL), compared to 17% with FIT <50ng/ml, p value was 0.02 95% C.I. 0.09-0.76 O.R. 0.14. Combining Hb and FIT levels, was also informative and predictive of small bowel pathology. 83% of patients, who were anaemic and had a FIT >50 ng/ml had clinically significant findings at SBCE compared to 21% pick up rate in patients with normal Hb and FIT levels, p value was 0.05 95% C.I. 0.22-1.03 O.R. 0.05. Overall the sensitivity for a FIT >50 ng/ml for detecting small bowel pathology was 83% with a specificity of 92%, giving a positive predictive value of 83.3% (95% C.I. 56%-95%). Antiplatelet use was not predictive of a positive FIT as, 16.7% of patients with a FIT >50 ng/ml were on anti-platelet agents, compared to 83.3% who weren’t.

Conclusion: FIT is useful at predicting clinically significant small bowel pathology at the time of capsule endoscopy. It may help better identify and prioritise patients who would best benefit from referral.

Disclosure of Interest: All authors have declared no conflicts of interest.

Aims & Methods: Our aim in this study is to examine the prevalence of the different manifestations portal hypertensive enteropathy and it’s correlation with the Child-Pugh score (CTP) in cirrhosis using video capsule endoscopy (VCE). At a single center, we performed a retrospective chart review study of patients between the age of 18 and 80 with cirrhosis, who had VCE study between January 2010 and January 2016. Based on the published literature we divided the portal hypertensive enteropathy lesions in our study into vascular lesions (arteriovenous malformation (AVM), red spots, bleeding or varices) and mucosal lesions (mild inflammatory changes or severe inflammatory changes which are a mosaic, congested and friable mucosa).

Results: 100 patients with cirrhosis had a VCE study. The mean age was 62.82 years. Male gender was predominant with a 64%, while the Caucasians represented 82% of the cohort. The most common etiologies of the cirrhosis were chronic alcohol abuse followed by chronic hepatitis C virus (HCV) and non-alcoholic steatohepatitis (NASH). 8 patients had negative EGD exam for any active bleeding, esophageal varices (EV), portal hypertensive gastropathy (PHG) or gastric varices (GV). 31 of them (60%) had features of portal hypertensive enteropathy in their VCE. 1B. 45 patients had negative EGD exam for any active bleeding, esophageal varices (EV), portal hypertensive gastropathy (PHG) or gastric varices (GV). 31 of them (60%) had features of portal hypertensive enteropathy in their VCE. 1B.

**Introduction:** There are very few reports about long-term outcomes in patients with negative balloon assisted enteroscopy for suspected overt small bowel bleeding (obscure-over gastrointestinal bleeding).

**Aims & Methods:** The aim of this study is to evaluate long-term outcomes and risk factors of re-bleeding after negative double balloon enteroscopy (DBE) for suspected overt small bowel bleeding. We investigated 297 patients undergoing DBE for suspected overt small bowel bleeding between December 2004 and April 2016 at Sendai Kouei Hospital. Prospectively collected data were reviewed, and 83 patients (27.9%) showed negative results in the first antegrade and/or retrograde DBE.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Conclusion:** Enteric-coated aspirin, clopidogrel, and loxoprofen were identified as risk factors causing overt SBB during a relatively short period after administration.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy (CE) is a useful and noninvasive modality for investigation of the small intestine, and currently, it has become the first-line method of choice for the diagnosis of obscure gastrointestinal bleeding (OGBB). Use of antithrombotic agents including antiplatelets and anticoagulants is associated with gastrointestinal bleeding. Antithrombotic users account for a large portion of patients with OGBB, and those with OGBB often undergo CE. It should be noted that some patient with over OGBB discontinue antithrombotic agents at the time of CE, which may affect endoscopic findings.

Aims & Methods: To examine the effect of discontinuation of antithrombotic agents on the diagnostic yield of CE, and to assess the predictive factors associated with positive CE findings in patients using antithrombotics who develop overt OGBB. Between March 2004 and December 2015, 130 consecutive patients (75 male; mean age, 71.9 years) taking antithrombotics who underwent CE for overt OGBB were enrolled, whereas patients who underwent double-balloon endoscopy prior to CE were excluded. Findings were considered positive if the observed lesions could explain the bleeding, while findings including isolated red spots and a single small polypl were considered negative. The primary endpoint was the difference in the rate of positive CE findings between patients who continued or discontinued antithrombotic agents. Furthermore, a propensity score analysis was performed to reduce the effects of bias in potential confounding factors. The secondary endpoint was to assess the predictive factors for the positive CE findings by using multiple logistic regressions.

Results: Of the 73 patients who continued antithrombotic agents, 36 (49.3%) patients had positive findings in the small intestine (ulcer/erosion [n = 24], angioectasia [n = 7], tumor [n = 4], and blood pooling [n = 1]). While of the 57 patients who discontinued these agents, 35 (61.4%) patients had positive findings (ulcer/erosion [n = 17], angioectasia [n = 11], tumor [n = 3], and blood pooling [n = 4]). The rates of positive CE finding did not differ between the two groups. Even after propensity score matching, discontinuation of antithrombotic agents did not affect the rate of positive CE finding. In multivariate analysis, the lowest hemoglobin level before CE examination was an independent predictive factor associated with positive CE findings. The odds ratio per 1 g/dL increase in the lowest hemoglobin level was 0.85 (95% confidence interval, 0.71–0.98). However, other factors, including sex, age, and discontinuation of antithrombotic agents, were not associated with positive CE findings.

Conclusion: Discontinuation of antithrombotic agents did not affect the diagnostic yield of CE with overt OGBB, and lowest hemoglobin level was associated with positive CE findings.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1938 EFFICACY OF REBAMIPIDE TO PREVENT LOW-DOSE ASPIRIN-INDUCED SMALL INTESTINAL INJURY

S. S. Ylov

Gastroenterology, Peoples Friendship University of Russia, Moscow/Russian Federation

Contact E-mail Address: sivlov@mail.ru

Introduction: Long-term use of low-dose aspirin (LDA) is associated with development of peptic ulcers, gastrointestinal bleeding, enteropathy. For prevention of LDAs and minor intestinal mucosal injuries, presently the first-line therapy according to several guidelines. However, gastric acid suppressants, like PPI, do not prevent small intestinal mucosal injury. The recent clinical trials showed that rebamipide stimulates the production of prostaglandins, thereby preventing mucosal injury. This could improve mucosal breaks in small intestine in patients receive LDA.

Aims & Methods: We aimed to investigate the protective role and efficacy of rebamipide for prevention low-dose aspirin-induced small intestinal mucosal injury and enteropathy. Subjects comprised patients undergoing longlife low-dose aspirin therapy prescribed by cardiologist. Patients with a high-risk of gastrointestinal bleeding were excluded. This trial was performed as a randomised open-labelled clinical study with the permission of an institutional review board. The trial was included 100 patients (50 cases in each group) received gastro-coated low-dose aspirin 100 mg. The Group PPI received LDA plus pantoprazole 40 mg, the Group RBD received plus rebamipide 300 mg. Before starting therapy, we checked the background characteristics of each patient (H pylori, use of LDA, NSAID, bismuth, PPI, and endoscopic findings). Gastroduodenoscopy and capsule endoscopy were performed, and the fecal occult blood reaction and faecal calprotectin levels were measured before, two and four weeks after drug administration. After the therapy, we asked physicians and patients about medication compliance and side effects. Capsule endoscopy was then repeated. The primary endpoint was the change in the number of mucosal breaks from baseline to 4 weeks. The secondary endpoints were the rates of side effects.

Results: The fecal calprotectin levels significantly increased in Group PPI, they did not increase in Group RBD. The number of small intestinal mucosal injuries by capsule endoscopy in Group PPI increased significantly up to 3.9 after 4 weeks of LDA treatment. There was not detected new small intestinal injuries in Group RBD. Stomach ulcer, bleeding or stenosis were not found in any subject. There were no significant differences in the presence of fecal occult blood in both groups. There were no significant side effects in Group RBD.

Conclusion: In conclusion, rebamipide is effective and sufficient for preventing mucosal injury of the small intestine induced by low-dose aspirin. These results show the gastroprotective and enteroprotective effects of rebamipide, suggesting that it may be a good choice in low-dose aspirin users with gastrointestinal toxicity that is not suppressed by acid suppressants alone.

Disclosure of Interest: All authors have declared no conflicts of interest.

Introduction: Capsule endoscopy allows high-quality imaging of the small bowel. Newer capsule with a panoramic viewing mode is available and might increase the detection rate of bleeding lesions in patients with obscure gastrointestinal bleeding. Furthermore, an improved patient acceptance rate is expected.

Aims & Methods: In a randomized prospective comparative multi-center study, patients with obscure gastrointestinal bleeding were included and examined with Capsocam SV-1 or with PillCam SB 3. Discriminant analysis of bleeding lesions, transit and evaluation time and adverse events were evaluated. Physicians were interviewed about their experience with both capsules and the evaluation software. A detailed subject questionnaire analyzed acceptance of each capsule system. Three months after initial capsule endoscopy follow-up procedures were documented.

Results: One hundred eighty-one patients with obscure gastrointestinal bleeding were recruited into the study. After exclusion of 28 patients 153 patients were randomized and Capsocam SV-1 (n = 78) or PillCam SB 3 (n = 75) was administered. Capsocam SV-1 detected more cases of bleeding (31/79, diagnostic yield 39.7%) compared to PillCam SB 3 (26/75, diagnostic yield 34.6%, n.s.). Transit time of both capsules was not different. Evaluation time with PillCam SB
3 was superior to CapsoCam SV-1 (27 min. vs. 40 min, p = 0.01). 95% of the physicians were satisfied with each capsule system and evaluation software. The acceptance rate of the patients to retrieve the CapsoCam SV-1 was high. Adverse events/SAEs were 17.9%/1.3% with CapsoCam SV-1 and 16%/0.0% with PillCam SB 3. Re-bleeding rate was 28.75% within 3 months.

**Conclusion:** Both capsules allow high-quality imaging of the small bowel. CapsoCam SV-1 detected more lesions, however, relevant bleeding sources were visualized by both capsules. Physician's satisfaction was high with both capsule systems and evaluation software. Patient's acceptance with CapsoCam SV-1 was unexpectedly high. SAEs were 0% with PillCam SB 3 and 1.3% with CapsoCam SV-1.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**PI940 VALIDATION OF A SCORE CHART TO PREDICT THE RISK OF CHRONIC MESENTERIC ISCHEMIA: A DISCRIMINATIVE AND USEFUL TOOL IN CLINICAL DECISION-MAKING**

**Introduction:** Chronic mesenteric ischemia (CMI) is the result of insufficient mucosal perfusion of the gastrointestinal tract, mostly caused by atherosclerotic stenosis of the mesenteric arteries. Other causes of CMI are vasculitis, median arcuate ligament syndrome or non-occlusive ischemia (NOMI) due to decreased cardiac output or hypoxia-oxygenation. The diagnosis of CMI remains challenging as chronic abdominal pain is common and mesenteric artery stenoses are frequently observed in the general population but not necessarily related. Harki et al.(1) designed a score chart to predict the risk of CMI based on a cohort of CMI suspected patients. This score chart consists of patient characteristics (female 1 pt, weight loss 1 pt, cardio-vascular disease 1 pt) and radiologic evaluation (50–70% celiac artery (CA) stenosis 1 pt, > 70% CA stenosis 4 pts, 50–70% superior mesenteric artery (SMA) stenosis 1 pt and > 70% SMA stenosis 3 pts). A total score of 0–2 pts predicts an absolute risk of CMI of 0–21%, 3–6 pts a 22–46% risk and ≥ 7 pts a risk of ≥ 79%. We aimed to validate this prediction model in a prospective large multicenter patient cohort.

**Aims & Methods:** Patients suspected of CMI referred to two Dutch specialized CMI referral centers were included consecutively from January 2014 to August 2016. After diagnostic work-up of medical history taking, mesenteric CT-angiography and/or conventional catheter angiography, and a functional test examination, imaging of the gastrointestinal arteries with either CT- or MR-angiography was performed. A definitive diagnosis of CMI was made if successful treatment resulted in durable symptom relief. The score chart to predict the risk of CMI was computed for each patient.

**Results:** A total of 246 patients were included and consensus diagnosis of CMI was made in 108 (44%) patients, which resulted in 96 (39%) patients with a definitive diagnosis of CMI after a positive response therapy. A definitive diagnosis of CMI was made if successful treatment resulted in durable symptom relief. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient.

**Conclusion:** The score chart for CMI based on patient characteristics and anatomy is a reliable tool to discriminate the risk of CMI and useful for clinical decision-making, for example to adopt a wait-and-see policy in patients with a low risk and immediate vascular intervention in patients with high risk of CMI.

**Disclosure of Interest:** All authors have declared no conflicts of interest.

**Contact E-mail Address:** l.vandijk@erasmusmc.nl

**Introduction:** Isolated stenosis of the celiac artery (CA) or the superior mesenteric artery (SMA) is frequently detected in patients with abdominal complaints. These patients may suffer from chronic mesenteric ischemia (CMI) causing nonspecific abdominal complaints as postprandial pain, nausea or diarrhea. However, the existence of single atherosclerotic mesenteric ischemia is a topic of continuous clinical debate and reports on the effectiveness of single mesenteric artery revascularization are scarce. We evaluated the long-term clinical success rates for single CA or SMA revascularization in patients with gastrointestinal symptoms and confirmed mesenteric ischemia.

**Aims & Methods:** Data were collected from all 97 consecutive patients with gastrointestinal symptoms and a single mesenteric artery stenosis referred to the outpatient clinic of our tertiary care institution for analysis of CMI between January 2006 and October 2010. All patients underwent a standardized diagnostic work-up for CMI at baseline consisting of medical history taking and physical examination, imaging of the gastrointestinal arteries with either CT- or MR-angiography and/or conventional catheter angiography, and a functional test for detecting mucosal ischemia using either tonometry or visible light spectroscopy. All cases were discussed in a multidisciplinary meeting attended by a vascular surgeon, interventional radiologist and gastroenterologist, all specialized in CMI, leading to an expert based consensus diagnosis. Patients with consensus diagnosis of CMI underwent surgical or endovascular revascularization. The primary outcome was clinical response to revascularization, defined as relief of presenting symptoms as experienced by the patient.

**Results:** Consensus diagnosis of CMI was obtained in 62/97 patients and all consensus patients were revascularized. Isolated CA stenosis was present in 55/ 62 patients (89%) (31 vascular disease; 24 median arcuate ligament syndrome, MALS) and isolated atherosclerotic SMA stenosis in 7 patients. After a mean follow-up of 5.5 ± 3.0 years, 42/62 patients (68%) experienced sustained symptom relief. Responders to revascularization had a BMI increase during follow-up in contrast to the non-responders (+0.43 ± 2.5 versus −1.06 ± 2.4 kg/m², p = 0.033). Response to revascularization was not related to lesion localization (CA 67% versus SMA 71%, p = 0.825) or lesion etiology (MALS 63% versus vascular disease 71%, p = 0.483).

**Disclosure of Interest:** All authors have declared no conflicts of interest.

To summarize, the validation of a score chart for predicting the risk of CMI was performed. The score chart was shown to be discriminative and useful in clinical decision-making. The long-term clinical success rates for single CA or SMA revascularization were evaluated, showing sustained symptom relief in 68% of patients. Further research is needed to confirm these findings in a larger patient cohort.
CA = celiac artery; SMA = superior mesenteric artery; MALS = median arcuate ligament syndrome

<table>

Conclusion: Revascularization of the CA or SMA provides long-term symptom relief in 68% of patients with chronic gastrointestinal symptoms and confirmed mucosal ischemia due to single mesenteric artery stenosis. This provides the opportunity to help patients with otherwise unexplained, refractory abdominal complaints.

PI9142 UNDERUTILIZATION OF ENDOSCOPIC ARGON PLASMA COAGULATION FOR TREATMENT OF BLEEDING GASTROINTESTINAL ANGIODYPLASIAS: AN INTERNATIONAL MULTICENTRE COHORT STUDY
K. Groote1, M. Mattheussen1, G. Hollera, E. Van Geenen1, D. Meerman2, L. A. De Schauwer3, D. McNamara2, J. P. h. Drenth1
1Gastroenterology And Hepatology, Radboudumc, Netherlands, Nijmegen/Netherlands
2Department of Clinical Medicine, Trinity College, Dublin/Ireland

Contact E-mail Address: karina.groote@gmail.com

Introduction: Endoscopic argon plasma coagulation (APC) is the first-line treatment in patients with iron deficiency anaemia or overt bleeding resulting from gastrointestinal angiodyplasias. In the minority of patients active bleeding angiodyplasias are seen during endoscopy, but in contrast non-bleeding angiodyplasias can be an incidental finding. This can make the decision whether to treat endoscopically detected angiodyplasias with APC difficult.

Aims & Methods: The aim of this study is to investigate the need for repeat endoscopies with APC in patients with angiodyplasias who were left untreated during the index endoscopy performed for iron deficiency anaemia or overt bleeding. We initiated an international, multicentre cohort study to collect clinical, laboratory and endoscopic data from angiodyplasia patients. Cases were identified through a systematic search in endoscopy reports from 2010–2015 with follow-up until July 2016. Inclusion criteria was endoscopic detection of angiodyplasia in the context of overt bleeding or iron deficiency anaemia. Exclusion criteria were other vascular anomalies and angiodyplasias as incidental finding. The primary outcome was repeat endoscopy with APC.

Results: A total of 197 patients with proven angiodyplasia as cause for anaemia or bleeding were included (mean age 68 years; 58% male). Median follow-up was 37 months (range 18–57). In 52% of the cases (n=103) APC treatment for bleeding angiodyplasia(s) was performed at the index endoscopy. Repeat endoscopy with APC was necessary in 17 patients (18%) in whom angiodyplasias were detected but left untreated during the index endoscopy. Median time between index and repeat endoscopy was 21 weeks. A total of 48 patients (51%) who received a purely diagnostic index endoscopy were in need of other treatment modalities (e.g. iron supplementation, blood transfusion, stop anti- coaguulants). Anaemia and/or overt bleeding resolved spontaneously in 24 patients (26%).

Conclusion: A substantial proportion of patients with clinical symptomatic angiodyplasia bleeding do not receive APC at the index endoscopy and continue to be dependent on iron supplementation, blood transfusion or undergo repeat endoscopy with APC.

Disclosure of Interest: All authors have declared no conflicts of interest.

PI9143 DIGESTIVE INVOLVEMENT IN SYSTEMIC DISEASES: A UNIVERSITY HOSPITAL EXPERIENCE
W. Khannoussi1, K. Chhit2, H. Bachir2, G. Krassas1, A. El Meekoua1, S. Hamza2, H. B. Alaoui3, K. Serraj2, Z. Ismaili3, W. Khannoussi

3Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal

Contact E-mail Address: wkhannoussi@yahoo.com

Introduction: Digestive manifestations in systemic diseases including vasculitis and granulomatosis is broad and can affect any segment of the digestive tract and related organs. The clinical symptoms are not specific and it can be challenging for diagnosis. The other difficulty remains the interference of digestive side effects of medication used.

Aims & Methods: We aimed to review various digestive manifestations of systemic diseases. This was a retrospective study from Feb 2009 to Sep 2016 in internal medicine and gastroenterology departments. The exclusion criteria was incomplete data concerning the diagnosis of the systemic disease.

Results: We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 ± 11.3 years. The mean BMI before surgery was 41.6 ± kg/m². There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before

Patients symptoms and clinical findings were: Abdominal pain in 32 cases (22.9%), nausea and vomiting in 7 cases (5%), stool modification 15 cases (10.75%), jaundice in 4 cases (2.95%), dysphagia in cases (71%), hematemesis in 4 cases (2.95%), splenomegaly in 8 cases (5.7%), ascitis in 13 cases (9.3%), digestive bleeding 17 cases (12.1%). Laboratory findings: elevated liver enzymes in 18 cases (15.9%), alkaline phosphatase elevation 15 cases (19.2%). Radiological findings: 17 ascitis (14.4%), 12 digestive thickening (10.16%), 6 hematomas (5.08%), 14 splenomegaly (11.86%), 2 portal cavernoma (1.6%), 3 portal thrombosis (2.5%), 4 esophageal distention (3.4%), acalculus cholecystitis in 2 cases (1.6%), portal hypertension (1.6%), steatosis in 3 cases (2.5%), 3 hepatic angioma (2.5%), acute pancreatitis in 2 cases (1.6%), 2 mesenteric ischemia (1.6%), 1 biliud chARR (0.8%), 1 hepatic carcinoma (1.8%). Upper gastrointestinal Endoscopy findings: hiatus hernia in cases (8%), esophagitis in 11 cases (11%), esophageal varices in 2 cases (5.7%), Gastritis in 18 cases (15.9%), diathesis in cases 16 cases, ulcers in cases (8.6%), 4 celiac disease (11.42%). Lower GI endoscopy: Crohn’s disease in 1 case (8.3%), ulcerative colitis in 1 case (8.3%), 1 hyperplastic polyps (6.3%), 2 colitis (16.6%). Esophageal manometry: motility disorder in 4 cases. The most used drugs were immunosuppressive drugs, steroids and hydrochloroquine, all causing digestive side effects mainly abdominal pain.

Conclusion: The digestive involvement is around 10% of cases in the most represented systemic diseases, the main symptom is abdominal pain probably related to medication, but endoscopic modifications are mainly non specific but we found some association with celiac disease and IBD. Liver involvement was noticed in 15% of cases.

Disclosure of Interest: All authors have declared no conflicts of interest.

WEDNESDAY, NOVEMBER 01, 201709:00-14:00 NUTRITION III - HALL 7

PI9144 CHANGES IN LEVELS OF VITAMIN D IN OBESE PATIENTS SUBMITTED TO BARIATRIC SURGERY
A. Vaz1, R. Guerreiro2, S. Sousa1, P. Queirós3, T. Gago1, J. Roseira1, H. Guerreiro3
1Gastroenterology, Centro Hospitalar do Algarve, Faro/Portugal
2Clinical Pathology, Centro Hospitalar do Algarve, Faro/Portugal
3Gastroenterology, Centro Hospitalar do Algarve, Portimón/Portugal

Contact E-mail Address: anam.vaz@hotmail.com

Introduction: An association between obesity and vitamin D deficiency has been reported in several studies. This may be explained, among other things by the sequestration of the fat-soluble vitamin D in the adipose tissue. Bariatric surgery, including Roux-en-Y gastric bypass (RYGB) is an effective treatment for more extreme cases of obesity, promoting significant weight loss and consequently reduction in some obesity-related health problems. However, the problem of vitamin D deficiency doesn’t seem to be solved after RYGB and can even be exacerbated by the changes in digestion and absorption of this nutrient after the surgery.

Aims & Methods: The aim of this study was to analyze the prevalence of vitamin D deficiency (VDD) and vitamin D insufficiency (VDI) in a population of obese patients, before and after being submitted to RYGB. We included patients patients selected to undergo RYGB for obesity. We measured anthropometric values and the levels of 25-hydroxy-vitamin D (25[OH]D) before and 1 year after the procedure. VDD was defined as serum 25(OH)D <20ng/mL and VDI as serum 25(OH)D concentrations between 20-30ng/mL. Levels of 25(OH) D >30ng/mL were considered normal.

Results: We included 39 patients. Thirty-two were females (82.1%) and the mean age was 43.6 ± 11.3 years. The mean BMI before surgery was 41.6 ± kg/m². There was a significant decrease in BMI after surgery and, on average, the mean total body weight loss was 34% and the mean excess BMI loss was 90%. Before
bariatric surgery, 52.3% of patients had VDD and 36.8% had VDI. After sur-
gery, the number of VDD increased to 71.1% (p < 0.0079). The mean levels of
25(OH)D decreased significantly from 19.8 ng/mL before surgery to 16.6 ng/mL
after surgery (p < 0.05). There was no correlation between the amount of weight
loss and the changes in the levels of 25(OH)D in our study.

Conclusion: There is a high prevalence of vitamin D deficiency in obese
patients eligible for bariatric surgery. The level of deficiency tends to increase after
RYGB. This population of patients should, therefore, be offered an adequate
level of vitamin D supplementation, especially after the procedure.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1946 INTRAGASTRIC BALLOON: A CRITICAL VIEW IN NON ELECTIVE BARIATRIC SURGERY PATIENTS
R.J.F. Fernandez1, E. Usuy2, C.F. Diestel3, S. Barrichello3, A. F. Teixeira1, M. Galvao Neto3

Contact E-mail Address: ricfittipaldi@hotmail.com

Introduction: Bariatric surgery is established as an excellent therapy for obesity.
However, lower degrees of weight loss without surgical indication also impact on
patients’ health and quality of life, and the intragastric balloon (IGB) may be a
treatment option.

Aims & Methods: We aimed to assess the efficacy of excess weight treatment with
an IGB in patients with overweight and grade I obesity at EndogastroRio Clinic. A
total of 717 patients were analyzed. A liquid filled IGB was used. The patients
had initial body mass index (BMI) between 27 and 34.9 kg/m². The level of
significance was set at p < 0.05.

Results: 615 patients were women. 131 patients had overweight and 586
had grade I obesity. Mean age was 37.97 years (17–75). Weight loss results and
thyroid treatment success rates are shown on table 1. Percent excess weight loss (%EWL)
was higher in overweight group (p < 0.0001) and percent total body weight loss (%TBWL)
was higher in the grade I obesity group (p < 0.0009). 96 (73.28%) overweight patients and 132
(22.52%) grade I obesity patients reached a normal
BMI(<25 kg/m²).

Conclusion: Endoscopic treatment of obesity with an IGB shows to be an excel-
alent therapeutic option to non elective patients for bariatric surgery according to
BMI criteria.

Disclosure of Interest: M. Galvao Neto: I declare that I have received personal

P1947 SPATZ3® ADJUSTABLE INTRAGASTRIC BALLOON TREATMENT: A BRAZILIAN MULTICENTRIC EXPERIENCE
R.J.F. Fernandez1, C.F. Diestel3, M. Galvao Neto3, A. F. Teixeira1, E. Usuy2, S. Barrichello3
1Dept. Of Bariatric Endoscopy, Endogastro Rio, Rio de Janeiro/Brazil
2Bariatric Endoscopy, Gastro Obeso Center, Sao Paulo/Brazil
3Dept. Of Gastroenterology, Usuy Clinic, Florianopolis/Brazil

Contact E-mail Address: ricfittipaldi@hotmail.com

Introduction: Intragastric balloons (IGB) are already used worldwide in the treat-
ment of overweight and obesity, with established success. The Spatz3® adjustable
balloon brings the possibility of balloon volume control during all the
intervention, possibly reducing the risk of early removals due to intolerance and
greater weight loss when compared to traditional IGBs.

Aims & Methods: We aimed to analyze the initial 25 months results regarding
weight loss and complications with Spatz3® adjustable intragastic balloon in Brazil. In this
retrospective longitudinal study were included patients submitted to Spatz3® adjustable IGB treatment between October 2014 to April 2017 in four
private clinics in Brazil. The IGB Spatz3® was filled with a standard volume of
600 ml that was downward or upward adjusted when necessary. The patients
presented a minimum body mass index (BMI) of 27 kg/m². Were analyzed the
complications of Spatz3® treatment and BMI reduction, percent total body
weight loss (%TBWL) and percent excess weight loss (%EWL).

Results: 422 patients underwent implant Spatz3® balloon in the period. The
complications (14.28%) at the present study were: early balloon removal
(6.89%), gastric ulcer (3.94%), spontaneous deflation (1.48%), gas production
inside the balloon (0.98%), gastric perforation (0.23%) and Malory Weiss Syndrome (0.23%).
There was no death at the present study. Twenty-eight patients underwent downward adjustment due to intolerance (mean volume
reduction: 162.86 mL) and all of then kept in the treatment (no early removals).
190 patients have completed the treatment (minimum 9 months of gastric balloon
stay). The BMI decreased from 37.69 to 31.51 kg/m² (p < 0.0001), body weight
diminshed from 107.67 to 90.16 kg (p < 0.0001) and excess weight dimished from
36.79 to 19.27 kg (p < 0.0001). Eighty-six patients underwent upward adjust-
ment, the adjustment resulted in a further mean weight loss of 4.2 kg (9 to
20 kg), the range of upward volume was 281.73 to 66.58 mL (100–420 mL)
and the moment of the procedure was 7.06 ± 1.64 months. The group of patients that did
the upward adjustment didn’t have a higher %TBWL, %EWL or a higher BMI
reduction, when compared to the group that did not (p = 0.4413, p = 0.9245,
0.2729 respectively).

Introduction: Intragastric balloons (IGB) are already used worldwide in the treat-
ment of overweight and obesity, with established success. The Spatz3® adjustable
balloon brings the possibility of balloon volume control during all the
intervention, possibly reducing the risk of early removals due to intolerance and
greater weight loss when compared to traditional IGBs.

Aims & Methods: We aimed to analyze the initial 25 months results regarding
weight loss and complications with Spatz3® adjustable intragastic balloon in Brazil. In this
retrospective longitudinal study were included patients submitted to Spatz3® adjustable IGB treatment between October 2014 to April 2017 in four
private clinics in Brazil. The IGB Spatz3® was filled with a standard volume of
600 ml that was downward or upward adjusted when necessary. The patients
presented a minimum body mass index (BMI) of 27 kg/m². Were analyzed the
complications of Spatz3® treatment and BMI reduction, percent total body
weight loss (%TBWL) and percent excess weight loss (%EWL).

Results: 422 patients underwent implant Spatz3® balloon in the period. The
complications (14.28%) at the present study were: early balloon removal
(6.89%), gastric ulcer (3.94%), spontaneous deflation (1.48%), gas production
inside the balloon (0.98%), gastric perforation (0.23%) and Malory Weiss Syndrome (0.23%).
There was no death at the present study. Twenty-eight patients underwent downward adjustment due to intolerance (mean volume
reduction: 162.86 mL) and all of then kept in the treatment (no early removals).
190 patients have completed the treatment (minimum 9 months of gastric balloon
stay). The BMI decreased from 37.69 to 31.51 kg/m² (p < 0.0001), body weight
diminshed from 107.67 to 90.16 kg (p < 0.0001) and excess weight dimished from
36.79 to 19.27 kg (p < 0.0001). Eighty-six patients underwent upward adjust-
ment, the adjustment resulted in a further mean weight loss of 4.2 kg (9 to
20 kg), the range of upward volume was 281.73 to 66.58 mL (100–420 mL)
and the moment of the procedure was 7.06 ± 1.64 months. The group of patients that did
the upward adjustment didn’t have a higher %TBWL, %EWL or a higher BMI
reduction, when compared to the group that did not (p = 0.4413, p = 0.9245,
0.2729 respectively).

Conclusion: This study shows that Spatz3® IGB treatment is an effective proce-
dure for weight reduction, without mortality but with higher morbidity rates
when compared to traditional IGBs. Even more, the downward adjustment
treatment seems more effective in preventing the early balloon removal. Although the
upward adjustment does not show to be able in providing a greater weight loss.

Introduction: The endoscopic treatment of obesity and over weight with intragastric balloon (IGB), is a safe and effective option. Nausea and Vomiting are the most common side effects after IGB implant.

According to A. Scudiero Sanches, 71.1% of patients experience nausea and 57.9% have vomiting; in a systematic review with more than 3000 patients showed that nausea and vomiting are the fifth leading cause of early explantation. The reported symptoms are more common in first days post implant.

Regarded as one of the major causes of gastric balloon early removal, is important to evaluate in daily practice the frequency of patients requiring intravenous hydration to quell nausea and vomiting during the first day of the accessory use.

Aims & Methods: Evaluation of Frequency of vomiting and number of patients requiring intravenous hydration (HEV) after gastric balloon placement. This was a retrospective analysis of medical records of 340 obese and over weight patients treated with intragastric balloon, between November 2013 to December 2016 in the endoscopy service of the Division of the Endoscopy Hospital in São Paulo.

The implant was performed by 3 endoscopists with experience in bariatric endoscopy, all procedure were performed under moderate sedation and anesthetist’s care. The patients used ondansetron 40 mg once a day, and antiemetic drugs (dimenhydrinate 50mg) 8 to 9 times per day. Approximately 9.48% of the patients required intravenous hydration after gastric balloon placement.

Results: There were 340 patients treated with intragastric balloon between 2015 and 2016. The present study showed 74.41% vomiting until the third day after placement of the IGB, and it is in accordance with literature. Those 252 patients who had vomiting, 67.38% presents frequency of 0 to 5 times per day and 32.42% of the group 5 to 10 times per day. Approximately 7.48% of the patients required intravenous hydration and there were no early explant.

Conclusion: Gastric balloon causes vomiting in the early days post implant in 74.41% of patients and cause dehydration requiring Intravenous fluid therapy in 9.48%. We also recorded were about the numbers and frequency of vomiting and if there was need for intravenous hydration during the first three days after intragastric balloon implant.

Patients’ body mass distribution had a clear improvement, with a significant reduction of the basal metabolic rate of 1893.24 to 1694.67 was noted. Endoscopic approach with gastric balloon provides a significant weight loss and helps patients acquiring healthy habits

Introduction: Endoscopic methods, especially the intragastric balloon (IGB), have been shown to be effective for the treatment of excess weight.

Aims & Methods: We aimed to assess the efficacy and complications of excess weight treatment with a non adjustable IGB. A liquid-filled IGB with a volume of 600 to 700 ml was used. The patients had a minimum initial body mass index (BMI) of 27 kg/m2 and were followed up by a multidisciplinary team consisting of a nutritionist, a doctor and a psychologist. For statistical analysis, the patients were divided into groups according to sex and degree of excess weight (overweight and grade I, II and III obesity). Data were analyzed using descriptive statistical methods, the Student t-test, and analysis of variance followed by the Tukey post-test. The level of significance was set at p < 0.05.

Results: A total of 5874 patients were analyzed. The incidence of complications was 7.32% (n = 430) as listed below: 299 (5.09%) early IGB removal, 58 (0.98%) absence of weight loss or weight gain. The incidence of gas production inside the balloon was 0.20% (n = 12) and the incidence of leakage was 0.54% (n = 32); pregnancy was 0.32% (n = 19); gastric perforation was 0.06% (n = 4); upper digestive bleeding was 0.05% (n = 3); Wernick Korsakoff syndrome due to excessive vomiting was 0.01% (n = 1), pancreatitis and esophageal perforation was 0.01% each (n = 1). Of the 5444 remaining patients, 4081 (74.9%) were women and 1363 (25.1%) were men. Mean age was 38.38 years. The patients showed a significant weight loss, with a significantly lower final BMI (mean: 30.08 ± 5.06 kg/m2) than the initial BMI (mean: 36.94 ± 5.67 kg/m2) (p < 0.0001). Mean BMI reduction was 6.85 ± 3.06 kg/m2 (range: 0.25–29.79). Mean percent total body weight loss (TBWL) was 18.42 ± 7.25% and mean percent excess weight loss (EWL) was 65.66 ± 36.24% (range: 3.99–336.14). The weight loss in kilograms was 19.13 ± 8.86. The treatment success rate (%EWL > 25) was 93.0%, as follow: overweight was 99.0%, grade I obesity was 95.83%, grade II obesity 93.65% and grade III obesity was 86.09%. Percent EWL was higher in the overweight group (OW) (131.45%±EWL), followed by grade I obesity (G1O) (76.67%), grade II obesity (G2O) (50.61%) and grade III obesity (G3O) (45.45%) sequentially (p < 0.0001). Percent EWL was also higher in women (69.71%±EWL) than in men (53.39%±EWL) (p < 0.0001).

Results are better shown in table 01.

Aims & Methods: We aim to explore the role of FODMAPs in triggering IBS symptoms by investigating visceral sensitivity, intestinal inflammation and short chain fatty acid (SCFA) in stress induced IBS mice model. Fructo-oligosaccharide (FOS) as one of the most frequently exposed FODMAPs in daily life was used in this study. Mice were subjected to water avoidance stress (WAS) condition (1:1/day for 10 days) or sham stress (basal condition; 1/day for 10 days) with oral gavage of saline or FOS (8g/kg) for 2 weeks. Then visceral sensitivity was measured by abdominal withdrawal reflex (AWR) in response to colorectal distension (CRD) and histologic analyses were used to evaluate mucosal inflammation. Immunohistochemistry, reverse transcription, and staining were used to estimate mucosal mast cell, levels of cytokines (IL-6, IL-23, TNFα, IL-10, IL-1β) and SCFA, respectively.

Results: Visceral hyperalgesia and low-grade inflammation in WAS mice as a model of IBS. In WAS condition, increased visceral sensitivity and mucosal mast cell (12.3 ± 2.61 vs. 8.33 ± 3.55, P < 0.01) were observed in FOS-administered mice compared with saline-administered mice. In WAS condition, cytokine expression was mediated by FOS with increased IL-23 (3.17 ± 2.11-fold, P < 0.05) in ileum and IL-1β (2.45 ± 1.55-fold, P < 0.05) in colon compared with saline. In addition, the average concentrations of acetic (2.48 ± 0.62 vs. 1.04 ± 0.10, P < 0.01), propionic (0.48 ± 0.09 vs. 0.33 ± 0.09, P < 0.05), and butyric (0.64 ± 0.06 vs. 0.10 ± 0.03, P < 0.05) acids in total SCFA (3.61 ± 0.89 vs. 1.79 ± 0.17, P < 0.001) significantly increased in FOS-administered mice compared with saline-administered mice in WAS condition. In basal condition, no difference of visceral sensitivity, intestinal inflammation and SCFA were observed between mice treated with FOS or saline.

Conclusion: Oral gavage of FOS leads to both an increase in visceral sensitivity and gut inflammation in stress induced IBS mice. These effects are link with the production of SCFA in the gut which involved in the regulation of sensitivity and intestinal immune activation. These findings support the hypothesis that visceral hypersensitivity and intestinal inflammation aggravated by certain FODMAPs may be responsible for IBS symptom generation, and indicate an alternative mechanism of the efficacy of the low-FODMAP diet for IBS patients.

P1952 GENOMIC ANALYSIS OF THE MULTISPECIES PROBIOTIC PRODUCT VSL#3
D. Mora1, W. M. De Vos2, F. P. Douillard3
1Department Of Food Environmental And Nutritional Sciences, University of Milan, Milan/Italy
2Rupu Immunobiology And 3 Dept Of Food Hygiene, University of Helsinki, Helsinki/Finland

Contact E-mail Address: diego.mora@uniimi.it

Introduction: Several formulations consisting of live lactic acid bacteria, including bifidobacteria, are marketed as probiotic products. However, these products are often difficult to understand how they work. Other probiotics further application in treating diseases, limits comparative studies, and prevents predicting their efficacy. We have previously addressed this by providing genomic and functional characterization of single commercial strains (Kainz et al 2009, Douillard et al 2013, Tytgat et al 2016). The multispecies product VSL#3 is marketed globally for treating colitis ulcerosa, pouchitis, and irritable bowel syndrome. To provide a rational basis for understanding the function of VSL#3 and generate a baseline for future studies, the genomes of all 8 strains that make up this multispecies product were determined and used to predict their function. The strains were provided by the facility which is currently producing both the single strains and the blend mix (CSL-SACCO System, Zelo Buon Persico - Lodi - ITALY).

Aims & Methods: The individual strains of multispecies product VSL#3 were grown to stationary phase and DNA was extracted with established methods. The DNA was subject to paired-end Illumina sequencing using a HiSeq2000 platform, assembled and annotated as previously described (Douillard et al 2013).

Results: The next generation sequencing provided high quality genomes of all 8 strains that are components of the multispecies product VSL#3. Detailed phylogenetic and genomic analysis confirmed the species composition to be as indicated in the VSL#3 product specification and showed the 8 strains of this multispecies product to belong to the species Streptococcus thermophilus, Lactobacillus acidophilus, Lactobacillus paracasei, Lactobacillus plantarum, Lactobacillus helveticus, Bifidobacterium breve and B. animalis subsp. lactis (this species included two strains). The species L. paracasei and L. casei were highly related and in need for further official taxonomic resolution. The annotated genes of the assembled genomes were used to identify genes involved in potential probiotic functions. Full sets of genes for the production of tight adherence pili were observed in the Bifidobacterium spp. and are known to produce a signiﬁcant adhesion to host cells. Other putative genes that promote intestinal integrity, and influence host cell development (O’Connell Motherway et al 2011). Moreover, a series of signaling proteins were identiﬁed in the genomes of the Lactobacillus spp., including surface layer proteins and soluble and cell wall associated proteins that we showed to interact with the mucosal surfaces and dendritic cells (Konstantinov et al 2008; Kankainen et al 2008; Tytgat et al 2016).

Conclusion: The genomic analysis of the VSL#3 strains confirmed the product specifications, defined the baseline genetic coding capacity, and predicted a number of probiotic mechanisms that could explain the efficacy of this multi-species product.

Introduction: Disease prevention and public health awareness are fundamental to reduce morbidity, mortality and health-related costs. Extensive research led to identification of causes of gastrointestinal (GI) diseases; however, the public is still difficult to get population involved. The goals of our pilot campaign are: (a) to raise awareness about GI diseases, risk factors, signs, symptoms, in order to convince people to change behavior and to prompt them with concerns to visit doctors as early as possible; (b) to facilitate communication between healthcare providers and population; (c) to determine the knowledge of health personnel about the appropriate diagnostic investigations. Any information we can share may also benefit patients and their families, in recognition of the many people who suffer with the pain and discomfort caused by GI disorders.

Aims & Methods: We organized population-based events, out of health facilities during which: (a) giant inflatable anatomical models of GI organs that can be visited inside, were installed; (b) educational panels and brochures were set and exhibited both inside and outside the models; (c) videos illustrating endoscopy exams and histopathology examinations were projected and discussed; (d) clinical cases, also mimicking patient encounter, were simulated.

Results: We started an innovative strategy focused on the keywords: multidisciplinary team, scientific rigor but simple words, people attraction, creating communication, in Parma and neighbouring Cities. Specialists in Gastroenterology, Anatomic Pathology, Radiology, Surgery, Biochemistry, Nutrition, together with pre- and post-graduate Students, discussed various aspects of gastrointestinal diseases. Selected people were examined by ultrasound exams. Municipalities and civil society were also involved to ensure organizational efficiency. The most discussed topics regarded dyspepsia, gastritis, helicobacter pylor infection, gastrointestinal reflux disease, alcohol abuse, cirrhosis, hepatitis, irritable bowel disease, inflammatory bowel disease, GI cancer, food allergy and intolerance, optimal nutrition in health and disease. The event performed in the main square of Parma lasted two full consecutive days and was attended by about 3,000 people, most of which also filled a questionnaire. A total of 120 ultrasound examinations were performed. In neighbouring Cities the events were organized for one day; as a consequence, the number of participants was lower in proportion, but very satisfactory.
Conclusion: The events were educational and enjoyable for all age groups. The interactive approach and the environment out of health-care centres facilitated population to feel comfortable and eager to learn, as well as clinical cases simulation provided a valuable entertaining experience. This strategy of raising public awareness of GI diseases seems promising, we are refining the model for a national campaign.

Introduction: Amino acids are essential metabolites which play a role as protein constituents. Moreover, amino acids and their metabolites feature in regulation of anaabolic and catabolic metabolism, detoxification processes, and act as neurotransmitters. Concentration of circulating amino acids reflects about dietary protein intake and can be an indicative of malnutrition. Changes in the amino acid homeostasis are observed in coeliac disease (CD) [1] due to malabsorption caused by enteropathy but also because of the treatment with gluten-free diet (GFD) shown to be low in the important nutrients.

Aims & Methods: A randomized, placebo-controlled interventional trial was designed to assess the influence of an oligofructose-enriched inulin (OEI) as a supplement of GFD on plasma profile and urine excretion of amino acids in CD patients strictly following GFD at least 1 year. We randomized 34 children diagnosed with CD into a group receiving 10 g of OEI daily and a placebo (maltodextrin) group during a 12-week nutritional intervention. Amino acid profiles in urine and plasma was analysed via gas chromatography/mass spectrometry detection.

Results: At the baseline and after supplementation, 22 and 27 amino acids were identified in plasma and urine, respectively in both groups of children. Significantly higher levels (p < 0.05) of alanine, serine, asparagine, glutamine, threonine, tyrosine, histidine, methionine, lysine, aspartic acid, alanine, glutamic acid, hydroxylysine and cystine were determined in urine of OEI group after intervention as compared to the baseline and placebo group. The analysis of amino acid profiles in plasma samples showed a significant increase (p < 0.05) of majority of amino acids in both OEI and placebo groups after intervention. However, the concentrations of glutamine and glutamic acid were significantly higher (p < 0.05) in the OEI supplemented group.

Conclusion: Our study showed that supplementation of GFD with OEI impacts the amino acid homeostasis in CD children. OEI in GFD increased a total concentration of amino acids in both urine and plasma. Higher excretion of amino acids in urine accompanied with increased amino acid content in plasma may indicate the improved absorption or/and stimulated de novo synthesis of proteins. Increase in the concentration of glutamine can stimulate recovery of the intestinal mucosa by itself or by the involvement in the synthesis of cytokine known as negatively correlated with intestinal mucosal damage [1], therefore we can suspect that OEI added to GFD can help in restoring of the intestinal barrier integrity.

Disclosure of Interest: All authors have declared no conflicts of interest.

P1955 LONG-TERM TRENDS IN HEMATOLOGICAL AND NUTRITIONAL STATUS AFTER GASTRECTOMY FOR GASTRIC CANCER

J. Kim

General Surgery, The Catholic University of Korea, Seoul/Korea, Republic of Korea

Contact E-mail Address: doctor2003@catholic.ac.kr

Introduction: The quality of life and nutritional management after gastrectomy are major issues for gastric cancer patients, as is oncological surveillence. Weight loss usually follows gastric resection, with reported losses ranging from 10% to 30% of the preoperative weight. This loss has been attributed to inadequate oral intake, rapid intestinal transit time, and bacterial overgrowth. Timely, appropriate nutritional intervention can minimize diet intolerance, weight loss, and micronutrient deficiencies that often follow surgery.

Aims & Methods: This study investigated long-term trends in hematological and nutritional parameters after gastrectomy for gastric cancer and evaluated the influence of the reconstruction type on these trends. The medical records of 558 patients who underwent curative gastrectomy with standard lymph node dissection for stage I gastric cancer between January 2006 and December 2013 were reviewed. The hematomatological and nutritional parameters evaluated included haematoglobin, ferritin, vitamin B12, total protein, albumin, total cholesterol, triacylglycerol, and calcium. The patients were followed up for 6 months postoperatively and then annually until death, cancer recurrence, or follow-up loss.

Results: In the long term, ferritin and triglyceride gradually decreased after gastrectomy, while the other parameters decreased slightly or were stable. In the comparisons according to reconstruction type, the Roux-en-Y group had the lowest levels of hemoglobin, ferritin, vitamin B12, total protein, albumin, and total cholesterol beginning 6 months postoperatively compared with the Billroth I and II groups. However, only ferritin and vitamin B12 had significant differences in the 5-year cumulative incidences of deficiency according to the reconstruction type, whereas albumin, triglyceride, total cholesterol and calcium did not.

Conclusion: Although malabsorption and malnutrition are common in patients after a gastrectomy, most nutritional parameters were stable or decreased slightly in the long-term and were not markedly influenced by the reconstruction type or extent of gastrectomy. Therefore, for more accurate nutritional assessment after gastrectomy, multidirectional nutritional support should be considered rather than simply measuring biochemical parameters.

Introduction: Celiac disease is an autoimmune enteropathy induced by the ingestion of gluten. The classical form has become a minority. Currently, the most frequent forms of presentation are extradiagnostic with various manifestations, among others, reproductive disorders. The aim of our study is to assess the frequency of these disorders in celiac disease and their evolution under gluten-free diet.

Aims & Methods: Descriptive retrospective study of 173 patients with celiac disease followed in the department of diseases of the digestive tract of the Ibn Sina Hospital in Rabat, over a period of 18 years.

Results: In 173 patient with celiac disease, 58 patients had reproductive disorders. There are 53 women and 5 men. The average age was 32.25 years, the diagnosis of celiac disease was made after surgery at the beginning of the disease, the reproductive problems were never isolated but always associated with other digestive signs at the time of diagnosis of celiac disease. These disorders are represented by: delayed puberty in 11 cases, secondary amenorrhea in 13 cases, irregular menstrual in 12 cases, absence of development of secondary sex characteristics in 8 cases, spontaneous abortions in 7 cases, menometrorrhagia in 4 cases, primary sterility in 5 cases early menopause in 6 cases, premature delivery in 3 cases primary amenorrhea in 2 cases and intrauterine fetal death in 1 case. All our patients have had a gluten-free diet. 15 Patients lost to follow-up, 2 patients died, and 12 patients undergoing follow-up. The remaining 29 patients, the evolution of reproductive disorders under gluten-free diet was favorable in 26 cases (90%), with the normalization of cycles in 15 cases, resumption of cycles in 6 cases development of secondary sex characteristics in 2 cases, fertility resumption in one case, initiation of cycles after primary amenorrhea in one case and delivery of a newborn at term after premature deliveries in one case. The evolution was unfavorable in 3 cases with the notion of miscarriages in 2 cases and intrauterine fetal death in 1 patient and the absence of cycle resumption in 2 cases.

Conclusion: The reproductive disorders associated with celiac disease are frequent and varied. In our study, these disorders responded very well under a gluten-free diet conducted in 90% of the case. These disorders are thus reversible under this diet.

Introduction: Total gastrectomy can profoundly influence patients’ nutritional status and is associated with an increased risk of post-operative complications. The optimal route for nutritional support remains controversial. This systematic review and meta-analysis was conducted to determine the optimal route for nutritional support following total gastrectomy.

Aims & Methods: This systematic review and meta-analysis was conducted by searching relevant databases for randomized controlled trials (RCTs) comparing different nutritional support routes after total gastrectomy. Data were pooled using a random-effects model, and outcomes were analyzed using a fixed-effects model.

Results: Of 105 randomized patients, 102 were enrolled as modified intention-to-treat population. Overall morbidity was significantly greater in patients receiving parenteral nutrition compared with enteral feeding (OR = 1.23, 95% CI: 0.64–2.36, p = 0.25), but not in patients who received enteral feeding (OR = 1.23, 95% CI: 0.64–2.36, p = 0.53).

Introduction: Patients with severe intestinal failure depend on life-long home parenteral nutrition (HPN) therapy (PN) support. Repeated central venous catheter (CVC) loss due to complications, including mechanical damage, compromises vascular access. It remains unclear whether repair of damaged CVCs is an effective strategy to extend catheter life, avoid surgical replacement and maintain venous access.

Aims & Methods: The objective of this study was to characterize patients who underwent catheter repair and to evaluate effects on catheter survival and describe complications. This study concerns a retrospective analysis of all catheter repairs that were performed in HPN patients at the Radboud University Medical Center between January 2000 and May 2017. Primary endpoint was the difference in catheter survival in the presence or absence of catheter repair. To this end, a non-parametric survival analysis was performed. Secondary outcomes included localization of catheter damage and frequency of repair-related complications within 1 month after catheter repair.

Results: A total of 50 repairs in 38 CVCs of 32 HPN patients were included in the analysis. 16 CVCs (52%) were damaged at the distal end, near the screw thread of the catheter. 25 CVCs (95%) at the junction between the rigid and flexible part of the catheter, and 9 CVCs (18%) at the full length of the catheter. The mean time to catheter repair after placement was 2.2 years (95% CI: 1.5–2.9 years). The mean catheter survival after repair was extended by 1.4 years to 3.6 years (95% CI: 2.69–4.46; p = 0.01). No repair-related complications occurred within 1 month after catheter repair.

Conclusion: Repair of damaged CVCs significantly extends catheter life in HPN patients with intact venous access. Catheter repair is a safe procedure.

Introduction: Catheter-related complications (CRCs) in home parenteral nutrition (HPN) patients are a threat to both catheter and patient survival. Taurolidine 2%, an antimicrobial catheter lock solution (CLS), is an effective intervention to extend catheter life, avoid surgical replacement and maintain venous access. It remains unclear whether repair of damaged CVCs is an effective strategy to extend catheter life, avoid surgical replacement and maintain venous access.

Aims & Methods: The aim of this retrospective study was to evaluate long-term clinical outcomes of our HPN patient cohort that uses the CLS taurolidine. Between 2008 and 2016, all adult HPN patients requiring a central venous catheter (CVC) placement at the Department of Gastroenterology and Hepatology (DH) who used taurolidine as CLS were included. CRC incidence rates/1000 catheter days were described. Kaplan-Meier analysis was used to determine the time until a first CRC. Cox proportional hazard analysis was performed to identify risk factors for a first CRC.

Results: In 221 HPN patients, 658 CVCs (418 Hickmans, 172 PACs, and 28 non-tunneled CVCs) were inserted, comprising 261225 catheter days. Median survival for Hickmans, PACs and non-tunneled catheters was 175 (43–544), 310 (61–827) and 14 (7–19) days, respectively. During eight years of follow-up, 17 CRBSI occurred and 80 catheter-related occlusions (CRO). CRBSI and CRO rates/1000 catheter days were 0.74 and 0.34, respectively. In 47% and 32% of patients, at least one CRBSI and CRO occurred, respectively. Median time to first CRBSI or CRO was 246 (54–817) and 215 catheter days (5–2070). Numerically, but not significantly, CRBSI and CRO rates decreased over time. The sole use of intravenous fluids was associated with a significantly lower risk for CRBSI (RR 0.32).

Conclusion: CRBSI and CRO rates in HPN patients to date on long-term taurolidine 2% as CLS. Overall, CRC incidence rates were low when compared with the literature. We found no evidence for a decreased effect of taurolidine over time.

P1962 INTESTINAL DYSBIOSIS IN PATIENTS WITH SHORT BOWEL SYNDROME DEPENDENT ON TOTAL PARENTERAL NUTRITION IS REFLECTED BY ALTERED METABOLOME IN FAECES

L. Bajer1, M. Kostovcek1, J. Hradecky2, T. David1, P. Wohl1, J. Spicak1, P. Drasich1, M. Cahova1

Contact E-mail Address: lukasbajer1@gmail.com

Introduction: Patients with short bowel syndrome (SBS) exhibit substantial disturbances in gut microbiota composition, which implicates significant alterations of intestinal metabolism.

Aims & Methods: The aim of this study was to perform genetic and metabolomic analysis of stool samples collected from SBS patients totally dependent on parenteral nutrition (TPN). We compared the stool samples from 9 healthy individuals and 8 patients with SBS dependent on TPN. Faecal microbiota composition was assessed by sequencing of variable V3 and V4 regions of 16S rRNA gene using Illumina MiSeq TM platform. Library preparation, template purification and template sequencing was performed using the Illumina’s protocol. Obtained data were filtered by quality and length and processed for alpha and beta diversity analyses using QIIME software package. SCFA profile was measured using solid phase microextraction (SPME) coupled to gas chromatography and high resolution mass spectrometry employing time of flight mass analyser (Pegasus GC-HRT; LECO, USA). D-lactate content was determined using Megazyme kit.

Results: Weighted UniFrac analysis revealed significant differences between control and TPN subjects. In healthy controls, most abundant phylum was Firmicutes (64.2 § 7.5%), followed by Bacteroidetes (22.5 § 9.1%) and Actinobacteria (8.9 § 4.5%). Proteobacteria were found only in one control sample. In TPN group, Firmicutes reached 66 § 29% of microbiota but Bacteroidetes were absent and Actinobacteria significantly reduced (1.6 § 4%). Proteobacteria were found in all samples (23.6 § 15%). The most abundant metabolites in control stool samples were short - chain fatty acids (SCFA): acetate, propionate and butyrate. In the TPN group, lactate predominated significantly, while SCFA were absent in the intestinal content of these patients.

Conclusion: Long-term dependence on total parenteral nutrition results in dysbiosis of the intestine residue characterized by extinction of Bacteroidetes and appearance of Proteobacteria. This was reflected by the changes in the composition of prevailing metabolites in stool.

P1963 COMPARING RISKS OF ADVERSE EVENTS ASSOCIATED WITH PERCUTANEOUS ENDOSCOPIC GASTROSTOMY (PEG) PLACEMENT BETWEEN THE MODIFIED INTRODUCER TECHNIQUE AND THE OVERTUBE ASSISTED PULL TECHNIQUE

H. Matsui1, H. Inomata1, H. Horiiuch1, N. Tamai1, K. Sumiyama1
1Department Of Endoscopy, Jikei University School of Medicine, Tokyo,Japan

Introduction: Techniques of percutaneous endoscopic gastrostomy (PEG) placement can be divided into two techniques, the pull technique or the introducer technique. Although the difference in procedural safety for the gastrostomy placement, the pull technique, in which the PEG catheter is delivered through the oral cavity and the hypopharynx, inevitably contaminates the peristomal site. A series of studies directly comparing the newly developed modified introducer technique using a blunt cannula compared with the conventional pull technique demonstrated that the modified introducer technique was more preferable regarding procedure related adverse events. Meanwhile, use of an overtube while guiding the catheter into the stomach in pull technique succeeded the reduction of the bacterial implantation. It is still unclear if the modified introducer technique or the overtube assisted pull technique would reduce risks of adverse events.

Aims & Methods: In this study, we retrospectively investigated risks of adverse events associated with the modified introducer technique and the overtube assisted pull method.

Results: During the study period, 236 PEG placements were done in 234 patients. The average age was 69.3 ± 12.5. The modified introducer technique was applied in 167 procedures (70.8%) and the overtube assisted technique was applied in 69 procedures (29.2%). The reason for PEG was placed aiming for the cancer patients in 132 procedures, cerebrovascular accident in 51 procedures, aspiration pneumonia in 32 procedures, and others such as infection and disuse atrophy in 21 procedures. Age (the overtube assisted pull technique > the modified introducer group) and gender (to the modified introducer group) were important factors. The risk of clinically significant adverse events were not different between the two groups. There was no significant difference in the types and the rate of adverse events between the two groups. However, severe peristomal bleedings were observed only in the modified introducer technique group. Four patients required suture placements and 3

United European Gastroenterology Journal 5(5S)
patients required blood transfusion for the peristomal bleeding. In a univariate analysis, age, the rate of aspiration pneumonia as the reason for the PEG placement were higher in patients encountering adverse events (p < 0.05) (table 1). Also, serum platelet level, serum albumin and the rate of nutrition supports for cancer as the reason of the PEG placement was lower in patients encountering adverse events (p < 0.05). In a multivariate analysis, lower serum platelet level was solely recognized as a relevant predictive factor for adverse events (p < 0.05). The types of the technique used were not relevant to risks of adverse events.

(continued)

**Conclusion:** There was no significant difference in overall risks of adverse events between the modified introducer technique group and the overtube assisted pull technique group. However, the modified introducer technique may be associated with higher risks of severer adverse events. Especially, special care should be taken in patients with lower serum platelet level.
