adapt to the new environment (Black et al., 1990, 1992; Naumann, 1993). In fact, cross-cultural training is critical for expatriates who do not know the host nation's culture, work ethics and social etiquette. Cross-cultural training can help those individuals not only to adjust faster to the new country, but also to be more efficient, effective and successful in their overseas assignment. Through cross-cultural training expatriates gain a better understanding and more knowledge about the host country and this in return enhances their self-efficacy; it reduces their anxiety levels and allows them to absorb culture shock. It thereby gives them an advantage over someone with no cross-cultural training, because the trained expatriates are familiar with the host country and this facilitates faster cross-cultural adjustment.

The training should include pre-departure training, on-site training and repetition training where every few months a refresher training workshop is offered. Training offers numerous advantages to the expatriate, by helping expatriates deal with culture shock and unexpected events better and it also lessens the uncertainty of interactions with host nationals. It is understandable that companies struggle to develop an appropriate mental frame of reference for their expatriates for dealing with unfamiliar cultures. However, they need to rectify this as expatriates need a frame of reference in the form of cross-cultural training and mentors.

Researchers such as van Reine and Trompenaard (2000) have discovered that different national cultures prefer different learning styles and environment, and the company needs to deliver the training in the most effective manner. However, Waxin (2004:69) also point out that the method of training should be specifically tailored "*to the cultural distance between the expatriate's country of origin and the host country*". Thus, an understanding of Hofstede's dimensions would assist in this process. In addition, Vance and Paik (2002) point out that for cross-cultural training to be effective it should be consistent with the cultural characteristics of the host country. Companies would also benefit from using their former expatriates as trainers, as those former expatriates have been there, and can put themselves in the shoes of the new expatriates (Harris, et al., 1999). Additionally, the former expatriates can act as mentors. A mentoring, coaching and development system can be developed and new expatriates can be trained in that way.

Most participants in this research have indicated that they prefer hands-on training and that they would like to have a mentor who they can approach and ask for advice when they need help.

Cerdin (1996) found that if cross-cultural training is not provided by the companies most expatriates will not attempt to train themselves. So the companies must conduct this training if they wish to see the benefits in their expatriate staff.

4.8 Host country national's advice for improvements

Research shows that many host country nationals would like to see changes and improvements in some styles of expatriate managers. Those changes include the expatriate manager's leadership, decision making, communication and group work. In terms of leadership, the following changes would be desirable; expatriate managers need to be friendlier, available, respectful of subordinates and their suggestions. In terms of decision making, the host country nations would like to be involved in the

decision making process by those who will be affected by the decisions made and have a clear definition of goals.

In terms of communication; there should be more group problem solving and teamwork as well as exchange of opinions and ideas between managers and subordinates. This indicates that the training approaches used need to reflect both the industrial and the cultural environment.

5 Conclusion

Our world seems to be becoming smaller and more people live and work overseas in countries which are very different to their home country. Hence, there are a vast number of reasons why cross-cultural training is important; it simply is imperative when it comes to helping and supporting expatriates in their development and success overseas. From a company perspective, if their personnel are adequately trained for the overseas assignment they will be more successful and contribute to increasing the overall efficiency and profitability. The company could avoid losing their financial investment and their investment in staff. In addition, the company can overcome the belief that their way of doing things is superior to that of others. The lack of training or no training at all, has been associated with higher expatriate failure rates.

The online survey as well as the six case studies in this research represented a variety of professional fields and activities; not only project management. This gave the authors a better insight into how, and if, expatriates are getting cross-culturally prepared. When asked about cross-cultural training all six case studies have agreed that it is of high importance to provide expatriates with adequate, appropriate and up-to-date cross-cultural training. Additionally, if the recommendations made in this paper are integrated and implemented into the cross-cultural training, it would benefit all parties, the expatriates as well as the companies. International companies need to understand that investing in people gives the greatest and most effective return.

Abstract:

Education and training of Quantity Surveyors (QS) is subjected to conflicting pressures; firstly from Academic Institutions, which seek to address the academic learning of students; secondly from Industry, which is the graduate employer and thirdly the Professional Body, the regulator of the profession. This can cause tensions between these main stakeholders resulting in greater levels of employer and graduate dissatisfaction and obstacles to early career development of the Quantity Surveying graduate. These problems are further exacerbated in the current economic recession. The research investigates the changing developmental needs of QS within a post recession industrial environment. These must satisfy the aspirations of industrial, academic and professional stakeholders such as the RICS. The RICS provide a comprehensive list of basic, core and optional competencies for the QS. These were comprehensively reviewed to provide the basis for the survey questionnaires with the use of an Expert Forum and literature. Two detailed surveys were conducted; one to obtain views of the industry and the other targeting academia with respect to the RICS QS competencies and the debate of “training versus education”. The research revealed that the stakeholders, mainly the employers and academics, hold diverse views of the development needs for graduate QS. There is wide spread variation in the interpretations, the expected levels of attainment and the perceptions of the level of actual achievement of competencies by graduate QSs. The research proposes a framework that enables to define expectations, ambitions, and practical constraints in QS education that will lead to better understanding, effective collaboration and greater satisfaction in producing a Quantity Surveying graduate who will be seen as fulfilling the requirements of all stakeholders.

Keywords:

academic, industry, quantity surveying competencies, QS graduate, RICS

1 Introduction

Entry of graduates and others into any faculty of the Royal Institution of Chartered Surveyors (RICS) as fully qualified Chartered Surveyors comes only after success in the Assessment of Professional Competence (APC). This is true of the Quantity Surveyor (QS) as for any other. A successful candidate must demonstrate that they have attained certain competencies determined by the Education and Membership Board of RICS. In

the case of the graduate, these competencies will have been acquired as a result both of their formal university education and (in some cases) workplace training which they have received, whether as Part time students in employment or during a work Placement. In either case, the applicant will have undergone a period of full time employment beyond graduating, further enhancing their overall skills profile. It will be appreciated that there is a balance to be struck between the level and type of competence which should be expected, and can be achieved, in the universities and that born of exposure to experience only available within the workplace. To some extent the two must be complimentary. It has emerged over the years that both Academia and Industry have certain expectations of one another, rightly or wrongly, as to what each can and will achieve as a vehicle for graduate learning. These are encapsulated within the “education versus training “debate that has dogged the relationship for as many years as formal Quantity Surveying education has existed.

It will be seen that, at best, there is scope for misunderstandings between the stakeholders as to what is being required and what is being achieved. At worst there may be actual gaps in the education and/or training being offered and received or, at least, some discrepancies between the levels of attainment. This study aimed at investigating the changing developmental needs of Qs within a post recession industrial environment that satisfies the aspirations of industrial, professional and academic stakeholders. The research sought to review competencies and analyse the views of industry and academia on graduate education aiming to ascertain and deliver a framework for alignment of different stakeholder views.

The research approached the problem from two angles; a literature review and two surveys of industry and academia. The surveys were comprehensive and simple descriptive statistics were used for analysing and presenting the results. It has become apparent that the diverse views of industry and academia can only be harmonised through active mediation by the RICS as the guardian of the profession. This research therefore, proposes a framework for alignment of views based on 5 key recommendations. The successful implementation of the framework for alignment of views requires a concerted effort by all stakeholders in the development of graduate Quantity Surveyors who are industrially relevant, professionally qualified and who have a sound academic background.

2 Development of the QS Profession

Significant growth in undergraduate level education of Quantity Surveyors (QS) stems from the late 1960’s and early 1970’s with the progression from Diplomas through to Honours Degrees. “The Future Role of the Quantity Surveyor” (RICS, 1971) identified specific competencies which led to the rapid development of the profession. In 1983, “The Future of the Chartered Quantity Surveyor” (RICS, 1983) further consolidated the professional status of the QS. The “QS2000” (Davis Langdon Everest, 1999) recognised a number of forces acting on the QS profession, highlighting both the changes to the client body and to the construction industry. The academic and training needs of Qs are pulled in different directions by three key stakeholders. Academics are interested in producing a rounded graduate with the basic foundation in knowledge for further development (RICS, 2009) whereas the industry is looking for a graduate who can contribute immediately both to the daily functions of business and to its growth. The RICS is interested in maintaining professional standards and quality benchmarks.

Hence, there is a three directional pull on the development needs of the QS. Professional body influence such as RICS is often reflected in academia through accreditation of degree programmes meeting its criteria and through the setting of the competencies required for the achievement of professional status. The present education system of the Quantity Surveyor does not recognise these opposing needs of the QS and hence often produces a graduate whom the industry sees as not fulfilling their requirements. This leads to problems, with greater levels of employer and graduate dissatisfaction.

Added to this is a more fundamental failure on the part of all parties to appreciate the dynamics of the market sector. Most new graduates appear to be entering more non-traditional quantity surveying routes. It has been shown both through research (Perera, 2006) and through 1st destination Surveys (UNN Returns, 2001 – 2008) that a large majority of new graduates find employment not in Private Consultancy Practice (PQS) or the Public Sector, as was the case until the mid 1980's, but with Main Contracting and specialised subcontracting organisations. Much of the academic content which reflects the structure of the RICS would seem directed at those employed in the former roles, paying less attention to the skills inherent in the latter. The emergence of Commercial Management (Lowe and Leiringer, 2006; Walker and Wilkie, 2002) as a distinct discipline encompassing the role of the Contractor Quantity Surveyor (CQS) must affect the traditional role of the professional QS.

3 Research Methodology

The research was carried out in two distinct data gathering phases culminating in analysis and reporting. A detailed literature review was carried out to explore the “training vs. education” debate, identify the QS competencies and their interpretation.

Expert forum: a ten member expert forum was established consisting of 3 academics, 3 PQSs, 3 CQSs and one RICS academic board member. The views obtained from this forum via a series of interviews inform the development of the questionnaire surveys.

Survey of the academia: a comprehensive web-based survey of 41 questions addressed academics representing all 26 RICS accredited QS programmes to capture views of academics on QS education. The survey was issued to 106 academics from which 65 responses were received, 45 of these being suitable for analysis.

Survey of the industry: A comprehensive web-based survey of 39 questions addressed PQS, contractors' QS, public sector and other specialists across firms in the UK using RICS member database to identify their perception of graduate QS. 2946 chartered surveyors were randomly selected from the RICS member database. A total of 615 responses were received whilst 301 of these, having complete responses, were analysed.

Both surveys were first piloted among a small sample of volunteers representing industry and academia. The review of feedback obtained through a discussion session led to modification of the questionnaires. The primary areas of investigation include: Role of the QS & related Developments, RICS Quantity Surveying Competencies, Quantity Surveying Education, Study & placement, and RICS Membership Routes & Training.

4 Findings and Discussion

4.1 The survey respondent profiles

The survey respondents for both surveys were well experienced in QS work, with over 90% having more than 10 years experience. 44% of the academic respondents were programme leaders. Just over half of industry respondents were PQSs, the rest equally spread between contracting (17%), the public sector (15%) and other (15%).

4.2 Role of the QS & Developments

The role of the QS is defined by current and future workloads and trends in development. The industry survey identified the key areas of work presently important for the QS. The top 3 core competencies: T062 Procurement and tendering, T067 Project financial control and reporting and T074 Quantification and costing of construction works directly map to the highest workloads identified. Both professionals and academics appear to agree that the largest growth area will be that of Refurbishment followed by Building construction and Building services. The rate of development of sustainability and e-business activities was also emphasised by both groups. The similarity in median scores together with low deviation suggests agreement amongst most academics. Practitioners, for their part, show a wider variety of opinion over this.

4.3 RICS Quantity Surveying Competencies

The RICS sets the competencies required for the attainment of professional status. The RICS Competencies are arranged into three groupings, depending upon their perceived relevance to the role of the QS (RICS, 2009b):

Mandatory Competencies: personal, interpersonal, professional practice and business skills common to all pathways and compulsory for all candidates.

Core Competencies: primary skills of the candidate's chosen [RICS] pathway

Optional Competencies: selected as an additional skill requirement for the candidate's chosen [RICS] pathway from a list relevant to that pathway. In most cases there is an element of choice, though driven, usually, by their employer's specialism.

These competencies are expected to be attained at three possible levels:

Level 1: Knowledge (theoretical knowledge)

Level 2: Knowledge and practical experience (putting it into practice)

Level 3: Knowledge, practical experience and capacity to advise (advising)

There are 10 Mandatory competencies, 7 Core competencies and 7 Optional competencies (two to select). The RICS stipulates that an APC candidate needs to achieve all Mandatory competencies at Level 2 or above, all Core competencies at Level 3 and 2 Optional competencies at Level 2 or above. This section analyses the views of the respondents to establish the expected level of achievement by the graduate QS. In the absence of a threshold benchmark standard for graduate competencies, it is important to ascertain what key stakeholders perceive a graduate should achieve. This section aims to establish a consensus view on the level each competency should be

achieved at by a graduate from an RICS accredited degree programme. The overview comparison of all competencies between Academia and Industry is given in Figure 1 and Figure 2 respectively. In overall terms academics' expected levels for all three types of competencies are higher.

Figure 15. Overview - Expected Graduate Competency (Academic)

Figure 16. Overview - Expected Graduate Competency (Industry)

4.3.1 Expected level for Mandatory Competencies

Whilst academic responses to this section appear somewhat biased towards Level 2, the industry response appears more logical, expecting the highest level of experience to be at Level 1, falling to the least being at Level 3. In both cases the highest ratings were given in the areas of M010 Team working and M004 Communication and negotiating and M007 Data management, all being transferable skills. Of those competencies that do feature at Level 3 within both industry and academic assessment, M010 Team working appears once again. This acknowledged degree of expertise may stem from its increasing use as a vehicle of teaching and assessment within university programmes of study. Final assessment of Mandatory Competencies is presented in Figure 3 & 4 below. The majority view indicates that in general those Mandatory competencies are being achieved at Level 1 except for M006, M007 and M010. This is very much in line with RICS recommendation.

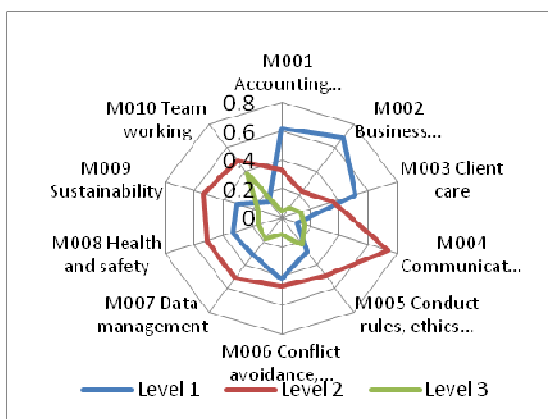

Figure 17. Expected Level of achiev. of Mandatory Competencies for New graduate QS (Academic)

Figure 18. Expected Level of achiev. of Mandatory Competencies for New Graduate QS (Industry)

4.3.2 Expected level for Core Competencies

In this, the most discipline-specific area, both academics and industry most frequently seek competency at Level 2. Respondents from academia display a higher expectation at Level 3 than do industry.

As above industry are being more realistic in their expectation, as a new graduate is unlikely to be in a position immediately to advise clients etc. as the acquisition of Level 3 suggests. Academia is either perhaps exhibiting wishful thinking, or else is unaware of the actual requirements of Level 3. What is disconcerting in both these analyses is that a considerable number expect Core competencies to be achieved at Level 3. The academic survey indicates Level 3 expectancy at 36% whereas the comparative figure for industry is 27%. Both these are very high and indicate possible misinterpretation of level classifications or unrealistic expectations. The final assessment of core competencies that can be deduced from this analysis is given below.

Figure 19. Expected Level of achievement of Core Competencies for graduate Qs (Academic)

Figure 20. Expected Level of Achievement of Core Competencies for Graduate Qs (Industry)

Core competencies largely define the primary role of the quantity surveyor. However, there is no consensus view on achievement of core competencies, with some in industry stating it should be at Level 1 and some academics stating it should be at Level 2. Therefore, it is recommended that Core competencies be achieved at Level 2 in part as indicated. This is also justified by the fact that most programmes have the capacity to proceed to Level 2.

4.3.3 Expected level for Optional Competencies

With regards to Optional competencies the rankings of both respondent groups show much the same pattern, their most likely expectation of attainment being Level 1 only, expectation of Level 3 being by far the least. Again, industry responses are far less at Levels 2 and 3 than those of academia, reflecting a more realistic picture perhaps, one born of experience. The specialisms of T008 Capital Allowances, T045 Insurance, T025 Due Diligence and T020 Corporate recovery and insolvency each are being the highest in ratings by both respondent groups. Both academia and industry attach greater significance to T016 Contract administration giving it an expected ranking of Level 2, born of the fact that it is often considered a key function of quantity surveyors. The final assessments of optional competencies are presented in Figures 7 & 8. There is considerable argument for T016 Contract administration, T063 Programming and planning and T077 Risk management to be achieved at Level 2 mostly arising from academics. It is recommended that Optional competencies be achieved at Level 1 for all competencies and extending in part to Level 2 for some competencies.

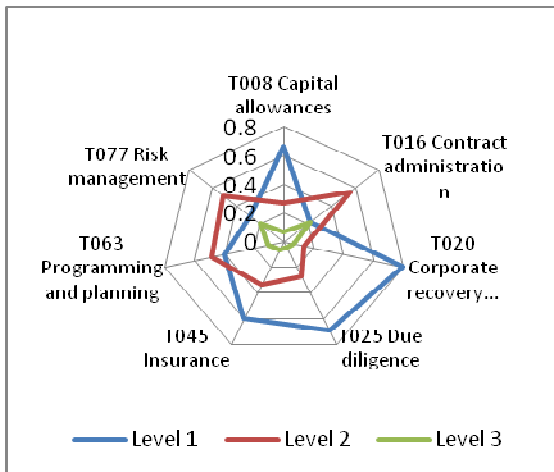

Figure 21. Expected Level of achievement of Optional Competencies for Grad QSs (Academic)

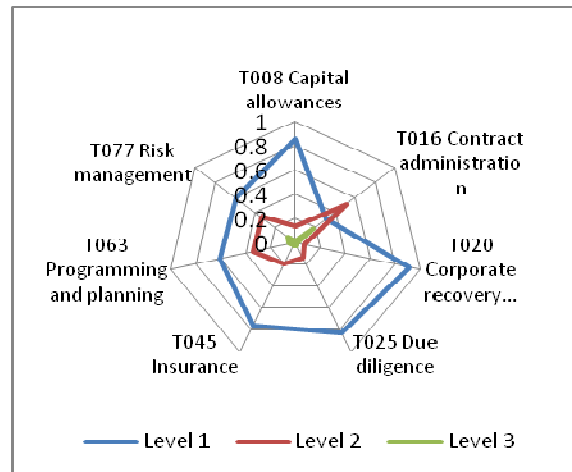

Figure 22. Expected Level of Achievement of Optional Competencies for Graduate QSs (Industry)

4.3.4 Cross comparison of levels of expectation, achievement and importance of competencies

A comparison of industry survey respondents' views on the Expected level of attainment, the Importance and Level of achievement of competencies by graduates is cross plotted to evaluate relationships between these criteria (Figure 9).

Figure 23. Cross comparison of competency expected level, importance ranking and graduate achievement

The Expected level has been re-scaled to 1 to 5 to graphically compare with Importance ranking (scaled 1 to 5) and perceived Achievement (scaled 1 to 5). From this comparison it is clear that whilst high importance is attached to a competence there may be a comparatively lower level of achievement. This is clearly evident with T067 Project financial control and reporting and T074 Quantification and costing of construction works competencies. Other clear gaps in expectation and achievement are with M002 Business planning, **M003 Client care, M004 Communication and negotiation, M005 Conduct rules, ethics and professional practice, M006 Conflict avoidance, management and dispute resolution procedures, M010 Team working, T010 Commercial management of construction, T013 Construction technology and environmental services, T017 Contract practice, T022 Design economics and cost planning, T062 Procurement and tendering, T067 Project financial control and reporting, T074 Quantification and costing of construction works, T016 Contract administration, T045 Insurance, and T077 Risk management.**

Those competencies highlighted in bold above show the greatest gap between achievement and importance. These include 9 of the 24 competencies (3 mandatory, 4 core and 2 optional competencies) which have a significantly high importance in the role of the quantity surveyor.

4.4 Quantity Surveying Education

The surveys probed in detail the views of both academia and industry as to their level of understanding and awareness of aspects of education, university industry collaboration and other. Only half of the industry respondents felt themselves to be either reasonably or fully aware of the content of the curricula. As to their satisfaction with curricula content, 60% expressed dissatisfaction or partial dissatisfaction with the curriculum. This begs the question whether their dissatisfaction might be linked to their self confessed lack of awareness of the detail. Industry generally displays reasonable to full confidence with the level of lecturers' academic knowledge, QS Practice and use of teaching materials. Academics themselves indicate a very high level of confidence in the programme delivery capacity.

Industry and academic collaboration in the delivery of QS programmes is vital to the success of graduates. Therefore, academics perceptions of industry's willingness to collaborate were matched against the willingness of the industry to collaborate. A less promising picture emerged; 75% of academia saw the possibility of collaborative activity as likely or very likely but the equivalent figure for industry amounted to only 28%. Further, 47% of academics perceived the RICS – University Partnership Agreement process as successful while 22% saw this as partially so or unsuccessful whilst 31% were undecided. This suggests consensus on the overall concept of the partnership but a considerable amount of scepticism about the partnership process, which warrants further investigation.

Regarding the role of universities in producing a graduate quantity surveyor, there was a clear difference in perceptions between the two sets of respondents. Industry were almost equally split (57% to 43%) as to whether universities should produce surveyors for immediate QS employment upon graduation (Training) or, rather, graduates with overall knowledge and a good foundation in Quantity Surveying (Education). Academia took the opposing stance, preferring the Education approach by a ratio of 73% to 27%.

This mirrors quite closely the traditional perceptions within the “education versus training” debate. This crucial aspect sets the ethos for university programme provision and industry aspirations. It is abundantly clear that the industry prefer their graduate recruits to be more directly employable than they are today, an explanation perhaps for the high level of dissatisfaction expressed in graduate performance by Industry. But, the question is on the boundary of demarcation between university and industry as to producing a professional and converting a graduate to a professional.

4.5 Modes of Study and Placement

Asked to rate the importance of a structured placement training model, there was considerable agreement between both sets of respondents. Industry’s ranking of this as either very or extremely important came to 64% whilst academic gave this 80%. This may reflect the fact that whereas academics are used to training students within strict curricula, industry does not always perceive itself as providing structured training but, rather, a generalist training opportunity? When asked about their perceived opinions on the benefits of offering a placement, 90% of industry respondents proclaimed this to be, above all, a good test-bed for potential staff after graduation. 59% saw it as affording opportunities for a two way flow of knowledge between university and industry while, 44% saw it as a source of new ideas from current education.

4.6 RICS Routes of membership & Training

The graduate route was the clear preferred route to RICS membership of both industry and academic respondents, with 91% of academics and 71% of industrial respondents supporting this. Appreciation of the other routes (Assoc. RICS and the Senior Professional route) was fairly evenly distributed across both sets of respondents. Not surprisingly, those involved in delivering education tended to have a greater understanding of this matter. When evaluating the appropriateness of the routes to membership, a marked difference emerges between the two groups. Whilst the most favoured by both is still the Graduate route there is also a marked tendency by industry to support both the Senior Professional and the Assoc. RICS routes.

When considering the importance of attaining Chartered status in one of the leading professional bodies, both industry and academia are in agreement that by far the most important is the RICS with 56% and 62% of respondents respectively rating it extremely important. This is perhaps not surprising considering the survey population reflects full members of the RICS. With respect to the importance of a Structured Training Programme (STP) for APC, 95% of academia considered this to be either very or extremely important as against a total of just over 70% from industry. The level of provision of STP in industry is markedly low when compared with its perceived importance. A staggering 44% of industry respondents indicated that their organisation have no STP. Whilst it should be remembered that the sample sizes varied quite considerably there were 8% (24) of respondents from industry who ranked the STP to be not important at all as against 0% from the academia. There were a further 6% (19) from industry who thought it was of little importance. These are significantly worrying figures when APC guidance clearly champions the need for a comprehensive STP.

4.7 Alignment Framework

The research primary focus was to evaluate the views of the three main stakeholders in education of graduate Qs, the universities, industry and RICS. The universities were

represented by academics responsible for programme delivery whilst industry was represented by PQS, contractor or commercial (CQS), public sector and other specialist quantity surveyors. The views of these stakeholders and their relationship with the RICS and its role were also investigated.

There are considerable differences in views and levels of responsibility from all stakeholders, born mainly of inaccurate interpretations of competencies and lack of commitment. For example both industry and academia view structured training programmes for APC candidates as important but very few provide these. This is lack of responsibility.

There is no defined level of competency achievement for graduates. This leads to academia interpreting it in one way and industry interpreting it in another, resulting in discontent for both parties. This is lack of definition. The levels of achievement of competencies required for attainment of Chartered status is well defined by the RICS (2009a). But the expected level of achievement of competencies by graduate QS of a RICS accredited programme is not defined. This lack of a common benchmark for the interpretation of achievement of competencies clearly contributes to the dissatisfaction and false expectations on the part of the industry and demoralisation of the graduate.

In order to address this situation and thereby align views of industry, academia and even the RICS the following alignment framework with 5 key elements is proposed.

1. *Graduate competency threshold benchmark (GCTB)*: A clearly defined graduate competency level achievement threshold should be created that is clearly aligned with APC threshold benchmarks defined with graduate career progression in mind.
2. *Re-evaluation of status of competencies*: A detailed study should be undertaken to re-evaluate RICS QS competencies.
3. *University-Industry collaboration*: Greater levels of university and industry collaboration in developing and delivering QS programmes should be made an essential part.
4. *RICS-University-Industry partnership*: The current RICS-University partnership should develop more of a tripartite relationship with regular industry representatives forming part of the partnership.
5. *Review of stakeholder roles and responsibilities*: A radical review of how a Chartered Surveyor is developed from their early stages to Chartered status must be undertaken where the role of each stakeholder is well defined to avoid wrong interpretations and subjugating responsibility.

The dilemma of attracting high calibre people with good knowledge of industry practice to academia and retaining them is one which both universities and industry will have to resolve for the sake of development and enhancement of the profession.

5 Conclusion and Further Research

The research aimed at investigating the changing developmental needs of Quantity Surveyors within a post recession industrial environment that satisfies the aspirations of industrial and academic stakeholders. A review of RICS QS competencies was initially conducted followed by a survey to ascertain views of academics on QS education and a

survey to ascertain views of industry (consultants, contractors, public sector and other specialist chartered quantity surveyors) on similar subjects.

The RICS has formulated clear and detailed documentation (RICS, 2009) identifying, classifying and explaining QS competencies. These are primarily aimed at providing guidance to APC candidates seeking full professional membership of the institution. There are 24 QS competencies classified as Mandatory (10), Core (7) and Optional (7) achieved at prescribed Levels of 1, 2 or 3. There is no such systematic approach or guidance as to what level of competency need be achieved by a graduate completing an RICS accredited honours degree programme. At present, it is an estimation of whether core competencies are addressed accordingly. What was clearly found in this research is that the absence of a threshold benchmark that clearly defines graduate level of competence has led industry to have unrealistic expectations, and academia to aspire for unattainable levels of competence producing a less than satisfied graduate that lacks direction.

Diverse views were found on key elements of research relating to QS competencies, education and development. The primary reason for dissatisfaction with any process comes from the difference between expectations and outcome. There were very high expectations of graduate competencies but the outcome does not seem to satisfy these. There were several endemic problems related to QS competencies both in academia and industry, originating mostly from the absence of defined or prescribed levels of graduate competency. There were diametrically opposing views on the ethos of graduate education, industry seeing it more as training graduates for direct employment whilst academia saw it as educating graduates with a core knowledge base for professional employment. This issue is further aggravated by the industry having less trust in the curricula used and the academics knowledge of current practice. The industry is faced with the dichotomy of greater collaboration but lack of a suitable mechanism and commitment to proactively influence the process of graduate education.

The proposed alignment of views framework takes account of the underlying situation presented above (Perera & Pearson, 2011). Therefore a framework with 5 key elements was proposed and they include: Graduate competency threshold benchmark (GCTB), Re-evaluation of status of competencies, University-Industry collaboration, RICS-University-Industry partnership and Review of stakeholder roles and responsibilities. The outcome of successful implementation of the proposed framework requires a concerted effort by all parties for the development of Quantity Surveying graduates who are industrially relevant, professionally qualified and with a sound academic background.

The implementation of the key elements of the alignment framework will require further research in the development of the Graduate Competency Threshold. Further research will also be required to re-model the RICS partnership process as envisaged in the framework. RICS competencies need to be re-evaluated to find currency and relevance considering current and future developments of the profession. The final element of the alignment framework will also involve a considerable degree of research to fully establish the roles and responsibilities of the key stakeholders in the profession (industry, academia and the RICS) and to create a holistic view of the profession and how it develops the professional.

6 Acknowledgement

The authors would like to acknowledge the assistance received from all respondents to both the nationwide Academic and Industry surveys in the conduct of the research. We would also like to express our deep gratitude to all Expert Forum members, Mrs Vivian Small and all officials of the RICS for access to and permission to use their membership database. The financial support received from RICS Education Trust (grant No. 401) and co-funding by Northumbria University is highly appreciated for the successful completion of this research. Full details of the research could be found at <http://www.northumbria-qs.org/index.php/completed-projects/rics-alignment-of-views>.

Culture of External MENToring – using alumni to support current students

Dr Fiona Grant BSc (Hons) PhD FRICS MCIOB FHEA

Abstract:

This paper reports on a pilot project of mentoring students which has been run by Dr Fiona Grant, School of the Built Environment, Heriot Watt Univeristy. It describes the difficulties faced by full time UG students trying to develop and gain industry experience whilst completing their studies. The Culture of External Mentoring (CEMENT) initiative paired current students with alumni who had completed the same or similar degrees and who could provide support and guidance on course content, it's relevance and career advice. The outcome has achieved much more than previously anticipated with the relationship between student and mentor developing quickly and resulting in work placements, site visits, coursework case study material etc. The paper presents the mentoring scheme and the achievements so far in the areas of student employment opportunities, links to industry, course development and increased student motivation. It concludes by showing that involvement and collaboration between HEIs, employers and professional accrediting bodies is a key factor in creating a graduate with skills relevant for the 21st century.

Keywords:

confidence, employability, mentoring, opportunities, relevance,

1 Introduction

The current economic climate impacting on the construction industry has resulted in fewer undergraduate students finding work placements and gaining work experience as they complete their studies. The recession has led to contractors and private practices reducing their staff workforces and the slow recovery from recession has led to increased competition for the few vacancies available. Staff who have remained in employment during these unstable times are under increased pressure to deliver projects with minimal workforce and are working to capacity, resulting in them having limited time available to provided support, guidance and nurturing to the student/graduate who are keen to gain invaluable experience to support their studies. These circumstances have created a situation which is forcing current built environment graduates to turn to other careers, leading to a potential for large skills gaps in the industry.

When the market was buoyant and graduate employment was high, recruitment to the built environment profession was secure. Summer work experience, sponsorship, sandwich placements, graduate recruitment and part-time study had reached all time highs. Graduate positions were being offered to undergraduate final students in December of their final year, the job was secure and not resultant on the final degree classification obtained, merely on how quickly the graduate could commence work. This situation led to students having three or four job offers available and becoming strategic in the completion of their final year studies. Why work extremely hard to aim for a 1st or 2:1 when a lower classification was sufficient to secure employment?

This set of circumstances could not continue and the impact of the recession has certainly changed the situation. Employers have vigorously reduced graduate opportunities available, sponsorship schemes have faded away due to lack of employer commitment and summer work experience is extremely difficult for students to secure. Lack of response from employers to students' enquiries relating to work experience (many offering to work unpaid) are being ignored and unanswered. This behaviour is having an impact on students, getting them to question their choice to pursue a career in the built environment, with many opting to move to other professions once graduating.

This has led to:

- Limited opportunities for students to undertake work experience, thus receiving a poor return on CV enquiries;
- The relevance of the course material not being appreciated as practical application in industry is lacking;
- Students requests to have opportunities for site visits, guest lectures etc being hard to achieve;
- Students satisfaction of learning experience – low motivation due to lack of work experience;
- Students lacking confidence in their skills and knowledge, readiness for the workplace.

Some HEI websites suggest that the lack of placements became particularly acute in 2009. 'The impact of the recession on construction professional services' which found that 46% of such firms had made redundancies contributing to Office for National Statistics findings of a 400% redundancy rise for construction professionals between November 2007 and November 2009. Architects and quantity surveyors were affected the most. (Williams et al, 2010)

Employers are realising that due to a lack of work experience, graduating students need to be supported and introduced to the workplace. The theoretical knowledge gained at university needs to be out into practice (many for the first time after graduating) and this causes concern on the relevance and content of university degree programmes.

The lack of communication between academic, industry and professional bodies needs to be addressed and the three stakeholders need to be brought together to reduce the impact of the recession on current graduates.

Partnership universities foster stronger linkages with industry through the recognition of new knowledge or other advanced scholarship created in professional or equivalent environments. Recommendation – Research funding, teaching and accreditation. The future of Surveying Education, a report commissioned for the RICS Education Trust golden jubilee, March 2006.

This paper investigates one approach adopted to try an achieve this and evaluates its success.

2 Project aims

The aim of this initiative was to strengthen the links between construction management and surveying (CMS) undergraduate students and built environment professional practice by inviting previous CMS alumni; to mentor current students, providing support and contributing to their discipline knowledge development. In addition this helped to maintain the programmes position at the forefront of providing CMS provision and strengthened the awareness of the quality of our graduates, increasing their profile in the built environment profession, ultimately resulting in increased employment opportunities.

The pilot asked recent graduates to mentor students studying on the CMS programmes. This allowed current students to see the relevance of the course content and provided an opportunity to network with industry professionals.

The objectives were:

- Link programme content to industry practice – applied nature of degree
- Increase the opportunity to gain relevant employment – Summer and graduate employment
- Strengthen the links to companies and organisations who have employed current and past graduates
- Build the reputation and confidence of current student cohort as they complete their studies
- Encourage academic staff development and inclusion of employability in the curriculum.

3 Literature Review

The lack of employment opportunities is a result of the economic climate. In a report by Roberts it was stated that ‘In the current climate, there are limited opportunities for graduates. While there is a realisation that the industry needs to look forward two or three years, to a point in time when it is known there will be a need for graduates again, a lack of confidence is currently preventing this. There was evidence that input from industry in the form of guest lectures, awards, placements and sponsorships have been reduced due to financial cost in the current market condition.’ (Roberts et al, 2009)

Accordingly this has led to reduced opportunities with some programmes of study removing work experience as an explicit credit bearing part of the degree programme. Williams commented ‘Reasons given for the decline in sandwich courses include; placements become an optional variant in courses rather than compulsory. Lengthy placements reduce the fees that HEIs can charge to students and lengthen the study period for the student. Integrating work placements into the programme, quality assurance and assessment, proved difficult.’ (Williams et al, 2010)

‘Employers are recognising that this is a growing problem and have indicated that ‘In the current climate, that there are limited opportunities for graduates.’ (Roberts et al, 2009) Mentoring of students is one method of trying to address this situation and the impact this can achieve has been supported by the mentoring scheme employed in other areas. The ASME Professional Practice Curriculum enables engineering graduates and

early-career engineers to enhance their soft skills and make the transition into the workplace. They have found that ‘many young students lack sufficient experience to imagine what kind of work they might do as professionals’. One of their goals is by the use of mentors from industry to guide and support an undergraduate student and ‘provide a "map" of the terrain and a "travellers’ guide" to the professional universe they may someday encounter’. (ASME, 2011).

The impact of the current climate specifically on Scotland has led to major projects being put on hold or stopped. Williams reported in December 2010 ‘Famously, Scottish undergraduate degrees are at least four years and perhaps more in vocational subject so longer than is usual in the rest of the UK. In Scotland during 2008-2009, plans for major building projects were put on hold or collapsed, and house building ground to a standstill – though both of these happened across the UK. It was reported that Scotland lost more than 8% of its construction workforce 2008-2009, approximately 20,000 jobs.’ (Williams et al, 2010)

The impact of recession has varied across the regions. In January 2010, a Federation of Masters Builders survey suggested regional disparities in the recession’s impact on small to medium sized firms (Federation of Master Builders, 2010)

Existing sponsorship opportunities have had to be discontinued and employers are finding it difficult to commit to offering work placements. ‘An example was given where once practice had given guest lectures, awarded two to three sponsorships and taken students into the firm for 2+ weeks experience. If suitable, the students were given the opportunity to join the firm after graduating. This had initially worked well but interest from institutions and students had been lost. This, along with current market conditions, resulted in the scheme stopping.’ (Roberts et al, 2009)

Another impact is the Browne Report (2010). It is possible that clear expression of employment prospects by HEIs will become increasingly critical once the changes proposed by Browne as accepted by Government are in place. (Williams et al) This is further acknowledged in the work undertaken by The Built Environment Skills Alliance and was presented in their recent report ‘The Future of Higher Education’, it stated that ‘Precipitate cuts by HEIs in the lead up to the new system in 2012 may create mismatches leading to failure in graduate supply and built environment provision., It further concluded that there ‘is a need to a more closely coordinate and avoid inconsistencies of interpretation in planned changes to higher education funding across the UK leading to an intended consequence that could reduce capacity and deliver what is needed by the built environment industries and so ensure future opportunities for future graduates.’

The relevance of course curriculum to employment is a key component to ensure students are graduating with the appropriate skills. Although this can be partially achieved by work-based projects and case study material, this is not as effective as the realism of working on a live project in a work environment.

Experience of ‘real work’ being introduced in a phased way to younger students, for example, site visits being integrated into the final year programme, practical approaches to the final year projects where these are set up round a work based problem. It was said solutions derived from such projects had been taken up by employers. (Towards a Construction and Built Environment Higher Education Strategy)

The work undertaken by Roberts et al for RICS Scotland, The Future of Built Environment Higher Education in Scotland reviewed the role of professional body input in the curriculum. The Executive summary stated – High value was placed by students on input to programmes from industry professionals and industrial placements. A recurring theme in the focus groups was the need for students to link theory from their course modules to practice. Linked to this, the benefits of industry scholarships schemes were stressed by the students and postgraduate representatives, in particular, suggested more practical experience in their programme would enhance their learning experience.

This is further collaborated by the findings of Srinath et al (2010) investigating the relationship between HEIs, professional accrediting bodies and employers. ‘Greater levels of university and industry collaboration should be made an essential part in developing and delivering QS programmes. Industry should take a more proactive role in collaborating with and actively providing feedback to the universities.’

The work of Witt and Lill (2010) comparing individual competences with education provision and industrial needs shows that there is a need to compare an individual’s learning requirements (derived from the Industry – Individual comparison) with the available study programmes. This relates to the role of HEIs in defining and developing the knowledge area within which all these comparisons are being made. The HEIs’ curricula must exceed the requirements of the professional standards in some respects because they not only provide education and training for current employment in industry but also aspire to address research and future industrial needs.

The author feels the role of HEIs is to provide relevant content and knowledge and develop Constructive Alignment – of learning outcomes, subject material and assessment methods referred to a course and module level now need to be considered at degree level. By aligning the requirements of HEIs, employer and professional accrediting bodies with the student at the centre it is feasible to nurture a built environment graduate relevant for the 21st century. Figure 1 illustrates this.

This practice is being encouraged across the built environment discipline, a scheme launched in 2011 called ‘The Pledge’, securing future talent in construction is a campaign which strives to solve the problem of unemployed graduates drifting away from the construction industry, it is aimed at supporting graduates by encouraging companies to take on internships. (CIOB, 2011)

CIC skills have also backed this initiative and state that ‘The Pledge research has shown that if every firm took on an additional 2 of their staff as interns, this would be enough to give each currently unemployed graduate at least one placement, however to date built environment-related vacancies posted on the site are few and far between.’ (CICskills, 2011) The encouragement and incentives are there but the collaboration and long term benefits for the graduate, employers and the future of the profession needs to be strengthened.

Figure 1 illustrates this relationship between the three parties with the student’s development at the centre

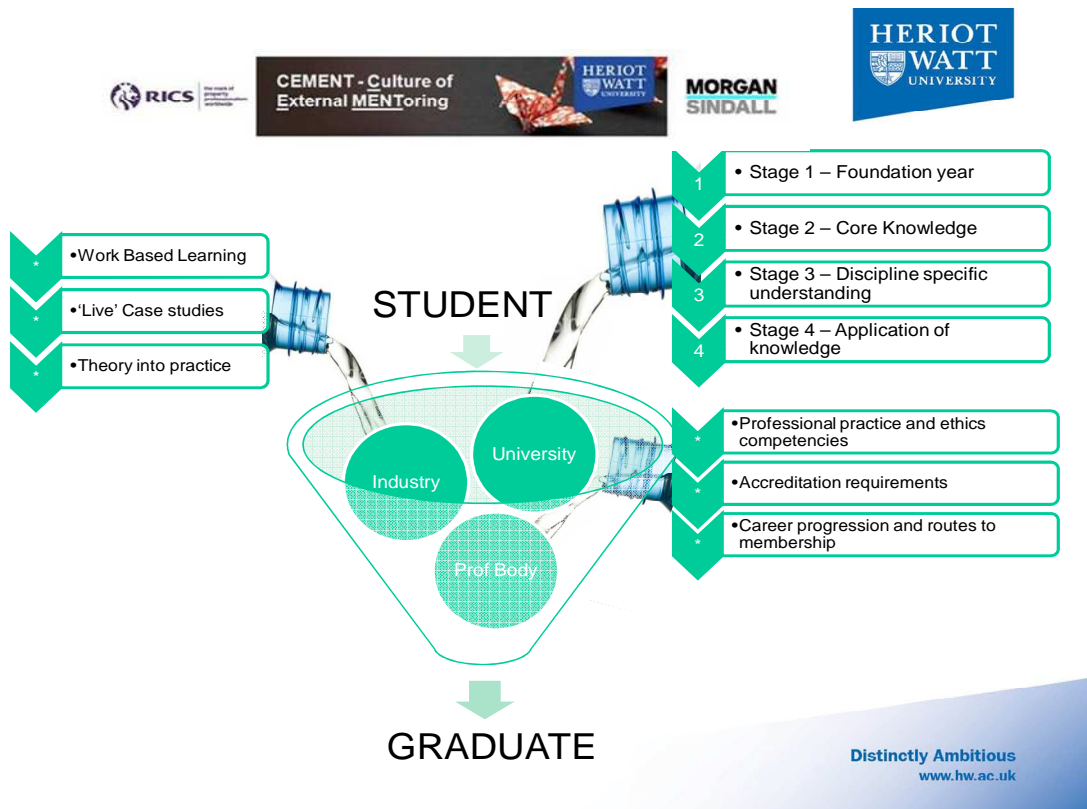

Figure 1: Development of relevant graduate skills

The findings from the literature review are summarised in the Table 1, it is interesting to note the various stakeholders concerns and issues with regards to the future of the built environment profession and the potential lack of graduate opportunities on offer due to the current influences from multiple factors impacting on education, career opportunities and students preparation for the world of work. The lack of collaboration between stakeholders is in many instances adding an extra layer of complexity to the problem and a more proactive and constructive effort to bring all together in working towards a solution has never been more important than at present.

Table 1: Stakeholders input in developing graduate attributes

Stakeholder	Relevance of course content	Opportunities for work experience during studies	Student employability skills
Student	This is not sign posted clearly enough and students are not confident in their abilities	Morale is low due to high rejection of CV enquiries and lack of opportunities and networking events	Students find it difficult to relate subject knowledge to work environment and find it difficult to describe their skills on their CV.
University	University documentation completed which is not directly linked to industry due to terminology used.	Sponsorship, sandwich degrees, work experience limited	This is sometimes difficult to promote due to students not liking theory with practice
Professional accrediting bodies	Course accreditation, competencies covered in curriculum and course content	Encourage students to undertake work experience and record competencies but this is difficult to achieve.	Low conversion rates from graduating students to full membership
Employer	Course content to meet the demand of the industry	Limited due to current economic climate	Students skills to meet the needs of the industry and the ability to develop in their career

4 Research Methodology

CEMENT has developed the opportunity for current undergraduate students studying Quantity Surveying, Building Surveying or Construction Project Management to have regular contact with industry through networking with Heriot-Watt past graduates and industry professionals.

By drawing on the School of the Built Environment's strong and well established links with industry and professional practice, a large number of CEMENT mentors agreed to participate. Many of our graduates are employed with the top ranked international companies; having successfully progressed in their careers, achieving senior roles, with responsibility for high value and complex projects completed around the world, the sharing of their experiences with current students has been invaluable. The achievement of our graduates is an outcome The School are very proud of and our aim is to continually strive to help our current students continue this high status and successful profile.

The relevance of the initiative to employability, professional competence and subject knowledge awareness has been a major factor in attracting both students and mentors to participate with such enthusiasm. It has played a key part in linking the taught course material with current practice, helping undergraduate students to establish the relevance of course content. The scheme has secured sponsorship from RICS Scotland and Morgan Sindall PLC (Scotland Region) who have welcomed the link and opportunity to participate.

4.1 Learning from mentoring

The objective of the mentoring relationship is concerned with facilitating learning. A useful model that explains how learning takes place is the Kolb's Learning Cycle shown in Figure 2 that stresses the importance of learners completing each of the four stages of

the cycle – **experience, reflection, generalisation** and **active experimentation** – before effective learning can take place.

Figure 2: Kolb's Learning Cycle

Learning requires opportunities to have an experience and to reflect upon it. Opportunities to work out rules or generalisations from these reflections allow the learner to experiment with new ideas or ways of doing things. Incidentally, it does not matter at which stage in the Learning Cycle the learning commences and it is equally appropriate for learning about personal issues as it is for work related issues.

Mentoring therefore may involve the provision of opportunities at all of the stages of the learning cycle. The Mentor and the Mentee will jointly decide on experiences that may be appropriate for the Mentee's learning and the Mentor may be able to provide access to these. After the experience, the Mentor will play an important role in encouraging the Mentee to reflect on that experience, perhaps by asking appropriate questions, or maybe even by asking the Mentee to keep some written log of their views.

Generalisation can be achieved by input from the Mentor – perhaps by giving their own experience of the topic, or by the Mentee reading books or journals about the topic and Active Experimentation may be the provision of another opportunity from which experience can be gained, and so on round the Cycle again.

4.2 The main requirements to be an effective mentor are:

Mentoring is essentially a means by which individuals learn and develop. It is different from a number of other learning situations as it is a relationship between two people and this is highlighted in most formal definitions of Mentoring e.g. “a protected relationship where **experimentation, exchange** and **learning** can occur, and **skills, knowledge** and **insight** can be developed”.

- **Commitment.** – to make the relationship work, Mentors need to be able to devote time and energy to the CEMENT initiative.
- **Action.** Mentoring requires action; results were only achieved by communicating with their Mentee regularly.
- **Skills required.** – Mentors were encouraged to work with their Mentee in objective setting, communicating, coaching and planning.
- **Effective networking.** – Opportunities to put their Mentee in touch with contacts, especially to develop wider industry awareness.

The diagram below shows the key characteristics of an effective Mentor.

Figure 3: Characteristics of a good mentor

4.3 Stages of the CEMENT initiative

The several stages in this particular programme are shown below:

- **Selection of Mentees:** Mentees are in their third year of study. The programme was publicised and outlined by the department of Construction Management and Surveying. The students have been participating in the programme as an integral part of their professional development practice within their studies.
- **The Matching Process:** Students were matched to a suitable Mentor by the CEMENT Programme Coordinator. Both Mentors and Mentees were then notified of their match by email at the beginning of the academic year.
- **First Contact - Getting to know each other:** Students were tasked to arrange an initial communication with their Mentor as soon as possible for this purpose at the start of the year, beginning the mentoring relationship.
- **Communicating and working together:** There were no hard and fast rules about how this would work. Each individual mentoring relationship was anticipated to work this out depending on the commitment of both parties, bearing in mind that previous participants in other schemes valued additional contact in addition to the minimum expectation of a meeting twice in each semester.
- **Reporting back by Students:** Students then provided feedback information on how their mentoring relationship was progressing at Mentor meetings held with their 'Academic' Mentor on two occasions each semester.
- **Reviewing and Evaluating Progress:** This was undertaken by both parties on an ongoing basis. There was also a formal evaluation involving all parties at the end of the programme.
- **Saying Goodbye:** Bringing this particular relationship to a close through an evaluation meeting over lunch with all the participants on the programme.

4.4 Time commitment

There are a number of aspects to this as illustrated in Figure 4:

- An induction meeting was held at the University together with other Mentors to learn more about the programme;
- The initial communication with the Mentee (Week 2 during Semester 1).
- Regular contact – at least a further three communications completed during the academic year, Week 9 or 10 of Semester 1, Week 2 or 3, Semester 2 and Week 9 or 10, Semester 2. Contact was in the form of e-mail, telephone conversation, face-to-face meetings of one hour (maximum) or involved the Mentee shadowing their Mentor for a day at their place of work, and;
- Final Evaluation and Review, evening event held at the end of Semester 2.

Figure 4: CEMENT time commitment over the academic year

5 Findings and Discussion

The CEMENT initiative has proved successful during the pilot year of delivery. The relationship between mentor and mentee worked and in many cases exceed the aims and objectives of the scheme. A selection of comments and feedback received from mentors and mentees is presented below:

“My mentor has been more than accommodating at responding to requests for information and a chance to meet and chat about his experience. We have recently had a day out and visited the head office and various current contract sites. The experience was invaluable and has possibly opened the opportunity to some Easter and summer work experience.” Student

“I had a meeting with my mentor which went very well, he has offered to meet up every fortnight on site and will set some tasks. He was very positive about the mentor scheme and had a welcoming attitude towards me. I believe that I will benefit from the external influence and am looking forward to the experience.” Student

“Excellent communication with students, he is very interested and is already looking at life beyond university and is asking how the modules he is studying relate to the industry.” Mentor

“The CEMENT programme I have found to be very useful for both the mentor and student. I introduce the student to e-mailing lists for invitations to seminars which are valuable for learning and networking.” Mentor

Additional benefits from the mentoring scheme have provided opportunities for guest lectures, site visits, case study material, review of course content and potential new course proposals, as well as CPD initiatives etc. Academic staff have also had the opportunity to clearly sign post to students the relevance of the course content and be able to relate this directly with the communication students have had with their mentors.

The success of this pilot has been the inclusion and involvement of the University Alumni and Careers Service to provide the contact details of past graduates and to assist in developing the role of the mentor. To duplicate this scheme in other institutions it needs to be led by an academic who has regular contact with the students (year tutor, programme leader etc) to keep the relevance and opportunities of the scheme clearly evident at the beginning. Once links to the mentor has been established by the student peer discussions on the rewards and benefits is sufficient for the student to take ownership and build the relationship with their mentor.

The rewards can be summarised as:

- Increased site visit opportunities
- Summer work placements being offered
- Industry Liaison Advisory Group - renewed momentum and involvement in curriculum design
- Higher profile of Construction Management and Surveying students in the built environment profession.
- Positive feedback from students; mentors; university and professional bodies

6 Conclusion and Further Research

The role of all stake holders in securing the future of the built environment profession has been examined in this paper and it is evident that a joint approach to addressing the current issues and circumstances is required to achieve a solution and create the momentum required for the solution to be long term and not based on only being successful when the market is favourable.

Encouragement and support to undergraduate students by industry mentors during their degree studies is key to developing a graduate who is prepared for the 21st century and can link the learning knowledge developed through their studies with the 'real' work environment. The earlier this can be encouraged in a student's learning process the greater the impact on their motivation and understanding of their future career potential.

The involvement of industry practitioners in a mentoring capacity has proved to have additional benefits for the HEI, the individual mentor and their employing organisation. It has helped mentors develop their skills in this area and has created a link between academic and university which is more structured and presented opportunities for dialogue not necessarily previously available.

The impact of having this clear link to industry has influenced the material content of courses and academic are now clearly signposting the relevance of the topics studied and the inclusion of employability skills in the curriculum, which in the past were there but never implicitly clear to students due to limited work experience.

It is planned to develop this initiative further to offer a similar opportunity for our postgraduate students during the next academic year; this will be a more challenging project due to the international cohort of students completing the degree programmes. To further investigate the benefits of the mentoring opportunities all students participating will complete a questionnaire at the beginning and end of the academic year to evaluate the impact of mentoring. This is similar to an exercise undertaken by Whiteside et al, when they introduced mentoring of undergraduate research assistants.

Achievements of the CEMENT initiative include:

- Increased opportunities for students to get out into the workplace.
- Relevance of the course material now appreciated as practical application in industry evident
- Students value opportunities for site visits, networking with industry, knowledge transfer etc
- Students increased satisfaction with their learning experience
- Students growing confidence in their skills and knowledge

We constantly hear that Universities, professional bodies and employers should be working in closer harmony to achieve the graduates of the future, even after the first year of operation this scheme is proving successful in achieving this as several students have gained placements with their mentors over the summer period.

Abstract:

An effective response is required to climate change and the steady diminution of resources of our natural world. We are all situated within and dependent upon the Built Environment for our survival. We all benefit from buildings and infrastructure. The creation, refurbishment and maintenance of this environment is a £100 Billion industry. Each new build operation, every refurbishment and the operation of existing systems all consume resources, in many cases scarce and non-renewable. What is vital is awareness in those actually responsible for the creation and renewal of the facilities referred to above? There can only be a concerted effort at sustainable building when there is genuine, informed, concern on the part of all members of the construction team. Perhaps we should look to our providers of construction-related education to instil students with increasing awareness of the issues. The current study examines the extent to which there is appreciation of issues of sustainability amongst educators and the extent of their inclusion within the curricula of (in this case) Quantity Surveying students at a northern university chosen for the study. The literature review findings and results from the content analysis of the series of interviews conducted suggest the level of inclusion appears to be low. This supports findings from the recent RICS research, which suggested that sustainability may be evident across only 3-5% of the curricula of most Quantity Surveying programmes, and incorporated at a basic level only.

Keywords:

carbon, construction education, quantity surveying, stakeholders, sustainability development

1 Introduction

“Construction has the potential to enhance rather than degrade the environment and to promote rather than exasperate social and economic equity. If this potential is to be realised, everyone within the industry will need to attain some level of sustainability literacy” (Murray and Cotgrave, 2007).

Given this statement, Murray and Cotgrave have set the stage for discussions on the future of the study of sustainability in the built environment. Many proponents in this area share this view and they believe changes are necessary to accommodate the needs of a changing world. The increasing emphasis on climate change has generated considerable interest in the sustainable development (SD) agenda throughout the world. In the UK, like any other country, there is increasing awareness of the significance and value of having a sustainable environment (Khalfan, 2006). The SD issue is one of the greatest challenges facing the world. In the built environment (BE), the challenges are large given the size of the construction industry, which account for 8% of GDP. The enormous amount of resources it consumes, the major impact of its products and activities on the BE in particular and the society at large, contribute to the economic well-being of the country; the social well-being of people and the impact on the environment (Cowling *et al.*, 2007; BERR, 2008). Theron (2010) estimated that the BE in its widest sense is responsible for 40% of CO₂ emission, as well as 40% of all energy used. The Kyoto protocol, EU Emission Scheme, recent changes in building regulations and the Climate Change Bill all indicate a growing recognition of the need to minimise the consequences of human activities on the environment. These initiatives have created the need for major reform in the UK construction industry and educational systems.

There are many proponents in this area who believe that the green agenda and construction education are intricately linked (Walton and Galea, 2005; Cotgrave and Alkhaddar, 2006; Hayles and Holdsworth, 2008; Theron, 2010). The rationale therefore, for embedding green issues within the construction curriculum is a powerful and imperative one. The rationale has mainly come as result of policy drivers and in some cases existing research or surveys in this area, but the response from academics so far is patchy. However, it is increasingly recognised that the curriculum should incorporate sustainability or green issues and produce graduates that are confident of taking care of the environment without damaging it for future users. Hayles and Holdsworth (2008) argued that the 21st Century is seen as the time for the UK universities to embrace new ways of working. This is especially important if the educational system is to continue to be competitive and also meet the needs of its increasingly demanding stakeholders. A major challenge for the universities however, appears to be on the question of its ability to provide products and, to an extent, services that meet stakeholders needs and aspirations, especially in relation to the sustainability agenda.

This paper has been developed in response to a growing interest in the sustainability agenda in the educational curriculum. The authors of this paper are particularly interested in identifying the quality and quantity of sustainability-related materials within the quantity surveying curriculum. The study is intended to describe the current state of affairs through the examination of a North East (NE) case study and identify broad and specific changes needed to bring about more incorporation of sound sustainable quantity surveying practices. However, the research project outlined in this paper attempts to establish and map the sustainability activities within the quantity surveying (QS) programme. To achieve this, a review will be undertaken to determine the main areas of interest in sustainable construction particularly in relation to the QS field. Primary data will be collected using a case study of the QS staff in Northumbria University in the NE of England. The results will be used to qualitatively map the extent of sustainability-related features within the curriculum in the QS programme. The findings from this paper will be drawn from both the secondary and the primary data analysis showing limited application of sustainability-related education within the

curriculum. Further research will aim to quantitatively map the extent of sustainability education within the QS curriculum and also recommend strategies of how such sustainability-related education can be incorporated into the curriculum to aid in producing graduates that can confidently take care of the environment.

2 Literature Review

“Sustainability”, “Sustainable Development” and “Sustainable Construction” are words that have become common currency in recent years. They are phrases that are interpreted in different ways, but the underlying suggestion is one of doing things differently and better. In the UK, with climate change high up on the government and industry agenda, sustainability arguments are in strong demand. Numerous definitions have been proposed by various proponents working in this area. Despite its ubiquitous use however, there is an apparent lack of academic definitions of what exactly sustainability is meant to be within the curriculum. This section will review the fundamental change of the Sustainable Development Education at Higher Education and identify the challenges the quantity surveying programme will face if the sustainability agenda is not addressed in the curriculum.

2.1 Greening the Curricula

In light of the above statement on the sustainability agenda, this paper explores the views of some academics of current sustainability-related education within the built environment curricula. A review conducted of research in this area found that there are a number of studies that have been done to explore the opportunity to embed sustainability agenda into the built environment curricula (Sayce *et al.*, 2009; Iyer-Raniga *et al.*, 2010; Hayles and Holdsworth, 2008; Cowling *et al.*, 2007; Murray *et al.*, 2006; Cotgrave and Alhadder, 2006; Fenner *et al.*, 2005; Perdan *et al.*, 2000). These studies have been carried out to encourage staff to make commitment to sustainability by making changes to their modules or provide new modules for student learning.

As early as 2000, Perdan *et al.* attempted to adopt a multidisciplinary approach to teaching sustainability for engineering students at the University of Surrey and they developed IT-based learning materials and case studies to facilitate students’ better understanding of concepts of sustainability and how solutions could be developed. Fenner *et al.* (2005) did similar study; they reviewed the education for sustainable development (ESD) in Engineering Department at Cambridge University and encouraged students’ self-reflective learning processes to obtain their own solutions for the challenges of Sustainable Development.

In the built environment, Cotgrave and Alkhaddar (2006) reviewed the undergraduates’ construction management curricula at Liverpool John Moores University and established that the sustainable design and technology was superficial within final year study. Further studies found that the students’ attitudes towards environmental issues were very low or non-existent. Murray *et al.* (2006) implemented a full curriculum to identify the gap in provision of sustainable construction education at Plymouth University. Their study found that although discipline-specific environmental aspects were being included in the curriculum, but few generic aspects of sustainability such as citizenship, poverty were being covered.

Cowling *et al.* (2007) argued that education for sustainable development has become increasingly significant within the built environment higher education curriculum at Kingston University. They explored students' familiarity, understanding and interest in sustainable development (SD) and how these developed over their time at the university. Their results showed that the school's emphasis on SD had an opportunity to contribute greatly to the students' awareness of the subject given that they entered the courses with interest but a low knowledge base.

Hayles and Holdsworth (2008) conducted an action research project at RMIT, Australia to embed sustainability agenda into the core curriculum of the school of property, construction and project management undergraduate programme. Their results showed how sustainability issues were embedded into three new modules. However, further exploratory research is needed to show how sustainability can be embedded within the whole of the built environment studies. In a more recent study, Iyer-Raniga *et al.* (2010) conducted research with construction management students at RMIT to compare students' sustainability activities between Melbourne and Singapore. Their finding showed that there does not appear to be any significant differences in the perceptions, knowledge and understanding of sustainability issues between the two sets of students.

While the list of previous works in the area of sustainability education in this review is not exhaustive, it does indicate the wide range of proliferation of research projects that should be considered in determining a more sustainable course of action to incorporate sustainability-related education within the quantity surveying programme.

2.2 Challenges facing the Quantity Surveying Professional

Having introduced the concept of sustainability in BE education, the following section of the review will report the challenges facing the QS professional.

Previous researches have provided some understanding of the meaning and significance of quantity surveying (Lee and Hogg, 2009; Perera *et al.*, 2010; Simpson, 2010). The role of quantity surveyor as suggested by RICS (1971) cited in Nkado and Meyer (2001) is associated with measurement and valuation. They argued that quantity surveyors provide a proper cost management of construction project in the context of forecasting, analysing, planning, controlling and accounting. Other proponents in this area have suggested that competent quantity surveyors must have a range of skills, knowledge and understanding which can be applied in a range of contexts and organisations. What is clear is that the roles and activities of quantity surveyors have now become extremely diversified, with a range of employers to match. Ashworth and Hogg (2007) argued that their skills have been enhanced to meet these needs. However, within the same period, sustainability has emerged as area of growing importance to the construction industry. In the UK a number of construction companies have re-branded themselves to try and meet the needs of the sustainability agenda. The responses of the industry highlight that there is growing interest in the sustainability issue and that the sustainability issue is beginning to be taken very seriously.

Achieving progress towards sustainability is critical to the future well-being of society and this has long been recognised by HEFCE (HEFCE, 2010). They have placed sustainability as a major objective both organisationally and within their sphere of influence and activity. It is suggested that universities have a big role to play in tackling the sustainability agenda (Jones *et al.*, 2008). In HEFCE (2010) report, it is argued that

the universities and colleges are in a unique position to lead the way and change the awareness of sustainability agenda. It is therefore expected that universities will be at the forefront of embedding sustainability both within their own institutional values and within the curricula that they deliver.

Dixon (2009) argued that there has been progress over the last two years in linking sustainability into professional practice globally, but he suggested that the key barriers continue to be lack of knowledge and lack of expertise from graduates and experienced professionals. This reflects the inadequacy of training and education in universities. In the recently completed EcoBuild conference in 2010, Paul Morrell, government adviser on construction stated that the government's greatest worry is how to satisfy the carbon and green agenda. He went on to state that the construction industry does not have the capacity to meet the sustainability agenda because the universities are not producing the graduates with adequate knowledge.

It is crucial for the whole construction sector to make strong contributions to sustainable development. Many construction professionals such as architects and engineers lead the sustainable construction in the world. The industry is continually raising its standards; however, there is lack of evidence showing that Quantity Surveying professionals are demonstrating sustainability leadership in the business and services environment. It is of paramount importance to identify what types of new skills are required by quantity surveyors in order to tackle the sustainability agenda. RICS (2007) in their review identified all kinds of surveyors' competencies and have also identified a number new skills required for QS to provide sustainability services through the life span of a building project. The identified areas are: value for money, whole life costing, cost of alternative materials, renewable energy schemes, recycled content schemes, the ethical sourcing of materials and labour. Other key elements also discussed in other literature include; sustainable procurement knowledge & skills and sustainability performance measurement. Furthermore, RICS also listed a number of responsibilities for QS in terms of sustainable development:

Protecting and enhancing the natural environment

Encouraging the sustainable use of resources

Reducing waste generation and responsible disposal of waste

Reducing energy consumption

Promoting community development and social inclusion

Minimise any negative social or environmental impacts of development

Promote sustainable land use and transportation planning and management

Promote sustainable design, development and construction practices, including whole-life costing

Much has already been written about the skills which will be necessary for QS to meet the challenges outlined above. However there is a huge skills gap between the quantity surveyor in higher education and new skills. So far there is little research conducted to

investigate the incorporation of sustainability-related education within the QS curriculum. Achieving sustainability education with the QS curriculum will require an exploration of the general definition of SD and its three spheres; the economic, the environmental, and the social. In addition, one must acquire knowledge of regulatory and technological issues that encompasses both the parts and the whole in dynamic interaction. Dale and Newman (2005) argued that the key to achieving these skills is adaptability, meaning the ability to change, particularly in a changed economic climate and the threat of global climate change. Clearly universities operating in the built environment field have a vital role in shaping the future pattern of practice and policy in relation to the sustainability agenda. So, it is vital to map the curriculum towards sustainability. As a high profile university in the UK, Northumbria University could make a substantial, exemplary and on-going contribution to sustainability education by aligning its curriculum to address sustainability issues within the QS programme. This will enable the staff to educate and inspire the new generation of quantity surveyors and influence them to be tomorrow's leaders in sustainable development.

3 Research Methodology

Two distinct data gathering methods were employed to develop the sustainability framework relevant to Quantity Surveying (QS) and to qualitatively map the extent of coverage of the identified sustainability knowledge areas in the QS degree programme of the School of the Built and Natural Environment at Northumbria University. These strategies are illustrated below.

3.1 Use of Published Sources

A detailed literature review was carried out to explore the sustainability agenda and its impact on construction related curricula in general and QS education in particular. The main areas of interest in sustainability and the RICS QS functions in the light of current practice and future roles were identified through the review. This culminated in the development of a framework which identifies the sustainability knowledge areas relevant to construction and QS roles. The framework triggered and provided the basis for the later strategy used in the research.

3.2 Sustainability Mapping Case-study

A series of interviews were carried out with key QS staff to review and verify the framework developed from the literature findings. Subsequently, their views on the extent of coverage of the identified sustainability knowledge areas in the QS degree programme at Northumbria University, which is the research case study, were probed.

3.2.1 Sample Population

The respondents include the subject director, construction economics professor, distance learning director, programme leader and the year tutors of the QS programme at Northumbria University. These persons were deliberately chosen based on their accurate knowledge of the programme as they play a significant role in designing and maintaining the curriculum used to teach the QS students. In their different capacities, they are familiar with the entire range of modules that make up the curriculum and also with the contents of each module. Based on the above and their appreciation of the

learning outcomes at every stage of the QS degree programme, they are able to advise on the extent of coverage of sustainability in the curriculum used to teach the students.

3.2.2 Quantity Surveying Degree Programme

The QS undergraduate programme is either studied as BSc (Hons) Full Time for 3 years full-time or 4 years sandwich. In Year 1, (otherwise known as Level 4), studies focus on the principles of knowledge on which quantity surveying is based including undertaking a UK-based residential field study visit. Year 2 (or Level 5) concentrates on the role of the Quantity Surveyor in practice and also prepares students for work in the optional placement year. Students are strongly encouraged to undertake a placement year as it gives them the opportunity to put into practice what they have learnt in the first 2 years of their study before progressing onto the final year. In Final Year (otherwise referred to as Level 6), the broader role of the Quantity Surveyor is investigated whilst further developing relevant academic skills and also undertaking an optional European-based residential study visit.

3.2.3 School of the Built and Natural Environment at Northumbria University

Being a major university of its kind in the North East of England responsible for training construction students for the professional world of work, its programmes have to be sound, up to date and at the fore front of knowledge. This is absolutely critical if these are to maintain their absolute relevance well into the future and to keep attracting applicants from within the region and beyond - not least its QS degree programme, which is RICS Accredited and the largest in the School. The adequate inclusion of sustainable development as it relates to construction and the current and future QS function is one of the principal elements that could enhance its construction related curricula of the School in general and the QS degree programme in particular. This is also an area within which the government hopes to increase academic funding in the nearest future as a means of promoting the global sustainability agenda. It is therefore necessary to examine the extent of coverage of sustainability within the QS curriculum, to enable the programme continue to produce seasoned graduates confident of taking care of the built and natural environments.

3.2.4 Interview Process

Each of the identified respondents was probed, using a predesigned question format, on the sustainability framework. The framework initially developed from the literature findings categorises those sustainability knowledge areas relevant to construction and the QS profession in particular, into 6 main categories with several subcategories. Based on their knowledge, the respondents were asked to explain to what extent each of the stated subcategories in the list is covered in the academic curriculum of the QS degree programme, perhaps covered as an outline, as a full lecture, or as a module on its own. If not in the syllabus, they were asked to explain whether such work is planned for the future as a learning objective or is considered not applicable based on their experience. Also they were given the opportunity to mention other issues which they think should have been included in the framework. Their opinions about the sustainability agenda in generic terms and in specific terms to the QS profession, programme and the industry were also captured.

The significance of using this process was to gather qualitative first-hand information from key staff members who have major input to and knowledge of the QS academic

curriculum, born of their experience of the profession. Their “take” on the sustainability agenda and its relevance to the QS degree programme were revealed. Content analysis of the interviews conducted helped to identify other issues not already included in the framework and served as a catalyst for its refinement. The extent of coverage of sustainability in the current QS curriculum was revealed and ideas on how better to incorporate sustainability education into the QS degree programme, where considered relevant, were suggested. The refined framework, which identifies the sustainability knowledge areas, considered relevant to the profession and the QS degree programme is presented in the following section.

4 Findings

The literature findings and the interviews led to the development of the final sustainability framework which identifies the knowledge areas relevant to the QS degree programme and the profession. The framework has been developed in the light of the current and future roles of the professional quantity surveyor as informed by the sustainability agenda. According to the findings from the research, QS graduates will need to have awareness and knowledge of the issues identified in the framework (though to differing levels of detail) to be capable of taking care of the built and natural environments now and in the future. The refined framework (see Table 1) categorises the sustainability-related knowledge areas relevant to QS education into 6 main categories (high level categories) with several subcategories (low level categories).

Table 1. Sustainability Framework relevant to QS Degree Programme

SUSTAINABILITY FRAMEWORK						
HIGH LEVEL CATEGORIES	CATEGORY A - BACKGROUND KNOWLEDGE AND CONCEPT	CATEGORY B - POLICIES AND REGULATIONS	CATEGORY C - ENVIRONMENTAL ISSUES	CATEGORY D - SOCIAL ISSUES	CATEGORY E - ECONOMIC ISSUES	CATEGORY F - TECHNOLOGY AND INNOVATION
LOW LEVEL CATEGORIES	<p>Sustainable development overview and principles</p> <p>Climate change and global warming issues</p> <p>Impact of the construction industry on the environment</p> <p>Sustainable construction concept</p> <p>Role of QS in sustainable development</p>	<p>Changes to Building regulation, e.g. Part L (energy efficiency) and Part F (means of ventilation)</p> <p>Code for Sustainable Homes</p> <p>Energy Performance Certificate (EPC)</p> <p>The Kyoto protocol</p> <p>Relevant EU Directives such as the EU climate policy, EU ETS, etc</p> <p>Climate Change Act</p> <p>Sustainable Construction Strategy</p> <p>Sustainable Procurement Action Plan</p>	<p>Protecting and enhancing the built and natural environments</p> <p>Environmental Impact Assessments (EIA)</p> <p>Environmental Management Systems: ISO 14001</p> <p>Environmental Assessment Methods: BREEAM, LEED, Green Star</p> <p>Reducing energy consumption, that is, emitted and embodied</p> <p>Reducing greenhouse emission such as methane, carbon, nitrous oxide and refrigerant gases</p> <p>Carbon Agenda (Carbon footprinting, Zero Carbon, Retrofit)</p> <p>Waste reduction principles (recycling, reduction, reuse, effective design)</p> <p>Brownfield development</p> <p>Natural resources, renewable and non-renewable materials</p> <p>Water usage and Sustainable Transportation Plan</p>	<p>Corporate Social Responsibility (CSR)</p> <p>Ethical issues such as ethical sourcing of materials and labour, for instance</p> <p>Equity and social justice</p> <p>Community development and social inclusion</p> <p>Health & safety</p> <p>Employment, training and education</p> <p>Social assessment methods (e.g. Design Quality Indicators, KPIs and benchmarking, etc)</p> <p>Cost Benefit Analysis (i.e. impact of human factors on the community)</p>	<p>Cost planning and management</p> <p>Value management or engineering (cost of alternative materials and designs)</p> <p>Sustainable procurement strategies</p> <p>Feasibility studies</p> <p>Whole-life appraisal/ Life cycle costing</p> <p>Financial incentives (such as subsidies, climate change level, aggregate tax, carbon credit, Brownfield land tax, etc)</p>	<p>Renewable energy technologies (Photovoltaic, Wind Turbine, Geothermal, Biomass, etc)</p> <p>Green Building Materials</p> <p>Rain water harvesting and Grey water collection systems</p> <p>Professional and management software packages such as BIM, etc</p> <p>Modern methods of construction: offsite production, use of precast material, lean construction, etc</p> <p>Passive design methods such as day lighting, intelligent facades, carbon storage and offsetting, etc</p> <p>Supply chain management</p> <p>Effective information control and management (using e-business)</p>

Content analysis of the interviews conducted was carried out and this helped to identify other issues not already identified from the review, and also served as a catalyst for the refinement of the sustainability framework relevant to the QS degree programme. The

next section presents a critical discourse and summary of the sustainability education, QS degree programme and sustainability framework, extent of coverage and ideas on promoting sustainability education in QS degree programme based on the literature review findings and content analysis of the interviews conducted.

5 Discussion and Conclusion

Awareness is growing amongst the general public, encouraged by Politicians at Local, National and International levels, of the need to reflect upon the relentless consumption represented by maintenance and growth of the Built Environment.

We shall not survive by mere reflection and associated promises but, rather, by making best use of those scarce and sometimes non-renewable resources left to us and by seeking sustainable solutions for the long term future. Those involved in the construction industry will be key players. Specifically, the Quantity Surveyors, with their perspective on the economics of construction will be crucial. However, this “economic perspective” must be expanded beyond that of mere capital cost of construction (the traditional boundary of their skill) to embrace a perception of the life time cost of the buildings, of the districts, of the cities even in which we all live, together with the infrastructures which serve and link them.

The researchers have examined the core body of knowledge currently taught to students on a Quantity Surveying degree, the very people who in five or ten years time, with other construction professionals, will be responsible for shaping and managing the built environment. Through a series of interviews with key staff, those responsible for developing and directing the Programme, the study revealed the role which sustainability plays in the students’ studies, and the importance afforded it by those who teach. More detailed work in future, through questionnaires issued to all staff responsible for the delivery of the degree, will look at specific module curricula.

The research findings so far appear to support those of earlier researchers in the area. The study results seem to indicate that there is quite a large sustainability-related void in the education of student Quantity Surveyors, and quite possibly those in other disciplines within our School, studying to be members of the construction team. The current research has indicated two possible causes. Firstly, it appears that realisation of the very real threat we all face is only just becoming apparent to Academic Institutions as a whole and to the Professional Bodies, who to a significant extent direct the pattern of our curriculum. Secondly, few existing academics have enough detailed knowledge of sustainability-related issues to incorporate the subject confidently within the materials which they deliver. They themselves were educated in and possibly also worked through times when the sustainability agenda had not yet been uncovered. Apparently there was no threat to address. To some extent, education on matters of sustainability needs to extend up the chain, to those doing the teaching as well as down it, to students now and in the future.

One practical reason cited for the apparent failure to recognise and address the significance of the sustainability issue, often given in apology and sometimes as an excuse even, is the lack of spare time or space within the existing curriculum. “So much to teach, so little time to teach it in” is the cry. However, awareness of the sustainability agenda and its importance to what we do is vital for our survival. Therefore, whilst it is

not suggested that academics should talk of nothing else, the research implications suggest that they might plant an awareness of its relevance to most things, emphasising it to a greater or lesser extent its importance across the whole of the existing curriculum. To certain subjects such as Law and Management it may indeed seem and be somewhat peripheral. To Construction Technology and Construction Economics, for example, it must surely be of fundamental importance?

The examination of the existing curriculum, and of curriculum leaders' perceptions of its content and delivery at one sample institution suggests some uncertainty as to exactly where, and how, sustainability-related issues should be delivered. It is hoped that eventually it will be possible to produce a template, illustrating the relevance of sustainability to each key subject area, and ways even by which it may be effectively incorporated. A number of specific suggestions were made by interviewees both as to the general direction which teaching might take, and on specific areas worthy of increased emphasis within the syllabus.

All (participants) agreed that an appreciation of the sustainability agenda should be a thread visible through all teaching at all levels. It was suggested more than once that where a multi-disciplinary School set-up existed every appropriate opportunity should be taken for students of differing disciplines to work through these issues together, as they will one day have to in their professional lives. There was agreement that, where possible, classroom work should take as its model, data from local schemes which exemplified good practice in the field. Also, current research within the School has much to offer. Opinions differed as to the value of studying in any depth the social costs of sustainability (as represented by exercises in Cost Benefit Analysis) – not seen by most as primarily the concern of the Quantity Surveyors. All were agreed however that the technological and cost implications were crucial, together with the ability to transmit these concepts effectively to clients.

Participants agreed that:

“ [whilst] Quantity surveyors are not there to advise on designs for sustainable development, which is the designers' job really [they] should be trained to understand the technologies involved and their implications more in terms of costs.”

As noted in a recent RICS research by Perera and Pearson (2011), sustainability ranks low in terms of the percentage part it plays in the curriculum at present, although other research has shown that a growing body of Professionals in practice do recognise the part it must play in their future workload. Surely academic institutions must do better than what has been done so far to equip the Quantity Surveyors of the future for what will surely be a pivotal role, in terms of the management of time, cost and quality in deciding the future costs to society of sustaining the Built Environment.?

As one interviewee remarked “SD is not going to go away... students are going to go out there in the next couple of years upon graduation to confront these issues which [are] out there and [are] not going to go away.”

6 Further Research

This paper presents the results of interviews carried out with quantity surveying staff at Northumbria University to establish the sustainability-related content within the curriculum. The research is part of a larger research within the school which aims at diffusing sustainability into the curricula of all built and natural environment programmes at Northumbria University. This research and others have established that a holistic understanding across the disciplines is needed in order to accommodate the still evolving concept of sustainability. Consequently, future research is needed to extend or map the sustainability education within other construction related programmes in the school. This will enable decision makers to have a better understanding of the situation. Also, it is of paramount importance for further research work to consider and explore the link with other stakeholders. A key strategy for incorporating sustainability education within the construction related programme would be to include professional bodies, industry and students' perspectives in future research work. For any meaningful strategy to be later developed based on this research, the input from various relevant stakeholders is necessary to establish what is required and how the strategy will be implemented. Finally, it is anticipated that this strategy will lead to the development of a methodology that schools or universities generally can use to incorporate sustainability education within their curricula.

Ethics, Leadership and Education

Mart-Mari Archer, Prof JJP Verster

University of the Free State, Bloemfontein, RSA

Email: archerm@ufs.ac.za, versterjpp@ufs.ac

Abstract:

The importance of ethics and leadership with respect to the education of young professionals as leaders within the built environment are perhaps not recognised as fundamentally important and therefore receive less attention than they should. Ethics and leadership form the basis of important management skills such as strategy and communication. Thus the education and development of students regarding ethics and leadership may effectively enhance the quality leadership in the built environment. A literature review and a pilot study were conducted prior to requesting students involved in the building industry to respond to various questions regarding the development of young professionals in the built environment. A structured questionnaire on the development of young professionals was sent to a selected group of students at the University of the Free State. The results may show how the current situation related to certain developments stands and may also indicate the importance of ethics and quality leadership. The value of the provisional study may lead to the understanding of the current development of young professionals as ethical leaders in the construction industry and may form the basis of a future comprehensive study on ethics and leadership strategy approach, ability and skills. It may also show development areas or inadequacies related to important skills, and may also encourage educators to place more emphasis on ethics and leadership, to ensure improvement in ethical communication towards successful outcomes of projects.

1 Introduction

Ethics and leadership education of young professionals within the built environment are perhaps not recognised as fundamentally important and thus receives less attention than it should. Ethics and leadership form the basis of important management skills such as strategy and communication. The education and development of students regarding ethics and leadership may effectively enhance the quality of leadership in the built environment.

2 Ethics

Ethics is the study and understanding of morality, moral principles, and the moral decision-making process (Fan, Ho & Ng, 2001: 20). Business ethics as an applied version of ethics typically involves two tasks: the normative task of providing justification for abstract standards of behaviour and the practical task of applying these standards to business conduct. Business ethics is the application of our understanding of what is good and right to that assortment of institutions, technologies, transactions, activities and pursuits which we call business (Velasquez In Fan, Ho & Ng, 2001: 20).

Ethics can be thought of as a person's ability to act in a socially acceptable manner and to make decisions based upon one's morals and belief structure (Lecher, 2002: 109).

Professional ethics concerns the study of the morality of the behaviour of professionals in their day-to-day practice. Professionals are primarily held responsible to the general public, but the morality of their behaviour is not only assessed in ordinary moral terms but also in terms of special professional norms. Dual standards of behaviour then arise from the particular profession and the general public. The training of professionals in ethics hence plays an essential role in socialising specific professional norms as well as predicting professionals' ethical considerations (Ho & Ng, 2003: 47).

Ethics are moral principles, which govern moral decision-making processes (Fan, Ho & Ng, 2001: 20). The abstract standards and practical application of ethical behaviour is important in business and the idea of what is correct should be applied to everyday working tasks (Velasquez In Fan, Ho & 2001: 20). Ethics determine a person's ability to act acceptably and make moral decisions (Lecher, 2002: 109). Professional ethics implies the moral behaviour of professionals in business. Professionals have to act ethically and have a responsibility to the general public. They are assessed not only on general ethical standards, but are also assessed on specific professional norms (Christabel Ho Man-Fong & Vincent Ng Chi-Wai, 2003: 47). A complex modern society and the increase in number of professionals making decisions necessitates that professionals act ethically and that the standards in which they work are upheld (Fan, Ho & Ng, 2001: 21).

Project management skill is the interrelationship of creativity, thinking and ethical behaviour (Helgadottir, 2008: 743). Even when professionals are inherently ethical, the pressure of the working environment may complicate and obscures their ethical course of action (Helgadottir 2008: 747). Professionals have to act lawfully and ethically. They have to fulfil their responsibility to their profession, colleagues, employers, clients and the public, an act which requires maturity of judgement (Fan & Fox. 2009: 60).

Some construction professionals have been involved unethical behaviour and found guilty of dishonourable conduct. A difficult economic climate adds to the stress of making ethical decisions. Professional ethical behaviour or lack thereof has subsequently come under the attention of the public who expect high ethical standards. This expectation has complicated and widened the study of professional ethics (Fan, Ho & Ng, 2001: 19).

Construction professionals face a number of ethical dilemmas specific to the construction industry. The conduct and practices of the professionals engaged in the South African construction industry are governed by the guidelines provided by the respective professional bodies and the South African Council for the Built Environment. Construction professionals are bound by the professional code of ethics to have a responsibility to society (Fan & Fox. 2009: 67). According to Donaldson (In Bowen, Akintoye, Pearle & Edwards, 2007: 631) ethical practices should promote economic efficiency by respecting others, avoiding negative practices such as nepotism and bribery, and to conduct business professionally.

The factors that make the construction sector prone to unethical behaviour include competition for contracts, bureaucracy for obtaining official approvals and permits, project uniqueness which makes price comparison difficult, opportunities for delays

and overruns, and that most much work is concealed by concrete plaster and cladding (Transparency International, 2005 In Bowen, Akintoye, Pearle & Edwards, 2007: 631). The cause of organizational ethical failure can be traced to the culture and the failure of leaders to actively promote ethical practice (Bowen, Akintoye, Pearle & Edwards, 2007: 632). It is therefore important for young professionals in the construction industry to develop ethics, moral values and professionalism at an early stage in their careers.

3 Leadership

A leader has the ability to provide and communicate a direction and vision to an organisation, to motivate others and to contribute to the realisation of the vision (Russel & Stouffer, 2003: 229). Leaders should have strong ethical standards, know what they stand for, have character and have a sense of ethical direction (Carrol, 2009: 86). Moral leaders want to succeed within the confines of their ethical standards. People think leaders should make ethically based decisions and have certain ethical behaviour and traits (Carrol, 2009: 99). According to Carrol (2009: 101) leaders have four responsibilities, namely fulfilling the mission, obeying the law, being ethical and a good citizen.

The construction industry faces leadership challenges that comprise unskilled people, an ageing workforce, dealing with change, transition, teamwork, communication, and training and education (Toor & Ofori, 2008: 622). The need for improved leadership skills in the construction industry has become an important issue (Skipper & Bell, 2006: 68).

4 Professional development and education

According to (Carrol, 2009: 46) business ethics can be taught. College students sometimes say that their values are set by the time they reach college and that nothing that takes they learn will change their view. In business ethics education, the aim is not to change students' feelings, but to sharpen their thinking. Dulaimi (2005: 182) mentions that education may be a narrow learning process of a fixed syllabus to pass an examination, or it can be the individual's exposure to varied experiences.

Professional education and training is the main concern of academics, associations and society. Construction professionals should learn professional values, integrity and competence during their university education. There are certain basic and important skills that are expected in each profession, which are best learned at universities (Chan, Chan, Scott & Chan, 2002: 45). Construction education institutions should plan their curricula carefully to encompass the appropriate training and professionals should undertake lifelong learning throughout their career (Chan, Chan, Scott & Chan, 2002: 49).

Academics and professionals propose the close collaboration between academics, industry and professional bodies to educate construction industry students (Toor & Ofori, 2008: 280). In addition to university education, participation in extracurricular activities, leadership and social activities and work experience in organisations also contribute to the leadership development of professionals.

Several challenges face the development and implementation of programs that cultivate professional skills and traits among undergraduate students. It is important to understand and properly address the challenges to ensure the an adequate professional development program.

Although formal education does not solely determine the level of professional preparation it provides the background and understanding for the challenges, problems and joys of practice. Formal education is also where the most people develop their understanding of ethical standards in their profession (Russel & Stouffer, 2003: 225). Students should not only acquire knowledge but should be prepared for the practicalities of the construction industry (King, Duan, Chen & Pan, 2008:13).

5 Research Methodology

The literature review included international and local articles on the importance of ethics, the development of leadership and the role of education in the building industry. A questionnaire was constructed on the basis of the literature review and divided into three sections, which included personal, internship and educational information.

5.1 Questionnaire Construction

The first section (personal) comprised questions on profession, extracirricular activities, work experience, social activities, reading, self study, and participation in community and outreach projects. The respondents indicated their level of participation in the abovementioned activities, the importance of certain education elements, and contributing factors to their professional development. In the second section (internship), the respondents indicated whether they were currently employed by a firm related to their profession. In the third section (educational), respondents had to rate the importance of certain educational elements that contributed to their education, knowledge and professional development. The ratings were indicated on a five point Likert scale with one the least- and five the most appropriate. There were several open-ended questions, where the respondents could give their own opinions, views or comments.

5.2 Sample

Fifty-two questionnaires were distributed in November 2010 among Quantity Surveying and Construction Management post-graduate students and final year Land and Property Development students. All students studied at the University of the Free State, at the department of Quantity Surveying and Construction Management. The students took part in an ethics, professionalism and the professional course as part of their study . The questionnaire was handed to the students and they were requested to return the completed questionnaire within an hour. The students were assured that participation was voluntary and the information was confidential.

5.3 Data Analysis

The data were summarised descriptively using Microsoft® Office Excel® 2007 to generate spreadsheets, tables and figures.

6 Research Findings and Discussion

6.1 Personal Data

The sample does not represent all students in the construction industry in South Africa; this is only a pilot study conducted at the University of the Free State, Bloemfontein. Further research will be undertaken in the near future at other tertiary institutions.

All the questionnaires (n=52) were completed and returned. The respondents' comprised quantity surveyors (79%), construction managers (8%) and final year land and property developers (13%).

From the data it is an indication that 40% of the respondents are involved at other organisations, clubs or bodies during their final year of studies, 19% of them are already in leadership positions at these organisations. Clearly this is a good indication of our leaders of the future and specifically the modern building industry. Twenty one percent (21%) of the respondent indicated that they are involved in community and outreach projects.

Table 1 Respondents' personal data (n=52).

Questions	Frequency	Percentage
PERSONAL DATA		
Course		
Quantity surveying		79
Construction management		8
Land and property development		13
Organisation, club or body involvement		40
Leadership position		19
Outreach/community involvement		21

6.2 Internship Data

Twenty three percent (23%) of the respondents are currently employed at firms related to their profession. This is a good indication that these students find the time to gain experience during their final year of studies. Work experience is a contributor to leadership and also professional development.

Table 2 Respondents' internship data (n=52).

Questions	Frequency	Percentage
INTERNSHIP DATA		
Currently employed		23

6.3 Educational Data

Self study is an important indicator of leadership potential. Out of the fifty-two (52) respondents thirty (58%) of them were engaging in self study at a frequent basis. Eight

(15%) respondents were engaging at a less frequent basis and nine (17%) at a more frequent basis. The average rating is calculated at a 59% of the students are engaging in self study, related to their profession, at a frequent basis. This indicates that the respondents regard self study as important to their knowledge of their relevant profession. Self study is a contributor to leadership development. These percentage indications reflect the total percentage of the respondents.

The respondents were also asked to respond to certain elements contributing to their knowledge regarding their profession. These elements include practical classes, site visits, study material, group work, research projects, attending seminars and conferences and computerised assignments and classes. The respondents indicated that research projects are the single most contributing educational element. Research projects refer to respondents ability to work independently, manage time effectively, self discipline, and to produce certain outcomes within a certain period of time. The student is accountable for his/her own work thus bears a great amount of responsibility. The abovementioned can be identified as leadership traits.

Table 3 Respondents' impact level regarding certain educational elements (n=52)

	1 – least impact	2	3	4	5 – most impact
IMPACT OF EDUCATIONAL ELEMENTS					
Practical classes	5	6	18	15	8
Site visits	6	6	11	18	11
Study material	0	7	20	19	6
Group work	1	18	24	8	1
Research projects	0	4	18	28	2
Seminar and conference attendance	6	5	16	21	3
Computerised assignments and classes	3	5	16	22	6

Site visits (56%) and computerised assignments and classes (54%) are indicated as the second and third most contributing elements to education. Study material (48%) is indicated as the fourth most contributing element and has a moderate influence on sufficient knowledge related to the respective professions. The attending of seminars and conferences (46%) fifth and practical classes (44%) are rated sixth most contributing element. The respondents indicated that group work (17%) has the least influence of all these educational elements. The element of group work and the participation in group work need some attention because this is regarded as a contributor and indicator of leadership. Thus it is proposed that the impact of group work is important.

The majority (69%) of the respondents indicated that these elements were adequately addressed during their studies. The contribution of class attendance to the student's education is important, according to the respondents' responses. The majority (77%) indicated that the attending of classes contribute to their education and professional development. The majority (52%) of the respondents indicated that they are satisfied with the current educational methods.

The respondents were also requested to indicate the importance of several elements contributing to their professional development. These elements consist of the following: leadership, motivation, ethics, creativity, communication, and research methods and people skills.

Table 4 Respondents' satisfaction level of current educational methods and importance level of certain elements contributing to professional development (n=52)

		1 – least important	2	3	4	5 – most important
IMPORTANCE IN PROFESSIONAL DEVELOPMENT						
Leadership		0	0	16	19	17
Motivation		0	1	11	27	13
Ethics		0	0	3	29	20
Creativity		0	4	16	25	7
Communication		0	0	6	20	26
Research methods		0	2	11	35	4
People skills		0	0	8	20	24

Ethics (94%) is indicated as the most important element contributing to professional development. Communication (88%) and people skills (84%) are also indicated as important to the contribution of professional development. Motivation (77%) and research methods (75%) are of moderate importance and leadership (69%) is indicated as a less contributing element. Creativity (61%) is indicated as the least contributing element to professional development.

The respondents realise and acknowledge the importance of ethics in the construction industry. Communication and people skills are also important related to the professional development of young professional in the building industry. The importance of leadership and creativity must be stressed this is an area of concern. These elements are to be included in discussions with the students to broaden their vision and to enable them to become visionaries. These elements also enable them to develop as ethical leaders of the modern building industry.

7 Conclusion

Students are the future leaders of the industry and they need to be well equipped for the modern industry. The early involvement of the students in extracurricular activities, work experience, social activities, reading and self study, and participation in community and outreach projects is a clear indication of the respondents positive attitude regarding leadership development.

Research projects are seen as the biggest contributing element to the development of leaders due to the fact the research projects refer to respondents ability to work independently, manage time effectively, self discipline, and to produce certain outcomes within a certain period of time. The student is accountable for his/her own work thus

bears a great amount of responsibility. Research methods were also indicated as the important contributing factor to professional development.

Ethics are also seen as vital because leaders need to be ethical.

8 Recommendation

Students should place more emphasis on the development of ethics and leadership, people skills and communication during their studies and use the available opportunities to further their leadership abilities. This can also be supported by the introduction of more group work and group activities, which are build environment oriented. The students need to be confrontend with leadership situations as well as ethical dilemmas. It is necessary to increase group work activities, practical classes and site visits during students' education.

Leadership skills of future professionals in the construction industry are important and that certain elements and activities during their study years contribute to leadership skill development. The students, providers, mentors, institutions and councils should recognise the role of these elements as important building blocks to leadership qualities.

Developing problem-based learning resources to encourage tomorrow's Professionals: The next stage - Fostering the Graduate Transition from Student to Professional

Melanie Hall¹ and Trefor Williams²

¹Faculty of Business and Society, ²Faculty of Advanced Technology,
University of Glamorgan, Treforest, Pontypridd CF37 1DL

Email: mrhall@glam.ac.uk; twilliam@glam.ac.uk

Abstract:

Graduate employment continues to be adversely affected by the economic climate. In 2009 the project team set out to improve the employability chances of construction graduates from the University of Glamorgan [UoG]. The project evolved from a variety of Government policy documents from (Leitch, 2006), (Welsh Assembly Government, 2008) and the (RICS, 2010) Consultation Document on employability which emphasises the importance of soft transferable skills which are central to professionalism. The work forms part of an inter-faculty study on professionalism. The faculties consisted of Advanced Technology and Humanities and Social Sciences. This project was partly funded by The Centre for Excellence in Learning and Teaching [CELT] as part of an Innovation in Learning and Teaching initiative. The methodology employed involved the re-use of a previous questionnaire with students in the first and final years of undergraduate awards. Feedback on professionalism has also been obtained in formal and informal discussions with industry representatives. This ongoing action research project to improve the students' understanding of professionalism has highlighted several questions relating to course content and delivery. These questions include what needs to be incorporated in the curriculum, how and when this is delivered and assessed. Problem based learning has been identified as a vehicle to facilitate the programme. The need to address staff development issues has also been identified. The action research continues.

Keywords:

surveying, professionalism, problem-based learning, action research

1 Introduction

1.1 Aims

- To improve employability of students on completion of their built environment undergraduate awards.
- To increase an undergraduate's understanding of professionalism
- To address the RICS employability threshold expectations.
- To develop problem-based projects, in conjunction with employer representatives, that would help to satisfy the aims set out above.

1.2 Objectives

The objectives of the research were to:

- initiate an action research project
- establish baseline of students' knowledge and attitudes to professionalism
- establish what employers expectations are regarding professionalism from graduates
- use the findings from the student baseline study and the employer interviews to inform the development of a new RICS accredited undergraduate quantity surveying and commercial management award

1.3 Rationale

The economic downturn continues. One commentator (Green, 2011) reports construction lost a further 24,000 jobs in the first quarter of this year with the number of workforce jobs dropping to its lowest level since mid 2003t whilst another (Anon, 2010) predicts that the government's recent public sector spending cuts could result in a further 104,000 job losses in construction.

The gloomy economic outlook combined with the recent requirements from RICS relating to the development of graduates' employability skills and greater employer/industry engagement encouraged the academic staff concerned to continue a project within the curriculum that would enhance graduate employability through propagating a positive culture of professionalism.

2 Research Methodology

2.1 Research design

The methodology used was designed to elicit attitudes and knowledge of students in regard to the concept of professionalism.

The authors wished to establish the attitudes and knowledge of students on the undergraduate built environment courses as a base line.

In order to establish the students' knowledge and skills, a structured tool assessing their understanding of the concepts associated with professionalism was used. This tool was derived from a number of sources. These sources had used particular terms in their definitions of professions and professionalism. This tool tested both the students' knowledge of the terms and their attitudes to professionalism.

A structured tool, relating words to concepts, was devised to reveal knowledge of aspects of professionalism thus creating a baseline of students' attitudes and knowledge. This tool incorporated nine areas which related to professionalism [refer to Appendix 1]. These common themes were generated from many sources including (Oxford Dictionary, 2009), (Fewings, 2009), (Maister, 1997), (Haralambos and Holborn, 2008) and the RICS and CIOB codes of conduct.

A quantitative approach was felt appropriate to establish a base line of students' skills and attitudes in relation to professionalism. The method also allowed the majority of students in the population to be surveyed thus maximising the efficacy and validity of the study.

2.2 Population.

All students registered on the first and final year of the full time and part degree undergraduate awards in Quantity Surveying, Project Management [construction] and Real Estate and Development at the University of Glamorgan in the academic years 2009-10 and 2010-11.

2.2.1 Sample

Students were surveyed three months into the academic year. They were fully informed of the project's aims and objectives and were given the opportunity to opt out of the survey. The questionnaires were completed anonymously.

Table 1. Questionnaire sample

Cohort	Population	Sample	% of population
2009-10			
First year	108	59	54
Final year	60	43	72
2010-11			
First year	101	29	29
Final year	80	37	47

2.2.2 Research Strategy

In order to increase the match between the expectations and needs of employers and students' attributes in a dynamic setting, action research was employed.

Action research is a research strategy to enable researchers and practitioners to work together to achieve an optimal outcome (McNeill and Chapman, 2005). (Lewin, 1946) first described this structured cyclical process to enable change to occur within a controlled environment. The process involves different methods of data collection including surveys, interviews meetings etc. These results are fed back to the stakeholders to assess the impact changes have had on their practice and if any further changes need to be made, thus refining the process until an optimum outcome has been achieved. Similarly (McNiff, 2002) describes action research as "*a term which refers to a practical way of looking at your own work to check that it is as you would like it to be*".

3 Results

3.1 Questionnaire results

3.1.1 Knowledge of concepts associated with professionalism

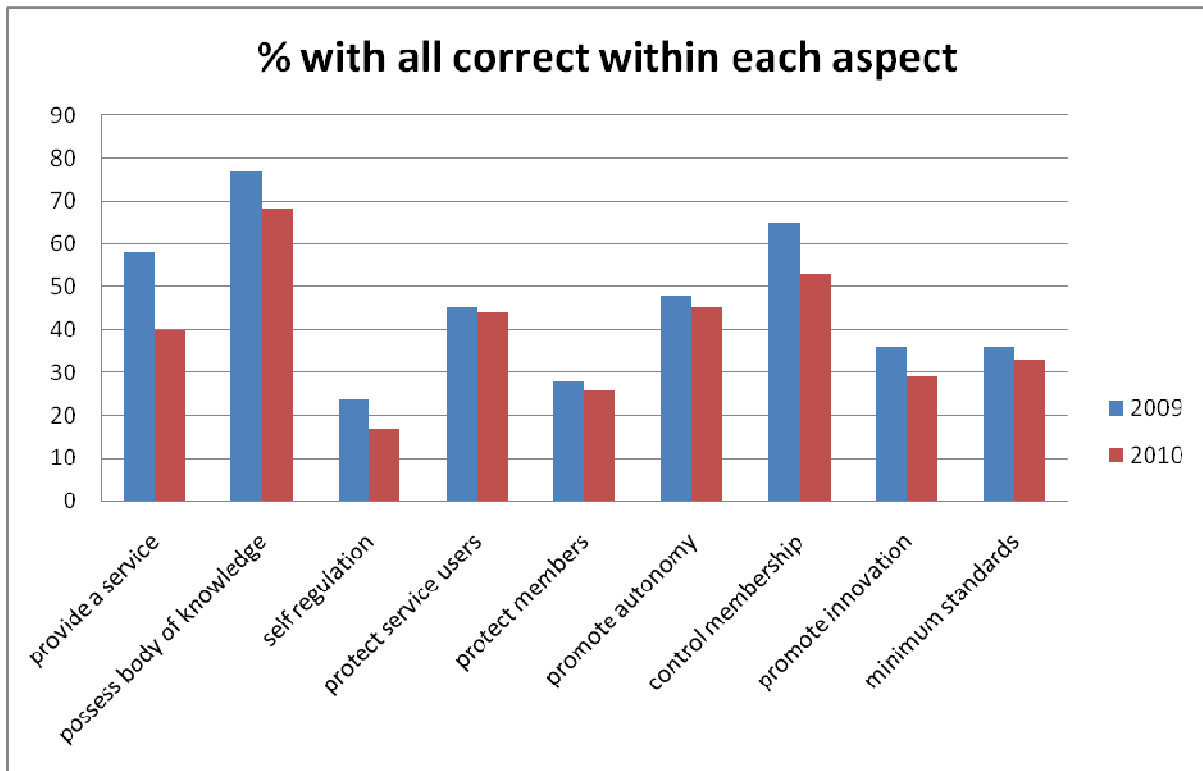

Figure 1 Results from questionnaire 2009 and 2010

Overall the results show that:

- There is a similar pattern of results over the two years with regards to the % of the cohorts that correctly identified the three correct phrases/terms associated with each of the nine aspects of professionalism detailed in Figure 1 above.
- Aspects that demonstrated the greatest understanding in both datasets were possess a body of knowledge; provide a service and control membership.
- Aspects that demonstrated the least understanding in both datasets were self regulation and protect members.
- In 2009 only three of the nine aspects produced a greater than 50% correct response. In 2010 this decreased to two of the nine aspects surveyed.
- No one correctly identified the three phrases/terms in all nine of the aspects.

Subsequent to distribution of the 2010-11 questionnaires the authors were invited to present their research findings in a seminar hosted by the university's Centre for Excellence in Learning and Teaching [CELT]. At this seminar feedback from participants highlighted that the terms "disciplinary measures" and "indemnify" may be ambiguous. The feedback suggested that whilst the terms were not considered to be incorrect there was a concern that participants may not recognise their significance in the context of professionalism. The authors note that these terms are contained within the two aspects which showed least understanding and will therefore re-evaluate the

questionnaire prior to further use. Despite their minor misgivings the overall feedback from the staff seminar was that the questionnaire was a useful tool to evaluate students' knowledge and attitude to being a professional.

The results also indicate consistency in the deficit of knowledge amongst the different student cohorts in relation to being a professional reinforcing the authors concern that this is an area that needs greater attention in the curriculum.

3.1.2 Results of questionnaire qualitative data

Two questions were included which asked the students to reflect on:

- What does being a professional mean to you?
- Why are you studying for your award?

Content analysis was used. The results provided a variety of statements which were grouped into key words. Results for both years are shown in Figures 2 and 3.

Figure 2 Meaning of Professional

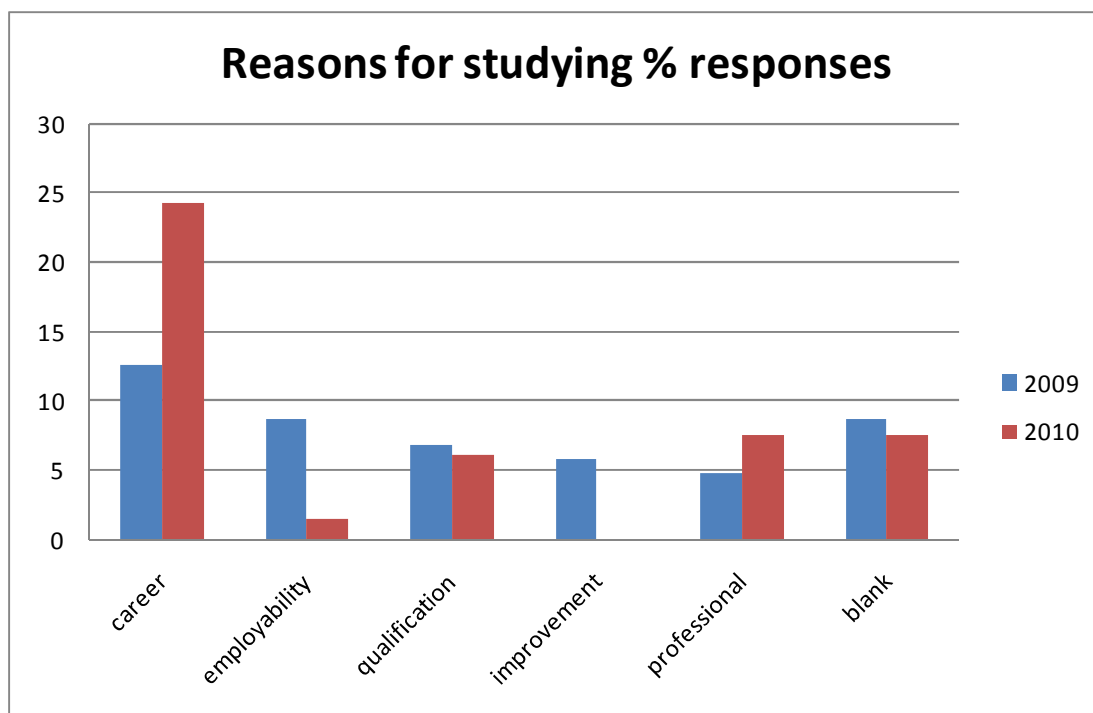

Figure 3 Reasons for studying

Whilst the terms identified from the content analysis remain similar for the two cohorts the percentage of responses for many of the terms differs considerably. This reinforces the results in the quantitative section of the questionnaire in as much as there is a clear confusion with regards to the meaning of the term professional and how it relates to their reasons for studying.

4 Discussion of results and review of relevant literature

4.1 Professionalism in the Quantity Surveying & Commercial Management award

In designing the new award it was decided that the use of project-based modules could be an effective vehicle to teach professionalism “themes” whilst at the same time influencing students’ professional attitudes and behaviours. It was felt that these modules offered the opportunity, in conjunction with employer inputs, to deliver 3 core strands of professionalism ie professional competence [knowledge], soft transferable skills [eg communication, teamwork, problem-solving] and professional socialisation [personal values, belief in service to public/client, belief in self regulation etc].

Figure 4 Hierarchy of professional development

The award contains a project based module in each of its three years. The project's professional competence and transferable skills content would be based on the adjoining modules from that year of study and the RICS employability threshold requirements. This content is the familiar territory of undergraduate education as outlined by (Duch *et al.*, 2001 p6):

- *Think critically and be able to analyse and solve complex, real-world problems*
- *Find, evaluate and use appropriate learning resources*
- *Work cooperatively in teams and small groups*
- *Demonstrate versatile and effective communication skills, both verbal and written*
- *Use correct knowledge and intellectual skills acquired at the university to become continual learners.*

The teaching and assessment of professional socialisation presents the authors with more of a challenge. In her discussions on teaching professionalism to pharmacy undergraduates in America (Hammer, 2006) comments:

In discussions about students and professionalism, one question that often arises is whether professionalism can be “taught.” There is certainly a body of knowledge about professionalism that can be learned, but does that ensure that the learner will demonstrate professional behaviors? Probably not. Professional socialization, however, which is the process by which students learn and adopt the values, attitudes, and practice behaviours of a profession, can be taught or at least influenced.

Traditional lecture and tutorial approaches seemed inappropriate for achieving the required objectives therefore the authors decided to review the literature on problem based learning to see if it offered possible solutions.

4.2 Problem based learning [PBL]

The decision to facilitate the professionalism and employability of our graduates through using problem based learning was motivated by three main reasons:

Firstly, Problem based learning is increasingly seen within higher education as a necessary approach in education for the professions. (Boud and Feletti, 1991 p.14) see problem based learning as “... a way of conceiving the curriculum which is centred around key problems in professional practice...”

Secondly, there is the issue of context. The questionnaire surveys at Glamorgan and the interviews with employers identified a probable cause of the lack of undergraduate understanding of key facets of professionalism was the lack of a real world context. They were not able to ground facets of professionalism in real work situations or experience. (Boud and Feletti, 1991) suggest that one of the defining characteristics of problem based learning is that context is of central importance to this method of learning. They suggest that effective learning takes place only when students are actively involved; using knowledge they are developing in a relevant and meaningful context. The prevailing economic conditions have resulted in far fewer students undertaking a sandwich placement which has further reduced their opportunities to use their knowledge in a relevant and meaningful context.

Thirdly, Problem based learning has its roots and traditions in the teaching methods of the ancient Greeks. As (Boud & Feletti, 1991) and (Savin-Baden & Howell-Major, 2004) discuss; problem based learning is not new. It is a method of learning that predates the advent of classes and course programmes. However, it is the association with Aristotle’s teaching methods discussed by (Savin-Badin & Howell-Major, 2004) that connect conceptually with the approach adopted in this research.

These three reasons will be further discussed in the sections that follow, but firstly it would seem useful to define problem based learning (PBL).

4.2.1 What is Problem based Learning?

(Duch *et al.*, 2001 p6), agreeing with (Boud & Feletti, 1991) suggest that:

“...In the problem based approach, complex real-world problems are used to motivate students to identify and research the concepts and principles they need to know to work through those problems. Students work in small learning teams, bringing together collective skill at acquiring, communicating and integrating information.”

According to (Savin-Baden and Howell-Major, 2004), problem based learning can be characterised more broadly by its student -centeredness in addition to its being focused around problems. They identify eight key features of problem based learning, five of which focus on the student experience and three that deal with PBL from the staff perspective. It is worth discussing the five student related characteristics:

Firstly, PBL takes into account the past experience of students.

Secondly PBL fosters student autonomy by encouraging them to take responsibility for their own learning.

Thirdly PBL centres on the processes rather than the products of knowledge acquisition. As Engel (1986) suggests problem based learning is a means of developing learning for capability rather than learning for the sake of acquiring knowledge.

Fourthly it achieves an interweaving of theory and practice.

Finally, the necessity for student's to work with others during problem based learning activities hones their communication skills in a way that enhances their interpersonal skills beyond their area of technical expertise.

4.3 Problem Based Learning as a method of educating professionals

Problem based learning came to prominence as a method of learning in universities within the field of medical education principally as a result of the seminal work by (Barrows and Tamblyn, 1980) in their book 'Problem -Based Learning: an Approach to Medical Education'. (Boud and Feletti, 1991) argue that this book changed the way medical education was taught at McMaster medical school in Canada and subsequently throughout medical education generally. The reason for this innovation was that PBL resulted in the creation of medics with enquiring minds and a desire to understand, rather than the traditional pedagogies which equipped doctors with a set of knowledge and responses that allowed them to earn a good living. Since then the use of problem based learning has begun to dominate within the arena of professional education because as (Boud and Feletti, 1991 p14) suggest, problem based learning is "... a way of conceiving the curriculum which is centred around key problems in professional practice ..."

Further, they see problem based learning within higher education as a necessary approach in education for the professions. They highlight the point that the ever expanding knowledge base of most professions precludes a novice practitioner being able to assimilate all the knowledge necessary in their undergraduate studies to become a fully autonomous professional. They also argue that it is more important for students to be able to research, discern and utilise information appropriately than to absorb all information academic staff deem desirable.

This argument is particularly relevant in the field of professional ethics where the code of conduct for a professional body cannot possibly cover every nuance or 'grey area' that a new practitioner could come across (see Hall & Williams, 2010). We would suggest therefore that in this arena it is even more important that students leave university having developed the knowledge, understanding and discernment necessary, coupled with humility to be able to apply a set of professional values and qualities to their professional work; and further to have the confidence to be able to ask for advice in those situations where they are unsure of the 'right thing' to do.

4.4 The Issue of Context

We suggest that utilising the techniques of problem based learning may better serve the development of student understanding of their own professionalism because the knowledge which is valued in problem based learning is that which can be used in context and interrelated, rather than that of knowledge presented in discrete, often unrelated subject areas. (Boud and Feletti, 1991 p22)

(Boud and Feletti, 1991) suggest that one of the defining characteristics of problem based learning is that context is of central importance to this method of learning. They suggest that effective learning takes place only when students are actively involved; using knowledge they are developing in a relevant and meaningful context. They also suggest that one of the benefits of PBL is that:

“... Problem based learning is closer to the real world of the professional and as such has greater validity with practitioners/professionals than a course of discrete unrelated subjects. ...”

(Wood, 2003) also considers advantages of PBL to be:

- *Student centred*—PBL fosters active learning, improved understanding, and retention and development of lifelong learning skills
- *Generic competencies*—PBL allows students to develop generic skills and attitudes desirable in their future practice
- *Integration*—PBL facilitates an integrated core curriculum
- *Motivation*—PBL is fun for students and tutors, and the process requires all students to be engaged in the learning process
- *“Deep” learning*—PBL fosters deep learning (students interact with learning materials, relate concepts to everyday activities, and improve their understanding)
- *Constructivist approach*—Students activate prior knowledge and build on existing conceptual knowledge frameworks

Wood (ibid) also considers the disadvantages of PBL as follows:

- *Tutors who can't “teach”*—Tutors enjoy passing on their own knowledge and understanding so may find PBL facilitation difficult and frustrating
- *Human resources*—More staff have to take part in the tutoring process
- *Other resources*—Large numbers of students need access to the same library and computer resources simultaneously
- *Role models*—Students may be deprived access to a particular inspirational teacher who in a traditional curriculum would deliver lectures to a large group
- *Information overload*—Students may be unsure how much self directed study to do and what information is relevant and useful

Wood (ibid) also reflects on the impact of PBL on the teaching staff as follows:

Introducing PBL into a course makes new demands on tutors, requiring them to function as facilitators for small group learning rather than acting as providers of information. Staff development is essential and should focus on enabling the PBL tutors to acquire skills in facilitation and in management of group dynamics (including dysfunctional groups).

Despite the potential disadvantages identified the authors believe that overall PBL, by providing a real world context within which students apply their developing knowledge has many advantages; it can help foster not only the application of knowledge to actual practice but can also help develop professional behaviours and attitudes .

4.5 Links to Aristotle

Conceptually there are two links with Aristotle’s ideas and this research. Firstly, our approach to understanding the notion of professionalism, (detailed discussion to be

found in Hall & Williams, 2010) is based around the idea that Professionalism may be better understood as a set of values and virtues that need to be internalised through a process of socialisation or formation. Aristotle thought that this process of developing values and virtues was difficult to teach and only developed over time. (Hammer, 2006) concurs with this idea that professionalism cannot be taught, but suggests that the values, attitudes and behaviours of a profession can be taught and influenced through the use of role models and reflection/discussion on real world situations. This provides further weight for the argument in favour of adopting PBL as an appropriate curriculum approach.

Secondly, (Savin-Baden and Howell-Major, 2004) highlight the link between Problem based learning and Aristotle's teaching methods. They suggest that for Aristotle teaching and learning was always focused around disciplined inquiry into some aspect of reality and that education should enable students to make rational judgements that interweaved and applied theory to the practical. Problem based learning in this context is a quest for knowledge where students use their reasoning abilities to manage or solve complex problems.

Overall the authors believe that the literature concerning Problem Based Learning (PBL) strongly supports their strategy for developing undergraduate professionalism.

5 Conclusions and recommendations

Action research has proved to be an excellent tool for continuous evaluation of the undergraduate courses in regard to development of content, implementation and evaluation of students' performance and facilitating industry/partner input. Action research often creates more questions than answers as ongoing evaluation and assessment of the project reveals the need to change in relation to perceived needs. This phase of the study has led to the following actions for the next cycle in the process.

1. There is a need to establish an end point for the "transition to professionalism" ie what basic professional attributes the industry would expect of a new graduate. This end point needs to be established in conjunction with employers and the professional bodies.
2. Having defined the end point it will then be necessary to design a coherent, logical progression from year one to year three of the award ie a journey to transition. This progression will include the nine aspects of professionalism referred to in the questionnaire.
3. Development of appropriate assessment tools and mechanisms, both formative and summative, to assess individual's progress on this journey. These mechanisms must be designed to emphasise the importance and relevance of the concept of professionalism to undergraduate development and employability.
4. Given the potential disadvantages of PBL identified in this paper it will be imperative to manage the changes involved in adopting this approach, especially in relation to staff and team development.
5. Last but not least there is the need to develop a framework whereby employers are fully engaged in the process of development, delivery and assessment. Thus

increasing the students' exposure to professional expectations and increasing their employability.

Solutions to the pedagogical difficulties with measurement in quantity surveying

Sean Ostrowski¹

¹Faculty of Advanced Technology
Glamorgan University, Wales, CF37 1DL

Email: ostrowski@btinternet.com

Abstract:

A number of common difficulties previously identified are the process, calculations, technology, the rulings, the SMM and speed. Each problem has a different theoretical framework and a different practical solution which is described in detail.

Keywords:

difficulties identified, solutions proposed

1 Introduction

This paper addresses the problems identified in the publication 'What Students find difficult about Measurement' for the RICS/COBRA Conference in Paris 2010.

The intent is to find out how to teach Quantity Surveying. Part of this research was to find out the difficulties encountered by students in measurement. A series of common difficulties were identified and an outline solution to these difficulties was developed. (Ostrowski, 2010).

The pedagogical principles for QS teaching have been set out in Ostrowski (PhD Thesis, 2011). It is now possible to suggest some practical proposals to overcome the difficulties. The pedagogical principles, the difficulties that have been encountered and the proposed solutions form part of a synoptic pedagogy for QS that is being developed. The difficulties over 5% of the total are examined and are highlighted below. The category entitled pleasure is not a difficulty and is not examined. The difficulty entitled drawings concern inaccurate manual drawings which is resolved by producing accurate AutoCAD drawings. This is set out below.

Figure 1 The difficulties

The Process	19% of the total
Calculations	13% ditto
Technology	9% ditto
Rulings	5% ditto
Speed	7% ditto
SMM	5% ditto
Drawings	<u>6% ditto</u>
Total	<u>64% of the total</u>

Each problem has a different theoretical framework and a different practical solution. Although Biggs (2003) does not consider teachers to be particularly interested in theories of learning he does consider that there is a need for a framework which is “...broad based and empirically sound...that easily translates into practice.” The theoretical concepts that underpin these proposals are included in order to be able to identify the reason for the difficulties and provide the direction for the practical solutions to deal with them. They comprise a series of broad headings concerning epistemological, cognitive, psychological, environmental and emotional components. Their relationship is a bricolage of elements of inter-related matters which form a spiral of learning similar to an helix as the level of cognitive development rises. For each difficulty there is a different emphasis and those that are relevant are examined in detail. They are summarised in the table below.

Table 1 Cognitive Framework

EPISTEMOLOGICAL	COGNITIVE	PSYCHOLOGICAL	ENVIRONMENTAL	EMOTIONAL
Procedural Knowledge	Knowledge	Behaviourism	Facilities	Attitude
Contingent Instruction	Understanding	Cognitive Psychology	Collaboration	Motivation
Contemporaneous Feedback	Learning	Constructivism	Groups	Risk Free

Each column forms part of a coherent framework of pedagogy for QS work and enables the appropriate pedagogical modifications to current teaching practice for the difficulties that have been identified. A brief review here introduces each section.

The epistemological elements concern the nature of the different kinds of knowledge with examples of which kind of knowledge is applicable to the various stages of

measurement. The process of measurement mainly concerns procedural knowledge and this requires contingent instruction and contemporaneous feedback. The cognitive elements are the nature of technical competencies in terms of knowledge, understanding and learning and how they relate to QS work.

The psychological elements concern the conceptual framework in which QS is learnt. The first element is behaviourism which proposes an appropriate stimulus to provide the responses that are generated by measurement. Cognitive psychology describes how the brain can be trained and improved, like a muscle, to undertake this work. Constructivism concerns the role of the learner in acquiring technical competencies.

The environmental elements describe the nature of the physical, social and cultural requirements to undertake an aligned teaching programme for technical competencies. The emotional elements concern attitude, motivation and a risk free environment for QS teaching.

2 Literature Review

There is very little research on the principles of teaching QS. Published work is mainly concerned with the impact of various teaching programmes and empirical reviews of numbers of students involved. The literature that has been reviewed concerns the principles of education and how they relate to professional education and training. They are discussed in detail in Section 4.

3 Research Methodology

The research methodology is a comprehensive review of the literature on the principles of education and how to apply them. This is a complex area and what has emerged is a framework of interrelated principles that are particular to the teaching of QS. These principles are applied to the difficulties that have been previously identified (Ostrowski, 2010) to form a series of proposals as set out in Section 4.

4 Findings and Discussion

4.1 Problems with the Process

4.1.1 Theoretical framework for the process

The ‘process’ is the difficulty in knowing what to do next. It is 19% of the total. What is the epistemology, what kind of knowledge is this difficulty concerning what to do next? This is remembering how to do things and concerns the acquisition of technical competencies. Biggs (2003) calls this functional knowledge and Eraut (1994) uses the term procedural knowledge. The most significant part of procedural knowledge is that it is acquired by practice. A further element of procedural knowledge is contingent instruction described by Wood, Bruner and Ross (1975) as the cognitive development process for assembling complex model structures. The process only works when help is provided if it is requested or the student is in difficulty. The third element of the epistemology is contemporaneous feedback. Mervarech and Werner (1985) indicate that mastery of problem solving skills required practice and contemporaneous corrective feedback and Biggs (2003, p.141) states that it is “...*outstanding important...*”.

The first item in the cognitive framework is the kind of knowledge in QS work and this has been described in the epistemology as procedural knowledge. Next is the nature of the understanding when trying to undertake this work. In the hierarchy of understanding (Bloom, 1956) the process of measurement is at the application stage of the taxonomy comprising progressive cognitive development. What method of learning is best suited to this problem? The process approximates to the conditioned response (Gagne, 1977) where a chain of procedures is implemented. He describes the conditions for learning of procedural knowledge as learning outcomes. It is characterised as participation and the typical activity is remembering how to do the taking-off. The capabilities that are required include grammar - to be able to put information in the right order - and translation, the transfer of the visual information on the drawing being converted to the format of the SMM. The internal condition that is required of the student is the intellectual skill necessary to carry out the work. The external conditions that are provided by the teacher are the opportunity for sufficient practice and a meaningful context.

Behavioural psychology provides a reason why the difficulty has occurred. The initial stimulus is that the subject is perceived as too difficult and this has a negative response. What is required is a positive conditioned response to provide the necessary motivation. Cognitive psychology (Woolfolk, 2004) indicates that the links in the synaptic nodes between the dendritic extremities can be developed and strengthened in practice. The direction of the development is provided by the teacher. The constructivist approach allows intellectual development that is specific to the individual with the teacher providing the necessary assistance. The scope for this development is restricted by the prescriptive nature of the SMM.

The environmental framework for this difficulty and those that follow is similar. The physical environment is that appropriate for practice of a technical competence with a large amount of documentation, and easy circulation of the teaching team to enable collaboration. The social and cultural environment is the requirement that the knowledge be experienced in the appropriate way for this subject with a diverse cohort of students.

The emotional requirements for these difficulties are also similar. The right attitude to enable cognitive development can be made available, the appropriate motivation, both positive and negative is required and these technical competencies are best acquired in a risk free environment where mistakes can be made without fear or ridicule from the teacher or the class.

The theoretical framework of not knowing what to do next provides indicators of the appropriate teaching solutions. The pedagogical modifications that are required are made up of the appropriate epistemological and cognitive requirements, the appropriate psychological input and the environmental and emotional factors. Each difficulty has a particular solution.

4.1.2 *Practical solutions for the process*

What are the particular teaching requirements to overcome this difficulty? There are three basic epistemological components. The first and most significant is that the 'process' requires to be taught as procedural knowledge, with contingent instruction and contemporaneous feedback. Procedural knowledge is taught by providing practice, which enables technical competencies to be acquired progressively, eg taking-off quantities for a particular trade by the use of a practical exercise. The second is contingent instruction. The later work of Wood (2001) confirms that there is a strong correlation between tutorial contingency and learning outcomes for procedural knowledge. What is successful is providing answers to questions when they are asked. What did not work was telling the students or demonstrating to them how to do it. This also means that the feedback needs to be contemporaneous, as the students carry out the practice. To ensure that all the questions are answered a suitable aligned teaching programme for contingent instruction includes the provision of supplementary instruction. The supplementary instruction is provided by using Peer Assisted Study Schemes (PASS) whereby successful students who are able and willing to participate provide answers to questions during discussions and workshops. The student tutors are able to provide the contingent instruction in the form of contemporaneous feedback in the time available and are perceived as more sympathetic to a diverse range of questions. Biggs (2003) describes PASS schemes for use in large classes and states that (p. 113) "*The cost-benefits of student-led groups in classes with higher enrolments are attractive.*"

The most relevant level for understanding the 'process' is application, although the student will move up and down the whole of the understanding hierarchy. The requirement for application is the repetition of the practice using the same rules that are applicable to various trades, eg the taking-off is repeated for different trades. The appropriate method of learning is the conditioned response which requires the provision of a series of procedures in the correct sequence to allow the student to form a chain of correct responses. This means that the information comes from a previously established threshold and is contiguous with small amounts of information with small gaps between them. eg the taking-off is repeated in the same sequence for each exercise.

The problem of the subject being too difficult can be explained in terms of behavioural psychology. The stimulus is the perception that the subject is too difficult and there is a negative response which is not to try from the outset. This can be replaced by providing the stimulus that the subject is not an intellectual exercise, it is a process like baking a cake or addressing a golf ball. The information is collected, the drawings and specifications, they are processed in accordance with the SMM and the result is Bills of Quantities. The answer is not required at the beginning, it emerges at the end of the process. This stimulus provides the positive response which is to make a start and proceed as far as possible. Cognitive psychology treats the brain as a muscle which can improve with exercise. Low or missing abilities can be initiated and improved with practice. The teacher provides the appropriate initial guidance to activate the cognitive development in the form of an introductory lecture or demonstration. The constructivist approach to technical competencies is useful because it acknowledges the personal construction of a scaffolding of knowledge which is acquired by the student with the help of the teacher.

The environmental conditions include the provision of a classroom facility comprising sufficient space for collaborative group work with work stations that can accommodate large amounts of documentation and the easy circulation of staff, tutors and students and where the results can be immediately assessed informally, using self and peer assessments. This precludes the lecture theatre. A class size of 20/25 is the limit for an individual lecturer with supplementary teaching resources provided for classes above this size. The practical environmental requirements remain similar for the remainder of the difficulties.

The emotional requirements begin with the provision of the appropriate attitude. The formation of groups for workshops allows the practice to take place on a collaborative basis where knowledge can be shared. The psychological problem of fear as a response to the perception of a difficult subject is alleviated by the stimulus which replaces isolation with collaboration. Ensuring that the exercises are conducted in groups that have a mixture of ability, experience, gender and race demonstrates that equality of opportunity is seen to be available. The collaborative nature of these groups ensures that there is no domination and that those that require help are assisted by their peers. The provision of student tutors also provides emotional assistance with the use of perceived sympathetic responses from contemporaries. The emotional requirements include positive motivation to provide the opportunity for the best to shine by making presentations and demonstrating leadership. Technical competencies are an arbitrary positivist paradigm (Cohen *et al*, 2007) and there is either a right or wrong answer. Therefore a negative motivation is also appropriate to maintain minimum standards and this can be implemented by maintaining the fear of failure if the wrong answer is provided. The emotional element includes providing a risk free environment where practice allows errors and questions that can be asked without any consequences or ridicule from the teacher or the students. The emotional components remain similar for the remainder of the difficulties.

The basic practical requirements are practice and contingent instruction.

4.2 Problems with Calculations

4.2.1 Theoretical framework for calculations

The 'calculations' is not knowing how to do the numerical calculations that are required. It is 13% of the total. Difficulties with calculations is the most fundamental problem that has been raised by the research in 'What students find most difficult about measurement' (Ostrowski, 2010). In terms of epistemology the cognitive obstacles of mathematical calculations are based on the lack of experience, both of society and of individuals. Piaget (1950) has proposed that historical obstacles are reflected in individuals' cognitive obstacles. For example the Victorians disbelieved the pictures of elephants because they were not in the collective experience of the nation. Mathematical equations are a cognitive obstacle to propositional knowledge individually, collectively and historically. Until they become common they will remain obstacles to the individual. Difficulties with mathematical calculations are a fundamental problem of cognitive development in this society. They will not be overcome by pedagogical modifications to teaching the technical competencies of QS work.

The cognitive framework commences with what kind of knowledge is this difficulty concerning calculations? This is propositional knowledge or intellectual skill (Eraut,

1994) which concerns discrimination and the capabilities in areas like language, mathematics and music (Gagne, 1977). In the hierarchy of understanding (Bloom, 1956) the process of measurement is at the analysis and synthesis stage of the taxonomy comprising mainly discrimination of concepts, rules and laws. In terms of methods of learning what kind of learning is best suited to this problem? Calculations approximates to association (Gagne, 1977) where links between the stimulus and the response are established, where a chain of procedures is implemented. The conditions for learning have been detailed by Gagne (1977) as learning outcomes and in this case is characterised by discrimination and the typical activity is the use of algebraic and trigonometrical formulas for calculating measurement areas. For propositional knowledge the capabilities that are required include numeracy. The internal condition that is required of the student is that student has learned the necessary mathematical skills and remembers how to use them. The external conditions that are provided by the teacher are a clear objective, the examples that stimulate recall, some guidance and demonstration and the opportunity for practise.

In behavioural psychology these calculations are again seen as too difficult. However this is propositional knowledge and a suitable stimulus to overcome this is problematical because the difficulty is a national, social and cultural problem. In cognitive psychology Entwistle (Ed. 1985) explains the work of Child and Eysenck and sets out the relationship between hereditary and environmental influences. There is a pre-existing facility for certain aspects of cognitive development like numeracy which inclines students to this kind of work. There may be links in the synaptic nodes between the dendritic extremities of neurological systems (Woolfolk, 2004) that need to be developed. The constructivist approach allows the individual to construct a scaffolding that has no prescriptive limitations although the extent of mathematical competence that is required is quite modest. The emotional framework overlaps with the epistemological and psychological components and the practical consequences are discussed below.

4.2.2 Practical solutions for calculations

What are the particular teaching requirements to overcome this difficulty? The teaching to help resolve these problems is a particular epistemology that is derived from the cognitive, psychological and emotional framework. The first is that 'calculations' require to be taught as propositional knowledge, described within cognitive psychology as the capability to train the brain. They can be significantly altered by environmental factors and they can be taught and practised and intelligence in this area can be improved, eg the use of the New Rules of Measurement (NRM) or how to deal with rogue items provide opportunities for propositional knowledge to be acquired. Within the understanding hierarchy that part most relevant to 'calculations' is analysis and synthesis. The requirement is the comparison of the results between different exercises, eg the working-up dimensions and the preparation of Bills of Quantities (BQs). The appropriate method of learning is association which is being able to infer links between the stimulus and the response (Gagne, 1977). This requires the close approximation of these links and their repetition provides this facility, eg the measurement of variations.

The emotional factor of attitude (Gagne, 1977) concerning the poor ability with numerical calculations is also part of this framework. This comes mainly from the perceived inequalities of a substantial minority whose diverse backgrounds require

individual attention. Work in South Africa on foundation years for disadvantaged students has indicated that the range of problems encountered required a high level of resources and personal attention, (Grayson, 1996 & 1997; Miabila, Maladje & Addo-Bedialo, 2006). The stigma of ignorance concerning numeracy is reduced where this is perceived to be a common problem. Availability and utility are provided by individual face to face teaching outside the classroom that is flexible and discrete from specialist teachers.

The basic practical requirements are that numerical fluency is generally at such a low level that individual remedial teaching is required.

4.3 Problems with The Technology

4.3.1 Theoretical framework for the technology

The ‘technology’ is not knowing the building processes that are being measured. It is 9% of the total. The problem lies within the concept of constructivism. Constructivism is that knowledge is based on personal experience and is described by Biggs (2003) as a scaffolding that can only be built by the student with the teacher encouraging this process of personal knowledge construction. The teacher provides the tools that are necessary with the provision of copious information. The advent of full time students severely limits the use of constructivism because they have no experience of the building site. Also the problem is the teaching of construction technology is usually taught as propositional knowledge, as an intellectual skill not a technical competence, is often very restricted and rarely deals with the details that are necessary for measurement exercises.

In the hierarchy of understanding (Bloom, 1956) the technology is at the ‘knowledge’ stage. The most appropriate way of understanding the technology is time spent on site. In the absence of this the input of vocabularies provides a vicarious knowledge of the technology. In terms of learning what method is best suited to this problem? The process approximates to the verbal association (Gagne, 1977) where a progressive increment of labels are learned using contiguity and repetition. The learning outcomes (Gagne, 1977) are characterised statements of information and the typical activity is remembering the name of things. For verbal information the capabilities that are required include vocabulary, visual identification and discourse. The internal condition that is required of the student is the memory and a cognitive strategy to improve the vocabulary. The external conditions that are provided by the teacher are provision of a context to stimulate memory with appropriate cues and variable repetitions.

4.3.2 Practical solutions for the technology

The ‘technology’ requires to be taught as verbal information (Eraut, 1994) eg the demonstration of particular technologies for a particular trade or the specific vocabulary of the SMM. In the understanding hierarchy that part most relevant for ‘technology’ is knowledge. The requirement is the provision of vocabularies, lectures, demonstrations, printed booklets and sketches, eg the identification of the same technology on layouts, elevations and sections. The appropriate method of learning is verbal association which requires the progressive increments of labels. This can become rote learning which is avoided by providing a suitable context, eg the identification of the technology on site provides the best method of learning by verbal association.

Industrial placement in a sandwich course provides the appropriate knowledge and method of learning. 'Thin' sandwiches, day release, provide a better interface between industry and teaching. However 'thick' sandwiches, placement for a full year, provide a compatible status to other professional degrees. Full time courses provide only propositional knowledge and are not appropriate.

There are three parts to the pedagogical modifications that are necessary. The first acknowledges that full time students are unlikely to be involved in the actual construction of a building or the measurement of the quantities involved. The solution is to confine the learning outcomes to propositional knowledge. The students will learn a little about construction and measurement but will not have a functional knowledge of these technical competencies. This means streaming part time and full time students. The second part of the solution is to provide procedural knowledge of construction technology. This requires the knowledge of skilled practitioners in the field to provide lectures on how to build buildings. This is a profound problem due to the lack of such resources. The use of specialist pedagogies like situated learning and experiential learning are being developed to try to address this problem. The third part of the solution concerns the simple timetabling of the teaching resources. The construction technology units need to be delivered before the measurement units to enable the vocabulary to be in place before the measurement is taught. The emotional elements are similar to those described in the section on process difficulties.

The basic practical requirements are substantial periods on site.

4.4 Problems with the SMM and rulings

4.4.1 Theoretical framework for the SMM and rulings

The 'Standard Method of Measurement' (SMM) is difficulty knowing how to use the book of rules for measurement. The 'rulings' is difficulty knowing how to use the specialist paper used for measurement. Both are 5% of the total and are similar problems with similar solutions. The reasons include constructivism and the emotional environment.

The personal knowledge construction has to be in compliance with the SMM and the rulings. This is particularly noticeable with non-cognate post graduates in the early workshops where it is often the case that their attempts to make personal interpretation of both the rulings and the SMM result in work that is a long way from compliance. The emotional element is the discipline of an arbitrary set of rules in a positivistic paradigm that leaves little flexibility in the use of the rules.

What kind of knowledge is using the SMM and the rulings? This is motor skills (Gagne, 1977) which concerns the use of specific tools. Fine motor skills include the careful application of dimensions onto the appropriate dimension paper in compliance with all the rules of the SMM and the identification of the specific application of a particular rule of the SMM for each and every dimension. These items of knowledge are often overlooked as teaching requirements in the hope that they will 'pick it up as they go along'. They make up 10% of the total difficulties and are persistent problems for some considerable time and they require formal teaching.

In the hierarchy of understanding (Bloom, 1956) the SMM and the rulings is at the application stage of the taxonomy comprising progressive cognitive development with some qualitative appreciation of the system. The most appropriate way of understanding the SMM and rulings is by repetition and contemporaneous feedback. In terms of learning what method is best suited to this problem? There are two methods of learning that are relevant (Gagne, 1977). The use of trial and error allows successive approximations. Although effective the repetition that is required is not a good use of resources. The second method of learning is the reward/reinforcement/motivation method. Positive motivation in the form of rewards comes from the provision of the correct response. There is also a negative motivation when the work is not in compliance and has to be repeated.

The conditions for learning motor skills have been detailed by Gagne (1997) as learning outcomes and in this case is characterised by simple execution of the required work. For motor skills the capabilities that are required include the fine motor skills of legible writing and visual co-ordination. The internal condition that is required of the student is the need to follow in the correct sequence and the necessary attitude to implement this. The external conditions that are provided by the teacher are instruction, demonstration, the opportunity for practice and contemporaneous feedback.

4.4.2 Practical solutions for the SMM and rulings

The SMM and rulings require to be taught as motor skills, the correct use of tools (Eraut 1994), eg the use of mensuration rules for SMM and physically applying them on paper or the screen. The application level of understanding requires repetition and contemporaneous feedback eg the physical dimensions and SMM references prepared by the students need to be reviewed and corrected before moving on to the next exercise. The appropriate method of learning is using reward/reinforcement motivation which allows right and wrong dimensions to be accurately marked and the necessary reinforcement to be implemented, eg the accuracy and presentation of dimensions is subject to a minimum standard. The use of trial and error can be effective for exercises that are easy to repeat. The use of proprietary software, eg CATO, Masterbill allows the easy implementation of successive approximations.

In the environmental framework the use of proprietary software is a problem because they require dedicated laboratories where access is limited, the number of software users is also limited and there are high charges for their use. These factors restrict the number of users and require repeating identical workshops, a significant waste of resources. Larger laboratories and the free use of the software for educational purposes would resolve this problem.

The basic practical proposals are the early use of simple motor skills exercises in the use of the rulings and the SMM.

4.5 Problems with Speed

4.5.1 Theoretical framework for speed

The 'speed' is the lecturer going either too fast or too slow. Both are well represented in the submissions. It is 9% of the total. The reason can be classified under various

headings. In terms of behavioural psychology the stimulus is the perception of the students that the information is provided at the wrong speed and therefore the response is negative in the form of anxiety or boredom. A large range of diversity and experience within the class also contributes to this problem. The appropriate stimulus is the adjustment of the speed and the response is the removal of anxiety or boredom.

What kind of knowledge is applicable to this problem? This remains procedural knowledge (Eraut, 1994) the acquisition of technical competencies. In the hierarchy of understanding (Bloom, 1977) the problems of speed concern the analysis and synthesis stage comprising mainly discrimination of concepts, rules and laws and the need to be able constantly to compare and contrast each piece of work until understanding is acquired. This is a personal process and the speed is different for each individual. In terms of learning what method is best suited to this problem? This is the process of the memory (Gagne, 1977) which comprises registration, short term memory, long term memory and retrieval.

The learning outcome (Gagne, 1977) in this case is attitude. For memory the capabilities that are required include obedience to the discipline and honesty concerning the results. The internal conditions that are required of the student are the necessary intellectual skills and a cognitive strategy to improve memory. The external conditions that are provided by the teacher are the need to overcome the emotional opinions of the students concerning whether the speed is good or bad.

4.5.2 Practical solutions for speed

The problems with speed initially concern the appropriate level of understanding and method of teaching but are primarily concerned with the epistemological factor of streaming.

In the understanding hierarchy the level most relevant to 'speed' is the use of analysis and synthesis. The requirement is the comparison of the results between different exercises, eg the working-up dimensions and the preparation of BQs. The appropriate method of learning is the development of the memory (Gagne, 1977) which comprises registration, short term memory, long term memory and retrieval, eg the teacher establishing the synaptic pathways by demonstration and the student strengthening them by repetition and retrieval.

The environment concerns the mix of full time and part time students. The question of the varying ability of students concerns the need for 'streaming' according to ability or 'setting' which is allocation according to ability in specific subjects. The effects are reviewed in Pupil Grouping: Literature Review Oct 2005 DfES Research Report RR680 which states "*...but low-achieving pupils show more progress in mixed-ability classes and high-achieving pupils show more ability in set classes.*" In most large classes there are full time students with no industrial experience and part time students with substantial industrial experience. The streaming has already taken place. The teaching should reflect these differentials. The need is to stream the students into separate full time and part time classes. This is often a fundamental problem given the resources available. However the cause of the problem is mixing the streams and the solution is to separate the streams. Each has a different teaching solution. For the part time students

who have the industrial experience and require technical competence procedural knowledge is necessary. Those without industrial experience, who will not become active professional practitioners, will require propositional knowledge. Even when the mixed streams are formed into uniform groups the tendency to form cliques undermines the process of collaboration. Equality and diversity is maintained at the cost of inappropriate teaching, poor learning outcomes for the students, anxiety by the slowest and boredom by the fastest. The mixing of these streams is therefore inappropriate. In the emotional components the provision of student tutors provides an opportunity for the slower members of the class to ask questions that might be considered, by them, to be too simple without slowing down the rest of the class.

The basic practical proposal is the streaming of the students into full time and part time classes.

The following table summarises the proposals for each difficulty and provides some examples.

Table 2 Proposals

DIFFICULTY	TEACHING		EXAMPLES
THE PROCESS	Epistemology		
		Procedural knowledge	Practice
		Contingent instruction	
	Contemporaneous feedback		
	Cognitive		
		Understanding	Application
		Learning	Conditioned response
CALCULATIONS	Cognitive		
		Propositional knowledge	Discrimination
		Understanding	Analysis and synthesis
		Learning	Association
		Emotional	Attitude
TECHNOLOGY	Epistemology		Substantial periods on site
	Cognitive		
		Knowledge	Verbal information
		Understanding	Knowledge
		Learning	Verbal association
SMM AND RULINGS	Cognitive		
		Knowledge	Motor skills
		Understanding	Repetition
		Learning	Reward/ reinforcement
SPEED	Cognitive		
		Knowledge	Procedural
		Understanding	Analysis and synthesis
		Learning	Memory
		Environmental	Streaming
			Practical exercise of taking-off quantities for a particular trade in collaborative groups
			Taking-off repeated for different trades
			Repeated in the same sequence for each exercise
			Measuring rogue items, use of the NRM
			Working up dimensions, BQ preparation
			Measuring variations
			Remedial teaching in numeracy
			Vocabulary of a particular trade, Vocabulary of the SMM
			Identify the same technology on plans, elevations & sections
			Long term site work
			Physically applying the rules of mensuration and the SMM to the dimension paper
			Dimensions and SMM references are corrected before the next exercise
			Accuracy and presentation of dimensions subject to minimum standards
			Practical exercise of taking-off quantities for a particular trade
			Working up dimensions, BQ preparation
			Demonstration
			Separate full time from part time

5 Conclusion and Further Research

The provision of QS teaching as technical competence in universities has been affected by the lack of a pedagogical foundation, increased student numbers and a greater diversity of students. It is hoped that this review of the basic requirements of teaching will help to ensure that the correct teaching is available despite the increasing restrictions on resources, space and time.

Screening and Selecting Project Managers for the Middle East

Abstract:

Cross-cultural training is of prime importance if the expatriates are to adjust speedily to the new environment and do well in the United Arab Emirates (UAE). Selecting the right people for the overseas job is important as the selected individuals need to have a desire and readiness to learn. Some researchers in this field referred to this as the “learning orientation” where people with high learning orientations like challenges and are ready to learn and people with low learning orientations like to play it safe and do not like challenges. The way the “right” people can be chosen for the overseas assignment is by pre-testing the employees. It is important that they are able to adapt to new and unfamiliar situations, many researchers believe that this characteristic is very important to success.

The mistake a lot of companies make is that they select staff that have been successful in the home country without testing them. These companies fail to realise that these employees need additional qualities such as being able to adjust quickly to new and unfamiliar environments and have the desire to learn about new cultures as well as being willing to change. Using six case studies this paper will analyse the importance of selecting the right people. All six case studies are Australian international companies operating worldwide including the UAE.

Keywords

cross-cultural training, learning orientation, selection criteria

1 Introduction

There are a vast number of reasons why cross-cultural training is important. From a company perspective, if their personnel are adequately trained for the overseas assignment they will be more successful by increasing the overall efficiency and profitability, and the company will avoid losing money (Cerimagic, 2010). In addition, the company can overcome the belief that their way of doing things is superior to that of others (Ono, 1992).

Cross-cultural training helps personnel to improve and to be able to interact effectively with local people and co-workers (Shenkar, 1995). Many researchers argue that companies have failed to pay attention to “screening, selection and training of potential expatriate staff and the non-technical skills they should possess.” (Forster, 2000:63).

The mistake a lot of companies make is that they select staff that have been successful in the home country without testing them. These companies fail to realise that these

employees need additional qualities such as being able to adjust quickly to new and unfamiliar environments and have the desire to learn about new cultures as well as being willing to change (Porter and Tansky, 1999).

Another major error that the companies make is the lack of cross-cultural training that they provide for the employees.

The way the “right” people can be chosen for the overseas assignment is by pre-testing the employees. It is important that they are able to adapt to new and unfamiliar situations. Porter et al., (1996) believe that this characteristic is very important to success.

2 Selection Criteria for International Assignments

In the recent years international human resource management specialists such as Black and Gregersen (1991), as well as Bonache et al. (2001) have developed a model that helps underpin the effective selection of personnel for overseas assignments. This model helps to make the selection criteria more effective.

This model identifies two types of adjustment:

- the anticipatory adjustment, and
- the in-country adjustment.

Firstly, the anticipatory adjustment is carried out before the expatriate leaves the home country and it is influenced by a number of important factors such as pre-departure cross-cultural training, which is designed to familiarize expatriates with the culture and work life of the host country.

Secondly, the in-country adjustment has five factors that influence it; to begin with the expatriate’s ability to stay positive, to deal well with stressful and high-pressure situations and to interact with the host nationals to better understand the host culture and values.

Thirdly, the expatriate should be clear about the job.

The fourth factor is the organizational culture, and how well the expatriate can adjust to it.

Fifth, is a no-work factor, and it is looking at how the expatriate faces the new cultural experience and how well the expatriate and his/her family/partner can adjust to the host country. The final factor identified in the in-country adjustment mode is for the expatriate to socialize and quickly find out who is who in the host organization.

After analyzing the relationships between host nationals and expatriate, Caligiuri (2000) reported that greater interaction with host nationals positively relates to cross-cultural adjustment when the expatriate possesses the personality trait of openness. Caligiuri (2000) also states that the personality trait of sociability was also positively related to cross-cultural adjustment.

According to Luthans and Doh (2009) anticipatory and in-country adjustment will have an influence on the expatriate’s mode and degree of adjustment. All expatriates go through a transition period after they arrive in a foreign country. There are ups and

downs, but with appropriate cross-cultural training and support the expatriates can quicker adjust to the foreign country and integrate much faster too.

McCormick and Chapman (1996) consider that anticipatory and in-country adjustment will have an influence on the expatriate's mode and degree of adjustment. Figure 1 shows the transition which expatriates go through after they arrive in a foreign country. There are ups and downs, but with appropriate cross-cultural training and support the expatriates can quicker adjust to the foreign country and integrate much faster too.

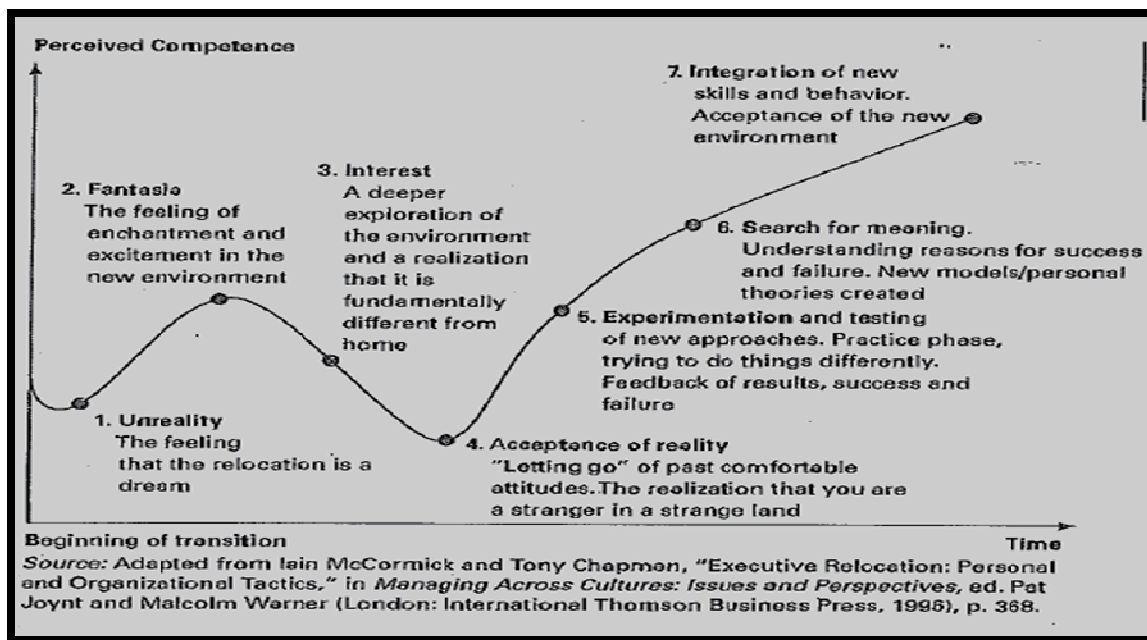

Figure 1: Transitions which expatriates experience
(Source: Luthans and Doh (2009:483))

Companies also need to consider both technical and human criteria when selecting expatriates. Expatriates that are sent overseas must be able to adapt to change.

Criteria that are important to be considered when selecting expatriates, are primarily their age, experience and education. Technical competence is important, but it is only one of a number of skills that an expatriate will need in a host country. If the company only selects an expatriate based on his/her technical skills the company may be setting the expatriate up to fail, because the expatriate will go overseas believing that he/she is project ready and they may not be able to deal with the challenges awaiting them. The chance of failure is likely to increase. In addition, companies usually want the personnel to have an academic degree as well as the desire to work abroad. Over the years companies have realized that balance is important and this is why they send both younger as well as older personnel overseas.

The literature suggests that cross-cultural training has long been advocated as a means of facilitating effective cross-cultural transfer of expatriates. While international organisations understand and acknowledge that cross-cultural training is important, in many cases they still do not offer any cross-cultural training to their employees. There are many reasons why companies do not offer cross-cultural training. Some believe that it is too costly and time consuming, or that training is not necessary, or effective. In

some cases it was reported that the project management industry is so fast paced that there is simply no time for cross-cultural training.

2.1 Learning

Once again selecting the right people for the job is important as the selected individuals need to have a desire and readiness to learn. Porter et al., (1996) and VandeWalle (1997) referred to this as the “learning orientation” where people with high learning orientations like challenges and are ready to learn and people with low learning orientations like to play it safe and do not like the same challenges. Those researchers argue that employees with high learning orientations are better candidates for overseas assignments as they want to learn and the training provided to them will have a high impact on them. Since no matter how good a training program is, if the participants are not willing to learn new skills and aptitudes the training is useless.

The way the “right” people can be chosen for the overseas assignment is by pre-testing the employees. It is important that they are able to adapt to new and unfamiliar situations, Porter et al. (1996) believes that this characteristic is very important to success.

Luthans (2004) wrote that another important area of consideration for developing good expatriates was the different learning styles of individuals. Learning is the acquisition of skills, knowledge and abilities that result in a relatively permanent change in behaviour (Luthans, 2004). Researchers such as vanReine and Trompenaard (2000) have discovered that different national cultures prefer different learning styles to match the environment and the company needs to deliver the training in the most effective manner. They have noted that Americans, for example, prefer an experimental approach while Germans prefer a theoretical-analytical learning style. It should be also noted that no matter how good the training was the new learned behaviours would not be used if they were not reinforced.

It should be noted that over the years better paradigms for social learning theory and cultural theory have emerged. This increases the impact and the likely success of cross-cultural training (Black and Mendenhall, 1990; Kim, 1993; Bhawuk, 1998).

Pruegger and Rogers (1994) suggested that interpersonal methods are more effective than didactic training programs. Waxin, et al. (2002) found that globally the most effective type of learning about a culture is by experimental training. However, Waxin, et al. (2005:69) also points out that the method of training should be specifically tailored “to the cultural distance between the expatriate’s country of origin and the host country”. In addition, Vance and Paik (2002) point out that for cross-cultural training to be effective it should be consistent with the cultural characteristics of the host country. Companies would also benefit from using their former expatriates as trainers, as those former expatriates have been there and can put themselves in the shoes of the new expatriates (Cerimagic, 2010).

3 Methodology

The case study approach has been chosen to conduct this research. Case studies have been used in many studies as a research method in many situations including such environments as sociology and business, and looking at individuals and groups (Yin, 2009). Interviews have been used to better understand the complex social phenomena

such as culture and its dimensions, for example. Each of the six case studies consisted of two in-depth interviews. This provided twelve interviews in total. Case studies allow researchers to “retain the holistic and meaningful characteristic of real-life events” (Yin, 2009:4) such as group behaviour, organisational and managerial processes. According to Grunbaum (2007) the case study approach has been used for several decades.

For the purposes of this research six companies were selected that had expatriate western project managers working for them (see Table 1). This research paper has been based on case studies because all the companies that have been listed in Table 1 (not named) have expatriate (western) project managers. The researcher had to control some of the environmental variations, while the focusing on large corporations allowed some variation and variety due to size differences (but not excessive ones) among the companies. According to the research carried out by Pettigrew (1988) the specifications focused on a particular population. In the case of this research it focused on expatriate western project managers and this reduced many extraneous variations and provided the potential to clarify the range (the field) of the findings.

Table 1: Summary Table of Cases

CASE	INDUSTRY
Case One	World’s largest privately owned engineering and construction companies.
Case Two	Structural engineering
Case Three	Project management and construction company.
Case Four	A development company, working in the residential, commercial, retail, funds management and hotel industry segments.
Case Five	Global network of professional firms providing audit, tax and advisory services
Case Six	Consultancy and construction

The interview questions were semi-structured and interviews were in-depth. However, every interview focused on the following criteria:

- Challenges
- Recruitment and importance of selecting the right people
- Cross-cultural training

The interviews were all recorded, next they were transcribed and then analysed via cross-case analysis. The extent of the sample was expanded by asking each interviewee if there was anyone they knew, who was a project manager and could make a contribution to this research. The interviewer also interviewed those individuals too and expanded the sample by around 20%.

4 Results

4.1 Challenges

Most of the challenges were due to the lack of knowledge on how things are done in the UAE compared to Australia. Those mental challenges could be avoided or minimised with appropriate training and preparation of expatriates. A social network and support group (or groups) would be very helpful as well. The extreme heat outside and the ice

cold air-conditioned offices inside whilst it sounds trite, can also be a physically challenging and can be a source of irritation to even the most seasoned expatriate.

4.2 Selecting the “Right” People for the Job

Many researchers argue that companies have failed to pay attention to “screening, selection and training of potential expatriate staff and the non-technical skills they should possess.” (Forster, 2000:63). This was a constant theme throughout the interviews and some interviewees confirmed this was the case with their colleagues.

Preparation of expatriate staff is important to help them be prepared for the unfamiliar environment, to have an rough idea of what to expect, as well as help them to avoid any major errors in business dealings and in the important social interactions. Even with adequate preparation expatriates will not be able to function at their fullest capacity as soon as they arrive in the UAE, as this is too soon in their assignment. This is why cross-cultural training needs to be an ongoing and reinforced process. Without it most expatriates will struggle in the new environment and may even return to their home country prematurely and feel bitter about their experiences.

As pointed out earlier, selecting the “right” people for the overseas job is important, as the selected individuals need to have a desire and readiness to learn. Porter et al., (1999) and VandeWalle (1997) referred to this as the “*learning orientation*” where people with high learning orientations like challenges and are ready to learn and people with low learning orientations like to play it safe. Hence, it can be argued employees with high learning orientations are better candidates for overseas assignments as they want to learn and the training provided to them will have a higher impact on them. What this research revealed is that, no matter how good a training program is, if the participants are not willing to learn new skills and implement those skills cross-cultural training will not help as these are not the ‘right’ people in the first place.

4.3 Recruitment

The expatriates in those case studies had all been recruited in different ways. Most had a phone interview while still in their home country and did not visit the UAE.

Case study firm five whose company has been in the UAE for the last thirty years did an initial phone interview where they ran through most of the difficulties that will come with working in the UAE. They look for people who have the necessary skills-set that is required to do the job. In addition, people who are known by the company’s staff or who have worked previously on projects with staff from the company tended to have priority and these people are sourced or contacted to discover their interest in working in the UAE, on these projects for this company.

Additionally, many firms look at the age of the person and maturity level of the people that they were interested in employing. All of their senior managers do a personality profile, specially carried out by a consulting company to make sure that the person is more likely to fit the job. This again is a basic and simple process that can save a great deal of frustration and possible failure later.

4.4 Cross-Cultural Training

It was obvious from the six case studies that cross-cultural training was of high importance to the firms and the respondents and that it should be provided by the companies. The findings also revealed that preparation of expatriates for the UAE

climate was considered absolutely vital. Nevertheless, even though the companies recognised that expatriates require being cross-culturally trained, most of the case study forms in this research do not offer adequate cross-cultural training. This research revealed that most of the interviewees do not get any pre-departure training; additionally majority of the interviewees report that they did not receive any training on site either after they arrive in the UAE. There are many reasons why companies do not offer cross-cultural training. Some of the cases studies suggested that cross-cultural is seen as too expensive or simply not necessary, as there is a believe that “you learn by doing” or you ‘sink or swim’.

Since proper and adequate preparation helps expatriates quickly feel part of the community, it is essential that such training and preparation is provided. However, preparation such as induction programs should be dynamic, up-to-date, relevant and interesting. The participants should feel that they are being well prepared and that the material being given to them is useful and very relevant. Neither the facilitators, nor the participants should feel that everyone is just going through the ‘motions’ or ticking a box. Senior managers should regularly check on the quality of these preparation workshops and encourage existing employees to attend to ensure their content is adequate and useful.

In the interview expatriates were asked what is important to learn about the UAE and the Emirates before starting to do business in the UAE. The respondents clearly noted that the culture was rated of high importance. Cultural awareness is the number one skill that is necessary in this environment and respecting the culture goes hand-in-hand with it. For example, expatriates need to learn everything about the country, its people, religion, customs, rules and regulations. Keeping updated with the rules and regulations is very important as they change very quickly.

Additionally, throughout this research it was found that personal relationships and trust are important. Hence, a lot of time and effort needs to be put in to establish that trust and confidence. Networking in the UAE is a must, and expatriates must maintain their integrity and reputation. A bad reputation will result in reduced work or no work at all, therefore learning by doing is not the best way to go about acquiring new and necessary skills. Being aware of the fixed and changing environment in these countries is essential and importing personal views, attitudes and prejudices can cause problems in these relationships. Assuming that the local person has the same views and attitudes as the expatriate about certain issues can cause embarrassing problems for the individual and the company. The expatriate has to be sensitive to this or her environment at all times.

4.5 Testing the Post Training Experience

The interview revealed that most participants agree that testing for post-training experience would be beneficial. This was a strongly held view by most of the interviewed staff.

The testing of the post-training experience can indicate if the training is working. If it is not for example, then the training can be modified. Additionally, the training can provide feedback and suggested improvements. This way the training is revised on a regular basis, it is updated and it is made up-to-date. In return this helps the company save money and have well trained workers who are able to deliver successful projects.

The post training experience can be conducted by either a mentor, who is mentoring the expatriate, or by the expatriate’s manager. The expatriate would not be asked to do a

self assessment as most individuals are unable to be objective when conducting self-assessments. Post training experience was important and it should be carried out by someone who works with the expatriate and not by the expatriate as people see themselves differently than what they are perceived by others.

5 Conclusion

Project management is not solely a technical activity. It is also highly dependent on the people working on those projects. With the right and adequate cross-cultural training project managers have the ability to learn new skills and behaviour, and alter those behaviours when required and be a high-performing individual .

By using six case studies and conducting in-depth interviews it was possible to gain a rich picture on what challenges project managers face in the UAE. The case studies also provided the researcher with feedback on how they were recruited and why it is important of selecting the right for the overseas job. Additionally, the case studies revealed that in addition to having selected the 'right' employees for the job cross-cultural training is necessary as well to teach and prepare the staff for the unfamiliar environment. This too will help staff in dealing with challenges more appropriately and make the staff more contented and probably more successful in working for that company.

Since people play an important role in every aspect of project management it makes sense to equip them with the necessary tools to perform at their best. It was stressed by many that technical competence was assumed by the companies and clients and the critical dimension was the ability of the company's employees to deliver their skills in a work and culturally sensitive environment.

However, cross-cultural training alone is not enough, the right people need to be recruited. Those individuals need to have the desire to learn and embrace the new culture and environment, to challenge themselves, and to have a positive attitude even when work and life in a foreign country get frustrating. Companies should put in more effort and emphasise their recruitment strategies, because if the wrong employees are selected all the money and time that is allocated towards training them is likely to be wasted.

University of Glamorgan, Treforest, Pontypridd CF37 1DL

Email: mrhall@glam.ac.uk; twilliam@glam.ac.uk

Abstract:

Graduate employment continues to be adversely affected by the economic climate. In 2009 the project team set out to improve the employability chances of construction graduates from the University of Glamorgan [UoG]. The project evolved from a variety of Government policy documents from (Leitch, 2006), (Welsh Assembly Government, 2008) and the (RICS, 2010) Consultation Document on employability which emphasises the importance of soft transferable skills which are central to professionalism. The work forms part of an inter-faculty study on professionalism. The faculties consisted of Advanced Technology and Humanities and Social Sciences. This project was partly funded by The Centre for Excellence in Learning and Teaching [CELT] as part of an Innovation in Learning and Teaching initiative. The methodology employed involved the re-use of a previous questionnaire with students in the first and final years of undergraduate awards. Feedback on professionalism has also been obtained in formal and informal discussions with industry representatives. This ongoing action research project to improve the students' understanding of professionalism has highlighted several questions relating to course content and delivery. These questions include what needs to be incorporated in the curriculum, how and when this is delivered and assessed. Problem based learning has been identified as a vehicle to facilitate the programme. The need to address staff development issues has also been identified. The action research continues.

Keywords:

surveying, professionalism, problem-based learning, action research

1 Introduction

1.1 Aims

- To improve employability of students on completion of their built environment undergraduate awards.
- To increase an undergraduate's understanding of professionalism
- To address the RICS employability threshold expectations.
- To develop problem-based projects, in conjunction with employer representatives, that would help to satisfy the aims set out above.

1.2 Objectives

The objectives of the research were to:

- initiate an action research project
- establish baseline of students' knowledge and attitudes to professionalism
- establish what employers expectations are regarding professionalism from graduates
- use the findings from the student baseline study and the employer interviews to inform the development of a new RICS accredited undergraduate quantity surveying and commercial management award

1.3 Rationale

The economic downturn continues. One commentator (Green, 2011) reports construction lost a further 24,000 jobs in the first quarter of this year with the number of workforce jobs dropping to its lowest level since mid 2003t whilst another (Anon, 2010) predicts that the government's recent public sector spending cuts could result in a further 104,000 job losses in construction.

The gloomy economic outlook combined with the recent requirements from RICS relating to the development of graduates' employability skills and greater employer/industry engagement encouraged the academic staff concerned to continue a project within the curriculum that would enhance graduate employability through propagating a positive culture of professionalism.

2 Research Methodology

2.1 Research design

The methodology used was designed to elicit attitudes and knowledge of students in regard to the concept of professionalism.

The authors wished to establish the attitudes and knowledge of students on the undergraduate built environment courses as a base line.

In order to establish the students' knowledge and skills, a structured tool assessing their understanding of the concepts associated with professionalism was used. This tool was derived from a number of sources. These sources had used particular terms in their definitions of professions and professionalism. This tool tested both the students' knowledge of the terms and their attitudes to professionalism.

A structured tool, relating words to concepts, was devised to reveal knowledge of aspects of professionalism thus creating a baseline of students' attitudes and knowledge. This tool incorporated nine areas which related to professionalism [refer to Appendix 1]. These common themes were generated from many sources including (Oxford Dictionary, 2009), (Fewings, 2009), (Maister, 1997), (Haralambos and Holborn, 2008) and the RICS and CIOB codes of conduct.

A quantitative approach was felt appropriate to establish a base line of students' skills and attitudes in relation to professionalism. The method also allowed the majority of students in the population to be surveyed thus maximising the efficacy and validity of the study.

2.2 Population.

All students registered on the first and final year of the full time and part degree undergraduate awards in Quantity Surveying, Project Management [construction] and Real Estate and Development at the University of Glamorgan in the academic years 2009-10 and 2010-11.

2.2.1 Sample

Students were surveyed three months into the academic year. They were fully informed of the project's aims and objectives and were given the opportunity to opt out of the survey. The questionnaires were completed anonymously.

Table 1. Questionnaire sample

Cohort	Population	Sample	% of population
2009-10			
First year	108	59	54
Final year	60	43	72
2010-11			
First year	101	29	29
Final year	80	37	47

2.2.2 Research Strategy

In order to increase the match between the expectations and needs of employers and students' attributes in a dynamic setting, action research was employed.

Action research is a research strategy to enable researchers and practitioners to work together to achieve an optimal outcome (McNeill and Chapman, 2005). (Lewin, 1946) first described this structured cyclical process to enable change to occur within a controlled environment. The process involves different methods of data collection including surveys, interviews meetings etc. These results are fed back to the stakeholders to assess the impact changes have had on their practice and if any further changes need to be made, thus refining the process until an optimum outcome has been achieved. Similarly (McNiff, 2002) describes action research as "*a term which refers to a practical way of looking at your own work to check that it is as you would like it to be*".

3 Results

3.1 Questionnaire results

3.1.1 Knowledge of concepts associated with professionalism

Figure 1 Results from questionnaire 2009 and 2010

Overall the results show that:

- There is a similar pattern of results over the two years with regards to the % of the cohorts that correctly identified the three correct phrases/terms associated with each of the nine aspects of professionalism detailed in Figure 1 above.
- Aspects that demonstrated the greatest understanding in both datasets were possess a body of knowledge; provide a service and control membership.
- Aspects that demonstrated the least understanding in both datasets were self regulation and protect members.
- In 2009 only three of the nine aspects produced a greater than 50% correct response. In 2010 this decreased to two of the nine aspects surveyed.
- No one correctly identified the three phrases/terms in all nine of the aspects.

Subsequent to distribution of the 2010-11 questionnaires the authors were invited to present their research findings in a seminar hosted by the university's Centre for Excellence in Learning and Teaching [CELT]. At this seminar feedback from participants highlighted that the terms "disciplinary measures" and "indemnify" may be ambiguous. The feedback suggested that whilst the terms were not considered to be incorrect there was a concern that participants may not recognise their significance in the context of professionalism. The authors note that these terms are contained within the two aspects which showed least understanding and will therefore re-evaluate the questionnaire prior to further use. Despite their minor misgivings the overall feedback

from the staff seminar was that the questionnaire was a useful tool to evaluate students' knowledge and attitude to being a professional.

The results also indicate consistency in the deficit of knowledge amongst the different student cohorts in relation to being a professional reinforcing the authors concern that this is an area that needs greater attention in the curriculum.

3.1.2 Results of questionnaire qualitative data

Two questions were included which asked the students to reflect on:

- What does being a professional mean to you?
- Why are you studying for your award?

Content analysis was used. The results provided a variety of statements which were grouped into key words. Results for both years are shown in Figures 2 and 3.

Figure 2 Meaning of Professional

Figure 3 Reasons for studying

Whilst the terms identified from the content analysis remain similar for the two cohorts the percentage of responses for many of the terms differs considerably. This reinforces the results in the quantitative section of the questionnaire in as much as there is a clear confusion with regards to the meaning of the term professional and how it relates to their reasons for studying.

4 Discussion of results and review of relevant literature

4.1 Professionalism in the Quantity Surveying & Commercial Management award

In designing the new award it was decided that the use of project-based modules could be an effective vehicle to teach professionalism “themes” whilst at the same time influencing students’ professional attitudes and behaviours. It was felt that these modules offered the opportunity, in conjunction with employer inputs, to deliver 3 core strands of professionalism ie professional competence [knowledge], soft transferable skills [eg communication, teamwork, problem-solving] and professional socialisation [personal values, belief in service to public/client, belief in self regulation etc].

Figure 4 Hierarchy of professional development

The award contains a project based module in each of its three years. The project's professional competence and transferable skills content would be based on the adjoining modules from that year of study and the RICS employability threshold requirements. This content is the familiar territory of undergraduate education as outlined by (Duch *et al.*, 2001 p6):

- *Think critically and be able to analyse and solve complex, real-world problems*
- *Find, evaluate and use appropriate learning resources*
- *Work cooperatively in teams and small groups*
- *Demonstrate versatile and effective communication skills, both verbal and written*
- *Use correct knowledge and intellectual skills acquired at the university to become continual learners.*

The teaching and assessment of professional socialisation presents the authors with more of a challenge. In her discussions on teaching professionalism to pharmacy undergraduates in America (Hammer, 2006) comments:

In discussions about students and professionalism, one question that often arises is whether professionalism can be "taught." There is certainly a body of knowledge about professionalism that can be learned, but does that ensure that the learner will demonstrate professional behaviors? Probably not. Professional socialization, however, which is the process by which students learn and adopt the values, attitudes, and practice behaviours of a profession, can be taught or at least influenced.

Traditional lecture and tutorial approaches seemed inappropriate for achieving the required objectives therefore the authors decided to review the literature on problem based learning to see if it offered possible solutions.

4.2 Problem based learning [PBL]

The decision to facilitate the professionalism and employability of our graduates through using problem based learning was motivated by three main reasons:

Firstly, Problem based learning is increasingly seen within higher education as a necessary approach in education for the professions. (Boud and Feletti, 1991 p.14) see problem based learning as “... *a way of conceiving the curriculum which is centred around key problems in professional practice...*”

Secondly, there is the issue of context. The questionnaire surveys at Glamorgan and the interviews with employers identified a probable cause of the lack of undergraduate understanding of key facets of professionalism was the lack of a real world context. They were not able to ground facets of professionalism in real work situations or experience. (Boud and Feletti, 1991) suggest that one of the defining characteristics of problem based learning is that context is of central importance to this method of learning. They suggest that effective learning takes place only when students are actively involved; using knowledge they are developing in a relevant and meaningful context. The prevailing economic conditions have resulted in far fewer students undertaking a sandwich placement which has further reduced their opportunities to use their knowledge in a relevant and meaningful context.

Thirdly, Problem based learning has its roots and traditions in the teaching methods of the ancient Greeks. As (Boud & Feletti, 1991) and (Savin-Baden & Howell-Major, 2004) discuss; problem based learning is not new. It is a method of learning that predates the advent of classes and course programmes. However, it is the association with Aristotle’s teaching methods discussed by (Savin-Badin & Howell-Major, 2004) that connect conceptually with the approach adopted in this research.

These three reasons will be further discussed in the sections that follow, but firstly it would seem useful to define problem based learning (PBL).

4.2.1 *What is Problem based Learning?*

(Duch *et al.*, 2001 p6), agreeing with (Boud & Feletti, 1991) suggest that:

“...In the problem based approach, complex real-world problems are used to motivate students to identify and research the concepts and principles they need to know to work through those problems. Students work in small learning teams, bringing together collective skill at acquiring, communicating and integrating information.”

According to (Savin-Baden and Howell-Major, 2004), problem based learning can be characterised more broadly by its student -centeredness in addition to its being focused around problems. They identify eight key features of problem based learning, five of which focus on the student experience and three that deal with PBL from the staff perspective. It is worth discussing the five student related characteristics:

Firstly, PBL takes into account the past experience of students.

Secondly PBL fosters student autonomy by encouraging them to take responsibility for their own learning.

Thirdly PBL centres on the processes rather than the products of knowledge acquisition. As Engel (1986) suggests problem based learning is a means of developing learning for capability rather than learning for the sake of acquiring knowledge.

Fourthly it achieves an interweaving of theory and practice.

Finally, the necessity for student's to work with others during problem based learning activities hones their communication skills in a way that enhances their interpersonal skills beyond their area of technical expertise.

4.3 Problem Based Learning as a method of educating professionals

Problem based learning came to prominence as a method of learning in universities within the field of medical education principally as a result of the seminal work by (Barrows and Tamblyn, 1980) in their book 'Problem -Based Learning: an Approach to Medical Education'. (Boud and Feletti, 1991) argue that this book changed the way medical education was taught at McMaster medical school in Canada and subsequently throughout medical education generally. The reason for this innovation was that PBL resulted in the creation of medics with enquiring minds and a desire to understand, rather than the traditional pedagogies which equipped doctors with a set of knowledge and responses that allowed them to earn a good living. Since then the use of problem based learning has begun to dominate within the arena of professional education because as (Boud and Feletti, 1991 p14) suggest, problem based learning is "... *a way of conceiving the curriculum which is centred around key problems in professional practice ...*"

Further, they see problem based learning within higher education as a necessary approach in education for the professions. They highlight the point that the ever expanding knowledge base of most professions precludes a novice practitioner being able to assimilate all the knowledge necessary in their undergraduate studies to become a fully autonomous professional. They also argue that it is more important for students to be able to research, discern and utilise information appropriately than to absorb all information academic staff deem desirable.

This argument is particularly relevant in the field of professional ethics where the code of conduct for a professional body cannot possibly cover every nuance or 'grey area' that a new practitioner could come across (see Hall & Williams, 2010). We would suggest therefore that in this arena it is even more important that students leave university having developed the knowledge, understanding and discernment necessary, coupled with humility to be able to apply a set of professional values and qualities to their professional work; and further to have the confidence to able to ask for advice in those situations where they are unsure of the 'right thing' to do.

4.4 The Issue of Context

We suggest that utilising the techniques of problem based learning may better serve the development of student understanding of their own professionalism because the knowledge which is valued in problem based learning is that which can be used in context and interrelated, rather than that of knowledge presented in discrete, often unrelated subject areas. (Boud and Feletti, 1991 p22)

(Boud and Feletti, 1991) suggest that one of the defining characteristics of problem based learning is that context is of central importance to this method of learning. They suggest that effective learning takes place only when students are actively involved; using knowledge they are developing in a relevant and meaningful context. They also suggest that one of the benefits of PBL is that:

“... Problem based learning is closer to the real world of the professional and as such has greater validity with practitioners/professionals than a course of discrete unrelated subjects. ...”

(Wood, 2003) also considers advantages of PBL to be:

- *Student centred*—PBL fosters active learning, improved understanding, and retention and development of lifelong learning skills
- *Generic competencies*—PBL allows students to develop generic skills and attitudes desirable in their future practice
- *Integration*—PBL facilitates an integrated core curriculum
- *Motivation*—PBL is fun for students and tutors, and the process requires all students to be engaged in the learning process
- *“Deep” learning*—PBL fosters deep learning (students interact with learning materials, relate concepts to everyday activities, and improve their understanding)
- *Constructivist approach*—Students activate prior knowledge and build on existing conceptual knowledge frameworks

Wood (ibid) also considers the disadvantages of PBL as follows:

- *Tutors who can't “teach”*—Tutors enjoy passing on their own knowledge and understanding so may find PBL facilitation difficult and frustrating
- *Human resources*—More staff have to take part in the tutoring process
- *Other resources*—Large numbers of students need access to the same library and computer resources simultaneously
- *Role models*—Students may be deprived access to a particular inspirational teacher who in a traditional curriculum would deliver lectures to a large group
- *Information overload*—Students may be unsure how much self directed study to do and what information is relevant and useful

Wood (ibid) also reflects on the impact of PBL on the teaching staff as follows:

Introducing PBL into a course makes new demands on tutors, requiring them to function as facilitators for small group learning rather than acting as providers of information. Staff development is essential and should focus on enabling the PBL tutors to acquire skills in facilitation and in management of group dynamics (including dysfunctional groups).

Despite the potential disadvantages identified the authors believe that overall PBL, by providing a real world context within which students apply their developing knowledge has many advantages; it can help foster not only the application of knowledge to actual practice but can also help develop professional behaviours and attitudes .

4.5 Links to Aristotle

Conceptually there are two links with Aristotle’s ideas and this research. Firstly, our approach to understanding the notion of professionalism, (detailed discussion to be found in Hall & Williams, 2010) is based around the idea that Professionalism may be

better understood as a set of values and virtues that need to be internalised through a process of socialisation or formation. Aristotle thought that this process of developing values and virtues was difficult to teach and only developed over time. (Hammer, 2006) concurs with this idea that professionalism cannot be taught, but suggests that the values, attitudes and behaviours of a profession can be taught and influenced through the use of role models and reflection/discussion on real world situations. This provides further weight for the argument in favour of adopting PBL as an appropriate curriculum approach.

Secondly, (Savin-Baden and Howell-Major, 2004) highlight the link between Problem based learning and Aristotle's teaching methods. They suggest that for Aristotle teaching and learning was always focused around disciplined inquiry into some aspect of reality and that education should enable students to make rational judgements that interweaved and applied theory to the practical. Problem based learning in this context is a quest for knowledge where students use their reasoning abilities to manage or solve complex problems.

Overall the authors believe that the literature concerning Problem Based Learning (PBL) strongly supports their strategy for developing undergraduate professionalism.

5 Conclusions and recommendations

Action research has proved to be an excellent tool for continuous evaluation of the undergraduate courses in regard to development of content, implementation and evaluation of students' performance and facilitating industry/partner input. Action research often creates more questions than answers as ongoing evaluation and assessment of the project reveals the need to change in relation to perceived needs. This phase of the study has led to the following actions for the next cycle in the process.

1. There is a need to establish an end point for the "transition to professionalism" ie what basic professional attributes the industry would expect of a new graduate. This end point needs to be established in conjunction with employers and the professional bodies.
2. Having defined the end point it will then be necessary to design a coherent, logical progression from year one to year three of the award ie a journey to transition. This progression will include the nine aspects of professionalism referred to in the questionnaire.
3. Development of appropriate assessment tools and mechanisms, both formative and summative, to assess individual's progress on this journey. These mechanisms must be designed to emphasise the importance and relevance of the concept of professionalism to undergraduate development and employability.
4. Given the potential disadvantages of PBL identified in this paper it will be imperative to manage the changes involved in adopting this approach, especially in relation to staff and team development.
5. Last but not least there is the need to develop a framework whereby employers are fully engaged in the process of development, delivery and assessment. Thus increasing the students' exposure to professional expectations and increasing their employability.

Critical Review: An investigation into the definition of non-cognate graduates in the context of professional quantity surveying education.

Yvonne Simpson

Senior Lecturer, University of Greenwich, Mansion House Site,
Avery Hill, Eltham, London SE9

Email: sy09@gre.ac.uk

Abstract:

This paper reviews the construction industry understanding of technocratic and generalist education. There exists a dichotomy in practice between cognate and non cognate graduates. Within this paper an exploration occurs around definition and context, themes are identified by critically appraising current relevant literature in a qualitative manner, with particular emphasis on analysis and interpretation. In particular, the rhetoric employed in the ethnography sample will be addressed through the definition of the terms cognate and non cognate. It is expected that this paper will act as a basis for future investigations into technocratic and generalist education for quantity surveyors bridging the terminology chasm and widening the debate into other professions.

Keywords:

non cognate, dichotomy, construction education, technocrat, generalist

1 Introduction

As an active chairman on one of the professional assessment panels, run on behalf of the Royal Institution of Chartered Surveyors (RICS), I have been involved in assessing professional competencies (APC) over a period of 16 years. From this activity, I have witnessed a trend in non cognate degree holders applying for assessment. This trend has grown and in the November 2009 assessments, held at Heathrow, the panel I chaired assessed non cognate degree holders only, 4 in total. I am particularly interested in this phenomenon as an educator and designer of an undergraduate degree specifically for the discipline quantity surveying.

I believe we require a debate upon the educational inputs and outputs of professionally accredited degrees, and from the research I have undertaken so far, there is little specifically aimed at the quantity surveyor. I did realise there was no definition given for non- cognate candidates and this would be an area to address. I have investigated the definition of professional education and then described the professional construction education. The context of these investigations have been undertaken by taking a global perspective and by attention to the political will that has historically shaped education within the UK. The overall discussion becomes one of generalist education verses technocratic education.

With this framework in place a review of literature in the subject of construction education was undertaken as a result it was found most emphasis was found to be placed upon skills, knowledge and the subsequent measurements of these. Examples

and definitions of generalist education and technocratic education emerge. It from this basis I have drawn a definition of non cognate degree holders as those holding a generalist degree and the cognate degree holder as those holding a degree in quantity surveying accredited by the RICS as a technocratic degree holder. This is reflected as a dichotomy in practice where a technocratic education is prescribed but a generalist education is also employed in growing numbers. This dichotomy is one which is worthy of investigation in further research and future papers.

2 Literature Review

2.1 Professional education (what is professional education)

I have focused upon professional education, the position of chartered quantity surveyor has been classed as a profession (Simpson 2010), hence the education pathway that emerged has followed the route of the professional and as a result can be viewed as technocratic in nature.

There is a plethora of information on professional education outside the construction industry particularly in the realms of teaching (Clifford & Guthrie 1990) and healthcare(?). Even 100 years after the first courses were set up in the profession of teaching the problems of vocational (work specific) educations fitting the constraints of the existing structure of higher education remain. The still relevant and pertinent discussions, regarding the fit of technocratic education held at the turn of the previous century, between Dewey and Snedden as cited in Garrison (1995) are still debated by Tan (2003), Tovey (1995), and Tribe & Tribe (1995). A long and many sided debate (Dewey 1916, Lodge 1947, Atkins 2003, Carr 1995, Garrison 1995) shows that professional education struggles with notions of an applied education rather than a generalist approach to knowledge. Professional education is shown to sit uncomfortably inside the structure of traditional seats of knowledge (Clifford & Guthrie 1998). This can be witnessed by the rise and fall of professional education can be easily plotted against the political and economic will of society at given times. (Carr 1995, Garrison 1995, Dewey 1916) Teaching in particular reacts to the changes in demographic changes that society makes, especially the birth rate but also the needs of a technological advanced economy. While quantity surveying education reacts to the economic cycles the construction sector weathers. (Hillibrandt 2000, Bonn). The view of Dewey as explained by Garrison (1995) is that education should be differentiated but that training should be left to the trainer and education should take the form of a generalist approach. However the model adopted within the USA and the UK is one where there is a mix of technocrat and generalist resulting in an unhappy amalgam. The offspring of this process emerges as class differentiation; of leaders and lead (Carr 1995), this, it could be argued, is reflected in the perceived status of graduates and their subsequent recruitment into the workplace.

2.2 A description of professional construction industry education

Construction professional education literature has been mostly in the remit of Architects and Engineers for both these professions have been in existence for several hundred years. They have a form of education and training with longer undergraduate programmes and extensive pupilage, indenture periods (Nethercot 1999) followed by a professional examination or later professional assessment which is made (RIBA, ICE).

This set pattern was adopted for surveying education and training, following the master and servant model. The Engineers were the first to move in 1977 to an accredited undergraduate degree, with an independent board – Joint Board of Moderator (JMB) representing Civil, services and mechanical degrees (Nethercot 1999). Quantity surveying education under the remit of the Royal Institution of Chartered Surveyors (RICS) followed suit. This is referred to in the Table 1 below:

Table 1: Quantity surveying changing educational structure
(Source: Simpson, 2010)

Quantity Surveying educational structure Pre 1980	Quantity Surveying educational structure present 2010
<p>Indenture, professional training Test of professional competence</p>	<p>Academic test- undergraduate degree Structured professional experience Assessment of professional competence</p>

2.2.1 Politics and QS education

The political will towards education, has changed since the industrial revolution in the 17c, here the liberal ideas affecting the free marketplace arose with particularly attention to the ideas of Adam Smith(1998). The change from an agricultural to an industrial marketplace was undertaken and Smith’s ideas influenced the type of education required to fulfil this political sea change. The market through the 20th century, particularly the quantity surveyor, (look up founding fathers info) moved to a conservative approach (Jarvis 1983) which suited the middle class professionals who are described as the service class (Simpson 2010, Jarvis 1983) and hence the style of education moving to address the market requirement, there was more emphasis is put upon tutelage, indentures and apprenticeships, the master and servant approach. In the later 20th century and into the 21st century attention has been moved to the monetarist approach, now referred to as neo liberal (Erant 2000, Denzin& Lincoln 2008), in the marketplace and was also evident in educational institutions with more growth in the polytechnics, now known as post 92 universities, this is important as the QS degree is solely found within these institutions and perhaps in two red brick universities. This can be witnessed by the rise of technocratic education under the conservative government lead by Margaret Thatcher (1978-90), an ardent pro monetarist, and a return to the free market with education driven to fuel market demand thus leading to a revival of professional undergraduate education. This didn’t occur in isolation within the UK but can be evidenced in the international construction education scene.

2.2.2 Global view of construction education

Globally, a review of educational structures within the commonwealth countries and English speaking countries found an educational system which echoes the UK professional educational route (Chan et al 2000), as described before. There has been research into construction education in non English speaking countries such as China (Shirong 2001) and Japan (Tan 2003). The aimof this research has been to investigate how best to educate the future managers of the construction industry. The Japanese approach centred upon the historically driven generalist education structure, where the elite intellectuals are generally educated then trained into roles. This mirrors the trend

that has been identified in the UK QS education system, over this new 21st century. Larger practices employ graduates with degrees in disciplines from outside the Construction Industry and train them through structured training schemes and post graduate degrees to become chartered surveyors.

Atkinson (2003) highlights this trend and refers to the division as cognate and non cognate students. He also suggests there is a move to studying an undergraduate degree for self interest before training for the workplace. If students are wealthier, based in the UK studying fulltime, they choose to study for intrinsic, self fulfilment rather than employment. He also discusses the value of education being of immediate use to society (technocratic) or intrinsic (generalist) and of use later to society. Atkinson's view ignores the bulk of undergraduate quantity surveyors who study part time and are financed by their employer rather than themselves or the state. When examining this stance the class distinction of Snedden's argument may still be relevant over 100 years later.

2.3 Skills, Knowledge, Education and Competencies

The bulk of publication into professional education particularly in the Construction Industry is focused upon the hard, technical skills and knowledge that are currency (Bourdieu 1973), in the workplace. This can also be reflected in the sister professions of law (Tribe&Tribe 1995) and accounting (Hanlon). This is hardly surprising as the learning styles in these professions lean heavily to the quantitative where numeracy is valued. It is simpler to give answers in a single output entity; the answer to the ultimate question of life, the universe and everything is the number 42(Adams 2004). These publications can be conveniently divided up into Skills, Knowledge, Education and Competencies.

2.3.1 Skills and Competencies

Skills are having the ability to carry out tasks well (Oxford English Dictionary 2010) in this case specific skills to carryout professional quantity surveying works. Professional skills (O'Donnell et al 2008)can be generic and specific, indeed there is a split in publications on this point with some the RICS(1992), Poon (2006), Eraut (2000) emphasising the specific skills whilst a general view on employability and personal skills has also emerged (Wilkie & Giddy 2003, Doidge et al 2000) There is plenty of evidence about the skills required in property, construction and surveying as published by the QAA (2008), interestingly within this document there is emphasis upon generic and specific skills, ensuring the mix of the two types of skills. The RICS will refer to the specific surveying skills in the terms of competencies (APC assessment guide 2008), similar to the measures used in NVQ's where the candidate can or cannot do identified activities. Ellis (1995) discusses this in the terms of action based competencies, these are highly visible actions which are successful or are not successful. Returning to the idea of generic skills at this point within construction education the skills are described as communication skills, dialogue, presentation (Doidge et al 2008).The RICS view these skills as level 1 competencies with customer care, people skills, ethics as basic requirements but divorced from the specific skills although there is an awareness of the requirement of composite skills (RICS 1992). Generic skills which are relevant to the profession of surveying are as stated by Eraut (2000) analysis, appraisal, communication, documentation, evaluation, management, quantification, synthesis and are reflected in the QAA (2008) document. Skills, it is being argued, are both generic and specific for a successful quantity surveying undergraduate to be able to reach the point of graduation.

2.3.2 *Knowledge*

A question, then arises, are QS undergraduates any different from the sister professions of law and accounting at graduation. The answer must be yes, there is a difference, as the knowledge base of lawyers and accountants will be very different, they all have a professional education but the knowledge base will be different. Knowledge is the currency that professions use to sell their expertise and services (Tovey 1995) and also to differentiate themselves from others (Downie 1990, Hanlon 1998, Fong & Choi 2009). This differentiation and subject specific knowledge is in demand by clients (Chan et al 2000) and gives a market advantages to those professional bodies who offer conservative (Jarvis 1986, Simpson 2010) style service, in this instance the RICS.

Knowledge in this professional context is seen as professional and codified (Goldthorpe 1982). Eraut (2000) explains this knowledge as implicit and explicit in nature. The discussion around competencies can address the explicit nature of certain knowledge but the professional is rewarded within quantity surveying for their implicit knowledge (Chan et al 2002, Bowen et al 2008, Simpson 2010), clients value personal tailored service rather than standard one size fits all approach. Yet another debate, around knowledge is that which is tacit Eraut (2000), simply learnt by doing, watching, listening and without conscious effort to acquire, perhaps reflected in the value of experience which again has no formal measure to substantiate the learning involved.

Within the debate around knowledge there is a drive in which to make implicit knowledge explicit so that it can be interrogated and measured. Ellis (1995) discusses this transformation of action based learning to measurable competencies and the desire to demystify the route to professional knowledge. The main drivers are political ensuring more transparency and accountability within the professions thus reflecting the political will of neoliberal education, to fit graduates for the marketplace.

2.3.3 *Education*

A whole discussion has taken place over the style of education being offered and the main arguments have been between liberal education (Tan 2003, Atkinson 2003, Dewey 1916) and vocational education (Carr 1996, Garrison 1996). There needs to be a new discussion reflecting the political implications of the neoliberal approach being adopted in the education and training sphere where equipping undergraduates for any type of employment is now a requisite. Wilkie & Giddings (2003) discuss these phenomena as employability and personal skills, perhaps in recognition there is in the Construction Industry sometimes a skills shortage and sometimes a skill surplus, as witnessed in the current economic climate of the 2009-11 recession. Interestingly, Wilkie & Giddings (2003) discussions are reflective of generic and intrinsic education meaning that the knowledge base is not that highly significant in the world of work.

3 Research Methodology

The work carried out has been done in a desk top study with critical review of papers texts and journals published and unpublished. The use of the internet to source information has been noted particularly for the definition of terms. There were many more papers investigated but not used specifically in the writing of this paper, I also carried out an examination of each papers' and text methodological approach and stance. From these papers the overarching suggestions regarding the selection of research methodology, over which would derive the most effect within this area of

research would be a qualitative approach. However, few writers used this method even if they recommended it for further consideration. In carrying out this research I found cases of analytical (Tovey 1995), normative (Simpson 2010), empirical (Eraut 2000, RICS 1992, Tribe & Tribe 1995), narrative (Doidge et al 2000), cognitive (Chan et al 2002), action based (Ellis 1995, CIB 1996) and grounded theory (Simpson & Dye 2009).

This paper suggest three themes which affect professional quantity surveying education, these being divided into the general, then specific to professional education and finally applied to quantity surveying education. At this point in the research, the overall approach has been one of qualitative investigation. In the belief that a differing set of data will be generated to those previous investigations, a social science perspective (Hart 2008) has been adopted, in this paper. To validate this initial investigation a cross interrogation was undertaken upon the findings and then subsequently the classifying of topics and debates arising (Cresswell 2007). In future the research will be expanded into other sources of published data, particularly the political landscape surrounding vocational educational history (Morse et al 2002). The approach, presently adopted has been working towards establishing reliability by using the means of cross interrogation of different sources and also examining political and methodological differences (Denzin & Lincoln 2008), that arise. This use of cross interrogation of the different sources goes some way to tackle the question of research reliability. Additionally, I have stated my personal position in undertaking this research (Cohen, Manion & Morrison 2009) however it is very difficult to prove reliability in qualitative research as suggested by LeCompte and Preissle (1993) cited by Cohen et al (2009) but if reliability is taken to mean as Cresswell (2007) suggests, where the researcher has been consistent in their approach to collection and interrogation of data then this current research meets this criteria and can be viewed as reliable. The result of this methodological review is that a qualitative desk based research was undertaken and sits within the anticipated criteria of reliability and validity.

4 Findings and Discussion

A discussion can now take place about the skills, knowledge and traits that an undergraduate quantity surveying will need to be taught throughout her education and what professional training is required on completion of the degree to enable a professional quantity surveyor to emerge as I intend to explore in future research works. To do this it is important to define the terms cognate and non cognate within the context of quantity surveying.

What is a non cognate graduate within the context of quantity surveying?

The Royal Institution of Chartered Surveyors (RICS) QS division in their publication about skills and knowledge (1992) are first to mention non- cognates, but give no definition of this term. In the paper published by the Chartered institute of Building (CIOB) there is a nod towards non cognate intakes into training due to the skill shortage within the Construction industry (Wilkie & Gidding 2003). Atkinson (2003) refers to cognate and non cognates and defines them in the terms of cognates having undertaken applied, practical and technical subjects at undergraduate degree level, I would suggest a technocratic education. Whilst, non cognates have general and theoretical undergraduate degree, here I would add the label generalist.

On investigation, the Oxford dictionary doesn't list non cognate as a word or term. The meaning it suggests for cognate is that of "having the same linguistic derivation as another or related; connected" which bears little resemblance of term in use in RICS (1992) and Atkinson (2003) writings. The most reasonable approach would be to look at the Latin basis of cognate ; two terms being most similar cogito – to think or cognosco – to learn, (UCS 2010) following logically on from this stance non cognate would be- not think or not learning. This is not a very satisfactory description of the two terms.

Another approach is to examine the meaning in use of non cognate, as Atkinson (2003) discusses non cognate is a general and theoretical degree holder, Tan (2003) discusses education in terms of strategic education, whilst I would use the term generalist degree holder. If these understandings are accepted what then flows from this understanding of non cognate is the quantity surveying understanding of cognate, this can be understood as being the opposite meaning in an educational framework; that of applied, practical technical undergraduate education. This I would describe as technocratic education. Therefore, I would define a cognate degree holder as someone who graduates from a professional accredited degree programme, in the case of the QS the RICS or CIOB. The definition of a non cognate degree holder would be a graduate holding a degree which is generalist in nature, and not accredited by the RICS or CIOB.

This division smacks of Snedden's (Drost 1967) and Dewey's (1916) discussions about class distinction of those who lead and those who follow. Snedden proposed this distinction based upon use of vocational education, to ensure those who are lead are more efficient. This dichotomy exists in professional undergraduate education; it is also mirrored in the professional practices adopted by the QS employers.

It is important to define these meanings of cognate and non cognate as terms to enable, exchanges of ideas and clear discussions within the QS sphere and that of professional education in the round. Once these terms are defined then meaningful debate can occur within QS education and others involved in professional education. Lessons can be learnt from other professional education routes and applied with benefit to the educational routes of QS undergraduates and post graduates. Other professions identified as indicators of future trends and changes are lawyers and accountants (QS, RICS 1992) and indeed these would facilitate discussions and comparisons of practice models.

At this point it would be meaningful to discuss the role of language, in particular the language adopted by a grouping to communicate with a targeted audience (Benz & Shapiro 1998). A reasonable approach to adopt in researching this grouping would be to follow ethnography method, especially to give a sense of the complexity of the situation where preconceptions and patterns of behaviour are studied (www.nus.edu.sg), thus enabling meaning to be uncovered in a holistic manner. Boudieu (Asgeir& Popkewitz 2008) is well renowned for his views on knowledge as a power base, he also discusses the sociological studies and use ethnography to exhibit other points of his philosophy. These points on knowledge, holistic overview, rhetoric and ethnography will give further direction to future studies in this area.

5 Conclusions and Further Research

Within this paper a critical review of published data has occurred, the methodology I have employed is has been discussed, springing from this analysis three main themes

were identified and classified as the generic, the specific and the applied to professional quantity surveying education.

There was undertaken a review of professional education then professional education pared down further to quantity surveying education. A context of global and political drivers has been described to give parameters to the research. The main focus found within this critical review of literature has is found to fall into three camps- skills, knowledge and education. The result of this critical review has identified a lynch pin requiring a definition of non cognate and subsequently cognate terms used within the texts. A definition of a cognate degree holder is offered as someone who graduates from a professional accredited degree programme, in the case of the QS the RICS or CIOB. The subsequent definition offered of a non cognate degree holder would be a graduate holding a degree which is generalist in nature, and not accredited by the RICS or CIOB.

An attempt has been made to define these terms, thus enabling future discussions and debates to occur within the professional quantity surveying education and those of accounting and law.

6 Acknowledgements

I would like to thank Dr Jill Jamieson, University of Greenwich, for her guidance and interest in professional education. All errors are my own.

Emerging markets

Sustaining the Localization of Quantity Surveying Profession in Sultanate of Oman

Abstract:

Oman shows a substantial development during the 21st century. The country has made a considerable growth on various industries which contributes to the growing economy of the state. Among which the infrastructure development contributes a significant value. The government of Oman has enacted a localization policy called “Omanisation” which aimed at replacing expat worker with trained Omani personnel. The implementation of Omani policy was applied to lower the unemployment rates for Omani citizens. Further, the Omanisation allows Oman to be self-reliant in human resources by decreasing dependency on expatriates. The Ministry of Manpower has taken considerable amount of steps to achieve the targeted omanisation policy through introducing the new laws and rules for the human resources recruitments. However, there are limitations induced by the factors which prevents to achieve the targeted localisation metrics. This paper aims at assessing the achievement of the policy has had over the years in various sectors. Further, this paper also discusses the factors against the implementaion of localisation which are pertained to omani Quantity Surveying (QS) profession in detail. The author has adopedted various data collection techniques such as interviews questionnaire survey and archival data analysis to unwind the fact regarding the challenges of the localisation policy facing in recent past years for the QS profession. The paper also recommends the posible ways to overcome these difficulties and sustains the localisation in QS profession.

nationalisation, omanisations, factors influencing localization, quantity surveying

1 Introduction

During 1970s, GCC countries began investing heavily in labour and capital intensive sectors such as infrastructure and real estate to support their economic growth. However, with shortages in the number of skilled nationals, many of the jobs that were created ended up in the hands of workers who emigrated to the GCC from other Arab or Asian countries (Shediak, and Samman, 2010). But, at present Gulf Cooperation Council (GCC) is facing a challenge against its enormous population increase, and its knock on effect as high rate of unemployment. Therefore, these countries have engaged in localization programs based on positive discrimination for the nationals to integrate a larger share of them into their workforce. The programs have names such as Omanisation, Bahrainization, Emiratization and Saudization (Albayrakoglu, 2010).

These localisation process needs to be carried out with greater care as these may have a positive and negative impact on the country's political, social and economic aspects (Rees, 2007). Further, the prevailing political instability in Middle East region influences the local government to follow a stringent localisation process without compromising the economic growth of their country.

In the case of Oman, the employment is largely dependent on nationality in their public sectors. In the public sector, Omanis held 70% of the jobs in 1999 and 91% in 2009, while in the private sector which contains most of the lower paying jobs 90 % of the employees were from foreign countries in 1999 and up to the end of January 2011, it was estimated to be 84% (Ministry of National Economy, 2011). There are many reasons for these differential ratios between the public and private sectors. However, the government of sultanate of Oman enforced the rules and regulations on recruiting the locals through labour laws as stated in chapter two of Oman labour law under Part I of Employment of citizens in Article 11.

“An employer must employ Omani employees to the greatest possible extent. A decision from me Minister will specify the percentage of Omanis to expatriates in the different economic sectors or activities of each sector according to the requirements of the circumstances and activity of each sector or according to the availability of the required Omani employees.

Employers must put all employees on the same footing when the nature and conditions of their work are alike.”(Oman labour laws, Article 11, Decree no. 35/2003)

Unlike the other neighbouring countries, the sultanate has realized the human resource potential of their local people and used a mixed approach for setting different localization targets percentage for different sectors of their workforce depending on the market requirements and availability of resources that are likely to be met for each sector. On behalf of the government, the Ministry of Manpower (2010) had revealed the Omanisation target for each sector. For example, target has been set for travel and tourism sector is 90%, telecom sector is 62%, industrial sector is 35% and sales and distribution sector set was 65%. As far as the contracting sector is concerned, the target of Omanisation is 30% for second and above category contracting companies (Ashok Kumar, 2008). As the private sector holds skilled and professional positions the government has taken many steps to improve the skills of their local workforces by means of strategic planning on the education sectors, training and development. Though the strategies were efficiently adopted in the sultanate for the achievement of their localization targets, there is a supply- demand problem (the demand exceeds the supply) in some sectors such as infrastructure, petroleum, energy sectors etc. However there are some sectors such as banking, health and transport which meet the targets. Hence studying the factors which affects the localization in each sector is paramount importance for the effective planning.

The infrastructure in Oman contributes to the major part i.e. 12% in its annual contributions on GDP that is nearly to 5.25 billion US dollars as compared with 10.9% in 2010 which was budgeted for 5.32 billion US Dollars (Hasan, and AlYaqout, 2011). The increased investment expenditure decided by the government is a matter of policy to continue with key infrastructure and development projects. Many of these projects are carried out by the multinational companies. The government focuses on the on-going support for private sector as subsidies to the sector is estimated at 1.55 billion US Dollars. According to the Ministry of National Economy, Oman is allocating 2.342 billion US Dollars during 2010 with the aim of creating jobs for Omani nationals as the

sector is heavily depends on the expatriates (Global research, 2011). This involves the decision making on the financial aspects of these projects, which has a higher stake on the above growth rate. The infrastructure project is one among the many sectors where the government has failed in achieving their localisation targets. The Quantity surveying profession in the infrastructure sector is one stream which holds almost all expatriate workers. This profession has a very big stake on making economic decisions on these multi-billion infrastructure projects. Hence preparing the locals for the future management is paramount importance. This paper takes the Quantity Surveying (Q.S) profession of infrastructure projects as a case for the study and investigates the factors attribute to the success of the localisation in this sector. The author used various data collection methods such as interviews and questionnaire interview to unwind the facts about the problem under study.

The paper consist of six sections, the next section discusses the literature on the general localization in middle-east region and the factors affecting the process. The third section explains the Oman's localisation on various sectors and its current status. The fourth section explains the methodology of the current study for the identification of the factors that endanger the accomplishment of localization target percentage with respect to QS profession. The data analysis and the discussion of the questionnaire interview and the focused interviews were discussed in fifth section. The last section discusses the conclusions with the recommendation for the successful future implementation of localisation strategies to achieve the planned targets.

2 Localization in Middle-East region

Middle-east region has not been modernized until the invention of the petroleum and its usage. Even after the invention of petroleum, the countries took a long time to realize the potential of their oil wealth. However, these countries have managed to modernize with the help of the expatriates for the past four or five decades. To sustain their growth, these countries were fully depends on the expatriates as there were no technical or administrative institutions to produce the suitable local work force until a decade before. Later, with the growing population and increased unemployment rate together with the vision to reduce the reliance of the expatriate workers, these countries decided to be self sufficient in all sectors of the workforce. The self- sufficiency in all the sector has not been achieved immediately, so many long-term strategic plans were proposed. The objective of these strategic plans is to replace the expatriates gradually with the competent local workforce over the years. However, the success of these localization were not been able to fully achieved in some sectors such as Construction, Oil and Gas, IT etc. but, it has been more than the target sets in some sectors such as banking, travel and clinical (Ashokkumar, 2008).

There are number of factors which affects the localization process in some sectors, these factors are inherited from the country's economy, tradition, education, culture, politics and foreign policies etc. Figure 1 shows the same. Further, these factors can also be categorized from the human behavioral aspects towards their prevailing social life to the complex professional and technical skills required for the profession. Many studies have been conducted to identify the factors affecting the localization with different perspectives in various sectors. Though all these literature listed out the same general factors in this part of the world, there are specific factors which pertained to the country and the sector under study. The picture depicts the various categories of these factors for enabling the readers to get a general framework of the issue.

In GCC region, the National Human Resources Development and Employment Authority have announced the findings of its latest study on the causes of long-term unemployment in GCC's economics related factors. The study concludes that labour market segmentation; falls of oil revenue and high remuneration in public sector were the main causes of unemployment of nationals in the private sector (Tanmia, 2006).

Figure 1 Factors affecting the success of Localization in GCC regions

Al-Dosary et al (2005) have also identified several factors which affects the Saudisation process such as 1. Saudi education system (Educational Factors), 2. Lack of enthusiasm(Cultural Factors), 3. Private sector's minimal interest on recruiting locals (Other factors) and 4. Lack of experience of local work force (Other Factors). Shaham, (2009) also reported that the GCC countries have a sponsorship system – kafala system (political factors), though this system have served its purpose during the initial stage, later produced its side effect such as over stay of the expat labor force. The lacks of enforcement policies along with the private companies were very much comfortable with these illegal low paid skilled labor force. Another study reported Gender inequality (Social Factors) is greatly influenced in many of the GCC countries (Metcalf, 2006). Further, the private sectors have the following common opinion about the local workers; 1. Less productive, 2. Under skilled (Rowe, 1992) 3. Unmotivated 4. Lack of English proficiency 5. The expatriates favoritisms to their fellow country workers 6. Lack of experience and 7. The social demand on public company jobs (Naser, et al, 2006).

3 The “Omanisation” A Status Report

In 1988 the government of Oman has pursued a localization policy called “Omanisation” aiming to gradually increase the participation of qualified locals in the labour market. In 1995, the vision 2020 for Oman’s Economy was launched, with a key focus on two main areas; one among the area is Omanisation and Privatization. This fact is aiming to replace migrant workers with Omani nationals, which will underpin education, training and employment policies and practice (Goodliffe, 2004). Within the initial years, the Omanisation targets were achieved in public sectors. Later, in public sector the supply exceeds the demand as it provides social security to local workers with perception of the provision for better incentives such as higher earnings, better working

conditions and pension benefits after the end of service. However, in the recent years, the inability of the public sector to absorb the Omani labour has led to a real problem of unemployment (Al-Nashif, et al, 2010).

As mentioned in Vision 2020, the government wants to encourage, develop and support the private sectors as the major driving force to develop their national economy. This increases more number of private participation in all the sectors in Sultanate of Oman. In response to this, at present, the private sectors become the major employing source but which practice to employ the expatriates as they are cheaper and skilled from Asian countries such as India, Pakistan, Bangladesh, Srilanka etc. However if the issue is further looked at closely, there are complex inter related issues with the countries policies on other strategic plans in the area of human capacity building.

Though an enormous encouragement exists from his Majesty and the government to enlarge the employment rates for Omani nationals. The government has established a High Committee for vocational Training, the Ministry of Social Affairs and Labour, and Ministry of Labour and Vocational Training to oversee the Omanisation process launched in 1991. Nevertheless, the government had also created a new Ministry of Manpower in 2002 and a new Labor Law was adopted in May 2003 that had advanced the policy implemented progressively (Albayrakoglu, 2010). Despite the government's considerable interest and active role in promoting Omanisation in the private sector, slow progress has been achieved and the ratio of Omanis to expatriates in the private sector is relatively low (Al-Lamki, 1998).

Based on the Ministry of National Economy (2011) the total manpower in private sector as at the end of January 2011 is around 1,148,477 workers where 84% represent the expatriate and 16% represent Omanis who are only registered with the Public Authority for social Insurance. Therefore, the question that needs to be considered is, why are employers continuing to take on more expatriate than Omanis, even when the government has openly declared a policy of preference towards companies that have Omanisation policies (Hutton, 2003).

In the recent years, all the public companies have achieved the planned targets of Omanisation percentage, in some sectors it exceeds more than the targets. However, the private companies lack in achieving the planned targets in most of the sectors. There are two perspectives on looking at the reasons for the less recruitment of nationals in private sectors; 1. The employee's perspective in selecting their employments in private or public sectors and 2. The private employer's perspective on recruiting the local people. The reasons listed out in the employee's perspective starts with their interest towards a government jobs for their lifelong employment, further educational opportunities, standard wages and benefits, working conditions, working hours and retirement benefits (Al-hamadi, et. al., 2007). The private sector employers are reluctant to recruit the locals since they are less productive, under skilled and unmotivated, limited English fluency, higher rate of absenteeism and increased expenses (Mashood, et al., 2009). In a nutshell, currently Oman is facing challenge to develop competent and effective Omani workforce, with limited dependence on expatriate expertise in some sectors where the Omanisation is not successful.

3.1 Oman's infrastructure growth

In Oman the construction industry is beginning to see returns from the diversification policies instigated under the Vision 2020 plan (Delotte, 2010-2011). Similarly, as

detailed in the 2011-2016 development strategy of Oman, there are two staple elements of escalation, first the emerging tourism sector and second the development of infrastructure.

Equally the UK Trade and Investment Office at British Embassy in Muscat also explained “In the current cycle there are many infrastructure developments such as roads, railways which will follow 2000km of coastline, ports and airports”. Apart from this the government is keen to establish two 750MW power plant projects, desalination plants etc. All these projects are awarded to the private companies. This increased the demand for the qualified and skilled infrastructure work force. Due the quota system, the private companies are required to recruit the local workers in order to enjoy the benefits from the government subsidies for achieving Omanization. The idea behind the process is not only creates the employment but also to train them for their future projects, for example in the power plants projects, employing more Omani workers will offer a long-term role during the operation and maintenance phase of these plants in the future (The big project ME, 2011). However, the private sectors are facing difficulty in getting the well qualified, experienced and skilled labours. Though the prevailing condition such as the scarcity of experienced construction Omani labours, the country’s construction private sectors are struggling to get fresh qualified and skilled local labours. Though the local labour and the private companies have least preference to select each other for their needs, there are other planning strategy related reasons which prevent the success of the infrastructure sector’s localization process.

3.2 The impact of localization on Quantity surveying profession in Oman

QS is an important profession in infrastructure projects. QS profession can be defined as “Services that cover all aspects of procurement, contractual and project cost management”. The competent QS personal has a stake on the following activities of any infrastructure projects; construction cost management, value addition throughout the life cycle of the project, budget allocation and control, decisions on the legal and contractual obligations and the success of producing a best value for money to their clients. The RICS (1998) has listed out the necessary competencies of a quantity surveyor as follows; Construction Contract Practice, Construction Technology & Environmental Services, Economics of Construction, Procurement and Financial Management, Arbitration & Other Dispute Resolution Procedure, Development Appraisal, Facilities Management, Insolvency, Insurance, Project Management, Property Investment Funding, Research Methodologies & Techniques, Taxation Allowances & Grants, Valuation, Measurement, and Law, apart from the other interpersonal skills. However, most local people think that quantity surveyor is one who takes measurement and does pricing (Muscat Daily, 2010), but in reality a quantity surveying firm believes that the role and responsibility of this profession goes much beyond this as listed as above.

Oman has the wealth and vision to allocate the budget for the infrastructure projects, but most of the time that the government realized that they always not getting the value for their money. The expat QS engineers don’t realize their role in value management and rarely took a lead role on saving the public money as they are not the nationals. The private infrastructure companies seldom find quality locals for their QS position. There are many reasons for this unavailability of human resources. The problem has roots in many areas however, the awareness about the profession, the motivation towards the profession and, the availability educational institutions to produce the quality human resources play a major role in this issue. This study has taken preliminary steps to

further validate these factors and give recommendations for the improvement. The methodology of the present study is discussed in the next section.

4 Methodology

The study method starts with the literature review on the localization in Middle East region and its related factors. This step helps to understand the big picture of the localization process in this part of the world. This is followed by the study on the status of current Omanisation process through literature review and interview with the respective ministries (random sampling). Then factors which affects the localization of QS profession is obtained through interview (random sampling) with five construction companies. The identified factors are further validated through the questionnaire interview with three targeted groups such as the foundation students, engineering students and the educational institutions. Figure 2 shows the study methodology as the first three steps have been already discussed in the above sections. The following section discusses about the factors affecting the localization of QS profession in detail through interview with the infrastructure industries.

5 The Experiment – Interview and Questionnaire Results and Discussions

The factors affecting the localization in QS profession are identified through interview with the five private construction companies. The interview was focused on the six categorized factors as mentioned in Figure 1. Ten persons have been interviewed and all the persons interviewed were having enough knowledge and background on the profession mainly at the middle and senior management level. The interview data is carefully analysed, the companies common response on addressing the availability of Omani QS applicants are very minimal and most of the time their demand is not been met. The results obtained from the private construction companies interview regarding their implementation of Omanisation policy is presented in figure 3. It is evident from the results that there is a scarcity of the competent local labour force in most of the companies.

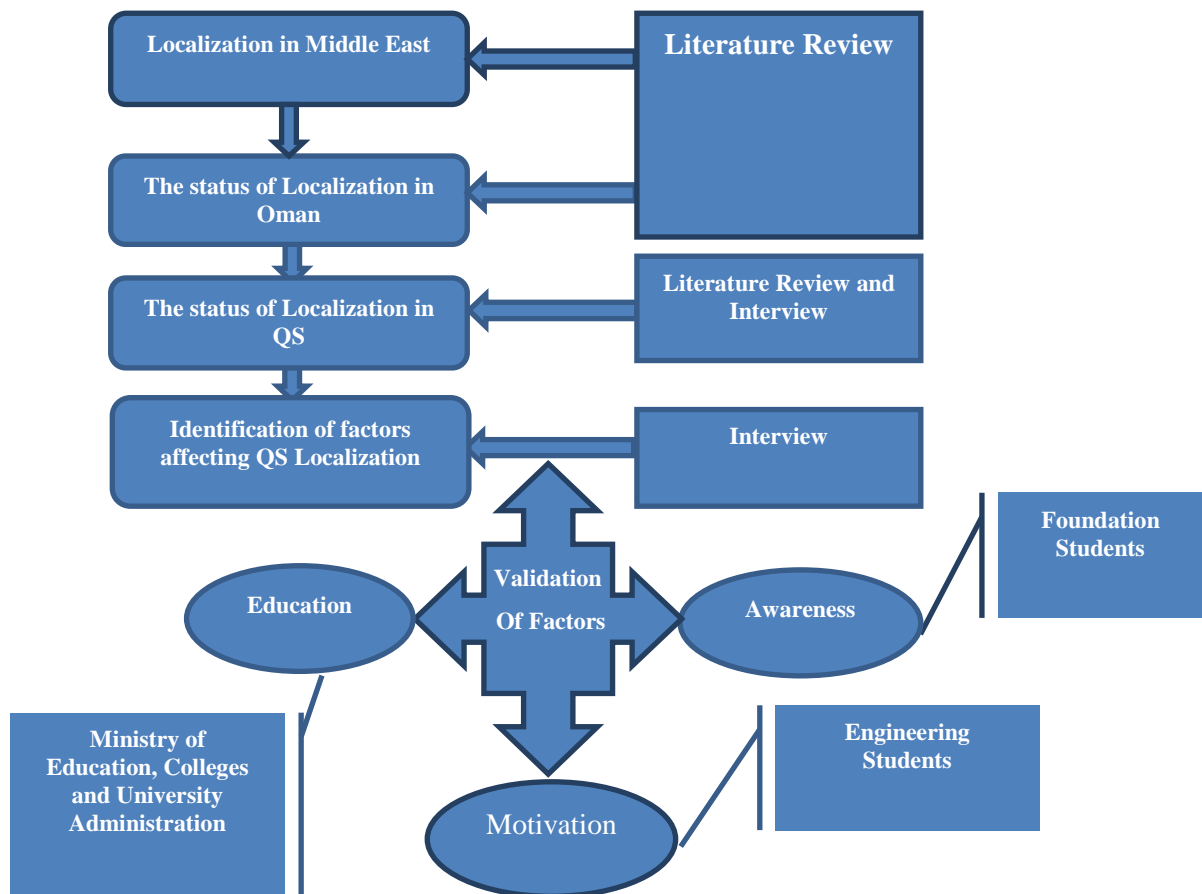

Figure 2. The Study Methodology

Figure 3. Scarcity of local labour force in construction

At present the construction work force contributes around 43 % of the total expatriate’s strength of 985,716 according to Ministry of manpower data. This necessitates the private sector needs around 125,000 local construction workers to meet the government’s Omanisation target of approximately 30% in construction sectors. From the interview it is observed that any construction firm requires at least 3% of QS workers in their total workforce in order to manage the QS related activities in their business. It creates the demand of around 3800 qualified QS Omani professionals in total. However, at present this much of their required capacity is not been met. This can be supported with the country’s existing educational institutions statistics, the country has 13 higher education institutions (both public and private) among which only 4 institutions offering QS programs among which only one institution offers a 4 year

bachelor degree and others offer 2 yrs. diploma in QS. Further, only 6 institutions offer civil engineering programs. Hence the total QS workforce capacity preparation is not meeting the country's demand. In addition, the private owners says that there are institutions and training organizations which offers the QS programs in diploma and bachelor level degrees, but the motivation of the graduates to become a lower level QS engineer is very minimal. All the local applicants want to secure a managerial position which mainly focuses on the construction management related issues. While addressing about their competences, the theoretical knowledge they acquired during their formal qualification is not meeting the standards at par with the expat workers. Many local QS personals are not aware of the responsibilities and duties of a QS engineer in terms of their project economical management.

From the interview with 10 project managers of various private construction companies of large, medium and small nature, it is concluded that the existing education system of lower capacity, lack of motivation to become a QS personal and the missing awareness about the QS professions are the main reasons to restrict Omanisation process. Since the scarcity of the QS educational capacity building is very much obvious with the data presented in the above paragraph, this has not been taken for further validation process. The facts about the motivation and the awareness factors are further substantiated with the questionnaire survey administered with the foundation students (foundation is the pre degree/ diploma course where the student is prepared ready to take up any of his interested engineering specialisation) and the QS diploma and degree students studying in various technical institutions. The general willingness of the students to take up civil engineering and especially their interest on preparing themselves on site related initial profession is very minimal. 60 questionnaire were circulated to the foundations students (foundation course is a preparatory course before the engineering enrolment) of the various technical institutions reveal that 27 % showed interest to study civil engineering profession which includes all the specialization viz. construction engineering, structural engineering, environmental engineering, Quantity Surveying etc.

Though the selection of civil engineering profession is high, it is not meeting the current demand created by the private construction companies which contributes around 43% requirement of total private workforce in all the sectors. The above results indicates that 27% of students were interested to continue their undergraduate in civil engineering, were 73% of students were interested to study other engineering programs. The minimal interest of students to study civil engineering could be due its site related (non-white collar job) factors. Amongst the 27% students who selected for the civil engineering have been asked about their awareness on QS profession, 37% responded yes, 36% No and 28% replied with I don't know. Further, the students who said that they knew about QS profession were asked the roles and responsibilities of a QS professional. None of the foundations students replied with the other answers except the quantity take off.

Further, 30 students, who are studying the QS course (diploma and degree) has asked question related to the role of QS in construction projects. All the 15 competencies discussed earlier in the paper were introduced to them. Surprisingly many of the competencies were not been identified by the students. This shows their lack of understanding on the subjects and their awareness of their role as a QS professional in future. The following chart in figure 4 depicts the results of the questionnaire. From the survey, it is evident that most of the students studying in QS program can't identify the competencies and their roles in the infrastructure projects. According to their knowledge, the QS profession is meant for Valuation, Measurement, and Project management.

Figure 4 Student's awareness about the role of QS competencies

From the present study, it is evident that the three factors; the availability of educational capacity of QS profession, the awareness about the QS profession and the motivation towards the QS profession are the main obstacles to achieve the localisation process in Oman. Apart from these factors there are typical other factors which exhibits the negative opinion about the private sector's wage, benefits, work culture, job security etc. with the employees and the opinion about the local work force such as lack of motivation, competency, English, absenteeism etc. with the private employers also have stake on this issue. However, proper planning on the educational capacity building based on the country's sector wise labour workforce demand may resolve the problem. There are examples for the success of this solution. For example banking and travel sectors in private companies have almost reached to the full Omanisation targets sometime exceeded the targets. This has been achieved due to the sufficiency in the capacity building together with the awareness and motivation of the local work force (Ministry of Information, 2002). Of course the government's policy rules have a major stake as a driving force, there are other factors which may specific to some sectors which needs to be strategically planned and managed to achieve the self-sufficiency in the localisation process.

6 Conclusion and further research

The political and social and economic conditions of Oman had an effect to its quality educational systems before 1970. The country has developed a lot from its initial renaissance in 1970, the government's economic status have been successful in the initial period with the help of expatriates. However, to sustain the same required self sustainment with the country's own work force in order to ensure the economic status as well as to ensure the employment to the nationals. The major obstacles during the process of localization in Oman were the training and development of nationals to enable them to be competitive against the global work force. The government has taken various efforts to ensure the same through ministry of higher education, ministry of manpower and ministry of economics. A significant amount of budget has been allotted to encourage the training and development of the local workforce. However, the competencies of the locals are inferior when compared to the global work force along with other behavioral aspects.

The realization of the main components of the future development and planning for the localization implementation strategy is much important. Fixing up the target without making the resources ready is the symptomatic cure than the cure for the cause. From the present study, it is evident that the QS profession is lacking in terms of getting qualified locals. The capacity of the available educational resources, the lack of awareness and missing motivations are the main factors which restricting the localization process of this profession. Hence the planning based on the need for the local infrastructure work force is paramount important at this point. Starting educational institutions and increasing the existing intake levels of the educational institutions may in future solve the problem. Many programs can be arranged for creating the awareness about a profession with the school children, the input towards them during their post secondary period has a greater impact on their career selection. The private authorities have to identify future motivational factors such as increase in basic wage levels, facilities etc. in order to motivate the local to select the QS as their profession. Increasing the capacity of the existing educational resources along with creating awareness and motivation about the profession with the locals may solve the problem under study. The current study is a preliminary study hence, limited data have been presented. The future study will be done and will focus on reinforcing the identified factors and necessary strategic planning to the success of localization process in Sultanate of Oman.

7 Acknowledgements

All Praises and thanks to Allah (God) for giving me the strength and ability to complete this paper successfully. Also, I would like to appreciate my friends who supported spiritually, Mr Nasser Al Julandani, Mr Lingiraj Hamdani, and Dr Joseph. Further, I would like to thank Caledonian College of Engineering in Oman for their financial support to attend the conference. Similarly I would like to appreciate the support of my beloved Mother, Father, brothers and sisters for their encouragement and support. Finally, I would like to thank my students and the company and the ministry personals who participated in the data collection for this study.

Environmental Law

Improving Environmental Performance through Innovative Commercial Leasing

Abstract:

The environmental impact of tenanted commercial office buildings can be reduced substantially while at the same time enhancing the productivity and wellbeing of their occupants. Given that relationships between office building owners, occupants and operators are largely defined by leases, it is crucial that the structure and content of those leases facilitate innovation and encourage the most responsible operating practices. Policy measures recently introduced in the UK and Australia provide incentives to improve the environmental performance of office buildings and new ways of easing the financial burden of environmental upgrades. Coupled with market drivers, these are likely to impact on commercial lease practices. However landlord-tenant relationships are still presented as barriers to improving environmental performance. More fundamental changes that align and reward owners and tenants for working together for mutual benefit are required. This paper explores the interplay between the content and structure of commercial leases and the behaviour of building owners, managers, tenants and occupants, illustrated through the experiences of a large Australian-based commercial office building owner/operator. With reference to practical examples it shows how conventional leases stifle innovation and illustrates the difficulties in drafting leases that enable a responsive approach to building management to be adopted. It tentatively presents a number of ‘model clauses’ for encouraging best environmental practices and concludes with a suite of recommendations.

Keywords:

commercial leases, environmental performance, leasehold innovation, energy efficiency, thermal comfort.

1 Introduction

This paper illustrates some of the opportunities and challenges involved in adapting tenanted commercial space to improve environmental performance and reduce energy consumption. Through a focus on the experience of a large Australian-based commercial office building owner and operator, Investa Property Group, we illustrate the complexities of improving the environmental performance of tenanted space. Given the scale of the impact that commercial property has on the environment, and its contribution to greenhouse gas emissions, it is crucial that a better understanding is

developed of the interplay between the technical possibilities of the building itself, the content and structure of leases, and the behaviour of the various actors involved in letting and using that space (owners, managers, lawyers, landlord and tenant agents, occupiers, and customers). Although in recent years there has been much talk, internationally, around the topic of 'green leasing' there is little evidence as to what is happening in the marketplace, what the process of negotiating green leases is like and the extent to which green leases are able to make a difference. With some rare exceptions, letting practices—in the UK, the USA and Australia—have remained largely untouched by the green agenda and both landlords and tenants are resistant to entering into commitments to work together to improve the environmental performance of the rented space.

A green lease has no fixed form, it is simply one that provides a leasehold structure that will facilitate and support the property being used in an environmentally efficient way. This can relate to any or all of energy use, water management, waste disposal, travel plans and the use of sustainable materials. It can flavour the whole leasehold relationship and include binding environmental performance targets, or can adjust usual provisions to encourage environmentally sensitive behaviour (For further discussion see Bright, 2008). It is clear that 'green transformation' of the letting market is not going to happen easily, but by telling the story of Investa's experience and drawing on other models available, we demonstrate the role leases can play in facilitating innovation within commercial office buildings and encouraging responsible operating practices.

Investa's experience is of value beyond Australia. Although there are detailed differences in the policy and regulatory environments of the major developed nations, and in the content of commercial leases, the essential issues faced are the same in the UK and in the USA. The central challenge is the 'split incentive', referred to extensively in legal and policy literature in each of these nations as a major barrier. The majority of investment grade property in these countries is let on a 'net rent' basis, which means that the tenant pays for the energy costs. As the landlord has responsibility for the building structure and equipment there is little financial incentive for the landlord to improve the energy efficiency of plant and equipment. The disincentive effect is compounded by the fact that the cost of any equipment upgrades will usually fall to the landlord who may be unable to pass the capital costs through the service charge. But there are other common features of leases, which likewise inhibit change; such as the length of leases, the rigidity of leasehold language, and the approach to 'fit out'. The problem is not confined to the wording of the lease itself. It extends beyond this to the whole process of letting – the role that agents play in agreeing 'heads of terms', how the occupied space is managed, and the way that the space is used.

It is unlikely that there will be a standardised response to the challenge as the nature of the issues is so complex, that no template or standard will ever be able to adequately do the job being called on. Rather, innovation is required in the way parties approach negotiations, define their self-interests and deal with each other throughout the lease term and at expiry. These principles can apply to all commercial lease arrangements and, importantly, can be addressed not only at the time of initial let but also through amendments to lease arrangements where a building's environmental performance or services to occupants is falling short of what might be defined as 'best practice'.

2 The lease relationship and its limitations

The relationships between the owners (/landlords), occupiers (/tenants) and operators of tenanted commercial office buildings are largely defined by leases. A typical office building lease protects the interests of the landlord and tenant without expressly dealing with matters of broader community concern, such as greenhouse gas emissions from operating the premises, waste recycling, water use, etc. Despite a growing awareness of the need to reduce environmental impacts from the operation of commercial office buildings—expressed in community concern, emerging rating schemes, tenant requirements, staff expectations, and emerging regulations, including disclosure regulations—the structure and content of commercial leases can impose significant constraints on the ability of buildings to be adjusted/updated.

In addition to the problem of the split incentive outlined above, there is the fact that leases tend to be very rigidly drafted and do not allow flexible responses to new situations. The length of leases means that these problems can persist over considerable time frames. In the UK, although two-thirds of new leases entered into in 2008/09 were for five years or less these short leases were more common on units with lower rental values. For the higher value properties, the proportion of leases less than 5 years in length is notably smaller, at 38 percent, and the proportion of leases longer than 16 years is 9 percent. Tenants who occupy larger units tend to sign longer leases (IPD, 2009). Leases may also contain extension options exercisable upon expiry, and in the UK there may be a statutory right to renew which will make it difficult to change leasehold terms even when the contractual term expires.¹ There is no public data on lease length in Australia but Investa's experience and (slightly dated, and limited) research suggests that the pattern is similar (Crosby, 2006).

The quickening pace of policy, regulatory and technical change in relation to environmental understandings of commercial space means that leases need to allow greater flexibility in order to maximise the opportunities available. The story of the implementation of the CRC Energy Efficiency Scheme (CRC) in the UK provides an illustration of the difficulties of lease language. The CRC is intended to encourage carbon savings within large organisations by requiring those who receive supplies of energy to purchase permits (CRC allowances) to emit the resulting carbon dioxide. Many landlords are required to be participants in the scheme. This increases the cost of supplying energy to tenanted space and, in tune with the idea of the net rent, several landlords intend to pass the cost of CRC participation onto tenants. The difficulty is that leases have not built the language of CRC into the service charge and general outgoings clauses so it is doubtful in many cases as to whether landlords can legitimately pass on the costs. Furthermore, there is a real risk that leases will not be 'future proof'. The property industry invested much time and debate into consideration of how to accommodate CRC into new lease drafting throughout 2009 and 2010, only to find that the new UK Coalition Government moved the goalposts significantly in its Comprehensive Spending Review of Autumn 2010, leaving the details of the scheme in a state of flux for some time thereafter. (For fuller discussion see Bright & Highmore, 2010).

In Australia, leases often set detailed specifications about management issues, often with reference to standards in the Property Council of Australia's Guide to Office Building Quality (PCA, 2006). This level of detail would be highly unusual in the UK.

¹ Landlord and Tenant Act 1954, Part II; *O'May v City of London Real Property Co Ltd* [1983] 2 AC 726 (HL).

In Australia the rigidity of this approach makes innovation difficult. A practical illustration is the standard provision for thermal comfort which provides for a fixed temperature range – this prevents building operators from making adjustments outside of this range even where that may promote greater comfort for the occupiers and be less energy intensive. Investa has been exploring how thermal comfort can be achieved with less energy use, but doing this has often involved breach of lease terms. This experience is explained in section 4 below, but for now the point to draw from this is that it shows how conventional leases stifle innovation.

3 Crucial relationships function outside the lease

‘Green’ provisions must be built into the expectations of the parties at the start of negotiations. In late 2010, the Northwest Energy Efficiency Alliance (NEEA) moved into a building in Portland, USA, on the basis of a green lease. NEEA explains how important it was to the leasing process that its brokers continually communicated NEEA’s environmental goals to the landlord and, indeed, only introduced NEEA to landlords that shared its sustainability vision (NEEA, 2011). In practice, most negotiations are conducted through landlords’ and tenants’ agents (figure 1) who are focussed primarily on getting a deal done, and if environmental goals are not introduced early on it will be difficult to build them into the lease itself. Research conducted in the UK by Crosby *et al.*, shows that the heads of terms agreed have a significant impact on the resulting lease (Crosby, Hughes, & Murdoch, 2005, pp. 167, 172). This has also been the experience of Investa; unless key ‘green lease terms’ are discussed as part of the initial heads of terms, there is considerable resistance to their inclusion in the resultant lease.

Figure 1: Lease negotiations are largely conducted through intermediaries

Various actors who play important roles in relation to how the space is used are not in fact party to the lease itself (figure 2). Property management is often outsourced to building operators who do not have a direct contractual obligation to the occupants / tenants even though they are crucial to the delivery of services described in leases and have a pivotal role in achieving environmental objectives.

The building manager may in turn subcontract elements of the building’s operations (mechanical services maintenance, lift maintenance, cleaning, security, etc.) to specialist providers, or act as agent for the landlord who contracts their services directly. Regardless of the contractual structure, the landlord is unlikely to maintain a close or direct working relationship with the service providers. Even in the case of landlords that internally manage their buildings,¹ the majority of specialist functions will be performed by people who have no direct connection to the lease. Furthermore, employees of the landlord with responsibility for operating a building will not usually have been involved in negotiating a lease and may not even have access to it.

The situation is similar for tenants. Negotiations between landlords and tenants take place at a corporate level, generally before the tenant occupies the demised premises. Individual building occupants may be employed by tenants, but they are not themselves

¹ Investa Property Group operates an internal model. A directly employed ‘property supervisor’ is based at each building and oversees the work of contract service providers.

tenants. Most occupants have neither access to a copy of the lease, nor awareness of the obligations of landlord or tenant.

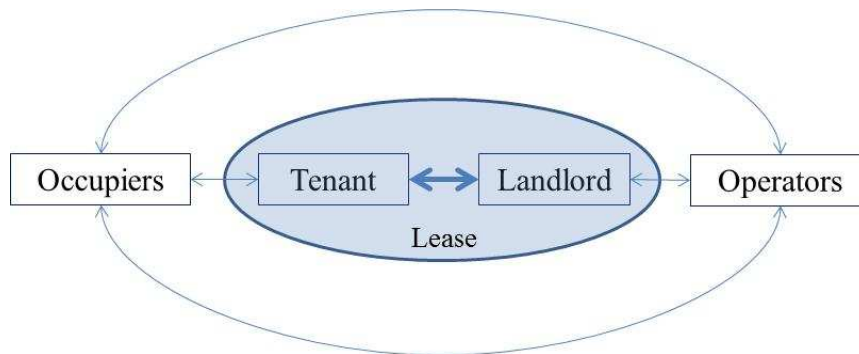

Figure 2: Once signed, the lease is the central relationship, yet it doesn't define or encourage broader engagement

Given that operators and occupiers of commercial office buildings are in most cases not familiar with the contents of leases between landlords and tenants, it begs the question: can commercial office building leases effectively facilitate innovation and encourage responsible operating practices? Put another way, does it matter whether leases prohibit or promote improved environmental performance if the people on the ground do not know what the leases say? This identifies a broader challenge. It is simply not possible to address environmental performance in the commercial built environment without understanding how the various communities using the building engage – with the space, with legal documentation, and practice manuals, and with other owners, occupiers, building managers, customers, employees and so on.

Clearly these questions are fundamental to determining whether leases can provide a basis for improving the environmental performance of commercial buildings.

We believe they can and they should. However it is clear that fundamental changes that align and reward owners and tenants for working together for mutual (and community) benefit are required. It will be necessary for innovative approaches to be adopted within leasing practices that take account of how occupiers behave and what occupiers want out of buildings. Operators need to be free to innovate in the way they run buildings, to be incentivised to do so, and to engage meaningfully with occupants regarding these kinds of issues. Furthermore, the content and structure of agreements between landlords and tenants will need to be understood by this wider group of stakeholders.

4 Some challenges illustrated through practice

The limitations and challenges mentioned above have profound implications for the operation of buildings and the wellbeing of their occupants in practice. Often landlords are compelled to instruct building operators to meet requirements that are not in the best interests of occupants and in doing so they waste energy and resources that could be put to better use. In other situations landlords must sit by as tenants make poor fit out decisions which impact their staff wellbeing and productivity. Some illustrations follow.

4.1 Thermal comfort

Office buildings exist to provide productive workplaces for their occupants. Insofar as it affects productivity, comfort is obviously important; however, there is no absolute standard for human 'thermal comfort'. The internationally-accepted definition states

that “*thermal comfort is that condition of mind which expresses satisfaction with the thermal environment*” (ISO, 1994). Everyday experience of office environments tells us that different people have different perceptions of thermal comfort at different times. Furthermore, those perceptions are impacted by a range of environmental and human variables (Fanger, 1970).

With the increasing prevalence of air conditioning in commercial offices, there has been a trend to codify in leases what constitutes acceptable thermal conditions. In Australia, where air-conditioning is universal, this has led to the prescribing of internal air temperatures of 20-24°C (21.5±1.5°C in winter and 22.5±1.5°C in summer) in typical commercial leases. For reasons yet to be understood, these prescriptions are significantly cooler than the 23-26°C recommended by leading international authorities on the subject (ASHRAE, 2010; ISO, 1994). Furthermore, these specifications take no account of other influences on human thermal comfort such as air velocity and the temperature radiating from windows. This inconsistency between leases and established comfort benchmarks is significant because energy use is directly proportional to the differential between internal and external temperatures (Ward & White, 2007). Also, because people adjust clothing to dress for the weather, so is occupant comfort weather and seasonally dependent (Morgan & de Dear, 2003; Ove Arup & Partners Ltd, 2008).

Landlords in Australia who attempt to provide air temperatures above 24°C during summer run the risk of breaching leases and incurring penalties, even though the conditions are likely to be more comfortable for occupants than those prescribed by the leases. A study by Investa during the Australian summer 2009/10 (where such lease boundaries were pushed on the basis of scientific rather than contractual advice!), found that a 1°C increase in thermostat settings was associated with a 6 percent reduction in daily air conditioning energy use (Roussac, Steinfeld, & de Dear, 2011). Furthermore, an analysis of data recorded via the company’s tenant “helpdesk” for a follow up trial (2010/11) found a 16 percent reduction in the frequency of “complaints” related to air conditioning relative to other building issues (Roussac, Steinfeld, & de Dear, Forthcoming). These results demonstrate significant potential for greenhouse gas emission reductions and comfort improvements, if only the leases would not preclude it!

4.2 Fit out churn

Fit outs and refurbishments consume large volumes of resources, much of it associated with “churn”. Churn refers to the replacement of building elements throughout the life of a facility. Using Investa’s portfolio as a guide (Investa’s is the largest portfolio of office buildings in Australia), it is estimated that each year between 10 and 15 percent of commercial office leases expire. At expiry tenants generally have the choice of whether to stay or go. It is common for landlords to offer incentives to stay and these are normally in the form of fit out contributions or cash. While Investa does not keep precise statistics, prior to the global financial crisis they estimated that 75% of expiries led to fit out contributions (to both renewing and new tenants) and the other 25% took cash and retained their fit out. So, from Investa's experience, the annual churn range is probably between 7.5 and 11.5 percent and the average life of a typical office fit out is just over 10 years (Terry & Moore, 2008)¹.

¹ Investa’s data for disposal of construction and demolition waste indicates a 56 percent reduction in fit out churn between 2008 and 2010, the period corresponding with the global financial crisis (Investa Property Group. (2011). Sustainability Report 2010 Retrieved 26 May, 2011, from <http://www.investa.com.au/sustainability/2010>). Tenants were choosing to retain fit out and stay in premises as a means of conserving capital during the economic downturn.

Fixtures, fittings and furniture are replaced even more frequently and have larger impact. Treloar *et al.* estimated that the total life cycle energy consumption of fixtures, fittings and furniture at a churn rate of 5.6 times over 40 years (i.e. a life of just over seven years) was close to, if not more than, the operational energy use for the case study building (Treloar, McCoubrie, Love, & Iyer-Raniga, 1999).

The implications of these figures are significant. It is clear that fit outs are more likely to be replaced because they become unsuitable than because they ‘wear out’. In many cases, fit out decisions at the commencement of lease impact negatively on indoor environment quality (IEQ) and occupant wellbeing by reducing the penetration of daylight and limiting the circulation of air, as found in a study by a team working at Cardiff University (CRiBE, 2007, p. 9). Landlords are often powerless to intervene in these decisions. Alterations clauses in leases commonly permit the tenant to install demountable partitioning and carry out non-structural work (subject to the landlord’s consent, not to be withheld unreasonably), again without reference to the environmental impact. It has also become standard for leases to require departing tenants to ‘make good’, i.e. remove all of the tenant’s property from the premises and repair or reinstate to a condition which is satisfactory to the landlord. Although this (partially) protects landlords from misconceived fit out decisions it increases waste yet further.

4.3 Excessive demand for building services capacity

A commercial office building’s quality is measured according to a range of criteria, including its capacity to provide tenants with services such as mechanical and electrical capacity. A high quality building is therefore generally one which boasts significant capacity to handle tenant loads, in addition to providing prestigious accommodation and views. The Property Council of Australia’s Guide to Office Building Quality is an example of a document which classifies office building quality, setting out minimum performance criteria which the market then uses to determine a building’s status.

Understandably, perhaps, tenants presented with benchmarks will typically seek performance towards the upper end of the scale in each of the categories for any given amount of rent, perceiving that greater service represents better value. This challenge was expressly acknowledged by the PCA in the 2006 version of its Guide, noting that “*higher, bigger, larger is not necessarily better*” and that excessive demands often lead to negative environmental and financial consequences (p. 7).

5 Significant innovations occurring outside leases

Even without effective green lease arrangements there are numerous factors driving the creation of more environmentally and socially responsible office accommodation, both via new construction and refurbishment. Corporate responsibility has become a significant factor in the decision making of large organisations and this desire to project an image of good corporate citizenship is influencing accommodation choices, particularly among larger institutions (Colliers International, 2010). Likewise, major property owners are competing to demonstrate ‘sustainability’ leadership credentials to their array of stakeholders, notably tenants, investors and staff. These demand and supply side factors are being brought together by growing evidence that environmental performance is associated with asset ‘quality’ and is contributing to higher investment returns (IPD, 2011).

Governments too are encouraging this change. The City of Melbourne, for example, now offers building owners the opportunity to recover the cost of financing environmental retrofit works from tenants through a charge linked to the City's rates collection (City of Melbourne, 2011). Likewise, the state of NSW has passed legislation—The NSW Local Government Amendment (Environmental Upgrade Agreements) Act 2010—“to allow local councils to enter into environmental upgrade agreements with owners of buildings and finance providers as a way of funding works to improve the energy, water or environmental efficiency of those buildings.”(Office of Environment & Heritage (NSW), 2010). The Green Deal in the Energy Bill currently before the UK Parliament adopts a similar approach.¹ Again, the aim is to make it easier to fund energy efficiency measures with no upfront costs, with costs recovered by a charge on utility bills.

The hope is that landlords will voluntarily make use of these funding opportunities. This may be optimistic. The UK government, in a signal that more forceful measures may be required, has made provision for a review to be undertaken of private rented properties (both domestic and non-domestic) by 1 April 2014 to compare the energy efficiency of rented properties with non-rented,² and power to make non-domestic energy efficiency regulations which could compel landlords to upgrade properties prior to letting (but this power can be used only if it will not materially decrease the number of properties available for rent).³ It is early days for the financing arrangements in Melbourne and NSW; however, there are indications that barriers, particularly in relation to the requirement for tenant consent and the accounting treatment of liabilities, are limiting the schemes' effectiveness: there has been no evidence of take-up to-date.

These various approaches all work to provide either an incentive to improve environmental performance or easier access to capital to fund technical improvements. But none of them address the problem of what you do in the face of leases that prevent technical changes being made, nor do they address behavioural issues. Furthermore, in the majority of cases, owners can only take up the opportunities if the building is currently unlet, or if the leases allow flexibility.

6 The case for broader engagement via the lease

Earlier we suggested that relationships between building operators and occupiers are largely defined by leases, and yet those parties tend to be unfamiliar with the contents of the leases that affect them. This is a problem, of course. The benefit of making changes to the structure and content of leases between landlords and tenants will be limited if changes do not focus on improving communication and collaboration with this broader group of stakeholders. What's needed is a broader and more collaborative approach to the defining of objectives, drafting of agreements and administration of duties. As mentioned above, intermediaries involved in the leasehold negotiations have a crucial role in setting the framework.

A further step is to increase the transparency of building performance. The most eco-efficient commercial office buildings exhibit a combination of excellent design and appropriate technology, together with highly competent and committed operators. Yet a building's eco-efficiency is not readily observable to occupants (who themselves also

¹ Energy Bill [HL] 2010-11.

² Energy Bill [HL] 2010-11 cl 39, as at 3 June 2011.

³ Energy Bill [HL] 2010-11 cl 46, as at 3 June 2011.

have an influence on building performance) and other stakeholders in the way that attributes such as views, location and finishes are. The EU's Energy Performance of Buildings Directive requirements for display certificates and the Australian Government's recently enacted Commercial Building Disclosure legislation are both designed to address this information gap. Both schemes, however, only require annual updates.

Raising awareness about buildings' operational performance was a key motivator behind the development of Investa's 2009 Sustainability Report, the first of its kind to incorporate an interactive data visualisation tool (ref. figure 3) (Investa Property Group, 2010). This 'bare all' approach, which provided insights into detailed monthly performance statistics at an individual building level, was expected to be popular with those staff associated with well performing buildings and less so with those operating the others¹. Feedback from Investa employees was somewhat surprising. In response to the question: "What do you think the consequences of publicly disclosing detailed building-level performance statistics will be for the future performance of Investa-operated buildings," 70 percent (N=52) from a sample of 74 staff (representing approximately 1/3 of Investa's workforce) surveyed upon their first exposure to the online data visualisation prototype rated them as either "very good" or "extremely good." Interestingly, the proportion was higher among those working directly within buildings at the 'property supervisor' level (9 of 12). 55 percent of staff (N=41) rated the public disclosure of detailed building-level performance statistics as being "very good" or "extremely good" for them "personally and/or professionally". Unsurprisingly, property supervisors working on buildings that had demonstrated significant eco-efficiency improvements were found to respond most favourably to that question, whereas those from poorer buildings were more cautious; though all were more than "slightly positive."

¹ Investa wanted to respond to feedback that previously reported aggregated portfolio performance data was of limited use for independent analysis because it masked much of the detail. Concerns about poorer performing buildings being perceived negatively were offset by the fact that most buildings would present well and that the publication of such data would be an 'industry first'.

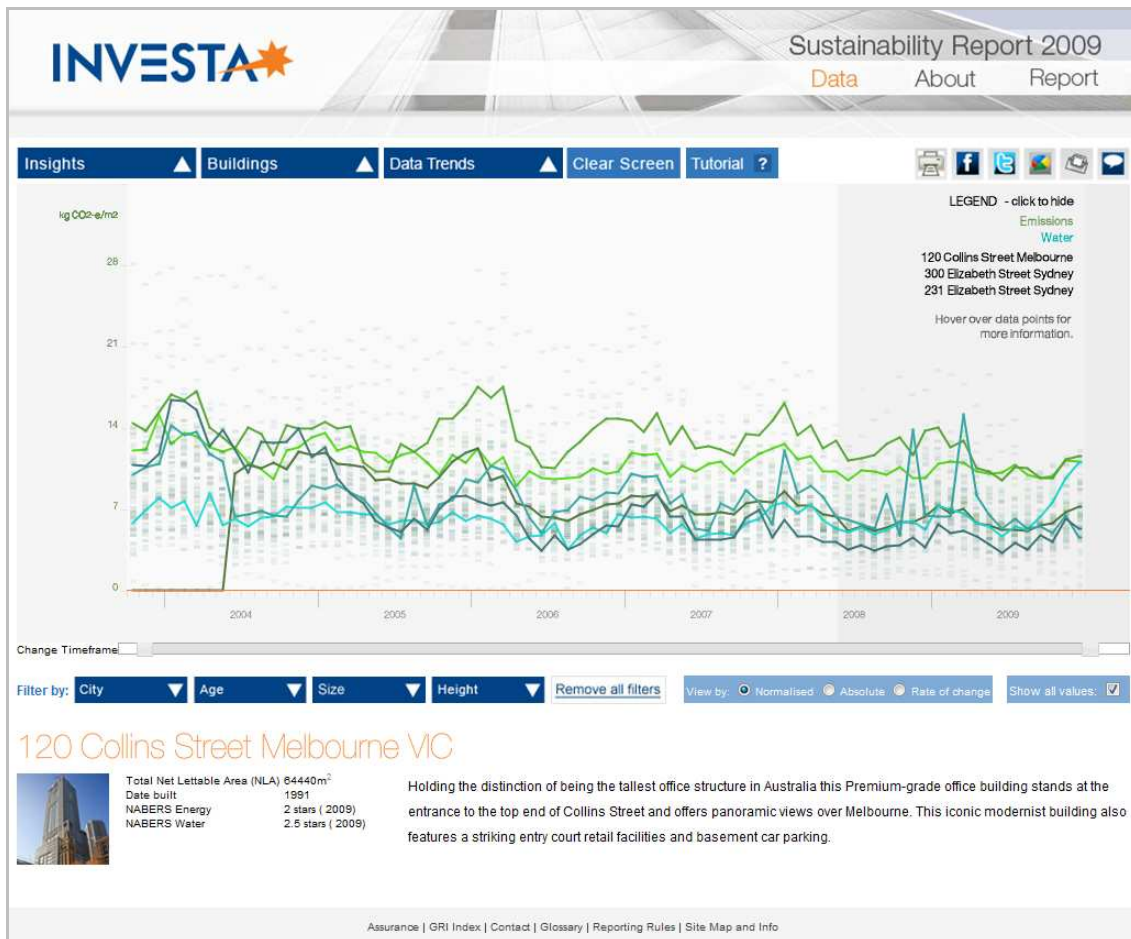

Figure 3. Snapshot of the Investa 2009 Sustainability Report’s interactive data visualisation tool showing monthly data trends.

(Source: Investa Property Group, 2010)

Lease obligations that require building operators to disclose detailed performance data in a form where ‘good/bad’ performance can be easily distinguished by building occupants may therefore be welcomed or resisted, depending on the performance leading up to disclosure. It is widely accepted that people are most productive in an organisational setting when they combine high levels of competence and commitment, where commitment is defined as a combination of an individual’s motivation and confidence on a goal or task (Hersey, Blanchard, & Johnson, 2001). Clearly the existence of an ‘audience’ can help to increase competence and commitment levels and drive better building performance. On the flip side, it has been found that “if either motivation or confidence is considered low or lacking, commitment as a whole will be low” (Hersey, et al., 2001).

Disclosure of poor operational performance without adequate support from a landlord willing to invest in the systems, training and tools to help building operators address that performance may therefore be counter-productive. Furthermore, to a poorly informed audience, more information is unlikely to deliver greater understanding or better behaviour (Janda, 2011). For these reasons it is crucial that initiatives be implemented as a suite that combines education with useful information, technology and a forum that facilitates working together.

7 A suite of examples for how we might do better

This section suggests a variety of ways the structure and content of leases can be improved to encourage better alignment between the stakeholders that influence the environmental performance of commercial office premises.

7.1 Green lease schedule

It is possible to promote environmental performance in a flexible way by agreeing a 'Green Lease Schedule' which can be attached to a standard lease. This can be comprehensive, or sketchy, depending on how much detail the parties wish to put in. Likewise, it can be aspirational (setting non-binding goals) or more prescriptive (setting binding goals and the consequences of breach).

An example of this approach is the Investa precedent lease, extracts from which follow:

16.1 Green Lease Schedule

- (a) The Landlord and the Tenant agree that:
- (i) the objectives outlined in the Green Lease Schedule are established to positively contribute to the working environment of the occupants of the Building and promote the efficient use of resources in the Building's operation;
 - (ii) they will each use reasonable endeavours to meet the objectives outlined in the Green Lease Schedule and to use the Premises and operate the Building in the spirit of progressively improving environmental performance as measured against the objectives outlined in the Green Lease Schedule;
 - (iii) they will consult with each other on issues or circumstances that may enhance environmental performance and will consider undertaking all such opportunities which are expected to have a positive impact on the work environment subject to an analysis of the costs and benefits;
 - (iv) they will constructively consult with each other on issues or circumstances that may detract from attaining the objectives outlined in the Green Lease Schedule;

(Investa Property Group, 2009)

The landlord commits to annual measurements, and the tenant to providing the landlord with information necessary to enable environmental reporting. The commitments are not binding and breach will not constitute a breach of the lease. Future landlords are not required to adopt the Green Lease Schedule. The problem of fit out churn discussed earlier is reduced by a tenant promise to incorporate energy, water and indoor environmental quality performance criteria into fit out design and equipment selection.

The Green Lease schedule referred to in the Investa lease is a 12 page document containing checklists used to indicate the landlord's and tenant's wide-ranging 'green lease' commitments (Investa Property Group, 2007b). Each of the checklists is reproduced from the Green Lease Guide, a publication developed by Investa in collaboration with the cities of Melbourne and Sydney and the NSW Government to educate the parties about the benefits and costs of various commitments. The Guide is used in conjunction with the lease and schedule and summarises the impact of each

commitment in terms of: financial cost, employee wellbeing, and corporate reputation (Investa Property Group, 2007a). The schedule is attached to every Investa lease.

7.2 Building management plans and committees

The green lease schedule discussed above differs from the Green Lease Schedule developed by the Australian Government under its Energy Efficiency in Government Operations (EEGO) policy. That policy requires, for the majority of office leases the Australian government enters into, a formal commitment to energy efficiency, including an agreement between landlords and tenants to commit to a minimum ongoing operational building energy performance standard, measured by the National Australian Built Environment Rating Scheme (NABERS). The schedule sets out the requirement for the creation of a Building Management Committee (BMC) and how it functions, including the Energy Management Plan the committee is required to develop, how building performance is to be monitored and periodical reporting on the outcomes (Australian Government, 2010).

A key advantage of this approach is the formalisation of the ongoing role of the BMC in developing, monitoring and implementing the EMP. Participants need the necessary skills to “meet the landlord or tenant’s needs and obligations”, however “they will not need to be accredited building or energy experts or hold specialist qualifications” (Australian Government, 2010).

Under the EEGO model, the BMC must include the landlord’s and tenant’s ‘energy representatives’ (Australian Government Solicitor, 2011, p. 21). There is no requirement that the committee include other stakeholders (although they are not excluded). We understand the BMC is a feature of the schedules used for larger tenancies where the government tenant has greater bargaining power (p. 20), however, we have not found evidence that government tenants are widely using the policy to drive “effective operational management” (Australian Government, 2010).

In the UK, there are few publicised examples of green lease provisions in use. The Better Buildings Partnership (BBP, a collaboration of London’s leading commercial property owners and allied organisations) produced a ‘green lease toolkit’ during 2009, but there is little evidence as to what impact it is having. This toolkit also promotes the use of a BMC which is tasked, *inter alia*, to set up and review an environmental management plan for the building, including specific targets (Better Buildings Partnership, 2009, pp. 9, 13, 14, 20, 21).

7.3 Green Improvements

Under a ‘net lease’ the ‘split incentive’ means that the landlord has limited financial incentive to install eco-efficient plant and machinery because the cost of servicing the building is borne by its tenants. A survey conducted as part of the New York City Office of Long-Term Planning and Sustainability (OLTPS) PlaNYC initiative found that 60 percent of NYC building owners believed the split incentive was an impediment to their investing in retrofits (PlaNYC, 2011). Approaches that overcome this “significant disconnect between those owning/managing buildings and those paying the energy bills” (All Party Urban Development Group, 2008, p. 25) may be crucial, therefore, in improving the environmental performance of buildings leased on a net basis.

In light of this challenge, Investa amended its precedent lease to permit the recovery of costs associated with capital works directly benefitting the tenants through a special amortisation charge applied to the rent. The concern that the landlord will be able to upgrade its buildings at the tenant's cost (expressed by tenants during the consultation process) is addressed by limiting the application to projects that will reduce outgoings costs to tenants and also reduce the environmental impact of running the property (i.e. energy and water saving projects, and some projects to enhance IEQ). The tenant's outgoings costs are not permitted to increase (due to the improvements charge) above the amortised cost of the project without written approval from the tenant. Subject to the improvement not causing an increase in the tenant's outgoings, the landlord can carry out a green improvement after a consultation period. The tenant must then allow the landlord to do 'all things reasonably required' to this end, even if 'quiet enjoyment' or access to the premises is affected.

Similar approaches have been adopted under the models recently legislated by the Victorian and NSW governments, and also for the model lease language in the PlaNYC "Energy Aligned Lease". Under the PlaNYC model, a building owner's capital expense pass-through is limited to 80 percent of the predicted savings in any given year. This provides the tenant with a cushion to protect against underperformance and the owner still receives the full reimbursement, however, the payback (recovery) period is extended by 25 percent (PlaNYC, 2011).

Investa's experience negotiating these clauses has been mildly positive, with the provisions making it through the negotiating phase on approximately 50 percent of occasions since they started being introduced in 2009. A large proportion of tenants has been willing to accept the fact that there may be free-riders in buildings where not all tenants have signed up to the new green improvements clauses, noting that their expense is always in proportion to their benefit. In some instances, however, particularly where government tenants are involved, tenants have expressed the view that the capital reimbursement provision is not justified because the landlord has the benefit of the asset improvement and a greater likelihood of retaining tenants at lease expiry. The (landlord's) counter to this argument is that it is invariably cheaper and more effective to conserve capital and offer a substantial tenant incentive payment instead.

7.4 Sustainability incentive (lighting controls)

As mentioned in the earlier section on fit out churn, it is common practice for landlords to offer financial incentives to new and renewing tenants. Depending on the level of demand, this may amount to 20-30 percent of the total rent payable over the term of the lease. Tenants are generally free to use the incentive at their discretion; however, it generally offsets the rent or contributes to the cost of fitting out the premises. Although conventions vary from market to market, it is usual in Australia for the landlord to provide floor and ceiling finishes, air conditioning and fluorescent lights as base provisions and the tenant fits out from there (often removing part of these components and reinstating at expiry). It is a tenant's decision whether or not lighting controls that automatically switch off lights based on occupancy should be installed.

In 2005 Investa introduced an initiative called the Investa Greenhouse Guarantee (Investa Property Group, 2005) designed to give tenants access to quality office lighting systems and expertise, with guaranteed environmental and investment benefits. While some tenants were motivated to take up the offer, it was found that many simply lacked the time and inclination to invest in lighting controls even though they would, in typical

cases, deliver guaranteed returns on investment of 30 percent and better. In response to this inertia, the company decided to introduce a ‘sustainability incentive’ that can only be used to pay for lighting controls. An arrangement was agreed with the partner company delivering the Greenhouse Guarantee to provide the controls for a fixed rate per square metre equivalent to the incentive being offered. The controls specification and all associated details are described in a schedule to the lease. Under this arrangement, where tenants must introduce automatic lighting controls if they are to receive the incentive, take-up is now in the order of 70 percent.

7.5 Re-work counter-productive clauses

Many clauses designed to protect the parties’ interests have unfortunate side-effects. Examples discussed throughout this paper include ‘make good’ requirements that oblige tenants to return premises to the state that existed prior to their fit out, even when this might involve stripping out still valuable materials, alterations clauses that pay no attention to environmental impact, and temperature control bands that take no account of the weather outside or occupants’ clothing choices. These things can be changed by amending standard lease clauses to take account of environmental impact. So, for example, the NEEA green lease specifies that all tenant improvement work must be performed in accordance with sustainability practices and maintain LEED certification for Commercial Interiors certification (LEED, or Leadership in Energy and Environmental Design, is an internationally recognised green building certification system, developed by the US Green Building Council) (NEEA, 2011). Likewise, a model clause in the BBP green lease toolkit provides that if proposed tenant alterations adversely impact on energy and water efficiency the tenant ‘will consider, [and, where reasonable, implement],’ the landlord’s suggestions to minimise this impact (Refer to BBP toolkit, p. 23). The cautious approach advocated by BBP reflects the commercial challenge in agreeing changes to standard leasing practices.

Investa’s lease, as well as emphasising the role of the schedule and the broader collaboration that entails, also seeks to eliminate some of the more problematic ‘industry standard’ clauses.

For rent reviews, the independent valuer must be instructed to take into account the sustainability incentive and the green improvement payments to avoid any erosion of the value of these when making a determination.

The landlord may require the tenant to *not* remove improvements to the premises made by the tenant that, in the landlord’s opinion (acting reasonably), improve the environmental performance of the premises. There is a similar provision in the BBP green lease toolkit (Refer to BBP toolkit, pp. 23, 24).

Some of these anomalies can alternatively be addressed by negotiating a green lease schedule. However if the schedule is not binding, as is the case with the Investa example provided above, this may leave an unsatisfactory degree of uncertainty. This was the motivation for the Northwest Energy Efficiency Alliance when it recently negotiated the inclusion of a variety of green aspects into the lease itself for its new premises in Portland’s Commonwealth Building (NEEA, 2011). The advantage, as described by NEEA, is that “if the building sells, the next owner will be required to stick to their predecessor’s commitments” (p. 6).

8 Concluding remarks

‘Green leasing’ has become the catchphrase to represent new approaches to leases that aim to promote improved environmental performance. Although we also use this language, it carries the risk of becoming stereotyped. In sum, what we argue for is an approach to leasing and managing let space that enables and encourages innovation, co-operation and collaboration. This involves not simply a re-examination of the structure and content of the lease itself but also the relationships between the landlord and tenant, building operators and users of the space so that practices take account of how occupiers behave and what occupiers want out of buildings. Operators will need to be free to innovate in the way they run buildings, to be incentivised to do so, and to engage meaningfully with occupants regarding these kinds of issues. Furthermore, the content and structure of agreements between landlords and tenants will need to be understood by this wider group of stakeholders. The following recommendations suggest ways of encouraging innovative leasing that put environmental concerns at the core of the relationship:

1. Start the discussions early in the negotiating process, make sure that agents understand the environmental goals, but don’t leave it only in the hands of agents.
2. Express clearly what constitutes good environmental design and performance (e.g. in green lease schedules).
3. Consider whether to use language that gives enforceability and will also bind future owners.
4. Commit to transparency and accountability for performance that goes beyond regulatory requirements.
5. Develop processes, such as a BMC, noticeboards, etc., that enable all stakeholders to be actively involved in the pursuit of, and commitment to, environmental goals for the duration of the lease.
6. If it is a net rent lease, use clauses that enable environmental improvements to be made in a way that overcomes the problem of the split incentive.
7. Review standard lease terms to consider their potential impact on environmental performance (particularly the alterations, making good, and rent review clauses).
8. Consider how control and responsibility are aligned within the lease, as in the lighting controls example considered above.
9. Build in adaptability for changes in technology, occupant expectations and legislation.

Public Participation and Environmental Impact Assessment

Mirjana Drenovak Ivanovic, LL.M.

Teaching Assistant of Environmental Law
Faculty of Law University of Belgrade
Serbia

Email: mirjana.drenovak@ius.bg.ac.rs

Abstract:

With the adoption of the Aarhus Convention, the question of whether there is a need for public participation in environmental decision-making has replaced the question of possible ways of public participation and a manner of achieving maximum effects from public participation. One of the procedures where the public is a participant in the decision-making is the environmental impact assessment. This paper analyzes the types of public participation in environmental decision-making, the benefits that could be achieved by means of public participation in decision-making in the environmental impact assessment, as well as preconditions for adequate public participation in environmental impact assessment. The paper also explores the development process of impact assessment of environmental legislation in Serbia and the transformation of the public's right to participate in environmental impact assessment. The review is provided on the relevant case law of Serbia, and the Comparative and Case Law are pointed to.

Keywords:

Environmental Impact Assessment, environmental values, Serbian environmental law, public participation

1 Introduction

The concept of the need for public participation in environmental decision-making is found in the Stockholm Declaration on the Environment. As stated in the first Principle of this Declaration: „Man has the fundamental right to freedom, equality and adequate conditions of life, in an environment of a quality that permits a life of dignity and well-being, and he bears a solemn responsibility to protect and improve the environment for present and future generations. In this respect, policies promoting or perpetuating apartheid, racial segregation, discrimination, colonial and other forms of oppression and foreign domination stand condemned and must be eliminated”.¹ The importance of public participation in environmental decision-making is also highlighted in Principle 10 of Rio Declaration: „Environmental issues are best handled with the participation of all concerned citizens, at the relevant level. At the national level, each individual shall have appropriate access to information concerning the environment that is held by public authorities, including information on hazardous materials and activities in their communities, and the opportunity to participate in decision-making processes. States shall facilitate and encourage public awareness and participation by making information

¹ Declaration of the United Nations Conference on the Human Environment, June 16, 1972.

widely available. Effective access to judicial and administrative proceedings, including redress and remedy, shall be provided.”¹ The basic principles of public participation in environmental decision-making were established by Aarhus Convention.² From the moment of Aarhus Convention’s adoption, the key question was no longer whether there is a need for public participation in environmental decision-making, but how to achieve optimal public participation in environmental decision-making. The paper analyzes the types of public participation in the environmental impact assessment, requirements to be met for the best results of public participation and effects achieved by involving the public in the environmental impact assessment. This paper presents the current solutions and reviews the development of environmental impact assessment in Serbian legislation. In addition, the paper points to the European Court of Justice.

2 Literature Review

The public is a necessary participant in the process of making environmental decisions in a formal and material sense. In a formal sense, the public, as an entity environmental decisions relate to, should be entitled to participate in making these decisions (Holder and Lee, 2007; Dryzek, 1997; Steele, 2001; Kelman, 1997; Fisher, 2010). In a material sense, the public is an essential participant in the process of making environmental decisions, because it contributes to the quality of decision-making in environmental matters (Holder and Lee, 2007; Bell and McGillivray, 2008; Nadal, 2008).

Environmental impact assessment is a unique procedure in which a decision is made on initiating projects which, based on estimates and taking into account all the information about the possible effects on the environment, could have an impact on the environment (Holder, 2004; Bina, 2007). As there are different forms of public participation in environmental decision-making, the paper discusses the forms that are unique to the process of environmental impact assessment (Morriss and Therivel, 2009). In addition, it is pointed to specific objectives necessary to achieve public participation in environmental impact assessment (Lee and Abbot, 2003), as well as prerequisites for adequate public participation (Bell and McGillivray, 2008; Kysar and Salzman, 2003; Felleman, 1997).

The paper points to the current statutory provisions of public participation in the environmental impact assessment in Serbia and the degree of compliance of Serbian legislation with the Aarhus Convention after the adoption of the Law on Ratification of the Convention on Access to Information, Public Participation in Decision Making and Access to Justice in Environmental Matters, May 2009. (Drenovak Ivanovic, 2011a). In addition, paper provides a review of the development of a legal framework governing the procedures for environmental impact assessment and indicates the change in attitude towards public participation (Todic and Durac, 2003a).

3 Types of Public Participation

„Recent decades have seen the emergence of a very widespread consensus that „public participation“ is a crucial element of good and democratically legitimate environmental decision-making. Consensus around public participation can be seen at every level,

¹ *Rio Declaration on Environment and Development*, Rio de Janeiro, June 3-14, 1992.

² *Convention on Access to Information, Public Participation in Decision-making and Access to Justice in Environmental Matters*, Aarhus, Denmark, June 25, 1998.

international, regional, national and local.“ (Holder and Lee, 2007, pp. 85; Rosener, 1997). In this sense, the key question of modern environmental law is not the existence of need for public participation in environmental decision-making, but the analysis of procedures and ways in which the public can take part in the protection of basic environmental values and assumptions to be met in order to give maximum public participation results (Schrader-Frechette, 1985; Fiorino, 1989).

The notion of public participation in environmental decision-making can be defined in a broad and narrow sense. In a broad sense, public participates in environmental decision-making with every activity that aims at influencing the practice of the legislative and executive powers regarding the protection of essential environmental values. Public participation understood in such a manner is present when the public elects representatives of legislative power in parliamentary elections, who will legislate in the field of environmental protection and influence the formulation of environmental policy (Bell and McGillivray 2008). In a narrow sense, public participates in environmental decision-making only when there is a possibility, stipulated by law, of its participation in the decision-making policy, plan or strategy in the field of environmental protection or in the procedures of issuing certain permits that are accompanied by environmental impact assessment.

The basic criterion for distinguishing forms of public participation in the narrow sense may be the moment of making public participation in environmental decision-making possible. We distinguish between cases in which the public has the opportunity to participate as early as when policies, programs and strategies of environmental protection are formulated, and those in which the public can only participate in the final stage of making concrete decisions. In the first case, it is a deliberative participation, which includes public participation in the process of achieving agreement on the grounds of environmental protection (Steele 2001). The public, in this case, is an indispensable party in formulation of environmental policy and has the ability to participate in the formulation of the general environmental policies and strategies that are later applied to environmental protection in a particular case. However, if the public has no opportunity to participate at the early stages of environmental decision-making, but only at the stage where decisions have already been formulated, and the public is given the opportunity to express an opinion on specific decisions, it is a stakeholder participation (Bell and McGillivray, 2008). This form of public participation sees the public as an important factor in achieving the protection of environmental values. However, the public, in this sense, is the party with no role in determining the extent and direction of environmental protection, but the one which, by expressing an opinion on already formulated decisions, contributes to their better quality. An example of this form of public participation is found in the procedures of issuing permits that are accompanied by the environmental impacts assessment, such as permit to use the land, or building and occupancy permits.

The distinction has not only theoretical, but also a practical value. If the model of deliberative participation is accepted and obligation of public authorities to provide the possibility of participation in the formulation of plans, programs and strategies of environmental protection is established, then the public has the ability to protect the right of participating in making these documents. Otherwise, the public can, as an expression of desire to achieve best practice or by informing the public about the activities in the field of environmental protection, invite the public to express their opinion. However, public opinion has no binding force (Arnstein, 1996). Administrative authority may consider an opinion disclosed in such a manner when making plans,

programs or strategies for environmental protection, but is not obliged to. In addition, the administrative authority is not obliged to explain the reasons why public opinion was not taken into account.

Since the public is largely engaged in the process of environmental impact assessment and since the public is guaranteed not only the right to participate in environmental decision-making, but also to the legal protection of this procedural right in the environmental impact assessment, there will be a discussion on public participation in the procedure of environmental impact assessment further on.

4 The Index of Environmental Impact Assessment Procedure

4.1 The Term of Environmental Impact Assessment

In terms of the Convention on Environmental Impact Assessment¹ in a transboundary context, environmental impact assessment represents the assessment of the impact that planned activities may have on the environment, particularly considering alternatives to the proposed activities and measures which, in the case of project approval, are necessary to be applied in order to accomplish comprehensive environmental protection (Lawrence, 1997). Environmental impact assessment may also be defined as a unique procedure in which a decision is made on initiating projects which can have an impact on the environment, based on estimates and taking into account all the information about the possible effects on the environment (Morriss and Therivel, 2009). It is a procedure that expresses the need to identify and predict the impact of certain legislative proposals, policies, programs and projects on the environment and human health, and to interpret environmental information that are relevant in a particular case (Munn, 1979). If the environmental impact assessment is compared with other instruments of environmental protection, we may see that the dominant feature of impact assessment is prevention.

Environmental impact assessment is applied to projects which could have an impact on the environment and which are in a planning or construction phase, as well as those related to technological change, reconstruction and capacity expansion, termination of work and removal of projects. In addition, the subject of environmental impact assessment are projects that are not approved for construction, or are used without the use permit, and which have been realized without the implementation process of environmental impact assessment.²

The procedure of environmental impact assessment in Serbian legislation is carried out in two or three phases. The first phase is deciding on the need to assess the environmental impact. This phase does not apply to projects for which impact assessment is required. The second phase is determining the extent and implications of environmental impact assessment study. This phase applies to projects with demand for environmental impact assessment at the previous phase, as well as to those projects for which the impact assessment is required. The third phase means deciding on the approval of the environmental impact assessment project study.

¹ *Espoo Convention on Environmental Impact Assessment in a Transboundary Context*, Finland, February 25, 1991, Article 1 paragraph 1 item 6.

² *Law on Amendments to Law on Assessment of Environmental Impact*, „Official Gazette of the Republic of Serbia”, no. 36/09, Article 2.

If the project in question is the one that requires environmental impact assessment or the one with the identified need for impact assessment, the applicant can not begin with its execution without the consent of the competent authority on the environmental impact assessment study. It further means that these projects can not be accessed without a prior procedure of environmental impact assessment and adequate public participation in making the study. In this sense, the environmental impact assessment represents the realization of idea of participatory democracy in environmental decision-making, i.e. ideas of the necessity of consultation and public participation in decision-making in cases of possibilities for certain projects, plans, legislative proposals and measures to have an impact on the environment (Holder and Lee, 2007).

Procedure of environmental impact assessment encompasses the right to access environmental information in a broad sense, as part of the right to access public information, the right to access environmental information in the narrow sense, as a right to access those environmental information that are related to the particular stage of the environmental impact assessment procedure, the public's right to participate in decision-making on the environmental impact assessment, and the right to legal protection of access to environmental information in the narrow and broad sense, or, in other words, the protection of the public's right to participate in the stages of environmental impact assessment (Drenovak Ivanovic, 2011b). An illustrative example that indicates the necessary connection of these elements is the case of the European Court of Justice *Djurgarden-Lilla Vartans Miljoskyddsforening*.¹ The Court, among other things, expressed the following opinion: „Thus, the fact relied on by the Kingdom of Sweden, that the national rules offer extensive opportunities to participate at an early stage in the procedure in drawing up the decision relating to a project is no justification for the fact that judicial remedies against the decision adopted at the end of that procedure are available only under very restrictive conditions.“² (Ryall, 2010).

4.2 Environmental Impact Assessment in Serbia

Procedure of environmental impact assessment in Serbia is applied according to the Law on Environmental Impact Assessment. Facilities, or activities that are subject to environmental impact assessment are determined by the List of projects under EU Directive 85/337/EEC as amended by the 97/11/EC.

The legal framework of implementation of environmental impact assessment in Serbia are: Law on Environmental Impact Assessment (Official Gazette of the Republic of Serbia, no. 135/04 and 36/09), Law on Strategic Environmental Impact Assessment (Official Gazette of the Republic of Serbia, no. 88/10), Decree on the List of projects for which EIA is mandatory and Lists of projects that may require environmental impact assessment (Official Gazette of the Republic of Serbia, no. 114/08), Regulation on the contents of requests for deciding on the need for impact studies and content requirements for determining the scope and content of the environmental impact assessment study (Official Gazette of the Republic of Serbia, no. 69/05), Regulations on the contents of the environmental impact assessment study (Official Gazette of the Republic of Serbia, no. 69/05), Regulations on the content, appearance and manner of keeping public records on executed actions and decisions of the environmental impact assessment (Official Gazette of the Republic of Serbia, no. 69/05), Regulations on the work of the technical committee for the environmental impact assessment study

¹ *Djurgarden-Lilla Vartans Miljoskyddsforening* (2009) EUECJ C-263/08

² *Djurgarden-Lilla Vartans Miljoskyddsforening* (2009) EUECJ C-263/08, Para. 49.

evaluation (Official Gazette of the Republic of Serbia, no. 69/05), Regulations on public release, presentation and public discussion of the environmental impact assessment (Official Gazette of the Republic of Serbia, no. 69/05). The legal framework governing the rights of public participation in decision-making in environmental matters in Serbia complies with the Aarhus Convention (Article 6-8). Aarhus Convention has become a part of Serbian legal system by adopting the Law on Ratification of the Convention on Access to Information, Public Participation in Decision Making and Access to Justice in Environmental Matters in May, 2009.¹

The adoption of the Environmental Impact Assessment Law and the Law on Environmental Protection in 2004 made significant progress towards the promotion of public participation in the environmental impact assessment. Previous legislation did not recognize the public's right to participate in decision-making in the process of environmental impact assessment. Under article 16 of the Law on Environmental Protection of the Republic of Serbia (Official Gazette of the Republic of Serbia Nos. 66/91, 83/92, 53/93, 67/93, 48/94, 44/95 and 53/95), an analysis of the environmental impact had to be made with respect to all facilities and works that may put the environment at serious risk. This analysis had to be approved by the ministry in charge of environmental affairs and such an approval forms part of the urban planning and technical documentation. The law did not provide for public participation in the decision-making process. In practice, the absence of legally established opportunity for the public to participate in the environmental impact assessment has led to serious difficulties. An illustrative example is the case from 1998 where plaintiffs appealed against the approval of an environmental assessment, seeking review of wrongly established facts in the first detailed analysis, including area of land involved, the level of dust in the air and on the ground, noise produced by the quarry, and the safety of citizens around the quarry. In this case, "there was no public participation in the development of the detailed analysis. Regulations of the Federal Republic of Yugoslavia and of the Republic of Serbia did not address public participation in decision-making regarding the preparation of environmental assessments. Consequently, there was no basis for the local residents to claim that their participation rights had been violated. The only opportunity for residents to challenge the conclusions, therefore, was to appeal against the decision approving the detailed analysis on the basis of legal insufficiency." (Todic and Durac, 2003a, pp. 190)

In the existing legislation in Serbia, public's right to participate in environmental impact assessment is standardized. After the competent authority has notified the public of application filed for environmental impact assessment and the application filed for determining the scope and content of the environmental impact assessment study, interested agencies, organizations and the public can submit their opinion within 10 days. It is a possibility for the public concerned to take part in the first phase (or in the second phase in the event of required environmental impact assessment), i.e. before making decisions on approval of a study on the environmental impact assessment when interested public can give an opinion about the need to perform impact assessment, and on the scope and content of the study. In addition, the public concerned has a right to participate in decision-making in the second phase of environmental impact assessment. This means that the public has a right to be informed on filed application for determining the scope and content of a study, within 10 days of receipt of the

¹ *Law on Ratification of the Convention on Access to Information, Public Participation in Decision Making and Access to Justice in Environmental Matters*, "Official Gazette of the Republic of Serbia", no. 38/09.

application to determine the scope and content, and the public concerned has the opportunity to express an opinion on the application within a specified period of time. In order to prepare for a public hearing on the environmental impact assessment study, the competent authority is obliged to inform the project sponsor, interested bodies and organizations and the public about the place and time of public access, public presentation and public discussion on the impact assessment study within 7 days of receipt of the application for approval of impact assessment study. In order for the public to prepare in the best possible way for a public hearing, it is normalized by Environmental Impact Assessment Law that a public hearing may be held at earliest 20 days from the date of notifying the public.¹

4.3 What is the Purpose of the Environmental Impact Assessment Procedure?

Involving the public in environmental impact assessment leads to an adequate and effective protection of the right to a healthy environment and to establishing a balance between the needs of present and future generations in distinguishing between environmental goods and environmental "evils." The question that arises is whether the goal of environmental impact assessment is the decision making, which is a product of compromise of administrative bodies, industry and the public, in a particular case, as a participant in the process, or the goal is absolute protection of the environment which includes compliance of proposed activities with the development policy? Study on the environmental assessment is a document in which the analysis and professional assessment of environmental factors' quality are presented, as well as their sensitivity to the area of planned activity, for which the environmental impact assessment procedure is carried out. The study analyzes the interplay of existing and planned activities. In addition, the study contains an element that refers to the prediction of direct and indirect harmful effects of specific project on environmental factors. This element brings the environmental impact assessment closer, as well as the process of formulating environmental policy. The answer to the question what is the difference between these two procedures depends on the answer to the question what is the objective of environmental impact assessment.

The environmental impact assessment is the preventive measure of environmental protection during which all data, necessary for determining the potential adverse impact of a specific project on the environment, are collected. If potential harmful effects are determined, it is necessary to compare the proposed activity with alternative measures. If the proposed activity is the best solution in a particular case, measures are established and proposed in the process of environmental impact assessment, by which, in a particular case, adverse effects can be prevented, reduced or eliminated. This means that the impact assessment procedure considers both positive and negative effects of the implementation of specific, concrete activity and impact of these effects on the environment. Environmental impact assessment study should not contain an analysis of impact of specific project on the implementation of development policies. This is because a study on the environmental impact assessment is produced by legal person or entrepreneur, if he/she is registered in the appropriate register for activities of design, engineering and making studies and analyses, and multi-disciplinary team consisting of persons qualified to analyze each of the factors of the environment. These persons are not competent to define the environmental and development policy, plan or program, but to determine the environmental impact of a specific project in a specific case.

¹ *Law on Environmental Impact Assessment*, Article 20 paragraph 3.

The objective of environmental impact assessment is establishing the impact of the proposed project or activity on the environment, rather than analysis of compliance of implementation with developmental or environmental policy of the state (Weston, 2002). If it were allowed for environmental impact assessment study to contain this analysis, the public could be misled about the real strengths and weaknesses of a particular project. In Comparative Law, an illustrative example is found in the case of *West Coast Wind Farms Ltd. v. Secretary of State and North Devon DC*¹ (Leitch, 2010). In this case, the opinion was expressed that the aim of determining the development state policy is achieving comprehensive protection of environmental values. This procedure requires identifying interests that influence its formulation and, by means of balancing these interests determining a unique development policy. The "balancing" of competing interests should take place when it is being decided whether or not to authorize the development - a decision which should be taken by elected and accountable representatives, as part of a political process." (Holder and Lee, 2007, pp. 565)

5 What is Achieved with Public Participation in the Process of Environmental Impact Assessment?

Response to a question about the goals that can be achieved by introducing the public in environmental decision-making can be approached from a philosophical standpoint and the standpoint of positive environmental rights. However, analysis of the goals to be achieved by public participation would be incomplete if we access it only from one or another point of view (Steele, 2001). In a further analysis, the basis is a Positive Environmental Law, and the additional elements are philosophical points of view on public participation.

Starting from the standpoint of Positive Law, the role of the public in environmental decision-making depends on whether this right, in the case of environmental protection, is stipulated by law. If so, public participation in environmental decision-making process is a condition for its legitimacy and viability. „As well as potentially improving results, public participation might be used to improve procedural legitimacy, tempering unease with the democratic condition of environmental decision-making.“ (Lee and Abot, 2003). In addition, if the law stipulates the obligation of government to allow the public expression of opinions in the process of environmental impact assessment, this means that the legislator had in mind the fact that public participation contributes to the quality of their decisions when regulating such a provision. Improving the quality of decisions in the process of environmental impact assessment is *ratio legis* for the standardization of mandatory public participation. Thus is realized an idea expressed in the Preamble to the Aarhus Convention: „improved access and public participation in decision-making enhance the quality and the implementation of decision“.²

If the Law on Environmental Impact Assessment did not standardize public's right to participate in decision-making, the public has a completely different role. First of all, by participating in a legally non-binding discussions, the public can express the views on certain activities that are subject to environmental impact assessment. In this way, the administration authority will be acquainted with the role that certain values have to the

¹ *West Coast Wind Farms Ltd. v. Secretary of State and North Devon DC* (1996) JPL 767.

² *Convention on Access to Information, Public Participation in Decision-Making and Access to Justice in Environmental Matters*, Aarhus, Denmark, June 25, 1998.

public in environmental decision-making (Steele, 2001; Lee and Abbot 2003). Consequently, although not legally binding, public opinion expressed in this way can influence the decisions of administrative bodies.

6 Theses of Adequate Public Participation in Environmental Impact Assessment

„Technological risk disputes are not just discrete technical or ethical disagreements. They concern how collective institutions should identify, understand and take action in relation to such risk.“ (Fisher, 2010, pp. 11). In that sense, it is necessary to take account of all aspects of public participation in the environmental impact assessment as a collective that identifies environmental risk and takes it into account when forming an opinion on its acceptability.

Public participation in the process of environmental impact assessment has a quantitative and qualitative dimension (Macnaghten and Jacobs, 1997; Duram and Brown, 1999). Quantitative dimension is reflected in the fact that the introduction of public participation in environmental impact assessment brings an additional element to this process that may influence the decision of the administration. In this sense, the administrative authority is obliged to consult and / or include disclosed public opinion in the moment when, using the delegated discretionary power, decides on the impact that the proposed activity may have on the environment. Public participation in qualitative sense means that the public, by expressing opinions in the process of environmental impact assessment, can contribute to perception of those aspects of proposed activities which administrative body would not have had in mind when making decisions, which are necessary for making lawful and appropriate decisions. In this sense, public participation is not an element that further burdens the environmental impact assessment, but an element without which this procedure does not lead to achieving environmental justice in terms of substance. The environmental impact assessment is a procedure in which it is necessary to consider alternatives of the proposed activity. The role of the public in qualitative sense is particularly pronounced in this matter. The public, in this case, has an opportunity to present not only an opinion in terms of the proposed activity, but to point out whether the existing alternatives lead to more adequate environment protection.

6.1 Informing the Public

In order for public to make a contribution in qualitative and quantitative sense to realization of environmental impact assessment, it is necessary to meet several conditions. First of all, it is the proper informing of public, i.e. allowing public assess to environmental information in broad and narrow sense (Kysar and Salzman, 2008).

In the legislation of Serbia, in the process of environmental impact assessment, the public has a right of access to environmental information in the broad and narrow sense (Drenovak Ivanovic, 2011b). The right of access to environmental information in the narrow sense refers to access to any information relating to the procedure of impact assessment. It is the data about the holder of the project, name, type and location of the project whose implementation is planned; time and location of potential access to the data; information and documentation from the requirements of the project holder; the nature of decision to be made on the basis of an application; the name and address of the competent organs. The competent authority has a duty to inform the public of these data within ten days of receipt of proper application on the need to assess the environmental

impact.¹ In addition, it is essential that the public has a right of access to environmental information in the narrow sense in the procedures of environmental impact assessment, established by law. An illustrative example in the comparative practice is found in the case *R (on the application of Edwards and another) v Environment Agency and others*. On 16 April 2008, the House of Lords handed down judgment in this case and Lord Hoffmann stated „when the whole question of public involvement has been considered and dealt with in detail by the legislature, I do not think it is for the courts to impose a broader duty.“²

The right of access to environmental information in a broad sense is the public's right of access not only to information relating to the specific procedures for environmental impact assessment and are part of the request on the need to assess the environmental impact, but also to access all the information which the public can access, and are in connection with the protection of essential environmental values. Since forming attitudes on environmental values is a key element in (non)acceptance of environmental risk on the public's side, the right of access to environmental information in a broad sense is the basis for proper public participation in the process of environmental impact assessment (Kelman, 1987; Dryzek, 1997; Fournoy, 2003). The right of access to environmental information in a broad sense is of particular importance for the process of environmental impact assessment, because it allows public access to a variety of environmental information, which enables educating the public about the state of the environment and awareness about the environment as a whole, whose certain aspects may be exposed to project influence, for which the environmental impact assessment is done (Felleman, 1997). This is the type of information held by public authorities, related to the threat or the protection of public health and the environment. The applicant is not obliged to give reasons for access, in the request for access to this information, but the law regulates the assumption that the justified public interest to know is always present when it comes to environmental information held by government.³

The right of access to environmental information in the narrow and broad sense is the basis for public's qualitative participation in the environmental impact assessment.

6.2 Entrusting the Public with Possibility to Participate in the Environmental Impact Assessment

The second condition that must be met in order to achieve maximum results of public participation is entrusting the public with an opportunity to participate in a form that is optimal in a particular case. In the earlier legislation of Serbia, before introducing the Law on Environmental Protection and the Law on Environmental Impact Assessment in 2004, there has been no right of public to participate in decision-making in the process of environmental impact assessment. It was planned for environmental impact assessment to be initiated with an investor's request for approval of the analysis of the object impact. In doing so, the citizens, as well as public, were aware of the existence of decision of giving consent to the environmental impact assessment only when the decision was final, or when the investor has already begun implementation of the activities for which the permit was issued. In such circumstances, the public had the opportunity to challenge the legality and appropriateness of the authority's consent on

¹ *Law on Environmental Impact Assessment*, Article 10.

² *R (on the application of Edwards and another) v Environment Agency and others*, (2008) UKHL 22.

³ *Law on Free Access to Information of Public Importance*, „Official Gazette of the Republic of Serbia”, no. 120/04, Article 15 paragraph 4.

the analysis of environmental impact, primarily by filing complaints and petitions (Todic and Durac, 2003b). For filing the appeal, as a regular legal remedy or any of the extraordinary legal remedies, it was necessary that the public is recognized as a party to the proceedings. Only in those cases where the public was recognized as a party to the proceedings, the public had an insight into the decision, and environmental information in the narrow sense, i.e. information regarding the process of environmental impact assessment. In practice, this led to reduced opportunities for the public, even after the decision on the environmental impact assessment, to challenge its regularity, because it was impossible to access not only environmental information in the broad and narrow sense, but the challenged decision itself. Requirements of the public concerned, in accordance with the previously applicable legislation, were considered as an appeal, if the appeal had been lodged in time. Requirements that were not made in the appeal period have been considered as a proposal to reopen the administrative proceedings, the demand for the abolition of emergency executive orders, or request for cancellation or abolition of final decision on the basis of official control (Todic and Durac, 2003b). Bearing in mind the above example, we conclude that the effect of public participation is largely dependent on the way the public is allowed to participate in the environmental impact assessment. If the public is not identified as a participant, and is not provided adequate information, despite the finding of alternative ways to participate in the environmental impact assessment, the public will not be able to contribute to decision-making.

To achieve maximum results of public participation, it is not enough to stipulate such possibility by law. It is also necessary to distinguish cases in which the public participates in the environmental impact assessment, i.e. impact assessment of specific activities on the environment, from those in which the public participates in the strategic environmental impact assessment, i.e. in the preparation of policies relating to the environment.

Proper public involvement in these activities can not be achieved in the same way. Namely, in case of public participation in the environmental impact assessment, the question of informing the public concerned, which has a significant role in relation to the public, is getting more attention. In fact, environmental information about the particular impact assessment procedure must be made public, but only the public concerned has an opportunity to present an opinion which the appropriate authority must take into account when deciding on the request to assess the impact on the environment, the request for determining the scope and content of impact assessment study, or a decision on approval of the environmental impact assessment study. In this sense, it is necessary to carefully identify who makes the public concerned, how to achieve timely and complete informing of public identified in such manner and how to include it in the assessment process from the initial phase.

When it comes to public participation in the strategic environmental impact assessment, the key question is at what stage the public should be involved. In an environmental impact strategic assessment, it is not necessary to identify the public concerned. Consequently, access to public informing in this case is different. The strategic environmental impact assessment procedure in Serbia is divided into three phases: a) preparation, which aims at decision-making on a strategic impact assessment, b) drafting stage of the environmental impact assessment report, and c) phase of consent, ie. adoption of the report. In preparation of the decision on strategic assessment elaboration, or the decision on non-elaboration of the strategic assessment, the competent planning authority shall request from the competent environmental

protection authority and other authorities and organisations concerned to submit their opinions, but not from public concerned or public.¹ In a report on strategic assessment, as the second phase, the starting point of strategic assessment, among other things includes the results of previous consultations with authorities and organisations concerned that are relevant from the aspect of objectives and evaluation of potential impact of the strategic assessment.² Public participation is provided only at the stage of deciding on the strategic impact assessment, i.e. in the third and final phase. The authority responsible for the preparation of plans and programs have an obligation to ensure public participation in the review report on strategic assessment before filing the application for approval of the strategic assessment report. „By favoring the participation of authorities and organizations to the public, and not including the public concerned in the process of making strategic assessment from the first phase, the level of public involvement in the process of preparing reports on the impact assessment is reduced.“ (Drenovak Ivanovic, 2011a, pp. 67).

One of the serious obstacles to implementation of the Aarhus Convention and Serbian legislation harmonized with it is little interest of citizens to participate in the procedures of impact assessment on environmental projects at the provincial level.³ In order to stimulate public interest in participation in decision-making on matters of mutual interest, primarily those relating to environmental protection, the Serbian government adopted the Decree on the Office for Cooperation with Civil Society in 2010. It was envisaged that the Office carries out tasks for the Government relating to the coordination of public administration bodies and encouragement of cooperation between public administration bodies with associations and other civil society organizations for the purpose of their participation in the preparation and monitoring of strategic documents and initiation of the adoption of regulations and other by-laws. Public education in environmental protection and rights and the establishment of coordinated cooperation between government and civil society should contribute to the greater interest of the public to participate in decision-making in environmental matters.

7 Conclusion

Environmental impact assessment is a complex process that includes several basic rights: the right of public to access environmental information in the broad and narrow sense, the right of public (concerned) to participate in decision-making and the right to protection of rights of access to environmental information and public participation. The paper analyzed the public's right to participate in decision-making in the environmental impact assessment.

In the modern environmental law, it is accented that the need for involving public in environmental decision making is indisputable. The paper analyzed the types of public participation in environmental decision-making, the benefits that can be achieved by public participation in decision-making in the environmental impact assessment, as well as prerequisites for public participation in the environmental impact assessment that lead to achieving maximum results. In this sense, it was established that the public, by

¹ *Law on Strategic Environmental Impact Assessment*, Article 11, paragraph 1.

² *Law on Strategic Environmental Impact Assessment*, Article 13, paragraph 1, item 6

participating in decision-making in the process of environmental impact assessment, contributes not only quantitatively but also qualitatively to impact assessment procedure. Quantitatively, because it introduces another element in the process of impact assessment that has an impact on the formulation of the decision, and qualitative, because the public contributes to the substantiality of concrete decisions by expressing their opinion. In addition, by means of expressing opinions in the environmental impact assessment, the public can contribute to the quality of concrete decisions, even though the law has not stipulated the right for participation in a particular stage. When the administrative body consults the public on certain activities which induced environmental impact assessment, it is under no obligation to present reasons for the decision and the reasons for accepting or not accepting the arguments put forward by the public. However, in this way, the administrative body gets important information about public attitudes on environmental values and the manner public accepts environmental risks.

In order for the public to have ability to competently participate in the environmental impact assessment, two conditions must be fulfilled. Firstly, the public must be provided with timely access to information regarding the environmental impact assessment, as well as information about the state of the environment. In addition, it is necessary to stipulate the public's right to participate in the environmental impact assessment. This results in public interest to assess the impact on the environment and the state of the environment, public's sense that it has an obligation to make decisions on environmental issues of which he is a part of, as well as better public understanding of issues relating to environmental risks and environmental impact assessment.

Making Incentives for Renewable Energy in China Work: Case Study on Shanghai Green Electricity Scheme

Gao Li

PhD Candidate, Faculty of Law,
The University of Hong Kong, Pokfulam,
Hong Kong

Email: gaoli@hku.hk

Abstract:

Being passed in 2005 and coming into effect on January 1st 2006, the Renewable Energy Law is the first comprehensive policy document that directly aims to promote renewable energy in China. It also acts as the legal basis for country-wide activity to drive renewable energy and to increase the share of electricity generated from renewable energy. During the past 5 years since the Renewable Energy Law's announcement, however, little research has been done to give a close look at how the law really works in practice, which accordingly becomes the focus of this article. By making a case study on Shanghai Green Electricity Scheme (Scheme) which creates incentives to drive renewable energy by local government in strict compliance with the Renewable Energy Law, the article explores the existing problems and barriers of this Scheme and discusses whether the Renewable Energy Law has addressed them and provided possibility to solve them in the long run, hoping to benefit the future law making and enforcement regarding renewable energy in China.

Keywords:

green electricity scheme, incentives, renewable energy law

1 Introduction

After 30 years' economic growth, China has become a divided society with remarkable growth rate on one hand, but also with deteriorating environmental conditions and astonishing resource scarcities on the other hand (Hallding, Han and Olsson, 2009). When the Hu Jintao-Wen Jiabao (Hu-Wen) administration took office in late 2002, they took a decisive shift in focus from the single-minded growth policies of the Jiang Zemin era to a broader notion of social development—in particular the search for an alternative path to industrialization “featuring high technology, good economic returns, low resource-consumption, low environment pollution and the full use of human resources” (Xinhua, 2006) under “the new guiding principles of *Scientific Development Concept* and the building of a *Harmonious Society*” (Halling, Hand and Olsson, 2009). The Hu-Wen leadership's development strategy has provided a historical opportunity for China to develop renewable energy and go green.

Against this backdrop, China has done a lot of right things to promote the development of renewable energy, including but not limited to developing an extensive set of laws, policies and programs in the pursuit of renewable and low carbon energy, setting a series of renewable energy related targets, making tremendous investment in renewable

energy field and participating in global efforts to facilitate renewable energy technology transfer and cooperation.

Among these policy measures, the announcement of Renewable Energy Law has been regarded as the most effective one and attracted the most attention. Coming into effect on January 1st 2006, the Renewable Energy Law is the first comprehensive policy document that directly aims to promote renewable energy in China. A lot of literatures talk about the significant role Renewable Energy Law has played in stimulating renewable energy and helping China to win a leading position in this field.

However, as Elizabeth mentioned, “even when you are looking at these big numbers that are coming out of China today, I think it really pays to give a close look at what is really happening on the ground” (Larson, 2010). Although 5 years have passed already since the announcement of the Renewable Energy Law, few people have tried to examine or evaluate its real effect, particularly in the following aspects: In what way the law has been enforced by local governments? To what extent the law has contributed to the generation and demand of renewable energy? What have been the pros and cons of the law?

Bearing these questions in mind, this article makes a case study on Shanghai Green Electricity Scheme, a scheme creating incentives to drive renewable energy by local government in strict compliance with the Renewable Energy Law. Specifically, the article examines the existing problems and barriers of this Scheme and discusses whether the Renewable Energy Law has addressed them and provided possibility to solve them in the long run, hoping to benefit the future law making and enforcement regarding renewable energy in China.

2 Overview of Shanghai Green Electricity Scheme

2.1 The Scheme in a Nutshell

The Shanghai Green Electricity Scheme offers electricity consumers in Shanghai the opportunity to “green” their electricity consumption by buying some amount of green electricity for which a premium needs to be paid. Through participation, Shanghai electricity consumers including both enterprise consumers and individual consumers can directly contribute to CO₂ reduction and environmental protection. The Shanghai Municipal Government guarantees that the additional payment for Green Electricity will be used to develop additional renewable electricity generating capacity such as wind farms. An independent supervising body is responsible for auditing the green electricity accounts and publishing the audit results to ensure that no more green electricity is sold than produced and that the consumers’ additional payment is used exclusively for developing renewable electricity generation capacity (Shanghai Green Power, 2005).

2.2 Guiding Principles

2.2.1 Voluntary Purchase

Consumers purchase green electricity on a voluntary basis.

2.2.2 Government Pricing

At present, the green electricity shall temporarily not participate in the price competition on the electricity market for going onto the grid. Its price shall be set by the government

according to the principles of “Being beneficial to the development and utilization of renewable resources, being economic and reasonable, being able to reasonably compensate for the cost and put apart room for profits”.¹

2.2.3 *Incentivizing Purchase*

The government of Shanghai Municipality encourages the development of green electricity and vigorously encourages consumers to voluntarily subscribe to green electricity by adopting the following measures:²

- ✧ The Shanghai Municipal Energy Conservation Supervision Center (SMECSC) shall regularly make public the list of users of green electricity, and award the honorary certificates to the users who have subscribed to green electricity.
- ✧ For the users who have signed with the electricity company a contract for a term of at least two years and annually subscribed to green electricity in the quantity of more than one million kilowatt hours, and whose purchasing capacity of green electricity accounts for no less than 10% of the previous year’s electricity quantity used for manufacturing main products, the Shanghai Municipal Development and Reform Commission (SMDRC) and Shanghai Municipal Economic Commission (SMEC) shall authorize the SMECSC to grant them the Emblem of Green Electricity. The users who have obtained the Emblem may use it within the period of purchase.
- ✧ For the users making outstanding achievements in subscribing to green electricity, the SMDRC and SMEC shall jointly award medals to them.

2.3 **Significance**

2.3.1 *Initiative Spirit*

Shanghai has become the first developing country city in the world to offer green electricity.

2.3.2 *Environmental Friendly*

Given green electricity is produced from renewable resources such as wind, solar and biomass, the generation of green electricity produces little or no pollutants to air, water and land, therefore helping to reduce CO₂ emissions and improve air quality in Shanghai. In addition, green electricity does not consume fossil fuel, so it is beneficial to sustainable utilization of energy. Finally, developing the renewable energy industry promotes Shanghai’s image as an environmentally conscientious and responsible city while improves local economy and employment (Shanghai Green Power, 2005).

2.3.3 *Driving End-Users’ Demand*

This Scheme represents Shanghai government’s efforts to enforce the newly issued Law of the People’s Republic of China on Renewable Energies (Renewable Energy Law). In particular, different from the commonly-used measures of promoting renewable energies through encouraging the generation of green electricity, this Scheme aims to advance the development of renewable energies by increasing the end-users’ demand for green electricity.

¹ Shanghai Green Electricity Marketing Promotion Regulation 2005, s 3(12).

² *Ibid.*, s 4(16, 17 and 18).

3 Working Mechanism and Existing Problems

3.1 Working Mechanism

The Shanghai Green Electricity Scheme was developed over 2004, formally launched in 2005, and was formally called and branded “Jade Electricity”. In June 2005, the Shanghai government issued *Shanghai Green Electricity Promotion Regulation (Regulation)*. The *Regulation* establishes legal framework and provides specific guidance for implementing the Scheme. It states that the aims are pushing forward the development and utilization of green electricity in this Municipality, improving the energy source composition, promoting the protection of environment and the sustainable development, and creating a good atmosphere of the whole society showing concern about the development of green electricity.¹ The *Regulation* was formulated in accordance with the newly issued *Renewable Energy Law* at that time and turned out to be an important measure of the Shanghai government to implement *Renewable Energy Law* and promote renewable energy in Shanghai.

The Scheme will initially support wind and PV electricity only. The approach adopted by the Shanghai government was “to start small and to let the Scheme develop and grow with increasing demand and increasing availability of renewable electricity” (ASTAE, 2006). To qualify as a Green Electricity user, customers must buy by yearly a certain amount of green electricity. For example, the minimum annual subscription shares for the residential household are ten quotas, with one quota defined as 12 KWh; the one quota for the enterprise (unity) user is set at 6000 KWh, and the minimum annual subscription shares are varied in accordance with the electricity volume consumed by that user in the preceding year.²

The green electricity subscription fees are counted according to the unit price of green electricity and the green electricity capacity subscribed to. The unit price of green electricity is determined by the difference between the average on-grid price of green electricity and the on-grid price of electricity produced by Shanghai coal-fired new generator as examined and verified by the State. The unit price, namely the incremental cost of green electricity, has initially been set at 0.53 Yuan/KWh. The green electricity capacity is purchased through customers’ voluntary registration in compliance with the above mentioned minimum annual subscription shares. The term for the subscription to green electricity shall be one year, two years, or three years respectively. The subscription fees for green electricity shall be paid monthly through the current channel and method of paying electricity fees.³ For example, if a household has subscribed to 10 quotas of green electricity, i.e. 120 KWh, for one year, then the household needs to pay an additional 63.6 Yuan for purchasing one years’ green electricity apart from the normal electricity bill. Given this total 63.6 Yuan will be distributed to 12 months, this household needs to pay an additional 5.3 Yuan when paying their monthly electricity fees.

3.2 Existing Problems

The biggest problem encountered by the Scheme is that the actual quantity of green electricity purchased is much smaller than expected.

¹ *Ibid.*, s 1(1).

² *Ibid.*, s 2(9).

³ *Ibid.*, s 2(10).

In June 2005, the Shanghai government held the Ceremony of Signing Contracts to Purchase Green Electricity. During this ceremony 15 industries and institutions signed contracts with Shanghai Municipal Electric Power Company (SMEPC) for a duration of 1-3 years and became the first consumers to purchase green electricity.

However, after that the process of subscribing to green electricity became very slow. Over one year later, i.e., by the end of 2006, only 22 industries and 6842 households purchased green electricity amounting to a total of 15.82 GWh. Particularly, around 2/3 of the 22 industries are foreign funded enterprises (Chen, You and Zhou).

In addition, among Shanghai's top 10 electricity-consuming enterprises, only Baosteel Corporation subscribed to 3 years' green electricity amounting to a total of 1.2 GWh. To make it more clear, the single year of 2006 will be taken as an example to demonstrate the insufficient purchase of green electricity. In 2006, the total amount of green electricity purchased was around 8.5 GWh while the amount of green electricity generated that year was more than 20 GWh. Notably, the green electricity purchased was less than half of green electricity generated in 2006. For the surplus green electricity, the SMEPC had to temporarily pay for the price differential between green electricity and electricity generated by conventional energy.

Instead of rising, the public's enthusiasm for purchasing green electricity even falls a little bit as time goes on. At the end of 2008, the green electricity's purchase amount only accounted for 13.5% of its' total supply amount in Shanghai (World Wind Power, 2009). Until recently, the green electricity scheme is not very popular with Shanghai citizens.

4 Barriers and the Way Forward

Given Shanghai's abundant renewable energy resources, advanced production capacity of equipments relevant to green electricity, and relatively high level of economic development and people's living standard, Shanghai has great potential to develop green electricity.

However, the Scheme has not been as successful as expected. According to a survey (Chen, You and Zhou, 2008) conducted by South-North Institute for Sustainable Development in 2006, the main reasons for customers' unwillingness to purchase green electricity are as follows: lack of sufficient understanding about green electricity (36%); unacceptable high price of green electricity (27%); no substantive benefits or returns to green electricity users (25%); lack of knowledge of how to purchase green electricity (10%).

4.1 Publicize the Scheme and Increase Public Awareness of Environmental Protection

To solve the problem of customers' lacking understanding about green electricity and lacking knowledge of how to purchase green electricity, the Shanghai government should take more effective measures to publicize the Scheme and gradually increase public awareness of environmental protection.

4.1.1 Specific Measures

First of all, to make the Scheme widely known by Shanghai citizens and enterprises, the Shanghai government should make full use of various media to introduce the Scheme

such as newspaper, books, magazines, TV programs (including mobile TV programs), websites, booklets, posters and public service advertisements. Secondly, the Shanghai government may cooperate with NGOs and the producers and investors of green electricity to better publicize the Scheme. Thirdly, “Better city, better life” is the Shanghai municipality slogan to promote its image as an environmentally conscientious and responsible city. Development of green electricity is an important measure for Shanghai to realize its commitment. If the Shanghai government can combine the Scheme with Shanghai’s city planning and development, the Scheme will attract more attention and gain more support. In addition, the Shanghai government needs to pay more attention to the large electricity users and encourage them to use green electricity. In the US, it is estimated that the total amount of green electricity purchased by the top 50 institution users surpassed 13.7 billion KWh annually, representing more than 70 percent of the green electricity commitments made by all the US green power subscribers (U.S. EPA, 2011). This has shown the significant role large electricity users may play and set a role model for the Shanghai government to emulate. Finally, the Shanghai government and SMEPC should provide better service and guidance to facilitate the purchase of green electricity.

4.1.2 Special Point

Given that green electricity is still quite new in China, most people have not fully realized the benefits of using green electricity. As we know, green electricity contributes to CO₂ reduction and pollution control mainly through its use of renewable energy and its clean production process. However, to end users, green electricity looks the same with conventional electricity. No matter green electricity or conventional electricity, they are transmitted through the same grid and users can hardly distinguish between them (Zhang and Gao, 2006). Therefore, during the publicity of green electricity, the Shanghai government should highlight green electricity’s substantial benefits to environmental protection, create culture of “using green and being environmental friendly”, and make the purchase of green electricity a kind of fashion.

4.2 Reduce the Cost of Green Electricity

The price of green electricity set by the Shanghai government is 1.14 Yuan/KWh and the price for conventional electricity is 0.61 Yuan/KWh. There exists an incremental cost of 0.53 Yuan/KWh between the two. The high price of green electricity has deterred many consumers to use it and become the biggest barrier to the development of green electricity. Actually, this issue of price differential is quite common in China. There is a difference between power purchase price for coal-fired and for renewable energy generation in a number of provinces. Coal prices are always considerably lower. For example, in the provinces of Xinjiang, Liaoning and Inner Mongolia the wind power prices are even more than double the ones from coal.

4.2.1 Reasons for Green Power’s High Price

Notably, such a price differential lies with the fact that the cost of electricity from renewable energy generation is higher than from coal. One reason for the relatively high cost of green electricity has been the weak domestic manufacturing industry in China. Specifically, renewable energy technologies are relatively nascent within the power sector and unlike conventional energy technologies do not benefit from the economy of scale. For example, in the wind industry, only a very small number of Chinese owned manufacturers have been established and they are significantly limited in the size and quality of the turbine they are able to produce. The small size and poor quality of

domestic manufacturing industry forces renewable energy developers to import costly equipment from overseas, which increases the cost of electricity from renewable energy and inhibits the growth of the local manufacturing industry.

Another reason for the relatively high cost of green electricity has been the lack of competition and the relatively small scale of market.

Last but not the least, a more significant contributory factor to the high cost of green electricity has been the low-cost of coal-fired electricity generation in China. The full cost of coal-fired electricity has not been fully reflected in its price (Zhang, 2009). For example, the costs of transmission and distribution are not accurately reflected in the coal-fired electricity price. As coal resources are primarily located in the north of China, far from demand centres in eastern and south-eastern coastal areas, true transmission costs are likely to be high by comparison with renewable energy given that the southeast coast of China is rich in wind resources. More importantly, the environmental externalities associated with coal-fired generation have not been reflected in the price of conventional electricity because of weak pollution control. Thus, internalization of the environmental damage within the cost of coal may help to decrease the incremental cost between green electricity and coal-fired electricity.

4.2.2 Current Solution to the Issue of High Price

Due to the relatively high cost, green electricity is currently unable to compete with coal-fired electricity. Under the Shanghai Green Electricity Scheme, the grid price of green electricity is set by the Shanghai government according to the principle of “Being beneficial to the development and utilization of renewable resources, being economic and reasonable, being able to reasonably compensate for the cost and put apart room for profits”¹ or through public bidding with prices no higher than those set by the government for similar projects. The difference between the on-grid price of green electricity and conventional electricity is absorbed through the voluntary purchase of green electricity by the public, or is to be passed on in the selling price of electricity in case some remaining unsold green electricity exists.

Clearly, the Shanghai government takes pricing as an incentive to promote the generation of green electricity and to increase its market scale. However, such a fixed price guarantee can only be temporary because it is anti-competitive and can not reflect the real cost of green electricity. From the long run, to reduce the cost of green electricity is the key to the success of the Scheme and the development of renewable energy. The Shanghai government states that with the deepening of reform in electricity system afterwards, Shanghai shall establish and perfect competitive market of renewable energy. In addition, the Shanghai government determines to gradually reduce the cost of generation of green electricity through reducing revenue and providing allowance in order to reduce the selling price of green electricity. Thus, we have reasons to believe that although the Scheme is currently small and confronted with some difficulties, it will grow with the increasing demand and increasing availability of green electricity and with the decreasing cost and decreasing price of green electricity.

4.2.3 Renewable Energy Law’s Constructive Role and Possible Drawbacks

Notably, the Shanghai government establishes and implements the Scheme in strict compliance with the relevant State provisions and in particular, the Renewable Energy

¹ *Ibid.*, s 3(12).

Law. In China, the central government sets the policy and legal framework to guide the development of renewable energy and the local governments are responsible to specify and implement the relevant provisions. Thus, the State-level laws and policies will also have a significant impact on the future development of the Scheme. As we know, the Chinese central government has long been concerned with the development of renewable energy and has made a strong commitment to growing the renewable energy industry. There have been a lot of national and provincial policy initiatives to foster the development of renewable energy. The Renewable Energy Law, which was passed in 2005 and came into effect on January 1st 2006, is the first comprehensive policy document that directly aims to promote renewable energy in China. It acts as the legal basis for country-wide activity to stimulate renewable energy and to increase the share of electricity generated from renewable energy. Hence, the Renewable Energy Law will be briefly examined here to see whether it addresses the four previously-discussed factors for green electricity's relatively high cost and provides the possibility of reducing the cost in the long term.

As previously mentioned, one reason for the relatively high cost of green electricity is the weak domestic manufacturing industry in China. To improve the quality and capacity of domestic renewable energy manufacturing industry, the fundamental way lies in the promotion of domestic technological innovation. The Renewable Energy Law stimulates domestic technological innovation mainly through encouraging investment in the research and development (R&D) of renewable energy, setting up a renewable energy development fund and establishing a feed-in tariff (FIT) system. Specifically, the Renewable Energy Law makes investment in renewable energy R&D a priority and provides that the government allocates funding for the scientific and technical research, application demonstration and industrialized development of the development and utilization of renewable energy so as to promote technical advancement in the development and utilization of renewable energy, reduce the production cost of renewable energy products and improve the quality of products.¹ The law also establishes a renewable energy development fund to support scientific and technological research, standard setting and pilot projects for the development and utilization of renewable energy, and to foster the localized production of the equipment for the development and utilization of renewable energy.² In addition, the Renewable Energy Law stipulates that grid utilities shall enter into agreements with licensed power generators to purchase all the renewable energy that they produce within the area of the grid,³ and the grid price of renewable energy shall be set by price authorities of the State Council.⁴ This implies establishment of a FIT system, an obligation on electricity suppliers to accept all power from renewable energy generators at a guaranteed fixed price set by the State. Given that the FIT system enables renewable power generators to capture the surplus created by technical change, it will stimulate them to invest in R&D to reduce costs and increase profits, thus providing a stimulus for technological innovation in China. Notably, the Renewable Energy Law promotes an innovative system for renewable energy technologies, which is likely to strengthen China's domestic manufacturing industry and hence to reduce the high cost of electricity from renewable energy.

However, room for improvement still exists. For example, the provision of renewable energy development fund does not specify the value of the increase in funding or the

¹ Renewable Energy Law of People's Republic of China 2005, s 3(12).

² *Ibid.*, s 6(24).

³ *Ibid.*, s 4(14).

⁴ *Ibid.*, s 5(19).

likely distribution of funding, so there is a risk that compliance could be satisfied with a very small increase or inappropriately targeted funding, contrary to the intention of the law. In addition, there contains no suggestion of tariff reductions overtime which could provide a further incentive for R&D investment in technological innovation among market participants. Finally, the Renewable Energy Law provides that middle and long-term targets for the total volume of renewable energy at the national level are to be set by the Energy authorities of the State Council subject to approval by the State Council,¹ and based on the national targets, provincial, regional and municipal energy authorities will prepare renewable energy development and utilization plans for their own administrative regions to be implemented subject to approval by governments at their own level.² This provides the basis for implementation of a mandatory market share policy (MMS), an obligation on electricity suppliers to source a proportion of their power from renewable energy generation. Given that MMS policy does not allow producers to capture the surplus from technological change, and universal pressure to reduce costs under MMS schemes can discourage R&D investments in favour of sourcing technology from abroad. This may prejudice technological innovation and hinder the development of domestic manufacturing industry. While experience in other countries has shown that the MMS is usually combined with tradable renewable energy certificates to ensure greater equity, efficiency and innovation that will deliver renewable energy at the lowest possible cost, there is currently an absence of such a mechanism to foster innovation and drive cost reductions in China.

To address the issue of insufficient competition, the Renewable Energy Law introduces the tender system, i.e., where there is more than one applicant, licenses for construction of renewable power generation projects will be determined through a tender system (Concession Programme).³ The Concession Programme may effectively stimulate competition and encourages a systematic effort to reduce costs through economy of scale and use of the very best available sites. The MMS mechanism can also provide pervasive competitive pressures, giving an incentive for cost reductions and project quality improvements.

As for the scale of market, the FIT and MMS can be used to stimulate an increase in market scale. The FIT helps to overcome the cost disadvantages of renewable energy sources and thus boost adoption of renewable energy technologies. Experience in other countries has shown a rapid increase in capacity following implementation of a FIT. For example, the FIT has been associated with a large growth in solar power in Spain, Germany and wind power in Denmark. The MMS may also be taken to scale up markets for renewable energy, but in a more steady way compared with the rapid increase led by the FIT. The US has been very successful in stimulating new renewable energy capacity through MMS policies. Increased market scale can reduce costs of renewable energy technology and bring economy of scale, which accordingly encourages further scale increases.

The Renewable Energy Law makes no reference to the low cost of coal-fired electricity generation in China. Compared with the relatively nascent renewable power industry, the conventional electricity sector enjoys more benefits during the decades of institutional and organizational adaptation. Particularly, the Chinese central government keeps electricity prices low in support of GDP growth for a long time and the

¹ *Ibid.*, s 2(7).

² *Ibid.*, s 2(8).

³ *Ibid.*, s 4(13).

environmental externalities associated with coal-fired generation have not been reflected in the price of conventional electricity. Now changes and improvements need to be made to pollution control policies so as to redress the economic balance between coal and renewable energy.

In short, the Renewable Energy Law helps to reduce the cost of green electricity and foster the development of renewable energy mainly through making provisions for implementing the three policy mechanisms, the FIT, the MMS and the Concession Programme. Actually, these are the most commonly used promotion policies in renewable energy field. However, the law does not specify the manner in which these three mechanisms will be combined. Given that these policies serve different purposes and have differing advantages and disadvantages, they need to be differentiated over time taking into account China's specific policy objectives, socio-economic conditions and the capacity to expand renewable energy production. In addition, the law would have been more effective and easy to be implemented had it paid more attention to details and included more specific provisions.

4.3 Incentivize Customers to Purchase Green Electricity

As mentioned above, the Shanghai government encourages customers to purchase green electricity mainly through increasing their sense of honour and promoting their public image. The primary encouragement methods include making public the list of users of green electricity and awarding them honorary certificates, Emblem of Green Electricity or medals. However, such methods have proven to be ineffective in providing proper incentives, and more initiatives should be taken to better incentivize customers to use green electricity.

4.3.1 Introducing Fiscal Incentives

Apart from giving commendation and honour, the Shanghai government may think about providing more attractive rewards for the users of green electricity. According to the survey in 2006, a quarter of respondents chose not to purchase green electricity because they were not satisfied with the relevant rewards and returns (Chen, You and Zhou, 2008). For example, some enterprises proposed that as a reward large users of green electricity should be allowed to emit more pollutants. Of course, this has been denied by the government (Yu, 2006). To encourage the wide use of green electricity, some measures involving substantive benefits such as preferential loans, direct subsidy to the users and tax reduction or exemption might be adopted as possible incentives.

For instance, experience in the Netherlands has shown a rapid increase in the demand for green electricity due to the adoption of tax incentive. Aiming at stimulating energy saving attitudes by consumers, the Dutch government started to collect the Regulatory Energy Tax (REB) on electricity consumption of all types since October 1996, irrespective of whether the energy resources used for generating electricity are renewable or not. Based on this tax policy, the Consumer-driven Strategy, a scheme encouraging the customers' voluntary purchase of green electricity promoted by the Dutch government from 1995, attracted little attention and consumer participation was quite modest. Later on, specifically beginning with 1 January 1998, the Dutch government introduced the "nil tariff" policy which exempts "domestic renewable generators and the selling of imported green electricity from the REB tax", thus allowing consumers subscribing to the green electricity not to pay the REB tax anymore (Dinica and Arentsen, 2001). This has led to dramatic expanding of customers' demanding for green electricity and now more than 20% of Dutch residents have chosen

to use green electricity. Also deserving mention is the fact that “the higher the REB tax goes, the more attractive it will be for consumers to subscribe to a voluntary green electricity scheme” (Dinica and Arentsen, 2001). Apart from stimulating green demand, given that green electricity users are exempted from the REB tax and given the high level of the REB tax in the Netherlands, this tax policy helps renewable energy companies to lower cost so as to provide green electricity products at almost the same price as conventional electricity products. Therefore, the REB scheme has proved to be one of the most effective Dutch policy mechanisms, functioning not only as a powerful fiscal instrument to stimulate green demand, but also as a subsidy scheme to encourage green generation and green investments (Dinica and Arentsen, 2011).

4.3.2 Combining Voluntary Purchase with Mandatory Consumption

Currently, the Shanghai Green Electricity Scheme is fully based on voluntary purchase. Given the relatively high price of green electricity, only some enthusiastic customers are willing to pay for it. Even many government organizations in Shanghai have not taken initiative in subscribing to green electricity. Thus, a shift from this pure voluntary system to a mixed parallel system of voluntary purchase and mandatory consumption might hold the key to the success of this Scheme. Actually, many countries have done very well in combining voluntary purchase with compulsory consumption. For example, all the US local governments are required to join the Green Power Partnership, a program aimed for promoting the purchase of green power, while other businesses, organizations and individuals are free to decide whether to buy green electricity or not. Similarly, in Germany, public utility companies are required to purchase green electricity. By collecting the REB tax, the Dutch government also combines voluntary purchase with compulsory consumption to increase the market demand for green electricity.

Abstract:

In connection with mitigating climate change, the European Union has committed to raising the use of energy from renewable sources to 20 % of overall Community energy consumption by the year 2020. The national target set for Finland is a challenging 38 % compared to 28.5 % in 2005. A traditional form of renewable energy is hydropower. In Finland, hydropower generates about 3 to 4 % of total energy supply at the moment, depending on the yearly rainfall. The national target set for hydropower production is 14 TWh in 2020, which means an increase of 0.5 TWh from the present situation. This subtle rise would consist of capacity increases in existing power plants and small hydropower. Although Finland is described as a land of a thousand lakes and therefore rich in water resources, increasing the use of hydropower is difficult on a large scale mainly due to national nature conservation legislation: namely the rapids conservation legislation. Another characteristic in Finnish geography is the flatness of the country; concerning hydropower, the modest differences in altitude mean smaller capacity plants generally.

This paper analyses the existing environmental legislation in Finland concerning hydropower and looks at the targets for promotion of renewable energy in the light of that legislation. The paper suggests some amendments to the existing national legislation: for example, the permit procedure is designed for large-scale hydropower plants, and the administrative burden may seem heavy for small-scale plants. Therefore, a lighter procedure might ease the promotion of small hydropower. One option that would ease the use of hydropower is to loosen the nature conservation legislation at some level without risking conservation values. In conclusion, in order to achieve the goals set for mitigating climate change, some amending of the traditional environmental legislation may be needed.

hydropower, climate change, environmental legislation, nature conservation, water law

1 Introduction

Climate change is one of the biggest challenges facing mankind in the near future. The European Union has taken action in order to mitigate climate change: the so-called EU

20-20-20 target consists of 1) decreasing emissions by 20 %, ¹ 2) improving energy efficiency by 20 %, ² and 3) promoting the use of energy produced with renewable sources by 20 %. ³ The target is set to be accomplished by 2020. The promotion of the use of energy from renewable sources is regulated by Directive 2009/28/EC. ⁴ The Directive divides the average EU target into more precise national targets; for Finland, this means that by 2020 the share of energy produced with renewable sources should rise up to 38 % of the gross final consumption of energy, compared to 28.5 % in 2005. This binding target is the third highest in the EU; only Sweden exceeding it with 49 % and Latvia with 40 %. ⁵

The Finnish Government has drawn up the Long-term climate and energy strategy that defines the main objectives and means for Finnish climate and energy policy in connection with the EU targets. ⁶ The objectives include the promotion of production and use of energy produced with renewable sources: as the strategy renews the Commission-set obligation of 38 % for renewable energy, it comments that the target is challenging and requires that energy end-use will decrease. The largest potential for promoting renewable energy is seen in wood-based energy, recovered fuels, heat pumps, biogas, and wind energy. Hydropower is described more as a steady energy provider than as a promising sector for increasing the energy production. ⁷

According to the Directive 2009/28/EC, EU Member States have to draw up national renewable energy action plans (NREAPs). ⁸ Finland's NREAP, among other things, breaks down the target of 38 % into different sectors of renewable energy production. The main focus in increasing renewable energy is on wind power and wood-based energy; however, hydropower is also mentioned. By 2020, hydropower production will increase by 0.5 TWh to amount to 14 TWh. ⁹ This subtle rise will consist of capacity increases in existing power plants and small hydropower, and require no changes to the existing legislation.

Utilisation of hydropower is regulated by the Water Act (587/2011): a permit is needed for establishing and operating a hydropower plant. The Water Act has recently been revised, ¹⁰ but regulation concerning hydropower does not alter significantly from the previous Water Act (264/1961). In deciding whether it is possible to grant a permit for a hydropower plant or not, the nature conservation legislation plays a crucial role: the Rapids Conservation Act (35/1987) and the special river conservation acts (concerning rivers Ounasjoki and Kyrönjoki) as well as the Nature Conservation Act (1096/1996)

¹⁰ The new Water Act was accepted in Parliament on 11 March 2011 and will enter into force on 1 January 2012.

with its regulation concerning the EU Natura 2000 Network. Consequently, the small potential seen in increasing the production of hydropower is caused largely by two reasons: most of the rapids suitable for hydropower plants are already in use or protected by nature conservation legislation.

This paper is a study about hydropower legislation in relation to climate law. The paper analyses the existing environmental legislation in Finland concerning hydropower and looks at the targets for promotion of renewable energy in the light of that legislation. The paper does not examine the economical aspects of electricity production with hydropower (e.g. windfall¹ issues). Neither does the paper thoroughly examine the Finnish legal praxis related to hydropower construction – there are plenty of rulings over the years - which would be a topic of a paper on its own.

This paper starts with an overview of the Finnish energy sector and particularly the role of renewable and hydropower therein (chapter 2). Then we look at hydropower more specifically: past, present and future (chapter 3). Chapter 4 is a review of the Finnish legislation concerning hydropower. This chapter answers to the following questions: who has the right to establish a hydropower plant, on which circumstances is it possible to build such a plant, and what else needs to be taken into account in relation to hydropower. Lastly, conclusions will be made in the final chapter: how does the hydropower legislation appear in the light of climate change and targets for the promotion of energy from renewable sources.

2 Background

According to the Statistics Finland's preliminary data, the total energy consumption in Finland in 2010 was 1445 PJ (petajoules) that is 402 TWh; of this amount 87.5 TWh was electricity consumption. In 2010, 47.5 % of energy was produced with fossil fuels (oil 24.5 %, coal 12.9 %, natural gas 10.3 %), 16.5 % with nuclear power, 6.5 % with peat, 2 % with other sources, 2.5 % with net import and 25 % with renewable energy.² The sources of renewable energy in energy production have traditionally consisted largely on wood-based residues. In 2006, the sources of renewable energy were: 1) black liquor and other concentrated liquors from industry (42 %), 2) wood fuels from industry and energy production (26 %), 3) small combustion of wood (13 %), and 4) hydropower (11 %). Other renewable energy accounts for 8 %; this includes wood-chips, heat pumps, recovered fuel, biogas, other biofuels, and wind power.^{3 4}

Energy supply differs from electricity supply due the significance of heating (both for the domestic and industry needs) in energy production and the suitability of different sources in electricity and heat production. As the table below shows, in 2010, combined heat and power production (CHP) and nuclear power account for nearly 60 % of the electricity production leaving hydropower the share of about 15 %. Around half of the

electricity is consumed by the industry (forest industry consuming 25 %, and the other sectors being chemical, metal, and other) and half is other consumption (heating, transport, and other).¹

Table 1. Electricity supply in Finland 2010
(Source: Finnish Energy Industries, 20112)

	TWh	Share (%)
CHP	28.5	32.6
- Industry	- 11.1	- 12.7
- District heating	- 17.4	- 19.9
Nuclear power	21.9	25.0
Hydropower	12.8	14.6
Wind power	0.3	0.3
Seperate	13.5	15.4
PRODUCTION	77.0	88.0
Net imports	10.5	12.0
ELECTRICITY SUPPLY	87.5	100

There is some geographical and climate information that needs to be stated about Finland. There are 187,888 lakes in Finland.³ Although Finland is rich in water resources, the flatness of our country makes the differences in altitude very modest, which means that we have smaller capacity plants generally. The flatness also causes that possibilities to reserve the water flow are limited since the reserve would need much more horizontal space than in steep terrain. Spring floods are usual because of melting snow and, therefore, the water flow is not even throughout the year. In connection with this, the yearly rainfall varies from year to year making the prediction of water reserves difficult and causing the yearly production of electricity by hydropower vary from year to year notably. Additionally, Finland is located relatively far north in the planet Earth, and the average yearly temperature is about 1.9 °C.⁴ In the wintertime, the need for energy rises significantly due to heating. The energy supply has to be built in a way that extra energy is available when extremely cold days occur causing the so called peak loads when the energy demand is at its highest level; additionally, the extra energy is needed to assure the security of the grid. This extra energy supply is called adjustment power (in Finnish säätövoima), and hydropower is very suitable for this purpose because the extra energy is quickly available.⁵ The significance of adjustment power will be emphasized further in the future as the share of wind power increases;⁶ on days when there is no wind and therefore no wind power, the lack of wind power has to be replaced with another kind of energy.

⁶ The target is 6 TWh by 2020. Ministry of Employment and the Economy (2010), *supra note 9*, p. 2.

Although hydropower is climate-friendly as a renewable energy source it does have effects on the environment. The watercourse is not in its natural state after establishing a hydroelectric installation. This change affects the biodiversity of the watercourse and the effects are greater in case an artificial lake is founded. One of the most obvious effects is on fishes and fishing. However these effects can be reduced by using fish ladders, fish bypass systems and fish lifts (upstream) as well as fish-friendly turbines (downstream). Moreover, control of the water level has effects both on the upper and lower course: on the upper course flooding and on the lower course too little water/stream may cause harm. On the other hand, hydropower plants may be actors in controlling flood risks, which are assumed to increase due to climate change.¹

3 Hydropower in Finland

The first hydropower plant that produced electricity nationwide was established in Finland at Imatrankoski in 1929. Till then, the hydropower plants had been smaller and produced electricity only for local use; mills have been used since the Middle Ages. The major rapids located in the Southern Finland were harnessed during 1930's and 1940's; the next few decades after the Second World War were the time of heavy increase in the hydropower capacity as the hydropower construction concentrated at the big rivers of Northern Finland.² After a slow phase in the 1980's, the development of hydropower generation picked up at the turn of the millennium when about 15 % of today's hydropower capacity, 3.000 MW, has been build.³

Nowadays, the share of hydropower in energy production varies between 3 to 4 % annually depending on the rainfall,⁴ which accounts for 10 to 20 % of the electricity production. At its peak the share of electricity produced with hydropower was in the 1950's and 1960's when it accounted for 90 % of electricity at its best. In 2006, there were 207 hydropower plants in use: 57 of those plants were large (production more than 10 MW), 83 were small hydropower plants (production 1-10 MW), and 67 were so called micro hydropower plants (production less than 1 MW). On an average year's rainfall, the electricity production of these plants is 12.9 TWh: of this amount large plants account for 91 %, small hydropower 8 %, and micro hydropower 1 %.^{5 6}

As mentioned above, the current hydropower capacity in use is 3.000 MW. According to a recent study, the whole potential in hydropower is about 5.100 MW; this number includes the hydropower in use and the potential. The potential consists of both water systems that are protected and unprotected; the potential can be divided to large, small and micro hydropower, as well. As can be seen in the table below, the largest potential in Finland for hydropower is situated in waters that are protected by the nature

⁵ Ministry of Trade and Industry (2005), *supra note 23*, p. 8 and 17.

⁶ Small hydropower is generally defined as sites with installed capacity of less than 10 MW. European Commission, Directorate-General for Energy, Renewables make the difference, p. 19. Available on the Internet at http://ec.europa.eu/energy/publications/doc/2011_renewable_difference_en.pdf (last accessed on 16 May 2011).

conservation legislation. However, there is some potential left unprotected.¹ Nature conservation legislation will be examined below in chapter 4.3.

Table 2. Hydropower potential not in use (MW)
(Source: Ministry of Trade and Industry, 20052)

	Unprotected	Protected and transboundary waters	Altogether
Large hydropower (more than 10 MW)	375	1.033	1.408
Small hydropower (1-10 MW)	144	286	430
Micro hydropower (less than 1 MW)	144	148	292
ALTOGETHER	663	1467	2130

According to another recent study, there is 934 MW potential in hydropower that is techno-economically significant; of this amount 365 MW is unprotected and 569 MW is protected. Additionally, there is 274 MW potential in other hydropower that is worth building; this amount consists largely of small and micro hydropower. Technically worth establishing small hydropower that is unprotected is 63 MW; about forth of this is in micro level.³ This study supports the view that the bigger part of the potential for new hydropower for electricity production is protected by the nature conservation legislation. However, there is some potential left outside the protection.

4 Hydropower legislation in Finland

4.1 The right to establish a hydropower plant

Water resources management is regulated by the Water Act (587/2011), which has recently been revised. According to Chapter 3 Section 3 of the Water Act, a permit is required for establishing a hydropower plant;⁴ a permit is always required regardless of the size of the plant. A permit is required for altering an existing plant or power increases, which are quite usual. The permit authority is the Regional State Administrative Agency whose decisions may be appealed to the Vaasa Administrative Court and further to the Supreme Administrative Court.⁵ There are several conditions that must be fulfilled before a permit may be granted.

The first condition is that either the plant may not hurt much public or private interest or the public or private interests will benefit significantly because of the plant compared to the disadvantages to the public or private interests that the plant would cause.⁶ In the first case the plant is regarded as a minor undertaking. In the second case, a comparison between interests will be conducted; as the value of the hydropower production, the

¹ Ministry of Trade and Industry (2005), *supra note 23*, p. 2 and 26.

² Ministry of Trade and Industry (2005), *supra note 23*, p. 26.

³ Finnish Energy Industries (2008), *supra note 19*, p. 177-179.

⁴ Water Act (587/2011) Chapter 3 Section 3 point 6 (respectively Chapter 3 Section 2 in the former Water Act 264/1961). In addition, a hydropower plant requires a building permit according to the Section 125 of the Land Use and Building Act (132/1999).

⁵ The Finnish courts of law consist of district courts dealing with criminal and civil cases, administrative courts reviewing the decisions of the authorities, and certain special courts (Market Court, Labour Court, Insurance Court and High Court of Impeachment). The decisions of the administrative courts can be appealed in the Supreme Administrative Court.

⁶ Water Act (587/2011) Chapter 3 Section 4. On how to assess the public and private advantages and disadvantages, see Sections 6 and 4.

price of average annual amount of electricity produced by the plant at least twenty-folded will be taken into account.¹ Moreover, there are some overriding reasons that prevent from granting the permit, such as danger to public health or security, or substantial harmful changes in the relations of the natural environment or in the water nature.^{2 3}

Second, the applicant must have a right to use the areas needed for the plant and the project.⁴ In relation to the permit decision, it is possible to decide coercive measures and compensation issues.⁵

Third, the applicant must have a right to use the hydropower on the site. That can be arranged beforehand (ownership or other right to use) or during the permit procedure (right to use common hydropower).⁶ Initiative for the right to use common hydropower can be made by a party or parties together who has/have at least one fifth of the hydropower in question. Primarily, the target is to make an agreement of the common use. Secondly, the initiative party/parties may offer other parties⁷ to participate on the hydropower plant. The participation procedure is done with the assistance of the permit authority.⁸ As a preliminary question, it may have to be found out who is entitled to the waterpower in question; this question is for the district court to decide, not the permit authority.^{9 10}

The permits for mills or other kind of hydropower plants have been given for the time being (not for a fixed-term). Therefore, in many cases the old permits are still valid. This situation will remain the same with the Water Act (587/2011).¹¹

4.2 Right to waters

The right to waters is based on two concepts: the water material and the ground of the water area. Historical development plays a central role regarding the right to waters.

¹ Water Act (587/2011) Chapter 8 Section 2 subsection 2 (respectively Chapter 3 Section 2 in the former Water Act 264/1961). In a recent permit decision PSY-2005-y-185 by the Northern Finland Regional State Administrative Agency, the comparison between interests was seen as following: the advantages amount to 112 million € and the disadvantages to 8.3 million € (p.316-327). Also available on the Internet at <http://www.avi.fi/virastot/pohjoissuomenavi/Ymparistojavesitalousluvat/Vesiluvat/Documents/P%C3%A4%C3%A4t%C3%B6kset/2011/psavi_paatos_32_11_2-2011-05-31.pdf> (last accessed on 2 June 2011).

The decision does not have legal force yet; time for appeal is still running.

² Water Act (587/2011) Chapter 3 Section 4 subsection 2.

³ See Supreme Administrative Court, case KHO 2002:86 about a hydropower plant and reservoir project in the Northern Finland. In this "Vuotos" case, the Court ruled that there was an overriding reason that prevented from granting the permit to the project; it would have caused substantial harmful changes in the relations of the natural environment or in the water nature. The maximum area of the planned reservoir was 237 km². This case is very important from the national point of view because for the first time the overriding reasons was used to reject a permit application by the Supreme Administrative Court.

⁴ Water Act (587/2011) Chapter 3 Section 4 subsection 3 and Chapter 2 (especially Chapter 2 Sections 12 and 13).

⁵ According to Section 15 of the Constitution of Finland (731/1999), everyone's property is protected and expropriation of property is possible only for public needs and against full compensation. In connection with small and micro hydropower, one question arisen is the existence of public needs for coercive measures. It is not possible to go deeper into this issue within this paper. See more on the relation between Water Act and protection of property, Parliaments Constitution Committee (2011), Statement on the proposal for water act PeVL 61/2010, Also available on the Internet at <http://www.eduskunta.fi/faktatmp/utatmp/akxtmp/pevl_61_2010_p.shtml> (3 June 2011).

⁶ Water Act (587/2011) Chapter 8 Section 2.

⁷ Who own at least one hundredth part of the hydropower in question.

⁸ Water Act (587/2011) Chapter 8 Sections 5, 8 and 9.

⁹ About the Finnish courts of laws, see *supra note 31*.

¹⁰ In some existing plants, the right to use hydropower is based on fixed-term agreements, which may cause problems when the agreement period is terminated. More on this issue, see Ekroos, A. (2008).

¹¹ Water Act (587/2011) Chapter 3 Section 8. See also Finnish Government (2009), Hallituksen esitys Eduskunnalle vesilainsäädännön uudistamiseksi HE 277/2009 (Government proposal for a Water Act), p 65.

The right to the water material may be targeted only at a water which the owner holds, in other words water in a water reservoir, well, other intake, spring, or artificial pond. In other cases the water is not owned but governed: the water with an open surface is governed by the owner of the water or land area in question.¹ Traditionally it is seen that open surface water or groundwater cannot be a subject to ownership because water is a natural resource which is continuously in circulation; this is why it is defined as governing. Governing is a special kind of right of possession that takes into account the restrictions set in the Water Act and other parties' rights to water. Governing is a priority right to use and also a limited right to dispose. The exact content of governing cannot be defined generally but case-by-case taking into account the restrictions set in the legislation and other parties' rights to the water.²

In Finland, the ownership of the water area is based on private ownership³ - the leading principle is that "he owns the water, who owns the land".⁴ The ownership of water areas can be sorted out to three ways. First, most of the water areas enjoy shared private ownership in which the water area belongs to several real estates nearby (common waters). This is due to historical reasons: the water area used to belong to the nearest village (so called median line principle which means that, for example, a lake between two villages is divided between the two villages by its median line) and since the Great Land Reform⁵ the real estates in the village according to their share of the land in the village. Still, in most of the cases these real estates in the village enjoy a shared ownership of the water area. Second, the ownership of some water areas is private but not shared. These water areas belong to a single real estate or form a real estate of their own (so called water real estates). Third, the state owns some water areas: the high seas and the centres of large lakes (so called common water areas); there are eight such lakes in Finland.⁶

Rapids have always been in a highlighted position compared to other water areas due to the importance and financial aspects of hydropower. In the Middle Ages the ownership of a mill site could be established by claim: the claimant had to own a share of the common land in which the mill would have been situated (be a land-owner in the village) or, in some provinces, be a citizen of that province. Additional condition in both cases was that he had to intend to build a mill on the site. Building of mills was promoted because they were considered to be of public interest. Later on, in case of common mill sites⁷, the land-owners in the village could build a common mill; if not all the land-owners were interested in building the mill, the court could empower the builder to do one alone⁸. The ownership of private mills could also be based on the

¹ Water Act (587/2011) Chapter 2 Section 1 (Chapter 1 Section 8 in the former Water Act 264/1961).

² HE 277/2009, *supra note 43*, p 46.

³ Private ownership of water areas is defined as German-Scandinavian whereas public ownership is of Roman Law heritage. Hollo, E. (1991) 103-104.

⁴ This is stated in the old Land Laws.

⁵ The Great Land Reform took place between late 18th century and early 20th century. In the reform, the shared ownership of the land in villages was divided and every land-owner in the village owned his share as piece of real estate. The reform concerned only land, water areas were excluded.

⁶ Laki , sisältävä määräyksiä välirajasta vedessä ja vesialueen jaosta (31/1902), Sections 1-3 and 9. See more about the right to waters Haataja, K. (1951), p. 139-236; Belinskij, A. (2010), p. 233-236;

⁷ The land-owners of the village owned a share of the mill site (and its waterpower) according to their share of the land in the village.

⁸ The court would set conditions, such as in which time the mill had to be build and how long the builder had the right to use the other villagers' share of the rapids. The "licence" was temporary.

ownership of a single real estate, immemorial enjoyment of a mill site, or an old judgement. Additionally, there were mills that were owned by the crown.^{1 2}

Depending on the individual case, the ownership of a mill may include the ownership of the water area in question or just the right to use the discharge and head in question; the building permit of the mill may have an indication of the character of the right to the water.³ In the Great Land Reform,⁴ generally the mills were formed to their own plots of land – either common (shared ownership by the land-owners of the village), or private – separate from other real estates in the village that were formed from the common land in the reform. However, this did not change the ownership of the rapids and the hydropower since the reform did not apply to water areas. Unless otherwise stated, the ownership of a water area, including rapids, is shared among the land-owners of the village according to their share of land in the village.⁵

There is a special rule concerning rapids situated in the water area between two villages: the owners of both sides have equal rights to the water flowing therein. This has been the situation for centuries now but this is stipulated in the Water Act (587/2011), too, concerning water areas that belong to two real estates or common land areas.⁶ In these cases, the median line principle does not apply in rapids because it may be that the watercourse is not symmetrical in both banks and most of the hydropower is situated on the other side of the watercourse. That is why it is stipulated that the owners of both sides share the waterpower 50-50%.

4.3 Nature conservation aspects

Since the 1970's, the conservation of rapids has become an important issue of nature conservation. First, the protection in legal context begun in court practice.⁷ Thereafter, the rapids have become subject to nature conservation by the special Rapids Conservation Act (35/1987) and two other special rapids conservation acts as well as by the general Natura 2000 nature conservation areas. Additionally rapids may be included in nature parks and wilderness areas.

The Rapids Conservation Act, given in 1987, prohibits the authorities from granting a permit for a new hydropower plant in certain water systems. In the Act, there is a list of 53 water systems or parts of water systems in which the building of a new hydropower plant is forbidden. However, the Act did not interfere with the existing plants on those water systems at the time when the Act was issued. Additionally, the river Ounasjoki is protected under the Act 703/1983 and the river Kyrönjoki under the Act 1139/1991. Consequently, these water systems or parts of water systems are excluded from new hydropower construction.

¹ In case of old mills, the ownership has been stated in the old decisions on the taxation of mills (in the 18th and 19th century).

² Haataja, K. (1951), p. 237-310.

³ Building permits to mills have been required since the 17th century. Haataja, K. (1951), p. 241 and 320.

⁴ About the Great Land Reform, see *supra* note 48.

⁵ Haataja, K. (1951), p. 310-361 (especially p. 330).

⁶ Water Act (587/2011) Chapter 2 Section 1 (respectively Chapter 1 Section 8 in the former Water Act 264/1961). HE 277/2009, *supra* note 43, p. 45.

⁷ See Supreme Administrative Court (1978), milestone case KHO 1978-A-II-123, which was the first ruling that rejected a plan for constructing a hydropower plant. In this "Huopanankoski" case, the Court put weight on the beauty of the nature and other values in the landscape, the values of the cultural history around the rapids, and fishes that would be devastated. The Court stated there was no public need for the plant, and advantages of the project were not significant compared to the disadvantages.

Natura 2000 network includes areas protected by the Habitats Directive¹ and the Birds Directive². According to Section 65 of the Nature Conservation Act (1096/1996), if establishing a hydropower plan is likely to have a significant adverse effect on the ecological value of a site included in Natura 2000 network the applicant is required to conduct an appropriate assessment of its impact. The permit authority may not grant a permit to such a plant, if the assessment procedure indicates that the plant would have a significant adverse impact on the particular ecological value for the protection of which the site has been included in the Natura 2000 network.³ Therefore, the Natura 2000 network is taken into account in the permit procedure of a hydropower plant.⁴

4.4 Other relevant legislation

Preceding the permit procedure for hydropower plants, an environmental impact assessment usually takes place. The assessment is regulated by the Act on Environmental Impact Assessment Procedure (468/1994) and the Government Decree on Environmental Impact Assessment Procedure (713/2006). The aim of the procedure is to promote the assessment of environmental impacts and their consideration in planning and decision-making as well as increase the information available to citizens and possibilities to public participation.⁵

Other relevant legislation worth pointing out concerning hydro power is the Act on Dam Security (494/2009) and the Act on Flood Risk Control (620/2010).

In general, financial support plays an important role in the promotion of energy from renewable sources. However, this is not the case concerning hydropower because of the little potential seen in its promotion and that the existing plants have succeeded in competing with other sources of energy. Still, when discussing renewable energy it is always justifiable to have a look at the subsidy system.

Legislation related to financial support for renewable energy has been totally renewed in the beginning of year 2011 and there are totally new instruments available. The Act on subsidies for electricity produced with renewable energy sources (1396/2010) introduces a feed-in tariff system to Finland from the beginning of 2011.⁶ This new feed-in tariff scheme seeks primarily to increase electricity production based on wind power by 6 TWh, and on forest chips utilisation by 22 TWh. Additionally, the Act includes a fixed subsidies system for electricity production for wind power, forest chips, biogas and hydropower. The fixed subsidy system is intended to power plants which are not applicable to feed-in tariff scheme, because of power limits, or because the spent fuel. This fixed system replaced the former subsidies of the Electricity Tax Act (1260/1996).

¹ Council Directive 92/43/EEC of 21 May 1992 on the conservation of natural habitats and of wild fauna and flora, OJ 1992 L 206/7.

² Council Directive 79/409/EEC of 2 April 1979 on the conservation of wild birds, OJ 1979 L 103/1.

³ Nature Conservation Act (1096/1996) Sections 65 and 66. The same applies to sites that are intended for inclusion in the Natura 2000 network and to plants either individually or in combination with other projects and plans as well as plants situated inside the Natura 2000 site or outside the site in case they are liable to have a significantly harmful impact on the site.

⁴ The influence of Natura 2000 network on a hydropower plant and reservoir project in the Northern Finland was among other issues under consideration in a recent and quite famous case KHO 2002:86 by the Supreme Administrative Court, *supra note 35*.

⁵ Act on Environmental Impact Assessment Procedure (468/1994) Section 1.

⁶ The Council of State approved on 24 March 2011, after decisions of the Commission in March, the new Government Decree (258/2011) according to which the Act came fully into force 25 March 2011.

Electricity produced with hydropower is entitled for 4.20 Euros per MWh of fixed subsidy compared to electricity produced with wind power or wood chips which is entitled for 6.90 Euros per MWh; electricity produced with biogas is treated the same way as hydropower.¹ Conditions of fixed subsidy are: 1) plant location and network connectivity meet the general requirements (e.g. located in Finland, economical qualifications) and same size requirements as the feed-in tariff production, 2) power plant is not and has not been part of the feed-in tariff system on the basis of electricity production with the same fuel, and 3) operator of the plant maintains reliable accounting of the fuels spent in the plant and its energy content, if it is possible to use different fuels in the power plant, for the calendar year. For the hydropower plants, there is a special size requirement that the total rated output of the generators may not exceed 1 MVA.² Therefore, only relatively small hydropower plants are eligible to subsidies.

The fixed subsidy system is based on the target price, but fixed subsidies will also be paid for those hours when the market price of electricity is negative at the power plant location.³ There are limitations for the fixed subsidies: subsidies will not be paid if the amount of electricity produced is less than 200 MWh during the calendar year. Production volumes on plant level may vary considerably, but in practice the 200 MWh means annual production of power plants, which generator rated power is about 20-40 kVA. Neither will the subsidy be paid for electricity generated by hydropower if the market price of electricity in the calendar year exceeds the average of 76.6 Euros per MWh.⁴

5 Conclusion

In Finland, the whole potential in hydropower is about 5.100 MW: about 3.000 MW is in electricity production already, about 1.500 MW is protected by nature conservation legislation or as transboundary rivers out of reach for energy production, and around 600 MW is available for hydropower construction, in theory. In practice, of this 600 MW only half is techno-economically significant and the number small-scale hydropower worth harnessing does not add up much. These figures explain the modest potential for increase seen in electricity produced with hydropower. However, since climate change mitigation calls for all the deeds to be exploited, also further promotion of hydropower may have an influence in Finland. The question is what can be done related to the legislation concerning hydropower.

First, the hydropower plant operators feel that the permit procedure is complicated and difficult. For instance, the owners of small and micro hydropower criticise procedure to offer initiative for the right to use common hydropower and see it as a historical remains slowing down the permit procedure.⁵ Consequently, the permit procedure is designed for large-scale hydropower plants, and the administrative burden may seem heavy for small-scale plants. Different scale of plants differ with their impacts on the

¹ Act on subsidies for electricity produced with renewable energy sources (1396/2010), Section 30.

² Act on subsidies for electricity produced with renewable energy sources (1396/2010), Section 31.

³ Act on subsidies for electricity produced with renewable energy sources (1396/2010), Section 33.

⁴ The feed-in tariff scheme will be financed from funds within the state budget. In the 2011 budget, an appropriation of 55.35 million Euros has been approved for production subsidies under the feed-in tariff scheme. Finnish Government (2010), Hallituksen esitys Eduskunnalle laiksi uusiutuville energialähteillä tuotetun sähkön tuotantotuesta HE 152/2010 (Government proposal for an Act on subsidies for electricity produced with renewable energy sources), p. 28.

⁵ Ministry of Trade and Industry (2005), *supra note 23*, p. 12.

environmental and nature. Therefore, a lighter procedure for small and micro hydropower would be justified and may ease their promotion.

As one example, the utilisation of small hydropower could be exempted from the permit procedure, at least in some cases; at its most unnoticeable form, micro hydropower device can be as small as a microwave oven producing electricity only locally and be comparable to solar power. Its environmental impact would probably be minimal but still, according to present legislation, it would need a permit (since a permit is always required regardless of the size of the plant) and therefore the right to use the waterpower in question. For the purposes of this kind of micro hydropower plant, it does seem as exaggeration.

Second option that would ease the use of hydropower is to loosen the nature conservation legislation at some level without risking conservation values. There are a few ways to conduct this: 1) power increases in existing plants, 2) establishing plants in protected areas which have dams for other purposes, and 3) utilisation of new micro hydropower could be accepted in the protected water systems. In all these situations, the absolute condition would be that conservation values would not be endangered.

In conclusion, in order to achieve the goals set for mitigating climate change, some amending of the traditional environmental legislation may be needed. Although subsidies are available for electricity production by hydropower and the target is in the promotion of energy from renewable sources, it seems that the traditional water legislation does not support this target. This paper shows a need for further research in the topic: an international comparative study to give insight into solutions used in other countries.

University of Helsinki, Helsinki,
Finland

Email: Eeva-Maija.Puheloinen@helsinki.fi; Ari.Ekroos@helsinki.fi

Abstract:

In connection with mitigating climate change, the European Union has committed to raising the use of energy from renewable sources to 20 % of overall Community energy consumption by the year 2020. The national target set for Finland is a challenging 38 % compared to 28.5 % in 2005. A traditional form of renewable energy is hydropower. In Finland, hydropower generates about 3 to 4 % of total energy supply at the moment, depending on the yearly rainfall. The national target set for hydropower production is 14 TWh in 2020, which means an increase of 0.5 TWh from the present situation. This subtle rise would consist of capacity increases in existing power plants and small hydropower. Although Finland is described as a land of a thousand lakes and therefore rich in water resources, increasing the use of hydropower is difficult on a large scale mainly due to national nature conservation legislation: namely the rapids conservation legislation. Another characteristic in Finnish geography is the flatness of the country; concerning hydropower, the modest differences in altitude mean smaller capacity plants generally.

This paper analyses the existing environmental legislation in Finland concerning hydropower and looks at the targets for promotion of renewable energy in the light of that legislation. The paper suggests some amendments to the existing national legislation: for example, the permit procedure is designed for large-scale hydropower plants, and the administrative burden may seem heavy for small-scale plants. Therefore, a lighter procedure might ease the promotion of small hydropower. One option that would ease the use of hydropower is to loosen the nature conservation legislation at some level without risking conservation values. In conclusion, in order to achieve the goals set for mitigating climate change, some amending of the traditional environmental legislation may be needed.

Keywords:

hydropower, climate change, environmental legislation, nature conservation, water law

1 Introduction

Climate change is one of the biggest challenges facing mankind in the near future. The European Union has taken action in order to mitigate climate change: the so-called EU

20-20-20 target consists of 1) decreasing emissions by 20 %, ¹ 2) improving energy efficiency by 20 %, ² and 3) promoting the use of energy produced with renewable sources by 20 %. ³ The target is set to be accomplished by 2020. The promotion of the use of energy from renewable sources is regulated by Directive 2009/28/EC. ⁴ The Directive divides the average EU target into more precise national targets; for Finland, this means that by 2020 the share of energy produced with renewable sources should rise up to 38 % of the gross final consumption of energy, compared to 28.5 % in 2005. This binding target is the third highest in the EU; only Sweden exceeding it with 49 % and Latvia with 40 %. ⁵

The Finnish Government has drawn up the Long-term climate and energy strategy that defines the main objectives and means for Finnish climate and energy policy in connection with the EU targets. ⁶ The objectives include the promotion of production and use of energy produced with renewable sources: as the strategy renews the Commission-set obligation of 38 % for renewable energy, it comments that the target is challenging and requires that energy end-use will decrease. The largest potential for promoting renewable energy is seen in wood-based energy, recovered fuels, heat pumps, biogas, and wind energy. Hydropower is described more as a steady energy provider than as a promising sector for increasing the energy production. ⁷

According to the Directive 2009/28/EC, EU Member States have to draw up national renewable energy action plans (NREAPs). ⁸ Finland's NREAP, among other things, breaks down the target of 38 % into different sectors of renewable energy production. The main focus in increasing renewable energy is on wind power and wood-based energy; however, hydropower is also mentioned. By 2020, hydropower production will increase by 0.5 TWh to amount to 14 TWh. ⁹ This subtle rise will consist of capacity increases in existing power plants and small hydropower, and require no changes to the existing legislation.

Utilisation of hydropower is regulated by the Water Act (587/2011): a permit is needed for establishing and operating a hydropower plant. The Water Act has recently been revised, ¹⁰ but regulation concerning hydropower does not alter significantly from the previous Water Act (264/1961). In deciding whether it is possible to grant a permit for a hydropower plant or not, the nature conservation legislation plays a crucial role: the Rapids Conservation Act (35/1987) and the special river conservation acts (concerning rivers Ounasjoki and Kyrönjoki) as well as the Nature Conservation Act (1096/1996)

¹⁰ The new Water Act was accepted in Parliament on 11 March 2011 and will enter into force on 1 January 2012.

with its regulation concerning the EU Natura 2000 Network. Consequently, the small potential seen in increasing the production of hydropower is caused largely by two reasons: most of the rapids suitable for hydropower plants are already in use or protected by nature conservation legislation.

This paper is a study about hydropower legislation in relation to climate law. The paper analyses the existing environmental legislation in Finland concerning hydropower and looks at the targets for promotion of renewable energy in the light of that legislation. The paper does not examine the economical aspects of electricity production with hydropower (e.g. windfall¹ issues). Neither does the paper thoroughly examine the Finnish legal praxis related to hydropower construction – there are plenty of rulings over the years - which would be a topic of a paper on its own.

This paper starts with an overview of the Finnish energy sector and particularly the role of renewable and hydropower therein (chapter 2). Then we look at hydropower more specifically: past, present and future (chapter 3). Chapter 4 is a review of the Finnish legislation concerning hydropower. This chapter answers to the following questions: who has the right to establish a hydropower plant, on which circumstances is it possible to build such a plant, and what else needs to be taken into account in relation to hydropower. Lastly, conclusions will be made in the final chapter: how does the hydropower legislation appear in the light of climate change and targets for the promotion of energy from renewable sources.

2 Background

According to the Statistics Finland's preliminary data, the total energy consumption in Finland in 2010 was 1445 PJ (petajoules) that is 402 TWh; of this amount 87.5 TWh was electricity consumption. In 2010, 47.5 % of energy was produced with fossil fuels (oil 24.5 %, coal 12.9 %, natural gas 10.3 %), 16.5 % with nuclear power, 6.5 % with peat, 2 % with other sources, 2.5 % with net import and 25 % with renewable energy.² The sources of renewable energy in energy production have traditionally consisted largely on wood-based residues. In 2006, the sources of renewable energy were: 1) black liquor and other concentrated liquors from industry (42 %), 2) wood fuels from industry and energy production (26 %), 3) small combustion of wood (13 %), and 4) hydropower (11 %). Other renewable energy accounts for 8 %; this includes wood-chips, heat pumps, recovered fuel, biogas, other biofuels, and wind power.^{3 4}

Energy supply differs from electricity supply due the significance of heating (both for the domestic and industry needs) in energy production and the suitability of different sources in electricity and heat production. As the table below shows, in 2010, combined heat and power production (CHP) and nuclear power account for nearly 60 % of the electricity production leaving hydropower the share of about 15 %. Around half of the

electricity is consumed by the industry (forest industry consuming 25 %, and the other sectors being chemical, metal, and other) and half is other consumption (heating, transport, and other).¹

Table 1. Electricity supply in Finland 2010
(Source: Finnish Energy Industries, 20112)

	TWh	Share (%)
CHP	28.5	32.6
- Industry	- 11.1	- 12.7
- District heating	- 17.4	- 19.9
Nuclear power	21.9	25.0
Hydropower	12.8	14.6
Wind power	0.3	0.3
Seperate	13.5	15.4
PRODUCTION	77.0	88.0
Net imports	10.5	12.0
ELECTRICITY SUPPLY	87.5	100

There is some geographical and climate information that needs to be stated about Finland. There are 187,888 lakes in Finland.³ Although Finland is rich in water resources, the flatness of our country makes the differences in altitude very modest, which means that we have smaller capacity plants generally. The flatness also causes that possibilities to reserve the water flow are limited since the reserve would need much more horizontal space than in steep terrain. Spring floods are usual because of melting snow and, therefore, the water flow is not even throughout the year. In connection with this, the yearly rainfall varies from year to year making the prediction of water reserves difficult and causing the yearly production of electricity by hydropower vary from year to year notably. Additionally, Finland is located relatively far north in the planet Earth, and the average yearly temperature is about 1.9 °C.⁴ In the wintertime, the need for energy rises significantly due to heating. The energy supply has to be built in a way that extra energy is available when extremely cold days occur causing the so called peak loads when the energy demand is at its highest level; additionally, the extra energy is needed to assure the security of the grid. This extra energy supply is called adjustment power (in Finnish säätövoima), and hydropower is very suitable for this purpose because the extra energy is quickly available.⁵ The significance of adjustment power will be emphasized further in the future as the share of wind power increases;⁶ on days when there is no wind and therefore no wind power, the lack of wind power has to be replaced with another kind of energy.

⁶ The target is 6 TWh by 2020. Ministry of Employment and the Economy (2010), *supra note 9*, p. 2.

Although hydropower is climate-friendly as a renewable energy source it does have effects on the environment. The watercourse is not in its natural state after establishing a hydroelectric installation. This change affects the biodiversity of the watercourse and the effects are greater in case an artificial lake is founded. One of the most obvious effects is on fishes and fishing. However these effects can be reduced by using fish ladders, fish bypass systems and fish lifts (upstream) as well as fish-friendly turbines (downstream). Moreover, control of the water level has effects both on the upper and lower course: on the upper course flooding and on the lower course too little water/stream may cause harm. On the other hand, hydropower plants may be actors in controlling flood risks, which are assumed to increase due to climate change.¹

3 Hydropower in Finland

The first hydropower plant that produced electricity nationwide was established in Finland at Imatrankoski in 1929. Till then, the hydropower plants had been smaller and produced electricity only for local use; mills have been used since the Middle Ages. The major rapids located in the Southern Finland were harnessed during 1930's and 1940's; the next few decades after the Second World War were the time of heavy increase in the hydropower capacity as the hydropower construction concentrated at the big rivers of Northern Finland.² After a slow phase in the 1980's, the development of hydropower generation picked up at the turn of the millennium when about 15 % of today's hydropower capacity, 3.000 MW, has been build.³

Nowadays, the share of hydropower in energy production varies between 3 to 4 % annually depending on the rainfall,⁴ which accounts for 10 to 20 % of the electricity production. At its peak the share of electricity produced with hydropower was in the 1950's and 1960's when it accounted for 90 % of electricity at its best. In 2006, there were 207 hydropower plants in use: 57 of those plants were large (production more than 10 MW), 83 were small hydropower plants (production 1-10 MW), and 67 were so called micro hydropower plants (production less than 1 MW). On an average year's rainfall, the electricity production of these plants is 12.9 TWh: of this amount large plants account for 91 %, small hydropower 8 %, and micro hydropower 1 %.^{5 6}

As mentioned above, the current hydropower capacity in use is 3.000 MW. According to a recent study, the whole potential in hydropower is about 5.100 MW; this number includes the hydropower in use and the potential. The potential consists of both water systems that are protected and unprotected; the potential can be divided to large, small and micro hydropower, as well. As can be seen in the table below, the largest potential in Finland for hydropower is situated in waters that are protected by the nature

¹ More information about the environmental consequences of hydro power, see for instance Pienvesivoimayhdistys ry. (2009), *Pienvesivoimalaopas*, p. 18, also available on the Internet at <<http://server.perlasoft.fi/vesivoima/images/Pienvesivoimaopas.pdf>> (last accessed on 10 June 2011); Finnish Energy Industries (2008), *supra note 19*, p. 38-41.

² Salokangas, R. (1968), p. 14-17.

³ During 1990 and 2004, 444 MW of new hydropower (including new plants and capacity increases in existing power plants) was established in Finland. Ministry of Trade and Industry (nowadays Ministry of Employment and the Economy) (2005), *Vesivoimatuotannon määrä ja lisäämismahdollisuudet Suomessa*, p. 9. Available on the Internet at <[http://julkaisurekisteri.ktm.fi/ktm_jur/ktmjur.nsf/all/6638E6EBAA886908C225701900465F55/\\$file/334642004.pdf](http://julkaisurekisteri.ktm.fi/ktm_jur/ktmjur.nsf/all/6638E6EBAA886908C225701900465F55/$file/334642004.pdf)> (last accessed on 8 June 2011).

⁴ Finnish Government (2008), *supra note 6*, p. 40.

⁵ Ministry of Trade and Industry (2005), *supra note 23*, p. 8 and 17.

⁶ Small hydropower is generally defined as sites with installed capacity of less than 10 MW. European Commission, Directorate-General for Energy, Renewables make the difference, p. 19. Available on the Internet at http://ec.europa.eu/energy/publications/doc/2011_renewable_difference_en.pdf (last accessed on 16 May 2011).

conservation legislation. However, there is some potential left unprotected.¹ Nature conservation legislation will be examined below in chapter 4.3.

Table 2. Hydropower potential not in use (MW)
(Source: Ministry of Trade and Industry, 20052)

	Unprotected	Protected and transboundary waters	Altogether
Large hydropower (more than 10 MW)	375	1.033	1.408
Small hydropower (1-10 MW)	144	286	430
Micro hydropower (less than 1 MW)	144	148	292
ALTOGETHER	663	1467	2130

According to another recent study, there is 934 MW potential in hydropower that is techno-economically significant; of this amount 365 MW is unprotected and 569 MW is protected. Additionally, there is 274 MW potential in other hydropower that is worth building; this amount consists largely of small and micro hydropower. Technically worth establishing small hydropower that is unprotected is 63 MW; about forth of this is in micro level.³ This study supports the view that the bigger part of the potential for new hydropower for electricity production is protected by the nature conservation legislation. However, there is some potential left outside the protection.

4 Hydropower legislation in Finland

4.1 The right to establish a hydropower plant

Water resources management is regulated by the Water Act (587/2011), which has recently been revised. According to Chapter 3 Section 3 of the Water Act, a permit is required for establishing a hydropower plant;⁴ a permit is always required regardless of the size of the plant. A permit is required for altering an existing plant or power increases, which are quite usual. The permit authority is the Regional State Administrative Agency whose decisions may be appealed to the Vaasa Administrative Court and further to the Supreme Administrative Court.⁵ There are several conditions that must be fulfilled before a permit may be granted.

The first condition is that either the plant may not hurt much public or private interest or the public or private interests will benefit significantly because of the plant compared to the disadvantages to the public or private interests that the plant would cause.⁶ In the

¹ Ministry of Trade and Industry (2005), *supra note 23*, p. 2 and 26.

² Ministry of Trade and Industry (2005), *supra note 23*, p. 26.

³ Finnish Energy Industries (2008), *supra note 19*, p. 177-179.

⁴ Water Act (587/2011) Chapter 3 Section 3 point 6 (respectively Chapter 3 Section 2 in the former Water Act 264/1961). In addition, a hydropower plant requires a building permit according to the Section 125 of the Land Use and Building Act (132/1999).

⁵ The Finnish courts of law consist of district courts dealing with criminal and civil cases, administrative courts reviewing the decisions of the authorities, and certain special courts (Market Court, Labour Court, Insurance Court and High Court of Impeachment). The decisions of the administrative courts can be appealed in the Supreme Administrative Court.

⁶ Water Act (587/2011) Chapter 3 Section 4. On how to assess the public and private advantages and disadvantages, see Sections 6 and 4.

first case the plant is regarded as a minor undertaking. In the second case, a comparison between interests will be conducted; as the value of the hydropower production, the price of average annual amount of electricity produced by the plant at least twenty-folded will be taken into account.¹ Moreover, there are some overriding reasons that prevent from granting the permit, such as danger to public health or security, or substantial harmful changes in the relations of the natural environment or in the water nature.^{2 3}

Second, the applicant must have a right to use the areas needed for the plant and the project.⁴ In relation to the permit decision, it is possible to decide coercive measures and compensation issues.⁵

Third, the applicant must have a right to use the hydropower on the site. That can be arranged beforehand (ownership or other right to use) or during the permit procedure (right to use common hydropower).⁶ Initiative for the right to use common hydropower can be made by a party or parties together who has/have at least one fifth of the hydropower in question. Primarily, the target is to make an agreement of the common use. Secondly, the initiative party/parties may offer other parties⁷ to participate on the hydropower plant. The participation procedure is done with the assistance of the permit authority.⁸ As a preliminary question, it may have to be found out who is entitled to the waterpower in question; this question is for the district court to decide, not the permit authority.^{9 10}

The permits for mills or other kind of hydropower plants have been given for the time being (not for a fixed-term). Therefore, in many cases the old permits are still valid. This situation will remain the same with the Water Act (587/2011).¹¹

¹ Water Act (587/2011) Chapter 8 Section 2 subsection 2 (respectively Chapter 3 Section 2 in the former Water Act 264/1961). In a recent permit decision PSY-2005-y-185 by the Northern Finland Regional State Administrative Agency, the comparison between interests was seen as following: the advantages amount to 112 million € and the disadvantages to 8.3 million € (p.316-327). Also available on the Internet at <http://www.avi.fi/fi/virastot/pohjoissuomenavi/Ymparistojavesitalousluvat/Vesiluvat/Documents/P%C3%A4%C3%A4t%C3%B6kset/2011/psavi_paatos_32_11_2-2011-05-31.pdf> (last accessed on 2 June 2011).

The decision does not have legal force yet; time for appeal is still running.

² Water Act (587/2011) Chapter 3 Section 4 subsection 2.

³ See Supreme Administrative Court, case KHO 2002:86 about a hydropower plant and reservoir project in the Northern Finland. In this "Vuotos" case, the Court ruled that there was an overriding reason that prevented from granting the permit to the project; it would have caused substantial harmful changes in the relations of the natural environment or in the water nature. The maximum area of the planned reservoir was 237 km². This case is very important from the national point of view because for the first time the overriding reasons was used to reject a permit application by the Supreme Administrative Court.

⁴ Water Act (587/2011) Chapter 3 Section 4 subsection 3 and Chapter 2 (especially Chapter 2 Sections 12 and 13).

⁵ According to Section 15 of the Constitution of Finland (731/1999), everyone's property is protected and expropriation of property is possible only for public needs and against full compensation. In connection with small and micro hydropower, one question arisen is the existence of public needs for coercive measures. It is not possible to go deeper into this issue within this paper. See more on the relation between Water Act and protection of property, Parliaments Constitution Committee (2011), Statement on the proposal for water act PeVL 61/2010, Also available on the Internet at <http://www.eduskunta.fi/faktatmp/utatmp/akxtmp/pevl_61_2010_p.shtml> (3 June 2011).

⁶ Water Act (587/2011) Chapter 8 Section 2.

⁷ Who own at least one hundredth part of the hydropower in question.

⁸ Water Act (587/2011) Chapter 8 Sections 5, 8 and 9.

⁹ About the Finnish courts of laws, see *supra note 31*.

¹⁰ In some existing plants, the right to use hydropower is based on fixed-term agreements, which may cause problems when the agreement period is terminated. More on this issue, see Ekroos, A. (2008).

¹¹ Water Act (587/2011) Chapter 3 Section 8. See also Finnish Government (2009), Hallituksen esitys Eduskunnalle vesilainsäädännön uudistamiseksi HE 277/2009 (Government proposal for a Water Act), p 65.

4.2 Right to waters

The right to waters is based on two concepts: the water material and the ground of the water area. Historical development plays a central role regarding the right to waters.

The right to the water material may be targeted only at a water which the owner holds, in other words water in a water reservoir, well, other intake, spring, or artificial pond. In other cases the water is not owned but governed: the water with an open surface is governed by the owner of the water or land area in question.¹ Traditionally it is seen that open surface water or groundwater cannot be a subject to ownership because water is a natural resource which is continuously in circulation; this is why it is defined as governing. Governing is a special kind of right of possession that takes into account the restrictions set in the Water Act and other parties' rights to water. Governing is a priority right to use and also a limited right to dispose. The exact content of governing cannot be defined generally but case-by-case taking into account the restrictions set in the legislation and other parties' rights to the water.²

In Finland, the ownership of the water area is based on private ownership³ - the leading principle is that "he owns the water, who owns the land".⁴ The ownership of water areas can be sorted out to three ways. First, most of the water areas enjoy shared private ownership in which the water area belongs to several real estates nearby (common waters). This is due to historical reasons: the water area used to belong to the nearest village (so called median line principle which means that, for example, a lake between two villages is divided between the two villages by its median line) and since the Great Land Reform⁵ the real estates in the village according to their share of the land in the village. Still, in most of the cases these real estates in the village enjoy a shared ownership of the water area. Second, the ownership of some water areas is private but not shared. These water areas belong to a single real estate or form a real estate of their own (so called water real estates). Third, the state owns some water areas: the high seas and the centres of large lakes (so called common water areas); there are eight such lakes in Finland.⁶

Rapids have always been in a highlighted position compared to other water areas due to the importance and financial aspects of hydropower. In the Middle Ages the ownership of a mill site could be established by claim: the claimant had to own a share of the common land in which the mill would have been situated (be a land-owner in the village) or, in some provinces, be a citizen of that province. Additional condition in both cases was that he had to intend to build a mill on the site. Building of mills was promoted because they were considered to be of public interest. Later on, in case of common mill sites⁷, the land-owners in the village could build a common mill; if not all the land-owners were interested in building the mill, the court could empower the

¹ Water Act (587/2011) Chapter 2 Section 1 (Chapter 1 Section 8 in the former Water Act 264/1961).

² HE 277/2009, *supra note 43*, p 46.

³ Private ownership of water areas is defined as German-Scandinavian whereas public ownership is of Roman Law heritage. Hollo, E. (1991) 103-104.

⁴ This is stated in the old Land Laws.

⁵ The Great Land Reform took place between late 18th century and early 20th century. In the reform, the shared ownership of the land in villages was divided and every land-owner in the village owned his share as piece of real estate. The reform concerned only land, water areas were excluded.

⁶ Laki , sisältävä määräyksiä välirajasta vedessä ja vesialueen jaosta (31/1902), Sections 1-3 and 9. See more about the right to waters Haataja, K. (1951), p. 139-236; Belinskij, A. (2010), p. 233-236;

⁷ The land-owners of the village owned a share of the mill site (and its waterpower) according to their share of the land in the village.

builder to do one alone¹. The ownership of private mills could also be based on the ownership of a single real estate, immemorial enjoyment of a mill site, or an old judgement. Additionally, there were mills that were owned by the crown.^{2 3}

Depending on the individual case, the ownership of a mill may include the ownership of the water area in question or just the right to use the discharge and head in question; the building permit of the mill may have an indication of the character of the right to the water.⁴ In the Great Land Reform,⁵ generally the mills were formed to their own plots of land – either common (shared ownership by the land-owners of the village), or private – separate from other real estates in the village that were formed from the common land in the reform. However, this did not change the ownership of the rapids and the hydropower since the reform did not apply to water areas. Unless otherwise stated, the ownership of a water area, including rapids, is shared among the land-owners of the village according to their share of land in the village.⁶

There is a special rule concerning rapids situated in the water area between two villages: the owners of both sides have equal rights to the water flowing therein. This has been the situation for centuries now but this is stipulated in the Water Act (587/2011), too, concerning water areas that belong to two real estates or common land areas.⁷ In these cases, the median line principle does not apply in rapids because it may be that the watercourse is not symmetrical in both banks and most of the hydropower is situated on the other side of the watercourse. That is why it is stipulated that the owners of both sides share the waterpower 50-50%.

4.3 Nature conservation aspects

Since the 1970's, the conservation of rapids has become an important issue of nature conservation. First, the protection in legal context begun in court practice.⁸ Thereafter, the rapids have become subject to nature conservation by the special Rapids Conservation Act (35/1987) and two other special rapids conservation acts as well as by the general Natura 2000 nature conservation areas. Additionally rapids may be included in nature parks and wilderness areas.

The Rapids Conservation Act, given in 1987, prohibits the authorities from granting a permit for a new hydropower plant in certain water systems. In the Act, there is a list of 53 water systems or parts of water systems in which the building of a new hydropower plant is forbidden. However, the Act did not interfere with the existing plants on those water systems at the time when the Act was issued. Additionally, the river Ounasjoki is protected under the Act 703/1983 and the river Kyrönjoki under the Act 1139/1991.

¹ The court would set conditions, such as in which time the mill had to be build and how long the builder had the right to use the other villagers' share of the rapids. The "licence" was temporary.

² In case of old mills, the ownership has been stated in the old decisions on the taxation of mills (in the 18th and 19th century).

³ Haataja, K. (1951), p. 237-310.

⁴ Building permits to mills have been required since the 17th century. Haataja, K. (1951), p. 241 and 320.

⁵ About the Great Land Reform, see *supra* note 48.

⁶ Haataja, K. (1951), p. 310-361 (especially p. 330).

⁷ Water Act (587/2011) Chapter 2 Section 1 (respectively Chapter 1 Section 8 in the former Water Act 264/1961). HE 277/2009, *supra* note 43, p. 45.

⁸ See Supreme Administrative Court (1978), milestone case KHO 1978-A-II-123, which was the first ruling that rejected a plan for constructing a hydropower plant. In this "Huopanankoski" case, the Court put weight on the beauty of the nature and other values in the landscape, the values of the cultural history around the rapids, and fishes that would be devastated. The Court stated there was no public need for the plant, and advantages of the project were not significant compared to the disadvantages.

Consequently, these water systems or parts of water systems are excluded from new hydropower construction.

Natura 2000 network includes areas protected by the Habitats Directive¹ and the Birds Directive². According to Section 65 of the Nature Conservation Act (1096/1996), if establishing a hydropower plan is likely to have to have significant adverse effect on the ecological value of a site included in Natura 2000 network the applicant is required to conduct an appropriate assessment of its impact. The permit authority may not grant a permit to such a plant, if the assessment procedure indicates that the plant would have a significant adverse impact on the particular ecological value for the protection of which the site has been included in the Natura 2000 network.³ Therefore, the Natura 2000 network is taken into account in the permit procedure of a hydropower plant.⁴

4.4 Other relevant legislation

Preceding the permit procedure for hydropower plants, an environmental impact assessment usually takes place. The assessment is regulated by the Act on Environmental Impact Assessment Procedure (468/1994) and the Government Decree on Environmental Impact Assessment Procedure (713/2006). The aim of the procedure is to promote the assessment of environmental impacts and their consideration in planning and decision-making as well as increase the information available to citizens and possibilities to public participation.⁵

Other relevant legislation worth pointing out concerning hydro power is the Act on Dam Security (494/2009) and the Act on Flood Risk Control (620/2010).

In general, financial support plays an important role in the promotion of energy from renewable sources. However, this is not the case concerning hydropower because of the little potential seen in its promotion and that the existing plants have succeeded in competing with other sources of energy. Still, when discussing renewable energy it is always justifiable to have a look at the subsidy system.

Legislation related to financial support for renewable energy has been totally renewed in the beginning of year 2011 and there are totally new instruments available. The Act on subsidies for electricity produced with renewable energy sources (1396/2010) introduces a feed-in tariff system to Finland from the beginning of 2011.⁶ This new feed-in tariff scheme seeks primarily to increase electricity production based on wind power by 6 TWh, and on forest chips utilisation by 22 TWh. Additionally, the Act includes a fixed subsidies system for electricity production for wind power, forest chips, biogas and hydropower. The fixed subsidy system is intended to power plants which are not applicable to feed-in tariff scheme, because of power limits, or because the spent

² Council Directive 79/409/EEC of 2 April 1979 on the conservation of wild birds, OJ 1979 L 103/1.

³ Nature Conservation Act (1096/1996) Sections 65 and 66. The same applies to sites that are intended for inclusion in the Natura 2000 network and to plants either individually or in combination with other projects and plans as well as plants situated inside the Natura 2000 site or outside the site in case they are liable to have a significantly harmful impact on the site.

⁴ The influence of Natura 2000 network on a hydropower plant and reservoir project in the Northern Finland was among other issues under consideration in a recent and quite famous case KHO 2002:86 by the Supreme Administrative Court, *supra note 35*.

⁵ Act on Environmental Impact Assessment Procedure (468/1994) Section 1.

⁶ The Council of State approved on 24 March 2011, after decisions of the Commission in March, the new Government Decree (258/2011) according to which the Act came fully into force 25 March 2011.

fuel. This fixed system replaced the former subsidies of the Electricity Tax Act (1260/1996).

Electricity produced with hydropower is entitled for 4.20 Euros per MWh of fixed subsidy compared to electricity produced with wind power or wood chips which is entitled for 6.90 Euros per MWh; electricity produced with biogas is treated the same way as hydropower.¹ Conditions of fixed subsidy are: 1) plant location and network connectivity meet the general requirements (e.g. located in Finland, economical qualifications) and same size requirements as the feed-in tariff production, 2) power plant is not and has not been part of the feed-in tariff system on the basis of electricity production with the same fuel, and 3) operator of the plant maintains reliable accounting of the fuels spent in the plant and its energy content, if it is possible to use different fuels in the power plant, for the calendar year. For the hydropower plants, there is a special size requirement that the total rated output of the generators may not exceed 1 MVA.² Therefore, only relatively small hydropower plants are eligible to subsidies.

The fixed subsidy system is based on the target price, but fixed subsidies will also be paid for those hours when the market price of electricity is negative at the power plant location.³ There are limitations for the fixed subsidies: subsidies will not be paid if the amount of electricity produced is less than 200 MWh during the calendar year. Production volumes on plant level may vary considerably, but in practice the 200 MWh means annual production of power plants, which generator rated power is about 20-40 kVA. Neither will the subsidy be paid for electricity generated by hydropower if the market price of electricity in the calendar year exceeds the average of 76.6 Euros per MWh.⁴

5 Conclusion

In Finland, the whole potential in hydropower is about 5.100 MW: about 3.000 MW is in electricity production already, about 1.500 MW is protected by nature conservation legislation or as transboundary rivers out of reach for energy production, and around 600 MW is available for hydropower construction, in theory. In practice, of this 600 MW only half is techno-economically significant and the number small-scale hydropower worth harnessing does not add up much. These figures explain the modest potential for increase seen in electricity produced with hydropower. However, since climate change mitigation calls for all the deeds to be exploited, also further promotion of hydropower may have an influence in Finland. The question is what can be done related to the legislation concerning hydropower.

First, the hydropower plant operators feel that the permit procedure is complicated and difficult. For instance, the owners of small and micro hydropower criticise procedure to offer initiative for the right to use common hydropower and see it as a historical remains slowing down the permit procedure.⁵ Consequently, the permit procedure is designed for large-scale hydropower plants, and the administrative burden may seem heavy for

² Act on subsidies for electricity produced with renewable energy sources (1396/2010), Section 31.

³ Act on subsidies for electricity produced with renewable energy sources (1396/2010), Section 33.

⁴ The feed-in tariff scheme will be financed from funds within the state budget. In the 2011 budget, an appropriation of 55.35 million Euros has been approved for production subsidies under the feed-in tariff scheme. Finnish Government (2010), Hallituksen esitys Eduskunnalle laiksi uusiutuville energialähteillä tuotetun sähkön tuotantotuesta HE 152/2010 (Government proposal for an Act on subsidies for electricity produced with renewable energy sources), p. 28.

⁵ Ministry of Trade and Industry (2005), *supra note 23*, p. 12.

small-scale plants. Different scale of plants differ with their impacts on the environmental and nature. Therefore, a lighter procedure for small and micro hydropower would be justified and may ease their promotion.

As one example, the utilisation of small hydropower could be exempted from the permit procedure, at least in some cases; at its most unnoticeable form, micro hydropower device can be as small as a microwave oven producing electricity only locally and be comparable to solar power. Its environmental impact would probably be minimal but still, according to present legislation, it would need a permit (since a permit is always required regardless of the size of the plant) and therefore the right to use the waterpower in question. For the purposes of this kind of micro hydropower plant, it does seem as exaggeration.

Second option that would ease the use of hydropower is to loosen the nature conservation legislation at some level without risking conservation values. There are a few ways to conduct this: 1) power increases in existing plants, 2) establishing plants in protected areas which have dams for other purposes, and 3) utilisation of new micro hydropower could be accepted in the protected water systems. In all these situations, the absolute condition would be that conservation values would not be endangered.

In conclusion, in order to achieve the goals set for mitigating climate change, some amending of the traditional environmental legislation may be needed. Although subsidies are available for electricity production by hydropower and the target is in the promotion of energy from renewable sources, it seems that the traditional water legislation does not support this target. This paper shows a need for further research in the topic: an international comparative study to give insight into solutions used in other countries.

Abstract:

“Man is here only for a limited time, and he borrows the natural resources of water, land and air from his children who carry on his cultural heritage to the end of time. One must hand over the stewardship of his natural resources to the future generations in the same condition, if not as close to the one that existed when his generation was entrusted to be the caretaker.”

(Delano Saluskin, 1991)

We are now facing the prospect of fossil fuels running out. The magnitude of the hydrocarbon resource gap, lack of significant alternative energy sources and disastrous impact on society of energy shortfalls leave few choices. Any gap between supply and demand must be met through increased efficiency or increased nuclear/renewable energy production. With the proposed development of 10 nuclear power stations providing 16GW of new capacity, the government appears committed to obtaining a significant percentage of the country's energy from this source. The sustainability of this power source in comparison to other forms of low carbon energy is of paramount importance.

The World Nuclear Association stated: '[nuclear power] is robust from a sustainable development perspective ...' Using the basic pillars of sustainable development (economic, environmental and social) this paper examines this statement using the proposed reactors at Hinkley Point, Somerset and Oldbury, (South Gloucestershire), as a case study.

EDF Energy plans to develop two new reactors at Hinkley Point with forecasted construction costs in excess of £9bn to produce a capacity of 3.2GW. The Company believes this will boost the regional economy by over £500m, particularly through job creation, during the construction period and beyond. Horizon Nuclear Power is to invest £15bn to produce a capacity of 6 GW and again positively impact on the regional economy.

These nuclear power stations will be located on the Severn Estuary, and thus enabling the abstraction of seawater for the cooling process. However, water is then returned to the sea at a 'slightly raised temperature'. Even small increases in temperature can create fluctuations in environmental conditions enabling the establishment of invasive/non-native or eurybiontic species that can rapidly colonise and threaten marine and coastal biodiversity.

Studies have also shown a decline in phytoplankton and zooplankton abundance close to the discharged water with possible impacts upon the wider food chain and overall ecosystem services.

Highly uncertain decommissioning and waste disposal costs are of key public and governmental concern when assessing the relative competitiveness and sustainability of nuclear power against other forms of low carbon energy. The Nuclear Decommissioning Authority shows current discounted decommissioning and clean-up liabilities for existing nuclear facilities of over £45bn. If sufficient provision for costs of decommissioning waste from the new proposed nuclear facilities are not properly provided for, the burden will fall on the taxpayer (either directly or indirectly).

The key issue here is to ensure that nuclear energy is truly sustainable and not simply shifting the economic and environmental burden of responsibility onto future generations to satisfy short-term political energy objectives.

Keywords:

nuclear power, sustainable development, thermal pollution, economics, intergenerational equity.

1 Introduction

Given the move to low carbon technologies in order to mitigate the effects of climate change (with nuclear generation currently reducing carbon emissions by 7-14%) (DECC,2011), the UK plans to invest heavily in nuclear power, with the impact on the Severn region now to be significant, following the rejection of the Severn Tidal Barrage scheme. However, there is currently a great deal of uncertainty and debate over the likely costs of expanding the UK's nuclear electricity generating capacity. Aside from the ecological and legal issues surrounding the building and operation of new nuclear facilities, economic considerations are very much to the fore, for the energy companies themselves, the government and the region.

The energy companies involved in new nuclear development in the Severn area are keen to promote the regional economic benefits from the schemes. Job creation and impact on the regional economy are seen as being key benefits. Horizon Nuclear Power state that 800 permanent jobs will be created at Oldbury (South Gloucestershire) during operation and a peak of 5000 jobs during construction(Horizon,2011). Hinkley C. (Somerset) is projected to provide "£100m of economic benefit for the regional economy during every year of construction" and "£40m per year in economic benefit for every year of the site's 60 year operation" (EDF Energy,2011a). EDF Energy reveals that 700 permanent and 200 contract staff will be required during the operation of Hinkley C. Furthermore, forecasts suggest a peak construction workforce of 5600, with 20,000-25,000 individual jobs being created over the 10 year construction period, with up to ¼ of these going to local people. To further support the local workforce, the company is to invest £6.1m in local colleges to help train potential employees and

create more new apprenticeships to provide 200 of the technicians required by the new power station. The company also has plans to establish a £20m community fund to be spent on local projects (EDF Energy, 2010).

The modern concept of sustainability has its roots in the technique of forest management practised by central European foresters in the eighteenth and nineteenth centuries (Schutt,1992). It was fundamentally an economic management technique and was not inspired by ecological or biological considerations (Schutt, 1992). The current definition of sustainable development is as much concerned with economic and social development as it is with environmental protection (Brundtland, 1987). According to Brundtland sustainable development (SD) is a process of transformation which, by combining economic growth with broader social and cultural changes, enables individuals to realise their full potential. This dimension of sustainability brings with it the recognition that development must adhere to the physical constraints imposed by ecosystems, so that environmental considerations have to be embedded in all sectors and policy areas. Sustainable development was one of many issues discussed by the International Court of Justice in the Danube Dam case (The Gabcikovo-Nagymaros(1998). In this case Judge Weeramantry in his dissenting opinion argued that the principle of sustainable development had already become part of modern international law and practice, however the court in its infinite wisdom stated that the ‘concept of sustainable development’ was one which expressed the need to reconcile economic development with the protection of the environment.

The EU incorporated the principle of sustainable development into Article 2 of the Treaty on European Union provided that the Community “shall have as [one of its tasks]...to promote throughout the Community harmonious, balanced and sustainable development of economic activities(Treaty of Amsterdam,1997), and Article 6 provides “Environmental protection requirements must be integrated into the definition and implementation of the Community policies and activities referred to in Article 3, with a view to promoting sustainable development”(Treaty of Amsterdam,1997). The Lisbon Treaty made this commitment stronger and the new Article 3 provides that “Union shall...work for the sustainable development of Europe...” indicating that strengthened sustainable governance is in place (Treaty of Lisbon,2007). In the UK the definition changed, from a trade off between the economy and the environment (DEFRA,1994) in 1994, to 2005 where the definition expanded to incorporate five guiding principles (Five principles include living within environmental limits, just society, sustainable economy, good governance and sound science). The effectiveness of UK sustainable development legislation however remains questionable, and none go as far as to impose a duty to achieve sustainable development. For example it is questionable to what extent the legal duty in the Planning and Compulsory Purchase Act 2004 Section 39(2) which requires all plan making bodies to exercise their function ‘*with the objective of contributing to the achievement of sustainable development*’ has any real content or value. However, the non-binding wording allows a great deal of discretion.

Sustainable development has been incorporated into national law in India, through the Vellore Citizens’ Welfare case(Vellore Citizens’ Welfare Forum v Union of India AIR [1996]) and in Sri Lanka through the Eppawela case(Bulankulama and Others v Secretary, Ministry of Industrial Development and Others SLR [2000]) and could under certain circumstances be said impose duties and obligations on public and private bodies (Razzaque,2002). This development, further suggests that the issue of the needs of the current generation and those of future generations are central to the Brundtland definition of sustainable development (Rauschmayer, *et al.*, 2011). Needs can be

distinguishable from preferences as they are considered the very minimum necessary for the survival of a species i.e. food, clean air and water and shelter a tolerable climate. There is however considerable debate about what we really ‘need’ (Redclift,1993). The problem is further compounded when we engage in judging the needs of the future generations owing to the fact that what is valued by one generation will not necessarily be held in the same esteem in the preceding generation (Bell, & McGillivray, 2008) .

In this context nuclear technology can amongst other things contribute significantly to the creation of a steady and abundant supply of electrical energy. It is suggested that electricity generated from the use of nuclear power satisfies the economic and environmental protection goals of the Rio Principles (Joskow,2009). Furthermore the energy aspect of nuclear power has links with the three dimensions of sustainable development – economic, environmental, and social. Energy services are fundamental for economic and social development. As energy use will continue to grow, its health and environmental impacts will have to be controlled, alleviated or mitigated in order to achieve sustainable development goals.

In a bid to establish nuclear energy as the solution to UK’s the energy problem, the government in 2010(Cabinet Office,July-2009) rebranded nuclear energy as a means of delivering a sustainable energy supply which mapped on to the internationally agreed Millennium Development Goals(UN Millennium Development Goals). To truly appreciate this aspect of nuclear energy we will analyse its environmental and economic implications.

2 Environmental Implications

The environmental concerns over nuclear power, such as the difficulties with the disposal of intermediate and high level waste, are well documented and it is beyond the scope of this work to address all these issues. However, a significant and little considered area of concern that could call into question the ‘sustainability’ of nuclear power is the ‘death by a thousand cuts’ ecological impact from the new power stations. The cumulative impacts of a small number of ‘minor adverse’ or ‘moderate adverse’ impacts (EDF, 2011b) combined over the operational lifetime of the power station could, ultimately, result in major adverse impact.

The consultation process for the Hinkley Point C (HPC) power station finished on 28 March 2011 (EDF, 2011b). As one of the statutory consultees, the Environment Agency (EA) provided a detailed response to the proposal and, in particular, addressed a number of ecological concerns (EA, 2011). These focussed upon three key areas of the main HPC development.

The locations considered for the intake and outflow pipes are shown in fig. 1. EDF (2011)b advised their preferred configuration to be intake at point A and outflow at point B. It is anticipated that the intake rate will be ‘low velocity’ at 120cumecs. Temperature of the discharged water will be raised by 12.5°C. The locations for the intake and outflow pipes represent the least damaging option. However, the Environment Agency (EA, 2011) expressed concern about a lack of appropriate assessment of the impact from the thermal plume particularly modelling in different conditions for example a ‘hot summer’. They require further studies to be undertaken and reviewed by the EA prior to a planning application being submitted.

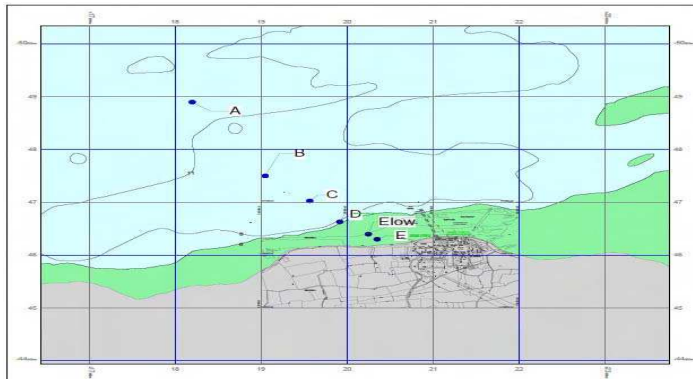

Fig. 1 Proposed locations for intake / outflow pipes (Source: Forster, *et al.*, 2011).

The thermal plume will have an impact upon the species assemblage within the Severn Estuary with warmer water loving fish, such as bass, thriving and colder water species, for example cod, moving away from the area (Forster et al. 2011). There is no mention within either the EDF (EDF,2011b) assessment or the Environment Agency (EA, 2011) response as to the potential for invasive / non-native species to colonise the area. There are no definitive criteria for determining whether a non-native species will become invasive. It is possible that the niche created by a cold-water species moving away could provide an ideal opportunity for a non-native species already present within the ecosystem to exploit (DEFRA 2011).

The BEEMS (Forster et al. 2011) study highlighted the likely impacts from cooling water discharge without biocide and discharge with biocide (likely hydrazine). There are no studies, as yet, into the impact of this chemical on the marine environment within the Severn Estuary. The Environment Agency has recommended further study (EA,2011).

2.1 Fish impingement / entrainment

It is this aspect of the nuclear power plant development that could, potentially, result in significant impact on the marine ecology of the Severn Estuary. Again, the Environment Agency expressed concern over a lack of robust survey methodology used by EDF to establish likely impact. They note that only using a beam trawl would not have sufficiently sampled the marine environment and would have missed those species present in the water column. Although it is acknowledged that the turbidity of the water within the Severn Estuary results in limited commercial fishing activity, the population of eel within the area is significant. It is reported that 95% of eel catch in the UK comes from the Severn Estuary (EA, 2011).

3 Relevant International, EU and UK Legal Instruments

There are several International, European and National legislations that need to be taken into consideration in relation to the proposed developments. These can be broken down into preventive and sanctioning legislation (Ginige,2002) and have been considered in depth in the April 2011 report produced by EDF Energy (EDF, April 2011). It is suggested that the majority of legislation can be adhered to with appropriate monitoring (EDF,2011b) by regulatory agencies. However it is suggested that there may be issues with regard to the Eel Regulations of 2010 (SI 2009 No. 3344) and EU Habitats Directive (Dir.92/43/EEC (1992)).

The European Eel Regulations 2010(COUNCIL REGULATION (EC) No 1100/2007) state that it is a requirement that mitigation is in place at the intake point for power stations to prevent impingement by eel. The European Eel has also been placed on the CITES (Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES),1973) register thereby adding a further level of protection for this species (E A, 2011). In addition, the impact on the marine food web of impingement / entrainment of smaller species, for example the brown shrimp (*Crangon crangon*) have not been assessed. Significant destruction of populations of these species could have impacts upon the ecosystem within the region and the possible further decline of protected species, for example Allis shad (Forster et al. 2011).

The Environment Agency (2011) subsequently supported the inclusion of a fish return device within the intake / outflow system for HPC. However, they require further details of the location of the fish return to ensure it is not within the vicinity of the thermal outflow (Payne, 2011).

3.1 Cumulative Impacts

The European Commission published a booklet titled *Managing Natura 2000 Sites: The Provisions of Article 6 of the Habitats Directive 92/43/EEC* in 2000(European Commission, 2000), giving detailed guidance on Articles 6(3) and (4) (European Commission, 2001) in 2001 and in 2007 a guidance document on Article 6(4)(European Commission, 2007) which was intended to 'further develop and replace' the section on Article 6(4) of the booklet of 2000((European Commission, 2007). The main aim of these documents was to ensure a coherent application of the Directive's provisions at national, regional and local level. Thus contributing to the establishment of sound management of the Natura 2000 network.

Habitats Directive attempts to ensure that those habitats that come under its jurisdiction per Article 6 are not significantly affected by plans or projects. Therefore, such plans or projects should not normally be authorised (Article 6(3)). The provisions of Article 6(4), which provide for compensatory measures, constitute an exception to those of Article 6(3) and must therefore be interpreted restrictively(European Commission, 2000), (European Commission, 2007). Thus in the context of Article 6(4), the question that needs to be asked is whether a plan or a project is likely to have a significant effect on the site concerned within Article 6(3) of Directive 92/43. Whenever the responsible authorities consider it probable that there might be a significant effect, they have to make an assessment. The requirement for an appropriate assessment of the implications of a plan or project is that there is a probability or a risk(Case C-127/02 *Waddenvereniging* [2004]at 43) that the latter will have significant effects on the site concerned(Case C-127/02 *Waddenvereniging* [2004]at 44). Furthermore any reasonable scientific doubt as to the absence of adverse effects on the integrity of the site must be removed *for authorisation to be given*(Case C-127/02 *Waddenvereniging* [2004]at 59) and Case C-239/04 *Commission v Portugal* [2006] at 31). In order to determine whether there is likely to be a significant effect, an appropriate assessment has to be made, according to Article 6(3) of Directive 92/43. The assessment under Article 6(3) of Directive 85/337(Dir. 85/337 (1985) OJ NO. L 175/40)only requires an assessment of a project on the environment in general, while the assessment under Article 6(3) is site-specific and must examine whether a plan or project adversely affects the integrity of the natural site in question: 'assessments carried out pursuant to Directive 85/337 or Directive 2001/42 cannot replace the procedure provided for in Article 6(3) and (4) of the Habitats Directive'(Case C-418/04, *Commission v Ireland* [2007] at 231). The

Commission documents suggest the type of considerations that should be taken into account for the assessment; in particular, the necessity to identify *all* potential impacts, including cumulative impacts, and to use the best available techniques and methods, to examine the most effective mitigatory measures in order to avoid, reduce or cancel the negative impacts and to use the best possible indicators for ensuring the biological integrity of the Natura 2000 network (Kramer, 2009). In the UK this aspect is reflected in regulation 61 of the Conservation of Species and Habitats Regulations 2010 (SI 2010 No. 490) which states that the competent authority, before deciding to undertake, or give any consent, permission or other authorisation for, a plan or project which—is likely to have a significant effect on a European site or a European offshore marine site (either alone or in combination with other plans or projects), and is not directly connected with or necessary to the management of that site, must make an appropriate assessment of the implications for that site in view of that site’s conservation objectives.

The Marine report (EDF, 2011b) made references to ecological impact from the HPC development with the majority deemed to be ‘minor adverse’. However, there are no studies assessing the cumulative effects of the ‘minor adverse’ and ‘moderate adverse’ impacts. An area of concern expressed by the Environment Agency (EA, 2011) was the, as yet unknown, potential impact from both Hinkley Point B (HPB) and HPC operating at the same time. This is a theoretical possibility with HPB due for decommissioning in 2016. Any delay in that decommissioning could result in a combined impact from both power stations.

Concerns regarding this oversight were flagged by EA in their report stating that “under regulation 61 of the Conservation of Habitats and Species Regulations 2010, if the combined impacts cannot be concluded to have no adverse effect on the integrity of the Severn Estuary SAC (Annex II fish species), then compensation may be required under regulation 66 of the Conservation of Habitats and Species Regulations 2010” (EA, 2011).

4 Nuclear Economics

The World Nuclear Association (WNA) believes that nuclear power is competitive against other methods of electricity production in terms of costs (World Nuclear Association (WNA), 2011) and Government consultants Mott MacDonald project “nuclear to be the least cost option in longer term, assuming DECC’s central fuel and carbon assumptions” (Mott MacDonald, 2010).

4.1 Uncertainty of Capital Construction Costs

In a 2008 White Paper on Nuclear Power, the UK Government originally forecast the construction costs of a new ‘first of kind’ reactor with capacity of 1.6GW to be £1250/KW (BERR, 2008). EDF Energy, who are consulting on plans to build 4 new European Pressurised Water Reactors (EPR’s) by 2025 have forecast the costs to be much higher. EDF Energy’s forecasts on their plans to construct two reactors at Hinkley Point, show costs of £9bn to produce a capacity of 3260MW, equating to a cost of £2760/KW (more than double the Government’s 2008 forecast) (EDF Energy 2010). Horizon Nuclear Power (a joint venture between E.ON UK and RWE) plan to invest £15bn in new facilities to generate 6000MW of electricity, with up to 3 new Pressurised Water Reactors (PWR’s) at Oldbury producing 3300MW (Horizon, 2011).

The capital construction cost of reactors is the greatest proportion of cost for nuclear power (70%) (Thomas,2009), with the fuel cost being relatively low. “Nuclear fuel costs make up only a small proportion (around 10%) of the overall plant running costs, compared to gas plant where fuel costs represent around 70% of running costs” (Horizon, 2011). As such, the assumptions made in the appraisal of such long term energy projects can have a huge effect on the financial viability and performance.

When comparing the economic costs and benefits of different technologies, it is important to have a common measure in which to express this comparison. The levelised cost expressed in £/MWh represents “the lifetime discounted cost of ownership of using a generation asset...expressed in cost per unit of energy produced” (Mott Macdonald, 2010). The 2008 White Paper forecast an overall positive Net Present Value (NPV) of £15bn, on plans to generate an extra 10GW of electricity using nuclear power. The central scenario used in this forecast (using a 10% discount rate) resulted in levelised costs of £38/MWh for nuclear power, although this varied between £31/MWh - £42/MWh when different discount rates were applied over a 40 year period(BERR,2008). Given the uncertainty surrounding the capital costs of construction, the levelised costs/MWh could be far higher than detailed in the 2008 White Paper.

The UK Government’s own 2010 study into the Severn Tidal Barrage scheme showed that nuclear power compared favourably against other low carbon technologies. However, the levelised costs/MWh projected by consultants Mott Macdonald for that study, were significantly higher than originally thought. Using the Government’s central scenario of a 10% cost of capital (to reflect the return required by a private investor), Nuclear Power was forecast to cost £69/MWh, as against Coal with Carbon Capture and Storage at £110/MWh and Offshore Wind at £129MWh(DECC 2010a).

However the modelling undertaken by Mott Macdonald produced a wide range of estimates dependent on the discount rate used, the start date of the project and whether the technology represented First of a Kind (FOAK) or Nth of a Kind (NOAK). Under their ‘medium’ scenario for a FOAK PWR, the projected cost increased to £3744/KW and then fell to £2913/KW as the learning curve took effect. Mott Macdonald caution however, that although the NOAK costs are much less, they are “not applicable this decade” (Mott Macdonald, 2010).

The DECC now estimates that plans to provide 16GW of new capacity in the form of 10 new reactors, will require some £40bn of investment (DECC, 2011). However, given the uncertainty of forecasting, this may be many billions higher.

4.2 Decommissioning Cost Concerns

The costs of decommissioning are also of key concern when assessing the relative competitiveness of nuclear power against other forms of low carbon energy. Decommissioning and waste disposal costs are forecasted as being approximately 9-15% of the capital construction cost of a nuclear plant (Semple Fraser 2011). In its Annual Report and Accounts for 2009/10, the Nuclear Decommissioning Authority (NDA) shows existing discounted decommissioning and clean-up liabilities of over £45bn(Nuclear Decommissioning Authority (NDA) 2010). Public concern exists that the costs of decommissioning are being stored up for future generations to deal with and that the burden will fall on the taxpayer. The 2008 White Paper makes clear that in addition to energy companies funding the development and building of new nuclear

power stations, the full burden of decommissioning and waste management will lie with those energy companies (BERR, 2008). The argument is made that decommissioning costs are factored into the initial investment appraisal process. Decommissioning and waste costs (of £1.27bn for an example individual reactor) were included as part of the Government's 2008 forecasts. When discounted over a 40 year period, these costs added only £0.31/MWh to the overall cost (BERR, 2008). However, Mott Macdonald's 2010 projections used a standard discounted increase of £2.1/MWh to account for decommissioning and waste costs in all scenarios, providing a levelised cost incorporating a "cradle to grave aspect" (Mott Macdonald, 2010). These wide ranging forecasts highlight the uncertainty surrounding the provision of adequate resources to fund these future decommissioning costs, whether from the energy companies themselves or ultimately through the taxpayer.

4.3 Proposals to Meet Decommissioning Costs

The UK Government is currently consulting on proposals to introduce a Funded Decommissioning Programme (FDP) which will establish a framework for financing the eventual decommissioning and waste management of the new nuclear facilities. Final guidance on this is expected to be published in the latter part of 2011. The purpose of the FDP is to ensure that energy companies "are able to meet the full cost of decommissioning and their full share of waste management and waste disposal costs" (DECC, 2010b). Each energy company will be required to set up an approved fund, making regular payments to contribute sufficient resources over the lifetime operation of the nuclear plant. An appropriate investment strategy will be required to generate sufficient returns to cover the estimated costs of decommissioning, waste management and disposal, with arrangements to be made in the event of shortfall in the fund value. However the fairly recent problems associated with endowment mortgages within the financial services industry, illustrate perfectly the problems of ensuring adequate financial performance of investments when projecting decades into the future. Volatile market performance, wide ranging growth estimates and highly uncertain future costs, create a difficult environment for the operation of the fund. The flaw within the endowment mortgage industry was overambitious growth projections and therefore highly prudent financial planning will be the key to successful accumulation of sufficient funds to meet the eventual liabilities. This of course is not an insurmountable problem given the financial instruments available for financial planning. Low risk, undated government stock with a current redemption yield of 4.91% could be employed to calculate the required annual contribution to the fund. Changes in the contribution would be required when yields change to keep the fund on track. Long dated government stock (15 years+ to redemption) could be used towards the end of the operation of the plants, with maturity coinciding with plant closure. Potentially, ultra-long dated stock running for say a 40-50 year period might even be available, although yields are not necessarily attractive over such a long time frame (Telegraph 2011). Fund assets will be periodically compared to the target value of the fund and appropriate action required should a shortfall be evident. Protection against a material shortfall may take the form of insurance, financial instruments or an upfront endowment (DECC 2010 b).

4.4 Uncertainty Surrounding Cost Assumptions and Potential Final Liabilities

The government will assume liability for the eventual spent fuel disposal, with the money from the fund being used as compensation for this service. The government proposes to set an index-linked 'Final Price' for the provision of this waste disposal service. This final price will be set at the end of a deferral period (30 years into the

operation of the plant) when it is believed that there will be less uncertainty over waste disposal costs (DECC 2010 c). This final price will take the form of a variable cost per unit expressed as £/tU (pounds per tonne of uranium). The government plans to introduce a maximum cap to this final price for the disposal costs of spent fuel, to create a degree of certainty for the energy companies. Using an example 1.35GW PWR operating for 40 years, this cap would be set at £1,104m (DECC 2010 c) based on a cap price of £978k/tU. However concern exists that the cap price may prove to be insufficient to meet the eventual waste disposal costs and that the taxpayer will end up heavily subsidising the industry. Analysis of NDA liabilities shows that spent fuel disposal costs are rising at 4.5% above inflation (Jackson, 2011). Using this information, it can be forecasted that the spent fuel disposal base cost (being used by the government) of £193k/tU will rise above the cap price by the year 2047. For a reactor operating over a 40 year period between the years 2020-2060, this will lead to a £131m shortfall in the amount necessary to cover the full cost of decommissioning and waste disposal. Jackson (2011) forecasts even greater subsidy requirements of £1,127m for a 60 year PWR. A second concern highlighted by analysts, is that the government's base cost of £193k/tU for the disposal costs of new nuclear waste is based on optimistic assumptions when compared to the disposal costs of existing nuclear waste. Jackson (Jackson, 2011) believes that "it is likely that disposal costs of Advanced Gas Cooled Reactor (AGR) and PWR spent fuels will be very similar" and that "disposal costs of PWR spent fuels may have been significantly underestimated and may need a public subsidy". This is evident when comparing the spent fuel disposal cost of AGR at £659k/tU against the government's base cost for PWR of only £193k/tU. This variation comes about from the government's questionable assumption that PWR spent fuel will cost 50% less to dispose of than AGR spent fuel, with a further 42% reduction applied for economies of scale arising from a 10 reactor new nuclear build programme (Jackson, 2011). In an independent report for Greenpeace, Jackson (Jackson, 2011) quantifies the underestimation of the actual disposal cost of spent fuel for PWR at £280k/tU, leading to a further required subsidy of £296m (for a 40 year PWR) or £445m (for a 60 year PWR). The uncertainties involved in both government and independent forecasts, cast doubt on whether by setting a maximum cap, the full costs of decommissioning and waste disposal will actually be met by the nuclear operators despite strong assurances from the government. Any indirect subsidy for the nuclear industry actually penalises other forms of renewable energy as they suffer cost comparison on a potentially unfair basis. The risk is, that in the desire to create energy security using the (so called) least cost option, more truly sustainable forms of energy may be overlooked with economic and environmental legacies left for the next generation to tackle.

5 Future Generations

We have up to now looked at the environmental implications and the economic aspects of nuclear energy related to this case study. The focus has been on the effects that new nuclear development will have for the current generation. However, in order to fully appreciate the issue of sustainability and legacies we need to turn our attention to the effects on future generations.

As mentioned earlier one of the groundbreaking aspects of the Brundtland report was putting the very long-term onto the environmental policy agenda as reflected in the Rio Declaration 'The right to development must be fulfilled so as to equitably meet developmental and environmental needs of present and future generations' (Rio

Declaration, 1992). This aspect was further reinforced by the Johannesburg Declaration which contained references to ‘the generations that will inherit this earth’ (Johannesburg Declaration 2002) and ‘a long-term perspective’ (Johannesburg Declaration 2002 at para 26). Much of the theoretical debate on future generations revolves around the feasibility of formulating duties and rights in respect of people who do not yet exist (Carter, 2001). Furthermore, it is still unclear how normative concepts like ‘obligations’, ‘rights’ or ‘harms’ may be interpreted when applied to the intergenerational context. It is suggested that in the absence of a coherent ethical theory most people tend to attribute moral importance to the lives of future generations and the discussion on the matter is typically a rights based one. If you declare universal human rights for every individual, why should individuals born tomorrow not impose obligations on present individuals? It seems appropriate to consider future people as right bearers—even in the absence of a clear definition of what this implies for the present generation practically and legally (Gopel, and Arhelger, 2010). Furthermore reference to future generations from a European Union perspective is moving gradually from the implicit and non-binding level to an explicit and more binding one. Comparing references with regard to future generations in the Commission's 1974 recommendation concerning the protection of birds and their habitats (Commission Recommendation 75/66) and that seen in the Aarhus Convention (Aarhus Convention, 1998). The former is a good example of an indirect reference to future generations reflected in the statement that “[p]ublic opinion is coming to consider migratory birds more and more as common heritage” (Commission Recommendation 75/66) and the latter 1998 Convention contains specific description of how rights of future generations transformed into present duties “every person has the right to live in an environment adequate to her or his health and well-being, and the duty, both individually and in association with others, to protect and improve the environment for the benefit of present and future generations” (Aarhus Convention, 1998 Art. 1). It should be noted that European environmental legislation to date has only referred to future generations randomly and inconsistently (Gopel, and Arhelger, 2010 pg 4).

6 Conclusion

As stated earlier future needs and preferences are themselves dependent on several factors and therefore may make it difficult to evaluate. However thanks to the spread of sustainable development policies there is emerging a fundamental norm concerning the relationships across generations which requires each generation to pass the planet on in no worse condition than it received and provide equitable access to its resources and benefits (Weeramantry, 2011).

In order for the nuclear energy sector to declare itself ‘sustainable’ its environmental and economic legacies must be assessed from the perspective of “*respecting the limits of the planet’s environment, resources and biodiversity*” (DEFRA, 2005) together with the cumulative effects of ALL the new nuclear power stations.

Indeed as Ambassador Frans Van Haren noted with regard to the responsibilities faced in relation to the environment:

‘We are its custodians. If we destroy the Earth wilfully through greed or through ignorance we will destroy life. There is therefore also a normative, or if you prefer, an ethical aspect to environmental policy formulation and planning’
(Van Haren, 2003).

Abstract

Lately, as the population in the big cities has increased, it has become necessary to pay attention to some environmental situations, perhaps not very harmful in past years, but that now can cause very serious and irreversible health problems to population. The industrial development in these urban areas has released very high levels of pollution, and it has become necessary that the regulations and public policies respond to the new environmental conditions, initiating a new culture of protection of the ecology.

Keywords:

ecology, environment, habitat, Mexico, pollution

1 Introduction

It is mandatory, indeed, that the government reviews the conditions in Mexico City, the ninth most populated urban area in the world. The lack of zoning restrictions and emission controls have aggravated the problems of overcrowding, a high pollution level, and the degradation of the health of the individuals. The government has promoted the issuance of legal ordinances, as well as the implementation of diverse actions and public policies, in order to prevent and control the problem.

2 The problem of the contamination in Mexico City.

A clean environment for a healthy development of individuals is considered, without a doubt, a right of those who live in this planet. The conservation and restoration of the ecological conditions that protect all the living species is an activity that must be important to all, government, individuals, and companies in general.

By nature, the species grow and develop in natural environments, and these provide the elements that encourage their procreation and perpetuity, with the unique reservation of the proper changes of the evolutionary process. The environment also can be managed, to a degree, so that some species, as in humans, can develop to fulfill their natural assignment and provide the satisfaction of their own needs. Independent of whether it is a natural or managed environment, it is the right and obligation to accomplish these actions and to maintain, whenever possible, the standard of life and development within a concept of dignity and well-being.

Cullet, (Cullet, 2011), considers that the right of the people to a healthy environment can be located in the context of the human rights. On this matter, he points out “that international environmental law and human rights law, have intertwined objectives and ultimately strive to produce better conditions of life on earth...they both seek to challenge universal that must often be solved at the same time at the individual and global levels...”

Without a doubt, a healthy atmosphere improves the well-being of individuals and tends to protect the primary value, which is life, as well as its natural or managed habitat for existence and subsistence. This can be translated into a human right, from this point of view.

At present, it is important to mention that the protection of the environment is not included in the Universal Declaration of Human rights. For that reason its legal standing, according to the doctrines and regulations, at this time, does not establish a legal instrument that allows its enforcement when the environmental laws are violated.

Although some countries do not regulate the preservation, conservation and restoration of the environment like a human right, it is necessary to state that the degradation and reduction in the conditions of the environment, can impact seriously on health, food and life, which is part of the Universal Declaration of Human rights, therefore, indispensable its observance so that the individuals reach a worthwhile life.

Mexico is a country that in the last 50 years has increased the industrial activity, as well as the growth of the population. Therefore, this is the subject of the highest priority for the government to protect the environment by setting the congruence in industrial activities, population increase and environmental protection.

In Mexico, since the seventies, the ecological subject has reached a paramount importance, and preoccupation at the same time. The topic of the environment had its highest world-wide level, and environmental laws were issued in all of the states. Many public actions were accomplished. Public policies were implemented by the Federal government as well as international treaties were signed, in order to avoid or control the contamination.

The important subjects that have been handled in this matter are, for example, the management of toxic waste from the industries; moderation in the use of automotive vehicles; official environmental opinions about polluting agents as a mandatory requirement for those who wish to initiate an industry; high fines to the violators of the ecological regulations; establishment of minimum quality standards for products and services in order to avoid contamination; national and local urban and ecological plans; proper zoning of industrial areas, etc.

The problem of deterioration of the environment in Mexico, was aggravated by the disorderly migration of people, from the rural areas towards urbanized zones, where they thought that it was easier to obtain the satisfaction of their needs that their native places of origin did not provide to them.

One of the reasons for the movement of farm workers to the larger cities was the inability to endure the rising costs and interest rates that the government organizations and banking institutions charged them for working the ground in better conditions,

reaching, therefore, a greater productivity. There is no doubt that the urban centers of the industrialized countries with their disproportionate population growth contribute to the deterioration of their environment. That is the reason why they need to take sufficient measures to avoid or to lessen the impact of an irresponsible activity, as well as a deficient environmental regulation.

Therefore, the Mexican legislation, from the seventies, began to see the necessity to maintain an environment healthy where their population can be developed under favorable conditions.

2.1 Regulation about settlements of human groups.

In 1976, the federal government issued a general law regulating the population to settle down irregularly across the country. Some changes, to date have been made to this original regulation. The intention was that the population centers, irregular and disorderly established in the different cities and towns across the country, would stop becoming a potential or real danger for the environment. As a result of mistaken or insufficient planning of the urban zones, the needs of the increasing population, such as education, housing, services, entertainment, food, employment and others were not addressed adequately.

In order to establish the modalities in the real estate zoning determining the form to take best advantage of the soil and the conservation and restoration of the environment, the Political Constitution of the Mexican United States was modified, creating the legal frame of this new subject.¹

The General Constitution,² was modified, as needed, in order to define the congruence between the federal government and the states for regulating the population across the country, setting a concurrent coordination among them all.

The law about the regulation of populace,³ has as a main objective, to plan the arrangement and stabilization of the population in the country, therefore, the establishment of the basic norms for the foundation, conservation, improvement and growth of the populated centers.

The figures about provisions, uses, reserves and destinies were created, as a means for the rational use of urban areas, now and in the future. It is in this law where the subject regarding the environmental protection is introduced, with the fundamental objective to maintain the balance of the ecological conditions and the conservation of the natural resources.

Therefore, as an indirect result of the control and stabilization of the population groups inside the Mexican Republic, it was an important and necessary issue to regulate the environmental protection. In the capital city, the Federal District, DF, the subject of the population density was regulated by the Law of the Urban Development of the Federal District, in 1999, with some reforms at the present.

By this law, the basics for the planning, programming and regulation of the territorial ordinances, as well as the development, improvement, conservation and urban growth in

¹ Article 27.

² Article 73, XXIX, C.

³ Original title: Ley General de Asentamientos Humanos.

the zone are taken into consideration. It also has the intention to protect, conserve, recover and consolidate the urban landscape of the DF and the elements that integrate it.

2.2 Environmental regulation

Mexico is considered a developing economy, and although its industry does not reflect high tech standards, it accomplishes several types of manufacturing activities, many of them produce a high index of pollution and are harmful to the environment by all kind of emissions, with irreversible consequences in the health, natural resources, and resulting, in some cases, with an alteration in the genetics in foods.

Therefore, there is a need for creating a new cultural behavior in the care of the environment. In that context, the Federal Constitution is modified once more in 1987 creating the legal framework for the environmental protection, preservation and restoration of the ecological balance.¹

According to changes in the Constitution, the congruency between the federal government and the states was made. This constitutional reform established the legal support, so in 1982 the General Law of the Ecological Balance and Protection to the Atmosphere², was issued by the Congress. The objectives of this law are:

- 1 To guarantee the right of the people to live in an suitable atmosphere for their development, health and well being.
- 2 To define the principles of the environmental policy and the instruments for its application.
- 3 Preservation, restoration and improvement of the environment.
- 4 Preservation and protection of the biodiversity, as well as the establishment and administration of the protected natural areas.
- 5 Prevention and control of the water, airborne and soil contamination.
- 6 To involve the people in the task of protection of the environment.
- 7 Establishment of measures of control and security to fulfill enforcing the administrative and criminal penalties that may be deserved.

It is important to notice that the DF is one of the most populated cities on the planet, with excessive urbanization, even in the areas considered as ecological reserves, and rating a very high contamination index.

As pointed out earlier, the migration from the farms to the cities, particularly towards the center of the country, contributed to the overpopulated condition. In the year 2000 the Environmental Law of the Federal District was issued, as a measurement to mediate the problem and to lessen its aggravation, which as of now, has not been effective in diminishing the emission of polluting agents in the zone.

The reasons are mainly the high population index, the lack of a committed environmental culture of the inhabitants, and suitable handling and implementation of the public policies.

¹ Article 73, XXIX, G.

² In 1971 there was a background of this law in Mexico City, it was the Federal Law to Prevent and Control Contamination

The capital city, the DF, is a political boundary, but the growth of the urban area has extended into other bordering localities and has formed a geographic continuity called conurbation, named technically as Metropolitan Zone of the Valley of Mexico.¹

The metropolitan zone, according to the last population census of 2010,² has around 21 million inhabitants, in a surface of 7815 square kilometers, which makes it an area of extreme population density, which means that there is an average of almost 2800 inhabitants per kilometer.³

These data is not totally indicative, because the more affluent economic zones have a smaller population density, unlike those of lower income that have bigger number of inhabitants by square kilometer. If the environmental quality is based on the population index, the geography of the city that is surrounded by hills and prevents the circulation of the air aggravates it. The establishment in zones of high risk, like gorges, the deforestation, the erosion of the ground, contamination of the water, the illegal toxic waste handling, the apathy of the public servants to enforce the ecological public policies, the excessive number of automobiles with high smog emissions, excessive and irregular operation of the water-bearing mantles that produce the drought of the wooded zones, lacking of technology in the treatment of the domestic wastes, as well as a lack of awareness of the inhabitants, it is easy to imagine the great environmental deterioration in the metropolitan area.

The main polluting agents emitted to the air in the capital city are ozone (O₃), sulphur dioxide (SO₂), nitrous oxide (NO_x), carbon monoxide (CO), lead (Pb) and other particulates of soot and dust, all of them highly harmful to the health of the people and almost all coming from automotive vehicles; besides the proliferation of factories in the city and constant maintenance work in the streets and the avenues.

An Atmospheric Monitoring System was established, by means of which a scale is set to measure the pollution levels in the DF, denominated Metropolitan Index of Quality of the Air, better well known by its abbreviations IMECA. This indicator measures from 0 to 500 the concentrations of polluting agents based on the repercussion that they can produce on the health of an individual when breathing the contaminated air.

A scale of 50 IMECA is equivalent to a quality of air not harmful to the health of the people, whereas 300 IMECA means serious damages to the respiratory system and to health in the general. It is considered highly contaminated air and in that case, the government of the city can implement emergency measures to control the overall impact. Also colors have been used to warn the people on the levels of the airborne contamination in the city. This means that the representative fraction of the IMECA indicates the pollution level of the air, and the color, the degree of risk to which the health of the population in the city is exposed.

The values of IMECA are as follow:

1 From 0 to 50 IMECA: The quality of the air is good and has yellow color.

¹ At the present, there are 55 metropolitan zones in all the country.

² Source: Nacional Geography and Statistic Institute, INEGI.

³ The whole country, continental and insular areas included, has a surface of 1 964 375 of kilometers squared, with a population, to 2010, of 112,3 million inhabitants.

- 2 From 51 to 100 IMECA: The air continues being acceptable and has green color.
- 3 101 to 150 IMECA: The quality of the air is not appropriate for certain sensitive groups, like people with respiratory or cardiovascular conditions; or children and elderly people. Outdoor activities that imply a vigorous exercise should be limited when the color orange is issued.
- 170 IMECA or more: The phase of environmental pre contingency is activated by the existence of organic or inorganic particles in the air. In a greater level than 175 IMECA, phase I of the program of environmental contingency activates.
- 4 From 201 to 250 IMECA, is represented by the purple color. In this situation, the quality of the air represents a serious danger for the health of the people.
- 5 More than 250 IMECA, represents a serious risk to health, and the government of the city will declare an environmental alarm and activate phase II of the environmental contingency program.

This subject is regulated by the Environmental Law of the Federal District, issued on 1996, whose main object is to protect the environment, as well as the limitation and control of contamination and the restoration and ecological conservation of the zone. By this law any action or omission, that become a potential or real risk to the health of the people, may be punished and a compensation can be claimed as a repayment of the deterioration caused by any work or activity, when the previous situation cannot be restored.

This law is innovative because it introduces a series of ecological concepts and introduces as a public policy, the figure of the environmental verification to businesses and factories, and the obligation to make a environmental impact report when opening.

3 Environmental programs

The public policies concerning the environment issued by the city government have not been effective in bringing about an acceptable air quality. Before that, the city government had created the Program of Environmental Contingency, with two important policies established in order to diminish the problem of the contamination.

These programs are as follow:

- 1 Program “Does not circulate today”
- 2 Program of mandatory vehicle verification

The program “Does not circulate today” initiated by the end of 1989 restricts the circulation of one fifth of the automobiles with registry in Mexico City and the surrounding urban area of the metropolitan zone, from Monday through Friday, on the basis of the last digit of the vehicle plate number.

Initially the program was implemented for winters only, subsequent to rains. That was when the phenomenon of the thermal inversion in the city was most significant. It was at that time that the number of polluting particles in the atmosphere was heaviest. In 1990 it was extended to a permanent program.

In this program, only the automobiles 1993 or newer that do not meet the limits of polluting emissions allowed and those of model previous to the 2004 destined to public service, stop circulating one day of the week. Emergency vehicles, or those whose

motors use liquefied petroleum gas, LPG, or vehicles used for the transportation of stolen, wrecked vehicles or vehicles needing repair, as well as in the case of people with permission by reasons for incapacity, are excused of this restriction.

For the operation of this program, a label of a determined color is adhered in the windshield to indicate what vehicles must not circulate on certain days of the week, from 0500 to the 2200 hours, as it is shown next:

Day	Last plate number	Color
Monday	5 or 6	yellow
Tuesday	7 or 8	rose
Wednesday	3 or 4	red
Thursday	1 or 2	green
Friday	9 or permissions and plates without a number	blue

A modification to the program is the “Does not circulate on Saturday”, effective from 2008, because a high level of IMECA is registered on Saturdays.

This program is for those vehicles of internal combustion and works as follows:

- 1 First Saturday of every month, vehicles with plates ending in 5 and 6, do not circulate;
- 2 Second Saturday of every month, vehicles with plates ending in 7 and 8;
- 3 The third Saturday of every month the vehicles with plates ending in 3 and 4;
- 4 Fourth Saturday of every month the vehicles plates ending in 1 and 2;
- 5 Fifth Saturday, when the month has one, the vehicles with plates ending in 9 and 0, as well as circulating permissions for cars that do not have a plate number.

The program is not mandatory on holidays and Sundays; all automobiles are allowed to circulate, unless a severe environmental contingency appears unusually. Also, the holograms with plates ending double 00 “zero”, or 0 “zero” are exempted of the program.

The program “Does not circulate today” is also for vehicles with registry in other states of the Mexican Republic or other countries. There is a table for them so they can follow the rules of the program. For those who do not obey the program “Does not circulate today”, fines can be levied and the automobile can be towed away, at their own expense.

b) The mandatory vehicle verification program “establishes the calendar and the rules according to which all the registered automotive vehicles of internal combustion in the Federal District will have their emissions tested during the first semester of year 2011, except the motorcycles, the automotive hybrids (gasoline - electricity) that by their technological characteristics are impossible to apply established protocols to them, according to the Official Mexican Norm NOM-047-SEMARNAT-1999, automobiles for collection and the agricultural tractors, the machinery dedicated to the mining and construction industries.”¹ are exempt.

The obligation to verify the vehicles extends to owners, possessors and in general, to any driver of an automotive vehicle. The units whose plates end in 00 “double zero”, are

¹ Official page of the Program of Mandatory Vehicle Verification of the Secretariat of the Environment of the City of Mexico, <http://www.sma.df.gob.mx/verificentros/> viewed the 25 of May of 2011.

verified every two years because they fulfill the required conditions to avoid the airborne contamination, according to the rules of the program.

For the operation of the mandatory verification, “verifying centers”,¹ have been created in the city, and they must adhere to the established protocols of the NOM.

Each verification center has cameras in order to prevent maneuvers taking place for disobeying the environmental dispositions that rule this program. The verification procedure consists of three stages:

- a) Visual inspection of the systems and devices of the vehicle such as filter of activated charcoal, air filter, seals of the oil and fuel tanks.
- b) Measurement of the smoke emissions and its coloration in order to determine the level of polluting agents that the unit produces.
- c) Measurement of hydrocarbon emissions and carbon monoxide, through technical tests.

Besides the verification, there are also some control operative actions in the streets and avenues, such as mandatory supervision and monitoring of the verification centers; inspection of the operation, procedures and proper handling of documents and official labels; accreditation of factories and evaluation of the technical quality.

4 Legal aspects of the environmental regulation in Mexico City.

As was mentioned before, the protection of the environment in Mexico is not considered a human right, but “a diffused” right. This means that the right for a clean environment is not entitled to a certain person, but to an undefined group of people, in this case, to all the inhabitants of Mexico City.

In other words, there is not an entitled person who can claim a legal standing to his right for a clean environment, and cannot demand it through a judicial procedure, since the environmental affectation appears at a general level, not individually or personalized.

This affectation does not occur to a single person but all throughout the world, which means that it has expansive effects towards the communities of a city. The environmental rights also denominated by “third generation” or collective rights of the towns or groups. The protection to the environment, in the Mexican legal doctrine, is considered a right, when claimed, does not have a procedural support that the affected people can make valid in a trial, even though an administrative regulation about environment exists.

The aspects that the environmental laws regulate in Mexico, have to do with periodic inspections by the administrative authorities to industries and the power to fine them, or close them, when the NOM² is not observed. Also, the deterioration of the environment can have criminal repercussions and the violation of the effective environmental legislation, can constitute a serious corporal penalty.

¹ Mandatory Vehicle Emission Verification Centers.

¹¹ Mexican Official Norm, NOM, are mandatory dispositions that establish standards of values, measures and characteristics, maximums and minimums to that they must subject the production of benefit or consumer goods of services, to guarantee the quality of the same. The NOM are regulated in article 3, fraction X of the Federal Law on Metrology and Normalization. The NOM are equivalent to ISO (International Standard Organization)

As mentioned before, by constitutional disposition, there is a legislative concurrence in the environmental regulation, therefore, it is considered a non centralized function, which means that each state is allowed to enforce the dispositions that its independent power considers advisable to protect the environment.

The capital city, DF, Environmental Law establishes several obligations for the individuals, for example, an obligatory official opinion about prevention, risk and impact to the environment of a new factory to be opened bordering the protected zones, or constructions in lots bigger than 5.000 square meters, or the management of dangerous and toxic residuals in companies with industrial activities. This regulation also establishes penalties for those that do not fulfill these dispositions, nevertheless, does not indicate a jurisdictional action for the rest of the people by which they can demand the reestablishment of the ecological order when the environmental laws and regulations are violated.

This means that it is an imperfect or incomplete right, since there is not a procedure that allows the inhabitants of the city to exercise this prerogative. In other words, there is not a guarantee in the environmental laws for claiming a violation to their right in this subject. The inhabitants of the capital city can only report to the authority any disobedience to the ecological regulation, but more severe and effective public policies are required, enforced and entitled to the population, in order to obtain and keep a healthier environment, providing all needed legal tools.

It is necessary to continue presenting populace campaigns for creating consciousness among the people and authorities for observing all environmental regulations, not because of a fine but by conviction; to enforce the recycling systems; rationing of natural resources; reduction in the use of automotive vehicles, and understand that this is the only place we have and it is our responsibility to take care of it.

CCS Directive Article 21: The Third Party Access- Comparative Study Between Finland and UK

Inga-Liisa Paavola¹

¹Faculty of Law
University of Helsinki, Helsinki
Finland

Email: inga-liisa.paavola@helsinki.fi

Abstract:

Carbon dioxide capture and storage (CCS) is a relatively new technology in the context of climate change mitigation strategies. Its legal and regulatory implications are not yet wholly developed. This paper takes a brief comparative look at the regulatory principles in Finland and UK especially relevant to the Article 21 of the CCS Directive that regulates so called third party access to CCS infrastructures. The Article 21 of the CCS Directive provides regulations of a third party access regime for both CO₂ transportation and storage infrastructure. Third party access regulations are essential when promoting co-operation between owners and potential users both on the construction and use of CO₂ infrastructure. What is more, regulations try to ensure that smaller third parties are not disadvantaged or overcharged when seeking access to storage sites or pipelines and that infrastructure resources are brought forward in a way that reflects likely foreseeable future demand.

Creating an effective fit for purpose regulatory regime is also crucial to the demonstration of CCS. National and EU legislation has been agreed to address this. An (European Union) EU CCS Directive contains requirements to ensure that third parties are able to access CO₂ transportation and storage sites in a transparent and non-discriminatory manner.

Keywords:

CCS, CCS Directive, Finland, Third Party Access, UK

1 Introduction

Creating an effective fit for purpose regulatory regime is also crucial to the demonstration of CCS. National and EU legislation has been agreed to address this. An EU CCS Directive contains requirements to ensure that third parties are able to access CO₂ transportation and storage sites in a transparent and non-discriminatory manner.

Arrangements for third party access are important because there are considerable up-front costs and economies of scale in pipeline construction. Access to CO₂ infrastructure could also become a significant competitive factor in the power generation and other high emitting industries. This could lead to a conflict between the efficient use of resources and wish for greater competition. There are currently no CCS pipelines or storage sites in the UK and CCS is not currently a commercially demonstrated technology. Economic factors will also be important in determining the timing and scale of investment in CCS infrastructure.

Arrangements for potential users to obtain fair, open and non-discriminatory access to carbon dioxide (CO₂) transport networks and storage sites are required because such access could become a condition for entry into, or competitive operation within, the internal electricity and heat market, depending on the relative prices of carbon and carbon capture and storage (CCS).

The current regulations involve the establishment, as required by Article 22 of the CCS Directive, of a dispute settlement mechanism to enable expeditious settlement of disputes regarding access to CO₂ transport networks and storage sites which recognises the transport and storage capacity which is available or can reasonably be made available.

In the UK, demonstration of the full chain of CCS – capture, transport and storage – at commercial scale is the vital next step, the various technological stages of the CCS chain have been shown to work but have not yet been demonstrated end-to-end at large scale on a power station. In Finland there are no storage places so the chain of CCS will be restricted to capture and transport. On the other hand, it is probable that the importance of effective transport will emphasize.

The introduction section should provide an overview of the article as well as the background and context of the paper. Starting from general to provide the ‘big picture’ moving down to specifics, this section should provide a rationale that justifies the research, i.e. why there is a necessity to conduct a research on this particular subject. This can be done by providing evidences of problems that needs solution and/or identified knowledge gap in a specific domain, level, geographical location, society, sector, industry, and so on supported by key references. As the response, a clear research agenda can be described specifying research aim and objectives in order to clarify the purpose of conducting the investigation.

Following this, the author needs to describe in general how the research can be or had been done to satisfy the aim and objectives, i.e. a brief discussion on the research methodology. This should highlight the research design, data collection methods and data analysis conducted or to be conducted in the research. Research limitations, scopes and boundaries should be explained as well to manage the expectations of the readers/audience.

The findings of the research at this stage have to be outlined here emphasising on the originality and general contributions of the investigation and preferably specific contributions of this paper. It is also a good practice to clarify who exactly will or expected to benefit from such investigation. This should be closely linked to the research rationale, aim and objectives.

2 Literature Review: Current CCS Legislation

2.1 Legislation in the UK

The UK already has a legal framework which covers pipelines. This is set out in the Petroleum Act 1998 (offshore pipelines) and the Pipe-lines Act 1962 (long distance onshore pipelines) in combination with the Planning Act 2008. While these Acts are not specific to CO₂, their provisions extend to pipelines carrying CO₂ and already go a very long way to meeting the Directive’s requirements in relation to pipelines. There is currently no equivalent legislation for CO₂ storage sites.

The existing arrangements for pipelines essentially allow regulatory intervention to require modification of a pipeline prior to construction where this would avoid the construction of an additional pipeline and also to secure access for third parties to existing spare capacity. In both cases the consenting authority is also able to determine the associated financial arrangements. In more detail, the existing legislation on pipelines prohibits the construction of a pipeline without consent, allows the consenting authority to require the modification of the design of a pipeline to provide additional capacity to convey the same or similar material or, for an offshore pipeline, to change its route, determines the financial arrangements for any modification, provides for the consenting authority to be able to secure access by a third party to an existing pipeline designed for the purpose of conveying the substance in question and set the conditions under which that access should be granted.

Under these arrangements the onus is on the parties to reach agreement on commercial terms on the joint development of, or access to, pipelines but if the process of commercial negotiation fails then the consenting authority has the power to intervene to ensure fair access.

These arrangements also protect the rights of pipeline owners. For example under the Pipe lines Act 1962, modifications to a proposed pipeline (by way of conditions in a pipeline construction authorisation) can be required only where the consenting authority is satisfied that there is evidence of demanding existing or likely to arise over the same or a similar route. And, when imposing requirements related to third party access to an existing pipeline, the consenting authority must be satisfied that granting such access would not prejudice the proper and efficient operation of the pipeline for the owner's use.

2.2 Legislation in Finland

In Finland the Act on the Redemption of Immoveable Property and Special Rights (603/1977) regulates situations where regulatory intervention is required to be done in the case of "common needs of the society".

According to Article 1, in the case of Redemption of Immoveable Property and Special Rights that law must be followed if no other regulation says otherwise. So far there is no other regulations that could meet the requirements of the CCS Directive and its third party access regulations.

According to the Article 3, immoveable property and special rights can be gained with the redemption or make restrictions to one's rights to use one's property.

Article 4 states, that redemption of the property or the special rights is allowed when common needs of the society requires so. It is not allowed when the same target could be reached with another means or if the negative consequences of the redemption are bigger than the profits.

The party that applies for the redemption can be a public or a private party; essential thing is the reason of common need of the society.

Both neither UK or Finland, there is currently no equivalent legislation for CO₂ storage sites. In order to transpose the Directive's obligations in relation to storage sites the intention is to introduce arrangements based on those for pipelines. The main additional burden from implementing the Directive will thus come from the extension of the

pipeline arrangements to storage sites. Depending on how those powers are discharged they could require a storage site to be expanded, or a third party to be given access to an existing site, and also determine the financial terms on which this will take place. Such an intervention could significantly change the financial risk profile for an investor in a storage project, especially in relation to contingent storage liabilities. The exercise of these powers will therefore be constrained (as they already are for pipelines) in order to ensure that the integrity of the infrastructure is maintained, the owners reasonable needs are protected and any determination strikes a reasonable balance between the interests of the parties and the risks they are bearing.

However, if the redemption would be done for building gaspipes or something that could be compared to those and no one opposes these plans or it is case of less significant redemption the allowance will granted by local authority(local surveying office.) Also if some other allowance also allows redemption at the same time other allowances aren't needed.

The preferred option is to extend existing legislation to bring them in line with the EU Directive on geological storage of carbon dioxide. Regulations of on pipelines and storage sites using the principles already contained in UK pipeline third party access legislation, including new provisions on making information available on capacity and technical specification to meet transparency requirements. The do nothing- option is not tenable as it would not implement the CCS Directive and thus leave the UK Government open to infraction proceedings.

It is believed that only in rare cases would a third party be seeking to access capacity on another's storage site at a time when its capacity was capable of being modified economically. A dispute over the terms for that access would be most likely if both parties were electricity generators and the owner saw advantage in restricting supply in that market by refusing access to a competitor. Whether that happens in practice would depend on the scale of the generators and which generation plant was expected to be price setting.

2.3 CCS And The Third Party Access From The Point Of View Of Competition

Where there is competition for limited capacity then the consenting authority is unlikely to require the owner to make the capacity available to a prospective user who values the capacity less than other prospective users.

In practice this means that in most cases the terms that would be determined by the Secretary of State are likely to be in line with those that would be offered by infrastructure owners were they to face effective competition from other infrastructure owners who also have sufficient spare capacity to store or transport carbon dioxide.

The terms determined by the consenting authority would also reflect the risks borne by the parties. For example, one of the issues that will have a significant impact on the cost of storage is the extent to which the contingent liabilities (that might arise in circumstances where the storage site requires remediation after it has closed for example) would be shared between the storage site operator and the originator of the CO₂ or the owner of the additional pipeline or storage site capacity. Whilst the CCS Directive makes the storage site permit holder legally responsible for such events, this would not stop the emitter and the storage site operator reaching agreement to share the cost in the unlikely event that such remediation was required. The extent that such risk sharing is practical will depend on the financial strength of the parties involved and the

availability of risk transfer instruments, such as insurance. Clearly the balance of risk in such circumstances would have an impact on the commercial terms of storage. Any determination by the consenting authority, where one of the parties assumed risks for the remediation of the site, would be very different from the terms in circumstances where those risks are shared. The consenting authority would use its judgement in such circumstances having regard to the specific commercial, financial and technical circumstances of the projects that come forward for determination.

In Finnish legislation, according to Article 5 of the Act on the Redemption of Immoveable Property and Special Rights the redemption can only be done with the allowance of the government.

However, if the redemption would be done for building gaspipes or something that could be compared to those and no one opposes these plans or it is a case of less significant redemption the allowance will be granted by local authority (local surveying office.) Also if some other allowance also allows redemption at the same time other allowances aren't needed.

The preferred option is to extend existing legislation to bring them in line with the EU Directive on geological storage of carbon dioxide. Regulations on pipelines and storage sites using the principles already contained in UK pipeline third party access legislation, including new provisions on making information available on capacity and technical specification to meet transparency requirements. The "do nothing" option is not tenable as it would not implement the CCS Directive and thus leave the UK Government open to infringement proceedings.

It is believed that only in rare cases would a third party be seeking to access capacity on another's storage site at a time when its capacity was capable of being modified economically. A dispute over the terms for that access would be most likely if both parties were electricity generators and the owner saw advantage in restricting supply in that market by refusing access to a competitor. Whether that would happen in practice depends on the scale of the generators and which generation plant was expected to be price setting.

CCS and clean fossil fuel technologies must be encouraged in the EU so that the Member States who choose to can keep carbon-based sources in their energy mix. The challenge facing European Union is the need to complete the fair internal energy market. Many national energy markets are still beleaguered by protectionism and these national reflexes keep energy infrastructure of the EU uncompetitive and possibilities to energy related activities unequal.

The Member States have their own competence to determine the rules of the CCS storage permits while they fall in the scope of energy policy. As there will be commercial inducements involved, it becomes a matter of internal market and competition too, in which the EU has an exclusive competence.

The situation concerning the division of the competences between the Member States and the EU is indefinite when it comes to CCS as a part of both competition and energy policies. When defining competences in energy policies, internal energy market and competition issues relating especially to CCS storage places, there could be more equal competition between energy companies at European level and CCS technologies, security and competitiveness of the energy supply in Europe can be guaranteed better.

According to the TFEU 26 Article The Union shall adopt measures with the aim of establishing or ensuring the functioning of the internal market and the internal market shall comprise an area without internal frontiers in which the free movement of goods and services.

Free movement of goods and services include also CCS-infrastructures and technologies. Reliable energy supplies at reasonable prices for businesses and consumers and with the minimum environmental impact are crucial to the European internal market and economy. The European Union has therefore identified energy as one of its priorities (COM(2006) 10). During the 1990s, when most of the national electricity and natural gas markets were still monopolised the European Union and the Member States decided to open these markets to competition gradually.

CCS-directive (Directive 2009/31/EC on the geological storage of carbon dioxide) sets criteria for the national competences to define eligibility to CCS storage permits in order to secure equal treatment of the energy suppliers. Member States do not need to set admission criteria for procedures for granting exploration permits, but where they do, they should at least ensure that the procedures for the granting of exploration permits are open to all entities possessing the necessary capacities. Member States should also ensure that the permits are granted on the basis of objective, published and non-discriminatory criteria. In order to protect and encourage exploration investments, exploration permits should be granted for a limited volume area and for a limited time during which the holder of the permit should have the sole right to explore the potential CO₂ storage complex. Member States should ensure that no conflicting uses of the complex are permitted during this time. If no activities are carried out within a reasonable time, Member States should ensure that the exploration permit is withdrawn and can be granted to other entities.

Chapter 5 of the CCS-directive regulates the third-party access to member states' own storage sites. Member States shall take the necessary measures to ensure that potential users are able to obtain access to transport networks and to storage sites for the purposes of geological storage of the produced and captured CO₂. Member States shall ensure that the procedures for the granting of storage permits are open to all entities possessing the necessary capacities and that the permits are granted on the basis of objective, published and transparent criteria.

The CCS-directive defines the common criteria in Articles 5-8 that must be obeyed when considering whether to accept potential users' exploration or storage applications. The access shall be provided in a transparent and non-discriminatory manner determined by the Member State. The Member State shall apply the objectives of fair and open access, taking into account the storage capacity which is or can reasonably be made available and the transport capacity which is or can reasonably be made available, the proportion of its CO₂ reduction obligations pursuant to international legal instruments and to Community legislation that it intends to meet through capture and geological storage of CO₂, the need to refuse access where there is an incompatibility of technical specifications which cannot be reasonably overcome and the need to respect the duly substantiated reasonable needs of the owner or operator of the storage site or of the transport network and the interests of all other users of the storage or the network or relevant processing or handling facilities who may be affected.

On the other hand, the right to have an access to another Member State's storage site does not have to be absolute or unconditional. As it is said in Article 8 of the CCS-

directive, transport network operators and operators of storage sites may refuse access on the grounds of lack of capacity. Duly substantiated reasons shall be given for any refusal. Member States shall take the measures necessary to ensure that the operator refusing access on the grounds of lack of capacity or a lack of connection makes any necessary enhancements as far as it is economic to do so or when a potential customer is willing to pay for them, provided this would not negatively impact on the environmental security of transport and geological storage of CO₂.

It must be acknowledged, that the geological CCS-storage sites may be subject to high level competition in the future because of their rather limited number that are not divided constantly through the Europe or the World. Naturally, this can have an effect on the functioning of the energy market in common. Hesitations whether there will be storage sites to utilize, may limit energy production with CO₂ emissions and due to this also technical development of CCS.

So, as a Summary of the proposed Third Party Access Regime it gives a frame that covers CO₂ transportation and storage infrastructure pre and post construction. It also suggests examples of access are modification of existing or planned infrastructure include increasing capacity, extending or adding taps to allow access. What is more, access should not be denied for lack of capacity or lack of connection if it is economic or the applicant is willing to pay for necessary enhancements. The first point is of course that the developer and applicant negotiate the terms of access. In UK, applicant can refer the issue to the Secretary of State for resolution but in Finland that is not confirmed yet.

3 Research Methodology

The starting point of the research is the national legislative environment of Finland. Legislative evaluation will make use of research methodology of legal dogmatics and environmental policy instruments research tradition. The problem-based point of view is highlighted in the sense that the research seeks to find a theoretical approach for analyzing the impacts of environmental legislation on innovation on the CCS technologies. The sources for the research are mainly the traditional sources of legal studies including sources such as national and international legal literature and scientific articles, the preparatory works of legislation and case-law. The challenges set by the evolvement of environmental innovations on legislation are studied also by means of legal comparison. Additionally interviews are conducted in order to fully understand the complex issues involved in innovation forces in the environment sector.

This research project centralized in legal policy instruments supporting CCS innovations in order to mitigate the climate change is a part of a planned larger scale programme concentrating on climate law and regulative means of mitigating climate change.

4 Findings and Discussion

If becoming more and more essential technology in the context of climate change mitigation strategies, it is important that CCS can be deployed without unnecessary regulatory hindrances.

Starting point for the CCS functions between the actors is surely voluntariness and freedom of contract. It might be expected that CCS actors will want to work together to exploit economies of scale in sharing CO₂ infrastructure and maximise the value out of the assets they have invested in.

There may however be circumstances where developers are more reticent about sharing their infrastructure, drag out negotiations and seek overly high terms. These could be as developers may be competing upstream with applicants and could achieve commercial advantage through refusing access. It may also be the case that a local monopoly develops which could exploit other potential users. As such, the opportunity to refer a negotiation to an independent party is likely to help support timely and fair negotiations. This will promote efficient use of infrastructure, realise economies of scale, help prevent multiple pipelines along similar routes and thereby reduce the environmental impact.

Failure to transpose these elements leads of course both Finland and UK open to infraction proceedings for not implementing the EU Directive on geological storage of carbon dioxide.

5 Conclusion and Further Research

Where there is competition for limited capacity then the consenting authority is unlikely to require the owner to make the capacity available to a prospective user who values the capacity less than other prospective users.

In practice this means that in most cases the terms that would be determined by the Secretary of State are likely to be in line with those that would be offered by infrastructure owners were they to face effective competition from other infrastructure owners who also have sufficient spare capacity to store or transport carbon dioxide.

The terms determined by the consenting authority would also reflect the risks borne by the parties. For example, one of the issues that will have a significant impact on the cost of storage is the extent to which the contingent liabilities (that might arise in circumstances where the storage site requires remediation after it has closed for example) would be shared between the storage site operator and the originator of the CO₂ or the owner of the additional pipeline or storage site capacity. Whilst the CCS Directive makes the storage site permit holder legally responsible for such events, this would not stop the emitter and the storage site operator reaching agreement to share the cost in the unlikely event that such remediation was required. The extent that such risk sharing is practical will depend on the financial strength of the parties involved and the availability of risk transfer instruments, such as insurance. Clearly the balance of risk in such circumstances would have an impact on the commercial terms of storage. Any determination by the consenting authority, where one of the parties assumed risks for the remediation of the site, would be very different from the terms in circumstances where those risks are shared. The consenting authority would use its judgement in such circumstances having regard to the specific commercial, financial and technical circumstances of the projects the come forward for determination.

In Finnish legislation, according to Article 5 of the Act on the Redemption of Immoveable Property and Special Rights the redemption can only be done with the allowance of the government.

However, if the redemption would be done for building gaspipes or something that could be compared to those and no one opposes these plans or it is a case of less significant redemption the allowance will be granted by local authority (local surveying office.) Also if some other allowance also allows redemption at the same time other allowances aren't needed.

The preferred option is to extend existing legislation to bring them in line with the EU Directive on geological storage of carbon dioxide. Regulations of on pipelines and storage sites using the principles already contained in UK pipeline third party access legislation, including new provisions on making information available on capacity and technical specification to meet transparency requirements. The "do nothing" option is not tenable as it would not implement the CCS Directive and thus leave the UK Government open to infraction proceedings.

It is believed that only in rare cases would a third party be seeking to access capacity on another's storage site at a time when its capacity was capable of being modified economically. A dispute over the terms for that access would be most likely if both parties were electricity generators and the owner saw advantage in restricting supply in that market by refusing access to a competitor. Whether that would happen in practice depends on the scale of the generators and which generation plant was expected to be price setting.

In Finland, this is how the CCS Directive is still not implemented. In addition to this as CCS becomes much more widespread in the future, competition is likely to be there and will develop which would limit the need for intervention. Still there is sufficient evidence that the benefits of a more interventionist approach is justified by the additional regulatory burden.

CCS and clean fossil fuel technologies must be encouraged in the EU so that the Member States who choose to can keep carbon-based sources in their energy mix. The challenge facing European Union is the need to complete the fair internal energy market. Many national energy markets are still beleaguered by protectionism and these national reflexes keep energy infrastructure of the EU uncompetitive and possibilities to energy related activities unequal.

The Member States have their own competence to determine the rules of the CCS storage permits while they fall in the scope of energy policy. As there will be commercial inducements involved, it becomes a matter of internal market and competition too, in which the EU has an exclusive competence.

The situation concerning the division of the competences between the Member States and the EU is indefinite when it comes to CCS as a part of both competition and energy policies. When defining competences in energy policies, internal energy market and competition issues relating especially to CCS storage places, there could be more equal competition between energy companies at European level and CCS technologies, security and competitiveness of the energy supply in Europe can be guaranteed better.

According to the TFEU 26 Article The Union shall adopt measures with the aim of establishing or ensuring the functioning of the internal market and the internal market shall comprise an area without internal frontiers in which the free movement of goods and services.

Free movement of goods and services include also CCS-infrastructures and technologies. Reliable energy supplies at reasonable prices for businesses and consumers and with the minimum environmental impact are crucial to the European internal market and economy. The European Union has therefore identified energy as one of its priorities (COM(2006) 10). During the 1990s, when most of the national electricity and natural gas markets were still monopolised the European Union and the Member States decided to open these markets to competition gradually.

CCS-directive (Directive 2009/31/EC on the geological storage of carbon dioxide) sets criteria for the national competences to define eligibility to CCS storage permits in order to secure equal treatment of the energy suppliers. Member States do not need to set admission criteria for procedures for granting exploration permits, but where they do, they should at least ensure that the procedures for the granting of exploration permits are open to all entities possessing the necessary capacities. Member States should also ensure that the permits are granted on the basis of objective, published and non-discriminatory criteria. In order to protect and encourage exploration investments, exploration permits should be granted for a limited volume area and for a limited time during which the holder of the permit should have the sole right to explore the potential CO₂ storage complex. Member States should ensure that no conflicting uses of the complex are permitted during this time. If no activities are carried out within a reasonable time, Member States should ensure that the exploration permit is withdrawn and can be granted to other entities.

Chapter 5 of the CCS-directive regulates the third-party access to member states' own storage sites. Member States shall take the necessary measures to ensure that potential users are able to obtain access to transport networks and to storage sites for the purposes of geological storage of the produced and captured CO₂. Member States shall ensure that the procedures for the granting of storage permits are open to all entities possessing the necessary capacities and that the permits are granted on the basis of objective, published and transparent criteria.

The CCS-directive defines the common criteria in Articles 5-8 that must be obeyed when considering whether to accept potential users' exploration or storage applications. The access shall be provided in a transparent and non-discriminatory manner determined by the Member State. The Member State shall apply the objectives of fair and open access, taking into account the storage capacity which is or can reasonably be made available and the transport capacity which is or can reasonably be made available, the proportion of its CO₂ reduction obligations pursuant to international legal instruments and to Community legislation that it intends to meet through capture and geological storage of CO₂, the need to refuse access where there is an incompatibility of technical specifications which cannot be reasonably overcome and the need to respect the duly substantiated reasonable needs of the owner or operator of the storage site or of the transport network and the interests of all other users of the storage or the network or relevant processing or handling facilities who may be affected.

On the other hand, the right to have an access to another Member State's storage site does not have to be absolute or unconditional. As it is said in Article 8 of the CCS-directive, transport network operators and operators of storage sites may refuse access on the grounds of lack of capacity. Duly substantiated reasons shall be given for any refusal. Member States shall take the measures necessary to ensure that the operator refusing access on the grounds of lack of capacity or a lack of connection makes any necessary enhancements as far as it is economic to do so or when a potential customer is

willing to pay for them, provided this would not negatively impact on the environmental security of transport and geological storage of CO₂.

It must be acknowledged, that the geological CCS-storage sites may be subject to high level competition in the future because of their rather limited number that are not divided constantly through the Europe or the World. Naturally, this can have an effect on the functioning of the energy market in common. Hesitations whether there will be storage sites to utilize, may limit energy production with CO₂ emissions and due to this also technical development of CCS.

So, as a Summary of the proposed Third Party Access Regime only gives a frame that covers CO₂ transportation and storage infrastructure pre and post construction. It also suggests examples of access are modification of existing or planned infrastructure include increasing capacity, extending or adding taps to allow access. What is more, access should not be denied for lack of capacity or lack of connection if it is economic or the applicant is willing to pay for necessary enhancements. The first point is of course that the developer and applicant negotiate the terms of access. In UK, applicant can refer the issue to the Secretary of State for resolution but in Finland that is not confirmed yet.

City University of Hong Kong, Hong Kong, China

Email: shalau2@student.cityu.edu.hk; bctam@cityu.edu.hk

Abstract:

The amount of CO₂ emission in the world has grown alarmingly, leading to a series of global environmental problems such as global warming and ocean acidification. All of these environmental changes threaten the existence of mankind. Since the construction industry accounts for 50% of the total carbon emission, holding down the CO₂ emission of the industry would be an effective way to slow down environmental deterioration. The construction industry in Hong Kong is developing rapidly accompanying with problems of energy consumption and carbon emission. This paper aims to compare the CO₂ emissions in the phases of construction process, maintenance and demolition, and estimate the carbon emission rate of different construction materials. Moreover, this study introduces some measures that the Hong Kong Government has taken to reduce carbon emission and their impact. Besides, several suggestions on potential effective methods are also introduced to help attain the objective of carbon reduction.

Keywords:

CO₂ emission, construction industry, structures of buildings, construction materials

1 Introduction

Greenhouse effect has become a critical problem around the world. The harms so induced include global warming, acid rain, rise in sea level, etc. Lives on the earth are threatened by all these phenomena. The primary cause of this bad situation is excessive greenhouse gas (GHG) emission, especially carbon dioxide (CO₂). Being regarded as one of the major carbon emission sources in the world, the construction industry has the responsibility to reduce the CO₂ emission. This study has summed up several major construction materials' impacts on CO₂ footprint and generalized the efforts that have been taken in Hong Kong for creating a sustainable environment. In addition, several potential measures which can help to slow down the GHG emissions are also discussed in this paper.

2 Literature Review

Greenhouse effect is one of the most serious problems threatening the existence of mankind on the earth. Being affected by the greenhouse gas, the global mean temperature rose by 0.74°C during the hundred year period between 1906 and 2005. Nine (2010, 2005, 2003, 2002, 2009, 2006, 2007, 2004, 2001) of the last ten years (from 2001 to 2010) rank among the 10 warmest years on record (HKO, 2011) (Figure 1). Moreover, greenhouse gas effect had led to global average sea level rose at an average

rate of 1.8 mm per year over 1961 to 2003 (HKO, 2011). The only way to suppress this crisis is to reduce the GHG emissions. GHG include water vapour, carbon dioxide (CO₂), methane (CH₄), nitrous oxide (N₂O), tropospheric ozone (O₃) and chlorofluorocarbons (CFC_s) (Buchanan and Honey, 1994). CO₂ is the most important one among these, which apportions 72% of the annual global GHG emissions. In order to slow down the environment deterioration, people around the world are pursuing effective ways to cut down GHG emissions. The Kyoto protocol limits national emissions to 13% above the 1990 baseline, and the EU Commission's "20-20 by 2020" policy commits Europe to cut GHG emissions by 20% by the year 2020 (Acquaye and Duffy, 2010). In French, a climate action plan was edited in 2005 which aims to reduce carbon emissions in the developed countries in 2050, in order to reach a global world reduction of 50% of the 1990 level. Additionally, the Inter-government Panel on Climate Change (IPCC) also stated that in order to constrain the global warming between 1.4 °C and 3.1 °C, a reduction of current annual GHG emissions by 52-90% by 2100 would be needed (Habert and Roussel, 2009).

Figure 1. Global Temperature Change
(Source: Hong Kong Observatory, 2011)

The construction industry is always regarded as the main source of GHG emissions around the world. A report (BIS, 2010) has revealed that the amount of CO₂ emission from construction is accounting for almost 47% of total CO₂ emissions of the UK. Li *et al.* (2010) also showed that construction is the third largest industry sector in terms of contributions to greenhouse gas emissions in the United States. Hong Kong, as a metropolis in the world, undoubtedly has to take the responsibility of GHG emissions, especially CO₂ emission. In 1998, Hong Kong emitted 0.1% of the global CO₂ production and 9% of which is produced by manufacturing and construction. From 1990 to 2005, the total carbon emission in Hong Kong has increased by 11% (Lam, 2007). Till 2007, the annual CO₂ emission in Hong Kong had reached 39,963,000 metric tonnes, which is 0.14% of the global total. Although carbon emission has been increasing in Hong Kong, its rate of growth has been lowered (Figure 2). In order to cut back carbon emission more effectively, efforts should be paid on anywhere which has the highest reduction potential. This study has compared CO₂ emission of different structures and construction materials for buildings. It also provided several methods to help reduce the CO₂ emission in Hong Kong, which can serve as a reference for construction projects.

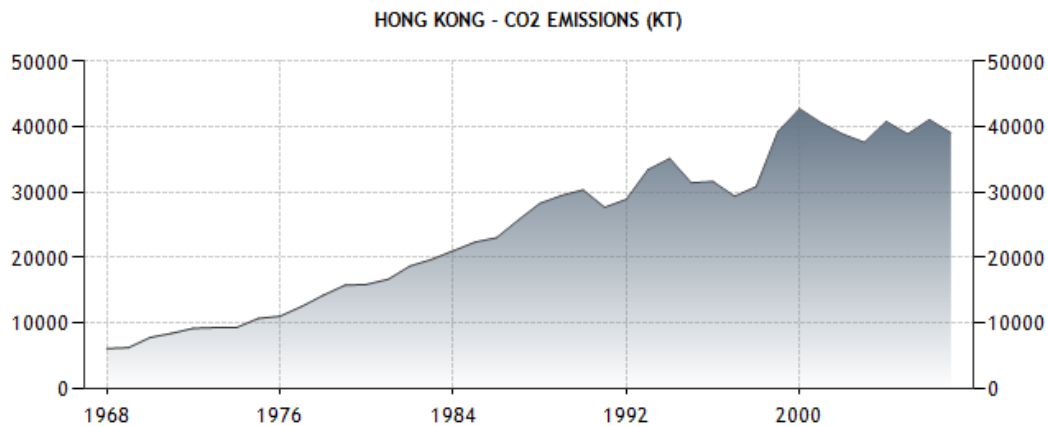

Figure 2. CO₂ emissions (kt) in Hong Kong
(Source: TradingEconomics.com, 2010)

3 CO₂ emissions of the construction industry in Hong Kong

The whole life-cycle of a building, from construction and maintenance to demolition, has certain impact on the environment, so the aggregate effects make it much more complex than any other products. In this study, each phase of the life-cycle of a building is analyzed in detail, in order to estimate the importance of each factor in contributing to CO₂ emission.

3.1 Construction process

Hong Kong is a dynamic commercial and financial centre with a large population of about 7.09 million at the end of 2010. The increasing population and the limited land resource (1,103 square kilometres) impel that most of the buildings in Hong Kong are of high-rise construction, leading to a high population density of 6,428 per square kilometre. Thereby, the common structural forms in Hong Kong are of reinforced concrete, steel and steel-reinforced concrete (SRC) structures.

3.1.1 Building materials

Reinforced concrete adopts rebars, reinforcement grids, plates or fibers to strengthen its tensile strength. Nowadays, the most common mode of reinforcement is the insertion of rebars, which are made of steel.

As described above, the main construction materials used in Hong Kong are concrete and steel although timber is also widely adopted. However, it is not possible to widely use timber as a structural material and timber structures are not suitable for high-rise construction. Therefore, in this study, wood will not be considered.

Concrete is a kind of composite material, of which the compositions are cement (commonly Portland cement), fly ash, slag cement, aggregate (crushed rocks and sand), water and chemical admixtures. Cement takes up the largest part other than aggregates. Nevertheless, the cement industry is one of two primary producers of CO₂, creating up to 5% of worldwide man-made CO₂ emissions, of which 50% is from the chemical process, and 40% from burning fuel (WBCSD, 2002). Mahasenan *et al.* (2003) indicated that yielding one tonne of cement will release 900kg of CO₂. Hence, the process of producing concrete contributes a lot to carbon emission. It is reported that the

embodied CO₂ of one tonne of concrete is around 100 kg (Sustainable Concrete Forum, 2010).

Another main construction material, steel, is an alloy that consists mostly of iron and with a carbon content between 0.2% and 2.1% by weight, depending on the grade. There are two ways to produce steel. The first one (blast furnace route) is accomplished using several interrelated processes including coke production, sinter production, iron production and steel production. Another one is achieved through an electric-arc furnace (EAF) using scrap steel as input (Climate leaders, 2003). The former method contains 25% of scrap steel while the raw material of the latter one is 100% of scrap steel. As a result, the CO₂ emitted by separated routes are different. Sandberg *et al.* (2001) showed that the global average of the total CO₂ emission by blast furnace route is 1.97 ton CO₂/ton steel, while by the EAF method, it is only 0.59 ton CO₂/ton steel. In order to make a clear comparison with other construction materials, the study will focus on the blast furnace route, and the EAF route will be further discussed in section 3.2.

As discussed above, reinforced concrete is made of both concrete and steel, the amount of carbon it generated per tonne has to be counted separately. Buchanan and Honey (1994) provided the data that the density of reinforced concrete is 2400 kg/m³, and the net carbon emitted from reinforced concrete is 182 kg/m³. Consequently, every tonne of reinforced concrete contains 0.08 tonnes of CO₂. Figure 3 shows the net carbon emissions from different construction materials.

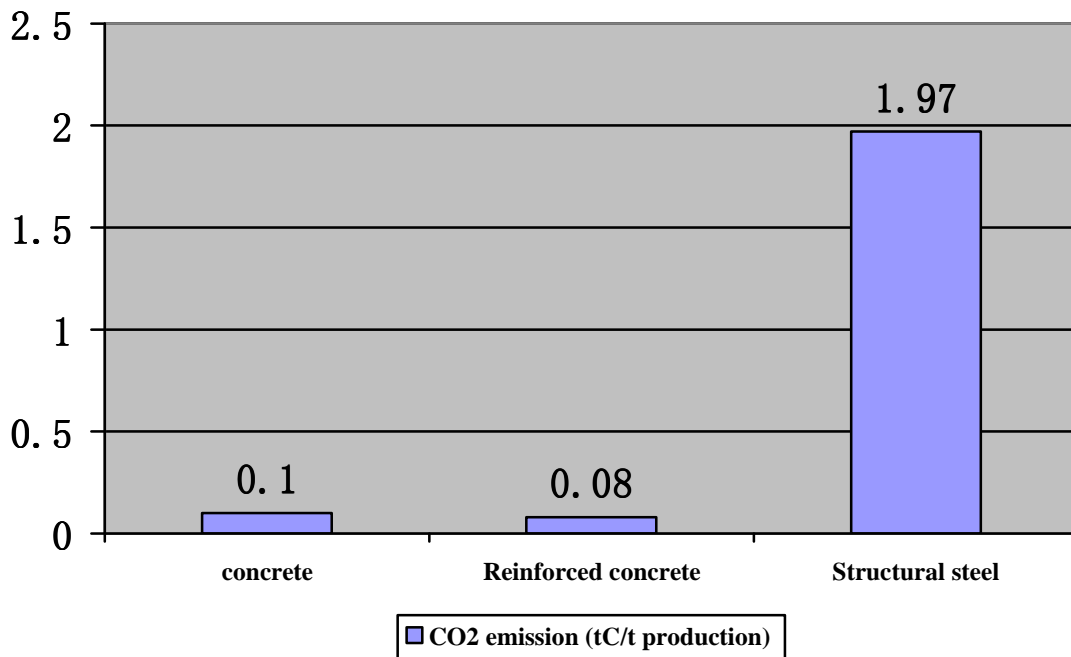

Figure 3. Net CO₂ emissions from manufacture of different building materials

3.1.2 Equipment and ancillary materials

During the construction process, utilization of equipment and ancillary materials generates CO₂ emissions. The specific activities which consume energy and generate CO₂ include: workers transportation, materials transportation, heavy machines transportation, equipment operation, and some temporary supporting measures such as heating and cooling, etc. The most highly consumed energies are electricity and diesel.

Electricity is crucial to the construction process, which supports most on-site equipment and help to create proper environment. There are mainly four modes of electricity generation: hydraulic electrogenerating, thermal power generation, wind power generation and nuclear power generation. In Hong Kong, thermal power generation and nuclear power generation are the dominating approaches. Census and Statistics Department (2010) reported that coal dominates the fuel mix for power generation (about 54%), followed by natural gas (about 23%) and nuclear power imported from the Mainland (about 23%). Coal burning power system has the largest carbon emission of all these systems. Conventional coal combustion systems result in emissions in the order of $>1,000 \text{ g CO}_2\text{eq/kWh}$, and current gas powered electricity generation has a carbon emission around half that of coal ($\sim 500 \text{ g CO}_2\text{eq/kWh}$), because gas has a lower carbon content than coal (POST, 2006). By contrast, nuclear power generation emits little CO_2 to the environment (about $5 \text{ g CO}_2\text{eq/kWh}$). As a result, the average carbon emission by electricity is $656.15 \text{ g CO}_2\text{eq/kWh}$. Since the average utility power for building construction per square metre is about 359 kWh , the impact on the environment is estimated at $235.56 \text{ kg CO}_2/\text{m}^2$.

Diesel is another energy source mostly used for materials, workers and equipment transportation and operation of some machines. In the research of Oka *et al.* (1993), they found that primary energy of 8-12 GJ is necessary to construct one square metre of floor area. Meanwhile, Acquaye and Duffy (2010) presented the fossil fuel emission factor of $0.073 \text{ t CO}_2/\text{GJ}$. Thereby, the average carbon emission brought by fossil fuel is $730 \text{ kg CO}_2/\text{m}^2$.

3.2 Maintenance and demolition

3.2.1 Maintenance of buildings

Building maintenance includes: maintaining the normal operation of the facilities (for example, lift and air-conditions), maintaining the power supply, repair of the inner structure and surface of the building, keeping cleanliness of the building, etc. During this phase, large amount of electricity has to be consumed. Suzuki and Oka (1998) made an estimate and obtained the result that the average annual energy consumption was determined to be $1.21 \text{ GJ}/\text{m}^2$, which is equal to $220.54 \text{ kg CO}_2\text{eq}/\text{m}^2$.

3.2.2 Demolition of buildings

To obtain the life cycle figure of carbon emission of a building, it is necessary to consider the work of demolition. In this phase, the recycling of construction materials has a great effect on carbon emission estimation. Most of the demolished concrete is transported to the landfill for disposal, but large amount of steel can be collected and refined by EAF.

Steel is the world's most recycled construction material and approximately 40% of all steel production is based on recycled scrap. In the construction industry, steel used in construction has a very high rate of recycling at the end of life. As reported by Galvanizers Association (2011), some 86% of structural steel is recycled as scrap charge used in furnaces and 13% is dismantled and used directly for new structures. It is easy to collect and treat the steel, and no matter how many time it is recycled, its inner properties will not change at all. Therefore, the average CO_2 footprint of steel of a construction activity is equal to only $0.02 \text{ t CO}_2/\text{t steel}$.

4 Measures to reduce CO₂ emissions

4.1 Efforts for CO₂ reduction

The Hong Kong government is striving hard to reduce CO₂ footprint and create a more sustainable environment. In order to provide a sustainable future and ensure that the future generations can continue to thrive in a clean and green environment, many departments have devoted efforts on supporting a sustainable environment and cut down GHG emissions, which include: Architectural Services Department (ASD), Development Bureau, Electrical and Mechanical Services Department (EMSD), Hong Kong Housing Authority (HKHA), Environmental Protection Department (EPD) and Urban Renewal Authority (URA).

In the aspect of energy efficiency and conservation, the government has drawn up many plans to improve energy utilization ratio and reduce pollution. For instance, the voluntary Energy Efficiency Labelling Scheme, Mandatory Energy Efficiency Labelling Scheme, Energy Efficiency Registration Scheme for Buildings, Mandatory Implementation of Building Energy Code and Scheme on Fresh Water Cooling Towers. These activities and schemes can enhance the energy utilization ratio effectively, reducing the energy end-use per GDP (HK\$ billion) by 32.81%, and the energy end-use per capita from 41.02 GJ in 1998 to 40.91GJ in 2008 (EMSD, 2010).

For the construction industry, the Hong Kong government has also made many efforts to promote green building construction. The policy of allowing private buildings to increase floor areas including green and amenity features for enhancing the living environment has been designed to create a more healthy and comfortable living environment for residents and cut down the workload of the building facilities. The government has also launched “the considerate contractor site award scheme” and “the green contractor award scheme” to encourage the private sector to make a sustainable design and save energy during the life-cycle of buildings. Wetland Park and the Stanley Municipal Services Building are two models of green buildings constructed by the government.

4.2 Other potential methods

In order to slow down the greenhouse effects and create a sustainable environment, more and more individuals and organisations have participated to search for effective methods. Some potential measures are introduced as follows:

First and the basic method is the production of a sustainable design for a building. A rational design, fully exploiting natural light for illumination and natural wind for ventilation, will not only save electricity for lighting and air-conditioning, but also enhancing the indoor air quality.

Secondly, select environment-friendly materials. These materials include recycled construction materials, renewable resources, and some newly developed materials with low or non-toxicity/ noxious gases. By taking full advantage of these materials, the GHG emission can be reduced as much as possible and resources could be saved. On the other hand, it provides a comfortable living and working environment for people as well.

One more useful way is to apply new power sources. Solar energy is a clean and renewable energy convenient to use. Nowadays, solar energy has been widely used in

different aspects of people's daily life; for example, solar water heater and solar powered auto. Solar energy could be used for electricity generation, heating and cooling, boosting chemical reaction etc. Since solar energy is not available at night and in the cloudy or rainy days, people have conceived good methods to store it. In the construction industry, solar energy has also been introduced into the architecture. Many countries have tried to combine this energy with their sustainable buildings, and have obtained some positive effects. However, the high cost of equipment and the geographical limitations limit the wide application of solar energy. More efforts are needed to solve these problems.

Concrete recycling is another useful measure to mitigate GHG emission. In the phase of demolition, concrete of buildings can be recycled. The recycled concrete can be used as the aggregate in new concrete, particularly the coarse portion (PCA, 2011); not only saving the resources consumption, but also save the cost of production. It is estimated that the cost of transporting concrete to the landfill can be saved as much as \$0.25 per tonne/mile, and the cost of disposal as high as \$100 per tonne can be eliminated (Concrete Network, 2010). Recycling of concrete has been adopted in many countries such as the United States, Japan, China and Taiwan etc. It is believed that more and more countries and districts will adopt this technology.

5 Conclusion and Recommendations

The construction industry, one of the major energy-consuming sectors, has to take the responsibility of mitigating GHG emissions in the world. In Hong Kong, the increasing population and limited available land resources constrain buildings to be high-rise. As a result, concrete and steel become the most popular construction materials. By comparing these two materials, it reveals that producing 1 tonne of concrete creates 0.1 tonne of CO₂. Additionally, little concrete can be recycled during the demolition period in Hong Kong. Correspondingly, the CO₂ footprint of steel production is 1.97t CO₂/t steel. However, 99% of the steel are renewable and put into use after reprocessing. Hence, the total carbon emission rate of steel of one building is about 0.02t CO₂/t steel, which is far less than that of concrete. Reinforced concrete, which is comprised of concrete and rebars (steel), has the carbon emission rate between concrete and steel, which is about 0.08t CO₂/t reinforced concrete.

During the life-cycle of buildings, electricity and fuels (mainly fossil fuel) generate large amount of GHG as well. Their CO₂ footprints are also estimated. For electricity, its carbon emission rate in the construction period is 235.56kg CO₂/m², and in the maintenance period is 220.54 kg CO₂/m², totally 451.60kg CO₂/m². For fossil fuel, it is 730kg CO₂/m².

The four materials discussed above are the main sources of the GHG emission. However, there are also many other influencing factors which could change the quantities of carbon emissions of buildings such as the environment around the buildings, some micro and local climates, and personal factor, etc. Therefore, when deciding on the use of the major construction materials, other measures from externality should also be considered.

During the last decade, Hong Kong has always been struggling for the carbon reduction and a sustainable environment. What is gratifying is that both the energy end-use per capita and carbon consumption per capita have declined comparing with ten years

before since more and more people attach importance to the greenhouse effect and greater efforts will be taken to create a low carbon environment.

Email: O.O.Lade@wlv.ac.uk; D.A.Oloke@wlv.ac.uk

Abstract:

Rainwater harvesting (RWH) in its broadest sense, is a technology used for collecting and storing rainwater for human use (including small scale industries) from rooftops, land surfaces or rock catchments using simple techniques such as jars and pots as well as engineering techniques. In most urban areas, population is increasing rapidly and the issue of supplying adequate water to meet societal needs is one of the most urgent and significant challenges. This work is part of a wider ongoing study to investigate the environmental engineering and socio-economic benefits/barriers of RWH in Nigeria. The purpose of this is to: appraise the various RWH technologies available nationally and internationally and evaluate the potential for their sustainable application in Nigeria and adoption. The review reveals studies on RWH have been mainly: potentials of domestic RWH to provide water in rural and peri-urban areas, recycling of storm water for household use such as WC flushing, household garden and car washing, recharge of groundwater through RWH, RWH systems for improving crop production. There seems to be few reports on the combination of rainwater and grey water to promote potable water savings, GIS-decision support tool for RWH and optimization of rooftop RWH system to provide energy saving approach for the community. The paper therefore concludes that RWH is an option where good quality fresh surface water or groundwater is deficient.

Keywords:

potential, rainwater system, implementation, rainwater harvesting, Nigeria

1 Introduction

Water is an essential element for all life and is used in various ways – for domestic and industrial purposes. It is also part of the larger ecosystems on which biodiversity depend. Water is a key resource whose unavailability, will lead to non sustainability of other resources, human and natural. However, climate change and a steady increased in industrial and agricultural activities have revealed that water as a resource is restricted in availability on an ad-lib basis (Madulu, 2000). It has been noted that as human population increases and people seek better living standards; as economic activities continue to grow in scale and diversity, the demand for fresh water resources will continue to grow (Vasudevan and Pathak, 2005).

Rainwater is a major source of fresh water and the activity of collecting rainwater directly for beneficial use or recharging it into the ground to improve groundwater

storage in the aquifer is known as rainwater harvesting. Dependence on groundwater to meet the growing demands has increased tremendously. When there is a gross imbalance between the natural recharge and extraction of water over a period of time, the decline of water table becomes significant with reduction of yield. The only option available for the present day society is to improve the recharge over and above the natural processes. RWH and recharge is one such promising option that has artificial recharge methods. It is estimated that with prudent artificial recharge schemes and waste water recycling, *circa* 25% of India's water requirements in 2050 can be met (Sakthivadel, 2002).

The world's population has reached approximately 6.6 billion in 2010. It is expected that under a medium fertility scenario, the global population will likely reach 8.9 billion by the year 2050 (Andrew –Lo, 2003). About 20% of the population currently lacks access to safe drinking water, while 50% lacks access to safe sanitary system (Turshaa *et al.*, 2000). RWH is of high importance in sustainable development, unlike other sources which may be subject to depletion or possible pollution. RWH is one of the renewable resources and have no adverse environmental impacts.

The purpose of the study is to appraise the various RWH technologies available nationally and internationally and evaluate the potential for their sustainable application in Nigeria and adoption.

1.1 Location

The study areas are three cities in Nigeria namely Ibadan, Lagos and Port-Harcourt selected on some basic considerations as shown in Fig. 2.

Ibadan is the capital of Oyo state ($7^{\circ} 23'16''N$, $3^{\circ}53'47''E$), situated in the south-western Nigeria. Ibadan was chosen because it is a residential area and groundwater pollution rate is also high. The cost of developing surface water is very prohibitive due to poor management of wastes which are usually dumped into streams and other surface water. Yet, being located in the rainfall rich area of the country with up to 1350mm annual precipitation, rainfall resources can be gainfully explored.

Lagos lies in the south-western Nigeria ($6^{\circ}27'N$, $3^{\circ}24'E$) and was selected due to her susceptibility to sea intrusion and prevalent industrial wastes resulting in groundwater pollution. These scenarios have made both groundwater and surface water resources to be expensive. Incidentally, rainfalls are usually torrential especially during the wet season leading to severe floods. Hence, tapping of rainwater will help alleviate this problem as well as providing potable water for the hugely populated city of Lagos.

Port-Harcourt is the capital of Rivers state in Nigeria, situated in the south-eastern ($4^{\circ}47'21''N$, $6^{\circ}59'55''E$). It is an oil refining city, being a main export earner of crude oil. Port-Harcourt was chosen because it is an oil exploration and industrial region and so there is the potential of high levels of groundwater pollution. The streams and rivers are also prone to contamination by oil exploration businesses. The city is one of the most abundantly blessed cities, rainfall wise in Nigeria with 2,300mm annual precipitation. Rainfall harvesting thus constitutes a veritable source of water provision and a means of flood control.

Fig.1- Map of Nigeria showing the study areas.

2 Objectives

The main objective of this paper is to review the various rainwater harvesting technologies available nationally and internationally and evaluate the potential for their sustainable application in Nigeria and also the potential of their uptake/adoption. It is envisaged that the work will develop a framework for improved and sustainable rainwater harvesting regime in Nigeria.

3 Research Methodology

A desktop study was carried out to review:

- (i) Rainwater harvesting techniques globally.
- (ii) Existing RWH techniques in Nigeria.

4 Findings and Discussion

4.1 Global Initiatives on Rainwater Harvesting

Africa

In Tanzania, only about 50% of the rural population has access to reliable water supply and over 30% of the rural water scheme is not functioning properly despite the significant investments in the provision of water between 1965-1985 (Kariba 2002; Madulu 2000). Kossa (2005) concluded that a participatory problem analysis performance and sustainable management of RWH will be greatly enhanced in Tanzania. In South Africa (SA) the potential of domestic rainwater harvesting (DRWH) has been explored to provide water in rural and peri-urban areas that conventional technologies cannot supply. A GIS based decision support system was developed by (Mwenge *et al.*, 2009) to indicate the areas of SA suitable for RWH and quantify its hydrological impact as runoff reduction for any selected percentage of adoption. Work on population growth induced agric intensification of Ewaso Ng'iro river basin, Kenya was conducted by Stephen *et al.* (2007). This study has led to the formulation of sustainable land and water resources management policies and strategies for water-scarce river basins. The social sector rehabilitation and development programme, 1993-1996 revealed that only 43% of the urban population of Zambia had access to safe water and sanitation. This led Lubinga *et al.* (2003) to study the potential of RWH in urban Zambia. The laboratory analysis of the harvested water showed that the water was suitable for drinking purposes.

Asia

In the Trans Indo–Gangetic plain (India), Ambast *et al.* (2006) helped solve the problem of groundwater decline due to indiscriminate use of groundwater for cultivation of rice-wheat. It was revealed that the recharge rate through this system is almost equal to a shallow cavity/filter well yield (about 11litres/second and its cost is about INR 10/100m³). Singapore has an annual rainfall of 2250mm, but water demand are constantly increasing due to industrial development and increasing population. A study was carried out on roof water harvesting from high rise building in which over 84% of the population lives (Adhityan 1999). The study reveals that a monthly saving of about \$14,449.78USD in water expenditure was realized with this system. The major cities in South Korea are experiencing water scarcity, which implementation of rainwater harvesting systems has the potential to mitigate. Ju *et al.* (2010) studied the microbiological and chemical characteristics of harvesting rainwater and reservoir water as alternative water resources in South Korea. The study reveals that all the harvested rainwater met the requirement for grey water and not for drinking water. In the city of Taipei, Taiwan Ming-Daw *et al.* (2009) developed a method for establishing the probabilistic approach relationship between storage capacities and deficit rates of rain harvesting.

European Union

In Sweden, water is still an abundant natural resource where only 0.5% per year of available resource is used. However, local drinking water supply system is vulnerable to shortages and water quality deterioration. Edgat *et al.* (2005) used a computer model to analyse use of rainwater for WC flushing, laundry, irrigation and car washing. The

analysis showed that rainwater will contribute to important savings in drinking water. Furthermore, the south and east of the UK are under water stress which will worsen with hotter summers and increased development. This led to a study by Hassell (2005) on solutions to increasing water shortage in these areas. The researcher concluded that RWH is a solution to the increasing water shortages, since its usage in buildings will reduce demand for potable water and reduces storm water problems in overloaded sewers.

Oceania

Australia is experiencing fresh water scarcity due to declining rainfall and increasing temperatures. The cost effectiveness on the use of rainwater tank for residential environment was carried out in Australia due to its serious water crisis (Vivian *et al.*, 2010). The research revealed that rainwater is an economic option for all households in the region. Integration of local water resources (rainwater, storm water and sewage effluent) was carried out in South Australia (Marks *et al.*, 2006) as a potential to increase population grown from 800- 2,400. Rainwater tanks was assess as adequate for all in-house uses excluding toilet flushing while a combination of reclaimed sewage effluent and harvested storm water resources was found adequate for non-potable uses, including toilet flushing, household gardens and public open space.

The Americas

In the USA, the influence of climatic cycles on water availability, increase in retirement communities in the semi-arid south-west and a drift in population density in coastal areas has led community planners to adopt the interaction of land-use with the quality/quantity of water supplies. Sekar *et al.* (2007) developed a spatially-explicit method to evaluate the cost of harvesting in the Taunton River Watershed in Eastern Massachusetts, USA. The results demonstrated that a spatially-variable harvesting strategy can be used to minimize runoff loss and to augment water supplies. Germany is not a water poor country as rainwater utilization in households has become widespread since 1980s. Research was carried out on the recycling of storm water (polluted rainwater from streets and courtyards surfaces) and its reuse as service water (Erwin 2007). The study revealed that with simple inexpensive treatment rainwater from polluted surfaces, such as traffic areas can be treated to a high quality service water for household use such as toilet flushing and laundry activities without hygienic risk and comfort loss for the user. Rainwater harvesting is abundant in most of Brazil. The potential for potable water saving using 62 cities was investigated (Enedir *et al.*, 2006). The study revealed that 34-92% has potential for potable water saving using rainwater depending on the potable water demand. They also conducted a study on the potential for potable water savings by using rainwater and reusing grey water in a multi-residential building composed of three blocks in Southern Brazil. The result of the study found grey water as the most cost effective system.

4.2 Rainwater Harvesting in Nigeria

RWH is a worldwide practice of meeting the increasing demand for fresh water. In Nigeria, it is practiced in the southern part as rainfall is widely for eight months in a year with mean intensity of 180-225cm. RWH is practiced at individual, household, community and occasionally local or state government level to augment dwindling water supply to urban centres. Oni *et al.*, (2008) examined the techniques and materials

used for RWH with a focus on the geographical spread of its use in Edo state, Nigeria. Their study reveals that majority of the people empty their tanks mid-way into dry season, suggesting that the current volume of the tanks is inadequate for water sustenance during the dry seasons. The influence of ageing roof on the quality of harvested water from various roofs in Nigeria was studied by Eletta and Oyeyipo (2008). The concentration of zinc and iron were found to be significantly different from the aged and the new roofing sheets and the sample collected from the source. Rim-Rukeh *et al.*, (2007) investigated the efficiency of pollutant removal in raw harvested rainwater through adsorption of a fixed-based filled with bone char in Agbor, Nigeria. Their study revealed that raw harvested rainwater subject to such treatment has a good quality compared to WHO standard for drinking water. A rainwater harvesting system was designed in Otukpa community, Benue sate, Nigeria using local materials Onoja *et al.*, (2010). Although RWH is a practice of everybody in this community, the supply is inadequate for their sustenance through the dry period of the year. A conceptual research framework was developed for this study as illustrated in Fig. 2.

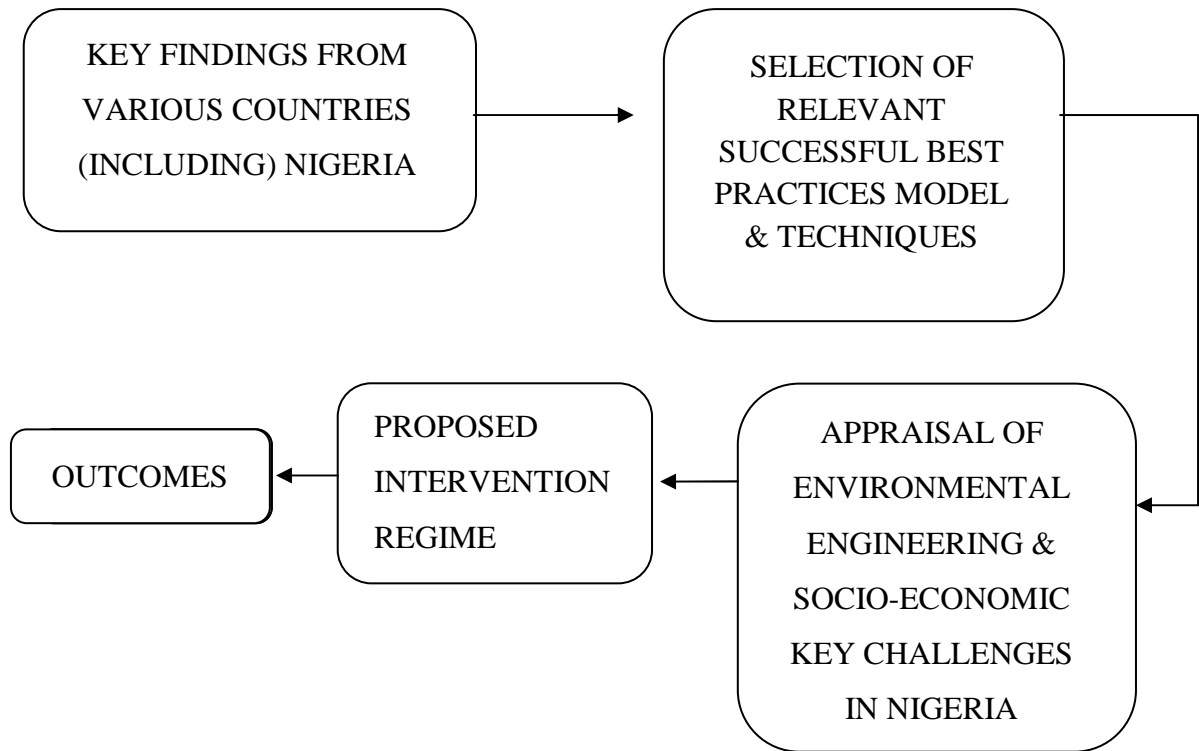

Fig.2- Conceptual Research Development Framework

5 Conclusion

The paper seeks to investigate the potential of RWH in Nigeria as part of efforts aimed at improving adequate water supply to meet societal needs and to ensure equity of access to water in Nigeria. Studies on RWH have been mainly: (1) Potentials of domestic RWH has been explored to provide water in rural and peri-urban areas, (2) Recycling of storm water for household use such as WC flushing, household garden and car washing, (3) Recharge of groundwater through RWH, (4) RWH systems for improving crop production. There seems to be few reports on the combination of rainwater and grey water to promote potable water savings, GIS-based decision support tool for RWH and optimization of rooftop RWH system to provide energy saving approach for the community. The paper therefore concludes that RWH is an option where good quality fresh surface water or groundwater is deficient. RWH system as a potential of serving as alternative water sources for increasing water supply. Although the work will primarily be focused on developments for the Nigerian context, it is envisaged that the output will engender wider application in similar developing countries and form the basis for future sustainable technology transfer to such countries from the developed world.

Financial analysis of the property market and property assets

Redlining in residential mortgages in Johannesburg, South Africa

Charles Muzi Nsibande¹

¹Bogoje Properties,
Johannesburg, South Africa

Email: m_nsibande@yahoo.co.uk

Abstract:

The term "redlining" was coined in the late 1960s by John McKnight, a Northwestern University sociologist and community activist. It describes the practice of marking a red line on a map to delineate the area where banks would not invest; later the term was applied to discrimination against a particular group of people (usually by race or sex) no matter the geography.

Even though the practice is widely reported in the United States, redlining occurs in many developed economies of the world, especially in the major cities of developed countries. The exposure of the practice in the United States is a result of the legislation framework that has been developed to combat redlining.

The aim of the research on the paper was to study redlining practice within the greater Johannesburg area. The aim can be summarised by the following objectives: firstly, to investigate the evidence of redlining in the greater Johannesburg area, to test its existence; secondly, to investigate the reasons why the areas were redlined; thirdly, to understand what the South Africa government and society did to combat the redlining practice.

Keywords:

mortgage, mortgage risk, redlining, reinvestment

1 Introduction

Redlining is defined as the practice of denying or increasing the cost of services such as banking, insurance, access to jobs, access to health care, or even supermarkets to residents in certain areas. Redlining is associated with a geographical area rather than a population profile. In the earlier days of redlining, a line would be drawn on a map, by a mortgage lender, showing an area where the lender would not grant mortgage bonds.

The main debate in the paper was between the mortgage lenders and the mortgage seekers. The debates were based on the reasons for redlining, why mortgage lenders practice redlining. The mortgage lenders' arguments were based on finance and default risk principles whereas the mortgage seekers based their arguments on socio-economic issues and their rights to access to finance in order to improve their economic status.

This paper is based on research carried out in 1997 and 1998. The findings, reported on this paper, are based on interviews with the stakeholders: mortgage seekers and mortgage lenders, which consisted of four major banks in Johannesburg.

The paper seeks to address three key issues:

1. whether there was redlining in greater Johannesburg
2. the reasons why mortgage lenders redlined certain areas
3. what the South African government and society did to eradicate redlining

2 Literature review

2.1 Existence of redlining

As far back as 1978, a study in Newcastle Upon Tyne, United Kingdom, by Kirby (1978) indicated that some districts in the city were entirely overlooked by Building Society Associations funds, usually on the grounds of the age of the properties. It was in fact commonly assumed that many Building Society Associations operated a system of Redlining whereby certain inner-city districts are regarded as off limits to investment.

In South Africa, in the 1990s, a similar practice, whereby the South African Weekly Mail (1993) was quoted, “a red menace is spreading through the leafy northern suburbs of Johannesburg: not communists in the shrubbery by bank Redlining policies in the figurative line demarcates a no lend area”. A study carried out by the Human Sciences Research Council (HSRC) in 1991 found evidence of redlining in Johannesburg and supported the inner-city phenomenon. The study found that redlining in greater Johannesburg was dominant in Hillbrow, Berea, Joubert Park and the Central Business District (CBD) residential, which are all within the inner-city boundaries of Johannesburg. Crankshaw and White (1991) in their paper, “Racial desegregation and the origin of slums in Johannesburg’s inner-city” also found evidence of redlining in Johannesburg. Crankshaw, *et al* noted racial bias and argued that allowing non-whites to live in the inner-city of Johannesburg contributed in the redlining of the “grey areas” by financial institutions before the new interracial and democratic government of 1994. Nsibandé (1999) found evidence, in his research, of the practice of redlining in the greater Johannesburg area.

In the United States of America, Holmes (2000) in his article “neighborhood racial composition and mortgage redlining: a nationwide analysis” found that redlining was also widely practiced in the USA across the whole country. Holmes study provided statistical evidence that neighborhood racial composition may affect the flow of mortgage credit in some regions. Squires et al (1996) have published many findings of the practice of redlining in residential mortgages in the United States of America.

From the above articles, it is clear that redlining is widely practiced in many areas around the world. This makes it necessary to seek an understanding behind the reasons for redlining in mortgage lending, why financial institutions practice it.

2.2 Reasons for redlining

2.2.1 Risk versus return

In modern finance theory, Sharpe (1964) explains best how an investor prices assets in uncertainty. The capital asset pricing model, Sharpe developed, explains that an investor requires higher returns from more risky assets as compensation for the additional risk taken on the more risky asset. The theory is widely applicable in pricing of investment instruments and can be applied to residential mortgages. In residential mortgages, applying this principle means, a mortgage lender will require a higher return from

granting mortgages in higher risk areas. Hence, areas that mortgage lenders perceive as more risky will be expected to yield higher returns for the mortgage lender to compensate for the additional risk a mortgage lender is taking.

2.2.2 Pricing of residential mortgage loans

In areas that mortgage lenders perceive as risky, the mortgages must be priced to an extent sufficient for the mortgage lender to compensate the risk being taken. In an ideal market, the mortgage lender could price the mortgages “high enough” to compensate whatever risk being taken in the lending to a risky area. However, legislation and market forces prevent the mortgage lenders from going “high enough” to cover all their risk. Therefore, mortgage lenders are limited to a cap on the interest or required return that they can charge on a mortgage loan. This means that if the mortgage lender has a limit or a cap, the mortgage lenders would not be sufficiently compensated which compels the mortgage lender to abstain from making that investment. This results in redlining of areas that are perceived to be too risky or areas where the mortgage lenders cannot charge sufficient interest to cover the additional risk they are taking.

A mortgage lender will only grant a mortgage loan if the interest charge compensate for the required return on the investment.

2.3 Combating redlining in the USA

In the United States, it is easier to investigate and charge the mortgage lenders because of the “home mortgage disclosure Act of 1975” and the “community re-investment Act of 1977”. These two laws work hand in hand. The disclosure Act requires Financial Institutions to release their mortgage lending records, including rejections. If there is evidence of redlining based on the data released under the disclosure Act, the community re-investment Act mandates the Financial Institutions (culprits) to provide access to Home Mortgage Loans through their local branches and service the local areas. Nowadays, there are other laws that support these two Acts like the Equal Credit Opportunity Act.

In recent times, there are several other organisations and State Institutions who monitor Financial Institutions’ Mortgage lending practices. To name a few, there is the Association of Community Organisations for Reform Now (ACORN); Green-lining Coalition (San Francisco group); and the Southern Christian Leadership Conference (SCLC). In recent years, these organisations have advised minority group in the United States to deposit their savings with minority banks to avoid being discriminated in cases where certain Financial Institutions proved to be practicing discrimination. With the help of these organisations, communities have managed to bring forward charges of redlining in Baltimore, Chicago, Atlanta and Los Angeles. According to Roberts (1994), in some instances, there has been compensation paid out to communities, as it was the case in Hartford. In this case, the Justice Department, Federal Reserve of Hartford, and the Federal Trade Commission ordered Shawnut National Corporation to pay one million dollars in a discrimination suit in Mortgage lending before they could be granted permission to operate in Hartford. Shawnut National Corporation had to find seventy to one hundred people to share the one million dollars compensation.

3 Research methodology

The research on this paper was based on interviews carried out in 1997 and 1998 in greater Johannesburg. The participants in the research were made up of mortgage

seekers, consisting of estate agents, home owners, valuers and property professionals, civic organisations and Council employees, and mortgage lenders, consisting of the four major banks in Johannesburg, namely, Standard Bank, ABSA Bank, First National Bank and Nedbank.

4 Findings and Discussion

4.1 Mortgage seekers

4.1.1 Estate Agents

The mortgage seekers all agreed to the existence of redlining in greater Johannesburg. Two contradicting views were expressed by the mortgage seekers as to why mortgage lenders were practicing redlining. One group found redlining policies justifiable while the other found the redlining policies detrimental to the real estate industry.

The first group believed that redlining policies were economic and financial measures applied by the mortgage lenders to protect themselves against unwanted and unnecessary exposure to risk. The Estate Agents believed that redlined areas were not conducive for investment and accepted that such areas should be redlined. They emphasized the importance of client profiles of the applicants rather than the area and believed the redlined areas were a result of poor credit worthiness. The Estate Agents emphasized that a good applicant with low default risk could get a mortgage bond in any area irrespective of whether the applicant believed an area was redlined or not. This view was supported by arguments made by mortgage lenders to be discussed in later sections of this paper. It was a hard line approach to the subject and it was worth exploring and debating with the Estate Agents who supported that view.

The latter group believed the mortgage lenders' redlining policies were not justifiable and were in fact worsening the condition and environment of the areas already redlined. The Estate Agents believed the mortgage lenders were critical players in unlocking the potential of areas and were controlling the destiny of suburbs in greater Johannesburg. The Estate Agents saw redlining as a form of segregation of areas and people. They saw mortgage lenders as "engineers" of urban slums through redlining. This line of discussion supports arguments made by activists and other human rights organisation that fight segregation of areas or people. Similar arguments have been made in the United States and the United Kingdom.

On the failure or non-existence of secondary mortgage markets in South Africa, the Estate Agents acknowledged that the current government had initiated positive measures but felt it was not enough to provide guarantees for mortgage lenders to lend in any area of Johannesburg. The Estate Agents felt more needed to be done to provide sureties for mortgage lenders.

4.1.2 Residents

The views of the residents of the inner-city supported the argument that mortgage lenders were to blame for all the redlining that was happening in their areas. They felt it was unfair and was a segregation measure by the Financial Institutions. However, it must be noted that the residents were not familiar with lending criteria applied by Financial Institutions in granting mortgage bonds or loans. They were also not familiar with default risks or the concept of pricing of risk that the Financial Institutions were applying.

4.1.3 Property experts

The valuer's opinions and the building inspector's opinion that value and depreciation of real estate in areas that were redlined was justifiable for redlining by mortgage lenders supports the arguments of the Financial Institutions interviewed in the research. Literature does not support the hypothesis that redlined areas are a result of negative collateral as it could not be proven in the United States that there was a correlation between falling real estate prices and redlining of areas. This was recorded in the study Swago (1996) entitled, "low cost housing developments have no effect on the values of neighbouring properties".

The experts' opinion vested more on the values of the real estate than on the attributes of the residents as they felt Financial Institutions considered extensively the future values of the real estate in granting mortgage bonds.

4.1.4 Property Project Managers

Project Managers had a better understanding of the subject of redlining in greater Johannesburg and also had better success in getting mortgage bonds in areas that were perceived to be redlined. The Project Managers had established firm relationships with the mortgage lenders and worked closely with them in raising funding for their projects in the inner-city of Johannesburg. The mortgage lenders even went further to advise them on how to better succeed in getting mortgage bonds in the inner-city. However, they were also faced with the same challenges as the residents, especially the deteriorating conditions of the inner-city of Johannesburg and the crime. They even went further in understanding the extent of exposure of the mortgage lenders in high risk areas like the inner-city of Johannesburg. None the less, they also acknowledged the existence of redlining in the inner-city of Johannesburg.

4.1.5 Civic Organisations

Civic organisations in greater Johannesburg followed the argument of the activists and the residents of the inner-city of Johannesburg. They believed that racial and economic segregation was a major factor in determining areas that were redlined. They followed their arguments with examples like, the fact that the majority of the people living in the inner-city, where redlining was prevalent, were Blacks and low income earners, hence the Financial Institutions found it justifiable to redline such areas on the basis of high default risk. Studies in the United States of America were inconclusive on determining the correlation between racial groups in the United States and higher default risks. Such findings are recorded in the study completed by Andrew Holmes in 2000.

However, Civic Organisations in South Africa were restrained as they could not prove their assumptions since Financial Institutions were not compelled to reveal their mortgage bonds applications' records. There were no laws in South Africa similar to the home mortgage disclosure Act of the United States.

4.2 Mortgage lenders/Financial institutions

The Financial Institutions took a hard line on the discussions of redlining. They defended their lending criteria on the bases of sound financial decisions, according to lending practices and government regulations.

The biggest problem in greater Johannesburg though, particularly in the areas that were redlined, was the poor demographic profile of the residents. This presented the Financial

Institutions with a case of poor real estate characteristics coupled with applicants who had poor credit worthiness, resulting in the areas being prone to be segregated and redlined.

The Financial Institutions all objected to racial bias on their practices and emphasized that their criteria was based on credit worthiness, irrespective of race. In South Africa, the racial bias is complicated by the demographic make-up of the income levels whereby most of the poor and low income earners are the Blacks and most of the rich and high income earners are the Whites. It is often easier to blame everything on race rather than income levels when one considers why certain racial groups are not getting mortgage bonds approval, for example.

5 What the South African government and society did to combat redlining

In the United States, redlining policies began in the 1930s and were based on racial bias. In the South African scenario, the Lending Institutions, together with developers, withdrew from the “black” townships in the 1980s (notably, in 1984 and 1986) because of boycotts to mortgage repayments. These boycotts were not directed at only Financial Institutions, but at all service providers in the “black” townships in protest against the government’s segregation Laws. This was at the height of the struggle against apartheid. The communities in the “black” townships developed a culture of not paying for services. The Financial Institutions withdrew from whole areas without appraisal of investment opportunities and risks. In a similar way, electricity would be switched off from whole areas without discrimination of who has paid or not. Lending to the “black” townships was considered off-limits.

In October 1994, the post-apartheid government made an agreement with the Financial Institutions to return to the Black townships is what was known as the Housing Accord. The accord can be summarised by the following statements made by the communities and the association of Mortgage Lenders, respectively, “we commit ourselves to an intensive campaign to change the hostilities between Financial Institutions, Local governments and communities and bring to an end the tradition of non-payment for rent and Bond Boycotts...”, and “greater accessibility of credit for lower income earners can dramatically reduce the numbers of families relying solely on government housing subsidy. Absent from the lower end of the housing market for some time, we representatives of the banks and broader financial sector commit ourselves to a resumption of lending on a scale large enough to allow a significant number of South Africans to become first time home owners”.

The accord was followed by the Record of Understanding (ROU) signed by the Government and the Association of Mortgage Lenders. The Financial Institutions pledged to provide fifty thousand loans to low income earners in the Black townships and the Government pledged their commitment to encourage the residents to repay the loans. The Government launched the “Masakhane” campaign. “Masakhane” means “let’s develop one another”.

In addition, the post 1994 Government took it upon itself to encourage businesses to re-invest in the inner-cities of all major towns in South Africa. The Government introduced tax breaks under Urban Development Zones (UDZ), passed under the Revenue Laws amendment of 2003, whereby inner-city areas in all major towns around the country

were demarcated and any investment companies make within the demarcated areas receives a tax break. This has encouraged re-investment into the inner-city of Johannesburg and there has been a surge in development projects from 2004 to 2010. There have been a lot of conversions of office buildings in Johannesburg to rental stock. Security has also been improved and the overall conditions in the inner-city have improved.

During the research, there were a number of Housing Trusts and a mortgage Indemnity Fund that was operating in greater Johannesburg. One of these funds was the Inner-city Housing Upgrading Trusts (ICHUT). Then there was the Mortgage Indemnity Fund (MIF). The main objective of the trusts and funds was to combat redlining and allow financial institutions to return to areas where they had stopped lending to. They assisted with projects' deficiencies and additional risks associated with redlined areas. The areas covered by the trusts and funds were the inner-city and the "black" townships where Financial Institutions had stopped lending in the 1980s and early 1990s. The trusts and the funds offered various forms of assistance including short term insurance and sureties (indemnity). The trusts and funds also engaged with the communities to try and stabilise the environments and bring stability to an area where lending had ceased. One way they carried out this was to encourage ownership and owner-occupancy in the inner-city. They aimed to bring up the owner-occupancy to about 30% as they believed higher owner-occupancy resulted in more stable environments.

The MIF's other objective was to eradicate redlining completely in Johannesburg and bring about an environment that was conducive to investment in the whole of Johannesburg. The MIF covered political risks and operated mostly in areas where there were rents and Bonds boycotts as a result of the resistance to Apartheid. They engaged with the communities and encouraged them to pay for services and for Bonds' instalments. They also assisted in ensuring there was rule of law and order in the areas and supported all court orders that were made in the areas which had previously experienced civil unrest.

6 Conclusion and further research

The research showed that redlining practise existed in greater Johannesburg. During the research the findings brought to light the reasons for redlining, why mortgage lenders were engaged in the redlining practise. The research also brought into light some strategies that could be used to combat the redlining practise. The research did not test if the measures taken by the South African government and society were effective in eradication the redlining practise in greater Johannesburg completely.

This research could be extended to other areas to determine if the redlining practise exists in those areas. The literature review showed that it is applicable to many areas around the world. More research, on strategies and measures for combating redlining, need to be made for effective eradication of the redlining practise.

Health and safety

Concrete Construction Safety: Investigating (Western) Australian Formwork Practice

Andrew Whyte¹ and Paul Brandis¹

¹Dept. of Civil Engineering,
Curtin University, Perth, WA,
Australia

Email: andrew.whyte@curtin.edu.au

Abstract:

Preventing accidents from occurring is a primary concern for the Australian construction industry. One area where incidents have occurred, at a more than acceptable rate, is in the use of formwork; recent formwork failures in Australia illustrate these are just as significant as a permanent structure failure. Whilst most formwork failures are found to concern differing inadequacies in practice, the occurrence of formwork failures may be prevented by targeting reform at their root cause; this paper presents the findings of detailed investigations examining the guidance and legislation governing formwork practice in Australia. An analysis of documentation governing Australian formwork practice, alongside industry perceptions provide a rounded and extensive view of the current situation. Findings highlight the limitations of using a legislative-based model of control, and also express the importance of formwork design education and training.

Keywords:

concrete, formwork/scaffolding, construction-safety, Western-Australian

1 Introduction

Accidents and work-practice incidents can be costly, time-consuming and damaging for company reputations. Even more concerning is that anytime an incident occurs there is a chance that human life may be impacted - even lost. To prevent incidents, safety in practice must be a primary thought for all engineers. The Engineers Australia Code of Ethics (EA, 2010) makes specific reference to the importance of health and safety in its charter, placing responsibility for this aspect above private interests, including profit. However, despite this emphasis, there are occasions when safety standards lapse and incidents occur. One area where incidents have occurred, at a more than acceptable rate, is in the use of formwork.

To ensure a high standard of practice is pursued by all engineers, this paper is concerned with current safety standards in Australian formwork practice. Standards Australia (SA, 2010a) defines 'formwork' as the "temporary works erected to mould and support cast in-situ concrete". Even though, as this definition indicates, formwork is 'temporary' it should not be subject to lesser safety standards than any permanent structure. Recent formwork failures in Australia illustrate the catastrophic consequences that formwork failures have and can be just as significant as a permanent structure failure. Whilst most formwork failures are found to concern differing inadequacies in practice, the occurrence of formwork failures may be prevented by targeting reform at their root

cause. Therefore, this paper presents the findings of detailed investigations examining the guidance and legislation governing formwork practice in Australia. In addition, it highlights the limitations of using a 'legislative-based model of control' and also expresses the importance of formwork design education and training.

The following discussions communicate existing knowledge on formwork practice, as well as a summary of the findings of various case studies of formwork failure in Australia. This is followed by an analysis of documentation governing Australian formwork practice, alongside industry perceptions to provide a rounded and extensive view of the current situation. Industry professionals interviewed in this investigation were senior representatives from: Global Construction Services; Foundation Engineering; Hawkins Engineering & Construction; Syntect Consulting; Engineers Australia National Industry Relations Management; Standards Australia Formwork Development Committee.

2 Background Information

Formwork as we know it today has largely been shaped in parallel with the major developments of concrete construction observed throughout the twentieth century. Previously perceived as 'merely a tool used in construction', literature suggests formwork is now being regarded as the complex works it is. This may be a reason for principal contractors' now largely taking project management roles and, subcontracting-out formwork practice (Ferguson, 2010). Construction technology has also developed over time and proprietary formwork systems are now frequently used in the Australian concrete construction industry. These systems are largely pre-engineered and prefabricated, leading to economies in the design and construction of formwork. However, studies have shown that assumptions made in the design of such systems are often inadequately communicated (Pallet, 2001). Care must also be taken in regard to the continued re-use of such systems, which removes the opportunity to seek economies in design on the premise of its 'short life'. With new entities becoming involved in the construction process, whether it is formwork suppliers or subcontractors, issues with cooperation, coordination and communication have become apparent.

Project management is complicated by the fact that its key parameters - cost, schedule, safety and quality, are often competing objectives. In the context of formwork, its use is on the critical path and it can contribute to as much as 60% of the total concrete construction costs (Hurd, 2005). Formwork will therefore often determine project success in terms of both schedule and budget. With most businesses driven by their bottom line, it is important to remember project cost-saving measures that lead to formwork failure defeat their own purpose. However, with the moral need to address safety subject to differences in opinion (Hinze, 2000), regulated guidance stands as the only consistent means to address safety.

Australian Standards are often perceived to be the figurehead litigation that holds engineers to account. However, this ideology comes with a false belief that compliance with Australian Standards outweighs the fundamental responsibility and obligation to provide a safe workplace in line with the occupational health and safety legislation (Travers, 2009). Safety of formwork practice in Australia is governed by state-based occupational health and safety legislation, which varies from state to state. Common to all legislative frameworks is the condition to comply with the national Formwork Standard, AS3610, for structural integrity requirements. Codes of practice are

sometimes provided as advice on acceptable ways of complying with the obligations under state legislation and should be adopted as a method of risk management. Under Western Australian legislation, AS3610 is referenced as a code of practice for formwork, however its suitability in addressing legal obligations is arguable. More concerning, the suitability of using AS3610 in its intended purpose as a design Standard is also open to debate. Research has demonstrated many flaws in understandings of formwork practice that have not been effectively communicated through the Standard (Ferguson, 2010).

3 Australian Formwork Failures

Although there have been significant legislative developments in formwork practice over the years, the level of safety in Australian formwork practice appears to have changed very little. In 1966 formwork for a bridge in Welshpool collapsed due to standards of design, which were deemed to be, at best, “barely adequate” (MRWA, 2010). This issue of standard appears to still exist as evident by an August 2010 bridge formwork collapse in Canberra, caused by trivial design flaws (SMEC, 2010). The fact that these incidents, decades apart, have occurred from issues in design standard highlights a pertinent topic for engineers, especially considering there have been incidents in formwork that have put lives at risk and cost construction companies millions of dollars. The following discussions provide a brief summary of the major findings of three recent Australian formwork failures.

3.1 Robert Sergi Bridge Collapse (October, 2000)

In October, 2000, a formwork collapse occurred during the construction of a bridge in Corio, Victoria. This collapse demonstrated the full destructive potential of formwork failures with the bridge now posthumously named to commemorate the fatality of Robert Sergi. A report released by the State Coroner’s Office (SCV, 2000) has found the collapse was largely attributed to false economies, with the principal contractor requesting a change in the formwork design to reuse material that was already in stock. Furthermore, it is believed that the principal contractor altered the headstock beams with little consultation, under pressure to get the job finished within existing timelines. Many other factors were found which demonstrated poor standards of design and construction practice; however these were not directly attributed to the collapse. The findings of this collapse drew attention to many important variables that influence the standard of formwork practice in Australia. Aside from the importance to recognise potential for false economies, key considerations were: when using subcontractors, the principal contractor cannot extricate itself from the works; and education and training of engineers needs improvement.

3.2 Christchurch Grammar School Slab Collapse (November, 2009)

In November 2009, a formwork collapse occurred during the construction of a suspended slab at Christchurch Grammar School in Claremont, Western Australia. No injuries were recorded. A report released by the Construction, Forestry, Mining and Energy Union of Western Australia (CFMEU, 2009) detailed the findings of preliminary investigations into the collapse. The report suggested that the formwork failed due to insufficient bracing, which led to buckling of the formwork standards (supporting column elements). Despite such trivial design flaws, it appears as though the collapse may largely be attributed to poor construction management, which allowed these flaws to remain unnoticed.

3.3 Gungahlin Drive Extension Collapse (August, 2010)

In August, 2010, a formwork collapse occurred during the construction of a bridge forming part of the Gungahlin Drive Extension works in Canberra, Australian Capital Territory. The collapse was catastrophic; 15 workers were injured and the project was expected to be delayed by four to six months. A report released by Snowy Mountains Engineering Corporation (SMEC, 2010), found the collapse was attributed to the main girders (spanning 13m) not being braced to prevent lateral movements induced by the three percent cross fall of the bridge deck. A number of additional shortcomings in the formwork design and construction practice were also found, with several differences noted between the ‘as-constructed’ details and the documented design. A concerning element to this case is that considering the collapse occurred after substantial completion of the concrete pour, it may follow that there has been several other cases in the Australian construction industry where formwork could have been considerably close to failure and no one was even aware. Although the collapse was attributed to trivial design flaws, this collapse again highlights the importance of maintaining a high standard of construction management.

3.4 Communicating Lessons Learned from Past Failures

Despite improvements in the industry over time, the above case studies demonstrate that formwork incidents are still occurring in modern construction. Given the periodic similarities between the failures, one could argue this may be due to the restrictions placed on communicating lessons learned from failures. Due to litigation and confidentiality under the Privacy Act of Australia, information available on construction failures is often limited and rarely covered, unless the incident is particularly dramatic or results in loss of life. The Office of the Federal Safety Commissioner (OFSC, nd) has worked with industry to develop case studies on various occupational health and safety issues, which present ‘anonymous’ findings and overcomes issues with the Privacy Act. However, beyond the immediate provision of the Privacy Act, one must also consider the need to preserve intellectual property rights, as well as the prevention of community apprehension. Thus, the release of information on formwork failures needs to be mediated, which may reduce the effectiveness of the system.

4 The Australian Formwork Standard, AS3610

The Australian Formwork Standard, AS3610, was last fully revised in 1995. Two years following its release, the Standards Development Committee for Formwork (BD-043) started reviewing AS3610 in an attempt to keep up with developments and innovation in the industry. Since then, the Development Committee has produced two drafts for public comment, one interim amendment and partially republished the Standard with the introduction of AS3610.1-2010 covering ‘Documentation and Surface Finish’ in February 2010. Despite draft revisions of AS3610 focusing on enhancing design guidance, proposed amendments to the Standard in this respect have failed to reach consensus. Consequently, the guidance governing Australian formwork design practice is limited to that provided fifteen years ago and the suitability of AS3610 is currently in doubt. While Part Two of the Standard remains undeveloped, further shortcomings exist through the coexistence of AS3610.1-2010 and AS3610-1995. Releasing the Standard in parts potentially has long-term benefits of improving the development process; however, both Standards currently cover the same material. This presents a high risk of confusion and could potentially lead to inconsistent practice.

Industry professionals actively involved in Australian formwork practice have presented alternative views on the suitability of AS3610 in its current state. However, many have expressed strong concern that change is needed or at least desirable. Continued development of AS3610 will bring the Standard up to date with current construction practice and ensure suitable guidance and accountability. Although drafted developments of AS3610 have largely focused on improving design guidance, it may be argued that a consensus would have been reached by now if any substantial shortcomings did exist. Regardless, it has been recognised there is always room for improvement; even if it is just to improve efficiency in practice. It must therefore be asked what is happening to AS3610 now?

Andrew Caswell (Caswell, 2010), a Senior Project Manager with Standards Australia, suggested there were no developments currently taking place, nor have there been any developments since the release of AS3610.1-2010 in February 2010. With recent changes in the way Standards Australia develop standards (SA, 2010b), it is necessary to propose a 'Net Benefit Case' demonstrating the positive impact the development will have. Given the recognised shortcomings of AS3610 in its current state, there are considerable grounds to pursue continued development of the Standard. However, with a lack of consensus in its development and 13 years to trial conflict resolution measures, it is likely that continued support of invested interests would no longer exist.

In addition to the abovementioned limitations of the 'Standards Development Process', there is also considerable resistance to future development of AS3610 for a number of other reasons. Industry opinion has suggested a large portion of the Australian formwork industry believe nothing is wrong with AS3610 in its current state, while another segment of the industry is opposing change due to the effects it may have on their competitive standing. On a more general note, the industry support for future development of AS3610 may come down to it being written in terms of 'performance-based' requirements. This is an issue as it has become apparent there is industry demand for a more user-friendly form of guidance. Thus, it may be appropriate to consider the development of alternative forms of guidance.

Parallel to recent developments of AS3610, a 'Formwork Design Handbook' (Ferguson, 2010) was drafted by active members of the Development Committee. The Handbook was initially intended to overcome the lack of consensus in the development of AS3610, allowing for the communication of good work that had been achieved by the Committee. However, its development identified many flaws in the Standard, which needed to be addressed first, therefore slowing the progress on drafting the Handbook. In line with the proposed changes to AS3610, the Handbook was then intended to replace the existing commentary to the Standard and align supplementary guidance with these changes. As a result of the draft Standard failing to reach consensus, and a change in the conditions of contract for the Handbooks development, the drafting of the Handbook is currently stagnant (Ferguson, 2010b). Given the handbook seems to more suitably address the industry demand, it may be appropriate to continue its development and publish it with the intentions of it being adopted as an "informal standard". In the absence of suitable guidance in the current industry, it is necessary to consider the actions that must be adopted by practising professionals to ensure safe formwork practice.

Compliance with AS3610 is a primary obligation; however it should not be the only requirement. It is impossible to expect an Australian Standard to address every conceivable situation. An engineer's defence therefore lies in their ability to prove they

have carried out their due diligence, highlighting flaws in relying solely on AS3610 regardless of its recent developments. However, given the doubt placed over the suitability of the Standard, there is increased importance for engineers to consider new research and developments that conflict with the provisions of AS3610 and make informed engineering decisions. This is to uphold a commitment to the Engineers Australia Code of Ethics and act on the basis of adequate knowledge (EA, 2010). To assist this process, it is suggested communication of new research and developments should be conveyed to the industry through an online database.

5 Western Australian Legislative Framework

In addition to its use as an Australian design Standard, AS3610-1995 is also referenced under Western Australian Regulations as a code of practice. Given Australia is governed by a 'State-based Regulatory Scheme', the legislative approach to governing formwork practice varies nation-wide. New South Wales and Queensland have both developed independent codes of practice to govern formwork practice and this arguably puts doubt over the Western Australian legislative framework given the State Government has not adopted the same approach. A comparison between AS3610 and the New South Wales and Queensland codes of practice indicated substantial shortcomings for regulating safety for formworkers. Given AS3610 is a 'performance-based' standard it tends to list the required outcomes rather than giving practical guidance on suitable processes to achieve those outcomes, as the interstate codes do. This is because Australian Standards are not legal documents and must be applicable on a national level. Thus, the use of AS3610 to provide practical guidance on meeting the statutory obligations set by differing state legislation is arguably inappropriate. It may be suitable to reference AS3610 within a code of practice, but it should not be adopted as a standalone document for such purposes. This has been supported by the opinions of various industry professionals, some of those actively involved in the Standard's development.

As part of a commitment to the Engineers Australia Code of Ethics to act on the basis of adequate knowledge, it can be argued that industry professionals practising in Western Australia should be aware of the interstate codes of practice. However, findings suggest this may not be an accurate perception. In any case, the choice to adopt interstate legislation relies on a value judgement about which legislation is most appropriate. This undermines the codes' power and transfers the governing authority to the engineer. Having a national-based legislative framework would reduce the risks associated with this 'personal choice' approach.

6 Education And Training

Although there is benefit in improving the guidance and legislation governing Australian formwork practice, the suitability of a legislative-based model of control is somewhat limited. Hence, the provision of education and training to support these developments is essential. Professional opinion has provided a general consensus that education of formwork design is an area that needs big improvement, with some concern expressed that it does not happen more often. Education may be provided through a number of different mediums; however it is argued that some are more suitable than others.

At an undergraduate level, there is clearly some benefit to the education of construction technology skills in general. However, current engineering graduates are rarely placed in a role where they are required to design and check formwork specifically. Thus, given the limitations in providing a comprehensive set of learning outcomes at a tertiary level, it is more appropriate to develop skills in other areas. These limitations are addressed through the graduate attributes set by Engineers Australia, which state an accredited tertiary education program must establish an expectation to undertake lifelong learning and a capacity to do so. The industry should not be relying on tertiary education to provide adequate learning in the formwork area, rather there is a prominent need for general industry-based education and training to compliment the skills learnt at an undergraduate level.

At the industry level, there is some degree of education and training available, however it is at a rudimentary level. Formwork engineers practising in large corporations are generally trained using in-house educational packages and on-the-job learning. However, independent practitioners are not so lucky and are largely relying on the dearth of research and literature that is available, as well as supplier information, the Australian Formwork Standard and past experience. 'Engineering Education', as a wholly-owned subsidiary of Engineers Australia, provides professional development courses to engineers practising in the industry. However, the technical content of these courses is limited and they tend to focus more on managerial and leadership type skills which are non-discipline specific. Technical courses are occasionally provided by the 'National Committee on Construction Engineering' (NCCE) as a specialist group formed under the Civil College of Engineers Australia. These courses rarely cover the topic of formwork, at present, however they are less formal and Alexandra Sparvell (Sparvell, 2010), the National Industry Relations Manager for Engineers Australia, has suggested that the NCCE are more approachable with proposals for new educational topics. In addition to education provided by Engineers Australia, there are some private organisations who offer short educational courses. However, there is some quality control issues associated with these programs, as they are not accredited and audited by Engineers Australia. Engineers Australia is therefore a key organisation involved in the development of professional engineers. However, there has been varying opinions presented on whether there would be sufficient industry demand to warrant such courses being run. In any case, there would certainly be some benefit in providing technical courses. Beyond technical understanding, it has also been suggested that implementing a formal education process would play an important role in the communication of lessons learned, as discussed earlier.

7 Conclusions and Recommendations

7.1 The Australian Formwork Standard, AS3610

To overcome the issues inherent in AS3610's development, it is recommended that the 'Formwork Design Handbook' continue to be developed and published as an 'informal' standard. Given the Handbook has a high focus on providing practical guidance; it is more suited to industry demands for a more 'user friendly' national design standard than what would be achieved through a revision of AS3610. Although this would not be published with the same distinction as the Australian Standard, it is a means to communicate recent research and developments. Nevertheless, this recommendation does not come with the premise that AS3610 can remain unchanged without limiting the virtue of the guidance governing formwork practice in Australia. Rather, it presents a fast-tracked and cost-effective solution to overcome the apparent issues. The Handbook

was already substantially completed by active members of the Formwork Development Committee and its development is stagnant, waiting on a suitable contract to determine the publishing rights. Standards Australia and the Concrete Institute of Australia have previously expressed interest in publishing the Handbook. To this end, it is recommended that both entities pursue the opportunity to publish the Handbook in consideration of the benefits of its development. This will allow the successful organisation to be at the forefront of improvements in contemporary formwork practice across Australia.

7.2 Western Australian Legislative Framework

Given substantial concerns with the current Western Australian legislative framework, it is recommended that the Australian Formwork Standard should not be adopted as a code of practice. Although referencing AS3610 as a code of practice under State legislation is better than the choice to provide no code of practice, its adoption falls considerably short of 'best industry practice'. Thus, it is recommended that the Australian Government consider the implementation of national-based occupational health and safety legislation. This will ensure consistent practice throughout Australia and remove the need for industry professionals to make value judgements on which legislation provides the most adequate and rigorous standards. It is recognised this investigation into formwork practice is insufficient to determine the full viability of this solution. It is therefore suggested that future research should aim to provide a suitable 'cost: benefit analysis' of such a progression taking place.

7.3 Education and Training

To support the developments in guidance and legislation suggested above, it is recommended that formwork design education and training needs to be provided at an industry level. Given Engineers Australia has an established role in providing opportunities for professional development; it is argued that it is the most appropriate entity to do so. Furthermore, this will allow for the provision of suitably accredited courses that are subject to quality auditing. Engineering Education courses are rarely targeted on technical aspects of discipline-specific topics. Therefore, it will be more suited to foster the development of education on formwork design through the National Committee on Construction Engineering (NCCE). Provided that Engineers Australia is a 'not-for-profit' organisation, this would require a visible industry demand. In addition, it would also be necessary to source industry professionals willing to present at such seminars. To address the former need, it is argued that the most appropriate way forward would be for Engineers Australia to recognise the need for such education, demonstrated through the findings of this study, and conduct a national survey amongst its database of members to assess the industry demand. If found suitable to warrant the development of education courses on formwork design, industry presenters could then be sourced through industry bodies like the Standards Australia Formwork Development Committee or, more generally, the National Register of Chartered Professional Engineers. In addition to the provision of education and training courses generally, it is also recommended that the NCCE should supplement this process with the communication of new research and developments. It is suggested this service could be made available through an online database linked to the Engineers Australia website. To assist this process, it is recommended that the NCCE could subcontract out the collection of modern research to members of the Formwork Development Committee, who are already actively involved in sourcing new information.

Factors in personal health and safety (H&S) of women in the South African construction industry explored from the perspectives of both genders

Jane English and Paul Bowen

Abstract:

The construction industry in South Africa is short of skills. Legislation tasks the industry with increasing the profile of women in traditionally male workplaces. Using empirical data regarding the environments in which women work in the construction industry, the relationship between women, the working environment and their susceptibility to HIV infection is explored. Data were gathered using a combination of questionnaire surveys and detailed face-to-face interviews to gain perceptions of employers and site-based employees. The findings are discussed in terms of personal on-site health and health and safety (H&S) and transport to and from site. Female employees desire greater staff supervision and security on sites for their health and H&S. H&S in women working together – at least five in a group - on site is seen as a prerequisite for minority groups of women to perform successfully. Women are perceived by men more than women to be at greater risk of sexual harassment on site. Age of respondents plays a factor in that younger females are less concerned about male gender defined attitudes than are older women, and young women employees, more than any other group, perceived an advantage in adopting macho behaviour as a potential barrier to male gender attitudes. Further advantages in women workers on site was that female workers are less likely to accept unsafe site conditions than are men. However, whilst personal H&S of women on site was considered to be less than optimal, transport to and from sites was not considered problematic. The findings illustrate the risk of exposure of women working on construction sites to contracting HIV and AIDS.

Keywords:

construction sites, HIV and AIDS, South Africa, women's health and safety (H&S)

1 Introduction

This paper considers the risks that women entering and working in the South African construction industry would be exposed to, particularly H&S, and HIV and AIDS. The topic is explored first through a background to women employed in the construction industry in South Africa; secondly, through factors which may inhibit or increase the spread and effects of HIV/AIDS on the workforce; and thirdly, through the empirical study.

The Construction Industry Development Board (CIDB) is mandated to involve women at all levels of the construction industry, yet both unskilled and skilled labour are in high risk HIV/AIDS categories (Development Works, 2002; Ahwireng-Obeng and Akussah, 2003; CIDB, 2006; Bowen *et al.*, 2008a). The issues facing South Africa in this drive for inclusion have been looked at internationally and over time (Sommerville *et al.*, 1993; Gilbert and Walker, 2001; Gurjao, 2006). Motivation for increasing the presence and profile of women in construction, perceptions of the industry by female school-leavers, male attitudes and dominance and low retention rates of qualified women have all been considered.

In South Africa, where there are many small and micro enterprises which offer ease of entry into the workforce, more than half the workforce is employed informally (Horwitz, 2000; Haupt *et al.*, 2005). Early studies in HIV/AIDS relate that the informality of an industry – as in unstructured employment and working practices – has a negative impact on the spread of the disease (Barnett and Whiteside, 2002). H&S and H&S, particularly HIV/AIDS, is an issue for the construction industry. Women are more vulnerable to contracting HIV/AIDS than are men because of their more depressed economic state (Kanabus and Fredriksson-Bass, 2008). Findings from global studies were that there are approximately 12 million women worldwide living with HIV/AIDS compared with approximately 8.3 million men – an indicator of women’s more socially-vulnerable position (Tallis, 2008). Whilst the disease has stabilized in Sub-Saharan Africa with about 50% of the population being infected, Africa carries 67% of all the deaths attributed to AIDS globally (UNAIDS, 2008).

Africa is no exception to these conditions and HIV/AIDS has become a pandemic in many African countries, moving from high-risk groups such as sex workers and injection drug users to the general population, largely because of pervasive gender inequality (Women and HIV/AIDS, 2006). Unsurprisingly, South Africa has had alarming statistics for the spread of this disease. By the end of 2005, 1.4 million people had died since the start of the pandemic in South Africa. Out of the population of 48 million, some 5.5 million (11%) were described as HIV positive (Dorrington, 2006). According to research, after mining and transport, the construction industry is considered to be the most affected by the pandemic, while also being the least responsive (Bureau for Economic Research / South African Business Coalition on HIV/AIDS, 2004; Meintjes *et al.*, 2007).

Thus, personal risk to women is a factor which must be considered by the South African construction industry as part of their endeavour to encourage women to join the industry. At the end of 2003, that is 10 years after the arrival of democracy in 1994, a 53% unemployment rate among black South African women overall was recorded (South African Institute of Race Relations, 2002/2003). Yet, many of these women are heads of households or *de facto* heads of households where their husbands have moved to the cities or mines as workers - as reflected in the comment by Nelson Mandela: “*Rural people and rural women in particular, bear the largest burden of poverty in South Africa*” (Mandela, Government Gazette, 1995: 5). For all this, many African cultures are extremely patriarchal and, although HIV prevention campaigns usually encourage people to use condoms and have fewer sexual partners, women and girls in Africa are often unable to negotiate safer sex and are frequently involved with men who have several sexual partners (English, 2002a; Kanabus and Fredriksson-Bass, 2008; AIDS South Africa, 2009). The situation becomes severe in cases where women live in poverty and have limited resources, because sex will often be used as a means of survival and thus, gender inequality can become lethal (Ghosh and Kalipeni, 2005).

2 Impact of chauvinism in the workplace

In studies on women who work in the construction industry, it was found that there are numerous references to the constant sexual harassment and innuendoes from male colleagues experienced by tradeswomen, which are subliminal to legislation, and thus cannot be reported (Eisenberg, 1998; Whittock, 2002). Some victims found it wore them down, but many coped and found that they were able to overcome it by refusing to react to the banter. There are more sinister cases described where women have been set up to have accidents (Eisenberg, 1998; Whittock, 2002). Examples of life threatening hostility have been described, such as physical assault, and of women having had heavy tools dropped on them. An account from an apprentice electrician described two occasions on which she was set up to suffer severe electrical shocks. In both instances, she detected the misdemeanour beforehand (Eisenberg, 1998).

In an extensive study undertaken by Grün (2004) in the South African workplace, she commented that discriminatory behaviour contributing to gender gaps occurred at the hiring stage, with African women suffering the most. Women may be given work, but male chauvinism still affects them adversely (Grun, 2004). The Department of Public Works has more recently included a policy of awarding contracts to female firms under the policy of affirmative procurement (CIDB, 2004). In a study on workplace dynamics for women, Bowen *et al.* (2008b) found that whilst incidences of *harassment* do occur, their frequency is comparatively small with females experiencing proportionately more sexual (males: 2%; females: 17%) and gender (males: 2%; females: 30%) harassment at work than their male counterparts.

Factors resulting in women leaving the construction industry in the UK can be classified into two groupings: working environment characteristics and private life demands (Court and Moralee, 1995). Literature over a decade highlighted the issue of retention of female labour within the industry with many women leaving the industry in their early thirties, often to start a family (Court and Moralee, 1995; Gurjaoe, 2006). The perception on the part of many women that they feel obliged to make a choice between a career and a family is also noted by Dainty *et al.* (2000). Sinclair (1998) proposed the existence of a number of masculine subcultures which underlie attitudes and behaviours relating to sex and sports, bullying, and paternalism. On the other hand, Dorsey and Minkarah (1993) found that personal satisfaction with a job well done, recognition, inclusion in decision-making, and fair remuneration are gender-blind in their importance.

Sufficient numbers of female workers in a group on site required for H&S has been viewed as important (Greed, 2000). Denmark offers an example of H&S in numbers having been achieved through women constituting one third of all Danish house painters and a half of apprenticed painters (Pedersen, 2004). This body of women also provides role models for future generations of women. Thus, it would appear from the literature that chauvinist attitudes exist, but can be overcome and changed where there is a will to do so.

3 Distance and transport, and their impact on health risks

The current South African Construction Charter notes that work conditions on some sites are exceptionally poor with extended periods away from home, long hours, an unsafe working environment, and inadequate housing arrangements being particularly negative for women (CIDB, 2006). All these stresses are further compounded by poor communication between employees of different cultural backgrounds (English, 2002b). Furthermore, these factors, though domestic and social, create sexual H&S risks for women (Olufemi, 1999). Research conducted in South Africa (English, 2003) was confirmed by research conducted in the UK (Lyll and Hawkins, 1993; Fielden *et al.*, 2001) that the H&S hazards of site work are a barrier to women and that construction sites need to be healthier and safer for workers, particularly women, to feel comfortable.

A part of workplace H&S for women employees is their getting to and from work. The literature describes lack of transport as being a discriminatory factor against women working in construction (Sommerville *et al.*, 1992; English *et al.*, 2005). Another singular feature of construction that affects health and the potential spread of HIV/AIDS is that it is both site-based and transitory, involving travel (Rogerson, 2000). The construction sector also helps develop major transport and infrastructure routes; transport routes are, in themselves, risk areas for the transmission of HIV because of the constant movement of people and the fact that prostitutes utilize trucking routes to ply their trade. Constant movement of people in transport routes is one of the greatest aggravators of risk of HIV transmission, because it aggravates almost all the other HIV transmission probability factors such as lack of social responsibility, lack of stable family, and lack of liability for consequences of behaviour (Rogerson, 2000; ICAD, 2004). Informal work practices also have employees living away from families in temporary accommodation with few recreational facilities, for long stretches of time – the risk of HIV being contracted is increased, thus reducing experienced skilled and supervisory employees essential to the growth of the construction sector. All these factors aggravate the spread of the AIDS virus (Simon-Meyer, 2005).

4 Age of workforce and HIV/AIDS

In Haupt *et al.* (2005), the researchers found that the age of workers has relevance to the spread of the disease. Older workers come from poor backgrounds, have a lifetime of inadequate nutrition and are susceptible to poverty-related diseases, such as TB, hypertension, and ischemic strokes (Haupt *et al.*, 2005). This combination between vulnerability to poverty-related diseases and age means that the time between HIV infection and the onset of AIDS will be much shorter for older workers (Haupt *et al.*, 2005). A study conducted by Bowen *et al.* (2008a) reviewed a large sample of construction employees in terms of their age, nature of employment, occupation status, and region. The material was analysed with a view to determining their correlation with the prevalence of HIV. Their findings were that the high-risk category was employees that are semi-skilled and whose skills are needed on multiple sites. These individuals, such as drivers, are more likely to work away from home a great deal. The age category most at risk thus was older as they had acquired skills, i.e. those between 30-49 years of age. The majority of skilled construction workers are between 30-39 years old, while general unskilled labourers are predominantly 20-29 years old. The researchers concluded that skill level and age are positively correlated with the prevalence of HIV peaking in men between ages 30 and 39 – the age group described above (Bowen *et al.*, 2008a).

According to the mortality report from Statistics South Africa (Stats SA, 2006), the death rate for women aged 29 to 39 years more than tripled from 1997 and 2004 compared with men whose rate doubled. Women's death rates are now higher than those of men at a working age (Anderson and Phillips, 2006). The large increases in death rates for women in their 20s and 30s are considered to be primarily due to AIDS (Anderson and Phillips, 2006). Furthermore, women in childbearing years are the fastest-growing segment of the population to be infected, with the probability of pregnant women being HIV positive increasing from 0.7 per cent in 1990 to over 30 per cent in 2005 (Dorrington, 2006).

5 Research method

A study was conducted in South Africa between 2004 and 2007 on the attitudes and perceived barriers to women gaining entry and training in construction. The data were drawn to reflect the following key areas: personal and demographic detail (and, in the case of employers, some information about the company); employment conditions, particularly conditions relating to gender and H&S. The responses were drawn from a sample size of 73 female current and potential employees. The sampling spread was justified by the outcomes of a pilot study. The pilot study had focussed on a sample of 26 women sourced through the South African Women in Construction association. But, following this, it was decided to include men and women as men are traditionally in the position of employers. Questionnaires were disseminated and interviews conducted in the Western Cape, Gauteng and Kwazulu-Natal. Respondents comprised 176 construction respondents comprising 60 owners / managers and 116 employees. Comments from the interview text not attached to the questionnaires were distributed for triangulation of interpretation, tagging with memos and for analysis. Drawing on the work of English (2007), comments were coded via three alternative forms, namely:

(1) *Potentially Positive*: the comment is helping; could help; is needed to help; or is possible; or gives advice on positive change. (2) *Negative*: the comment describes attitudes which block women's progress and will continue to do so. (3) *Currently Positive*: the comment is absolutely and currently true and the answer is yes.

The total number of respondents' comments on the different topics totalled 883, of which the gender breakdown was male (55%) and female (45%). This reflected the approximate balance in gender of the samples. These 883 comments were analysed into 1,670 expressions of opinion on the different topics. Using such codes permitted analysis of every statement made in response to open questions in the questionnaire and given in the interviews (English, 2007).

6 Findings and discussion

6.1 Male chauvinism and attitudes

Responding male employers and employees were slightly more negative (46%) than were women (41%) regarding the topic of male chauvinism, as they either expressed chauvinistic views themselves or stated that they felt women would suffer from chauvinism. Responding female employers (59%), far more than male employers (11%), were potentially positive about the potential to overcome chauvinism. Responding employees had the opposite reaction to women experiencing chauvinism: women employees were more negative than were male employees – presumably from

experience, but as with female employers, were more potentially positive and currently very positive that male chauvinism is not a barrier to female employment on construction sites. Indeed, neither responding gender believed in the need for macho behaviour by women. Nor did they consider that there is greater acceptance of women with feminine traits.

Respondents made numerous references to sexual harassment. Female respondents were not as concerned about sexual harassment as were the male respondents. The greater number of negative responses was from men (83%) compared with women (63%), with the current positive results coming only from women. Thus, more men than women hold the view that women are more at risk of sexual harassment than are men. These findings are similar to those relative to the need for numbers of women to work together for them to feel safe. Women, thus, are inherently more positive than are men that these barriers can be overcome. Furthermore, these results support findings reported in literature that men have more conservative views on women working in construction (Bennet *et al.* 1999; Dainty and Bagilhole, 2000).

H&S at work is an issue for concern given the few currently positive statements and numerous negative statements from both genders among the respondents. Overall, 41% of the survey sample supported the statement that women are less likely to accept unsafe conditions than men, but far more women (35%) than men felt this to be true. An overall majority of 83.8% (and 9% more women than men) of respondents agreed that the work environment on a construction site does not meet the personal hygiene requirements of women (an aspect of personal H&S). The greater proportion of the comments were, however, potentially positive that personal H&S is currently not adequate, but could become so with appropriate intervention.

The number of women for H&S in numbers was claimed by the total sample to be a minimum of five women working in close proximity on a site or, alternatively, 34% of any given number of workforce on site – albeit this could be a far greater number. Female employees (75% currently and potentially positive: 25% negative) were consistently more positive than male employee respondents about women working on site but considered that there should be high numbers on-site and expressed a need for greater supervision and security on sites for their H&S. Thus, given H&S in a group, women were potentially positive about the possibilities for women in construction. Male respondents were more negative (46% positive: 54% negative) about women working on sites. This result may reflect that men feel so negative about women on site that they do not feel any intervention would help, whereas women are potentially positive should appropriate intervention be in place.

6.2 Distances and transport

Another aspect of personal H&S is safe transport between home and workplace. Transport was perceived as a minor problem for women by both genders of owner / managers. However, twice as many women as men made this a priority and were less positive (54% of women compared with 26% men in this number); possibly because of the impact transport can have on H&S and managing children. Both genders of employees by contrast considered it the least of the problems with relatively fewer women than owner / manager women giving it any importance (female employees 71% least problem: female employees 29% greatest problem; male employees 94% least: Male employees 6% greatest problem). This, again, may be related to the job being more valued at employee level.

Amongst employees, it was more problematic for labour and artisans – that is, those on sites - than for purely administrative staff but remained an overall minor issue for the latter. Perhaps expectations are not high in this regard as transport is rarely provided on sites - and yet poor transport can mean women are alone in isolated areas that could put them at risk of sexual attack and possible exposure to HIV/AIDS. This factor was commented on by a male respondent.

6.3 Age

Of the responding employees, younger women believe it more necessary to appear macho than do older women – a reflection of their feeling less safe on sites. For example, 67% in 25-35 year old age bracket compared with 33% in the 5-45 year old age bracket stated that they would feel less vulnerable if appearing macho. Older women might arguably be less likely to attract younger male interest and thus have less need to appear less feminine.

7 Conclusions and further research

The current Construction Charter (CIDB, 2006) notes that working conditions on some construction sites are exceptionally poor. Extended periods away from home, long hours, an unsafe working environment, and inadequate housing arrangements are all particularly negative for women. The literature advances that factors such as male chauvinism, sexist attitudes, ignorance, poor education, poor socio-economic status, informal work practices, the proliferation of labour-only subcontracting, tribal customs, and cultural myths, all contribute towards a negative picture for women employees in the South African construction industry. Female perceptions of feeling personally unsafe on construction sites go beyond accident risk to include lack of personal hygiene facilities, harassment and sexual threat and a sense of risk related to having too small a presence.

Any and all of these factors can lead to a greater risk of sexual harassment for female workers and hence greater exposure to the risk of HIV/AIDS infection, exacerbating what is already a pandemic situation for Southern Africa with its drastic impact on households and families. Male resentment towards women on site could put female workers at risk of sexual harassment or attack (symbolic of male needs for power and control), thus increasing the risk of exposure to HIV/AIDS infection. There were only two comments on HIV/AIDS in relation to women on sites. This possibly is a reflection of the low level of knowledge and level of concern that exists about the disease (Haupt and Smallwood, 2004) with a female employee admitting that whilst employees know that their company has a programme for HIV/AIDS awareness and protection, she did not remember the support to which it entitled them.

The high HIV prevalence among low / semi-skilled employees is attributable to a combination of limited levels of education, low / semi-skilled employment, and mobile labour. Construction firms need to take cognizance of the presence of these risk factors, and undertake targeted interventions such as education, treatment and support programmes - with particular emphasis on areas of high risk. Whilst most of the respondents considered transport a minor problem, the construction industry in South Africa cannot be complacent on this issue and certain findings reflect concern.

Against this negative view, however, the positive perceptions of female respondents in the survey research stand out. For example, female respondents believe that problems of

male chauvinism on construction sites can be overcome, which reflects the positive views of women that have been described in literature reviewed above.

While equal representation in the workforce might be a considerable way off, the achievement of H&S at work for women workers on construction sites would do much to redress and counter the currently negative realities of their employment. This lies squarely in the hands of employers. It should be reflected in recruitment practices, staff orientation, training and development programmes, and in the overt culture and employment policies of every construction company. The opportunity is open for the South African construction industry to be a leader in this regard, to shed its traditional image of male-dominated and conservatism, and be a significant contributor to arresting the pervasive spread of HIV/AIDS on this continent.

Abstract:

Project management software packages have been around for quite a long time to help managers to run construction projects effectively. Building Information Modelling (BIM) – also known as Object-orientated Modelling technology was used at the beginning in architectural design which has become more widespread in structural and services engineering. The development of BIM modelling has made the tool more users friendly. As a result, BIM became widely used by most construction practitioners in their specialist areas. For health and safety (H&S) practitioners within construction project management, this tool has not been fully explored. BIM technology has the potential to be used in H&S planning procedures, particularly those related to tasks on construction sites.

The section of the research presented in this paper intends to explore and review health and safety issues on construction sites with the sole intention of using better visualisation software to meet the needs of health and safety site practitioners in understanding such health and safety (H&S) problems. A framework of an integrated visual tool is developed for better H&S practice on site that may be used actively by all practitioners, starting with site induction which addresses, *inter alia*, personal hazard perception. The intention is to find a way forward in addressing ‘real’ health and safety site issues that may not be easy to understand by practitioners without the full aid of visualisation.

Keywords:

health, safety, construction site, BIM, 4D modelling

1 Introduction

The construction industry is well known as one of the most dangerous industries in which to work (Gibb *et al.*, 2010). Despite the fact that the United Kingdom (UK) construction sector only accounts for approximately 4% of UK employees, 27% of all reported occupational fatalities are from the construction industry as reported in Health and Safety Executive (HSE, 2010). The nature of the construction process widely contributes to this relatively high fatality rate. These characteristics include the dynamic work environment, multiplicity of operations, proximity of multiple crews, industry fragmentation, and industry culture (Hallowell, 2010). The recurring problems in the construction industry led to the establishment of a commission by the UK government, which was led by Sir John Egan.

Most of the recommendations proposed by Sir John Egan in ‘*Rethinking Construction*’ in 1998 have not all been implemented by the construction industry. However, most large construction firms have made a tremendous effort to achieve the recommendation of a 20 % reduction in accidents. Although there are still problems with small and medium size construction firms that make up the bulk of the industry (HSE 2010), the awareness is there among practitioners and academics in finding innovative solutions to address most of what was said in the Egan report. HSE, the government controlling body, has also made progress in the areas of H&S regulations, guidelines and approved code of conducts, as well as creating H&S awareness among construction practitioners. H&S management is therefore important on all construction projects.

Although, health and safety management is widely practiced within all manufacturing industries, in construction, site conditions cannot be controlled as ‘pure’ manufacturing industries in terms of production processes as we know it, as such, health and safety becomes paramount. Planning and management is an essential prerequisite for all construction projects and their practitioners, as without a deep understanding of the issues involved in construction activities, lives will be lost and extraneous costs will be realised due to accidents, in addition to other after effects such as tarnished image of the construction firm.

Many researchers also pointed out that there was a lack of integration between construction process and health and safety issues (Sulankivi *et al.*, 2010). In order to reduce the frequency and severity of construction accidents, firms implement safety programmes and procedures that include written H&S plans and training (Hallowell, 2010). Nevertheless, lack of H&S training and practices were identified as key factors behind many construction accidents (Sulankivi *et al.*, 2010).

On construction sites, operatives change over time due to varying work requirements. Each construction site has its specific hazards, and these differ from one location to another, which in turn cannot be generalized. New employees usually come on board without prior knowledge of possible hazards they may face during their work on the construction site. Existing tools may not be adequate for induction training due to their limitations including lack of providing a wider picture of the site. 4D visualisation has been approved to be a good tool for demonstrating many design and construction problems due to their ability to show many tasks in 3D over specific period of time.

This paper reports on a component of a project exploring new ways of integrating BIM technology for use during the construction of facilities and construction projects to understand hazards and its perception for inductees. The literature review discusses: the site processes that are viewed as real determinants of H&S for construction sites; the current application and usage of BIM in the construction industry, and visualisation as a safe option in opening up new avenues of H&S management, particularly in the area of induction of site personnel and developing better ways for understanding the perception of site hazards.

2 A Kaleidoscope for Construction Site Activities

This section develops and discusses the literature for an integrated approach in the usage of BIM and planning software to optimise better health and safety site operations on construction projects. The planning literature is first investigated and the relevant literature on health and safety management on construction site is also explored. It also

expands on the importance of site induction and tries to put construction site induction in wider personnel induction context, which is a must for any site personnel. This section concludes by reviewing the importance of visualisation as a necessary factor that will address some of the gaps that have been identified within the health and safety literature. It also raises the possibility of using 3D software packages in developing better ways of site induction approach through visualisation of hazards.

2.1 Construction Project Planning

Construction project planning and management is a balancing act of leading and managing people, as well as using and managing resources within given constraints conditions, in an efficient and effective way, to achieve the desired artefact. The constraints include but not limited to time, cost, quality and safety, which are predominant during the realisation of the constructed artefact. Hence construction project management contains both the qualitative aspects as well as the quantitative aspect of management. Most of what is required within the quantitative area has been codified in dedicated project management tools (i.e. planning and scheduling software), like programming in the CPM method, resource levelling and the like. In all projects, the act of specifying, visualising and developing the planning schedule for construction has been done using dedicated work breakdown structures (WBS) within the software environment which is now common in projects. Once such plans are developed they are then followed and implemented to bring about the project. However, until recently, most of the information required in using this planning/programming software usually comes from both the CAD drawings and other related sources (Watson, 2010), that are not really related in terms of the WBS and subsystems used in each platform. However, with the development of BIM, and the life cycle realisation of the project in one holistic environment, most of the H&S information can be done directly in a single environment. There are some advantages that this paper intends to explore in relation to the use and application of the integrated approach within the 4D modelling for the benefits of most site workers.

Construction site planning and operation involves the selection of temporary facilities; equipment and their operations; the selection of competent construction personnel; and the planning, organisation and selection of an effective and efficient site layout design. Construction safety induction involves familiarising construction personnel to site specific safety and health issues that will degrade or impinge on the progress, efficiency and productivity of site personnel during site operations (John, 1999).

2.2 Health and Safety in Construction Industry: Site Induction

The practice of health and safety management in construction can be summarised in the following areas:

Safety legislation, regulation, standards and guidelines

Appointment of CDM coordinator by the client

Designers health and safety considerations upstream in the creation of the artefacts and how it should be implemented during the implementation of the project

Management of health and safety management during construction for site personnel

Not forgetting the development of health and safety plan and the creation of the health and safety file right through the life cycle of the project.

Health and safety management is therefore part of the wider planning and management process of the construction project. Soltani and Fernando (2004) suggested that one way to make this industry better in terms of health and safety is to implement effective H & S regulations during the planning of the project. The failure of planning appropriate support infrastructure affects safety, quality, and productivity adversely (Soltani, 2004). Dolores et. al. (2009) used questionnaire methodology to analyse the H&S regulations and requirements in construction industry. The authors determined that there are 10% lower accident rate in general after the *Health and Safety* policies came into force. Some commentators also suggested that within the site organisations themselves, health and safety should be implemented , not in terms of project, by project bases (Ciribini and Galimberti, 2005; Cameron and Hare, 2008), more in a granular level.

Construction presents significant obstacle to repeated hazard analysis. Construction sites undergo dynamic change in ways that fixed industrial facilities do not; works team (i.e. work gangs) are transient, the physical structure and spaces change, as well as the environmental conditions (i.e. in weather). Another difference is that in construction, workers of one team are frequently exposed to dangers posed by the workers of other, unrelated teams. Performing risk analysis before any activity at any time is essential but difficult, even if the same activity is performed repeatedly, since the site conditions change through time. This demands more effort than most contractors or workers are willing to invest, and therefore safety management in construction sites commonly suffers from low level of efficiency, with effective risk analysis performed rarely (Tang, 1997; Sacks, 2010). In the absence of an efficient and effective way of predicting peak risk levels, safety management on construction sites is performed at constant level of effort, focusing on provision and use of personal safety equipment, training, accident and near-miss investigations, and taking steps to fulfil regulatory requirements (Sacks, 2010). Given the dynamic nature of construction sites, analysis of construction activities and their related hazards is inadequate for reliable risk assessment if it does not explicitly account for the likelihood of exposure of potential victims to hazardous situations. Hence it may be necessary to study safety hazards of sites through realistic simulated site environment.

To achieve safety and health assurance, it is necessary to have to established sound codes and guides which adequately describe what a good safe practice is, how it can be achieved and how it is measured. Without a mention of quality assurance this is nevertheless what we set out to achieve in the field of temporary works (Quinion, 1980). Induction is the first point of contact for the site personnel as well as others that have to come on site. However, within this paper we are limited to the discussion of new site personnel induction.

Most construction site personnel tell you that although health and safety induction should be site specific, but the differences from one site induction to another is marginal. The personnel believed that they know and are familiar with the routine of site safety inductions. However, (as familiarity breeds contempt) personnel need reminders to make them more safety conscious, especially in terms of site hazard perceptions. One way in which this can be achieved is through visualisation.

2.3 Visualisation

Most recent studies on health and safety have been on the way visualisation can be used to integrate some of the problems encountered in managing by regulations and enforcement alone. Among such key commentators are those who proposed a scenario based SIMCOM+ tool to investigate safety on construction sites. It analysed the structural information including some temporary facilities, equipment, workers and materials in order to identify the collision among different entities on construction sites. Kuen-Chen and Shih-Chung (2009) identified conflicts on static or dynamic construction sites and determined the distance between large dynamic objects in virtual construction sites by different scenarios through VC_COLLIDE algorithm. Sacks et al. (2009) proposed algorithm based methodology CHASTE (Construction Hazard Assessment with Spatial and Temporal Exposure) that calculates the probability of a potential victim during loss-of-control events (Chavada, 2010). The following subsections discuss visualisation in more detail.

2.3.1 4D CAD

A range of 3D CAD visualisation tools are used in the construction industry to communicate design ideas between all the stakeholders in the design and construction process of a construction project (Ganah et al, 2005). One of 3D CAD techniques limitations is that they do not provide a 3D representation over time whereas 4D CAD does that at any specific time of the project construction process.

4D modelling tools link a project's scope in 3D with the construction schedule to graphically simulate the construction process. Many research efforts have discussed the potential of these tools to significantly improve design coordination and construction execution. Koo & Fischer (2000) argued that 4D models allow reviewing the planned status of a project in the context of a 3D model for any desired time which allows project managers to ensure the integrity of the main schedule, revealing potential time-space conflicts and logistical problems, supporting the communication of product and process knowledge and allowing efficient tracking of the work progress. Furthermore, 4D models facilitate communication with subcontractors and improve the collaboration between the project team.

The use of 4D models may also help in identifying and eliminating many construction related problems before going to site (Aouad & Tanyer, 2005) in understanding site hazards. It displays the progression of construction overtime and sometimes dramatically improves the quality of construction plans and schedules (Rischmoller et al., 2001).

4D CAD proved to be a useful tool in assisting planners to visualise alternative construction sequences based on alternative decisions made (Koo and Fischer 2000 and Dawood et al. 2000) however, it should not be considered as only planning tool as it relies on available information to provide a graphical simulation of the project schedule and the planner uses these tools as means of visualising and comparing, rather than developing and implementing different decision alternatives (Waly, 2001).

Traditional approaches used for representing construction planning information in an abstract textual description of construction activities may lead to the fact that the planners need visually conceptualise the sequence of construction activities and subcontractors may elaborate the construction plan because it lacks necessary detailing

(Rwamamara et al 2010). Such detailing can be provided through graphical visualisation methodology, for example BIM methods.

2.3.2 BIM

Building Information Modelling (BIM) – also known as Object-orientated Modelling technology was used at the beginning in architectural design it has become more widespread in structural and services engineering. The term BIM is not just referring to a category of leading edge software for designing buildings but it goes beyond that to a process view in which the focus lies on the information over the full lifecycle of a building (Watson, 2010). It directly relates to a project team's ability to visualise, understand, communicate and collaborate. Harty et al (2010) described BIM as a set of practices or activities describes the new ways of working that emerged through the implementation process. Succar (2009) gave a deeper description for BIM as he defined it as a set of interacting policies, process and technologies generating a methodology to manage the key building design information in a digital format throughout the building life-cycle.

Nowadays, each construction project is complex and dynamic system, which makes construction planning, design and site and construction management complex and difficult (Zhang & Li 2010). BIM is widely considered to be an enabling technology with potential for improving communication between stakeholders, improving the quality of information available for decision making, improving the quality of services delivered, reducing time and cost at every stage in the life cycle of a building (Smith & Tardif 2009). One of the key advantages of IBM over 2D and 3D CAD is that IBM represents and manages not just the graphics, but also information- information that allows the automatic generation of drawings and reports, design analysis, schedule simulation, facilities management etc-ultimately enabling the building team to make better-informed decisions. The planned work sequence of work is usually part of BIM which can be used later to produce animations of the construction process of a building over time, therefore showing how the work on site should be carried out according to plans of work and contractual responsibilities. In addition to that, BIM has the potential to be used beyond the design stage to include the construction and operation of a building with the concept of a digital virtual building that parallels the real building (Watson, 2010). Thus the technology can prove crucial to the success of a project by effectively controlling the construction schedule, budget, quality and the reducing risks (Ku & Mills, 2010), through time controlled realistic simulation.

BIM technology has the potential to be used in safety planning procedures particularly those related to tasks on construction sites. 4D modelling tools can be used to link a project's scope in 3D with the construction schedule to graphically simulate the construction process. Construction tasks on site can be modelled in a 4D CAD production model, in which the model produced by designers used as the starting point. Previous studies have found that certain sets of movement characteristics for construction facilities such as tower crane arm movement, movement of construction vehicles etc. This may enable the system to simulate the construction more realistically. This may enable a system to simulate the construction more realistically (Zhang and Li (2010).

Harty et al (2010) investigated the use of BIM to assess the access adequacy to install new services and perform health and safety assessment –looking for trip hazards. This project did not investigate how health and safety on site during construction can be

assessed and addressed. The utilisation of 4D-BIM technology may improve occupational safety by connecting the safety issues more closely. However, the uptake of this technology within the construction industry is partial and fragmented (Harty et al 2010).

The literature review shows that, as of now BIM usage is confined mostly to the design and planning stages of the project, with very little of it being used in the construction phase of the project in relation to H&S through hazard perception. However, the construction phase is where the bulk of accidents, H&S occurrences are recorded. Also it is in the construction phase where personnel induction is ongoing due to the high churn rate of personnel in the construction industry. Concentration of contracting firms (i.e. medium and small firms -subcontractors) is predominant within the construction phase. However, planning software packages are not frequently used by these subcontractors to keep track of progress, as most of these subcontracting firms do not actively practice tracking their projects through computerised planningtools. New methods are needed to help alleviate some of these problems that may be contributing factors in appreciating health and safety management proactively.

3 Research Methodology

The focus of the paper is on the use of Building Information Modelling (BIM) H&S for construction sites induction. The methodology for the project is more qualitative in approach than quantitative. As such, the first stage of the project is to assimilate all the relevant literature in understanding our study domain. This entails literature on BIM, visualisation, planning, health, safety and risk on construction projects, as well as other associated works. The research instrument of the data is an eclectic approach of the literature which involves both deductive as well as inductive understanding in acquiring the knowledge for future syntheses of the knowledge gained.

The next stage will be using such knowledge to develop a generic modelling approach that will take into consideration, the object oriented modelling understanding that have been used in BIM technology, as well as planning software. This will incorporate developing new classes, frameworks and building blocks that will be replicated when using the integrated scenario for each construction site. However, for this paper, a section of the different stages will be reported to give the reader an understanding of how the research will develop.

4 Integrated BIM approach for Site Induction

Rather than expose the individual to ‘real’ safety and health concerns, the specific site accident ‘hot spot’ can be simulated and the improvement to the personnel’s hazard perception improved considerably, with the aid of BIM and project management software in sync (i.e. 4D modelling). In Figure 1 the architecture is presented.

Figure 1: Top Level Site Safety Induction Framework

The site induction hazard perception toolkit architecture is made up of four parts:

The BIM software with its library of information

The project management software with the resources and planning of the desired project

The algorithms making use of information from both packages

The user interface

Before the integration can commence the planning software and the BIM should have a way of integrating the information of a particular object that is to be created, such that recognition of such object is the same. Secondly, the different stages of the object in real time should be stored in such a way that a time sequence scenario can be created in the BIM environment. Thirdly the visualisation of the developing project should be such that safety concerns can be visually seen as the project progresses.

As the construction sequence is developed, the integration should be able to monitor critical safety areas and show in time sequence how certain hazards develop on site, through the expert system that is lying behind the 4D scenario.

Each part of this architecture is being developed using object oriented methodology and SSM. As such each part is considered a high level object in its own right, and will be developed independently.

The BIM environment will be used to develop the 'new' construction components, that will be directly related to the WBS used within the scheduling software. Critical safety areas will be developed that will show the site inductees what he should be expecting on site.

The algorithms will be used to control the different construction scenarios that will typify site perceptions in a realistic environment. The new recruit hazard awareness will be tested in the past completed stages of the project, ongoing work and future realistic phases of the project. This will all be made possible by algorithms augmenting the health and safety regulations, codes and guidelines at each stage of the project.

5 Conclusion

Health and safety on construction site can either make or break a contractor, if not properly managed. As such, all personnel need to be properly inducted in managing their health and safety concerns, which are usually done by the current site induction.

Construction personnel are always inducted when they are new to specific site, through prescribed induction manual and training that have been developed through industrial institutions or in-house induction materials. Over time the personnel moving from one site to another become familiar with the induction material, and take the induction for granted. However, accidents are still occurring on sites and hence more proactive methods are required. BIM is now prevalent within the construction industry, especially in design and planning of construction projects. The usage of BIM in this research on construction execution, have the potential to help augment practitioners understanding of their sites, by so doing reduce their probability of accidents. The Building Information Construction Health and Safety (BICHHS) project tried to develop a new way for enhancing the personnel understanding of site hazards, especially in real time as site inductions can happen as the project progresses.

6 Future Works

The development of the intelligent algorithms for identifying site hazards will be the next stage of this research project. The system will enable new site operative to identify potential hazards they may face during their work on construction sites as part of their induction training on health and safety. The system will be tested and validated through real life case studies and measurement matrices for site personnel developed as a way of gauging their hazard perception.

Abstract:

Supervision of construction workers on a site is crucial to ensure construction worker safety, to maintain the quality of work performed and to maintain acceptable levels of productivity. The act of supervision itself requires the site foreman to physically monitor workers in an environment that is constantly changing throughout the construction phase. This is not always an easy task on a medium to large multi-storied building site with several trades working simultaneously on multiple floors. The construction site typically consists of skilled and unskilled workers and crews of workers that are involved in the various crafts. There exists a need for construction foremen to know the location of construction workers within a site. Academicians and industry professionals have demonstrated the use of Radio Frequency Identification (RFID) Tags in construction applications in the past few years. RFID tags have successfully been used to track construction materials, equipment and personnel. Studies indicate that the use of RFID tags in construction improves the overall process of construction. Building information modeling (BIM) technology is emerging as the industry standard in the architecture, engineering and construction (AEC) sector. BIM is being used as a comprehensive design, management, visualization, communication and facility maintenance and management tool. The role of three dimensional (3D) visualization tools in construction has increased steadily with the availability of faster, cheaper and versatile software and hardware computing tools. This paper presents a virtual reality decision support framework by combining RFID technology with BIM technology to monitor construction workers on a construction site to improve the process of site supervision. The proposed framework is based on making pertinent site supervision decisions based on location of construction workers within the site. The location of workers may be obtained by using active RFID tags.

Keywords:

site supervision, worker monitoring, RFID, BIM, sight safety, worker productivity

1 Introduction

The use of information technology applications in the architecture, engineering and construction (AEC) sector has been on the upswing for the past decade. The latest technology that is rapidly changing the landscape within the AEC sector is Building Information Modelling (BIM). This paper explores the possibility of combining radio frequency identification (RFID) technology with BIM and a few associated implications to construction site safety due this combination. It is argued that the use of this combination of technologies can provide a safer work environment for the construction

worker and provide construction site foreman a critical tool in maintain a safe and productive work environment.

Supervision of construction workers on a site is crucial to ensure construction worker safety, to maintain the quality of work performed and to maintain acceptable levels of productivity. The act of supervision itself requires the site foreman to physically monitor workers in an environment that is constantly changing throughout the construction phase. This is not always an easy task on a medium to large multi-storied building site with several trade contractors working simultaneously on multiple floors. The construction site typically consists of skilled and unskilled workers and crews of workers that are involved in the various crafts. There exists a need for construction site foremen to know the location of construction workers within a site.

2 Research Aim

This study aims to develop a framework for decision-making based on construction personnel monitoring in a virtual environment by combining BIM and RFID technologies. It is envisioned that the proposed framework will allow construction site foremen to improve site supervision practices. Consequently, the proposed framework can potentially improve construction site safety and productivity.

3 Research Methodology

A comprehensive literature review for the study has been conducted, leading to the following two phases under which this research is proposed to be conducted:

3.1 Phase 1: Conceptual Framework Development and Validation

A conceptual framework for field supervision using RFID technology along with BIM technology has been developed at this stage. This conceptual model will be further refined by conducting interviews with construction site foremen and again through industry wide questionnaires.

3.2 Phase 2: Development of Prototype and Scenario Simulation

A prototype virtual environment will developed to combine RFID technology with BIM technology. The waterfall model for software development is expected to be adopted in this process. For the purpose of this study, off-the-shelf active RFID tags and readers will be used along with commercially available BIM software. The application programming interface (API) for the BIM software and the RFID hardware will be used to develop the prototype virtual environment. The conceptual framework and the prototype virtual environment will be further validated by conducting scenario based simulations in three separate case studies, in a construction job site.

4 Literature Review

This research aims to create a framework for site supervision based on monitoring construction personnel in a virtual environment using RFID and BIM. Literature review is presented for the role of BIM, visualization, RFID technology and field supervision, as it pertains to the construction industry.

4.1 Building Information Modelling

Two dimensional (2D) drawings to represent buildings were the norm in the AEC industries until a few years ago. Several 2D drawings, predominantly produced using lines, were required to represent an object in 3D, resulting in inconsistencies within the various views. Even before the use of BIM, researchers have been experimenting with object-based models for buildings (Papamichael K. et al., 1997). BIM technology is based on representing a building using intelligent objects. These objects in a BIM model can be real objects with 3D characteristics such as beams, walls, equipment etc., as well as abstract objects such as spaces, rooms and areas. These objects are often referred to as parametric objects, as they are built with certain inherent rules, such as requiring a door to be imbedded in a wall and move with the wall (Eastman C.M. et al., 2008). BIM technology improves the overall quality of design, provides better performing buildings, and requires fewer change orders during construction. BIM allows the contractor to optimize the schedule and cost of the project while also providing for an efficient handover of buildings to owners for operations and maintenance.

Several industry practitioners and academicians that it is more than just a software tool can consider the semantic definition of BIM less important than the acknowledgement. The true impact of BIM is the enabling of comprehensive, digitized and collaborative processes within the AEC industries. The American Institute of Architects (AIA) recognized this seismic shift in the process of designing and constructing facilities and has proposed a new delivery method, namely 'Integrated Project Delivery' (IPD). BIM is the cornerstone of realizing the benefits proposed in this new methodology for project delivery. The use of BIM in the US construction industry has been on the rise and is predicted to continue to increase (McGraw Hill Construction, 2009)

However, formal definitions do exist for BIM and the National Building Information Model Standard (NBIMS) defines (Facility Information Council, 2007) a building information model as "A digital representation of physical and functional characteristics of a facility. As such it serves as a shared knowledge resource for information about a facility forming a reliable basis for decisions during its life-cycle from inception onward." For the purpose of this paper BIM is referred as 'BIM technology' since the inherent data model within BIM is used as a vehicle to incorporate RFID technology.

4.2 Role of Visualization in Construction

Visualization in the architecture domain has always been an important element (Brown, 2003). Complex tools for digital visualizations are now increasingly making their way into the construction industry (Koutamanis, 2000). Digital visualization tools are increasingly seen in the construction industry. Researchers Kamat, Martinez, Behzadan (2001, 2005 & 2008) and others have created, improved, demonstrated and validated the use of complex visualization and simulation tools in the construction industry. Their research has led to the creation of augmented reality based visualization tools that can be used in construction (Behzadan & Kamat, 2009). Researchers have used visualization tools to simulate the movement of cranes to prevent collision during construction (Kang et al., 2009; Tantisevi & Akinici, 2009). The role of visualization tools has especially been on the rise in the area of 4D simulation and virtual construction (Cam et al., 2003; Waly & Thabet, 2002). 4D visualizations have been shown to increase the efficiency of planning and scheduling procedures in the construction industry (Chau et al., 2004). Messner and associates (2006) demonstrated that visualization tools can be used in the realm of sustainable construction as well.

4.3 RFID Technology

RFID is a wireless sensor technology that is based on the transmission and decoding of radio waves. This technology has been in popular use at least since the Second World War when British aircrafts used this technology to differentiate between enemy and friendly crafts returning to their base stations (Domdouzis K. et al., 2007). Today RFID technology is used to track objects, livestock and people. It is widely accepted that this technology will replace the use of Bar Codes for tracking purposes (Wu N.C. et al., 2006). The technology consists of an RFID tag that is attached to the object being tracked and an RFID reader, attached to antenna that identifies the tag when it is within the range of the reader. Radio waves of varying frequencies may be used in the process of tracking RFID tags, depending on the type and purpose of the application. A typical assembly of this tracking mechanism is shown in figure 1.

The use of RFID technology in construction processes has been steadily advocated by academicians and researchers for at least the past decade (Jaselskis & El-Misalami, 2003; Lu et al., 2011). The technology has been successfully used in construction for tool tracking (Goodrum et al., 2006), material tracking (Ren et al., 2010), managing construction documents (Elghamrawy & Boukamp, 2010) and supply chain management of construction materials (Wang et al., 2007). Researchers Navon (2005, 2007) and associates have demonstrated the need for automated project performance control on construction sites and suggested the use of RFID as means to achieve the same. Wang (2008) demonstrated that it was possible to enhance the processes of inspections in construction by means of RFID technology.

Figure 1: Typical Active RFID Tags and Reader Configuration

Researchers have shown that RFID systems can be used for building maintenance (Ko, 2009) and facility management systems (Ergen E., 2007). Dziadak et al., (2008, 2009) have demonstrated that RFID technology may be used to track underground utilities to prevent accidental abrasion or rupture during construction. Ergen, Akinci et al. have demonstrated the use of RFID (2008) in multiple instances for life cycle management of equipment and material tracking (Ergen et al., 2007). Similarly researchers Haas, Song, Caladas, Grau and Razavi have done substantial work in validating the use of RFID technology for construction applications. They have demonstrated the use of RFID tags

to track on-site materials and automating the supply chain of fabricated pipe spools (Song et al., 2006).

RFID technology has been demonstrated to assist construction safety. Early warning systems to prevent collision with heavy equipment were developed using RFID technology (Chae & Yoshida, 2010). RFID technology was used to understand near miss accidents in order to prevent potential future accidents (Wu et al., 2010). Full scale emergency response systems for cities in the event of extreme events are being developed and tested using RFID in combination with other technologies (Peña-Mora et al., 2010). It has also been used to demonstrate its applications to real-time information for safety applications in the construction industry (Teizer et al., 2010; Riaz Z., 2006).

The use of visualization tools along with RFID technology has been proposed by researchers (Sorensen et al., 2009). Pilot studies to show the combination of 4D CAD with RFID technologies have been conducted to demonstrate its use in material tracking (Wenfa, 2008). In one study Chin et al (2008) demonstrated that the combination of passive RFID tags with 4D CAD technology saved 17% time in material tracking operations.

4.4 Field Supervision in Construction

It is globally accepted that safety risk to construction workers is very high. Over 2800 deaths have occurred in the U.K, over the past 25 years, as a result of construction activities (Health and Safety in Construction Industry, 2009). The role of monitoring is an important aspect of maintaining a safe work environment (Loosemore M., 1998). The role of the foreman in monitoring workers on a construction site is important to ensure a safe work environment (Flin R. & Yule S., 2004).

Productivity of construction workers is directly related to the profitability of a construction project (Motwani et al., 1995). Construction worker supervision plays an important role in improving construction productivity and quality. The longitudinal study done by Kines et al. (2010) demonstrated that construction foremen were coached to improve site safety conditions by 9.5%. Similarly importance for the role of the site foreman has not changed over the years, as shown by Fung et al. (2005), Salminen & Saari (1994) and Lemna et al. (1986). Studies have also revealed that jobsite supervision was rated as the most important, among a list of issues to improve productivity on the construction site (Arditi, 1985). Studies have also been conducted to monitor construction workers using video cameras using identification technologies (Teizer & Vela, 2009). However these studies also indicate several problems with tracking construction workers using video camera technologies, partly since it is based on line of sight technology and also since algorithms for automatic recognition of personnel are not fully developed yet (Yang et al., 2010).

In conclusion, three things have become evident from the literature review:

The site foreman plays an important role in maintaining a safe work environment on a construction site (Loosemore M., 1998; Kines P. et al., 2010; Fung et al., 2005). Similarly the site foreman's role is crucial to maintain quality control and acceptable levels of productivity (Salminen & Saari, 1994; Lemna et al., 1986). Also, studies to monitor construction workers using video surveillance technology have shown limitations in worker identification and more so, it is based on 'line-of-sight' based technology (Teizer & Vela, 2009).

The use of digital visualizations in the construction industry is on the rise and not merely in the form of creating BIMs but to schedule and plan construction work (Chau et al., 2004), prevent crane collisions (Kang & Miranda, 2006), for sustainable construction (Messner et al., 2006) and other uses (Kamat & Martinez, 2005).

The use of RFID technology in construction has been validated to manage materials (Grau & Caldas, 2009) and tools (Goodrum et al., 2006) on the jobsite, improve the supply chain of material delivery (Song et al., 2006) and for facility management (Ergen E., 2007). In fact new digital visual tools were created using RFID for the creation of 4D schedules (Chin et al., 2008). Studies to use RFID technology to track construction workers on a jobsite have not been found.

The literature review supports the need to combine RFID technology with BIM technology to create a visualisation tool to assist site foremen in monitoring the movement of construction workers.

5 Conceptual Framework

A conceptual decision support framework, based on location monitoring of site workers using the combination of RFID with BIM will be developed to enhance the site supervision practices on US construction sites.

Figure 2. RFID + BIM Construction Site Supervision Decision Support Framework

A framework to implement the decision support system is presented in figure 2. A software solution is being developed to implement the decision support framework. The site foreman can intervene in a potentially hazardous situation on the construction site by using the software solution. The software solution currently under development is expected to show the site foreman an image, as demonstrated in figure 3. The image in figure 3 can alert the foreman can, who immediately ensure that the visitors are not in the way of debris falling, as a result of the work done by the demolition crew. The conceptual decision support framework for site supervision based on RFID and BIM technologies is presented in figure 3. The site supervisor is expected to assess the construction site on a day-to-day basis and assign levels of safety risk to various physical zones within the site along with specific workers that are allowed to operate within each zone. The RFID tag and reader combination along with the BIM model will

provide a virtual environment for the site supervisor alerting the supervisor of possible site safety issues, thus allowing the supervisor to intervene in appropriate circumstances.

Figure 3. RFID + BIM Virtual Prototype Environment Development Strategy

As part of this framework, a software solution to integrate RFID and BIM will be developed, as shown in Figure 4. Active RFID tags are used in this study along with RFID readers, which are installed at pre-determined locations on the jobsite. Each signal from RFID tags will need to be stored in a database. The Application Programming Interface (API) for the RFID hardware will be used to transfer information about the tags into a database. The information will include the tag identification number, time the signal was received and the Received Signal Strength Indication (RSSI). The information will be further processed using established methods (Grau et al., 2009; Razavi & Haas, 2010; Ergen et al., 2007; Song et al., 2007) for locating RFID tags to determine the approximate location for each tag.

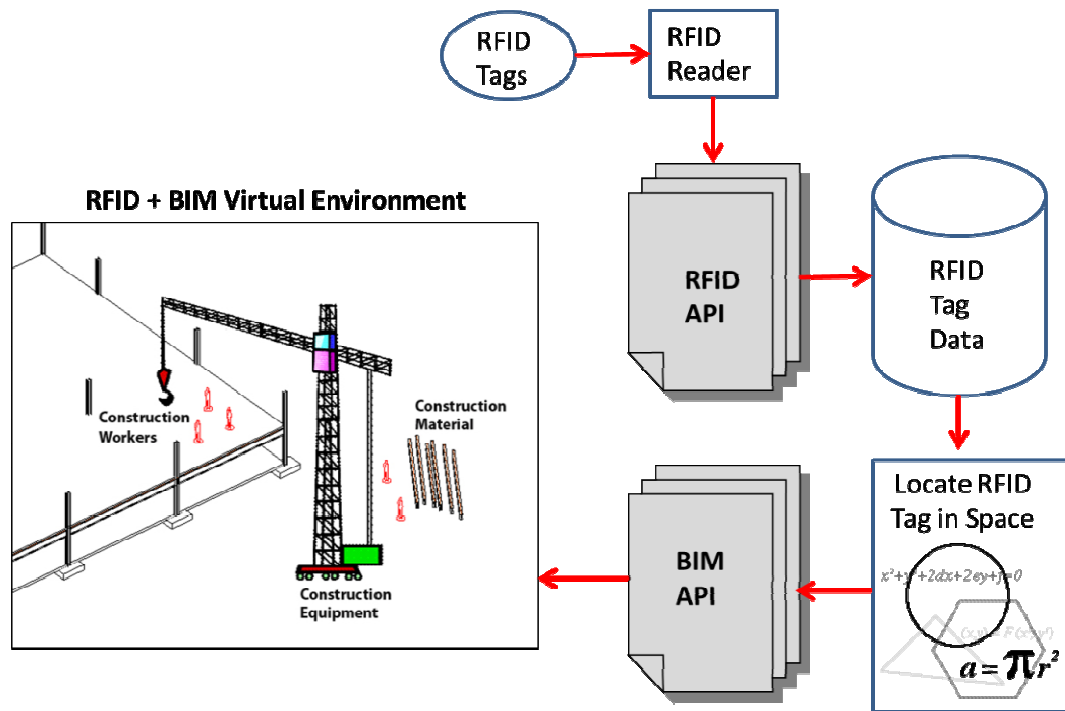

Figure 4. RFID + BIM Virtual Prototype Environment Development Strategy

It must be noted that the precise location of an RFID tag cannot be determined within a physical space. However, a high level of accuracy can be attained by employing an extensive network of readers and using triangulation algorithms. The research done by Khoury and Kamat (2009) shows that the precise location of people or objects in an indoor environment requires line of sight based systems. However the work done by Ko (2010) shows that RFID tags can be located with increasing efficiency in a 3D space using multiple localization methods. Several methods (Song & Haas, 2007) (Razavi & Haas, 2010) for locating RFID tags were proposed by them, some of which might have some potential uses for the purpose of this study. Another method for locating RFID tags, called the 'Centroid' method, was proposed on an industrial project by Grau and Caldas, which seemed to improve the precision of locating RFID, compared to the proximity method developed by Song & Haas (2007). Location tracking using RFID has been successfully developed and utilized in an outdoor environment (Behzadan et al., 2008; Lu et al., 2007), however location tracking in an indoor environment while construction is taking place can be difficult. For the purpose of this study, an approximate location of each tag will be used. The tag location information will then be incorporated into the BIM using the API for BIM software and a prototype virtual environment would be created.

6 Further Research

A comprehensive literature review has provided the research team with a possible application for combining RFID technology with BIM technology by monitoring the movement of construction workers within the site. A preliminary conceptual framework has been established to create a decision support framework for the site supervisor by creating a prototype virtual environment. The conceptual framework will be further developed by conducting interviews and questionnaires of site foremen. Feedback from the validation process will be used in developing the prototype. This prototype will be further tested in a construction environment to validate the framework of site supervision based location monitoring of construction workers.

Abstract:

The role of land in economic growth and poverty reduction globally is well known. Land provides the main source of livelihood for many in the developing world where agriculture is the main economic activity. It is, thus, not surprising that land accounts for 50% to 75% of the national wealth in many developing countries. Land registration has been regarded as the way forward in enhancing access to agricultural credit required to improve productivity, economic growth and poverty reduction. However, various empirical studies conducted in Africa and other developing countries have not been able to establish a discernible link between land registration and enhanced access to credit, agricultural investment and productivity. The aim of this paper is to critically examine the model linking land registration to credit access and to provide theoretical as well as practical reasons as to why such a linkage may be non-existent in the developing countries. It is argued in this paper that land registration per se cannot guarantee access to agricultural credit due to: (a) the presence of highly correlated risks in the agricultural sector; (b) the failure of registration to guarantee land ownership security and (c) the lack of an alternative and more reliable source of income for small scale rural farmers. Government intervention through state-led insurance or guarantees schemes for agricultural credit, agro-processing and provision of socio-economic infrastructural facilities like irrigation; storage and improved transport system are recommended as the way forward.

Key Words:

agricultural credit, developing world, land registration

1 Introduction

The critical role that land plays in the economies of countries all over the world is well recognised. Land provides the space for every human and economic activity. It is, thus, not surprising that land accounts for 50% to 75% of the national wealth in many developing countries (Bell, 2006). Land and buildings in the UK contributed about 57% of the national wealth in 1997, while the value of real estate represented 45% of Bangkok's GDP in 1997 (MacGee, 2006). In the advanced world, economic historians like North and Thomas (1973) and Rosenberg and Birdzell (1986) have documented the role played by, particularly, private real estate in the economic development of such countries. A large percentage of the average household's asset portfolio especially in the developing countries is said to be made up of land (Davies and Shorrocks, 2005). It is estimated that housing constituted 48.7% of household wealth of Indonesia in 1997, that of India in 1991 was 40.3% and china in 1995 was 36.2%; In the advanced economies,

about 33% to 50% of the median household assets are said to be made up of made up of land (MacGee, 2006).

The importance of land in terms of agriculture is also well known especially in the developing countries where agriculture is the backbone of their economies. The contribution of agriculture to the socioeconomic development of such economies includes the fact that agriculture remains the major contributor to GDP, employment, foreign exchange and food supply; In addition, agriculture is commonly regarded as an essential basis for industrial growth by feeding industry with the required raw material, providing the market for industrial output and freeing up excess labour to work in industry (Enoma, 2010).

Despite its major contributions the agricultural sector is beset with several problems in Africa and other developing countries. It is a well known fact that agriculture is characterised by small-size family-held farms which are operated on non mechanised and non commercial basis. For instance, 80% of farms in India are less than two acres and 95% are less than five acres; agriculture is also mostly rural based where about 70% of the population resides (Rahji and Adeoti, 2010). In the developing world, farmers are usually resource poor and though the government sometimes intervenes to provide financial support it falls short of the amount required and the processes involved are quiet complicated (Akram et al., 2008). One problem that most farmers (especially small scale rural farmers) by virtue of their poverty status encounter is the constraint on credit access; Limited credit access has been identified as a major constraint to agricultural growth as it prevents or delays the adoption of modern technologies (Yaron, 1992). It is thus not surprising that the reduction in the contribution of agriculture to the Nigerian economy has been attributed to the non-existence of a national credit policy as well as the absence of financial institutions that can provide farmers with credit (Rahji and Adeoti, 2010).

The problem that small scale farmers encounter in accessing credit has been hugely attributed to the insecure nature of land rights and lack of collateral; the situation is made worst by the weak legal framework for reinforcing contracts which make collateral foreclosure difficult (Yaron, 1992; Besley, 1995). There is thus the need for a mechanism that will guarantee land ownership security, ease the collateral constraint and make their foreclosure much easier. It is in this light that many authors have recommended land registration as the tool to enhance access to credit. While some studies have established a significant positive relation between land registration and credit access (Feder et al., 1988) several other studies found that either no relation at all exist between the two or the established impact on credit access was found to be insignificant (Angel et al., 2006; Carter and Olinto, 2003; Galeana, 2004; Gilbert, 2000; Place and Migot-Adholla, 1998; Mighot-Adholla et al., 1991; Broegaard et al., 2002; Pender and Kerr, 1999; Petracco and Pender, 2009).

The aim of this paper is to attempt to provide theoretical and practical explanations as to why land registration per se cannot be a panacea to the credit constraint problem faced by small scale farmers in the developing countries. This is achieved through a critical review of the relevant literature. The rest of this study is organised as follows; section two will look at land registration. In section three, the link between Access to agro-credit and land registration will be discussed. Section four outlines the limitations of the credit effect argument. Finally, section five is devoted to the conclusion.

2 Land Registration

Land registration is the process of recording all land ownership data into a national or central database that can easily be accessed by the general public as well as the continuous update of such data to render the database a mirror image of the actual land ownership. There are basically two forms of land registration – deed and title registration (Deininger, 2003; Larson, 1991). According to Deininger (2003) deed registration simply involves legally recording land transfers during the time the transaction is being carried out. This may usually require the seal of a judge to give the transaction document a legal status. One is said to attain legally recognized rights to land upon conclusion of a transaction agreement or contract. However, the fact of registration carries with it no implication of title prior to registration and there are no guarantees for the accuracy of such information (Larson, 1991). Unlike deed registration, however, in title registration, it is the recording of land rights into the register that renders such rights legally valid and qualifies the proprietors for statutory guarantee (Deininger, 2003). Though the two are difficult to differentiate it is often argued that the presence of a statutory warranty of title under the title registration system is the main distinguishing factor. It should however, be noted that in practice, title registration in some countries such as Germany, Sweden and Denmark involves no State guarantees and protection for registrants is only derived from ‘public faith’ (Zevenbergen, 2002).

3 Access to Agro-credit and Land Registration

It has often been argued that land registration has the potential to promote economic growth and poverty reduction in the developing world (Bromley, 2005; de Soto, 2000; Feder et al., 1988; World Bank, 1975). This appears to depend strongly on the extent to which land registration can perform the following primary functions of: (a) improving land tenure security; (b) reducing or eliminating land ownership uncertainty and related disputes and litigations; (c) facilitating the operation of land markets or land transactions; (d) reducing the time and cost of verifying ownership; (d) reducing information asymmetries (e) raising land values and (f) enhancing access to investment credit.

Land registration is seen as a tool for facilitating land market transactions because it works to reduce information asymmetries in all land related transaction by providing all parties in land transactions with the same amount of ownership information (Deininger, 2003). Reducing the level of information asymmetries in land transactions leads to a reduction in transaction costs (in terms of time and other resources spent verifying ownership data) and speeds up land related transactions by eliminating or drastically reducing any uncertainties and disputes surrounding land ownership (Byamugisha, 1999). If registration is capable of reducing land conflicts it will provide a boost to lenders taking land-based collateral. Ownership conflict over land could be very costly to banks. Firstly, it may prevent banks from repossessing the land. Secondly, even where the bank repossesses the land selling it may be difficult. Buyers may be less willing to purchase lands known to be involved in ownership disputes as those who purchase such lands may be exposed to reprisal actions from disputing parties.

Furthermore, land registration allows lenders to check the register to ensure that any land been presented for collateral purposes does not have any encumbrances on it that may turn out to be a hindrance during repossession. Since all registered interest in land

is given priority over all other claims, it presents lenders with the opportunity to publicise their interest in land-based collateral. This ensures that borrowers do not present the same land as collateral for credit from another lender without the notice of the first lender. Even when it happens, prior claim rights are given to the first lender to register a charge on the land. Land registration thus could be seen as a system for establishing prior claims among lenders. Having said that, it should be clearly stated that collateral registries where they are in operation can equally perform some of these functions.

After pledging their land as collateral for credit some landowners also have the tendency to sell the land without the notice of the lender. With land registration this will not be possible. Under the title registration system where there are statutory guarantees, lenders are able to enter a charge against land which is then guaranteed by the state. This effectively becomes a form of insurance for lenders.

As stated earlier, land registration is seen as the key to improving investments and economic development in the LDCs. One of two channels through which this is achieved is the supply-side effect. The argument here is that through the functions performed by land registration (stated above), land is converted into a secure and better form of collateral that can guarantee access to investment credit for increased economic growth and poverty reduction – this is the de Soto effect. According to de Soto (2000) the poor usually possess landed property which could be key to eradication of poverty but unfortunately, these assets are defective and cannot be used to generate wealth mainly because of the absence of registered property titles and therefore does not permit their use as collateral for loans to finance business or investment activities.

This lack of formal registration creates mistrust among lenders with regards to the validity of ownership rights as well as increasing cost of verification to prohibitive levels (Field and Torero, 2004). Land registration supposedly therefore solves these problems and facilitates credit markets by making land a highly desirable asset for collateral purposes. Deininger (2003) argues that the provision of registered land titles is often a precondition for access to formal credit for the medium to long term making collateral an integral part of all credit markets. This is a suggestion that collateral and registered titles on land-based collateral are always a necessary requirement in granting credit. This may not be entirely true as lenders may tend to be amount conscious when taking collateral. Where the loan amount is substantially small relative to the collateral cost, this argument will not hold unless the lender is capable of shifting this cost to the borrower.

There are a number of factors that may trigger the need for collateral. The most important amongst these factors is probably the perceived risk of the borrower. If the lender is confident a loan will be repaid without any problems, there may be no need for collateral given the cost of processing and foreclosure involved. Collateral therefore, may only be necessary in instances where the risk of default is significant. It is thus an insurance against default and a last resort to loan recovery. Taking collateral does not necessarily imply that it will be foreclosed during default. Lengthy court procedures and litigations not caused by disputes over ownership may make foreclosure virtually impossible especially in the developing countries. This may happen irrespective of whether or not a land is registered. In granting credit, banks may usually focus more on factors such as cash flow, profitability and credit history to ensure that any amount advanced will be repaid without recourse to collateral foreclosure. What this implies is that even where collateral is provided lenders may still want to avoid foreclosure as

much as possible because of the uncertainties that may be associated with it. Collateral could thus be considered a secondary as opposed to a primary requirement in granting credit. The possession of collateral will not guarantee access to credit. It may only enhance one's chance of obtaining credit where collateral becomes a necessary requirement triggered by substantial borrower risk of default. With a significant risk of default, a borrower may not be able to secure credit without offering collateral. However, where the lender is almost 100% sure that the borrower will default, offering collateral may still not be able to enhance the chances of securing credit. To summarise the above discussion, collateral could sometimes be a necessary requirement but can never be sufficient requirement for accessing credit.

With regards to land registration, it may only be useful to formal lenders in as far as it provides documentary proof of land ownership that is easily verifiable. On the issue of ensuring landownership security in the LDCs, land registration may be less relevant to lenders as land disputes have persisted after several years of introducing land registration. If the most important role of registration to lenders is the provision of documentary proof of ownership, such proof could be obtained from unregistered documents such as land deeds. It is not inconceivable to argue that banks will accept unregistered land as collateral where the borrower can provide sufficient documentary proof of ownership such as deeds and other informal documents. In the situation described earlier where borrowers may be required to provide land-based collateral before a loan is approved the issue of whether or not the land is registered may be inconsequential.

The argument here is that when taking land based collateral lenders may have other concerns that are more important than whether or not the land is registered. These include the location and market value of the land, as well as ability to provide documentary proof of ownership (which can be met without registration). The peculiar properties of land such as its immovability, relatively low maintenance requirement as well as the fact that it is difficult to be permanently damaged (virtually indestructible) make it a very suitable collateral asset (Binswanger and Rosenzweig, 1986 in Byamugisha, 1999 and Deininger, 2004). A good collateral asset among other things must be one that is easily marketable or realisable. The extent to which land registration can reduce land disputes might influence the ease with which land can be sold as well as its desirability for collateral purposes.

4 Limitations of the Credit Effect Argument

The argument that access to credit can be guaranteed through land registration is mostly based on the assumption or somewhat incorrect assertion that land registration is the panacea to land disputes. This assertion has no empirical basis in the developing nations. According to Atwood (1990) land registration could actually reduce security and lead to more conflicts in instances where overlapping customary and residual right of women, uneducated, nomadic and other marginalised groups were not recognised and recorded in the process. In countries like India, Mexico, Peru, South Africa, Tanzania, Senegal and Egypt, Payne et al (2009) observe that de facto security of land ownership already existed before the introduction of land registration programs; Indeed in Afghanistan and India for instance, it is reported that registration actually led to an increase in land disputes. If land registration has failed to solve the problem of insecurity, the basis of the argument linking registration to credit access is flawed and must be discarded.

The inability of small scale farmers to secure formal credit is not a function of the lack of registered land titles but other more important factors. For instance, in Peru, Angel et al (2006) report that no study found a direct causal link between land registration and credit access. In Bogotá, Gilbert (2000) establishes that the possession of registered land title made no difference to formal credit availability; indeed, the most serious problem faced by formal lenders is not the absence of registered land title but the nature of the assets which such poor people often offer as collateral. Savings and loans corporations in Colombia for instance are said to have strict rules about which kinds of building and their location are to be considered in advancing loans (Gilbert, 2000).

Furthermore, borrowers' ability to repay loans is a critical factor considered in granting credit. Failure of a borrower to demonstrate beyond reasonable doubt that they are capable of repaying a loan will most likely result in their failure to attract credit irrespective of whether or not they possess registered land titles which they are willing to offer as collateral. This is confirmed in a study by Angel et al (2003) which found that the main reason why people were denied credit was the low borrower repayment capacity and not the absence of registered titles. For farmers in the developing world to attract formal credit to expand their businesses, they must be able to demonstrate that such businesses are profitable and can generate sufficient amount of cash regularly and reliably to repay any advanced credit. This is where the challenge lies. Agriculture appears to remain largely in the hands rural based peasants who can barely have enough to feed themselves. To make matters worse they appear not to have alternative regular sources of income that could be used to secure credit.

Lending involves a fixed cost irrespective of the loan amount. Such costs include the cost of screening and monitoring, processing collateral and cost of enforcing payment or loan contracts. With the relatively small loan amounts that small scale farmers appear to demand, such fixed cost may render the cost of borrowing unaffordable to farmers and thereby restrict their access to credit.

Probably, the most important credit constraint factor for the agricultural sector in the developing world is the inherent risk. The sectors could still be said to depend largely on nature and is thus exposed to risk of unfavourable climatic conditions which could create other risks such as price and output risks. The consequences of price and output risk are well documented for Uganda and Mali. In Uganda, the experience of very good maize harvest from 2001 to 2002 caused drastic fall in prices and farmer incomes and subsequently affected some banks as loan repayments were affected; in the case of Mali the proportion of the credit portfolio considered at risk for a number of credit unions increased from just 3% in 1998 to 12% in 1999 as a result of a significant decline in cotton prices (Llanto, 2007).

Climatic conditions coupled with price fluctuations expose farmers' incomes to risk at a level above that experienced by people in other sectors and this affect loan repayment by farmers (Yaron, 1992). Such systemic risk as adverse weather changes and global price fluctuations are said to be responsible for the unwillingness of commercial banks to finance the sector (Llanto, 2007). There is no need stressing that unfavourable fluctuation in climate, output and prices usually make it virtually impossible to recoup investments made by these farmers and those who finance such investments by credit will find it difficult to repay. The associated volatile revenues may reduce lenders' confidence in the repayment capability farmers. With farmers perceived as highly risky borrowers who are almost certainly going to default, even the possession of registered titles to land will not enhance their chances of obtaining credit.

Without any deliberate comprehensive intervention by government, the price and output fluctuations will continue and the seemingly rising poverty amongst farmers may never come to halt. Reducing these risks will require investment in infrastructure. The provision of irrigation facilities will reduce overdependence on rainfall. The provision of storage facilities will also help control supply, reduce post harvest losses and provide some price stability. Alternatively promoting agro-processing will create a ready market for agricultural products as a solution to the problem of lack of market and price depression. Without good transport network linking farm lands to market centres, cost of transport will not only increase but also post harvest losses. In a rain-fed agricultural regime where the necessary agro-infrastructure base is weak, where inputs are difficult to access and where ready markets for agricultural products are not there, agricultural investment will remain unprofitable and unattractive. The banks are not likely to be willing to fund such unprofitable investments and the farmers themselves are likely to divert any funds made available to them into financing their consumption expenditures instead of investing.

5 Conclusion

The literature has been inundated with arguments that land registration is the key to unlocking the problem of agricultural credit constraint in the developing world. This argument is often made against the backdrop of the wrong assertion that registration will guarantee land ownership security and thus enhance the collateral properties of land. An examination of this argument has shown that in most instances in the developing world land registration has failed to promote security but has rather increased insecurity. Registration only provides legal recognition of ownership and in some instances guarantees for ownership of registered lands. However, security involves more than just legal recognition and that's why land disputes continue to exist in the developing world despite the implementation of various land registration programs. If registration fails to ensure security then it cannot be linked with improvement the collateral value of land and access to credit as seen in the literature.

Furthermore, the land registration and access to credit argument assumes that collateral is always a necessary requirement in applying for credit. In reality however, this may not be the case. Having said that, even if collateral were required to trigger credit supply, in the case of land based collateral, the land must not necessarily be registered to make it acceptable if only the borrower can provide other documentary proof of ownership. Land registration cannot guarantee access to credit for small scale farmers in developing countries because it is not a necessary requirement in taking land-based collateral.

The main factor responsible for the credit constraint among small scale farmers is the peculiar nature of risks the sector is exposed to. It appears formal lenders in developing countries are unable to manage these risks and therefore avoid lending to the sector as much as possible. Any risk that cannot be managed for whatever reason is not worth taking. Small scale farmers who are mostly rural dwellers usually do not have reliable alternative sources of income to offset the negative impact of agricultural risk. The recommendation here is for the state to stop providing direct financial support to farmers as such schemes have failed in the past. All such monies could however be put into an insurance fund that can be used to guarantee loans for farmers. The state could also facilitate the development of warehouse receipt systems and commodity exchanges which could be critical mechanisms for managing agricultural sector risk and enhancing

access to credit. The diversification of the rural economy could be significant towards providing farmers with more stable non agricultural related incomes to enhance their chances of obtaining formal credit. There are therefore more important factors that formal lenders look out for in granting credit other than just the possession of registered land-based collateral. Concentrating all efforts at providing farmers with secure land rights is most likely going to fail in guaranteeing credit access to such farmers in the developing countries.

Abstract:

This paper will assess the impact of the tin mining activities and its effects on the built environment and, specifically, housing in Jos Region. Utilising secondary data, which maps out ten (10) different locations in the region the paper highlights the level of radioactive substances (X-ray, beta –ray and gamma rays), and presence of heavy metals in the environment. Subsequent analysis shows that the radioactive substances exceed the international standards and therefore have a serious impact on the health of the local population who reside in the affected area. This is particularly significant as people use the contaminated soil as a basic material for their homes as well as farming and food production. With overpopulation of neighbouring city and rising house prices, an increasing number of people have moved to the tin-mining areas often without any knowledge about the perils of contaminated soil. At the same time, the planning authority has no presence in the affected area as it falls outside its jurisdiction. However, there is an urgent need to address this problem and prevent people from moving to this area otherwise this would become a serious long term human catastrophe. Drawing from international experience the paper argues that it is possible to develop housing in former tin mining areas but require careful remediation and engagement by the public and private sector.

Keywords:

abandon mines, contaminated land, development, housing, home,

1 Introduction

Housing is a major component of the built environment, and it is affected by other components of the environment such as social services utilities and infrastructure associated with it. Humans' social, economic and political activities have profound impact on the natural environment. The production of the built environment has a major impact on the environment including climate change and environmental change that create health problems (Bruntland Report, 1987; Onibukun, 1990; NHP, 2006; Obateru, 2004; Agbola and Kassim, 2007; IPCC, 2007; Wapwera, 2008; Rydin, 2011).

In Nigeria, the national housing policy was formulated with the ultimate goal of ensuring that all Nigerians own or have access to decent accommodation at an affordable cost. Despite the level of progress being made in industry, education and services, the simple refuge in affording privacy and protection against the forces of nature is still beyond the reach of many, especially the poor and the disadvantaged (Mabogunje, 1978; Onibukun, 1990). Jinadu (2004) in his study highlighted qualities of a good house to meet the needs of the occupant, thus a good house should have a quiet environment, privacy, cleanliness, living and outdoor space, safety and aesthetic satisfaction. A house must also have good quality building materials which meet the needs and aspirations of the occupants as well as contributing to this physical, mental and social well-being of the individuals. It should also be served with the basic community facilities like roads, electricity, water, recreational facilities and sewage/refuse disposal (Anderson, 2000; Obateru, 2004; Wapwera, 2008, 2009).

The quality of housing remains an issue of concern to developers, builders, policy makers as well as planners. Studies have shown that majority of low income earners and the poor in the developing countries live in substandard housing and poor quality neighbourhoods. This is more prevalent in the rural areas, mainly because the houses are constructed using low quality building materials. The situation is worse, in environments characterised by environmental degradation, derelict lands, environment with serious economic decadence and culture among others giving rise to a poor environmental quality, which in turn has influence on housing quality being a component of the environment (Jinadu, 2004; Agbola, Egunjobi & Olatubara, 2007; Wapwera, 2008; Ayanbimpe, Wapwera and Kuchin, 2010). See figures 1 and 2.

Figure 1 Location of housing close to mining ponds Figure 2 Location of Dragline to form mining ponds
(Source: Reconnaissance survey, 2009)

Mining as a process of extraction of raw materials for industrial use can leave behind a legacy of environmental pollution for generations to come (Benevento *et al.*, 1997; RIC Report, 2006). In many developing countries due to lack or/weak policies and regulative measures, mining has caused severe environmental pollution that are hazardous to the local population. Mining activities took place in Jos Plateau, Nigeria, over a century ago leaving behind ponds posing a danger, and constraining the movement of people, goods and animals; hence, the zone is tagged 'disaster' area (Howard, 1975; Wapwera, 2009; Mendie, 2009).

The processes and methods of mining have varying degrees of environmental impacts/effects on the landscape. The spoil hills that resulted from these activities by estimate occupy 325 sq km (about 41%) of the Jos Plateau, while the area destroyed which is about 267sq km is characterized by mining paddocks and tin tailings (Howard, 1975; Aguiwo, 1997 in Gyang and Ashano, 2010). This accounts for about 30% of the land being unproductive either due to gullies with depths and width of gullies up to 12.2m and 2.4m respectively and to about 7,240 km. This is manifested in the presence of the moulds and ponds that are potential danger to human lives and the physical environment. See figures 3 and 4.

Figure 3: Burrow pits results of Pre-Tin mining activities. Figure 4: Mine Ponds results of Pre-Tin mining activities

(Source: Greater Jos Master Plan 2007)

The effects/impacts of Tin mining activities are observed from different perspectives, including from industrial uses like food preservation, paint, plastic and pesticides (positive). It also has consequences of poisoning, affecting the soil water and the environment. Contamination by heavy metals (Pb, As, Cu, Cr, and Ni) and radioactive substances (X-ray, beta -ray and gamma rays) are major factors that affect the health of the people and quality of their housing in the Tin mining region (Douglas, 1996; (Leblanc *et al.*, 2000; Lee *et al.*, 2001; Marques *et al.*, 2001; Ibeanu, Akpa and Mallam, 2004; Ajayi, 2008; Alshaebi *et al.*, 2009; Gyang and Ashano, 2010).

The overall aim of the paper is to assess the impact and effects of tin mining activities on the built environment and specifically housing in the Jos Plateau Tin Mining Region (JPTMR) of Nigeria. Firstly, identify and determine the level and availability of heavy metals and radioactive substances. Secondly, analyse the level and availability of heavy metals and radioactive substances. Thirdly, assess the impact of the heavy metals and radioactive substances on housing in the tin mining areas and observe how this area could be transformed.

2 Research Methodology

The methodology is quantitative in nature, with secondary base evidence obtained from previous works on Jos plateau tin mining region (geological, geophysical and chemophysical field surveys). Extracts from Toro sheet 148 north central Nigeria, it shows where samples of water and soil with tailings were taken to check for equivalent dose of the natural gamma- emitting radionuclides (^{238}U , ^{232}Th and ^{40}K), as well as mineral and chemical composition. Same sample was also used to determine the hardness in water as a result of the presence of the substances in the water (Gyang and Ashano, 2010). The instruments used include; scintillator (NaI (TI) photomultiplier to detect and take count of gamma and alpha radiation count per second and measurement of soil natural radioactive were made using a multi- channel pulse-height analyser (Canberra Series 10 plus) coupled to a 76mmX76mm NaI (TI) scintillation detector (Ajayi, 2008). While the instrument use for water is Esticks EC500 for conductivity and Jenway 3150-pH/ for temperature (thermometer) amongst others.

A total of 20 surface samples (soil) of natural origin were collected from a number of locations spread across the region. These were at depth levels of 0 to 6 cm, as adopted by Ajayi, 2008; Ibeanu, Akpa and Mallam, 2004 to determine the equivalent dose in human body and in building construction materials to the natural gamma- emitting radionuclides (^{238}U , ^{232}Th and ^{40}K) (Beretka and Mathew, 1985). Gross gamma and alpha radiations counts data obtained in counts per second (c/s) were converted to exposure in reagent/hour and these were exposure rates again converted to absorbed dose rate in rad/hour using the relation between absorbed dose rates (Da0 and exposure (E) as given by Grasty *et al.* (1984). A PUG-7 radiation meter combined with a T/A

probe was used to measure the radiation levels in the soil samples. This generally allows for appropriate measurement depending on the strength of the radiation. Measurements of the soil's natural radioactivity were made using a multi-channel pulse-height analyser (Ajayi, 2008). For water the instruments used to test different parameters were for conductivity, pH, and temperature the Esticks EC500 conductivity meter and Jenway 3150-pH/temperature (thermometer) meter, respectively. Total hardness was determined using titrimetric method, while turbidity was measured using Secchi's Disk. Other instruments used were litmus paper for pH, spectrophotometer for anion analysis (Gyang and Ashano, 2010).

2.1 The Study Area

The Jos area of Nigeria is located on a granite plateau, 1900m above sea level in the north central part of the country (See fig.II). The geological formation of this area lends itself to the lithological formations composed of the basement complex, biotite granite and new basalts (Ajayi, 2008). Tin and columbite ore are associated with greisenized, Biotite granites. The Jos Tin industry started around 1904. The primary purpose of the industry is to mine Tin Ore and mill the same for Tin and some by-products (especially columbite) for exportation. The rock materials are used extensively for slabs, aggregates, rockfills and other forms in building construction in and around Jos; and this continued to increase as more and more people built houses to cater for the increasing need for accommodation.

Jos Tin Mining region is located in the northern and central parts of Jos Plateau State, north central geo-political region of Nigeria. It is bounded approximately by latitudes 8° 0'55''N and 10° 0'N, and longitude 8° 0' S 22'' E and 9° 0' 30''E and the locations of the samples collected according to Gyang and Ashano, (2010) were latitude 9° 30'N and 9° 33'N and longitude 8°53'E and 8°59'E. It is one of the many geographical (physiographic) regions recognized in Nigeria. See figures 5 and 6.

Figure 5: Location of Plateau State

Figure 6: Tin Mining Region

Source: GIS Lab, University of Jos, Nigeria 2008

It is a distinct physiographic region, with altitude of about 1,200m above sea level. It is about 800m above the surrounding plains to which it descends through several steep, stepped escarpments at some points, and rises to about 1,500m above sea level at its highest point (Eziashi, 2000).

2.2 The Jos Plateau Tin Mining Region (JPTMR)

Jos Tin Mining region derived its name from the geological landscape known for tin mining activities that was carved out of the present day Plateau State. Fig. (II). The region covers nine local government areas in plateau state. These include: Jos North, Jos South, Jos East, Boko, Bassa, Riyom, and Barkin Ladi, Mangu, and Pankshin. It covers about 43% of the total land area of the Jos Plateau amounting approximately to

3,670 km sq. It consists mainly of the undulating areas of Plateau state (Ajaegbu 1986; Eziashi 2000).

2.3 Description of Sample Locations

Samples were collected from areas around Rock Heaven, Zaria road, Jos, Kufang village off Miango road, Jos, Mills extracting columbite as a main objective and from the banks of a stream in Anglo-Jos. Cassiterite is washed directly in the stream and tailings heaped beside the stream (Adiuku-Brown and Ogezi, 2004). Materials analysed were soils, water and Tailing sample collected from various locations in Nigeria. The samples were reported as being used for roasting and frying of groundnut, plastering and construction materials, such as for residential buildings. These samples were oven dried for soils, ground to powder and used. A weighted quantity of sample sufficient to fill a 230 cm³ cylindrical plastic cup was used for the gamma ray counting. The samples were triply sealed and stored for a minimum of 24 hours under a temperature of 105⁰C in an oven to dry. Other studies examining similar environmental pollution as a result of Tin mining have also employed the same method of sampling and instruments for analysis in Malaysia (Mohsen, Pauzi and Azizah Jaafar, 2007).

This condition was checked by allowing radium to reach equilibrium. Water sample was collected from the mine ponds, well water and boreholes within the study area. The water was collected in polyethylene 250ml screw cap bottles. All the vessels used for the collection of the water were sterilized. Cation analysis vessels were soaked in 2% HNO₃ (Nitric acid) while for anion were soaked in 6% HCL (Hydrochloric acid) except for Cl analysis. Tests were made for conductivity using Esticks EC500 conductivity Jenway meter and pH scale and thermometer. The total hardness of water was determined using titrimetric method, while turbidity was measured using Secchi's Disk (Gyang and Ashano, 2010).

3 Findings and Discussion

The Results of ionizing radiation carried out on the sample of soils from the locations in different parts of the areas with basalts on the plateau show that the gamma radiation dose rates vary from 0.03-0.058 rem/yr (0.32-0.58mSv/yr), while dose rate due to alpha and beta radiations is from 0.16- 0.32 rem/yr. The total dose rate from both alpha/beta and gamma radiation from the basalts within the Jos Plateau therefore is between 0.19-0.36 rem/yr. The implication of the results explains that the natural radiation levels in basalts around the Jos area are low, generally below the maximum permissible exposure for general public. This makes the basalts radiologically safe for use for instance in building construction with little likelihood that safe radiation levels in such buildings will be exceeded. The alpha and beta gamma radiation particles been exposure are dangerous radioactive materials that produce can be taken into the body via food (WHO, 1993;UNSCEAR, 1992). Hence, prior to this study Arena(1971) and Shapiro, (1972) had argued that ionizing radiation may cause injuries to the brain, damage of eye lens resulting in cataracts; damage to the ovaries or testes which may cause sterility; damage to the bone marrow which affects the body's ability to fight infection. The extent of radiation injury will however depend on the period of exposure, distance to source and shielding between source and target (Solomon, et al 2002). This is a corroboration with the work by Mohsen, Pauzi and Azizah Jaafar, 2007; Hamzah *et al.*, 2008 all in Malaysia. Other studies by Adiuku-Brown and Ogezi, 2004 reveals that there is a gross significance as it relates to Thorium (Th) and Uranium (U) as radioactive by any given route , a decay of say , uranium -238 series , for example ,

consist of fourteen steps , eight involving alpha decay and six involving Beta decay. Radium (Ra), radon (Rn) and thorium (Th) are among the radionuclides emitted in the process. See table 1

Table 1. Radioactive substances and radiation/ionization level in study area
(Source: Adopted from Adiuku-Brown & Ogezi, 2004)

Hazardous pollutants	Health impact	Dose rates (rem/yr)	Implication	Substances emitted (radionuclides) steps(x)
Gamma Radiation	Injury to brain, damage eye leading to cataract, ovaries, testes (sterility), bone marrow and inability of the body to fight infection.	0.03-0.058 rem/yr	Low(permissible exposure)	Radium (Ra) Thorium (Th)
alpha Radiation (δ)	Injury to brain, damage eye leading to cataract, ovaries, testes (sterility), bone marrow and inability of the body to fight infection.	0.16- 0.32 rem/yr	low(permissible exposure)	Radium (Ra) (-226 series) Thorium (Th) Uranium(U)x 8
beta Radiation (β)	Injury to brain, damage eye leading to cataract, ovaries, testes (sterility), bone marrow and inability of the body to fight infection.	0.16- 0.32 rem/yr	Low (permissible exposure)	Radium (Ra) Thorium (Th) Uranium(U)x 6 (-238 series)

The following effects of the decay and emission of radionuclide exemplified in the use of tailings in building construction can trigger off radioactivity in building. Thus, radon is able to accumulate to hazardous levels in buildings constructed or resting on tailing. Furthermore, the use of Tailings in roasting of groundnuts can lead to ingestion of radionuclide such as radon. Radon produces other - products which lodge in the lungs and eventually produce lung cancer. The use of tailings in children's play ground can lead to a direct ingestion of radioactive elements or their radionuclides. The general indiscriminate disposal of tailings can pose a threat to human health which is a negation of one of the 1999 national policy on environment as road fills. Tailings have no cementing, material. Therefore the radioactive elements and their radiogenic products can easily be washed into neighbouring streams. Radium – 226 is particularly toxic if ingested through stream waters (United States DOE, 1986).

In addition to the radioactive elements identified in the tailings, manganese, iron, lead, cadmium and zinc were also detected during chemical analysis (Adiuku-Brown and Ogezi, 2000b). As a result of these findings the following effects are possible; lead is very toxic at lower concentration (Bryce-Smith, 1971). Lead poisoning damages the kidney, liver, reproductive organs, central nervous system and the brain. This was observed recently in Nigeria where over 400 children were killed from lead poisoning in Zamfara state, northern Nigeria, which spread over 7 villages in less than six months (Mason, 2010). Cadmium and lead are formed from particularly stable bonds to some active sites of some proteins (enzymes) and can be associated with the protein replacing the carboxyl hydrogen, or disrupt the disulphide bridge , or replace the hydrogen of the sulphhydryl group , denaturing the protein and impairing its normal metabolic activities (KrausKopf, 1979). Some heavy metals (zinc, iron and manganese) which in normal concentrations are essential components of biochemical systems are toxic when present in the body in higher concentrations (Forstner and Wittmann, 1983). See table 2

Table 2: Health impact of Hazardous pollutants (Heavy metals and radioactive substances)
(Source: Adopted from Adiuku-Brown & Ogezi, 2004)

Hazardous pollutants (Heavy metals)	Health impact	Dose rates (ppm) and Implication	Constituent elements
Monozite			Ce, La,Sn, Th, U in traces.
Zircon			Zr, Y,Sn, Fe, U.
Zinc	Toxic in high concentration	(430)	Zn
Lead	Damages kidney, liver, reproductive organs, central nervous system and brain.	Disrupt disulphide bridge, denature protein and impaired normal metabolic activities in the body. (413)	Pb
Manganese	Toxic in high concentration	(800)	Mn
Cadmium	Form a stable bond to protein enzymes and denaturing it.	Disrupt disulphide bridge, denature protein and impaired normal metabolic activities in the body (2.0)	cd
Columbite	Eye, brain, skin and blood related diseases	Damage of cells of organs listed.	Nb, Fe, Mn, Ta, Sn
Cassiterite	Eye, brain, skin and blood related diseases	Damage of cells of organs listed.	Sn, Nb
Fe ₂ O ₃ (%)	Toxic in high concentration	(16.14)	
Sn O ₂ (%)		(0.32)	

The conclusion drawn by Adiuku-Brown and Ogezi, 2004, was that it is unsafe to use the mill tailings scattered in major locations in residential areas and streams channel to build houses or roast groundnut as they contain radioactive materials and toxic elements. Tailings should be properly disposed of in a carefully sited location earmarked strictly for the purpose. There is the need to carry out extensive public enlightenment on the possible hazards that can accompany the indiscriminate disposal and utilization of tailings, and monitor compliance.

3.1 Analysis: Microscopic, X-Ray Fluorescence and Chemical

The microscopic analysis was to identify the minerals in tailings. The crystal of zircon (Uranium incorporated due to similarity in size and charge) And Thorium in monazite as well as Uranium. The *X-Ray Fluorescence* was essential for the identification of the presence of Uranium and thorium in the Tailings obtained. The elements are manganese, iron, cadmium, zinc and lead the samples were digested using HNO₃, HCL and HClO₄ mixture. Fusion with Na₂CO₃ and Na₂O₂ was used in the digestion of samples, for SnO₂, determinations. Reagents blanks were also prepared and standards were digested and analysed along with samples to be apply some correction factor. UNICAM atomic absorption spectrophotometer was used for the analysis (Adiuku-Brown and Ogezi, 2004). See table 3.

Table 3: Minerals and Mean concentration of constituent elements
(Source: Adiuku-Brown & Ogezi, 2004)

Minerals	Constituent elements	Analysis	Mean concentration by heavy metals
Columbite	Nb, Fe, Mn, Ta, Sn	Cd (ppm)	2.0
Cassiterite	Sn, Nb	Mn (ppm)	800
Zircon	Zr, Y,Sn, Fe, U.	Zn (ppm) , Pb (ppm)	430, 413
Monozite	Ce, La,Sn, Th, U in traces.	Fe ₂ O ₃ (%), Sn O ₂ (%)	16.14 , 0.32

3.2 Water Analysis

Results for water analysis show that the tin mining activities carried out on the project did not affect the quality of the water, though there are traces of Manganese, iron, and chromium observed in some samples cannot be said to be significant enough to warrant

panic, except for fear of bioaccumulation (Gyang & Ashano, 2010; Adiuku-Brown and Ogezi, 2004).

3.3 Housing Analysis

For the purpose of analysis on housing conditions five level scales were used to determine the level of quality. Depending on the conditions of the various parts of the building viz; very good, good, fair, poor or derelict; using variables that determine the functionality and satisfaction of the housing facilities, such basic amenities, materials use for the construction of the buildings all contribute to the conditions and quality (Onibokun, 1990; Anderson, 2000; Obateru, 2004; Wapwera, 2008; 2010) (see Table 4)

Table 4: Conditions and characteristics of Buildings in the study area
(Source: Wapwera, 2008; 2010; Ayanbimpe, Wapwera and Kuchin, 2010)

Condition of Buildings	Characteristics	Implication
Very good	No need for repairs, have the needed basic amenities such as water, electricity, kitchen, toilets, good refuse/sewage disposal and in a good environmental quality	The building is physically and structurally sound.
Good	Requires minimum level of repairs. It must have sound foundation and walls, with little or no cracks or leakages on the roof. With the needed basic amenities	It is structurally sound
Fair	Have cracks on the walls, leaking roofs, and broken windows to enhance its physical condition and bring it back to its original state. It may be lacking in some basic amenities	The buildings structurally require some level of repairs.
Poor	Devoid of basic amenities, and when available are not adequate. Some parts of the buildings have collapsed and are not habitable. Such houses require immediate reconstruction they may not have possess any facilities at all.	The physical structure of the building requires major/minor repairs or renovation and may require urgent attention in order to upgrade the building and make it habitable (derelict state).

From the research conducted, houses/structures were built on polluted lands; soils with contaminants were used as building materials while water containing such contaminants is used for consumption for domestic purpose and sanitation. The air in most of the houses has dust that contains these contaminants. More than 75% of respondents had complaints of respiratory systems, frequent headache, eye irritation and skin rash. 61 % of the homes showed dampness of the indoor environment, with more than 50% of the settlements not within the planned areas. 60% of the houses lack proper drainages, toilets and waste disposal facilities and 43% of the houses were old and some dilapidated. See table 5

Table 5: Occurrence of Fungi in Relation to Responses to Features of Questionnaire
(Source : Ayanbimpe, Wapwera and Kuchin, 2010)

Features of questionnaire	Number of positive responses	Number of fungal isolates (%)
Unplanned settlement	72	55 (14.7)
Age of building (Old)	61	43 (11.3)
Lack of toilet/drainage facility	87	24 (6.3)
Lack of waste disposal facility	87	45 (11.8)
Dampness of building	87	87 (22.9)
Mold growth in the home	17	42 (11.1)
Symptoms (respiratory, eye)	106	24 (6.3)
Arthropod infestation	126	60 (15.8)

The above analysis has shown the extent of environmental pollution and its impact on the health of local residence. It is important to assert that half of the households

surveyed fall outside what is termed as planned area. This has further implication as it demonstrate the ineffectiveness of the planning system and lack of environmental protection. The Jos metropolis and local government authorities seems unable to do anything about this environmental hazard. This could be attributed to lack of resources including finance, legislative and institutional capacity in terms of planning and control. In the area of planning, the local governments in the metropolis should have urban and regional planning departments, create and monitor developments, as well as make funds available for development control at that level.

This next section examines alternative solution to development of contaminated land. This is achieved through examination of the case study Mines in Malaysia where private developer has transformed former tin mining area into a thriving and safe and quality area.

3.4 Alternative Solution to Development of Contaminated Land

Drawing from international experience, a case study of how a former tin mining area has been used to develop mixed use housing, business and recreation centre through careful remediation of the engagement of public, private partnership is presented. A typical example is the Bukit Buruntung, Kuala Lumpur Malaysia called the ‘Mine City’ (Kaur, 2009).

Mine city (formerly known as Mines Resort City) is an area Located 40 kilometres north of Kuala Lumpur, Malaysia, that has experienced Tin mining activities some years back. This area is about 840 ha of land with all the features of a derelict environment, just as the Jos Plateau Tin Mining region. A private developer Mines Excellence Golf Resort Bhd built three five-star hotels within its RM3 billion, another developer Mines Golf City development in Bukit Beruntung, Selangor also developed on that same piece land. They developed and set up a boutique hotel, a wellness hotel with golden standards and a hotel for golfers for more than RM300 million (Kaur, 2009). See figure 7.

Figure 7: Bukit Buruntung, Kuala Lumpur Malaysia
Source: Kaur, 2009)

The developer intends to establish a university designed for golfers and a health clinic and spa. And to turn Mines City into a world-class destination for golfing and for health tourism, set up a few golf and wellness hotels in Malaysia and it would be ideal to have two in Mines City, also involve other boutique hotel and spa operators to be involved to set up shops at the golf resort. The 840ha Mines City is being developed by Mines Golf City (MGC) Sdn Bhd. There are 70:30 joint ventures (partnership) between Mines Excellence and Country Heights Holdings Bhd. MGC is launching the development of

a 63-hole golf course on 320ha, which would be Malaysia's largest. The development includes townhouses, 500 bungalow lots, an equestrian and driving academy, schools, sports facilities, food outlets and parks on the remaining land (Kaur, 2009). Table 6 outlines the history of Mines City from its inception.

Table 6: Chronology of development of Mines Resort
(Source:<http://www.countryheights.com.my/mrc.php> http://en.wikipedia.org/wiki/Mines_Wellness_City)

YEAR	DEVELOPMENT
1888	The story started a hundred years ago, when a Chinese immigrant Chan Wing came to Malaysia and discovered tin ore in a site abandoned by Europeans earlier. This became the largest tin mine in the world. Mining in the area left a gaping hole 2 kilometres long and a kilometre wide, and 200 meters deep.
1988	Malaysian Government alienated the land to Country Heights Holdings Bhd (CHHB) on 30 March 1988 for the development of recreational and tourism.
1990	From a scarred and derelict wasteland, the world's largest open cast tin mine was transformed into The Mines Resort City. The Mines Resort City was carved out beginning with the construction of Mines Wonderland.
1997	Launch of *Mines Waterfront Business Park, *Palace Beach & Spa, Mines Shopping Fair, *Palace of the Golden Horses and Malaysia International Exhibition & Convention Center. *The Mines Resort City played host to several international events.
1999	Mines Golf Club hosted World Cup Golf and Women's World Cup Golf where Tiger Woods. The Mines Resort City hosted the World Formula One.
2004	Golden Horses Health Screening Under the expansion of Golden Horses Health Screening Services
2006	Palace Beach & Spa Re-branding exercise for Mines Beach Resort & Spa, now known as "Palace Beach & Spa", Country Heights Vacation Club, now known as "Palace Vacation Club" and Country Heights Health Sanctuary and now known as "Palace Health Sanctuary" to creating a unified branding with PGH.
2007	Purchase of Mines Shopping Fair for cash by Capitaland of Singapore for RM432 million (first international investment in the scheme)
2008	Golden Horses Health Screening Country Heights officially launched the Traditional Chinese & Complimentary Healthcare Centre (TCM) together with the Ministry of Health Malaysia. Despite the real estate bubble burst and sinking subprime issues in the financial industry, Country Heights have successfully introduced Mines Golf City, a 63 hole luxurious golf course and homes.
2010	CapitaMalls Asia has re-branded Mines Shopping Fair to a contemporary neighborhood shopping mall with a major upgrading work, including additional retail space, revamping the carpark system, changing new wash rooms, creating additional link bridges and new sets of escalators inside the mall
2011	Mines Wellness City (formerly known as Mines Resort City) is an integrated Health and Wellness resort city in Malaysia. It is both an expansion and transformation of the current Mines Resort City.

The expansion of the city is part of the Malaysian Government's Economic Transformation Plan (ETP) which is spearheaded by PEMANDU (Performance Management and Delivery Unit), under the Prime Minister's Department. The development of Mines Wellness City will lead and contribute to increased economic activity, job opportunities and GNI. By the year 2020, the City is envisioned to be a RM 5.5 billion development, playing a central role in tourism and becoming the foremost wellness destination in the country and in the south east of Asia.

Mines Wellness City showcases the company's legendary transformation of a derelict tin mine, devoid of economic and social value, to an internationally-acclaimed venue that showcases superior wellness facilities and practices. See figure 8.

Figure 8: Mines Resort City in Malaysia (Kuala Lumpur) Figure 8 shows the development of the derelict area into a tourist haven, before and after.

Figures 9-12 show the transformation of the derelict area into multiple land use for revenue generation and source of employment for Malaysians over the years.

4 Conclusion and Further Research

This paper has analysed the impact of tin mining on the Jos area. The analysis conducted in the region shows the impact of the economic activities (exploration and exploitation of tin) that has rendered the area derelict. Furthermore, tin mining has left a legacy of hazardous impact on the inhabitants of the area taking away their fortunes (socio economic potential) which determine to a large extent their provision of basic infrastructure in the house. The devastation from the mining activity has affected the physical landscape of the area making it difficult for the provision of urban facilities, utilities and services. Other impacts are felt on the soils, water and air which have culminated into different life experience for the inhabitants. This is partly due to unchecked and unregulated building activity in the absence of planning authority in the study area. It is not within the jurisdiction of the planning authorities, in both the state and local government level. There is an urgent need to address the problem and prevent people from moving to this area, as development of housing in the tin mine area requires careful remediation and engagement by the public and private sector.

The paper has demonstrated that tin mining activities has not favoured local construction of housing by the peasants or low income earners, who use locally sourced construction materials due to the presences of heavy metals and radioactive substances within their immediate vicinity. Subsequently, the environmental impact of tin mining on the Jos Plateau in Nigeria in terms of pollution of land, water sources and housing has been particularly significant. In this context the research has identified high level impact of hazardous heavy metals on the health of the inhabitants of the area and impact of the radioactive substances with dose rates that appears low but with long term effects on the inhabitants (for fear of bioaccumulation) living within the zone as it affects the quality of the physical (water, soil, air) and the built environment (Housing). Furthermore, abandoned mine ponds and heaps of mine spoils etc are found to cause

particular environmental damage. Other damage includes the geographical impact on the natural and the scenic beauty of the area due to presence of lotto and prospecting pits that abound and impacts of both hazardous heavy metals as well as the radioactive substances on housing in the study area. The paper also highlights the long term economic and social impact of abandoned mining in the region and drawing from international experience it demonstrates how it is possible to transfer such affected areas into prosperous and safe residential and recreational areas. An important issue highlighted is the need for a radical approach to funding the transformation of such areas through partnership between private and public sector. This has been demonstrated by examining the development of the Mines City in Malaysia where partnership between the government and private developers has enabled the successful transformation of a former tin mining area.

5 Recommendations

The following recommendations are made to address the housing and environmental hazards posed by the mining activities through;

1. Planning and regulative control in the Jos tin mining region (JPTMR): ensure effective planning to discourage development but facilitate the improvement of the affected areas through; appropriate land use planning to restrict the use of contaminated sites. To prepare and adopt a regional plan to identify areas of contamination and implementation of appropriate measures to clean the pollutants to turn the area into a safe and habitable environment.
2. Legislative framework to regulate mining activities to prevent similar occurrence in other areas. Reclamation after mining should be encouraged and to increase awareness of people to the dangers of contamination and hazardous impact of tin mining on their health and well being.
3. Establishing pilot projects such as self-help housing schemes to demonstrate remediation of contaminated sites and use of safe building materials for housing with funding by the government and donor agencies to the inhabitants to build their houses.
4. Public-private partnership can be an effective way in transformation of blighted areas such as Jos region. The experience of Mines City has demonstrated the effectiveness of public-private partnership and long term strategic government policy.

6 Acknowledgement

This paper is a part of my PhD Research 'A potential application of spatial planning in Jos, Nigeria'. I am grateful to my employer the University of Jos, Nigeria for funding my research project through the Education Trust Fund (ETF).

Abstract:

Clients changing demands with regards to cost and time efficiency of projects promotes the adoption of alternative procurement paths. The peculiarity of risks within such procurement options are different from those risks found in traditional procurement methods. Clients adoption of design and build procurement method arises from its perceived ability to integrate the design and construction processes thereby saving time. In design and build contracts, the contractor is responsible for both the integrity of the design as well as the quality of the final construction product. The perceived time saving from the integration of the design and construction process exposes the project to other risks. There is tendency of increased cost as a result of the fact that cost planning may not be adequately concretized. Majority of the construction risk is transferred to the contractors as a result of contractors' involvement as designer and builder. This study examines the risks associated with design and build procurement system in Nigeria. The research also evaluates the impact of the risk on design and build projects. A structured questionnaire was used in collecting data from respondents. Sixty questionnaires were distributed among contracting and consulting organizations involved in design and build projects in Lagos state. Forty questionnaires were returned representing a 67% response rate. Frequency, percentage and mean item score were used in analyzing primary data collected for the study. The study shows that rainfall, increased material cost, bribery and corruption, uncertain contract provisions, inadequate construction planning, incompetent planning, environment damage/pollution and delayed payment are the most frequent risks associated with design and build procurement systems in Nigeria. The impact of risk factors on design and build procurement are mostly evident on project cost overrun, dissatisfaction on quality of work, time overrun, claims, and accumulation of interest on loan facilities. The study recommends that when considering tenders for design and build projects, contractors should pay attention to client's financial status and other economic dynamics of the construction industry. Contractors should adopt the most effective risk response strategy in handling risks associated with design and build projects with a view to achieving project objectives.

Keywords:

design and build, Nigeria, procurement methods, project objectives, risk

1 Introduction

The Nigerian construction industry continues to occupy an important position in the nation's economy even though it contributes less than the manufacturing or other service industries (Aibinu and Jagboro; 2002). The construction sector has contributed a great deal to the country's resources through its output and employment opportunities.

This positive effect on the economy comes with some form of uncertainties. This view is supported by Chan and Chan (2004) who reckon that the construction industry is a dynamic entity due to the level of uncertainties involved in technologies, budgets and development processes. Different researchers have joined in the ongoing debate on the appropriate construction project delivery method suitable to ensure project objectives are met.

Construction performance over the last three decades has been broadly criticized due to increasing problems cut across many areas in construction. Some of the problems related to the separation of design from construction, lack of integration and effective communication, high levels of uncertainty, changing environments and increases in project complexity (Naoum; 1995) and risk inherent. Construction piece are unique and built only once, thereby leading to increased risk on construction projects (Zavadskas, Turskis and Tamosaitiene; 2010) and most notably, the design and build procurement method.

According to Adnan, Jussof and Salim (2008), the increasingly complex and varying demands placed upon the construction industry by the clients do not only stem from the need to provide more sophisticated commercial and industrial working environments at minimum cost and maximum speed, but also from the fact that the organizations of the clients are also complex in nature with different categories of consumers requiring discrete solutions to their procurement needs. This has made choosing a procurement method for construction work, one of the many important decisions that construction clients have to make.

Construction clients have been searching for effective project delivery methods to maximize project performance in recent decades. There is the traditional project delivery method; also known as design bid build (DBB) and alternative project delivery methods such as design and build (DB), package deal, turnkey and management contracting. Currently, no particular project delivery system is most appropriate for any kind of construction project.

Traditional procurement method is commonly used to undertake construction projects. This project delivery method has a number of disadvantages associated with its use. Clients changing demands with regards to cost and time efficiency of projects promotes the adoption of alternative procurement paths. The peculiarity of risks within such procurement options are different from those risks found in traditional procurement methods.

Design and build is an arrangement where contracting organization takes sole responsibility, normally on a lump sum fixed price basis, for the bespoke design and construction of a client's project (Masterman, 1992). Design and build is a procurement method where one entity or consortium is contractually responsible for both the design and construction of a project (Murdoch & Hughes, 2000). The perceived time saving from the integration of the design and construction process exposes the project to other risks. There is a tendency of increased cost as a result of the fact that cost planning may not be adequately concretized. Majority of the construction risk is transferred to the contractors as a result of contractors' involvement as designer and builder.

Accordingly, the objectives of this study are:

1. To identify and assess risk involved in design and build method of procurement system.
2. To evaluate the effect of risk on design and build projects.

Against this background, an examination into the various risk associated with the design and build procurement method will provide an interesting and challenging field of study.

2 Literature Review

2.1 Risk and project delivery methods

Hibberd and Basden (1996) suggest that risk is the prominent criterion that will determine the selection of a delivery system. As suggested by literatures of previous studies such as Liou and Wang (1992), considerations should be given to the issue of risk transferring and/or sharing in a bid to achieving the project objectives, prior to the decision on project delivery system. This gives rise to the selection of the best project delivery method appropriate for a particular construction project from risk management position, which require evaluating large amount of risk data, carry out subsequent risk analysis and to effectively manage project risks in order for the project goal to be achieved (Aklnel and Flsher; 1998). Therefore, choosing an appropriate system of project delivery can lower the risk for clients and improve the possibility of success for the projects.

2.2 Design and Build

Design-Bid-Build (DBB) is a conventional way that is widely used in different countries and has been applied in different building projects (Tsai and Yang; 2010), while design and build is the oldest approach that is regarded as a new and alternative delivery method (Ibbs, Kwak, Ng and Odabasi; 2003). The separation of design and construction functions which was not the case with traditional system is brought closer together for the client's benefit. In the design and build system, detailed design and construction are both undertaken by a single contractor in return for a lump sum price. The contractor's responsibility is to integrate the design together with the erection of the construction facility. The process allows for factors such as time, quality, and innovation to be considered in choosing a contractor as against price.

Design-build is not an entirely new project delivery method. In centuries past, it was the only procurement method available (Design-Build Institute of America, 1994). Its roots originate in the ancient "Master Builder" concept where responsibility for both design and construction resided with one person (Twomey 1989). However, during the 1900s, project procurement systems have primarily utilized the process of design-bid-build (Ndekugri and Turner 1994).

Current project delivery markets are experiencing resurgence in the use of design-build procurement (Yates 1995). The effect of this rapid growth is twofold. First, there is an increased entry into the market by both contractors and architect-engineers (AEs) possessing little or no design-build experience. This is evident from the increase in volume of design-build contracts.

One key advantage of using D&B is the opportunity to integrate the design and construction components, and Saxon (2000) argues that integration of design and construction offers better performance in time and cost and results in lesser defects.

Adams (1999) has shown that majority of clients regard D&B as the optimum route to obtain value for money. Smith (1995) suggests that the popularity of D&B arises from its perceived ability to bring design and construction processes closer together culturally, while Hughes (1992) argues that D&B offers a high degree of cost certainty, encourages economical solutions, and enables value to be considered as well as price. McDermott (1999) has argued that benefits of design and build include closer integration of design and construction teams as well as increased level of synergy of the team.

D&B procurement is not a panacea, and it is not without limitation. The apparent drawbacks of this method as stated by Masterman (1992) are:

- Relatively fewer firms are truly specialized in health care facilities, and therefore less real competition, and in-house design and build firm is an entity (so compensation for weak parts of the firm is not possible)
- Higher tender price due to less competition (higher risk imposed on the contractor and two separate design teams with some duplicating efforts)
- Bids are difficult to compare since each design, programme and cost will vary
- Client driven changes (unfortunately essential for most hospital projects) can be more expensive both indirect cost and in disruption costs if the contractor's building sequence is affected
- Client brief must be adequate, and the opportunity for disputes would be increased due to incomplete documentation
- Client is at risk where the contractor does not fully appreciate the full risk associated with design. Similarly, the client is at risk if the contractor does not have full indemnity insurance cover.
- Limitation for client in choice of design team
- Design quality is inferior to those produced under traditional procurement method (although well-designed and aesthetically pleasing buildings can be obtained with D&B, the client's control over this aspect is less and difficult)
- With consultant novation, the consultants may experience a conflict of interest owing to the change of employer
- Client's project management is by no means easy in comparison with traditional procurement method

3 Research methodology

A literature review was conducted for the purpose of identifying risk factors associated with design and build procurement. The variables identified represent a list of factors upon which D&B project delivery method was assessed. Cross sectional research design was adopted for the study. 60 Structured questionnaires were administered, with 40 returned, free from error, omission and inconsistencies; representing about 67% response rate. The study focused on the contractors and construction professionals with a considerably stable organizational structure, and those organizations who have been operating in the Nigerian construction industry for more than five years. The respondents were asked to indicate their opinions by ticking the appropriate responses required for each question. The "mean score" method was adopted to establish the relative importance of the risk factors and the effect of risks. A four point likert scale was used, the numerical value 4 represents frequent occurrence while 1 represents no

occurrence, this was used to calculate the mean score for each variable, which was then used to determine the relative ranking of different variables by assigning ranks to the mean scores, with low mean scores assigned low ranks and high scores allocated high ranks.

4 Findings and Discussion

Descriptive statistics about the respondents' organisation are shown in Table 1.

Table 1. Demographic data of organization

	Frequency	Percent (%)	Cumulative Percent
Type of organization			
Contracting organisation	14	35	35
Consulting organisation	22	55	90
Contracting and consulting	4	10	100
Type of contracting organization			
Building contracting	3	16.7	16.7
General contracting	8	44.4	61.1
Building and civil engineering contracting	7	38.9	100
Type of consulting organization			
Architectural	3	11.5	11.5
Building	6	23.1	34.6
Quantity surveying	8	30.8	65.4
Structural	6	23.1	88.5
Architectural and quantity surveying	3	11.5	100

Table 1 indicates that out of the 40 responding organizations, 14 are contracting organisations representing 35% of the population, with 4 of them (10%) operating as both contracting and consulting organisation. Majority of the responding organization (55%) fall into the consulting category of type of organisation. But of the contracting organization, 44.4% carry out general contracting as their construction activity, while 38.9% are involved in both building and civil engineering construction activities. A small percentage of the respondents embarked on building works as their main source of income. Consulting organizations that make up the population comprise of quantity surveying consultants, structural, building consultants and architectural firms having representation in the survey.

Table 2 shows the demographic data of the respondents with the following information; years of experience, academic background, academic qualification, profession affiliation and level of membership amongst other things.

Table 2 Demographic data of Respondent

	Frequency	Percent (%)	Cumulative Percent
Academic qualification			

HND	20	50.0	50.0
BSc	15	37.5	87.5
MSc/MBA	5	12.2	100
Professional qualification			
NIA	4	10.8	10.8
NSE	7	18.9	29.7
NIOB	10	27.0	56.8
NIQS	14	37.8	94.6
Others	2	5.4	100
Level of membership			
Graduate	23	65.71	65.71
Corporate	10	28.57	94.29
Fellow	2	5.71	100
Construction experience			
Less than 5years	22	55.0	55.0
6-10years	11	27.5	82.5
11-15years	3	7.5	90.0
16-20years	2	5.0	95.0
Above 20years	2	5.0	100
Professional Background			
Architect	3	7.9	7.9
Quantity Surveyor	7	18.4	26.3
Builder	11	28.9	55.3
Civil Engineer	14	36.8	92.1
Others	3	7.9	100

As shown in Table 2, majority of the respondents are have formal educational qualification and are registered with relevant professional bodies. This implies that all the respondent have the formal knowledge to provide primary data for the research. The table also reveals that 45% of the population have construction experience above 5years. 55% of the respondents have experience in the construction industry between 1 and 5years. This informs that the respondents are sufficiently knowledgeable in construction matters to know the risk factors involved in design and build procurement. Civil engineers constitute 36.8% of the respondents- the highest proportion, closely followed are builders and quantity surveyors with 28.9% and 18.4% representation.

Based on the responsibility of performing risk management functions in organization, 29.7% of the respondents express that the Director/partner has the responsibility of performing risk management functions in their organization, 17.1% of them refer to other management level employee, 7.3% of them refer to person specially employed as risk analyst while 37.8% of them agree that chartered quantity surveyor. Majority of the respondents agree that chartered quantity surveyors are the best, saddled with the responsibility of performing risk management functions in their organization.

Table 3: Responsibility of performing risk management functions

Risk Management	No of Response	Percentage	Rank
Chartered Quantity Surveyor	14	37.8	1
Director/partner	11	29.7	2
Other management level employee	7	17.1	3
Person especially employed as risk analyst	3	7.3	4
Others	2	4.9	5

Table 4: Incidences of risk factors and Types

	Frequency	Percent (%)	Cumulative Percent
Are there incidences of risk factors on your construction projects (N=40)			
Yes	34	85.0	85.0
No	6	15.0	100
If yes, please identify (N=34)			
Design risk	6	17.6	17.6
Financial risk	11	32.4	50.0
Design and financial risk	5	14.7	64.7
Financial and construction risk	8	23.5	88.2
Design, financial and construction risk	4	11.8	100

Table 4 shows that 85% of the respondents have observed incidences of risk factors on any of their construction projects, with the remaining 15% reporting that they have not at any time observed any of the highlighted risk factors on any of the organisation's construction projects.

Out of the 85% of the sample who have reported incidences of the risk factors on their projects, 32.4% of them stress that financial risk has occurred significantly on construction projects. 23.5% of the population opine that both financial and construction risk has been observed on construction projects undertaken by their organisation; the lowest of the lot in Table 4.5 is the presence of all three (design, financial and construction) risks at the same time on construction project(s).

4.1 Risk identification

In Tables below, the risk factors affecting the design and build procurement system are highlighted under different heading. The mean scores of the risk factors that are associated with this type of procurement system are shown in the tables below. The mean limit is 3.00, any factor equal and above 3.00 is considered as somewhat frequent in design and build procurement while factors below the mean limit is regarded as rarely frequent or do not occur at all.

4.1.1 Group 1: Natural phenomenon

Table 5 indicates that rainfall with a mean score of 3.41 is the most frequent factor observed in design and build procurement system under natural phenomenon.

Table 5: Risk identification in design and build

Natural phenomenon	N	Mean	Rank
Rainfall	37	3.41	1
High gale	38	2.13	2
Fire	40	1.58	3
Earthquake	40	1.18	4

Other equally less frequent risk factors under this category include high gale (windstorm), fire and the least frequent; earthquake with mean score of 2.13, 1.58 and 1.18 respectively.

4.1.2 Group 2: Economic/finance

As shown in Table 6, increased material cost is regarded by respondents as the most frequent risk factors associated with design and build procurement system. This is evident with a mean score of 3.35, which falls under somewhat frequent, as against the other risk factors. Difficulty of financing the construction project and strong competitors in the construction market closely follows increased material cost during the construction projects.

Table 6: Risk identification in design and build

Economic/finance	N	Mean	Rank
Increased material cost	40	3.35	1
Difficulty of financing	40	3.30	2
Strong competitor	40	2.73	3
Low market demand	37	2.54	4

The risk factor which rarely occurs during construction project under economic/finance heading is low market demand with a mean of 2.54.

4.1.3 Group 3: Politics/society

Bribery/corruption occurs the most on construction projects when considering risk factors under politics/society as shown in the Table 4.8 below. High powered lobby is also a common occurrence in the Nigerian construction industry and most especially during design and build procurement system.

Table 7: Risk identification in design and build

Politics/society	N	Mean	Rank
Bribery/corruption	40	3.65	1
Lobby	40	3.05	2
Rigid bureaucracy	37	2.62	3
Language/cultural barrier	40	2.23	4
Change of law	40	2.10	5
War/revolution/riot	40	1.72	6

There exist rigid bureaucracy in design and build procurement, which is placed third with a mean score of 2.62. Change of law and war/revolution/riot are risk factors which rarely occur during design and build procurement system with 2.10 and 1.72 respectively

4.1.4 Group 4: Industrialized characteristics

The survey only highlighted two risk factors under the industrialized characteristics heading, namely; monopolized bidding and labour union.

Table 8: Risk identification in design and build

(D) Industrialized characteristics	N	Mean	Rank
Monopolized bidding	40	2.98	1
Labour union	40	2.27	2

Monopolized bidding, as depicted in Table 8 above, comes first in order of occurrence, while labour union comes in distant second with 2.98 and 2.27 mean score respectively.

4.1.5 Group 5: Contract

Unequal contract provision has the highest level of occurrence in design and build procurement system with a mean score of 3.11. Other risk factors which seldom occur under this category include misjudged cost estimation, dispute among entities and defect warranty.

Table 9: Risk identification in design and build

Contract	N	Mean	Rank
Unequal contractual provision	37	3.11	1
Misjudged cost estimation	37	2.92	2
Dispute among entities	40	2.58	3
Defect warranty	37	2.41	4
Inadequate insurance	37	1.92	5
Unjust arbitrator	40	1.65	6

Inadequate insurance and unjust arbitrator are the least factors in terms of occurrence in design and build procurement system in Lagos state.

4.1.6 Group 6: Construction

Table 10 depicts that inadequate construction planning with mean score of 3.22, new technology implementation with 3.15 and too high quality standard with 3.11(in that order) are the three most frequent risk factors under the heading which occur during design and build projects. The risk factors which occur rarely include faulty job field survey mobilization due to clashes of several projects and inadequate procurement planning with 2.70 and 2.68 re

Table 10: Risk identification in design and build

Construction	N	Mean	Rank
Inadequate construction planning	37	3.22	1
New technology implementation	40	3.15	2
Too high quality standard	37	3.11	3

Faulty job field survey	37	2.70	4
Inadequate procurement planning	37	2.68	5

4.1.7 Group 7: Job site

Incompetent planning, incompetent management and incompetent coordinator make up this category of risk factors. Incompetent planning with a mean score of 2.90 is the most frequent risk factor considering job site heading. Incompetent coordinator and incompetent management have mean scores of 2.88 and 2.78 respectively and hence can be regarded as rarely frequent risk factors as shown in Table 11 below.

Table 11: Risk identification in design and build

Jobsite	N	Mean	Rank
Incompetent planning	40	2.90	1
Incompetent coordinator	40	2.88	2
Incompetent management	40	2.78	3

4.1.8 Group 8: Safety/Environment

Table 4.13 reveals that environment damage and/or pollution occurs the most amongst safety/environment category though it must be said that it seldom occur as compared to other categories.

Table 12: Risk identification in design and build

Safety/Environment	N	Mean	Rank
Environment damage/pollution	40	2.55	1
Traffic or work hour restriction	40	2.30	2
Third party objection	38	2.29	3
Accident related loss	40	2.25	4

Traffic or work hour restrictions, third party objections and accident related loss in that order occur rarely during design and build procurement system. Their mean score reads 2.30, 2.29 and 2.25 respectively.

4.1.9 Group 9: Client

Late payment, unreasonable demand, feasibility study, reliance on architect/consultant, financial problems/bankruptcy are one of the few risk factors which can be regarded as occurring somewhat frequent under client related category with mean score above 3.00

Table 13: Risk identification in design and build

Client	N	Mean	Rank
Late payment	40	3.25	1
Unreasonable demand	40	3.15	2
Feasibility study	40	3.12	3
Reliance on architect/consultant	40	3.07	4

Financial problems/bankruptcy	37	3.05	5
Jobsite superintendent being incompetent	40	2.73	6
Reference by subcontractors	40	2.73	6
Relation with the third party	38	2.63	8
Difficulty in choosing business dealer	40	2.50	9

Relation with the third party and difficulty in choosing business dealer with mean score of 2.63 and 2.50 respectively makes the above mentioned risk factors to be labelled as less frequent factors during design and build projects under client related category of risk factors.

4.1.10 Group 10: Designer

The most notable problem associated with construction projects is the frequent design change which affects the outcome of projects in more ways than one. Frequent design change is considered to occur the most as a risk factor associated with the design related factor (designer). Another risk factor worthy of note is vague drawing and specification which is ranked second with a mean score of 3.03.

Table 14: Risk identification in design and build

Designer	N	Mean	Rank
Frequent design change	40	3.25	1
Vague drawing and specification	37	3.03	2
Constructability	37	2.76	3
Incomplete construction area	38	2.61	4
Incompetent supervision skills	40	2.60	5
Lack of fair stance	40	2.35	6

Incompetent supervision skills and lack of fair stance comes rear in the risk factors associated with designers with mean score of 2.60 and 2.35

4.1.11 Group 11: Contractor

The list highlighted in Table 15 below shows contractor related risk factors associated with design and build procurement systems. The tendency of having higher construction cost compared with the bid taking is the most frequent risk factor that the contractor is exposed to with this form of procurement system. Other frequent risk factors are the stringent contractual terms and low working morale of staffs and site workers of the contractor; this is confirmed in Table 4.16, with the mean score of 3.05 each

Table 15: Risk identification in design and build

(I) Contractor	N	Mean	Rank
Higher cost than bid taking	40	3.33	1
Stringent contractual terms	37	3.05	2
Low working morale	40	3.05	3
High personnel mobilization	40	2.80	4
Lack of trustworthy support by subcontractor	37	2.78	5
Short of capital/equipment	40	2.75	6
Shortage in machine tools and workers	40	2.73	6
Shortage of manpower or experience	40	2.70	8
Low safety awareness	40	2.67	9

Erroneous allocation of human resources	40	2.60	10
Deficit contracting	40	2.35	11
Local jobsite particularity	40	2.15	12

There are also risk factors such as erroneous allocation of human resources, deficit contracting and local jobsite particularity which form part of contractor related risk factors which occur the least during design and build projects.

4.2 Effects of risk on design and build procurement systems

In Table 16, the effects of risk on design and build procurement are highlighted. The mean scores of the effects that affect design and build procurement are shown in table. The mean limit is 4.00, any factor equal and above 4.00 is considered as critical to this form of procurement system while effects below the mean limit is regarded as less critical.

Table 16: Effects of risk on design and build procurement system

Effects of risk	N	Mean	Rank
Cost overrun	38	4.45	1
Dissatisfaction of work	40	4.03	2
Poor financial management	32	3.88	3
Time overrun	38	3.79	4
Claims	38	3.76	5
Accumulation of interest on loan facilities	38	3.71	6
Delayed payment	38	3.63	7
Insolvency	32	3.53	8
Inability to resolve claims and disputes	37	3.49	9
Low users' satisfaction	40	3.48	10
Delay in completion	38	3.45	11
Inefficient service delivery	34	3.44	12
Low quality	40	3.40	13
Abandonment of projects	40	3.40	13
Bankruptcy	40	3.38	15
Shoddy work	40	3.37	16
Dangerous safety condition	38	3.37	16
Cash flow problems	38	3.34	18
Unhealthy relationship with the client	40	3.30	19
Extension of time	40	3.27	20
Poor management of project	40	3.22	21
Poor communication	40	3.22	21
Unethical practices	38	3.16	23
Delay in certification	40	3.08	24
Rework	40	3.03	25
Contract bias to one party	40	3.03	25
Determination of contract	35	2.97	27
Poor environmental impact	38	2.91	28

Table 16 indicates that cost overrun with a mean score of 4.45 is the most critical effect associated with risk in design and build procurement systems used on a construction project. Other critical effects include dissatisfaction of work, poor financial management, time overrun and claims with mean scores of 4.03, 3.88, 3.79, and 3.76 respectively. Rework, contract bias to one party and determination of contract are shown in the table to have less critical effects on design and build procurement; while poor environmental impact with a mean score of 2.91 is said to exert least critical effect on design and build projects.

5 Conclusion and further research

Financial risk is one of the most significant risks experienced by organisations during construction projects in the industry. Such risk include the inability of client to pay as at when due and difficulty in financing. Earthquake has not at any time been recorded within the shores of the country and hence undoubtedly received the least frequent risk factor under the natural phenomenon heading. Bribery/corruption and lobby in the

highest places have become part and parcel of the construction industry. This is evident in the research, where it was considered somewhat frequent with a high level of occurrence within the industry. Misjudged cost estimation on the part of quantity surveyors gives rise to more problems than one. Amongst which include claims, dispute and some instances litigation.

Environment damage/pollution is one of the risk factors associated with design and build projects as it is with any other project. The public and the environment at large are exposed to hazardous atmospheric pollution which arises from construction related activities. Poor environmental impact is not considered to be a critical effect as a result of risk factors on design and build projects. The most critical effects, risk has exposed the project participants on design and build projects include cost overrun, dissatisfaction of works, poor financial management and time overrun. The effects which exert the least influence on D&B projects are as follows: contract bias to one party, determination of contractor which could be as a result of insolvency of the contractor and poor environmental impact of the construction projects on the environment.

This study recommends that contractors should adequately assess design and build projects in order to identify the risk elements associated with such projects, and then decide on appropriate risk management techniques to adopt in handling such risks to ensure overall project success.

Abstract:

It has now become increasingly noticeable that there has been an increasing trend towards the adoption of asset management by public bodies including local authorities. Since 2003 Scottish councils have been legally obliged to adopt asset management as the strategic framework for managing their property assets. The trend for increased adoption of asset management has come as a result of evidence of inefficiencies associated with the manner in which local authorities managed their property assets and the realisation of potential benefits that are likely to arise if asset management approach is followed. The purpose of this paper is to assess the extent to which Scottish councils have effectively implemented aspects of the processes associated with asset management practice. There are about four commonly identified asset management processes including: strategic planning processes, corporate property management arrangements, property information management system, and capacity building. The focus of this paper is on the latter two. The paper is a research based on a survey investigation of all thirty two Scottish councils. A questionnaire based survey and interview of a select number of key stakeholders was carried out. The research findings suggest that councils have had limited success in developing appropriate strategies for capturing and managing information to aid decision making. Local authorities have been equally unsuccessful in building property management capacities. In particular they have had limited success in developing effective organisation of their property management services as the basis for implementing a more corporate and strategic approach to capital and asset planning. As no similar study has been carried out on asset management in Scottish councils, the findings of this research are of interest to Scottish councils and other public sector organisations in Scotland and beyond.

Key Words:

asset management processes, best value, effective implementation, improved service delivery, Scottish councils

1 Introduction

In recent years councils, like many other public bodies, have had to respond to changes that have affected public services in the wake of rising public expectation. The

evolution of public services in the context of rising public expectation has led to the pressures for substantive changes in the funding and delivery of public services. Such changes are intended to increase efficiency, effectiveness and responsiveness of service delivery to users (Crawford, 2003; Baldry, 1998; Hood, 1991). The initiatives to improve efficiency and effectiveness of service delivery have also affected property management (Boyne, 2002; Kalganova and McKellar, 2006). In response government entities, both national and sub-national, have been advocating that property assets be managed in a strategic way similar to other assets such as human and finance. Asset management is the strategic framework that governments advocate as the means by which property assets could effectively support efficient and effective service delivery (CIPFA, 2008). Various initiatives have been employed in recent years to encourage the adoption of asset management and its associated processes.

In Scotland the initiatives to encourage local authorities to take on board a strategic approach to property asset management could be traced back to the late 1990s. The 1998 Local Government White Paper contained proposals for modernisation of the capital finance framework for local authorities (Department of the Environment, Transport and the Regions (DETR), 1998). The paper proposed allowing councils to take more responsibility for making decisions about their internal distribution of resources including introducing a strategy framework for managing property assets.

The Scottish government responded by introducing the Local Government in Scotland Act (2003) to improve accountability for the use of public assets and public funds within a legislative framework that secures Best Value (CIPFA, 2005). The Act has imposed a legal duty on councils to adopt *Asset Management* as a framework for managing public property assets. The adoption of Asset Management to public property asset management has also been advocated by the Royal Institution of Chartered Surveyors (RICS) (2004).

Most recently in Scotland, the Scottish Government's "Efficient Government" agenda has Asset management as one of the five work streams (CIPFA, 2008). The initiative cites the better management of assets by all parts of government as a key element in the drive for efficiency gains and recommends that Councils have an asset management plan in place.

There have been other initiatives designed to promote the adoption of asset management by Scottish Councils. These have included the publication of asset management guidelines for education property assets by the Scottish Executive and UK audit bodies (CIPFA, 2008; Scottish Executive, 2003), Audit Scotland giving time to councils to prepare asset management plans, movement by councils away from annual to three yearly budgeting, researchers and commentators emphasising the benefits of strategic asset management (Male, 2006; Jolicouer and Barrett, 2004) and through budgetary pressures (RICS, 2004).

According to the Chartered Institute for Public Finance and Accounts (CIPFA) (2008) in the past councils, in common with most other organisations in the public sector, have not in any systematic way considered how their assets have been used and deployed to effectively support service delivery. A number of academic studies and professional reports, going back to the 1980s, have been carried out evaluating corporate property management in the public sector. The studies and reports have highlighted shortcomings associated with public sector property management. The principal reports on the subject have been those by the Audit Commission (1988); Ceri Davies Report on the National Health Service (1982); Audit Commission reports on Local Authorities (1988); the

National Audit reports on the Crown Estates (1988), the National Health Service (1988); the civil estates (1988); and the Metropolitan Police estate (1989).

The main criticism of these reports was that there had been lack of a strategic approach to management of public property property (Gibson, 1994; Avis et al., 1989; Bon, 1992; Bon et al., 1994; Gibson, 1994; Joroff, 1992; Veale, 1989). The lack of a strategic approach to property management led to inefficient utilisation of assets. Inefficiencies were as a result of the commonly practised reactive management arrangements, nonexistent property performance monitoring, not developing property information systems needed to produce essential property information to aid decision making, inadequate valuation standards and practices (Bond and Dent, 1998), fragmented management, physical and economic underutilisation of properties, insufficient maintenance and repair, and failure to account for the real cost of holding an asset including the opportunity cost (Gibson, 1994; Kaganova, Nayyar-Stone, and G. Peterson, 2000; Kaganova and McKellar, 2006).

Public sector organisations were therefore not achieving Best Value in the way they managed their operational property assets. This is because they lacked effective strategic asset management processes. In response, public bodies including councils, have responded by adopting strategic asset management as a framework for managing land and buildings. Asset management is defined by Edwards (2010) as “the systematic and coordinated activities and practices through which an organisation optimally manages its physical assets, and their associated performance, risks and expenditures over their lifecycle for the purpose of achieving its organisational strategic objectives”. The definition emphasises the necessity of a formal approach to the management of assets. The formalised approach is characterised by certain identifiable elements or processes associated with asset management.

The study sought to evaluate the extent to which Scottish councils have effectively implemented aspects of the processes associated with asset management practice following the adoption of asset management. In order to deal with this aim, two objectives aligned to asset management processes were set. First, the study evaluated the extent to which councils successfully built property management capacities by developing an effective organisation of their property management services. The second objective related to assessing the extent to which councils have successfully developed and are maintaining property information systems with fully adequate and appropriate data to support asset management life cycle decisions.

2 Literature Review

The focus of the research was on asset management processes rather than on the outcomes. Outcomes are the impacts of the actions and activities associated with asset management processes (CLG, 2007). The necessity to focus on asset management processes rather than outcomes or performance is due to the inherent difficulties of explicitly identifying successful performance with regard to good practice processes in operational properties. As McDonagh (2002), puts it: “... *identifying successful performance in a corporate property asset management setting is much more difficult than for traditional “investment” real estate or for corporate organisations as a whole. In the latter two situations overall quantitative output measures such as the internal rate of return, return on equity, or return on assets, or qualitative assessments such as comparison to core business objectives or industry benchmarks are relatively easy to*

apply. In contrast, corporate real estate, including operational property, outputs are usually the internal inputs to another part of an overall process. As such they are likely to be closely tied to the nature of the organisation, may have no market in which pricing or performance comparisons can be made and therefore be very difficult to measure across a range of differently structured and focused organisations”.

Citing Gibson (1995), asset management performance is therefore focused on the process of real estate decision making. It is hypothesised that, if there are better processes to deal with real estate, then better decisions more in line with the organisation’s overall goals will result. McDonagh (2002) cites a number of studies that have been carried out on corporate property asset management processes and their impact on property management performance. A number of processes have been found to be most effective in improving property performance. Amongst these processes is the need to provide the necessary leadership to help build property management capacity and having in place effective property management information systems. For instance, McDonagh (2002) cites the studies done by Zeckhauser and Silverman (1982), Hite, Owers and Rodgers (1987), Sanford and Hook (1987), Rutherford and Stone (1989), Avis, Gibson and Watts (1989), and Teoh (1992) on the existence and structure of corporate property management groups and the necessity of developing effective organisation of property management services. Similarly, property management information system is an important armoury of the asset management process. Prudent decision making requires monitoring data and that it is extremely difficult, if not impossible, to make informed real estate decisions without a property management information system (Hentschel and Utter, 2006).

In a recent work by York Consulting and the Department for Communities and Local Government (CLG) (2007) reviewing asset management processes in English councils they reached similar conclusions. The study abstracted the asset management processes found to be effective in affecting asset management performance into certain key process groups and subgroups. The key process groups include the development of corporate property management groups; effective organisation of property management services as the basis for implementing a more corporate and strategic approach to capital and asset planning; capacity building in order to have a corporate approach to project management; and the existence of a property information system with relevant information (Department for Communities and Local Government and York Consulting, 2007).

3 Research Methodology

Asset management processes are an important precursor to effective asset management performance. Councils were therefore evaluated for the success of their asset management arrangements by examining how effectively they had deployed and executed some of these asset management processes.

3.1 Key Issues That Were Investigated

The research evidence (CLG, 2007) had identified a number of good practice processes. However the focus of this paper is on two of these namely the ongoing collection of property data and their use in managing assets more effectively; and developing property management capacity (Table 1).

Table: 1 Good Practice Processes or Critical Success Factors for effective property asset management

Item No.	Capacity building process elements
1	Setting out clear property management responsibilities at a corporate and service level
2	The council should make available adequate resources at a corporate level, to review property assets and running costs
3	Existence of a corporate approach to project management based on the PRINCE 2 gateway process or similar
4	Development of internal project management capacity by establishing specialist teams with appropriate project management training
5	Roles and responsibilities in relation to project management are clarified
6	Development of project management protocols and guidelines
Item No.	Property management information system process elements
1	Having an adequate property information system for gathering, storing, maintaining and updating information to support property management functions
2	Populating the property information system with adequate information about Core / Basic data (size, value, lease details etc) on operational property
3	Populating the property information system with adequate information on:
	a) the condition of the properties
	b) the suitability of the properties
	c) the capacity (sufficiency) of the properties
	d) property usage (hours used)
	e) environmental performance of buildings e.g. CO2 emissions
	f) accessibility issues e.g. DDA compliance
	g) asbestos content of buildings
	h) health & safety surveys
	i) energy performance certificates
	j) required maintenance i.e. backlog in priority banding
	k) maintenance spending patterns e.g. planned to reactive ratio
4	The asset management service should maintain an effective performance management framework comprising a suite of performance indicators, to help to continuously review and improve performance
5	Have in place a Benchmark Framework so that the unit costs are benchmarked against other councils and other similar organisations
6	The Council should have in place annual performance plans, agreed by council members, setting out targets for improvement
7	The council should ensure that annual performance plans are included in public performance reporting
8	The Council should develop processes through which to consult with partners / stakeholders, service users, the general public and staff regarding capital programme and property-related issues

Source: Department for Communities and Local Government and York Consulting (2007)

Therefore, two good practice processes identified in Table 1 formed the criteria for evaluating Scottish Councils' success in implementing asset management processes.

3.2 Scope of the Study and Methodology

The study was limited to evaluating asset management as it relates to operational properties. These are properties which are used direct service delivery or support service delivery such as administrative offices. With these property types data protection and confidentiality is less of an issue as there are no landlord and tenant contractual arrangements. All thirty two Scottish councils were investigated with eighteen of them responding which represents a response rate of 56%.

Figure 1: Survey Response Rate (59%)

Data was collated from targeted departments and personnel. For instance data was sourced from property and facilities departments, service users and service departments as well as finance departments. However, only property departments namely asset managers, estates surveyors, and valuers responded. In terms of response rates these were 44% from asset managers, estate surveyors / valuers the return rate was 56%, with no responses received from facilities managers and service users.

Figure 2: Response Rates by Profession and Service Users

The Association of Chief Estates Surveyors (ACES) in Scotland, which is an umbrella body for all heads of property departments in Scotland, assisted by distributing the questionnaires to its members for completion.

The data was gathered using a structured questionnaire as well as face to face interviews with a select number of subjects. Questionnaires were sent to all thirty two councils' Chief Estates Surveyors who distributed these to relevant personnel. In addition interviews were conducted with three asset management personnel in three different

councils. The interviews were intended to gather rich data to supplement the evidence obtained using questionnaires. The decision to use these techniques was because the investigation sought to find out what those involved in the subject of investigation thought, felt or believed about the impact of asset management on best value (Robson, 1996). The questionnaire as a research instrument was chosen for this study because it is a cheap method of data collection, reduces bias error, allows for greater anonymity and easy coding (Nachimias and Nachimias, 1982; Bailey, 1987; Fink and Kosecoff, 1985; Bryman, 1989; and Robson, 1996).

The Likert scale was used to measure the participant's attitudes., It was chosen in preference to other scale measures because it is very widely used, is relatively easy to develop, is robust and it has internal consistency (Robson, 1996). The data was scaled by categorising it from strongly agree, agree, neutral, disagree and strongly disagree (scaled 1,2,3,4 and respectively). The categorisation enabled the transformation of the collected qualitative data into a form which was capable of quantification, where necessary.

4 Results and Discussion

As already stated at 4, good practice processes formed the criteria for evaluating the effectiveness of Scottish Councils' asset management processes. The results and research findings for each of these broad areas are discussed below.

4.1 Capacity-building process

Councils' asset management processes were also evaluated in terms of the extent to which asset management processes contributed to capacity building (CLG, 2007). Effective capacity building process is evidenced by clear delineation and allocation of asset management responsibilities; adequate resourcing of asset management activities; the existence of a corporate and formal approach to project management; establishment of specialist project management teams; as well as development of project management protocols and guidelines.

There was modest success evidenced by the fact that in just over six in ten councils there are clearly delineated property management responsibilities at a corporate and service level. However, asset management responsibilities are very poorly resourced. Less than two in ten councils indicated that they had adequate resources to review property assets and running costs.

The research findings are that councils have been very unsuccessful in developing corporate and formal approaches to project management and putting in place specialist project management teams. In all of these areas only one in four indicated that they had developed capacities in these areas. Councils did not fair any better when it came to clarification of project responsibilities or with regard to putting in place project management protocols and guidelines. In councils where project management practices were in place, just under half (45%) of them indicated that there is clarification of roles and responsibilities in relation to project management. Similarly, just over three in ten (36%) of councils stated that they had developed project management protocols for and guidelines.

4.2 Information and evidence processes

The development and maintenance of a property information system with fully adequate and appropriate data is central in reviewing property portfolios before management decisions about acquisition, operation, maintenance and disposal of properties can be made (Loyd, 2010; Male, 2010). A number of factors were evaluated in order to establish the extent to which councils' arrangements with regard to information and evidence processes had been successful. The factors evaluated included considering the existence of a property information system with relevant information on the current property portfolio; the availability of property performance indicators; and the existence of processes for consulting partners or stakeholders, service users, the general public and staff regarding property-related issues.

The evidence suggests that councils had been very successful in collecting information but ineffective in making effective use of such data. For instance about seven out of ten councils stated that they had adequate basic core data and property information systems for gathering, storing, maintaining and updating information to support property management functions. In terms of the nature of information, just over 80% of councils considered that they had adequate information on property condition and suitability. However, less than half of local authorities indicated that they had sufficient data on property sufficiency and usage.

About half of the councils stated that they did not gather sufficient data on the sustainability of properties nor on other indicators. In particular, the property system conveyed inadequate information about the environmental performance of buildings in terms of CO₂ emissions; health and safety surveys; energy performance; required maintenance; maintenance spending patterns; benchmarking; agreed performance targets; and processes for consulting with partners. The exceptions were in terms of information on accessibility issues such as the DDA compliance and asbestos content of buildings where more than seven in ten councils considered that they had captured sufficient data.

It is clear that councils still have a long way to go in developing their information systems to capture relevant data on the sustainability of buildings, to help deal with maintenance arrangements, for reporting purposes and consultation with stakeholders. These findings are consistent with those reached by the Audit Commission (2009), which though only focused on education assets nonetheless reached similar conclusions. The Audit Commission study found that "the majority of Scottish councils report good arrangements for collecting property data, but good operational data is not always used to support decision making".

The successes with regard to information on asbestos content and accessibility issues could be attributable to the legal requirement to capture these data sets.

5 Conclusion and Further Research

The study sought to assess the extent to which Scottish councils have effectively implemented aspects of the processes associated with asset management practice. Two asset management process areas were evaluated for evidence of success. These included processes associated with capacity-building and development of appropriate property management information system. A number of study findings emerged from the study.

he research evidence, with regard to capacity building process, suggests that councils have largely failed to build capacities in order to effectively manage property assets and deal with major capital projects. The modest success has been in having clearly delineated property management responsibilities. However, councils have largely been unable to adequately resource asset management arrangements.

With regard to Information and Evidence the study found that councils, while successful in having property information systems for capturing data, they have largely failed to populate them with appropriate and adequate data needed for management decision making purposes.

The research findings have implications for a number of organisations and most especially public sector bodies. The findings are of significance to a range of public organisations such as local authorities, the National Health Service, Central Government Departments, Universities, executive agencies and many other public bodies. These bodies can use the research findings to improve the way they manage their property assets. With improved management of property resources local authorities and these other public bodies are likely to realise huge savings from their property assets, provide service users with properties that are fit for purpose as well as being able to rationalise property assets to release capital. As public bodies are in the business of providing services, by improving their operational property asset management arrangements this would be beneficial to councils and other public organisations in terms of realising efficient service delivery and achieving best value.

The research only looked at aspects of asset management processes. The research theme is further being developed as part of doctoral studies. The doctoral research is evaluating the effectiveness of asset management but investigating all the processes involved asset management as well as evaluating asset management performance. In terms of the study subjects, the study is extended to include English and Scottish Councils.

Human and organisational aspects

The effects of workplace stress upon construction professionals in South Africa: a survey

Paul Bowen¹, Peter Edwards², Helen Lingard² and Keith Cattell¹

Abstract:

Workplace-induced stress has ramifications in terms of its side effects. Besides the threat risks these pose to the health and well-being of individual workers, more general issues arise in terms of performance and occupational health and safety. Negative coping mechanisms give rise to similar risks. As part of a larger opinion survey-based investigation into workplace stress, the perceived effects upon professional architects, engineers, quantity surveyors, and project and construction managers working in the construction industry in South Africa were explored, together with the coping mechanisms used to deal with them. A web-based online survey yielded 676 responses. Few survey respondents find it easy to relax after hours. More than a quarter claim that stress at work puts a strain on family life, and constrains social relationships and activities. Consumption of alcohol is widespread, with 40% of respondents consuming 3-9 units per week. Cigarette smoking is reportedly moderate overall but heavy among a minority. Appropriate stress management measures should be implemented within the construction industry, and the nature of professional work explored in greater depth with a view of ameliorating stress ‘hotspots’. The construction professions can play a significant part in this.

Keywords:

construction professionals, coping mechanisms, side effects, workplace stress, South Africa

1 Introduction

The U.S. National Institute for Occupational Safety and Health (NIOSH) defines workplace stress as “the harmful physical and emotional responses that occur when the requirements of the job do not match the capabilities, resources, or needs of the worker” (NIOSH, 1999). Houtman (2005) found that work-related stress was the second most common work-related health problem across 15 European Union countries. Physical and mental health impairment relating to stress are also associated with longer periods of work absence and higher direct costs per health claim than other injury/illness categories. Work-related stress is associated with cardiovascular diseases (Kivimäki et al., 2002), musculoskeletal disorders (Hoogendoorn et al., 2000), and repetitive strain injuries (Ariëns et al., 2001).

While an array of information about workplace stress, its effects and implications is emerging, little is known about its prevalence and impact in the South African construction industry, particularly among construction professionals.

A web-based, online opinion survey has been conducted to explore the nature and extent of workplace stress experienced by professionals working in the construction industry in South Africa. Data were collected from responses to questionnaires administered to South African registered architects, civil engineers, quantity surveyors, and project and construction managers. This paper reports on the findings of part of the larger survey, namely, the side 'effects' of workplace stress and mechanisms used to cope with it.

2 The effects of workplace stress

According to the Job Demand-Control (JDC) model of workplace stress, work that is simultaneously high in demands and low in control produces the most stressful responses and is most damaging to health (Belkic *et al.*, 2004; De Lange *et al.*, 2004). The JDC model of work stress is reported to reliably predict workers' psychological well-being, job-related well-being and burnout (Hausser *et al.*, 2010). However, none of these studies attempts to distinguish between different professional occupations involved in the same industry.

The effects of stress may be broadly classified into psychological effects, physical symptoms, and effects on home life (Houtman, 2005). Psychological effects encompass tension, anger, frustration, unhappiness, depression, loss of self-confidence, and difficulty in relaxing outside work hours. Physical symptoms typically include disturbed sleeping patterns, unexplained symptoms of nausea and stomach disorders, headaches, and difficulty in concentrating. The effects of stress on home life include strained domestic relations, and constrained social relationships and activities (Leiter and Durup, 1996; Bakker, 2009). While all these effects are known to occur, whether or not different effects can be associated with different professions is less well understood.

There may also be gender issues. Sang *et al.* (2007) report that female architects experienced significantly higher levels of work-family conflict and reported lower levels of job satisfaction and higher turnover intention than their male counterparts. In the South African context, ethnic and cultural factors could also have a bearing on workplace stress and its effects. To date, this question is uninformed by evidence from any other country on continental Africa, nor is it contextually explored by the authors cited in this section.

3 Research design

A multi-part opinion survey questionnaire was designed, incorporating closed, dichotomous, declarative, rating and multiple-choice questions. The questions cover a catalogue of issues drawn from the work of Sutherland and Davidson (1989), Haynes and Love (2004), Ng *et al.* (2005), Leung *et al.* (2007, 2008a, 2008b, 2010) and Love *et al.* (2010). In addition to gathering self-assessments of the levels of workplace stress experienced by construction industry professionals in South Africa, the questionnaire explored the physiological, psychological and sociological effects of stress and the coping mechanisms used in mitigation.

A web-based, online method was adopted to administer the survey to the construction professions. The statutory and non-statutory bodies that regulate the registration and professional activities of construction professionals in South Africa were contacted for assistance in communicating details for the online link. The statutory bodies include: the South African Council for the Architectural Profession (SACAP), the Engineering Council of South Africa (ECSA), the South African Council for the Quantity Surveying Profession (SACQSP), and the South African Council for the Project and Construction Management Professions (SACPCMP). The non-statutory professional associations include: Consulting Engineers SA (CESA), the SA Institute of Civil Engineers (SAICE), and the Association of SA Quantity Surveyors (ASAQS). A pilot study (also web-based) was used to confirm the adequacy of the survey instrument and its administration, and the full survey was launched in late September 2010, remaining open online until mid-November 2010. Precise response rates to online surveys, where URL links are distributed by third-party organisations, are difficult to ascertain. Table 1 gives the indicative responses to this survey.

Table 1. Responses to online stress survey by South African construction professionals

	Architects (SACAP)	Engineers (CESA, SAICE)	Quantity Surveyors (ASAQS)	Project and Construction Managers (SACPCMP)	Total
Distribution (N)	3025	1842 (+ 457)	1449	3359	9675
Response (n)	269	168	179	60	626
Response %	8.9%	9.1%	12.4%	1.8%	6.5%

ECSA is unable to provide registration figures for the different engineer sub-groups. The voluntary associations, namely, CESA and the SAICE, emailed their professional civil engineers ($N=1842$) and civil engineering practices ($N=457$), respectively, but assuming that the practices will each have partners/directors who are members of CESA, the survey response rate for civil engineers is calculated as 9.1%. The response rate for project and construction managers is likely to be higher than 1.8% since many professionals registered with the SACPCMP will be qualified architects, engineers and quantity surveyors.

Arguably, the survey response rate is not critical to this type of research. The survey is intended to provide a 'snapshot' of workplace stress among construction professionals in South Africa, and to confirm the existence of stress-related issues. Further case-based research is intended to validate the survey findings and to explore them at greater depth.

4 Survey findings

4.1 Analysis of the data

The data have been analysed using the Statistical Package for the Social Sciences (SPSS V18.0 for Mac) software application. Where appropriate, cross-tabulation has been used to establish degrees of association between categorical variables; using the Pearson's

Chi-square test (or the Fisher's Exact Test where appropriate) at the 5% ($p=0.05$) level of significance.

4.2 Survey respondent profile

The survey demographics are not presented here in detail. In general, the survey respondents are experienced practitioners in private professional practice in South Africa, mostly white, male, English-speaking, and in a stable work environment. Almost two thirds of the respondents are aged 40+. The response sample shows some bias towards the perspective of smaller firms for quantity surveyors and architects.

4.3 Side effects of workplace stress

Survey participants were asked about the impact of stress upon their lives in terms of psychological, physiological and sociological effects. Five-point Likert scales (1 = most of the time; 2 = frequently; 3 = sometimes; 4 = seldom; 5 = very seldom) were used to elicit responses relating to frequency of the perceived experience. The results are shown in Table 2.

For all but three of the catalogued side 'effects' of workplace stress, significant differences between the professional groups are found in the reported frequency perceptions. The average frequency rating value for professional architects was consistently lower (i.e. the side effect is experienced more frequently) than all other groups across all three types of stress effect. Professional quantity surveying respondents ranked second in all but four catalogue items (feeling tense at work; difficulty in relaxing after hours; sleep disturbances; and strain on family life), and engineers generally third. The least affected group appear to be project and construction managers. Only two side effects generated an average frequency rating response of >4.0 (effect seldom – very seldom experienced): loss of confidence in oneself; and unexplained symptoms of nausea/stomach disorder. The side effect generating the lowest average scores across the groups (range 2.02–2.34 = most of the time/frequently) was the perception of a lack of appreciation from others for a job well done. For this side effect, no significant differences between the groups are found, suggesting that being valued at work is psychologically important to all construction professionals, regardless of discipline. While the average rating values suggest that no acutely intense side effects are consistently experienced by any of the construction professional respondents (Table 2: no mean rating score value <2.0), the finding that most of the mean rating values lie between 2.0 and 3.5 (frequently/sometimes experienced) suggests that employers and professional associations in the construction industry should give attention to ameliorating these effects in the workplace. Further research should focus more specifically on the type of workplace activities/environments that professionals engage in; since it is unrealistic to assume that different tasks each give rise to similar levels of stress.

Age is significantly related ($p \leq 0.009$) to all the side effects catalogued in Table 2, with proportionately more younger respondents reporting higher frequency of work stress 'effects.' Gender is also significantly related ($p \leq 0.048$) to all but being satisfied with one's own work, disturbances to regular sleeping patterns, and strain on family life and social activities. For the remaining factors proportionately more female than male respondents report higher frequency.

Table 2. Perceived frequency of the 'effects' of workplace stress

'Effects' of stress	Architects Mean rating value	Engineers Mean rating value	QS Mean rating value	PM & CM Mean rating value	All Mean rating value	<i>P</i> -value
Psychological effects:	(<i>n</i> =240)	(<i>n</i> =148)	(<i>n</i> =163)	(<i>n</i> =53)	(<i>n</i> =604)	
Feeling tense at work	2.11	2.41	2.49	2.57	2.33	<i>p</i> =0.001
Feeling angry at work	2.47	2.97	2.85	3.11	2.76	<i>p</i> <0.001
Feeling frustrated or misunderstood at work	3.44	3.79	3.70	3.96	3.65	<i>p</i> =0.003

Notes: Scale values: 1 = most of the time; 2 = frequently; 3 = sometimes; 4 = seldom; 5 = very seldom.
The *p*-values are from the Pearson Chi-Square test.

4.4 Coping mechanisms

A wide range of coping mechanisms in the form of leisure activities are reported by survey respondents. These include: fitness/gym sessions, spending time with family/friends, travelling, watching TV/ movies, surfing and other water sports, jogging, archery, meditation/prayer, yoga, cycling, shooting, fishing, hiking and camping, golf, gardening, squash, cooking, reading, model building, wining and dining, photography, woodwork, gaming, listening to music, martial arts, motorbike riding and 4x4 driving. It is not known if any of these are used primarily to mitigate stress, or if they are simply undertaken as part and parcel of normal, healthy life and well-being. Further in-depth investigation is needed to explore this.

With respect to the use of tobacco and alcohol, Table 3 shows that 84% of respondents report not smoking. However, the remaining 16% indicate smoking up to 40 cigarettes per day. Of those that smoke, age and race are significant factors ($p < 0.001$ for both) with smoking reported by proportionately more young and black construction professionals.

Table 3 shows that all professional groups report the consumption of alcohol, mostly in the range of 3-9 units per week. In South Africa, 1 unit is equivalent to 12g of pure alcohol; and the upper limit of alcohol consumption advised by the SA National Council on Alcohol and Drug Dependence is 21 units per week for males and 14 for females. In the survey, project and construction managers report consuming significantly ($p = 0.025$) more alcohol per week than other groups, with nearly 30% of respondents drinking 10 or more units per week. An explanation for this finding must await more extensive research.

Table 3. Survey respondents' self assessment of tobacco and alcohol consumption

Number of cigarettes per day (rating scale intervals)	Architects (n=242) (%)	Engineers (n=152) (%)	QS (n=164) (%)	PM & CM (n=54) (%)	All (n=612) (%)
None (1)	82%	88%	85%	78%	84%
1-10 (2)	6%	4%	7%	7.5%	6%
11-20 (3)	7%	3%	5%	7.5%	6%
21-30 (4)	2.5%	5%	2.4%	7%	3%
31-40 (5)	2%	0%	0.6%	0%	1%
41-50 (6)	0%	0%	0%	0%	0%
51-60 (7)	0%	0%	0%	0%	0%
Exceeding 60 (8)	0.5%	0%	0%	0%	0%
Mean score	1.39	1.24	1.26	1.44	1.32
Units of alcohol per week (rating scale intervals)	Architects (n=242) (%)	Engineers (n=152) (%)	QS (n=163) (%)	PM & CM (n=53) (%)	All (n=610) (%)
None (1)	14%	14%	21%	8%	15%
1-2 units (2)	35%	26%	27%	17%	29%
3-9 units (3)	36%	43%	35%	47%	39%
10-19 units (4)	12%	11%	13%	25%	13%
20 or more units (5)	3%	6%	4%	4%	4%
Mean score	2.55	2.70	2.52	3.00	2.62

Note: Pearson's Chi-Square test p -value = 0.025 for between groups alcohol consumption. In South Africa, 1 unit is taken as 12g (net mass) of pure alcohol. The relationship between professional groups and tobacco usage is not significant.

5 Discussion of the findings

5.1 Occupational / professional differences in stress experiences

It is noteworthy that the average frequency rating value for stress 'effects' measured in the survey was consistently lower (i.e. the side effect is experienced more frequently) for professional architects than all other occupational groups, while professional quantity surveyors ranked second in all but four catalogue items. It is possible that the nature of work undertaken by professional architects and quantity surveyors is substantively different (and more stressful) to work undertaken by other construction professionals.

However, it should also be noted that, in the present sample, architects and quantity surveyors tended to work for smaller firms than other professionals. MacDermid *et al.* (1999) argue that work is experienced differently in small compared to large firms. Work in small businesses is less subject to routine and specialisation and is often characterised by greater autonomy than in larger organizations. However, the opportunities for career development and advancement may be fewer and formal

mechanisms for the resolution of disputes are often lacking. The informal nature of human resource management in smaller organizations may also reduce workers' protections against discrimination. Smaller organizations generally pay less than larger ones and workers in small organizations have less access to benefits, such as dependent care assistance. However, workers in small organizations generally have greater control over their work schedules (MacDermid *et al.*, 1999). Also, recent research identifies 'portfolio' workers as being at particular risk of work-related stress (Totterdell *et al.*, 2006). Portfolio workers work for a range of clients over time in exchange for fees. They experience considerable variation in job demands, control and support over time and can experience periods of 'peak stress' when projects overlap (Totterdell *et al.*, 2006). While portfolio work is a characteristic of the work of many construction professionals, future research will examine whether these stressors are more prevalent in the work of architects and quantity surveyors, particularly those working for smaller firms.

5.2 Differences in stress experiences by age

The finding that younger workers are more likely to experience stress 'effects' is consistent with the findings of previous research which shows that older managerial workers report fewer sources of stress and higher levels of mental well-being than younger workers (Siu *et al.*, 2001). This may be explained by theories relating to aging which purport that work adjustment improves as workers age. This improvement manifests as a stronger internal locus of control in relation to work resulting in the adoption of more effective coping mechanisms (Aldwin, 1996). Arguably, older workers with greater experience are better equipped to appraise situations as less stressful (Siu *et al.*, 2001). However, there is also evidence to suggest that workers in different age categories experience the demands-control model of work stress differently (Shultz *et al.*, 2009). Older workers who reported having enough time to complete their work and who enjoyed high levels of autonomy were less likely to report stress even with high deadline demands, whereas schedule flexibility helped in reducing the likelihood of reporting stress associated with high problem-solving demands. Job control did not provide a similar protective buffer for younger workers. Shultz *et al.* (2009) conclude that, for older workers who may experience age-related reductions in both cognitive and physical resources are particularly in need of job control to mitigate stressful 'effects' of demanding work. Further case-based research in the construction professions will explore age-related experiences of work stress in greater depth.

5.3 Coping mechanisms and health-related behavioural responses

The results indicate that professional groups differ in terms of the way in which they cope with work stress, with construction and project managers tending to consume more alcohol when they experience work stress than other occupational groups.

Various taxonomies of coping with work stress have been developed in the literature. Coping styles are generally divided into two broad categories, sometimes termed direct action/active/problem-focused and palliative/passive/emotion-focused (Gonzalez-Morales *et al.*, 2006). The former refers to actions intended to eliminate or reduce a stressful situation while the latter describe attempts to reduce the discomfort associated with work stress. One stress response that would fall within the latter range of coping behaviours is the consumption of alcohol for 'escapist' reasons (Grunberg *et al.*, 1999).

Theories of job stress have posited that employees may consume alcohol in order to regulate negative affect and thoughts arising from aversive or stressful work conditions

(i.e., they drink for escapist or coping reasons). However, the empirical evidence for a direct or main effect relationship between work stressors and alcohol abuse is limited (see, for example, Frone, 2003). The research suggests that the relationship between alcohol consumption and work stress may be a complex one. For example, Grunberg *et al.* (1999) report that stress is only related to higher alcohol consumption for workers who believe that it will help them to cope. Wiesner *et al.* (2005) also report that the relationship between job stressors and alcohol consumption is moderated by gender, with men resorting to alcohol consumption as a coping mechanism more readily than women. This is consistent with previous research that suggests that women and men utilise different coping mechanisms to deal with work stress (Gonzales-Morales *et al.*, 2006; Watson *et al.*, 2011). However, in a mixed male and female sample of US workers, Frone (2008) reports evidence that both alcohol and illicit drugs are used during and after work to reduce tension resulting from work stress (conceptualised as overload and job insecurity), while illicit drugs are sometimes used before work to dampen stress responses workers expect to experience during work hours. Given the differences between professionals' consumption of alcohol observed in the construction research, it is possible that socialisation and normative behaviours of construction professions may shape drinking behaviours. Further, case-based research will specifically examine coping mechanisms utilised by both male and female construction professionals to better understand the nature and source of differences.

6 Conclusions

The findings of this research give rise to sufficient concern to warrant the further investigation of some issues at greater depth. Case-based 'long interview' methods are planned for this, subject to gaining appropriate ethical clearance and the acquisition of funds commensurate with the greater expense of this research method.

Further research is justified because the negative ramifications of workplace stress (including excessive use of alcohol, nicotine and other drugs; and increasing pressure on public and private health resources) have an inevitable ripple effect, spreading from individuals through families and extended families to communities and thus to society as a whole. The issues they represent are too important to ignore. Lowered professional work performance, as a result of stress and its negative consequences and coping mechanisms, has the potential to markedly affect the efficiency and productivity of the construction industry as a whole.

More information is needed about the nature of the work undertaken by each construction profession; how they go about it; which aspects are unique to each group and which are common; and what might make some tasks more stressful than others.

The construction industry itself, and the professional associations that service it, owe a duty of care to mitigate the conditions that give rise to workplace stress, wherever possible, and to promote and support measures that will enable construction professionals to not only cope with stress but also encourage them to maintain a healthy and balanced work/family life. Many of these measures do not have to await the outcomes of further, more detailed investigation. Professional associations in the construction industry, for example, could promote national and local seminars presenting generic early-warning stress detection methods for companies and individuals to use. Models for this already exist in the approach already taken in South Africa and other countries to the adoption and implementation of occupational health

and safety procedures. Healthy coping mechanisms for stress can be similarly promoted, following the healthier life-style approaches already used for illnesses such as heart disease, diabetes and alcoholism. Refinement of all these models can follow later, to incorporate the relevant findings of further research. The important thing is to start addressing and dealing with the issues of workplace stress in the construction industry now.

Trust as a Competitive Parameter in the Construction Industry

Abstract:

The construction industry has in many years been criticized for a limited increase in labor productivity and efficiency, which every year is estimated to cost the industry billion of pounds. A survey conducted point out trust as one of the main reasons for the ineffectiveness in the construction industry. Therefore, this research aims to define the concept of trust in a construction context, and investigates how it is possible to create trustful environments in the construction industry.

Based on different theories, a definition of trust in the construction industry is defined as an expectation of others in collaboration not to take advantage of others to cheat, because the norms say so, and that the most value is achieved through a trustworthy cooperation.

This research concludes that trustful environments in the construction industry is created through incentive models and by applying trust as a competitive tool in the tendering process. This tool could be an addition to already existing key performance indicator systems used to evaluate consultants, architects and contractors in tender situations. The research also presents a proposal for evaluating questions for the assessment of a trust indicator.

Keywords:

trust, incentive model, key performance indicator

1 Introduction

Since 1960 the labour productivity in the Danish construction industry has not increased remarkably compared to other industries (Anlægsteknikforeningen, 2005; Danmarks Statistik, 2010). This lack of increase in productivity is estimated to cost the Danish society about 3,5 bn. pounds yearly. The last 15 years of intense construction activity combined with low interest rates made it possible to finance ineffective building that could be sold at a high cost. The worldwide financial crisis has now changed that premise.

During the last decade the Danish construction industry has been criticized for being very tradition-bound, conservative and adversarial (EBST, 2000; Dansk Byggeri, 2006; ATV, 2009). The same tendency has been seen in other countries like UK (Akintola *et al.*, 2000), Sweden (Kadefors, 2004) and China (Cheung *et al.*, 2009).

The industry does not innovate and renew itself, hence old and ineffective construction process principles are used (Vind, 2009). The different state of the market in the construction industry could be the reason for the lack of innovation in the industry, cf. figure 1.

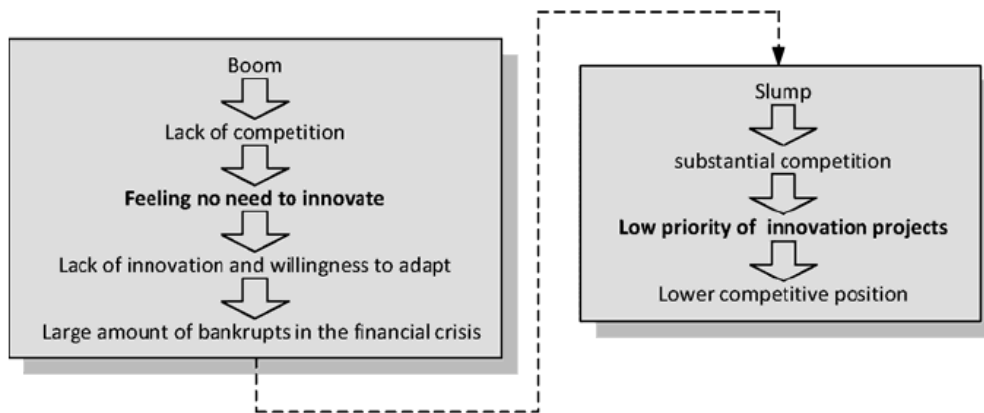

Figure 1. Innovation during boom and slump in the construction industry.

This is probably part of the reason why the productivity in the construction industry is so low. However, many improvement initiatives have been formed to increase effectiveness and efficiency in construction projects, but without positive outcome. (EBST, 2000; Regeringen, 2003; Dansk Byggeri, 2006; OEM, 2007)

In a typical construction project the client and architect often have a lower perception of value versus price than the contractor. This can lead to conflicts when the client does not feel his goals and demands are fulfilled. (Wandahl, 2005) Furthermore, the traditional mentality between client and contractor has long been identified as the major source of construction problems. (Cheung *et al.*, 2003)

Alternative forms of collaboration are rare in the construction industry, where partnering (trust based collaboration), only makes up for 11 % of all projects. (Kuben, 2008) The rest of the projects follow a traditional collaboration model, even though it in several occasions has been stated that alternative forms of collaborations, such as partnering, generates more value for all parts and can achieve savings up to about 10 % of total costs (Cheung *et al.*, 2003).

Core competences are needed if a company wants to differentiate itself from other companies (Johnson *et al.*, 2005; Lynch, 2006). If companies do not differentiate from other companies the possibility of getting “*caught in the middle*” occurs, which prompt competition based on price (Walters, 1999). In the construction industry many project tender are based on lowest price. Therefore, it is reasonable to think that the construction industry is lacking core competences.

Denmark is in general one of the most trustful nations in the world; about two out of three trust other citizens (Svendsen and Svendsen, 2006), but the Danish construction industry is characterized by a very mistrusting culture (Ingeniøren, 1999; Mieke, 2007). Could the lack of trust in the industry be one of the reasons for ineffectiveness in the construction industry?

This research seeks to define the main reason for the ineffectiveness in the construction industry indicated by the industry itself and to give ideas on how to change this. This paper's research question is:

How can trust become a competitive parameter in the construction industry?

2 Research Methodology

This part of the paper is designed to examine the methods used in the current paper, in order to establish valid results. This is a scientific paper, where a hypothetical deductive method is being used to answer the research question; however, an inductive method is used in the survey. (Føllesdal, 2005)

2.1 Survey

The choice was made to use an online electronic survey in order to evaluate the currency of the issues earlier described. The construction industry is composed of many different parts, in which it is not possible to get a qualitative interview with everyone. Therefore, it became essential to make sure, that a representative set of respondents were selected. Hence, Google Maps was applied to ensure that companies were scattered throughout the country.

Besides finding respondents on the internet, all former and present students from the M.Sc. in Construction Management education from Aalborg University were contacted. This had an influence on the average age of the respondents, which was lower than industry average. This was not considered a problem, as a former student still could have 10 years of experience, so his or her statements were assumed trustworthy.

When conducting a survey it is very important to make sure that the questions are given in such a way that they cannot be misinterpreted (Floyd and Fowler, 2009). To ensure that the questions in the survey were appropriate the survey was pretested among colleges.

In most of the questions, a 5 point Likert scale was applied. By using this scale the distance between the possible answers are equal. By having the same distance, it gives the possibility to calculate the average of the responses.

Some of the questions could not follow a Likert scale, i.e. the questions were more open. In the cases where questions could be answered openly, we tried to categorize the answers in groups of similar answers, in order to make statistics on the result.

2.2 Interviews

During the research of trust in the building industry two different interviews were made. Common for both of these interviews was the fact that they were conducted in a semi-structured manner, in order to make room for open dialogs. Both interviews were recorded and afterwards partly transcribed. Besides recording the interviews notes were taken, in order to make sure that all of the visual aspects (nodding etc.) of the interviews were captured.

3 Findings and Discussion

Before concluding anything from the survey approach, it is necessary to validate how well the sample size mirrors the population. The response rate of this survey is approximately 72 % with a dropout rate of 39 %. This is significantly higher than the typical response rate within the construction industry of only 20-55 %. (Wandahl, 2005) The variation in the respondents' years of working experience and professions such as contractor, client, architect, construction worker, consulting engineer and others is illustrated on figure 2 and table 1.

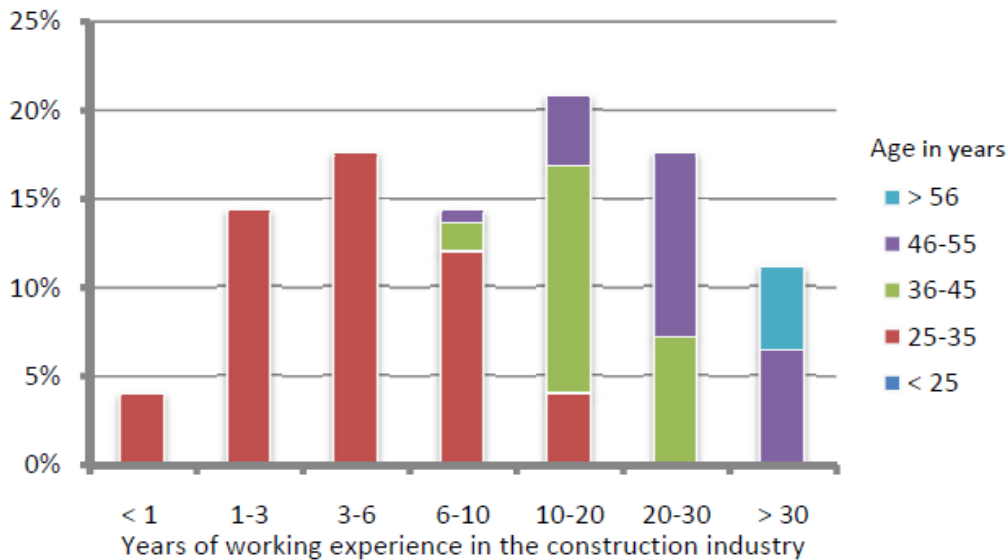

Figure 2. Respondents' age compared with their years of working experience in the construction industry. (Sample size 125)

The distribution among respondents' profession is not evenly distributed, cf. table 1.

Table 1. Professions of the respondents. (Sample size 125)

	Client	Consulting engineer	Architect	Contractor	Sub contractor	Other
Relative sample size	6%	31%	6%	34%	11%	12%

There is a lack of responses from clients and architects. This means that these have a substantially higher uncertainty than the remaining professions, so it may be inaccurate to base the industry's position on these results. However, it is shown that these two professions generally have a lower response rate (Wong *et al.*, 2008). Overall it is estimated, that the responses can be used to answer the issues earlier described.

The main purpose of the survey is to validate or invalidate the hypotheses and thereby identify some of the main reasons for the ineffectiveness in the construction industry indicated by the industry itself.

About 74 % of the respondents agreed or partly agreed with the statement that the working methods in the construction industry are difficult to change. Also about 74 %

agreed or partly agreed that the client in many projects emphasis the final product rather than the way to it, i.e. the construction process.

Generally the respondents describe the construction industry as not being innovative, but the companies in which the respondents work are however assessed to be innovative. Respondents also believe that they actively work to promote innovation in the companies.

Nearly every company in the construction industry is “*caught in the middle*” (Walters, 1999), if the definition of a core competence is used (Lynch, 2006; Johnson *et al.*, 2005). Many of the companies in the industry do not have a core competence which results in competition only on lowest price. The companies however know what they are good at, which is a step in the right direction.

In the Danish construction industry a traditional cooperation between client, contractor and consulting engineer is based on some common conditions (in Danish called: Almindelige Betingelser, AB92, ABR89, ABT93). The respondents are generally convinced that this kind of cooperation often creates issues concerning economics and responsibility that ultimately will decrease the value of the project. However, it is necessary for the parties in a construction project to insure themselves with contracts, rules and restrictions. The consequence of this is that open communications and honesty is uncommon (Cheung *et al.*, 2003).

The trust based cooperation type, partnering, is by the respondents assessed to be very functional and ensure the client most value for money, through budgetary and schedule compliance. The construction parties furthermore prefer greater openness in a construction project, because they assess that it will contribute higher earning possibilities for all parties involved.

The main reason for the ineffectiveness in the building industry, indicated by the industry itself, is the lack of trust. In table 2, some of the statements concerning how trust influence on the projects are listed.

Statement 1: A high amount of trust between parties in a construction project increases the value of the final product.

Statement 2: A high amount of trust between parties in a construction project provides overall a higher earning for all parties involved.

Statement 3: Increased openness between the parties promotes the company's ability to earn money.

Table 2. Answers to statement 1, 2, and 3.

option	Contention 1	Contention 2	Contention 3
Agree	66,9 %	40,7 %	34,7 %
Partly agree	27,1 %	41,6 %	39,0 %
Neutral	2,5 %	10,2 %	16,1 %
Partly disagree	0,0 %	0,8 %	3,4 %
Disagree	1,7 %	1,7 %	1,7 %
Don't know	1,7 %	5,1 %	5,1 %

Based on the survey it can be seen that the clients in a greater degree prefer alternative cooperation types rather than the traditional one's; typically based on the common conditions. This indicates that clients are starting to realize that the way to higher more value for fewer costs goes through selection criteria different than lowest cost.

4 Discussion

Before discussing how to create trust in the Danish construction industry, trust is defined. Also the trust index on national, construction and company level is described. The discussion leads to, what can be done, to ensure a more productive and trustful team effort concerning the construction period, all which should create more value for money.

There are three kinds of trust – concrete, general and institutional trust, where the general trust can be assigned to the construction industry. The general trust is defined as trust between two persons without any prior knowledge to each other. (Svendsen & Svendsen, 2006)

It can be argued that trust is a good indicator of social capital, and this term can be used to determine what trust is and what elements it consists of. Pierre Bourdieu (Svendsen & Svendsen, 2006) does not see any connection between social capital and trust and believes instead that social capital is the product of kinship relationships and other social networks. James S. Coleman (Svendsen & Svendsen, 2006) shares the same viewpoint on the networks but thinks that the social relationships are based on fundamental principles such as trust and respect. Robert D. Putnam (Svendsen & Svendsen, 2006) adds that common norms and values between people make the bond even stronger.

Trust can also be seen through game theory – *prisoners' dilemma* (Gintis, 2009; Fisher, 2009), where two prisoners are caught and asked to betray the other in order to go free or lower their sentence. In connection to this dilemma, the prisoners have to take into account whether or not they can trust each other. Torp and Lolle (2009) have described two kinds of trust:

- *Trust is linked to the expected behaviour of others, namely to how trustworthy we perceive them to be.*
- *Despite all differences you trust other people because you believe that others share your fundamental moral values.*

Doney *et al.* (1998) and Robinson (1996) gives another way to define trust:

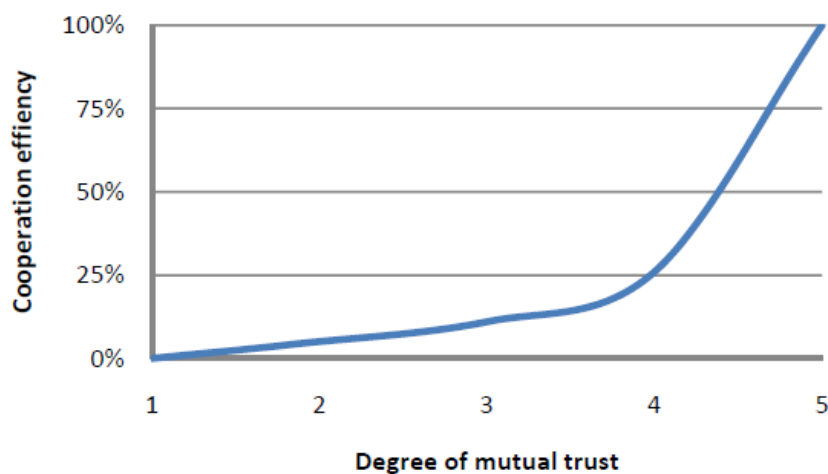

- *Trust is the expectation of regular, honest, and cooperative behavior on commonly shared norms and values.*
- *Trust is one's expectations, assumptions, or beliefs about the likelihood that another's future actions will be beneficial, favourable, or at least not detrimental to one's interests.*

This leads to this research's definition of trust concerning the Danish construction industry:

- *An expectation of others in a collaboration not to take advantage of others to cheat, because the norms say so, and that the most value is achieved through a trustworthy cooperation.*

4.1 Why is trust important?

Trust is important because it reduces the costs of control, optimizes the process and generally creates a more effective workflow. By increasing the general trust in a community with 10 % it has been shown to give a financial growth of 0,5 % (Svendsen & Svendsen, 2006). These savings can also be seen in the construction industry, where not only the costs of control are reduced but also the workflow becomes more effective with fewer flaws and errors. The link between trust and the cooperation efficiency can be seen on figure 3.

4.2

Figure 3. Link between trust and cooperation efficiency. (Olsen and Høgstved, 2006)

4.3 The creation of trust

To create and maintain trust certain elements are needed. Trust is created through long periods of trustful and unselfish acts, which can be conducted into following points (Høgstved, 2008):

- Open dialogs and exchange.
- Mutual understanding for other people's needs.
- Knowledge of others' values and conditions.
- Unselfish efforts to achieve common goals.

Olsen & Høgsted (2006) has made a hierarchy of needs that states some fundamental sets of elements that have to exist before trust between the parties can be achieved. Goodwill in the context can be seen as “Unselfish efforts to archive common goals.” The hierarchy of needs can be seen in figure 4.

Figure 4. The hierarchy of needs. (Olsen and Høgsted, 2006)

In the following trust indexes on different levels of the community is described.

4.4 Trust in Denmark

In general Denmark is seen as one of the most trustful nations in the world and in the past years it has been in the top of many studies of trust. There is no particular reason why trust is so common in the Danish society, but Svendsen & Svendsen (2006) argues that it can be traced back to the co-operative movements (in Danish called *andelsbevægelser*) back in the 1900, where farmers organized in associations. These associations lead to a higher trust level where the organizations were founded on common set of norms, values and goals (economic, rights, politic). (Svendsen & Svandsen, 2006)

In Denmark we have a saying “a word is a word”, which is a norm many people live by in their everyday life. Besides being the most trustful nation in the world, Denmark is also known as one of the happiest nations in the world. Whether happiness creates trust or trust creates happiness is unknown, but there seems to be a connection (Jespersen, 2008).

The situation is completely different in the construction industry where the cooperation normally is based on contracts, and where mutual trust is poor if even existing. The situation creates a conflict culture where the individual parties sub optimizes and only thinks in short terms when decisions are made. In the event of problems the parties are more interested in finding the guilty party instead of moving on and finding a solution to the problem. These standpoints have lead to an industry where there has been no increase in the effectiveness throughout the last decades.

On company level the culture is very trustful, which can be seen through open dialogs, an understanding of the needs of others, values and conditions and unselfish efforts to achieve common goals.

In the light of this paper it can be determined that the construction industry is surrounded by trust, why it must be possible to transfer some of the ideas, to increase the trust level in the Danish construction industry.

The construction industry must base their future cooperation on trust and honesty, and make use of the individual party's strengths, to insure the most optimal project.

Cooperation must be based on common norms, values and goals to insure that everyone is working in the same direction. In the following, two possible solutions are listed in order to increase teamwork and trust between parties.

5 Conclusion and Further Research

Today 2/3 of all partnering projects use incentives to create a better cooperation between parties. Therefore, this element is considered very useful in the creation and maintaining of better common trust. The incentive gives the different parties a common goal which makes them communicate and share knowledge. There are many ways on how to make an incentive, where the common goal is to move focus and ensure that elements important to the client are optimized. The incentive should work as an “eye-opener” for the joining parties, and make a “win-win situation” for all.

Another option is to make trust a competitive tool, where the individual parties are judged by their behaviour and get a grade on how trustworthy other parties consider them to be. This method causes the parties to act more trustworthy because their grade depends on it. The trust index can be included in the selection criteria's; where the client can select the most trustworthy partners.

Currently we have The Building Evaluation Centres key performance indicators. Their purpose is to make the selection process easier by giving companies grades on how well they meet certain expectations. The collection of key performance indicators is mandatory by law for state financed construction works, but can also be used by the private sector. The key performance indicators are measured by flaws and errors, accidents, time and money. An extra key performance indicator could be a trust index.

To measure trust the following questions has been constructed, where each question is being measured on its importance for the client, and afterwards a grade of how well the individual contractors has done on that particular point. These scales and grades are put together to make a key performance indicator on trust. The questions can be seen in table 3.

Table 3. Questions to determine the trust index.

Questions	Importance (1-5)	Grade (1-5)
Professional and contract based qualifications cooperation's		
The project is based on openness.		
Open dialogs and sharing of knowledge.		
Mutual goals, where other person's needs and values are considered.		
Display of goodwill and unselfish behaviour to reach mutual goals.		
Honesty concerning problems in your own subcontract.		
Maintaining a good cooperation between the individual parties.		
Optimizing meetings with contractors.		
Equivalence between the different parties.		
Overcoming occurring problems and conflicts.		
Follow agreements.		
Incur own errors.		

In both Danish and European tendering legislation it is possible to use all kind of selection criteria, if the criteria are measurable and unambiguous (Ussing, 2008). The establishment of a key performance indicator on trust makes it possible to select collaborators based on their level of trustworthiness. This leads to the main message of this paper:

Make as a client demands to your collaborative partners' trustworthiness because it helps to promote economic growth and better cooperation, and through this let trust become a competitive factor. Make as a client requirement for documentation of trust and weight this equally with economy.

The summary should then followed by flagging potential of further research emerging from the investigation. For ongoing research this may include the next stages of the research that will be conducted by the researcher to complete the research, whilst for completed research this may include emerging new possibilities revealed during the course of the research and/or potential for expansion based on the scope and limitation of the research set earlier.

5.1 Further research

This paper is a vertical analysis on the topic of trust, in the sense that the paper concerns a national, construction and company level. As a further research it would be appropriate to undertake a horizontal analysis, and hereby meaning, investigating what differences there are between the trusts in the construction industry compared to other industries in Denmark. By doing this, it will be possible to determine, whether the construction industry is unique when it comes to lack of trust.

Further research could be to compare the trust in different industries with the level of trust in other countries. By doing so it is possible to determine if the level of trust on a national level has any influence on trust in different industries.

6 Acknowledgement

This paper has been carried out in collaboration with Henrik Jensen, Joe Jim Jensen and Birgitte Krag Festersen, during their final thesis for M.Sc. in engineering with specialisation in construction management.

Abstract:

The construction consultancy sector of the Irish construction industry is made up predominately of micro; less than 10 employees, and small, less than 50 employees, companies these small and micro companies (SMC's) have specific management and development issues associated with them. For SMC's to remain competitive the generation and exchange of specialist knowledge in these fields is vital.

The aim of this research is to investigate the issues of Knowledge Sharing's role in company learning within a construction consultancy based SMC's in Ireland. The areas focused on in this research are:

Are there specific issues relevant to Small and Micro companies in the context of Knowledge Sharing?

What are the circumstances that should prevail to allow people to share knowledge?

What are effective methods of facilitating company learning and how can they be developed?

Using a hybrid research methodology the research tools of questionnaires and semi structured interviews, have been applied. The application of these tools will allow the accumulation and analysis of the primary data to support the discussions. Research completed to date points to lower levels of company support for company learning and knowledge sharing techniques.

The results indicate some strong cultural supports towards knowledge sharing are already in place in companies but an increased application of collaborative techniques to enhance company learning are required.

Ultimately the presentation of a company learning strategy to assist companies in implementing the process of knowledge sharing (KS) and company learning will be developed. The broad application of this company learning strategy among SMC's

would assist company learning to become a natural and integrated process supporting their day to day work.

Keywords:

company learning, knowledge sharing, Ireland

1 Introduction

Knowledge is the prime source of competitive advantage among small and micro construction consultancy companies in Ireland today. Professional skill and ability, technical efficiency and client centred service are all accepted as standard minimum requirements. Professional training or Mode 1 knowledge (Gibbons et al., 1994) is homogenised through college degrees and professional bodies training requirements. The one area where companies actively compete is in knowledge; their knowledge of the economy, the industry, the regulations, the client pool etc. How efficiently a company can marshal its staff knowledge and its company knowledge will be the key determinant on its survival in the industry.

Unlike other assets knowledge and knowledge sharing skills cannot simply be bought like another computer, printer, or hired as another staff member. A KS environment must be gradually developed and “grown” within a company (Ringer, 2007). This is achieved through the right culture and facilities occurring within a company (Payne and Sheehan, 2004). This research is focused on the role of KS within company learning of a company. It focuses on Mode 2 - knowledge from application (Gibbons et al., 1994) or tacit knowledge. The focus group of companies are small and micro construction consultancy companies within Ireland. This group was selected because of a striking lack of research undertaken on this particular sector of the industry. KS is a vast area of research with substantial literature support in the form of books, journals, web sites, conferences etc. (Nonaka and Takeuchi, 1995). The areas of KS that are focused on in this research are:

Are there specific issues relevant to Small and Micro companies in the context of Knowledge Sharing?

What are the circumstances that should prevail to allow people to share knowledge?

What are effective methods of facilitating company learning and how can they be developed?

Knowledge is a significant resource to companies but one that poses many difficulties in its management. Key to the difficulties is the effort required to maintain the maximum benefit or integrity of the knowledge once it is shared and distributed. Thus there are many strategies that can be formulated to leverage knowledge from staff into the wider company for improved performance. KS strategies will vary from country to country, from industry to industry and from organisation to organisation. Thus more needs to be understood about the specific issues effecting KS in small and micro construction consultancy companies (SMCCC) in Ireland.

The research conducted in this study is informed by the actual practices that exist in the area of KS in SMC in the Irish construction consultancy sector. It will allow companies to appreciate the areas they are progressing well in and to identify areas where greater potential for exploiting company learning exists.

Professional practice tends to be very much focused in the “now”, it is a thread that is repeated in the interviews on a number of occasions that staff and managers are focused on completing the job in hand and far less time is spent on the strategic development of the company. Academic research can assist companies in proposing potential future strategic paths for the company to pursue.

2 Knowledge Sharing within SMC's

In a company for KS to be seen as important the company's management need to focus on it. This can be achieved by assigning staff or responsibility for its instigation. For KS to be developed and expanded assigned staff or responsibility is required, here the role of knowledge managers are important. The tasks for knowledge managers are typically to control and filter knowledge to ensure their staffs has the appropriate knowledge infrastructure to compete the work required of them. Company managers should work out new roles, the role of knowledge manager that determine new skills for knowledge coordination and create a culture that allows staff to identify themselves within the company and to share knowledge for a common gain or competitive advantage. Staff's prestige or status within a company should derive more from sharing useful knowledge within the company than from owning it.

In Large organisations it is often easier for companies to have specialised staff for IT, KS, etc but within SMC's all staff tend to be involved in the direct service the company provided and there is very little scope for having specialised staff available. Thus for KS to develop in a company all staff need to have an appreciation for its benefits and how they can play a proactive role in KS development within their company.

KS provides the link between the individual staff member and the company. This attempts to transfer the knowledge residing in the staff member to the company level. KS is a dynamic process affected by factors that exist at company, team and individual level (Davenport and Prusak, 1998)(Davenport and Prusak, 1998)(Davenport and Prusak, 1998). (Bollinger and Smith, 2001) believe that if a supportive organisational culture and top management support are not in place, there will be little incentive for staff to share knowledge. (Bandura, 1986) corroborates this assertion, stating staff may decide not to demonstrate particular behaviour's if they believe it will not improve their status within the company. (Robinson et al., 2001) concludes that a lack of top management support can hamper the success of a KS strategy this view is also supported by (Al-Ghassani et al., 2002). Leadership from senior management in KS will help motivate others to get involved in KS. A supportive senior management to KS will encompass company motivation, proactive culture and mutual staff trust. These methods are also supported in (Egbu et al., 2010) research on KS critical success factors.

2.1 Culture

Culture reflects the deep foundations that a company is based on, its values, beliefs, history and traditions (Robinson et al., 2005). One cultural aspect which is crucial for KS is collaboration. This is because KS requires individuals to come together to interact and exchange ideas. How attitude to KS is developing within the company and extrinsically to the company within the broader industry is important. Because knowledge is often seen as a source of power, individuals may naturally tend to be reluctant to share it (Kim and Mauborgne, 1998). A number of researchers also identify the cultural barriers that exist and can hinder the implementation of a successful KS

strategy and learning approaches. A study carried out by (Peng and Akutsu, 2001) showed that cultural factors can have an impact on the knowledge transfer process. (Wyer et al., 2000) outlined some issues, which may constrain change in company culture; the commitment of top managers, top managers may constrain the progress by being reluctant to have open management approaches and empowering staff. (Hamlin et al., 2001) six-step model for the successful implementation of change management presents a comprehensive solution. A key driver in the implementation of change is that ownership, commitment and involvement to the new strategy must be secured throughout the company, including that of top-management.

A study carried out by (Peng and Akutsu, 2001) showed that cultural factors can have an impact on the knowledge transfer process. (Bollinger and Smith, 2001) believe that if a supportive organisational culture and top management support are not in place, there will be little incentive for staff to share knowledge. (Bandura, 1986) earlier reached this assertion, stating staff may decide not to demonstrate particular behaviours if they believe it will not improve their status within the company.

2.2 Motivation

Personal motivation to share the knowledge one possess must be understood so that a company can develop structures to encourage staff KS. Staff may think that possessing valuable or unique knowledge allows them to retain a competitive advantage over other staff (Bock and Kim, 2002). KS will be more likely if individuals are rewarded for this (Newell et al., 2002). For successful KS to develop a grass root desire must exist so employees contribute to and benefit from their company's intellectual resources (Hauschild et al., 2001). In order to build a knowledge-based enterprise, incentive systems should be focused on criteria such as KS and contribution, teamwork, creativity and innovative solutions (Wong, 2005). KS will be more likely if individuals are rewarded (Newell et al., 2002). Staff motivation goes hand in hand with staffs trust with each other and with the company.

2.3 Trust

Unless there is a high degree of trust within companies, people will be sceptical about the intentions and behaviours of others and thus, they may withhold their knowledge. Building a relationship of trust within a company will help to facilitate a more proactive and open KS process (Wong, 2005). Thus a culture of collaboration and trust will go hand in hand. The restructuring and downsizing of companies breaks the idea of lifetime employment and replaces it with a strong element of precariousness in the employment relationship (which adversely) impacts the level of trust in organisations (Sharkie, 2005). In Sharkie's research he put forward 6 factors that affect the level of trust an employee has in their company. They included

the worker's employment security with the organisation,

the employer's improving an individual's employability,

enlightened management,

perception of fairness,

supportive environment, and

rewards for work done.

If most or all of these factors exist in a company it is more likely that KS will occur. (Hendriks, 1999) and (Ardichvili et al., 2003) concurred that no matter how motivated staff are, they do not share knowledge with those they do not trust. (Levin and Cross, 2004) found that the level of trust affects not only the sharers but the seekers of knowledge too. (Andrews and Delahay, 2000) take the research further and claim that when there is trust between individuals, they are more likely to take note of and receive knowledge in addition to providing worthwhile knowledge in return.

2.4 Senior Management

Various researches have been conducted in this field using a variety of terms including small business owners, business leaders, entrepreneurs or business managers. For the purpose of this research the term senior management will be used to address these areas. For small businesses to succeed, it is important to understanding the effective behaviour's senior management has on their staff and the company. (Robinson et al., 2001) concludes that a lack of top management support can hamper the success of a KS strategy this view is supported by (Al-Ghassani et al., 2002) and (Robinson et al., 2005). (Carrillo et al., 2000) identify the need for leadership in KS which will help motivate others to get involved. Culture, trust, motivation and management style are all recognised as issues that impact on KS and by extension company learning (Arif et al., 2010) and (Egbu et al., 2010) work have also identified these areas. By senior management having an adaptive role they can adjust to their environment, learn from experience, and as a result, change their behaviour (Marcketti and Kozar, 2007). Senior managements leading role is necessary in order for businesses both large and small to be competitive in the modern economy. Managing knowledge is a critical capability for SMC's to master because it helps them leverage the key resources of staff knowledge and experience (Desouza and Awazu, 2006). An emphasis on forming meaningful relationships with staff has become increasingly more significant as senior management attempt to enhance both staff effectiveness and company performance. Besides, using knowledge directly, senior management must also transfer knowledge to staff. Seldom, do SMCCC's have the capabilities to recruit the best minds in the business; hence they must settle for less qualified but motivated individuals.

2.5 Facilitating Company Learning

It is understood that the capacity for thinking together in teams or as a company is different from individual intelligence. The main purpose of thinking together in a company is to enable coordinated action that contributes towards the company's strategic plan. Society value intelligent individuals but seem to lack ways of understanding and working with thinking in the team-as-a-whole. The size and complexity of professional skills required in SMC means that the knowledge required to run an effective enterprise is too great to be held in one brain. Hence, effective business leadership and management require the pooling of knowledge and "thinking skills" from a number of different staff members. Effective collaborative thinking is the "engine room" for the modern "knowledge organisation", and the "learning organisation" (Ringer, 2007).

Ringer's research centred on team interaction, in relation to the SMCCC's which are the focus of this research many of the companies contain only 3-5 staff members and this function very much as teams. Through Ringer's research a number of indicators were identified when poor quality company thinking was present. A number that are relevant to and furthered in this research are summarised as follows;

The atmosphere of a team does not feel safe for most participants to think and speak freely. Hence, individual thinking may be strong, but collective thinking is impaired because the thoughts of any one team member are not spoken and hence made available as stimulus for further thinking of other team members.

Teams type of thinking - convergent thinking is required for decision making. but divergent thinking is required when a team is seeking to be creative in the search for more options. Teams seldom specify what kind of thinking they need to be conducting. This lack of clarity can lead to confusion and low quality collective thinking.

Senior managers usually underestimate the psychological and emotional power of what they themselves say and do. In general, their every move is noticed by staff and these “data” have a powerful influence on “how we do things around here” – i.e. team or company culture

2.6 Company Learning

As knowledge is held by individuals it is the basis of company learning, The sharing of this knowledge among multiple individuals with different backgrounds, perspectives, and motivations becomes the critical step for organisational learning to take place (Balasubramanian, 1995). The lack of company learning is often crystallised for a company when a staff member is leaving .The experience and insight of a departing staff member is lost to the company if it has not converted that person’s knowledge into explicit form, and integrated it into the company so that it is ready for use. (Tserng and Lin, 2004) and (Kamara et al., 2005) agree with this point stating that when an expert or professional leaves a company the library of knowledge and experience gained by them also goes leaving little or nothing behind of benefit to the company. Companies learn haphazardly from experience and rarely capture it in ways that can be transformed into available knowledge embedded in the company memory (Huber, 1996). (Fiol and Lyles, 1985) show that company learning is multi-level, occurring at the individual, group and company levels.

2.7 Communities of Practice

Etienne Wenger (Wenger, 2001) is considered one of the foremost experts on CoP. He stated that CoP are a specific kind of community. They are focused on a particular area of knowledge or expertise and over time accumulate knowledge and build community knowledge. They develop their shared experience by interacting around questions, problems, solutions, and insights gained. They build a common store of knowledge and their community is based on the practice of that knowledge. CoP is governed by internal, informal, and unspoken rules dominated by specialised language development. If we accept that the role of CoP’s in the business environment is to share knowledge and improve the way the company does business, and that they are community workplaces where people can share ideas, mentor each other, and tap into interests, each CoP can be a focus of learning and competence for the company. Company culture seems to play a significant part in communities and how they operate. The members of a community need to trust each other and the company before they are willing to share their experience and understanding. Convincing staff to develop or participate in CoP requires on-going commitment from senior management to permit communities to self-organise and collaborate as they see fit with suitable encouragement and support. Successful communities maintain a clear purpose and active leadership. CoP’s should support innovation and staff creativity through collaboration and collective solutions.

3 Research Methodology

Because of the nature of trying to study practical KS in companies' cognisance needs to be taken of the complex and interdependent nature of the company issues, staff mix, work pressures and practices that exist. From reviewing research philosophies the most applicable was the Ontological and Epistemological perspective this tended towards the constructivist end of ontology and the interpretivist's end of epistemology. This philosophical stance resulted in the adoption of inductive reasoning being applied to the research approach and the selection, design and development of the research tool, questionnaires, to be applied which in turn impacted on the nature of data collection.

Quantitative research strategy will support deductive reasoning and the positivist range of the epistemologists' philosophy. Qualitative data collected is soft data designed to develop an in-depth understanding and explanation for people's behaviour, motivations and attitudes. (Naoum, 2006). The questionnaires structure used included opinion statements and a range of responses based on an adapted Likert scale. This research strategy will support inductive reasoning and the interpretivists range of the epistemologists philosophy. The literature review helped to gain a better understanding of existing theory, practice and current development on the area of research. Through the review specific research questions emerged that provided the basis for the development of a suitable research aim and research objectives. (Saunders et al., 2002) the data collection tool chosen was questionnaires and the designing stage consisted of initial design, redesign as necessary, pilot survey, feedback, final design, approval and issue. Altogether 71 questionnaires have been returned. The questionnaires were distributed to a cross-section of SMCCC's in Ireland.

4 Findings and Analysis

Despite the SMCCC offering different skills and services their basic structure and focus is similar. All work within the same industry, all are small or micro companies all have a high dependency of staff skills to fulfill their professional services and all work in hierarchal team structure.

The following tables 1 through to and including table 4 address the methods used by companies to facilitate company learning. The object of focusing in on these areas is to gain an understanding as to how companies are dealing with the difficulties of encouraging and maintaining company learning.

Table 1. Staff Motivation

How would you describe staff motivation to share new knowledge with:					
Adapted Likert Scale	Teams	Senior staff	Other staff members	Management	Administration staff
Poor	2.82%	4.23%	4.23%	0.00%	12.68%
Fair	15.49%	14.08%	9.86%	5.63%	23.94%
Neutral	18.31%	16.90%	26.76%	26.76%	32.39%
Good	53.52%	52.11%	47.89%	52.11%	21.13%
Very Good	9.86%	12.68%	11.27%	14.08%	8.45%

In relation to staff sharing new knowledge in table 1 we are seeing good levels being recorded in most areas. Administrative staff is the only area where these is lower levels of knowledge sharing taking place.

Discussion

Numerous bodies of research have highlighted the importance of strong positive motivation levels existing among staff to facilitate KS. It is encouraging that levels are so strong in this area as research has also shown it is difficult to develop positive motivation among staff that are resistant to sharing knowledge.

Table 2.Senior management involvement

Adapted Likert Scale	Are Senior Management Involved in:			
	Identifying knowledge sources	Contributing to company knowledge	Reviewing and distributing new knowledge	Resolving problems encountered
To no extent	4.23%	2.82%	7.04%	5.63%
To little extent	26.76%	14.08%	18.31%	7.04%
To some extent	46.48%	42.25%	43.66%	33.80%
To large extent	19.72%	39.44%	26.76%	52.11%

Table 2 highlights a reasonable level of senior management involvement in identifying, contributing to and distributing new knowledge. However the highest involvement is in resolving problems encountered.

Discussion

The research of the literature on numerous authors has shown that involvement and leadership by senior management is vital to the success of KS in a company. It is the senior management of a company that set the standards and targets that staff members need to attain. Table 2 shows the highest level of senior management involvement is with problem solving. This by its nature is a reactive type of management rather than a more proactive method which would see greater involvement in knowledge identification and contributing to company knowledge. Senior management's lower levels of involvement in these proactive areas of KS would appear that there is no real driving force behind KS in the majority of SMCCC in Ireland.

Table 3.Sharing Knowledge Attitudes

Adapted Likert Scale	Opinion Statements			
	The company applies knowledge learned from experience to new projects	Staff withhold their valuable information in order to retain an advantage over other staff	I would require an incentive from management to share valuable knowledge with other staff	Sharing knowledge will allow a company to develop
Disagree	2.82%	36.62%	40.85%	0.00%
Partly Disagree	4.23%	29.58%	28.17%	0.00%
Neutral	2.82%	14.08%	16.90%	5.63%

Agree	63.38%	19.72%	14.08%	25.35%
Strongly Agree	26.76%	0.00%	0.00%	69.01%

The opinion or attitudinal statements used in table 3 sought to look at company issues and their impact on KS. There is very strong feeling that application of knowledge learned is applied to new projects. Equally strong is the denial that staff would withhold their knowledge in order to gain an advantage. Very few staff members would require an incentive to share valuable knowledge with others and there is a strong belief among staff members that sharing knowledge will allow a company to develop.

Discussion

The outcome of each of the statements in table 3 is supportive of strong company learning and meaningful KS. Looking in conjunction with table 1 staff are motivated enough to share their knowledge and the vast majority do not require an incentive from management. Equally there is a strong belief that sharing knowledge is good for a company and will help it to develop and that few staff would knowingly refrain from sharing useful knowledge with another staff member.

Table 4. Methods of Company Learning

Adapted Likert Scale	Does the company support any of the following methods of company learning:					
	Personal research	Internal work exchange	Communities of practice	Internal training	External training courses	Continuing Professional Development
To no extent	7.04%	26.76%	28.17%	5.63%	18.31%	7.04%
To little extent	39.44%	19.72%	35.21%	9.86%	21.13%	15.49%
To some extent	33.80%	38.03%	25.35%	40.85%	39.44%	29.58%
To large extent	15.49%	9.86%	2.82%	38.03%	15.49%	42.25%

Table 4 suggested numerous examples of methods used to promote company learning. These methods are based on literature and research focusing on methods of company learning. All methods show some level of engagement by companies with CPD and internal training being the most utilised and internal work exchange and CoP the least used areas.

Discussion

Each of the areas noted in table 4 can have benefits for company learning as each involve the potential for both personal and company learning development. There is engagement at some level with each of the methods put forward but the area of CoP is not engaged in to any significant extent. This is a disappointing situation as much of the literature on KS points to the benefits of having active CoP integrated into a company and how they can assist in the advancement of KS. Added to this is the difficulty of trying to initiate the development of CoP as by their nature they are outside the normal management structure of a company and when the culture is supportive they will develop through staff initiative.

5 Conclusion and Further Research

A number of the questions posed at the outset of this research have now been answered:

Are there specific issues relevant to Small and Micro companies in the context of Knowledge Sharing? - In SMC's continual monitoring and checking of KS behaviour can be counterproductive. The development of cultural norms to promote sharing is preferred. This is supported by the research on SMC's and on communities of practice (CoP).

What are the circumstances that should prevail to allow people to share knowledge? – A strong culture of sharing and co-operation needs to be developed based on good levels of staff motivation and trust and strong senior management support.

What are effective methods of facilitating company learning and how can they be developed? – Company learning is a combination of individual staff development and team or company learning. Methods set out in table 4 suggest a number of methods of both individual learning and company learning.

For KS to become integrated into the majority of SMCCC in Ireland there needs to be engagement in a number of areas which are interdependent. All areas need to be developed in tangent so that a synergy will evolve and the benefits gained in one area will support the development of another area.

Who gets the jobs? Factors influencing the employability of property and construction graduates in the UK

Steven Devaney¹ and Deb Roberts¹

¹University of Aberdeen Business School,
Edward Wright Building, Dunbar Street, Aberdeen, AB24 3QY,
United Kingdom

Email: s.p.devaney@abdn.ac.uk; deb.roberts@abdn.ac.uk

Abstract:

Against a background of a strongly performing property market, the last decade saw a significant rise in entrants to postgraduate built environment programmes in the UK. This reflected the emergence of conversion programmes with the result that, across a range of built environment pathways, employers can choose between two types of graduates: those straight from an undergraduate programme or those who have taken, following a first degree in another discipline, a conversion course in property or construction at postgraduate level. Based on a sample of 12,582 graduates from the HESA Destination of Leavers dataset for 2005/06 to 2008/09, this paper uses probit analysis to explore if there is evidence that the level of degree programme that a student graduates from (undergraduate or postgraduate) systematically affects their probability of finding graduate level employment. It considers different built environment subjects and a range of other factors that may influence employment outcomes, including university type, mode of study, gender, ethnicity and age. The approach adopted allows for the fact that similar characteristics may affect both the probability of undertaking a taught postgraduate course and that of obtaining graduate level employment. Results suggest that postgraduate degrees in land and property management are positively associated with graduate level employment, but this is not so in the areas of quantity surveying or building surveying. The paper concludes by relating findings to the wider discussion on changes in UK Higher Education.

Keywords:

bivariate probit, construction, conversion courses, graduate employment, real estate

1 Introduction

A major development in the education of students for property and construction professions has been the creation of postgraduate conversion programmes. These enable graduates in other subjects to obtain, in a relatively short time, core knowledge and skills required for employment in these disciplines and for the subsequent workplace training needed to gain membership of a professional body. Such conversion degrees have proved very popular, attracting UK and overseas students, and have increased the supply of graduates, which had been in steady decline throughout the 1990s. Thus, employers can now choose between two types of graduates: those straight from an undergraduate programme or those who have taken a conversion course following a first degree in something else (and, possibly, an intervening period of employment).

Yet whilst this development is well known, there is little evidence on the employment outcomes experienced by each group of graduates. Anecdotal evidence suggests that graduates from conversion programmes are popular with employers and, in some cases, preferred to students from undergraduate programmes. However, it is important to explore whether or not this is so because of the implications it could have for future programme provision and wider education policy, particularly in the context of recent changes in Higher Education funding, the increase in undergraduate fees in England and Wales, and the debate about access to the professions (Department for Business, Innovation and Skills, 2011). Hence, this paper analyses the employment of each group within a quantitative framework using data from the Higher Education Statistics Agency (HESA). By employing probit modelling techniques, it finds that postgraduate degrees do provide an advantage for securing graduate level employment in some, but not all, built environment disciplines.

The paper is structured as follows. Section 2 sets the rise of taught postgraduate courses in property and construction in the context of the general rise in postgraduate education in the UK in recent years. It also notes some existing knowledge regarding employment outcomes before proceeding, in section 3, to describe in more detail the methods used to test such outcomes. Section 3 also outlines the data that is used before section 4 presents results. Section 5 concludes by discussing the implications of the research findings.

2 Background Literature

Postgraduate education in the UK has grown markedly over the last fifteen years. Between 1997/98 and 2008/09, the number of enrolled postgraduates rose by 36% compared with a 27% rise in the undergraduate population (Smith *et al.*, 2010). Particularly important has been the growth of taught masters programmes in this period, with their growth driven by international student enrolments, especially students from outside the EU (Sastry, 2004; House, 2010). Built environment subjects are amongst those that have shared in this growth, although with a greater emphasis on expanding part time provision than some other areas (Sastry, 2004; Boorman & Ramsden, 2009).

Taught masters programmes can take various forms, but it is possible to distinguish those that extend knowledge in a particular discipline from those that enable conversion to a discipline by non-cognate degree holders. In property and construction, examples of both can be found, but there has been notable growth in conversion programmes in recent years. This development occurred in the wake of falling undergraduate numbers for these subjects through the 1990s at a time when overall numbers in higher education were increasing (Dainty & Edwards, 2003; Wilkinson & Hoxley, 2005). For surveying, the creation of postgraduate conversion programmes was encouraged as part of RICS educational reforms, announced in 1999, which aimed to increase the number of high quality graduates entering property and construction professions.

The growth in student numbers on RICS courses since then has been well documented (e.g. Hoxley & Wilkinson, 2006; Key, 2010). Figures for new enrolments updated to 2008/09 are shown in Table 1. Undergraduate numbers have rebounded from a low point in 2002/03, whilst postgraduate numbers have increased dramatically from less than 500 such entrants in 2001/02 to over 5,000 by 2008/09. The latter trend now means that postgraduates make up the majority of entrants to RICS accredited programmes. Key (2010) notes a similar dominance in the number of programmes in the UK, with 183 RICS accredited postgraduate programmes in 2007 vs. 124 at undergraduate level.

Table 1. Number of entrants to RICS accredited programmes in the UK – 2000/01 to 2008/09

	2000/1	2001/2	2002/3	2003/4	2004/5	2005/6	2006/7	2007/8	2008/9
Undergraduate	2,949	2,572	2,554	2,688	3,064	3,660	3,727	4,031	4,258
Postgraduate	419	1,363	1,805	2,354	2,917	3,609	4,697	4,716	5,331

% Postgraduate	12%	35%	41%	47%	49%	50%	56%	54%	56%

Source: RICS Education and Qualification Standards

The rising proportion of graduates from conversion programmes is likely to have had an influence on the labour market for the property and construction professions. The popularity of postgraduate students with employers has been highlighted by Ashworth (2007), whilst Hoxley & Wilkinson (2006) note a positive response from employers in building surveying. This is tempered by concerns over the reduced time in conversion programmes for the delivery of technical knowledge (Birch *et al.*, 2005; Hoxley & Wilkinson, 2006). Nonetheless, these studies and press articles (e.g. Benyon, 1999) highlight a range of positive attributes that employers associate with postgraduates, such as maturity, motivation, wider experience and awareness, an ability to learn quickly and strong intellectual skills.

It should be noted, though, that much of the evidence on employment outcomes to date is anecdotal. In part, this reflects that there is limited data on whether the trends and qualities noted above translate into different outcomes for postgraduates in terms of employment. Research at the all subject level by HESA (2009) and House (2010) shows that postgraduates are more likely to be in full time paid work, more likely to be in managerial, professional or technical occupations and less likely to be unemployed at both 6 months and 3.5 years after graduation. In addition, there is a salary premium for postgraduates relative to holders of a first degree only. These advantages persist when analysis is split by mode of study (full or part time) and, as House (2010) notes, reflect not only the higher qualification level, but also the greater age and experience within postgraduate cohorts.

However, there are many other factors beyond qualification level that may be important for labour market outcomes in the property and construction professions and that have not been controlled for in previously published statistics. Furthermore, there are differences between built environment disciplines in the nature of their postgraduate programmes and there may be distinctive employer preferences with regard to level and mode of study (e.g. see Westcott & Burnside, 2006). Thus, whilst one might expect better outcomes for postgraduates given the greater investment by these students in their education, doubts about conversion programmes might be reflected in terms of little advantage for postgraduates in the job market. It is these issues that the analysis in this paper seeks to explore further using individual level HESA data that covers graduates from real estate and construction related degrees.

3 Methods

3.1 Modelling approach

The modelling approach adopted in this paper is based on the proposition that the probability of a graduate gaining graduate-level (as opposed to non-graduate level) employment is a function of the type of qualification they hold. In particular, the key

research question is whether students graduating from a taught postgraduate programme have a higher probability of gaining graduate-level employment than those from an undergraduate degree programme after controlling for other individual characteristics and macroeconomic conditions that may influence employability.

Based on this, a standard univariate probit model of the effect of a postgraduate qualification on graduate employment is given as

$$G_i^* = \beta_1 X_i + \beta_2 W_i + \delta PGT_i + \varepsilon_{1i} \quad (1)$$

where G_i^* is a latent variable denoting the probability of getting graduate level employment, X_i are personal characteristics affecting that probability, W_i are labour market factors and PGT_i indicates whether or not the individual holds a taught postgraduate qualification. In this model, ε_{1i} is taken as a normally distributed error term with a mean of zero and a variance of one that captures all of the unobserved determinants of the probability of gaining graduate-level employment.

The determinants of a having a PGT qualification could also be estimated using a univariate probit model as follows:

$$PGT_i^* = \beta_1 X_i + \beta_2 W_i + v_{1i} \quad (2)$$

where PGT_i^* is a latent variable denoting the probability of having a postgraduate degree and X_i and W_i are as defined above. v_{1i} is also taken as a normally distributed error term with mean zero and variance one, in this case capturing the unobserved determinants of the probability of having a postgraduate taught qualification.

If there is an overlap between the unobserved characteristics that determine the probability of getting a graduate-level job and the probability of having a post-graduate taught qualification, a univariate modelling approach such as that represented by equation (1) will produce biased results (Greene, 2000). In particular, the unobserved heterogeneity could result in ε_{1i} from equation (1) being correlated with the variables that explain PGT qualification. This in turn means that the PGT variable is not exogenous to G_i^* resulting in a biased coefficient on this variable.

Correcting for this endogeneity could be done using an instrumental variable (IV) approach, but there are potential shortcomings of this approach (see Greene 1998, 2000). Instead, the approach adopted in this paper follows that suggested by Greene (1998) and the following simultaneous recursive bivariate probit model was estimated:

$$G_i^* = \beta_1 X_i + \beta_2 Z_i + \beta_3 W_i + \delta PGT_i + \varepsilon_{1i} \quad (3)$$

$$PGT_i^* = \beta_1 X_i + \beta_2 W_i + v_{1i} \quad (4)$$

The error terms ε_{1i} and v_{1i} are jointly distributed as bivariate normal with means of zero, variance of one and correlation ρ . Z_i are factors that explain the probability of getting one of the endogenous variables (graduate level employment), but not the probability of having a PGT qualification. A key test for the bivariate model is whether the null hypothesis ($\rho = 0$) is rejected. Failure to reject this hypothesis means that the univariate probit model has consistent estimators. If ρ is found to be significantly different from zero and positive, then some of the unobserved factors increase both the probability of gaining graduate level employment and having a postgraduate degree and

this would lead to an overestimation of the importance of PGT qualification on graduate employment in a univariate model. Alternatively, if ρ is significantly different from zero and negative, then the estimated effect of PGT qualification on graduate employment from a univariate model would be underestimated. The variables that comprise vectors X , Z and W are explained below.

3.2 Data and model variables

Analysis is based on a sample of 12,582 graduates from built environment programmes included in the HESA Destination of Leavers from Higher Education (DLHE) dataset 2005/06 to 2008/09. Students are surveyed between 4 and 12 months after graduation depending on their graduation date.

A key issue given the research question is the definition of graduate level employment. A number of previous studies have used a classification developed by Elias & Purcell (2004) and which is applied here using the 3-digit Standard Occupational Classification (SOC) codes included in the HESA dataset. Table 2 shows the distribution of responses across the two binary dependent variables for all property and construction graduates in the sample. The 1,643 leavers not employed, but in “other activity” (including those undertaking further full time study and those assumed unemployed) are excluded from the graduate employability analyses.

Table 2. Employment type by qualification level

	Type of employment			Total
	Non-graduate level	Graduate level	Other activity	
First degree	1,081	7,104	1,401	9,586
Taught postgraduate degree	327	2,427	242	2,996
Total	1,408	9,531	1,643	12,582

The HESA data contains a wide range of variables. Gender, ethnicity and age group variables are included in both bivariate probit equations as previous research suggests that these influence both the probability of gaining graduate level employment and of undertaking further postgraduate study (Artess *et al.*, 2008). Similarly, mode of study is included in both equations since part time study may be more strongly associated with a postgraduate route and may have a positive effect on getting graduate level employment following graduation. Meanwhile, during the four years covered by the data (2005/06 to 2008/09), the macro economy (and property market) moved from a period of economic boom to recession. It was felt that such major changes would affect not only the chances of a graduate gaining employment but also the probability of them enrolling on a postgraduate programme. Hence, year dummies are used in both model equations to represent market conditions.

There are two types of variables which are included in only the graduate employability model (represented by Z_{it} in equation (3) above). University type is included on the understanding that employers may have preferences for graduates from certain types of institutions, but that this does not influence the probability of having a PGT qualification. In particular the 209 institutions included in the DLHE dataset were grouped into two broad categories: “old universities” (including Oxbridge, Russell group, 1994 group and other old universities) and “new universities” (comprising post 92 universities and FE or HE colleges with degree-level programmes).

In terms of type of qualification, it was possible, for first degree graduates, to distinguish those leavers with good (first class or higher upper second class degrees) from those with less strong academic performance (lower second class or third/unclassified). Students graduating from either a postgraduate research degree or an “Other undergraduate” programme were dropped from the analysis on the basis that they are unlikely to be competing for the same employment opportunities.

Finally, to capture differences across built environment subjects, the JACS 4 digit subject variable was used to distinguish four categories of programmes: construction, building surveying, quantity surveying, and land and property management. Means and standard deviations of the explanatory variables by each of the four subject areas are shown in Table 3.

Table 3: Proportion of each characteristic by built environment subject area

Observations	Construction n=6316	Building surveying n=2175	Quantity surveying n=2198	Land & property management n=1893
Female	0.168	0.165	0.145	0.314
Black	0.026	0.024	0.032	0.029
White	0.824	0.874	0.827	0.827
Asian	0.051	0.047	0.045	0.057
Other ethnic group	0.016	0.015	0.013	0.018
Unknown ethnicity	0.042	0.021	0.025	0.029
Non UK domicile	0.041	0.018	0.058	0.041
Over 24 years	0.457	0.457	0.413	0.425
Old university	0.267	0.180	0.230	0.588
Part time study	0.416	0.320	0.529	0.226
Good degree class	0.467	0.559	0.527	0.249
Medium degree class	0.239	0.244	0.319	0.139
Low degree class	0.080	0.037	0.068	0.025
PGT degree	0.214	0.160	0.086	0.587

There are some key differences between subjects. Land and property management has a higher proportion of females and graduates from old universities, and the highest proportion of taught postgraduate leavers. In contrast, there are few leavers with a taught postgraduate qualification in quantity surveying, but this subject has the highest proportion of students that studied part time. Construction and building surveying are more similar to one another but there are a higher proportion of PGT leavers in the former.

4 Econometric Results

Table 4 presents the bivariate probit results for all built environment leavers and compares them to the estimates from an equivalent univariate probit analysis (where each equation is estimated separately). The top half of the table relates to the probability of gaining graduate level employment, whilst the second half relates to the probability of having a taught postgraduate qualification.

The estimate for ρ in the bivariate model is 0.2328 and significantly different from zero at the 3% level. This suggests that a univariate model of graduate employment would

overestimate the significance of a postgraduate qualification. Indeed, comparing the estimates across both versions shows that whilst in the univariate model, PGT positively and significantly increases the probability of gaining graduate level employment, once the endogeneity of the PGT variable is controlled for, the coefficient becomes insignificant.

In contrast, having a good (first or upper second class) degree significantly increases the likelihood of gaining graduate employment relative to the omitted category of a lower second class degree, while having a third/unclassified degree significantly decreases the same likelihood. The land and property management subject dummy becomes insignificant in the bivariate model (as compared to negative significant in the univariate model). Otherwise, the coefficients on the other explanatory variables in the graduate employment equation are qualitatively similar across univariate and bivariate models and have the expected signs.

The results relating to the year dummy variables are interesting, especially comparing across the graduate employment and postgraduate qualification equations. The sign and magnitude of estimated coefficients in the graduate employment equation are as expected given that, compared to the base year of 2005/06, the economy grew in 2006/07 (year 2) and then entered a downturn in 2007/08 (year 3) which deepened in 2008/09 (year 4).

Turning to the estimates in the postgraduate qualification equation, while the 2007/08 dummy is negative, suggesting an initial negative effect of the downturn on PGT admissions, the coefficient for the final year (2008/09) has a positive and significant coefficient suggesting that poor employment prospects may have increased demand for PGTs in built environment subject areas. This is somewhat counterintuitive, but it could reflect either a lack of alternative employment options or expectations of an upturn in the property market by the time that students graduate. Other coefficients in the PGT equation are of expected sign and are similar across both versions of the model.

				Wald pgt = 3578.12 Prob>chi = 0.00		
				Pseudo pgt R2 = 0.2591		

Notes: ***, ** and * denote 1%, 5% and 10% significance levels, respectively. Omitted categories are white, under 24, full time study, new university and graduating with a lower second class degree. The omitted subject category is building surveying.

Tables 5 and 6 display results for each individual built environment subject area. The model specifications are similar to those above expect that, in these cases, subject

dummies are not required and the ethnicity variables are modified owing to the small number of observations in each category.

In only one of the four models is ρ significantly different from zero - the land and property management model. The sign of ρ in this model is negative, which suggests that a univariate model would underestimate the importance of having a taught postgraduate qualification for graduate employability. It follows that, in the other three subject areas, a univariate probit model of graduate employment would provide consistent estimates.

The coefficients in Table 5 suggest that a taught postgraduate qualification only has a positive effect on the likelihood of obtaining a graduate level job for Land and property management students. For the other disciplines, the coefficient is not found to be significantly different from zero. Meanwhile, non-white ethnicity appears to have a significant and negative impact on the likelihood of gaining a graduate level job in three of the four subjects after having controlled for the type of qualification held and other personal characteristics. Being over 24 is estimated to have a negative and significant impact for land and property management leavers, but is positive for building surveying. Studying part-time is also significant and negative for land and property management,

but positive and significant for the other subject groups, corresponding with preferences noted by Westcott & Burnside (2006). Finally, the results relating to the year dummy variables are interesting, suggesting that the economic downturn affected land and property management employment prospects and PGT applications more slowly than for the construction industry.

In relation to the three subject areas where ρ is not significantly different from zero, with one exception, the results from the univariate version of the model (shown in Table 6) are qualitatively very similar across all variables to those in the bivariate model. The exception relates to the coefficient on the PGT qualification variable in the construction subject area. While in the bivariate version of the model, this is insignificant, in the univariate model it is estimated as significant positive: having a PGT qualification increasing the likelihood of graduate employment. This difference between the two versions of the model in this subject suggests that there may be some features about the nature of PGT courses in construction that the existing bivariate model is not capturing and which require further research.

5 Conclusion

Property and construction are subjects in which marked growth has occurred in the provision of postgraduate conversion degrees. The analysis in this paper provides evidence as to the value of such a postgraduate qualification in securing graduate level employment on leaving university. Results from the estimations suggest that it has a positive effect on the likelihood of securing a graduate level job in the real estate sector and, possibly, within construction as well. However, it appears to confer no significant advantages in the fields of building surveying and quantity surveying. Meanwhile, other coefficients highlight differences between land and property management and the other

subjects, though, in all cases, a good first degree appears to be a positive factor and a third class degree has a negative influence on employment outcomes.

These results could have important implications for future programme provision and wider education policy, particularly in the current context of changes in higher education funding, the significant increase in undergraduate student fees in England and Wales, and the ongoing debate on access to the professions (Department of Business, Innovation and Skills, 2011). Evidence on whether the earlier introduction and increases in fees deters students from postgraduate study is mixed (Smith et al., 2010). However the larger fee increases being introduced in parts of the UK from 2012/13 mean that, in future, postgraduate programmes will have to demonstrate clear employability benefits in order to attract students. Hence, the trend towards higher numbers of conversion programmes could be reversed, with the possible exception of real estate where the employment advantages for postgraduates appear to be clear.

The results also showed the impacts of the recession on the employment prospects of all property and construction graduates. Ongoing cuts in public expenditure on construction and infrastructure projects suggest that the job market for graduates will be continue to be difficult in the foreseeable future. Therefore, competition between graduates from different types of programme may well become more intense. Meanwhile, other results in relation to gender and ethnicity variables suggest that access continues to be an issue for the property and construction professions and this is worthy of further investigation in its own right.

The research does have limitations, particularly in terms of the definition of graduate level job, which does not necessarily indicate employment in either the property or construction industries. Thus, further analysis to reliably determine relevant industry employment could be valuable. Analysis could also be extended to examine interactions between economic conditions and the advantages of postgraduate or part time study. Nonetheless, the results to date expand the evidence on labour market outcomes in the property and construction industries and, thus, add to the debate in this area.

6 Acknowledgements

The authors acknowledge the support of RICS Scotland for the initial research project from which this paper has been developed. They would also like to thank HESA for the provision of the underlying data on which analysis is based and Sarah Jewell for early guidance. The paper has benefitted from the comments from anonymous referees.

Abstract:

The expertise of end users' in the development of new building is acknowledged in participatory design. Participation in a design process provides children with valuable opportunities for voicing their views and ensures that the relevant customer (children) requirements are available in all phases of process, and that they are not lost when progressively transformed into design solutions.

This paper aims to presents an overview of the research method adopted for the study on participation of children in design process of children's hospital. Research methodology is the application of various systematic methods and techniques that create new knowledge. The selection of an appropriate research method influences the credibility of the research findings and is an important aspect of any research success. The paper brings forward the theoretical approach used in the research process from the theoretical underpinnings to the collection and analysis of data. It presents an example of case study research and describes challenges on the development of case studies.

case study, children's hospital design, design process, research method

1 Introduction

A considerable amount of studies in healthcare design research have been performed by Ulrich (1991a, 1991b, 1992, 2000, and 2001). He concentrates on finding the relationship between the designed environment of healthcare facilities and clinical outcomes for patients. A theory of supportive design in healthcare settings by Ulrich's (1991b:97) includes the assumption that "supportive surroundings facilitate patient's coping with the major stress accompanying illness. The effects of supportive design are complementary to the healing effects of drugs and other medical technology, and foster the process of recovery."

Ulrich's (1991b) theory has defined two major sources of patient stress: their illness and its repercussions, and the nature of the physical environment. Furthermore, he discussed that patient stress has a variety of negative psychological, physiological and behavioural impacts on patient wellness (Ulrich, 1991a, 1991b, 1992, 2000, 2001). The main core of Ulrich's argument is supporting patient wellness through minimising environmental stress.

Patient's total wellbeing, from physical to emotional and social needs, is the prominent parts of any medical consideration. In order to provide such environment in which a patient is supported and encouraged to total wellbeing, all the users (patients and staff) should have genuine participation in its designing and planning process.

Understanding children's and young people's perspectives and needs as the users of the healthcare facilities can be used to strengthen the capacity of policymakers, designers, and healthcare managements to prepare a supportive environment based on their needs (Bishop, 2008). Also, the decisions based on assumptions made by adults about the needs of children and young people can be minimised, which in turn can increase the likelihood of designing supportive hospital environments, from the children and young people's perspectives (Bishop, 2008).

It is essential to understand what children needs and preferences are, and respond with design solutions which meet those preferences in the best possible manner. As such, participatory design approaches are suggested as the means to enable better identification of needs, supporting value generation. However, there are challenges in implementing participatory approaches in building design, especially in complex environments such as hospitals, and with delicate clients such as children. Wilson et al (1997) defines user involvement as 'focus on users' and Heinbokel et al. (1996) defines it as 'participation of users'. Participatory design refers to a design process where different stakeholders are involved in the design and their tasks start from the early stages of the design and continue all through the process (Gould and Lewis 1985; Blomberg and Henderson 1990; Cherry and Macredie 1999; Maguire 2001; Gulliksen et al. 2003) Requirements can be elicited by the designers through a number of approaches, for instance workshops and discussion of design issues with users (Baeka and Lee, 2008).

For the purpose of this study, user involvement is defined as a development process incorporating ideas and feedback acquired directly from end users (in this case, children and young people) at various stages of the process (Nousiainen, 2008). Such participation should involve different groups of patients in hospitals, such as: young children and teenagers, short-term and long-term patients, as well as other special groups such as chronically ill children who have to return to the hospital repeatedly (Eriksen, 2000).

This paper, analyses types of philosophies, approaches, strategies and methods of data collection used in a research demonstrating the reasons behind utilising this scheme in this research.

2 Research aim and objectives

The aim of this study is to develop generic guidelines to help designers incorporate children's perspectives in designing children's hospitals. Focus is on providing not only a friendly environment but one that will promote recovery.

The objectives stimulating this research are:

1. To understand the role of participatory design with children in providing a proper children's hospital to promote recovery during the healing process.

2. To identify and investigate the structure of user involvement process and the methods used to carry out the process
3. To identify problems and issues associated with engaging children during the design process of children hospital
4. To study the process of identifying children's preferences and establish how the preferences were considered during the design process of the case studies

3 Definition of research methodology

There are different definitions of research methodology concept that have been stated. Saunders et al. (2007) described research methodology as: "Something that people undertake in order to find out things in a systematic way, thereby increasing their knowledge". Likewise, Kumar (2005) defined research methodology as "a taught supporting subject in several ways in many academic disciplines at various levels by people commit to a variety of research paradigms". A researcher uses the appropriate systematic methods to collect and analyse data and to properly identify issues concerning with the work as well as the objectives of his study - research methodology.

In the word of Peter and Howard, good research is rigorous, systematic, integrated, focused and objective (2001:595):

"Research that meets the criteria of rigour, a systematic kind of modelling in its articulation and which ties back its process to a solid grounding in what we know about the area that we're being researched, so that there is a total integration of varying viewpoints in the grounding of the research design".

Sexton (2000:76) describes the 'nested' approach as a holistic, integrated research method, generating a framework that "provides the researcher with a research approach and techniques that benefit from epistemological level direction and cohesion". Figure 1 demonstrates the application of the nested approach to this research. The next section concentrates on the paradigms driving the research.

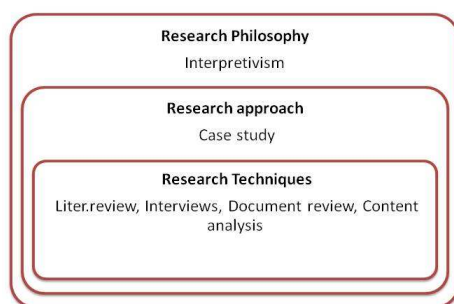

Figure 1: research methodology 'nesting'

4 Purpose of the research

Collis and Hussey (2003) classify the research according to its purpose; Exploratory research which is conducted into a research problem or issue when there are very few or no previous studies to which more information can be obtained from. Descriptive research is research which describes phenomena as they exist. Analytical or explanatory

research is a continuation of descriptive research. Predictive research aims to generalise from the analysis by predicting certain phenomena on the basis of hypothesised, general relationships.

Therefore, this research can be classified as exploratory, explanatory and even descriptive type of research. It was exploratory in identifying issues influencing children's participation in the hospital design. It was also explanatory as it provided evidence to better understand why problems arise during design process, and was descriptive, in that it aimed to establish the activities that take place during participatory design process.

5 Research philosophy

Easterby-Smith et al (1997) states three reasons to clarify the importance of research philosophy for the research methodology which are; a) help the researcher to refine and specify the research methods, b) assist the researcher to evaluate different methodologies and methods and c) it may help the researcher to be creative and innovative in either selection or adaptation of methods that were previously outside his or her experience.

Two main research philosophies; Positivism and Interpretivism have been recognised by number of authors (Easterby et al, 2002). Positivism argues that "working with an observable social reality and that the end product of such research can be law-like generalisations similar to those produced by the physical and natural scientists" (Remenyi et al, 1998). The interpretivist philosophy emphasises the difference between research conducted among people rather than those conducted among objects (Saunders et al, 2007). Therefore, the social scientist should welcome and appreciate the different views and meanings that people place upon their experiences (Easterby et al, 2002).

For the purpose of this study interpretivism philosophy has been adopted as overall research philosophy due to number of reasons. To achieve the aim of the study the researcher is required to identify different views of people who have been involved in the design process of the hospital (such as designers, planners and NHS staff). Hence, the study encourages the people to tell their ideas, opinions and experience about the design process of children's hospital.

The main purpose of employing the Interpretivism paradigm in this research is to investigate and understand the experiences, perspectives, and to identity development of a small sample of the experience-rich participants of this study. To achieve the aim of the study the researcher is required to identify different views of people who have been involved in the design process of the hospital (such as designers, planners and NHS staff). Hence, the study encourages the people to tell their ideas, opinions and experience about the design process of children's hospital.

6 Research approach: case study

A research strategy is a general plan on how to answer research question(s) and consequently satisfy the research objectives (Saunders et al. 2007). Yin (2003: 14) described the case study as a research strategy in two ways, first, the technical definition begins with the scope of a case study: "as an empirical inquiry that investigates a contemporary phenomenon within its real-life context, especially when the boundaries

between phenomenon and context are not clearly evident.” Second, “the case study as a research strategy comprises all-encompassing method; covering the logic of design, data collection techniques, and specific approaches to data analysis”. The aim of case studies is to reach a fundamental understanding of structure, process and process (Gummesson, 2000). It may be qualitative or combined qualitative and quantitative, depending on the circumstances (Yin, 1994; Silverman, 1998).

Case study is the most appropriate approach to satisfy the research aims and objectives of this study. It aims to investigate a contemporary event within its real-life context and Yin mentioned that case study is the most appropriate strategy to use in these kinds of studies. The main objective of this study is to gain empirically an in-depth understanding of the barriers affecting the engagement of children in design of children’s hospital. Some researchers such as Saunders et al. (2000), Jankowicz (2005) and Gummesson (2000) asserted that case study is used if the researcher wishes to gain a rich understanding of the context through getting a comprehensive and informative information (appropriate information). Further, Yin (2003) suggested the case study as an ideal approach for research that focus on the “what, why, and how” questions. This research explores barriers affecting the engagement of children in design of children’s hospital and the way to incorporate children's perspectives in designing children's hospitals, answering some ‘how’ and ‘what’ questions.

There is no definite answer to justify a single case or multiple cases strategy in a research. As Yin (2003) discusses that the single case can be used when it represents:

- The critical case in testing a well-formulated theory
- An extreme or unique case
- A representative or typical case
- The revelatory case
- The longitudinal case: studying a single case at two or more different points in times

Voss et al. (2002) argued that the advantage of single case study could be offering greater depth of study and its disadvantages could be limitations on the generalisability of conclusions drawn. It could also lead to bias such as misjudging the representativeness of a single event and exaggerating easily available data.

According to Yin (2003), multiple cases are generally used to replicate findings or support theoretical generalisations. In addition to that, multiple case study research increases external validity (Voss et al. 2002). In this way, the researcher chooses a multiple set of case studies which allows for a replication the same phenomenon under different conditions in appropriate research designs to confirm or disconfirm inferences drawn from previous ones (Yin, 1994).

6.1 Selection of cases

The Royal Alexandra Children’s Hospital: After a major redevelopment, the Royal Alexandra Children’s Hospital in Brighton reopened in 2007. The new Children’s Hospital is one of only seven dedicated paediatric hospitals in the UK. The new development was able to transform the old hospital to a relatively more spacious

structure with more than three times the size of the original building it replaced and doubled number of beds. The project has won 2008's Prime Minister's Better Public Building Award. The redevelopment plan was aimed to provide the best possible environment in which children could receive treatment and recuperate and creating a welcoming environment. The two main key elements in the success of the development are: recognising the needs of individuals, most notably young people and their families and high quality services for families and children through effective engagement with users.

The Royal Manchester Children's Hospital (RMCH): The RMCH is the largest single-site children's hospital in the UK comprising 371 beds, including 17 intensive care and 12 high-dependencies. It converts two children's hospitals at Pendlebury and Booth Hall to a single building. It has been intended to establish and maintain a sense of the human-scale, therefore minimising the anxiety of patients and families crossing the hospital threshold for the first time.

These hospitals has been selected as case studies for this research due to the fact that the design has taken place with a through consultation process, which involved number of staff, patients and their families to balance the needs of users and providers of services, in a complex environment.

7 Research techniques

Six major sources are suggested by Yin (2003) in doing case studies which are: documentation, archival records, interviews, direct observation, participation direct observation and physical artefacts. Yin (2003) noted that no single source of data has a complete advantage over others, while the various source are complementary.

7.1 Literature review and synthesis

According to Hart (1998:13) the literature review is "the selection of available documents (both published and unpublished) on the topic, which contain information, ideas, data and evidence written from a particular standpoint to fulfil certain aims or express certain views on the nature of the topic and how it is to be investigated, and the effective evaluation of these documents in relation to the research being proposed" Literature review has number of advantages such as: providing researchers the knowledge required to narrow the focus of their research topic, specifying the research problem in detail, identifying gaps in existing research knowledge, learning how to express certain views on the nature of the topic, identifying of neglected issues in previous researches, getting a rich source of secondary evidence on which to outline and finally creating a summary of research evidence (Burns 1997:27-29).A broad review of existing literature was carried out in this research to address the research and to create the context and insights into previous work.

7.2 Semi-structure interview

Easterby-Smith et al. (2002) considered the In-depth interviewing as the most fundamental of all qualitative methods. In-depth interviews try "to understand the world from the subject's' points of views, to unfold the meaning of peoples' experiences, to uncover their lived world," (Kvale, 1996:1).

Kvale (1983, p. 174) provided a definition of the qualitative research interview as "an interview, whose purpose is to gather descriptions of the life-world of the interviewee

with respect to interpretation of the meaning of the described phenomena”. The main objectives of the technique are to draw out the experiences and perspectives regarding to the participants and also providing the opportunity that the participants would be able to point out their own personal feelings and ideas with regards to specific subjects. Boyce and Neale (2006) discusses the main advantage of in-depth interviews techniques, compared to other data collection methods provide much more detailed information. Open-ended, focused interviews more structured questions, along the line of a formal survey are identified as main types of interviews used in case study research by Yin (1994).

In this research, a semi-structured interview approach was adopted and the questions are designed in the form of open-ended in order to provide a way to encourage them to talk and point out their experience in their own words.

In this type of interview, the questions can be asked about the behaviour or experience, opinion or belief, feelings, knowledge, sensory, and background or demographic of the participants (Patton, 1987).

The main weaknesses of interviews have identified by Yin (1994:80) as:

- Bias due to poorly constructed questions
- Response bias
- Inaccuracies due to poor recall
- Reflexivity - interviewee expresses what interviewer wants to hear

Tape recording, transcribing all the interviews and complementary data gathering method was used to reduce the effect of these weaknesses.

7.3 Documentary evidence

The qualitative document analysis is the systematic study of documents which refers to “an integrated and conceptually informed method, procedure, and technique for locating, identifying, retrieving, and analysing documents for their relevance, significance and meaning.” (Altheide, 1996:2)

Documents are created in particular contexts, by particular people, with particular purposes, and with consequences – intended or unintended, (Mason. 2002: 110). The documents may include media reports, website content, meeting minutes, and personal diaries (Pryor, 2003). Documents of diverse type have been collected and analysed, including:

- Case study organisation corporate publications
- Case study organisation public web site
- Electronic mail
- Presentation material
- Published information about the case studies on the internet

8 Data gathering

The first stage of the research aimed to identify and investigate the structure of user involvement process and the methods used to carry out the process.

The study, at this stage, was based on a literature review in the areas of process of participatory design with children and young people as well as the methods used to carry out the process. This review clearly demonstrated what the process of user involvement was like and the main goal for using the participatory design approaches as well as the potential benefits and challenges of such process.

Two case studies were developed that have involvement of children and young people during the design process. In each case study, the design process structure and problems and issues associated with engaging children during the design process were identified through documents and on interviews. A semi-structured interview technique has been used to obtain the necessary data from the design team, PFI members and NHS staff and to understand their experience and opinion of involving children during the design process of case studies.

Patton (2002) and Oberle (2002) express that there are no rules governing the number of interviews required for case study research, and the purpose of the study and available time and resources will affect the sample size in qualitative research. Accordingly, the total number of interviewees was 26 in the two case studies: 16 in Royal Alexandra children's hospital and 10 in Royal Manchester children's hospital. The number of interviewees was conducted according to the following measures:

- The researcher had managed to inform the project staff the purpose and questions of the interview. Some agreed to participate in the interviews, while others refused, as they did not have enough information about the research topic.
- To obtain as much as questions answered by the interviewees, as all the interviewees do not answer all of the questions and the amount of repetition in the answers obtained during the interviews.

The researcher arranged the interview times and dates according to the candidates preferences. Participants completed interview that ranged from 15-60 minutes in length. (Although the average running time for the interview was approximately 25 minutes, a few of the interviews were longer as the participants in these interviews were interested in discussing some topics at length). Occasionally participants were happy to carry out their interviews at the case study organisation to allow the researcher to access the appropriate documents. Otherwise, interviews were conducted through telephone conversation.

In order to make the process more effective and easier, the researcher sent the questions to the interviewees prior to interview meeting. It's worth to mention that the researcher was aware that this step could lead to bias.

9 Content analysis

Krippendorff (2004:18) defines the content analysis as "a research technique for making replicable and valid inferences from texts (or other meaningful matter) to the contexts of their use."Ole Holsti (1969) offers a broad definition of content analysis as such a

technique which tends to create inferences by objectively and systematically identifying specified characteristics of messages.

Leedy and Ormrod (2001:155) define this method as “a detailed and systematic examination of the contents of a particular body of materials for the purpose of identifying patterns, themes, or biases”. This method, reviews forms of human communication in order to identify patterns, themes, or biases and to identify specific characteristics from the content in the human communications. The researcher is exploring verbal, visual, behavioural patterns, themes, or biases. (Williams 2007).

Prior questions have to be addressed in every content analysis to allow for transparency in the process which are formulated by Lasswell et al (1952, p. 12) and have been adopted in this research as: "Who says what, to whom, why, to what extent and with what effect?"

For the purpose of this study, the content analysis similar to what is described by King (1998:118) as “template analysis” has been used. It has not been used to quantify the themes (or to engage any discussion on quantification of themes) in the analysed documents or data as identifying them was more important than verifying the number of times each theme has been referred to or has been discussed. To elaborate on template analysis, King (1998:118) defined it as “the essence of the approach is that the researcher produces a list of codes (a ‘template’) representing themes identified in their textual data. Some of these will usually be defined a priori, but they will be modified and added to as the researcher reads and interprets the texts”.

In this research, interviews were transcribed and arranged in to text files. A list of codes or labels to assign meaning to the descriptive or inferential information (Miles and Huberman, 1994) was developed prior to data analysis in two levels-high and low. The higher level was about more general themes describing features such as process, methods and issues where the lower level was more detailed. Each code was linked to the research objectives it was derived from. To facilitate the analysis of the data, the researcher has to search into the interviews for expressions or variables, which can be verified as a code or create a new code. Identifying new code then requires the researcher to loop around the cycle to search for the variables relating to the new code, this process carried out until no new code was found.

In order to perform the analysis of the both of case studies in this research, the NVivo software has been used. It has been expressed as a useful tool for the content analysis by Richards (1999):

It provides a range of useful tools for handling rich data records and information about them for browsing and enriching text, coding it visually or at categories, annotating and obtaining accessed data records accurately and swiftly.

The NVivo has tools for recording and linking ideas in many ways, and for searching and exploring the patterns of data and ideas.

It can manage the complexity of the data. As the user links, codes, shapes and models the data, the software helps to manage and synthesize the ideas.

10 Conclusion

Patient's total wellbeing, from physical to emotional and social needs, is the prominent parts of any medical consideration. Therefore, all the users (patients and staff) should have genuine participation in its designing and planning process. Participatory design approach is directly related to value generation; through exploration of user's preferences, it was possible to recognise it as a solution for meeting user's needs in the central importance of enhancing the customer satisfaction. This paper summarises the research methodology to achieve the research aims and objectives of this study.

It can be concluded that in order to develop a successful research, the true understanding of the philosophical issues should be accompanied by a clear definition and design of research strategy. The clear definition and design of research strategy would result in unbiased and more convincing research outcomes. The philosophical understanding of the research ensures the compatibility and consistency between research philosophy, approach and techniques.

Abstract:

To the eBusiness environment ‘cloud computing’ is known as the generic term for Information, Communication, and Technology (ICT). It serves as an umbrella term for the provision of services, such as storage, computing power, software development environments and applications, combined with service delivery through the internet to consumers and business. However, to a fragmented industry such as construction, the benefits of this service have still to be fully recognized. This paper presents the results of a Delphi questionnaire undertaken by 16 international experts on construction ICT. The paper analyses the expert groups opinions on the future of ICT in construction based on a cloud service which hosts construction-related applications. The survey was designed to evaluate opinions and to screen alternatives in order to discover new ideas relating to the topic. It was formatted into three main core sections; business process, cloud computing capabilities; and cloud-based business opportunities. Each of the sections analyzed the potential for developing a cloud-based construction service by identifying standardized deliverables, obstacles and opportunities for growth to the perceived benefits. The questionnaire itself is derived from an earlier survey based on cloud computing in the Irish construction industry and the results of this current questionnaire will identify further research questions. In order to establish if there was a strong relationship between the experts around the world; the paper presents quantitative results supported by the comments obtained from the qualitative analyses. The possibility of providing an interoperable process based on binding three focused construction applications through a single repository platform ‘cloud computing’ is the core focus of this paper.

Keywords:

building information modeling, cloud computing, Delphi technique, information communication technology.

1 Introduction

The structure of the questionnaire was divided into three sections; namely business process, cloud computing capabilities, and cloud business opportunities based on refining the results of a 2009 survey ‘Building Support for Cloud Computing in the Irish

Construction industry' (Redmond *et al.* 2010). Within each of these segments were questions designed to analyze the potential for developing a cloud service based on combining three essential applications; Building Information Modeling (BIM), project management and accountancy. The panel comprised of residents based in the U.S. (50% - 8 respondents), UK (34% - 6 respondents), and Australia and France both represented by an individual (16% - 2 respondents) totaling 16 experts. The experts were from varied backgrounds; such as construction IT research consultants, university academics, lawyer, cloud developers, cloud BIM developer, BIM vendors, and a representative from a leading professional body for qualifications and standards in land, property and construction. Weinstein (1993) identified that there are two types of experts: those whose expertise is a function of what they know (epistemic expertise), or what they do (performative expertise). Weinstein describes epistemic expertise as the capacity to provide justifications for a range of propositions in a domain while performative expertise is the capacity to perform a skill in accordance to the rules and virtues of a practice. The experts chosen for this survey are a mixture of either or both epistemic and performative. They are of senior position in an established firm or institute relating to construction and ICT. This paper illustrates the results and discussions of a Delphi questionnaire undertaken in 2010 which will be used to establish the necessity for a cloud computing collaborative process based on a common database for the construction industry and to identify topics that will be used to form questions for the next form of research.

2 Delphi technique

The Delphi technique is in essence a series of sequential questionnaires interspersed by controlled feedback, that seek to gain the most reliable consensus of opinion of a group of experts (Linstone and Turoff 1975). Wissema (1982) underlines the importance of the Delphi method as an exploration technique for technology forecasting. Wissema further acknowledges that the Delphi method has been developed in order to make discussion between experts possible without permitting a certain type of social interactive behaviour as happens during a normal group discussion and hampers opinion forming. Powell (2003) suggests that the Delhi technique represents expert opinion, rather than indisputable fact and that further inquiry to validate the findings may be important. Powell also concedes that a Delphi study will be further enhanced if its limitations, possible implementation of findings and future research directions are discussed. The structure of the questionnaire outlined in this paper was designed to evaluate whether there is a strong relationship between the groups of experts.

This Delphi questionnaire forms part of a primary research of a PhD methodology based on 'Grounded Theorism' which was applied to identify and categorize elements and to explore their connections to cloud computing and the construction industry. Sayre (2001) views 'grounded theory' as a model of using modes of questioning to develop theories rather than to study them as a process whereby discovery by developing theoretical propositions from interview data and field research, often accompanied by establishing categories, refining them, and revisiting the questions repeatedly until specific propositions are developed for future testing.

3 The Survey

The methodology used for the questionnaire included both quantitative and qualitative research (open and closed-ended questions). The attitudinal research focused on

subjectively evaluating the opinion or view of the respondent towards particular topic. The exploratory research was used to diagnose the situation, screen alternatives and discover new ideas. The structure of the survey comprised of the following sections:

3.1.1 Business process:

Identify if a cloud collaboration tool based on combining the open Application Performance Interface (API's) of accountancy, project management, and a BIM application would benefit the industry. The benefits of re-engineering a previous innovative solution with the concept of construction as a manufacturing process were investigated and compared to Kagioglou *et al.* (1999). Kagioglou *et al.* had identified that traditionally ICT had been seen as a driver behind changes in the design and construction process and indeed in many Business Process Re-engineering (BPR) initiatives.

3.1.2 Cloud computing capabilities:

Focus on Armbrust *et al.* (2009), obstacles to adopting and opportunities for growth of cloud computing. This section also analysed Lowe's (2010) review of the five challenges associated with moving backup to the cloud in order to provide new and informative literature on the cloud's capabilities in contrast to traditional network infrastructure. However, as a cloud becomes ever more successful there are leading experts finding comparisons with the Dot.com era and rebutting them; such as Wohl (2008). The final question in this section investigates if cloud computing has advanced from the many mistakes made by the Dot.com bubble.

3.1.3 Cloud based business opportunities:

The key attributes of this section are the benefits associated with cloud computing in comparison with traditional premise-based facilities. The primary question requests the respondents to refer to their own company when making a decision, such as, would cloud be a cost benefit to one's firm? The respondent's knowledge is also called into question asking for expertise on whether cloud benefits are essential for business growth and do Small to Medium Enterprises have the capability of using such a service.

4 Findings and Discussion

4.1 Business Process

4.1.1 Developing a cloud collaboration tool based on combining open API's of accountancy, project management, and BIM applications.

The overwhelming positive response to the question illustrated in Figure 1 has 50% of the experts agreeing and 29% strongly agreeing. However, after further analysis of this open-ended question; the experts identified areas for concern such as security and the difficulty involved with combining open API's with different applications. One such expert supported the concept of developing a cloud collaboration tool but was unsure of the approach of using existing API's to address the problem. Another potential issue is the notion of developing a HTML for BIM and allowing multiple software vendors to produce software on that new web-based platform.

The majority of the experts acknowledged that the key to integrated BIM is a common database preferably in the cloud containing information about component parts of building modeled in disparate software programs. One such expert revealed that they had already undertaken this process for several years, using cloud computing based on BIM with web services connected to other applications in the cloud.

Figure 1. Developing a cloud collaboration tool, in response to the question:

‘Would you agree that developing a cloud collaboration tool based on combining the open APIs of accountancy, project management, and BIM applications, would benefit the industry in having a standard supply chain service; please state the reason for your answer or if you think an alternative combination would be more effective (please name the applications).’

4.1.2 Construction as a manufacturing process

According to Kagioglou et al. (1999) the term BPR was first introduced in a 1990 article of the Harvard Business Review by Michael Hammer suggesting that re-engineering is “the fundamental rethinking and radical redesign of business processes to bring about dramatic improvements in critical, contemporary measures of performance, such as cost, quality, service and speed.” In conjunction with these benefits Kagioglou *et al.* listed the main process findings of a Engineering and Physical Sciences Research Council funded project (UK). The experts were asked to grade these process findings as illustrated in Table 1. The experts only had a mixed concern about two statements, namely, (1) the need for a coherent and explicit set of process-related principles to be managed by the whole industry with the intention of changing the strategic management of the common process and (2) the need for construction operations that form part of a common process controlled by a single integrated team. The problem relating to the first issue can be traced to the fact that companies prefer to manage their own standard procedures until they have to collaborate with the rest of the design team. The second problem refers to the notion of integrated systems being less competitive in comparison to an open standard system. In contrast the expert panel strongly agreed that the required model should be capable of representing the driver’s interest of all parties and be interchangeable allowing interfaces between existing practices.

Other strong indicators identified were the need for a generic and adaptable set of principles, standardised deliverables and a key emphasis on designing and planning to minimise error and networking during construction. The construction industry involvement being extended beyond completion – a post completion phase; received a high level of agreement (71%). The majority of the experts agreed with the process protocols, however having the whole industry reviewing the process and controlling the integrated system did receive negative responses. This is further identified in the open-

ended answers where one respondent stated ‘We need to treat facilities and infrastructure like manufactured “products” instead of chaotic “projects” delivered by a disparate rag team of individuals and companies with no common purpose.’

Table 1. Construction as a manufacturing process, in response to the question: ‘The following statements are related to construction as a manufacturing process. A major objective of the industry is to identify the ICT requirements needed to support a process protocol; please indicate your opinion on the following statements and please state the reason for your answer.’
(Sourced from Kagioglou *et al.* 1999)

Construction as a Manufacturing Process	Strongly agree	Agree	No Opinion	Disagree	Strongly disagree
The required model should be capable of representing the drivers interest of all parties involved in the construction process.	57%	43%	0%	0%	0%
There should be a generic and adaptable set of principles that allow for a consistent application of principles’ in a repeatable form.	23%	77%	0%	0%	0%
A need for a coherent and explicit set of process related principles, the new process should be able to be managed and reviewed by the whole industry with the intention of changing and systematising the strategic management of the common management process.	14%	43%	29%	0%	14%
The need for construction operations that form part of a common process controlled by an integrated system.	7%	50%	22%	14%	7%
A need for a process protocol that can be interchangeable allowing interfaces between existing practices and practice support tools to be operated.	57%	36%	7%	0%	0%
Standardised deliverables and roles associated with achieving, managing and reviewing the process during construction.	14%	79%	7%	0%	0%
Key emphasises on designing and planning to minimise error and networking during construction.	7%	57%	29%	7%	0%
Construction industry involvement to be extended beyond completion - a post completion phase.	50%	21%	22%	7%	0%

4.2 Cloud Computing Capabilities

4.2.1 The Top 10 Obstacles to and Opportunities for Growth of Cloud Computing

The option of using FedExing Disks (international mail service) to solve the issue of data transfer bottlenecks for large data transfers received an insufficient agreeing response of 43% and a disagreeing response of 28%. The no opinion mark of 29% indicated that this should not be the main deterrent and alternative options should be identified. The highest agreeing responses by the expert group were allocated towards standardizing API’s meaning a Software as a Service (SaaS) developer could deploy services and data across multiple cloud computing providers so that failure of a single

company would not take all copies of customer data with it, and scalable storage. This option of scaling presented an environmental solution by carefully utilizing resources which could reduce the impact of the data centre on the environment through short-term usage. Scalable storage and data lock-in received a total agreeing result of 86% and 85% respectively with no disagreeing responses. Another high level of agreement response was the data confidentiality and auditability with its suggested solution of deploying encryption, virtual LAN and networks middle boxes; for example firewalls and packet fillers.

Table 2. Top 10 Obstacles to and Opportunities for Growth of Cloud Computing, in response to the question: The following statements relate to the top 10 obstacles to and opportunities for growth of cloud computing; please indicate your opinion on these statements and if other please specify.’ The solutions are highlighted in red. (Sourced from Armbrust et al. 2009)

Obstacles and growth of cloud computing	Strongly agree	Agree	No Opinion	Disagree	Strongly disagree
Availability of service - Use multiple cloud providers	29%	35%	29%	7%	0%
Data lock-in - Standardise API's	14%	71%	15%	0%	0%
Data confidentially and audit ability - Deploy encryption	46%	39%	15%	0%	0%
Data transfer bottlenecks - FedExing Disks	21%	22%	29%	21%	7%
Performance unpredictability - Improve Virtual Machine support	14%	43%	29%	14%	0%
Scalable storage - Create a storage system	21%	57%	22%	0%	0%
Bugs in large distributed systems - Invent debugger	21%	43%	36%	0%	0%
Scaling quickly - Careful use of resources	29%	57%	14%	0%	0%
Reputation fate sharing (blacklisting) - Services similar to trusted emails	7%	50%	36%	7%	0%
Software licensing - Pay for use licenses	21%	57%	22%	0%	0%

The solution for data confidentially also suggested having geographical storage such as, services located in both the U.S. and Europe to deal with concerns about international law enforcements having the power to search email communications and various records, received no negative responses. As Table 2 illustrates the majority of the obstacles and their solutions received a high level of agreeing responses with such obstacles and solutions as; creating reputation guarding services similar to trusted emails services and inventing a debugger that relies on distributed Virtual Machines (VM); resulting in a high undecided response. Other ideas, such as improving VM support to combat performance and unpredictability, and using multiple cloud providers to prevent Distributed Denial of Service (DDOS); resulted in an above average agreeing response of 57%. The expert group also concluded that the option of pay-for-use licenses did seem attractive. In summary the solutions to the obstacles were broadly favourable to the group; however the solution for bottlenecks (Fedexing) needs more consideration. This section effectively highlights the benefits of cloud computing and demonstrations how the obstacles can be reduced.

4.2.2 Major Challenge for moving back-up to the Cloud

The issue of additional costs increasing because of the lack of knowledge on how backup patterns and needs meet one’s requirements in comparison with one’s selected vendor’s pricing projected a disagreeing response of 36% and an undecided response of

14%. This response was the highest disagreement result out of all the challenges indicating that it is not a major challenge. In a similar reaction the challenge of backup services outsourced to the cloud with the upstream speeds often capped at very low rates in contrast to the downstream side of a pipe, meaning a cloud-based backup would saturate an upstream connection received only a 57% high agreeing mark and low disagreeing mark of 29%. A considerable challenge noted by the expert group was security; which is a repeat of 4.2.1 ‘*The top 10 obstacles to and opportunities for growth of cloud computing,*’ where deployment of encryption was one preferred solution. However, this statement relates to compliance issues, such as special attention on contractual language, geographical diversity (if your provider offers geographical redundancy in their service) and termination agreements.

Table 3. The 5 major challenges for moving backup to the cloud, in response to the question: ‘Please rank in order 1 – 5 (1 being the highest) which of the following considerations do you think is a major challenge for moving backup to the cloud and if other please specify.’ (Sourced from Lowe’s 2010)

Challenge for moving backup to cloud	1 (High)	2	3	4	5 (Low)
Cost - not understanding backup needs	7%	43%	14%	22%	14%
Bandwidth - cloud saturate connection	14%	43%	14%	22%	7%
Security - encryption data	50%	29%	14%	7%	0%
Recovery - assess providers ability	22%	64%	0%	14%	0%
Vendor reliability - what happens to your data	43%	57%	0%	0%	0%

In review of this challenge; the expert group identified a high level agreeing rank of 79%, but this rank was eclipsed by the main concern (that of vendor reliability) which received 100% agreement rank. This statement presented the issue of negotiating up front about what happens to one’s data if a company goes out of business or is acquired. In continuation to the previous challenge; the statement citing the possible solution of working with one’s provider to assess their ability and willingness to help one quickly recover from disaster scored an agreement of 86% and a low rank of 14%. All of the noted challenges are recognized as a potentially serious issues for customers moving backup to the cloud; however, none more so than vendor reliability and recovery.

4.2.3 *Clouds Advancements on the Mistakes made by the Dot.com Bubble*

In this question the expert group were requested to rank their opinions on statements relating to the problems of the Dot.com market crash and why cloud computing will not become a similar bubble. The two most significant corrections were market requirements and a better educated market both receiving just over 90% agreement mark. The market requirements referred to new cloud applications that attempt to match what the best application in their category offers and then proceed to provide a better interface, better integration with other applications, and more web features. A better educated market meant cloud computing would offer access to applications more quickly than traditional decision and implementation processes. This statement also referred to the fact that cloud computing customers do not own the physical infrastructure, instead avoiding capital expenditure by renting usage from a third-party provider.

Figure 2. The cloud advancements on the mistakes made by the Dot.com bubble, in response to the question:

‘Please indicate your opinion on the following statements relating to the cloud advancements on the mistakes made by the Dot.com bubble and if other please specify.’ (Sourced from Wohl 2008)

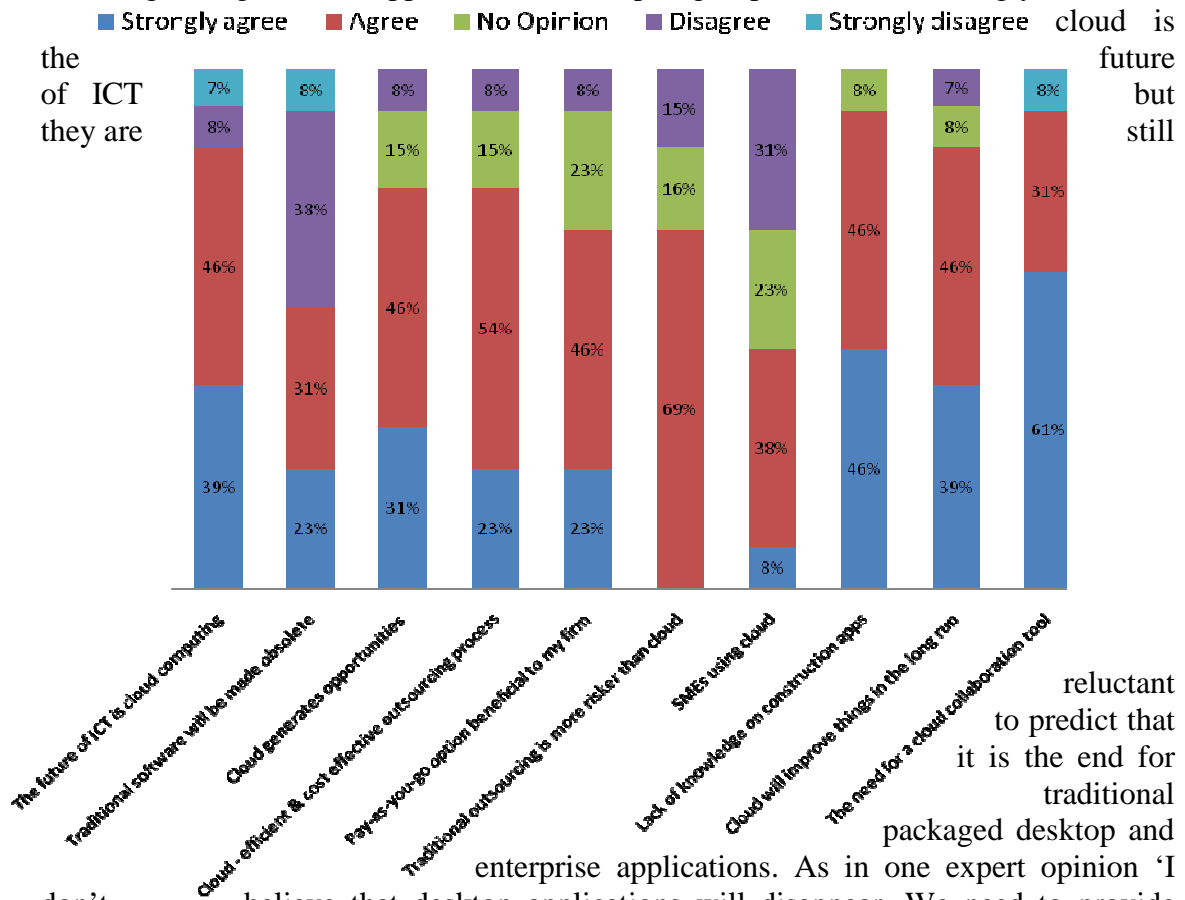

The market strategy of vendors focusing only on a particular part of a marketplace meant that vendors are not actively focusing on multiple demographics unless they have multiple product and market strategies; this resulted in an agreeing response of 84% (Market focus). The issue surrounding stronger business models identifying that cloud vendors plan to monetize their software by either making a charge for each user or each transaction received a modest agreeing response of 67%. This was probably in recognition that different size enterprises will require different models. The most undecided response of 46% was in relation to better financing taking into context that venture capitalists have swarmed into the market and provided additional development and more sustainable marketing investments. The reason for the expert group’s lack of enthusiasm associated with this correction is possibly related to the fact that the western world has not yet recovered from the global recession. The least positive response was outsourcing for outsourcers referring to the idea that vendors now believe it is better to partner for infrastructure than to invest in and run it oneself. The caution shown here was a repeat of the bandwidth issue (if backup services are to be outsourced to the cloud) in the previous question; it was identified as a challenge. The expert group has clearly indicated that the advancements of cloud computing are significant enough to warrant that there will not be a repeat of the Dot.com bubble, however there is still a considerable amount of caution in relation to the techniques involved.

4.3 Cloud Based Business Opportunities

4.3.1 Summary of cloud computing

In the expert groups opinion there is a lack of knowledge in the construction industry on the various types of construction cloud applications and due to the fragmented nature of the industry; a collaboration tool that provides interoperable software is a necessity.

This claim was further enhanced by the groups agreement of 85% (39% + 46%) indicating that the future of ICT is a service deployed from a centralized data centre across a network providing access to applications from a central provider and that cloud computing can act as a major agitator for improving ICT within the industry in the long run. The highest disagreement rank of 38% (15% + 16%) was related to the notion that the traditional packaged desktop and enterprise applications will soon be made obsolete by web-based, outsourced products and services which is slightly in contrast to the agreeing 77% response that suggests that cloud computing is an efficient and cost effective outsourcing process that gives company management the time to focus on their business. A similar result was also recorded for the statement that cloud solutions generate better opportunities by enabling enterprises to select more ICT priorities from an ever-growing menu of applications. The expert group has overwhelmingly stated that

reluctant to predict that it is the end for traditional packaged desktop and enterprise applications. As in one expert opinion 'I don't believe that desktop applications will disappear. We need to provide strong information assurance for the cloud to progress. We should provide several options for payment, from per-use to annual licenses'. The pay-as-you-go payment option did only receive a modest 69% approval however this question was also subject to asking the respondent would they themselves implement it. In contrast to previous questions relating to the risk of security, the view that cloud computing presents information risk, but probably not significantly more than in a traditional outsourced environment, indicates that the group does acknowledge cloud's creditability. Redmond *et al.* (2010) identified through a study of the barriers for adoption of cloud computing that vendors do not necessarily believe that construction SMEs have the capability of using cloud computing. The expert group's opinion resulted in a mixed outcome of 46% in favour, 23% undecided, and 31% disagreeing. In summarising the industry and its productivity one expert stated 'Web-based solutions are critically important to increasing efficiency and productivity throughout the construction industry'.

Figure 3. Summary of cloud computing, in response to the question:
'Please indicate your opinion relating to the following statements' (as indicated above).

4.3.2 *Perceived benefits of cloud computing*

The eight proposed perceived benefits of cloud computing were originally reported in Hore *et al.* (2010). These questions were sourced from Ramanujam's (2007) key points as to why Cloud/On-Demand would be a smart choice for companies. Hore *et al.* identified through a mixed vendor and consumer survey sample of 90 enterprises that only 10% of enterprises disagreed with certain attributes of the benefits, such as, reducing capital cost of purchasing software and not having to worry about disaster recovery. In analysing the expert group's responses again disaster recovery was evidently a concern, with the experts indicating a disagreeing response of 23%. The highest disagreeing response of 25% was directed towards having the ability to manage a premise-based facility so attention can be redirected towards the customer. The highest agreeing response of 92% highlighted the benefit of allowing one to pay-as-you-go, pay for usage rather than for software licenses and hardware infrastructure. This was in contrast to the previous question (summary of cloud computing) where the respondents only delivered a 69% confidence grade. Both managing a premise facility and frequent updates had the highest undecided percentage rank of 25%. The notion of having access to the best of breed technology did; however; result in a positive 75% whereas managing a premise facility represented the most negative responses of all the benefits. Easy role out and maintenance, spread out costs (avoiding capital expenses and installation), and passing the onus of supporting growth onto the Software as a Service vendor all received above average agreeing responses relating to their benefits. In assessing the problems associated with premise-based facilities one expert carefully summarized this issue 'Premise-based facilities must serve the mission of the company that builds such facilities. A cloud-based as-built-BIM should be utilized intelligently and effectively by the owner to make better business decisions more quickly. Not all premise-based management decisions need to be outsourced. That said, increased access to higher quality information is critically important and hosting that information on the web makes sense'.

Table 4. Perceived benefits of cloud computing, in response to the question: 'Please rank in order 1 – 5 (1 being the highest) which of the following perceived benefits do you think is a major attribute to the construction industry and if other please specify.' (Sourced from Ramanujam's 2007)

5 Conclusions and Further Research

The objective of this questionnaire was to analyze selected expert opinions on the future

Perceived benefits	1 (High)	2	3	4	5 (Low)
Allows one to get out of the business of managing a premise facility	25%	25%	25%	8%	17%
Allows one to pay as you go	33%	59%	8%	0%	0%
Easy role out maintenance	25%	50%	9%	8%	8%
Spread out cost	23%	54%	23%	0%	0%
Frequent updates	42%	33%	25%	0%	0%
Focus on growth	23%	38%	23%	8%	8%
No day to day maintenance	31%	46%	0%	23%	0%

of ICT in construction based on implementing a cloud service hosting three interoperable applications. The results indicated that there are several positive reasons as to why cloud computing should be considered, such as its ability to increase efficiency and productivity throughout the construction industry. In relation to BIM the experts acknowledged that the key to an integrated BIM is a common database (cloud) where component parts of the building are modeled in disparate software programs. The experts identified through the business process that construction development should be treated like manufactured products delivered by a team of professionals with a common purpose. The expert's reference to the Dot.com era emphasized that cloud was not a buzz word and that it has real substance. Including security; the main barriers to cloud computing are vendor reliability and recovering data. The main benefit of a cloud-based as-built-BIM is its ability to increase access to higher quality information resulting in faster business decisions. In conclusion; the results have demonstrated that the concept of developing a collaboration tool based on a common database is credible and that a cloud platform would be a key provider for an integrated BIM system. However, whether accountancy and project management applications are the most suited combination still needs to be determined and the process involved with developing such a service needs further investigating. The experts have evidently shown support for the concept but more data must be obtained and analyzed on how this service can be developed to meet the individual needs of professional practices at the design stage of a project.

6 Acknowledgement

This authors would like to thank; Mr. Deke Smith - Executive Director, buildingSMART Alliance at National Institute of Building Sciences, Dr. Marek Rebow – Dublin Institute of Technology, and Mr. Ry Bruscoe – Rev Up Render, Inc. Intractability of data on complex construction projects caused by the reliance on Construction Project Extranets: a case study

Barbara Chomicka

School of the Built and Natural Environment,
Glasgow Caledonian University, Glasgow, G4 0BA,
United Kingdom

Email: bchomicka@gmail.com

Abstract:

It is widely acknowledged that effective communication among team members on a construction project contributes to the success of that project. Efficiency gains in current information management and sharing practices, arising from a combination of database and internet-based systems, are also well recognised. Various studies support the range and scale of cost-saving potential on construction projects associated with the deployment of such systems. However, the experience on a recently completed large-scale development in the UK - MediaCityUK - raises concerns about the translation of this potential into actual use and benefit to construction processes and outcomes. Several factors common to many large construction projects: the huge amount and wide dissimilarity of information that is involved in the construction process, and project participants' widely varying specialties, expertise, education, professional skills, computer proficiency, and working environment, can impede the information management and communication on extranets, leading to very expensive and difficult-to-rectify mistakes. Finally, there are often material discrepancies between how architects of construction information management systems assume those systems will be used, and how they are actually used. These discrepancies can not only limit these systems' potential benefits, but also contribute to a range of defects associated with the intractability of user-submitted data.

Keywords:

data management, extranets, MediaCityUK

1 Introduction

In the UK, the majority of complex construction projects are delivered through Virtual Corporations (VCs) – project-based temporary organisations of clients, consultants and construction firms. Each partner in such organisations mixes and matches its 'core competency' with those of the other companies. The main objective of VCs is to assemble a 'best of everything' corporation that can take advantage of economies of both scale and scope. This evolution toward VCs is driven by the increasing complexity of construction projects and an increasing need for specialisation (Vrijhoef, 2004).

Current efforts to improve organisation and procurement methods increasingly focus on more effective management of VCs, e.g., through horizontal integration of firms involved in the construction effort through formation of strategic partnerships, team

selection strategies based on the appointment of one-stop, multi-disciplinary design firms, and various forms and degrees of design-and-build procurement strategies.¹

Two significant problems many VCs face are how best to co-ordinate all the activities carried out by the independent parties and exchange the large amount of complex data among those parties (Grabowski, 1998). The amount of information to be exchanged increases with the number of organisations involved in the project. Nowadays there can be more than 100 companies involved in the delivery of a large-scale scheme². The number of design documents (such as drawings, schedules and programmes) in such a scheme may exceed 60,000, and the combined number of all documents and processes associated with the project delivery may exceed 165,000³. Given the sheer magnitude of all this documentation, it is apparent that effective inter-organisational co-ordination – especially accuracy, effectiveness and timing of communication and exchange of information among project team members, i.e. having everyone working to the same up-to-date information – will be critical to the success of complex projects.

To facilitate effective collaboration, every VC uses some form of business integration tool that includes all functions of project management for the enterprise and its partners – a Construction Project Extranet (CPE).

It would be unusual nowadays to find a large construction project that does not use a CPE, which typically provides a web-based access and user interface, document storage, configurable process workflow (to manage flow of documentation), and audit trail reporting (to track status and progress across activities and the entire workspace).

Extranets are a powerful medium through which vast volumes of information can be manipulated in a sophisticated manner. There are many Application Service Providers (ASPs) who provide extranets, e.g.: BuildOnline, Causeway, Cadweb, Sarcophagus, BIW, 4Projects, Business Collaborator and Bidcom, which are combining to form an industry group (Suchocki, 2006).

Extranet utilisation has become a common pre-condition for participation in the tendering process and potential appointment as a project team member. For example, all members of the Design Team on the (currently) largest residential development in London (£4bn) are requested to make an allowance for the use of a ‘preferred Management Information System (i.e. BIW/Microsoft Share Point) to be specified/designated by the Client for storage, reconciliation and onward communication of design documentation’⁴ at the Request for Proposal stage (RFP).

However, despite long co-operation in networks among construction team members and many years of utilising extranets, the construction industry still frequently suffers from delays, budget overruns, quality issues and defects. The causes of such issues are the subject of wide-ranging research, and there is also extensive literature on drivers of and costs of rectification of defects in construction. Yet, no investigations into CPEs themselves as a potential driver of defects have been discovered.

¹ Conclusion from the initial review of tender submissions (May 2011) for the design and construction of the new £225m landmark tower.

² Observed on MediaCityUK

³ On MediaCityUK’ project extranet (BIW) on 2 June 2011 there were 165,876 documents and processes (60691 Documents, 5112 Forms and Processes, 86855 Comments, 13218 Instructions and Instructions Responses) and 39080 Defects.

⁴ EC Harris Request For Proposal (RFP) Form

Experience on a recently (December 2010) completed large-scale, complex development – MediaCityUK in Salford – suggests that certain problems associated with reliance on extranets, such as intractability and reduced interoperability of data, can contribute to a range of defects, and lead to very expensive and difficult-to-rectify mistakes. The initial feedback from the team involved in the delivery of another complex project (high-end residential scheme in London, project value: £50m, to be completed in June 2011) verified this problem, raising concerns about the translation of extranets’ potential into actual use and benefit to construction processes and outcomes.

The construction industry’s typically thin project margins (1% to 2%) only underscore the importance of the effective use of extranets (Chien *et al.*, 2010). With many ASPs claiming savings of 1.3-5% of construction costs through the use of extranets (Chien *et al.*, 2010), it is important therefore to identify any barriers to the realisation of those savings.

The paper consists of five parts:

1. Introduction: a theoretical analysis of current understanding of circumstances in which complex construction projects are delivered and tools utilised to facilitate collaborative working.
2. Literature Review: insight into the current research concerned with recognised problems linked to extranets’ deployment.
3. Case Study: project-specific challenges to the successful operation of extranet system on MediaCityUK project in Salford.
4. Findings: results and interpretation of case study’s findings.
5. Conclusion: insight into the implications of currently utilised extranets on the occurrence of defects on complex construction projects, and possible ways of mitigating such defects.

2 Literature Review

Four distinct sources of information and insights into the performance of construction collaboration technologies and their impact on project teams are considered in this review: 1) independent research by individual researchers and research groups, 2) research by project extranets providers, 3) research by the end users of these systems, and 4) direct practitioner input.

2.1 Independent research

The main focus of independent research into the performance of construction collaboration technologies appears to be on their collaborative working potential for project teams and end-user enthusiasm (El-Saboni *et al.*, 2009, Diez *et al.*, 2009), and potential and realised cost savings linked to extranets’ deployment (Sommerville *et al.*, 2004). The majority of published research focuses on the benefits associated with deployment of extranets, which might be grouped into four categories: 1) improvement in project team communication, 2) improvement in the distribution of information, 3) increased productivity and 4) provision of a collaborative environment (Chien *et al.*, 2010).

Some research has focused on barriers to the effective use of extranets in the construction industry, for example a study by Mitchell and Demian (2008), who

identified three groups of barriers to effective use of project collaboration tools: technical, people-related and managerial.

Regarding technical barriers, Mitchell and Demian survey results have highlighted that extranets are not delivering the speed of service required (32% of respondents finding extranets to be 'very slow' and 36% finding them 'slow'), and user feedback recorded by Wilkinson (2011) questioned the reasonableness of certain processes: 'I am sure I'm not the only document controller who has to sit twiddling my thumbs while I wait for the 500th commented document to print/download/save. It's boring but necessary work that some people think can be avoided by purchasing an archive at the end of the project'.

The second identified group of barriers – people – was the subject of a study conducted by Daniel and Elling (2004), who concluded that extranets, like many tools, are useless without the right people. In the Mitchell and Demian survey, 71% of users received two or fewer hours of training, and 66% of respondents identified that the training received was insufficient to enable successful operation of the extranet. A good insight was provided by an experienced document controller: 'We all know how it goes. Peter reluctantly goes off to a training session and comes back all enthused. He has a quick one-to-one with Paul who then teaches Sarah who passes her knowledge onto Mark. Meanwhile, Peter has been offered a shiny new job with the Dark Side and suddenly no one in the office has actually had any formal training. Nobody wants to suggest they should go because, after all, they're really busy, they have enough knowledge for what they need to do and, in any event, someone would have to pay. The software vendor offers but nobody wants to pay their rates' (Wilkinson, 2011).

Regarding the third identified barrier – managerial – Chien (2010) survey results revealed that client support for extranet usage is low. However, it has to be noted that this situation may be understandable on small- to medium-sized schemes due to significant set-up costs of extranets. On large complex projects clients are on the forefront of extranet implementation as their deployment moves away many risks from the client to the project team.

2.2 Research by the extranet providers

All project extranet providers use statistics to support the proposition that their applications are useful and beneficial to a project and its client, and generally to validate product performance.

2.3 Research by the end users

In line with the end user account set out, for example, by Atkins' Research and Innovation Manager Marek Suchocki (2008), despite widespread adoption of extranets, their impact has been largely restricted to controlled file sharing with little improvement in information-sharing procedures or practice.

2.4 Direct practitioner's input

The direct professional input presented in the Case Study highlights some disadvantages that should be recognised. The main recorded problems are linked to users' capability of managing a huge amount of data, spamming, spelling problems, frequent changes in project team membership and the nature of learning in construction.

3 Case study: MediaCityUK

Since May 2011 British Broadcasting Corporation's (BBC) programme-making departments are up and running from Europe's first purpose-built creative and media development in Salford. This metropolitan borough of Greater Manchester joined Singapore, Seoul and Abu Dhabi on the world's media map with its £650m first phase of MediaCityUK, consisting of 700,000 sq ft offices including the BBC and University of Salford, 250,000 sq ft high definition (HD) studios including the largest HD studio in Europe and one dedicated to the BBC Philharmonic, 60,000 sq ft of shops and leisure facilities including bars, restaurants and healthcare services, a public park, an events space twice the size of Trafalgar Square, 378 new apartments, a 218-bed Holiday Inn, retail units, a supermarket, a 2200-space car park, a new bridge, a new tram link to Manchester's city centre and a highway junction. Each of the three BBC buildings was completed ahead of the agreed delivery date and under the planned cost (Plunkett, 2010), and the whole of Phase 1 achieved standards that did not even exist when the construction commenced¹.

MediaCity's VC operated like a social unit, responding to perpetually changing needs, scope, programme, budget and strategy. Driven by the client (Peel Group) and contractor (Lend Lease), it utilised BIW's extranet solution to co-ordinate all activities and exchange the huge amount of complex data and information. However, unlike many other large, complex projects, MediaCity featured no remote co-ordination of the shared platform.

On large and complex projects the co-ordinator is usually not involved in design nor works. Most of his activities are aimed at facilitating deliberation among the VC's parties on the progress of the project and measures to be taken. The co-ordinator is usually controlling the flow of materials and the use of capacity, eliminating political factors, overcoming conflicts of interest and aligning priorities. Due to the remote nature of his role, a distant co-ordinator is often assumed by the project team members to have only superficial knowledge of their processes (Kornelius *et al.*, 1998).

The co-ordinator role, usually fulfilled by a consultant project manager, was initially considered for MediaCity, and there was an attempt to introduce and establish this function on the project. However, due to the timing of the introduction, with procurement processes and site operations already underway, it became apparent that the size of the project, amount of data and complexity of its processes would exceed any one individual's management capacity. In response to this challenge, MediaCity's extranet was converted to a bottom-up (instead of the typical top-down) system. Following simple rules set out in the protocol, participants populated and interacted directly with the database. Effectively MediaCityUK's extranet thus became a self-organising system that functioned as an environment, creating an interaction space for its participants.

Experience from another project, a still-under-construction mixed-use 36-storey tower in London (value: £136m), in which a contract administrator has taken on the co-ordinator role, demonstrates that problems associated with controlling the data flow on large complex schemes can occur irrespective of the adoption of a self-organising system.

¹ BREEAM Communities Excellent Award

The unusual extranet structure used on the MediaCityUK project followed Peel Group's general project organisation strategy, which relies on a large number of local, highly specialised firms providing customer service within their (often very narrow) expertise, instead of the appointment of one or two one-stop multi-disciplinary design firms, design team joint ventures or complex sub-consultancy arrangements.

In addition, the design-and-build procurement strategy, which is commonplace on large complex projects, was abandoned in favour of one of the most challenging procurement methods in construction: management contracting (MC).

These three strategic decisions – 1) lack of top-down administration of the shared platform, 2) very large number of collaborating partners, and 3) a very rarely (nowadays) adopted procurement strategy – along with the huge amount of data produced by a project of this scale, created an unprecedented amount of information that needed to be exchanged.

During the project lifecycle, numerous post-contract changes to the scope, programme and location and shape of the buildings further multiplied the amount of documentation. As a result, sufficient specific knowledge about management issues could not be brought in by any one project team member. To resolve the strategic problems arising from these unique circumstances, an extensive amount of inter-organisational learning took place.

The necessary inter-organisational learning followed the main characteristics of learning on construction projects. In the construction industry learning is based on a movement away from known problems rather than towards imagined goals – i.e., based on correcting experienced unfitness (defects) rather than striving for planned fitness-for-purpose (Brand, 1995). Actual defects and problems encountered on-site were the main prompts for (corrective) action.

4 Findings

The experience on MediaCityUK raised concerns about the translation of extranets' potential into actual use and benefit to the construction processes and outcomes on large, complex projects. With the increased complexity of projects come diseconomies of scale - intractability and reduced interoperability of data. The discussion of findings will focus on intractability of data linked to reliance on extranets as platforms for co-operation and information exchange.

Two main aspects contributed to the intractability of data: 1) the unprecedented amount of data to be managed and 2) human error.

4.1 The unprecedented amount of data

The amount of data uploaded on the extranet that had to be managed, referenced and reviewed grew from 4,277 documents (drawings, schedules, programmes, scopes of works, registers and so forth) uploaded in the first year (2007), to 19,459 documents in the second year (2008), reaching 25,884 in the third year (2009) and then declining

(following several sectional completions¹) to 10,833 documents in the fourth year (2010), giving a total of over 60,000 documents uploaded over a four-year period.

In addition to documents, there were also many (105,000) forms and processes that had to be reviewed, controlled and monitored – 3,106 in the first year and 29,353 in the second year. It was not possible to establish the statistics for the third and fourth year as every attempt to generate a list actually caused a fault in the extranet system preventing the request being completed – probably due to data overload.

The majority of case study literature concerned with extranets considers database sizes only up to 15,000 documents, and the teams involved in their delivery provided positive feedback on performance, save for occasional issues with internet speed and the need to download a great amount of data at the end of a project. Considering the difference in quantity of documents and processes (15,000 versus 165,000), it is possible that the problem of intractability of data simply didn't occur on case studies reviewed so far.

At the end of a second year of the MediaCity project, the cumulative sum of all documents and processes exceeded 56,000, prompting an ineffective and subsequently abandoned attempt to re-structure the data management strategy. This further raised a concern over how the optimum or equilibrium data cluster size could be determined within the project – and whether an algorithm governing this interaction could be found. Of course, some of the drawings had been superseded and some processes had been deactivated; nevertheless, the sheer amount of information to be processed at any one time posed a management problem and required a significant amount of on-site re-work.

In addition, as observed on smaller projects reviewed by extranet provider Cadweb (2010) during a performance evaluation of their product, extranet users created a significant amount of “spamming”. Cadweb reported that on projects using their product, every file uploaded was distributed to an average of 11 people rather than five. The amount of spamming on MediaCityUK is consistent with this observation.

The significant amount of data – 100 documents on average being issued on each working day in the third year of site operations – resulted in a problem faced by many environments, both real and virtual: the system reached a scale where the growth turned cancerous, i.e., beyond which growth without damage is not possible.

It is generally recognised that co-ordination becomes impossible when there are too many participants. Oversized populations require additional mechanisms to cope, such as pattern-matching tools and feedback (Johnson, 2002) – both instruments yet to be contemplated by extranet providers. An illustration of the undeniable benefits from implementing such tools is provided by one end user: ‘How about a nice button that downloads drawings with redlining and – this really is dreamland – a sheet that has all the written comments on it? These could be named something like this: (68)001_cmts.pdf, (68)001_red.pdf, etc’ (Wilkinson, 2011).

4.2 Human error

The wide variation among the project participants of specialities, expertise, educational background, professional skills and computer proficiency impedes the information management and communication of the project team, leading to very expensive and difficult-to-rectify mistakes. Examples of such mistakes are: construction of high-

¹ MediaCityUK Phase 1 consisted of 20 Sections

performance partition walls in line with a long-revised specification, in the wrong location (to superseded general arrangement drawings), and accidental omission of drainage outlets in post-tensioned slabs due to setting out of services being undertaken on the basis of architect drawings that are not cross-referenced to structural engineer layouts.

Human error affects the following aspects of data: versioning, searchability and publishing.

4.2.1 Versioning

Versioning is a process by which documents are uploaded, or ‘checked-in’ (in extranet vocabulary) to the document management system. This allows users to easily access the most-up-to-date version as well as retrieve previous versions.

Many problems arise from spelling mistakes and improper use of spacing and sequences of words and numbers. For example, if a user erroneously uploads a schematic document as file type “SCHE” (schedule) instead of the correct “SCH” (schematics) – an easy mistake to make – a schematic will be filed as schedule, and the association of that file with its previous versions will be lost. This could easily result in some team members working to a version that has been superseded.

Inconsistency in file naming is also common when drawings are reviewed, amended and re-saved by users. The mistake is not necessarily the result of user error. E.g., if there is more than one user accessing a file simultaneously, one user’s computer operating system may automatically re-save a file with a changed file name (e.g., as “0001(2).pdf” instead of “0001.pdf”).

Finally, due to the often small difference between different categories of documents, for example schematics (SCH) and sketches (SK), many files are classified in practise by their authors as other (OTH), simply to avoid incorrect filing.

4.2.2 Searchability

Searchability is the ability to find documents and folders using metadata. Documents can be searched using various attributes and document content. Metadata may, for example, include a revision identifier, the date the document was uploaded, issuing company, the identity of the user uploading it, recipients to whom it was issued, whether and when they have accessed it, or keywords.

Changes to the scope of the project or to protocols following extranet software upgrades (which can reasonably be expected on projects spanning more than one calendar year), user modifications to the filing system, and company mergers have created variations to established protocols and processes and contributed to data ‘loss’ – end users’ inability to find and retrieve information.

4.2.3 Publishing

Publishing a document on an extranet involves reviewing, authorising, printing and approving procedures. Despite the existence of protocols and company quality assurance processes, it is not unusual to find an odd page – among contractual documents or incorporated into a specification – contain personal user information, such as car leasing details or a credit card statement.

5 Conclusion

The delivery of large, complex projects by temporary organisations – Virtual Corporations – is characterised by a heavy dependence on the exchange of large and complex data and information. Various web-based project collaboration tools are available to facilitate co-ordination, accuracy, effectiveness and timing of communication and the exchange of information and data among project team members.

Most studies of such web-based project collaboration tools conclude that one of the main advantages of using extranets is that it ensures that all members of the project team have access to the most up-to-date versions of the various project documents, so that traditional mistakes generated from someone working from an old document or drawing are in theory removed (or at the very least reduced). However, the experience observed in the presented case study raises concerns about the translation of this potential into actual use.

The combination of extended fragmentation of the construction industry, the huge amount and wide dissimilarity of the information that is involved in the construction process, as well as a wide variation of specialities, expertise, educational background, professional skills, computer proficiency, and working environment among the project participants impedes the information management and communication on extranets, leading to very expensive and difficult-to-rectify mistakes. Also, on large-scale projects, where extranets are extensively used, team selection and procurement strategies resulting in increase of the quantity of project data and users further contributes to the problem of data intractability.

This study focused on the main identified driver of defects associated with the reliance on extranets: intractability of data. It also outlined the gap between current working practices in construction and behaviours assumed by the architects of such systems and researchers. In line with the end user account, the most frequently mentioned feature of extranets in academic research – accessible real-time data across the globe – is secondary to extranets' main purpose – controlled file sharing. 'Sure it's nice to send documents halfway across the world in seconds, or to be actively commenting on a drawing through a super-trendy interactive whiteboard, but at the end of the day, all these systems exist to stop someone being sued' (Wilkinson, 2011).

It is possible that problems associated with controllability of data can be resolved with Building Information Modelling (BIM). Following the completion of MediaCityUK scheme, the lead designer (co-ordinating architect) team commenced work on a £450m redevelopment of Leeds' city centre (Leeds Trinity) using BIM for communication and the development of information and data. BIM uses proprietary or open standard digital technology to provide a representation of all the physical and functional characteristics of a facility and its related project and lifecycle information (AIA, 2011). BIM allows each project team member not only to add to and reference back to all information they acquire during their period of contribution to the BIM model, but also to test proposed design solutions and assess buildability. Although the project is still in the early stage on-site, the feedback so far suggests that certain data intractability and reduced data interoperability issues¹ encountered on MediacityUK might have been avoided by deploying BIM.

¹ BIMs have their own known interoperability problems.

The MediaCityUK case study contributes to existing theory by showing that projects of that scale require a solution that goes beyond the vector-based CAD software and sharing of secure files. An important area for future research, therefore, is to gain a better understanding of the considerable risks associated with intractability of data on large, complex projects and whether this can be resolved by the combination of 3-dimensional shared models, pattern-matching tools and feedback.

6 Acknowledgement

The presented preliminary findings form part of the analysis of drivers and cost implications of defects' rectification on complex projects undertaken by the author as part of the PhD studies under the supervision of Professor J. Sommerville and Dr. Nigel Craig at the Glasgow Caledonian University.

Innovative research methodologies

Collaborative Efforts by a U.S. University to Produce Practical and Relevant Construction Research through Product Development and Intellectual Property

C. Ben Farrow¹, Paul W. Holley¹, and Richard Burt¹

Abstract:

Scholarly efforts among construction management (CM) programs in the U.S. have historically produced research results largely related to management practice theory, pedagogy, and select technical performance. While beneficial, this type of research frequently does not capture the attention of professional construction practice, due to its often being perceived as practically 'removed' from industry. As such, relatively little research within construction management programs is externally funded, as compared to counterparts in engineering and related disciplines. This disconnect represents an opportunity for CM programs to find ways to increase practical research in an effort to better engage practitioners. This case study explores collaborative efforts focused on new construction products, tools, and materials developed between students and faculty from both construction management and industrial design programs at a major U.S. university, joined by practitioners from both disciplines. This paper details the latest iteration of the program, now in its fifth year, with respect to academic/industry development and research, and illustrates how the program has yielded opportunities for faculty and graduate students to produce research, patented products and intellectual property for the university.

Keywords:

collaboration, interdisciplinary studies, product development, innovation, industrial design

1 Introduction

In the U.S., research by university faculty in construction management programs has typically focused on three areas:

Management techniques

Teaching and pedagogy

General parameters related to a materials or methods of construction

Of the ten most downloaded journal articles from the International Journal of Construction Education and Research during 2010, approximately one-third focused on methods of design and construction such as LEED or BIM. Another one-third of the articles focused on teaching in construction management programs. The remaining

articles focused mainly on management practice or theory (Gunderson, 2011). While not quantitatively significant, these articles represent a broad spectrum of construction research at U.S. universities housing construction management programs.

At the same time, productivity in the construction industry has been on a relatively consistent decline since 1960 (Melnick, 2007). Exact definitions of productivity vary, but the clear trend is a construction productivity index far from desirable. Such a trend appears alarming considering the productivity gains in such industries as automobile and electronics manufacturing. Specific reasons for this decline have not been fully detailed. Few, if any, argue that academic research related to construction at U.S. universities has made any major shift in construction productivity.

Safety may also be a tangible area where construction research has the potential to make a direct impact. Almost 6.5 million people work at approximately 252,000 construction sites across the U.S. on any given day (OSHA, 2011). OSHA further indicates that the rate at which fatal injuries occur in construction is higher than the national average in its category for all industries.

Many in professional practice might argue that academic research in the U.S. is distant and disconnected from what occurs on the construction jobsite. They might also argue that academic research often does not address real life organizational problems, and that academic research within the U.S. has limited relevance with regard to the tactile needs of the industry. This perceived disconnect between professional practice and construction academics has negatively impacted the growth of meaningful construction research within U.S. construction management programs, begging the questions:

How could U.S. construction management programs introduce meaningful, practical research? Could such research better engage industry practitioners? What other disciplines could best collaborate with construction researchers to add practical value to the industry? How could such relationships be forged and organized?

This paper presents a case study that explores collaborative efforts to address practical productivity and safety issues by developing new construction products, tools, and materials. The research was conducted at a major U.S. university by students and faculty in both construction management and industrial design programs. These individuals were joined by professional practice partners from both disciplines to provide input and guidance on the research and development. Now in its fifth year, the effort has yielded numerous peer reviewed published papers, closer ties to industry, and patented products that represent intellectual property for the university. While the long-term goals are for the innovative culture produced through the program to ultimately impact the classroom in the construction curriculum, this paper focuses primarily on the program output and research, and its potential impact on industry.

2 Literature Review

2.1 Construction Research Defined

Almost four decades ago, Paulson noted four key areas of construction research (Paulson, 1975):

Manpower and Organizational Development (training as well as organizational structure)

Management Methodologies

Innovations in Construction Methods

Construction Industry Dynamics (interaction with economy, government, labor, public)

More recently, Kulatunga et al further defined “Construction Research and Development” as “the systematic investigation to establish new or improved products, processes, management methodologies” to address the following (Kulatunga et al., 2007):

Customer Needs

Resource, Environmental and Economic Constraints

Government Regulations and Public Policies

Competitive Edge of Construction Firms

While stated differently, the definition of ‘construction research’ appears to not have changed much, and is still general in nature. Information resulting from this type of research is often generic in nature or simplified to conditions not realistic on a job site. Thus, results are not easily “translated into commercial advantage for any individual firm” (Courtney, 1999). Barrett and Barrett indicate that industry is often “disappointed with the contribution of (construction) research, either because it is too theoretical or because the simple solutions suggested do not work” (2003).

Such general research creates little incentive for U.S. commercial contractors to fund academic research in construction. Construction practitioners see working with academia as beneficial only to the extent that it “advances the company toward its goals” (Pertuze et al., 2010).

2.2 Practical Construction Research is Vital

Recent graduates of U.S. construction management programs generally operate in the field, earning their living on construction sites or in offices that support construction sites. As such, meaningful research for this group of individuals will “be applied and be geared toward field operations” (Mayo, 2000). Research that produces ideas or concepts that could be used directly by industry has the potential to positively impact the construction process.

Throughout history, improved productivity has been a consistent driver for economic prosperity. Research and innovation in construction is vital to improve productivity and to increase competitiveness (Tatum, 1989). If a clear connection could be made between academic research and new products that increase productivity, tangible benefits to the construction industry would be realized.

Funding of construction research projects undertaken by U.S. construction management programs is challenging (Mayo, 2000). The private sector represents possible sources of funding for U.S. Construction Management programs; however, they will require a commercial return on their investment (Courtney, 1999).

2.3 Potential Drivers of Future Construction Research

Several market factors' influences on what and how research is conducted at U.S. Universities are evident. These market factors occur outside the traditional paradigm of U.S. construction research; however, they have the potential to significantly impact future research trends.

2.3.1 Collaboration in the Built Environment

Shifts in project delivery approaches during the past thirty years have redefined the practice of design and construction within the U.S., with integrated models of project delivery involving teams of owners, designers, and builders becoming the rule, not the exception. The growth of the design-build delivery system as well as newer models such as integrated project delivery (IPD) are shaping the future of the built environment within the U.S. Other industry trends such as prefabrication and building information modeling (BIM) are requiring completely new perspectives on collaboration in the industry.

2.3.2 Collaboration in Academia

Similar trends toward collaboration are occurring in academia (Holley and Dagg, 2006; Selva and Carulli, 2007; Doerfler et al., 2009; Holley and Emig, 2010). By combining students of multiple disciplines in learning environments, students have the opportunity to recognize the goals of other disciplines, understand the knowledge base of participating parties, and learn how to work within a team to produce a product or service. U.S. design and construction programs are attempting to extend this beyond the classroom. The Architecture + Construction Alliance (A+CA) is one such organization that seeks to foster interdisciplinary work between architecture and construction management programs. Composed of 14 institutions in the U.S. that include design and construction within the same academic unit, a clear path toward greater collaboration in learning environment has been paved (Architecture + Construction Alliance, 2011).

2.3.3 Tight Margins for Private Firms

Construction firms compete on small profit margins. Firms are intensely competitive with the vast majority being small enterprises of individuals. With smaller firms and fierce competition, investment in research and development by U.S. construction firms has generally been small. Advances in construction within the U.S. tend to be project oriented. Many of these advances cannot be protected by intellectual property rights, thus disseminating rapidly through the industry.

As Courtney indicates, the costs of research are certain while the benefits are uncertain. In an environment where profit margins are small and competition drives the market,

little emphasis can be placed on “uncertain benefits” (1999). Thus, construction firms tend to view research and development as an optional rather than a core focus of their business (Roberts, 2002). At the same time, firms do not have sufficient margin to internally fund research and development.

Despite this historical resistance to research and development, new industry trends in technology (BIM and associated applications), green construction, and lean construction have provided opportunities for universities to reconnect with industry partners. As firms continue to embrace these tools and techniques in finding their competition edge, an opportunity exists for firms to tap university resources for research and development (Geiger, 2008). Research partnerships are most effective “when companies seek university expertise to address a broad spectrum of topics spanning several fields and intended to lay the foundation for future product development.” (Geiger, 2008) Long-term relationships are becoming more common as industry seeks opportunities for competitive advantages.

2.3.4 Collaborative Work Outside the U.S.

Extensive efforts have resulted in increased collaboration and subsequent innovation in the construction industry. In Australia, the Building Research Innovation Technology and Environment Project has studied the “creation, adoption and diffusion of innovations” (Hardie et al., 2005). This project was initiated by the Cooperative Research Centre (CRC) which is a “national research, development and implementation center focused on the needs of the property, design, construction, and facility management sectors” (Cooperative Research Centre, 2009). The purpose of this collaborative centre is “developing key technologies, tools and management systems to improve the effectiveness of the construction industry”.

In Europe, similar work has been conducted. Salford University in the United Kingdom has formed the “Centre for Construction Innovation”. Its advertised purpose is to “further the growth of knowledge capital with the construction sector” (Centre for Construction Innovation, 2009). The centre attempts to promote interaction and collaboration between academia and industry on research and development issues. They indicate that the benefit to industry is the “advancement of research and development into new knowledge based markets, services and products” (Centre for Construction Innovation, 2009).

2.4 Opportunities for Collaboration beyond Design and Construction

Despite the need for construction research and development, the U.S. construction industry has a variety of challenges inhibiting effective research and development. One of these challenges centers on connecting the output of research with consumption in the industry (Kulatunga, 2007). Another challenge centers on effective communication with all relevant stakeholders in the research and development process.

If universities are to be an active part of this research and development, it is “essential to invent new ways to deliver the construction output in an economically, socially, and environmentally acceptable manner” (Kulatunga, 2007). Kulatunga further argues that effective and efficient research and development is vital in the construction industry to meet future requirements of all stakeholders (2007).

The following case study examines one approach by a major U.S. university to collaborate on construction research beyond the traditional bounds of design and

construction by partnering with industrial design. Very few collaborative efforts have been undertaken between industrial design education and construction education in the U.S. to improve construction productivity.

3 Research Methodology

This paper presents a study of a collaborative interdisciplinary research and development effort between industrial design and construction management programs at one U.S. University over a five year period. During the evolution of the program, improvements, drawbacks, and output were tracked by the researchers. The program development was iterative in nature and was without precedence in U.S. construction disciplines. With limited data and no comparison studies, a qualitative approach is employed by virtue of articulating the program's results, success, and shortcomings as they relate to the efficacy of providing meaningful tactile research in construction education.

4 Discussion from Ongoing, Evolving Interdisciplinary Research

Many products, tools, methods, and apparatuses used throughout industry are the result of input by industrial designers. As discussed in the literature review, few attempts, if any have been made to integrate industrial designers with construction professionals in a research setting at a U.S. university. In an effort to make the research truly collaborative, industry professionals, executives, and tradesmen were also invited to participate in the work. It was unknown at the project's inception whether it would be a repetitive effort, but as the report will indicate, the researchers determined that there was significant opportunity in continuing the process.

Initial goals of the research project were as follows:

Provide subjects for faculty research that would consider products, tools, and materials, as opposed to historically traditional research on management process theory, and construction education

Expand interdisciplinary collaborative efforts and opportunities for collateral learning between 'builders' and 'designers' among students and practitioners

Potentially develop products that might ultimately benefit the construction industry

Provide potential intellectual property for the university and inventors

The program costs were initially internally funded by the academic unit, covering expenses of product development and other fundamental necessities.

4.1 Year One – 2006

The collaborative research team included faculty and students from construction management and industrial design programs as well as a panel of construction executives. Construction management students were enrolled in a Master's program largely populated by students whose undergraduate degrees were outside the construction industry. The industrial design students were undergraduate seniors.

Product development ideas were actively sought by participating faculty and industry members. A formal list of potential ideas was generated by discussion with the construction executives and eventually narrowed to a list of fifteen industry problems that needed a specific product developed to address the noted problem.

The development of the products generally followed the industrial design studio format (Figure 1). Industrial design students led the development while construction management students assisted and coordinated discussion with construction professionals.

Figure 1: Initial linear progression of product design process

Of the fifteen products designed in year one, two products generated the most interest (Figures 2 and 3). One product was a pipe joint “wrap” for use with solvent based adhesives on plastic piping in cold weather. Essentially, the product keeps the temperature of the adhesive high enough to cure. The second product was a truss-lifter that allows home builders to lift trusses quickly and efficiently to upper levels without the use of a crane. The heat wrap was licensed by the university to an outside company, and the truss lifter has been patented by an independent manufacturer.

Figure 2: First year product developed to allow pipe joints to cure in cold environments

Figure 3: First year product developed to hoist residential trusses

Several products developed produced subjects for faculty research. The pipe wrap was tested quantitatively, yielding reduced curing times for pipe joints installed in cold weather conditions. Field research of the truss lifter was done by construction faculty and students. Results indicated substantial market potential for the truss lifter and

suggested possible areas of improvement including tilting of the trusses at the top of the lift and improved operating gear to enhance safety of the entire crew.

4.2 Years Two and Three – 2007, 2008

Based on the results of year one, the internal funding was continued for years two and three. Two key developments resulted based on year one. First, participating faculty recognized the need for education on technology transfer and intellectual property issues. An approach was devised, and all products were presented only after provisional patents were filed with the U.S. Patent and Trademark Office. Second, the industry participants were shifted away from construction executives and toward middle managers and project managers. This change allowed for more frequent interaction with students during the semester and provided a more direct link with the end users of many of the products being developed.

During this time period, it became evident that the process was best suited for smaller products. The researchers believe it is primarily a function of budget and timetable; also, a smaller product allows for deeper focus by the student developers. One such product was a chair for post tensioned cables in elevated flatwork, featuring a “living hinge” as well as leg indicators that allow for identifying the location of tendon drapes once formwork is removed (Figure 4).

Figure 4: Post-tensioned cable chair for two-way slab construction

Again, several products produced published research. The PT chair produced peer-reviewed published qualitative articles, and clearly demonstrated that this was a successful way to include industry in the methodology. The chair was evaluated by university students and faculty using industry focus groups in major cities. These focus groups were composed of end-users of the potential chair including general contractors, concrete finishers, chair producers, and tendon and rebar fabricators. Papers were published by faculty members using the information gained in the focus groups. Such research provided a basis of information of potential outside manufacturing partners and provided ideas for a second generation development of the product.

4.3 Year Four – 2009

Several shifts were made in the research in year four. In the first three years, pairs of students worked on a specific project with all faculty and industry partners. In year four, students worked in teams with a dedicated faculty advisor and construction industry partner. This allowed teams to source problems, do research, and develop potential solutions in small, interactive, collaborative groups.

Year four also yielded the first informal partnership with industry. A curtain wall manufacturer asked a team of students to look at a specific connection issue that required excessive field labor to install. Representatives from the manufacturer became part of the student/faculty/industry team and provided support and feedback in the development process.

Second generation products were also examined in year four. The post tensioned chair from previous development was refined by a student team in conjunction with faculty focus group research (Figure 5). Based on raw materials to be consumed, the projected cost of chair manufacturing was reduced, and the chair was combined with elements of a product already in the marketplace. During the refinement process, a concrete industry company expressed interest in the product and worked with the students. Construction faculty and students then partnered with the interested firm to further evaluate the product. In this process, the chair has been shared with key stakeholders in the process providing information on marketability, final costs, and further product enhancement. All of these issues provide fodder for additional construction research.

Figure 5: Iterative Post-tensioned cable chair design

Partnerships were expanded in year four to include field superintendents and trade organizations. Many of these individuals worked in concrete and carpentry fields and provided a great source of problem generation.

Initially, the researchers hoped that the program would produce “ready for market” products. As year four concluded, it became more evident that this program may best serve an initial research and development component for industry. In such a model, products developed could then be transitioned to industry for further market study and improvement prior to offering a market-ready product. This approach is uniquely suited for furthering construction research as the products generate research. This research, in turn, generates refined product development. As products are refined, further research opportunities are apparent and market propensity improves.

4.4 Year Five – 2010

After four years of output, faculty leaders decided that an expansion of the program was necessary for long term success. Specifically, a year-long effort was envisioned as opposed to a semester-long approach in an effort to have appropriate product follow-up, manufacturing interface, problem sourcing, and partnership development. In April of 2010, an external three-year commitment of funding was secured for such an approach, which included resources for product development, post-development research, and industry partnering to pursue non-provisional patents.

Year five yielded the first major partnership with industry. One of the U.S.'s largest producers of construction related tools, products and devices partnered with the university, providing problem sourcing and development feedback.

Figure 6: Concrete Reader

Figure 7: Laser Mast

Figure 8: Ergonomic Kneeboard

Figures 6, 7 and 8 show three second generation efforts; 6 is a concrete reader which easily attaches to vertical formwork to easily show when the concrete is at the desired grade, and to also quantify it if poured too high. Figure 7 shows an improved interior laser mast to eliminate/minimize blocking and rough-in layout at multiple elevations simultaneously, and 8 shows a more ergonomic kneeboard for concrete finishers that transitions from a static position to one of swiveling, simply by shifting body weight. (all three with provisional patents secured.)

The results of year five continue to show process improvements, with faculty research subjects, manufacturing partnerships and expanded funding commitments key. The expanded year-round effort allows faculty leaders to improve industry relationships, pursue potential manufacturers, and to secure non-provisional protection on the products with the greatest market potential.

5 Conclusions and Further Research

Construction Management programs within the U.S. have struggled to produce meaningful, practical research of direct benefit to industry. Few construction management research agendas are externally funded when compared with more traditional engineering programs. This paper demonstrates one way in which collaborative endeavours with other disciplines and construction professionals were successfully used to produce relevant and practical research.

The current financial commitment will continue the effort through a total of at least seven years. Industry interest, manufacturing interest, non-provisional patents, and significant funding provide qualitative validation that the program is poised for potential long-term success. Quantitatively assessing efficacy towards the program goals as stated in the methodology, in its five years the program has produced over 60 provisional patented products, 12 of which were extended domestically, and four of which are non-provisionally patent-pending. Two others have licence agreements with private manufacturers, and over twenty articles in refereed journals and proceedings have been published in multiple disciplines enumerating research and development results. Faculty engagement in research continues to increase, and the university is now realizing its first private income from construction related intellectual property.

Future research is needed in the area of post-development support and the pursuit of intellectual property and market presence. Specifically, what factors most influence the development of products beyond the initial concept phase in construction? How could these best be measured, and what elements identify long-term success in such an endeavour.

Deciphering Design Process

Using qualitative methods to inform collaborative built environment research

Abstract:

The challenges faced by the building industry highlight the need for collaborative work between practitioners from different backgrounds. The building industry is becoming increasingly multi-disciplinary. Given this context, building practitioners should be able to integrate their design processes, working methods and problem-solving techniques. Multidisciplinary design is considered fundamental in the success of building performance; an aspect which is traditionally approached deterministically. This article argues that qualitative research methods are helpful to inform collaborative work between building practitioners. This paper presents previous research in the area of collaborative design and development of design aids with focus on simulation software for building energy performance. Despite the remarkable advances in this field, the development and assessment of design tools has, so far, been mostly reliant on quantitative methods and numerical approaches. It is argued that identifying the underlying principles and dynamics of building practitioners' work is likely to enhance problem-solving in project environments and inform design aid and software development research. Therefore, qualitative methods could potentially assist in deciphering the complex nature of building design. This paper introduces two research projects concerned with collaborative work between building practitioners working towards the delivery of optimised energy building solutions. It discusses the use of two qualitative methods; semi-structured depth interviews (SSDI) and ethnography to formulate an understanding of collaboration in project environments. The article presents the reasons for choosing this method, reflects on the research process and discusses challenges experienced throughout. The researchers aim to highlight that the use of qualitative methods could assist the development of design aids and tools.

Keywords:

design process, building practitioners, building energy performance, qualitative methods and multidisciplinary collaboration

1 Introduction

There is a long tradition in the use of qualitative methods in architectural and construction research (Franz, 1994; Carvalho et al., 2009; Oak, 2011). Project environments are characterized by the ill nature of their dynamics both in terms of problem solving and process (Rittel and Webber, 1974; Rosenman and Gero 1998). Qualitative approaches are suitable methods to enable a deep and rich understanding of complex phenomena whose borderlines are not well defined and lack full exploration. The old paradigm of architecture as an aesthetical and subjective area is being shifted by a technical performance-based view. Instead, buildings are regarded as machines

expected to satisfy needs and functions expressed by measurable indicators (Necdet, 2002).

These technical aspects are characterized by their numerical nature when analysed from the product perspective; building performance. Nevertheless, the design process and work dynamics in construction settings remain ill defined (Rittel and Webber, 1974). Therefore, inductive approaches to gain understanding become relevant to investigate alternative facets of project environments including their technical aspects. Built environment research aiming to improve performance of buildings is likely to benefit from qualitative approaches to build up knowledge through the awareness of building practitioners' experiences, viewpoints and contexts of work.

Social aspects arising from this type of research are unlikely be reduced to numbers. Qualitative research becomes a suitable mechanism to construct and explain project environments, especially given the high interplay of actors and technical requirements. The strength of qualitative research lies in enabling the researcher to be the key research instrument for describing, analysing and interpreting data. The information collected on field conveys a rich picture about the context and process. The understanding is negotiated between participants and researchers as experience is outlined and the context gains meaning. It is an ongoing process of constructing theory; to "*identify, develop and relate the concepts*" (Strauss and Corbin, 1998).

With regards to energy and low-carbon design, software developers have pooled their efforts towards designing tools that inform building design decisions. Building performance simulation (BPS) packages can be used to predict the dynamic responses of buildings to their environments and to evaluate and compare output results of different design options. Building designers routinely deal with a number of parameters that substantially influence a building's performance, such as orientation, form and fabric. They regularly make decisions with regards to material, glazing areas and systems, all of which affect performance of the building as well as the aesthetic quality of the building product. BPS therefore allows building designers to test and compare the effect of their ideas on the overall performance of the building, with regards to lighting, ventilation, thermal performance, among others. Results are fed back to alter or 'fine tune' ideas, to achieve better results (CIBSE, 1998). However in practice, software solutions are not always well-synchronised with the building design process. Despite remarkable advances in this field, users of BPS packages tend to be mainly researchers, physicists and experts who value empirical validation (Attia *et al.*, 2009). On the other hand building designers, to whom BPS promises considerable benefit, fail to integrate it within their design processes (Attia *et al.*, 2009; Morbitzer *et al.*, 2001).

2 The need for collaboration

This emphasises the increasing requirement of a multi-disciplinary collaborative design approach in the building industry. Factors to be considered in building projects are growing in complexity. The need for collaboration surfaces when a professional is unable to carry out a particular task himself, because it lies out of the realm of his own knowledge and skill (Kalay, 2001). Collaboration therefore becomes an enabling force, allowing completion of more tasks than would be ordinarily permissible, with maximum effectiveness.

In light of this, all members of the design team need to be able to integrate their design processes, working methods and problem-solving techniques, to ensure successful design performance. While this may seem a straightforward notion, collaborative scenarios between architects, engineers and sustainability consultants working towards enhanced performance of buildings are seldom synchronised. Kalay (2001) attributes this to a difference in worldview. Building practitioners tend to come from fundamentally different educational and professional backgrounds. Consequently, they have different goals, objectives and foundation belief systems. Collaboration may result in misunderstandings, confusion and frustration. A shared understanding, on the other hand, becomes possible when collaborators are aware of the differences between social positions and worldviews, shaping a united foundation of understanding between all team members. Understanding worldviews and shared realities therefore calls for use of qualitative social research methods, which enable us to decipher the complex natures of practitioners involved in building design.

Previous research acknowledging difficulties faced by building practitioners tend to use empirical methods to make changes and developments at software level. This includes development of new interfaces, for example in (Ochoa and Capeluto, 2009), development of new tools, examples of which are reviewed in (Malkawi, 2004) and suggestions of interoperability between BPS and Building Integrated Modelling (BIM) as illustrated in (Chaisuparasmikul, 2006) and (Hamza and Horne, 2007). These examples are far from being exhaustive, and are just used to illustrate the nature of research conducted in this field. In the few cases where research has been conducted to better understand requirements and needs of building practitioners, such as in (Attia *et al.*, 2009), data has been collected through large-scale surveys aiming at reaching generalisable results. While these attempts are helpful and provide key information for future software developments, this article advocates the need for in-depth understandings to inform quantitative work. Conducting social research on a narrower yet deeper scale may provide invaluable knowledge that could further assist quantitative and software-level solutions.

3 Research Projects

This section presents two research projects that use different qualitative methods. The first project, ‘Understanding communication between architects and simulationists’ uses semi-structured depth interviewing (SSDI) and the second one, ‘Unveiling low carbon processes’ uses ethnography. Both projects are concurrent and currently under investigation. They are interconnected in nature; both projects examine apparently ‘numerical’ aspects of problem-solving in building projects: thermal simulation and energy consumption. Here each project is individually introduced; describing aims and objectives, explaining research design, data-collection, analysis and interpretation and presenting aspects that are unique to each project. Common reflections on the use of social methods in built environment research are drawn from both projects and discussed in section 4, as well as common challenges and concerns. Finally, conclusions and further implications of adopting qualitative methodologies in built environment research are raised.

3.1 Project 1: Understanding Communication between Architects and Simulationists

This project investigates the difficulty of integrating BPS within architectural design process. This is attributed to low-grade communication between architects and

‘simulationists;’ members of the construction industry responsible for building energy simulation (engineers, building physicists and software developers). Research in the area of BPS is usually regarded as quantitative and empirical. This is not a surprising phenomenon; BPS relies on mathematical calculations to simulate reality, and to predict the effect of complex interactions between the building, surrounding environment, internal loads, systems design, indoor thermal comfort, etc. (Prazeres, 2006). Development of BPS software packages draws on fundamentals from several disciplines; physics, mathematics, material science and human behaviour (Malkawi, 2004). Hence, a numerical approach to this research area on the whole is presumable. Rather than using BPS packages themselves, this project suggests that simulationists should be relied upon to carry out energy calculations, and report results back to the architects throughout the process. Architects would therefore invest more time and effort into making informed design decisions, instead of attempting to translate the plethora of numerical outputs which are presented as calculation results.

3.1.1 Research Aims

A social investigation, advocating the need for in-depth understandings and insights on the users of the software, is presented. It aims to construct an image of architects’ and simulationists’ social worlds; their education, experiences, worldviews, paradigms, problem-solving methods and working needs. These are multi-layered, profound, subconscious and complex human interactions composing one’s professional identity. The research also aims at exposing and comparing these social worlds, highlighting similarities and differences between each group.

3.1.2 Research Design

The method chosen for data-collection is semi-structured in-depth interviewing (SSDI). A set of intensive individual interviews is conducted with each participant to construct a biographic narrative. The duration of each interview is typically between 1-1.5 hours for each session. Only few questions are prepared in advance of each interview to steer the discussion, allowing for the assumption that responses cannot be predicted in advance (Wengraf, 2001). Consequently, the interviewer can then probe further topics that come up by improvising new questions. The subject can express personal opinions, ideas, perceptions and beliefs. Improvisation gives the interviewer the opportunity to adapt to the subject’s world; sharing outlooks and concerns. Therefore, SSDI has been found appropriate for investigating such complex, multi-layered and profound issues ‘in-depth’ (Boyce and Neale, 2006). Purposive sampling is used to select interview participants. Four architects and four simulationists are interviewed; comprising eight participants in total. Architects are chosen based on the criteria that they work in medium to large-sized practices delivering sustainable design-solutions; working closely with simulationists to achieve this. Simulationist participants are required to have worked closely and regularly with architects who approach them to assess their designs.

A) Interviews 1-3: Each of the first three interview sessions is based on a thematic Central Research Question (CRQ). These are presented in table 1. Interview questions are developed from CRQs, to be aimed at each interview subject directly. Each interview is audio-recorded, transcribed verbatim and read prior to the following session. Observations are highlighted and impressions formed, which can be built upon during the subsequent interview session.

Table 1. Central Research Questions addressed during interview sessions

Int. #	Theme addressed		Central Research Question behind the theme
1	"Professional upbringing" and "professional identities"	Background education	CRQ 1: How do background education and experience help shape the worldviews of architects and simulationists, in relation to the building industry?
2		Professional experience	CRQ 2: How much are architects and simulationists aware of <i>their own</i> practice and problem-solving? How much of this knowledge is conscious and how much of it is sub-conscious?
3	Personal perceptions of the 'other' group		CRQ 3: How much are architects and simulationists aware of about <i>each other's practice</i> and problem-solving? How do they perceive its importance within their working processes?

B) Interview 4: The final session of the set of interviews is deliberately left 'open,' and not directly linked to a particular CRQ. It is conducted with the aim of clarifying topics discussed during the first three interviews, which may require further explanation. It is also conducted to either confirm or deny any impressions that the researcher may have previously formed, and to verify any observations that have been inferred. Questions prepared in advance of the fourth interview are contextual; their design being largely dependent on data generated during the first three.

3.1.3 Data-collection and Analysis

Unlike quantitative research, there is no definitive, clear-cut divide between data-collection and interpretation. They are strongly interwoven, and an image of the practitioner's social reality is constructed through interpersonal interaction between interviewer and subject (Strauss and Corbin, 1998). Meanings emerge from a conversational setting, instead of being forced through a theoretical perspective. Rather than occurring as a mechanical activity where analysis is a logically tight procedure, interpretation puts the researcher into the position of detective; looking constantly for recurring themes and patterns (Wengraf 2001). Furthermore, data collected informs the process as well as actively contributing towards the findings, allowing the researcher to revise any decisions that have been made throughout the project.

Analysis and interpretation occur frequently and across several stages. Data management and organisation as it is being collected is considered a crucial first step. This includes activities such as transcription and making detailed field-notes, which allow the researcher to observe each interview separately, and to acknowledge each as having its own coherence, structure and meanings. Primary themes and patterns are identified from the beginning, and less important material is promptly filtered. A loosely structured framework of codes is formed, and emerging themes, categories and patterns can be fit.

Two coding strategies have been proposed to synthesize and conceptualise findings from different interview transcripts:

1. Selective coding: A framework consisting of pre-defined codes; developed in accordance with the CRQ themes and interview questions. Relevant responses and statements could be coded into their respective categories.

2. Open-coding within newly-occurring themes; in line with the semi-structured nature of the research, open codes may be issues that are raised frequently during interviews, yet do not fit into the selective coding strategy. Coding categories are likely to increase and become more fine-tuned as more data is collected. Open codes are identified based on frequency of occurrence within the data.

The coding system allows the data to be observed vertically. Rather than examine each interview as a separate entity, data can now be interpreted crossing an entire set of interviews. Interpretations can be drawn by conducting comparisons across architects and simulationists to fulfil the aims of the research. Figure 1 below reveals exemplar alternative typologies of interpretation and comparison facilitated through adoption of a formal coding strategy such as the one described.

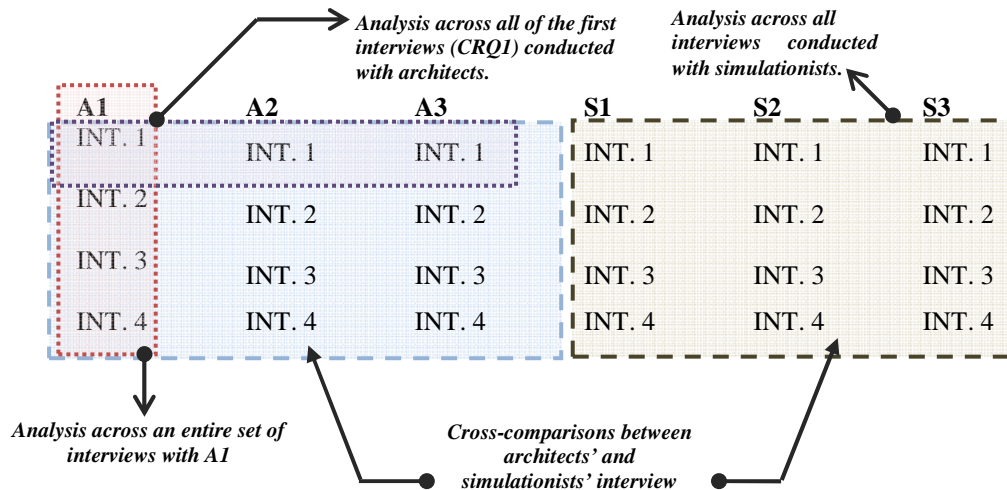

Figure 24 Alternative typologies of interpretation and comparison of coded data

3.2 'Going Native' to Unveil Low Carbon Processes

United Kingdom has committed to an 80 per cent reduction in carbon emissions in the building stock by 2050. Welsh regulations are aiming for higher CO₂ reduction targets compared to the rest of the UK. The Welsh Assembly Government is aspiring to enforce 55 per cent reduction of the carbon emission levels of new dwellings by 2013. However, it is uncertain that the construction industry will be able to deliver projects that meet those requirements (Maunsell, 2009; Zero Carbon Hub, 2010). Research suggests that despite the willingness of building practitioners to adopt low carbon practices, there are serious barriers that jeopardize the achievement of CO₂ reduction targets (NHBC, 2008; Hamza and Greenwood, 2009).

This project analyses formal mechanisms; legislation and policies intended to enforce the adoption of low carbon standards in project design. It aims to unveil the social process of understanding, learning and negotiating of low carbon concepts during project delivery and find the link between low carbon policies and informal adoptions during project delivery. The researcher is immersing herself in few architectural practices for a period between nine and eighteen months corresponding to real-time project development. Architects' context of work is the main 'setting' being studied; however, as projects progress, other practitioners working in design and construction phases are being involved in the research through other qualitative techniques such as interviewing and analysis of documentation produced by non-architects. An intentional trade-off between depth of immersion in a single setting and the use of a comparative case-study was made on the basis of identifying key commonalities and differences in delivery processes observed in few projects so to 'unveiling' low carbon process.

3.2.1 Ethnography as Research Approach

There are two aspects associated to low carbon design; the quantifiable factor and the qualitative factor. The first is concerned with building performance, assessed in a numerical fashion i.e. reduction of carbon emissions and estimated through simulations. The qualitative aspect is related to building as a process where communication, negotiation, tacit rules and experiential knowledge inform building development. In the latter, performance is correlated with the social processes adopted in the delivery. Energy performance is not only about quantitative procedures but also about non-material ones. It is the result of social processes that facilitate a shared view and ownership of energy matters that are reflected in targets for the product and the process.

The ethnographic approach used to analyse energy design intends to clarify how the performance element of building as a product is related to the social aspects of building as a process. Ethnography allows a close observation of how the dynamics of delivery process are either able or unable to embed performance in the product. One of the main limitations of numerical oriented research is their tendency to model idealised scenarios of use, reducing them to 'laboratory conditions' with high control of variables. In this situation, users and context of application are at risk of being misrepresented and neglected.

This project analyses product and process by identifying casual techniques and informal mechanisms that embed performance, their role in informing project delivery and their instrumentation as 'tools to encapsulate' low carbon knowledge. These techniques will be mapped against project schedule and deliverables. This could inform the development of mechanisms and tools to facilitate low carbon building delivery. Ethnography has been selected as the method suitable to understand low carbon process through the elicitation of participant's perspectives and experiences and the observation of project development (Hammersley and Atkinson, 2007).

Ethnographic data collection methods such as interviewing, participant observation and document analysis are being used to 'go native' and follow-up a small number of projects, explore and map the experiences and working process of practitioners delivering low carbon buildings. An actor network theory is being employed to 'represent' the context to reduce the risk of bias and assumptions during description and interpretation of the findings. This approach intends to overcome potential limitations and challenges of mapping the non-linear and iterative nature of low carbon process.

3.2.2 Research Design

Early concepts were developed through desk based studies and extensive literature review. Key topics were discussed with practitioners to gain a preliminary understanding of the context. This exploratory phase was followed by the analysis of real time project progress.

The first stage aimed to map the general panorama of low carbon delivery, in terms of technical knowledge and legislation awareness. The main data collection method was semi-structured interviews. Twenty-three interviewees were chosen through a theoretical sample based on a comprehensive literature review and the recommendations of key informants experienced in the Welsh building industry. Key informants are involved in initiatives to disseminate energy regulations and best practice in the Welsh construction sector. The participants belong to different educational backgrounds: architects, mechanical and services engineers, environmental engineers, sustainability

consultants, civil and structural engineers, employed by firms specialized in the non-domestic sector with a portfolio of sustainable and BREEAM certified projects. The early findings from this first stage informed the development of fieldwork protocols and research design during the project follow-up phase. It also contributed to the selection of projects analysed in the second phase, through snowball sampling.

The second phase corresponds to a deep study of real time project development. These building projects belong to the educational sector where non-speculative public clients aim for higher sustainable targets than those currently enforced by legislation. Therefore, their delivery process is likely to surpass minimum legislation thresholds. The data collection methods of this phase include interviewing, non-participant observation and document analysis. The data is being triangulated to compare the delivery process of different projects.

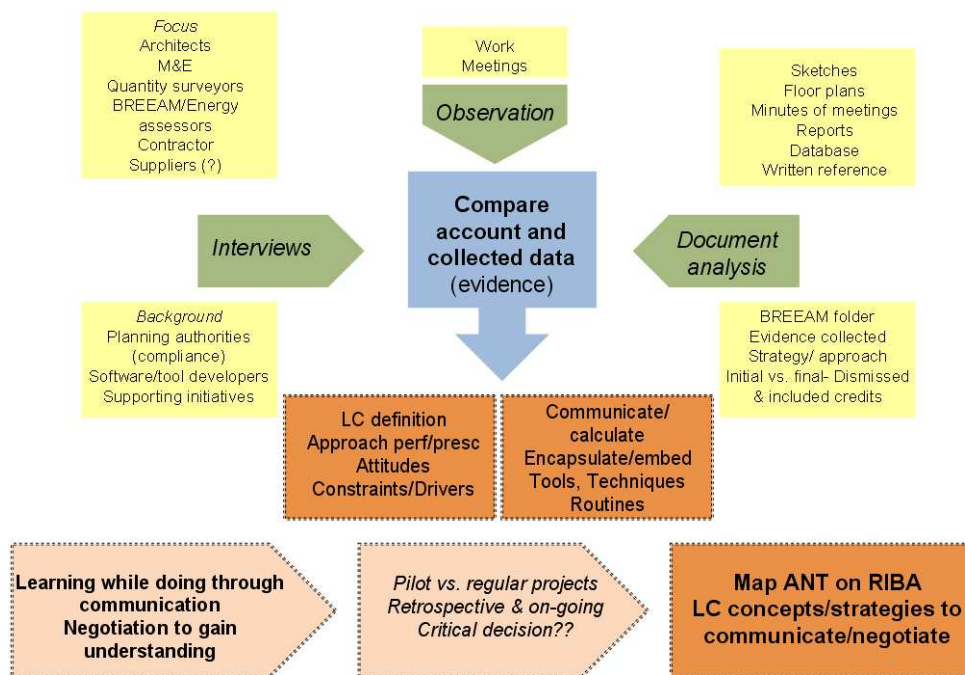

Figure 2 Data collection methods and themes explored in low carbon delivery process

In order to construct the context, special attention is made to the relation between self-accounts (first phase) and project follow-up observation (second phase). This combination of methods is used as a triangulation technique to gather evidence from different sources that could both corroborate and contest what is found on the field. It is important to remark that participants help to construct the context. Data by itself is not enough to construct it. Participants’ motivations, views, perceptions, attitudes and opinions outside the scope of building as a product and process are also contributing to building up context in the light of research enquiries.

The analysis of energy aspects of projects using an ethnographic lens seeks to reveal commonalities and differences in delivery, linking product and process. Techniques, tools and routines identified in the follow-up phase are compared to self-accounts obtained from interviews to ‘densify’ theoretical categories and inform findings.

4 Discussion of Research Projects

The projects outlined in section 3 are at early stages of progression. Therefore this discussion is centred around development of the method, rather than final research findings. The authors advocate the benefits and anticipated contribution of use of these methods within the wider body of knowledge, and outline limitations that qualitative researchers in the built environment are likely to face.

An initial approach to understanding the context might raise awareness about existing misconceptions and limitations of current implementations and attempts of integrating software, tools and aids. Meanwhile, research of energy in buildings involves technical and human aspects. Realisation of better performing buildings is not only the result of simulation and calculation tools but also the inclusion of practices, knowledge and worldviews adopted by building professionals. Qualitative methods help to identify gaps, breakdowns and needs in design and delivery processes, evaluating the adoption of design aids and assessing the implementation of tools that facilitate better practices. A closer examination of the context could help to represent patterns and behaviours, informing models and aids, and recommending applications and scenarios of use. One of the potential contributions of these early research projects is that they embark on a bottom-up approach, where the research examines the level of building practitioners from a wide range of backgrounds, up to the level of the tools that they use.

While this research promises the above benefits, it is also important to be aware of its limitations. While undergoing the projects, the researchers are facing the following:

Sample size: It can sometimes be difficult to determine what the ‘correct’ sample size is for qualitative methods, particularly when the aims of the research do not include producing generalisable results. A small sample size is often considered suitable as it may allow a deeper and more thorough investigation (Taylor and Bogdan, 1998).

Reliance on the participant: Qualitative methods rely on finding subjects who agree to participate, and building up a trusting relationship, so that the researcher is no longer considered an ‘outsider’ approaching participants and is therefore granted access to relevant data.

Understanding the participant: The researcher must be well-trained in reading and understanding the varying personalities of participants. The fact that each will have a different personality must be acknowledged, and each will therefore require a novel demeanour when being approached.

Thorough reading of collected data: The researcher must be aware of recurrent themes, patterns and statements in the data. Meaning may associate itself in what is not always clearly visible; or in what has not been directly conveyed. Common and repetitive patterns are equally as important as novel and original statements.

Contradictions: Positive and negative assessments of the same opinions or social phenomena by the same participant may arise. Contradictions may themselves be regarded as ‘data.’ Patterns or reactions such as confusion or uncertainty represented might be noteworthy.

Time-resources: Qualitative methods of data-collection and analysis are time consuming. Balancing research activities to work around participants’ schedules means

that a dataset could be conducted over a prolonged period of several weeks, making it unlikely to quickly reach publishable findings.

Criticisms: Ethnography is often criticised; arguing that the researcher is in a position to influence participants' behaviour and responses. This may be overcome by studying projects over a long period of time, while attempting to maintain a trusting relationship with participants to facilitate continuity of the research. Discussing outcomes of the research with participants may further contribute to this; while acknowledging the fact that ethnographic-based research is a process of negotiation and understanding between the researcher and participants.

5 Conclusions

This article has discussed the application of two qualitative research methods, semi-structured depth interviewing (SSDI) and ethnography. They are used to reveal the complexity of social aspects in fields traditionally regarded as purely numerical. The process, challenges and reflections about the implications of using qualitative approaches are presented. In the light of the discussion, the authors present final remarks related to the application of qualitative methods in built environment research:

Qualitative findings facilitate a wider understanding of realities that could become the departing point for further exploration using other research approaches aimed to generalize and explain phenomena. In the cases of the above projects, qualitative research lays the foundation to develop further enquiries to be tested in a numerical fashion.

Qualitative research in the architectural field, as well as with any other, is cyclical and iterative. It is not always possible to fully design the research before embarking on data-collection because, once the data begins to arrive, any decisions made will be under revision for the remainder of the research process. Data-collection and interpretation overlap; every activity contributing to data analysis forces the researcher to constantly revisit and refine the process, as well as contributing towards the final outcomes.

Research design enables to choose the evidence likely to 'saturate' overarching themes for interpretation and inform findings related to research scope and aims. This process initiates with first enquiries and leads the researcher towards mature levels of understanding – the fuller picture could only be constructed after uninterrupted loops of questioning, critical thinking and reinterpretation.

Use of qualitative research is at risk of being regarded as 'too subjective,' particularly in the eyes of members of the deterministic research community, since interpretation relies to a large extent on the researcher's position and standpoints. This needs to be acknowledged throughout the research process. Triangulation techniques enable the researcher to critically revise the method, reflecting on the findings and enhancing their rigour.

Complex Construction Projects between Remedies and Partnering

Abstract:

The imperatives of cooperation and competition conflict when providing Value for Money services in complex construction projects. While competition is mostly formalised through public procurement, cooperation is less formalised. Harnessing competition and cooperation is made difficult by the fine balance between transparency and trust. Transparency is needed to foster trust but the judicial ways in which transparency is reached shatter confidence. While project management highlights strengthened cooperation through partnering to develop successful projects, procurement regulations do not leave any formal space for it. Comparing Belgian and English complex construction projects indicates how to start mapping out various tensions in articulating competition and cooperation. In England, partnering has been introduced as a remedy for recurring litigations, which result in delays and high costs for the public purse. Partnering revolves around a fair exchange of information between parties to foster innovation. Public procurement directs information to all market players regarding the whole decision-making process of the public authorities. Yet, information regarding innovation needs protection. Institutionalisation of public control over elaborating and performing these complex projects leads to over-layered techniques, hindering the overall transparency of the system which supports high investments of public money in these projects. Belgian procurement is basically rigid. There are many judicial challenges, often claiming that public authorities failed in their duty to give proper formal justification for their decisions. This shifts discretion from public authorities to judges and experts to assess confidential information. Yet, besides these formalised solutions, cooperation between public authorities and contractors occurs at the margins of the law itself. In both England and Belgium cooperation and competition between public and private partners in complex construction projects are embedded in a wider context of legal rules and informal behaviour. The transparency and formalisation of these public-private relationships needs to be assessed beyond the parties, within the institutional and interpersonal dynamics.

Keywords:

complex projects, partnering, remedies, transparency

1 Introduction

Major construction projects are central to current policies kick-starting investments aimed at bouncing back from the current economic downturn. With tight financial constraints, governments are asked to optimize the taxpayers' money invested in these

projects more than ever. Yet, the means to achieve successful projects in public infrastructure are uncertain. Project management emphasises partnering as a way to design and maintain complex constructions. This suggests a high level of trust between public and private contractors, developed over long periods of time. By contrast, the law, especially public procurement, seeks to develop a competitive market for bidders and new entrants, willing to enforce public procurement rules through legal challenges. This approach trusts that legal rules have a beneficial impact on securing efficiency in market exchanges. The two approaches need to develop a common ground, building on the strengths of each to secure Value for Money (*VfM*) and successful projects. This paper seeks to map out some of the key tensions between these two approaches, based on a comparison of Belgian and English complex projects: the law is overly predominant in the first, while the second straddle procurement regulations and managing through partnering.

Complex construction projects are often organised through public private partnerships (PPPs) and private finance initiatives (PFIs). They integrate in one major project a range of contractual, financial or economic relationships. These projects are based on *'the bundling of construction, maintenance and sometimes other services into long-term "whole life" contracts under which private sector contractors are responsible for the construction and functioning of public buildings over many years, in return for annual payment by public authorities'*.¹ In PFIs, an additional layer of complexity lies in the use of private debt finance. The balance in these bundles of contractual and informal relationships is partially embedded in the legal context of each country: Belgium and England differ in their use of the techniques developed in EU public procurement. A common core of techniques used to foster competition may be challenged or supplemented by less formal techniques of cooperation.

At the heart of PPPs/PFIs, the tension between competition and cooperation is reflected in the interplays between transparency and trust. The need for innovation starts with actual techniques in construction projects and pervades the legal environment in which these projects operate. Information is needed to develop appropriate solutions to overcome the high risks in these projects. Parties thus have to trust each other. Trust needs also to be developed among the public and their representatives, by communicating project information justifying how taxpayers' money is spent. Yet, disclosing information may benefit competitors, enhancing their chances of winning the next tender. This logic does not work on its own however. From the start, there is an imbalance in the information spread between the various players: mechanisms fostering trust need to channel how information is exchanged. The variety of English and Belgian experiments illustrates how this balance in information is central to enabling successful complex projects.

Section 2 maps out the tension between partnering and information culminating in legal challenges and remedies in England, where a balance is developed through various layers of public control. Section 3 lays out the highly formalised context of procuring complex projects in Belgium, which curtails strictly public choices. It details how transparency may lead to displacing public discretion to judges and experts. Yet, informal practices of mutual exchanges between public and private partners have been very much developing in the corners of the legislation. Section 4 suggests that control of

¹ Select Committee on Economic Affairs, *Private Finance Projects and Off-balance Sheet Debt* (63-1 HL 2009-10) para 3.

transparency needs adaptation depending on where tensions arise and that alternatives to transparency may need to be worked out.

2 Challenging public choices in English complex projects

Investments in complex construction projects face a major issue, namely failures in the market and projects: prominent projects are delivered with major overruns both in budget and time, when they are not cancelled mid-way. The need to develop an efficient market and successful projects draws sustained attention to the factors underlying *VfM* and risk management. Gaps in information put *VfM* and risk-taking in jeopardy, deterring potential contractors. To reduce this information asymmetry, a change in the approach to the projects has been long encapsulated in how PPPs/PFIs were supposed to bring about new ways to manage public infrastructures and make public choices.

From both a construction (Hibberd, 2010) and a procurement perspective (Braun, 2003), PPPs/PFIs are presented as a dramatic change in the approach to complex projects. In practice, this change happens incrementally at three levels. First, partnering is presented as a bridge between complexity and innovation. At management level, it draws attention to the overall lifecycle of the project, from design to termination (Section 2.1). Secondly, PPPs/PFIs triggered the competitive dialogue, formalising the decision-making process related to complex projects. This specific procurement route is embedded in a tight system, where remedies should foster transparent decisions respecting public procurement regulations (Section 2.2). Finally, these first two levels of changes need to be coordinated, at both project and policy levels. Coordination happens as state institutions organise spaces for it to happen or when individuals seek to test the decision-making process all the way through (Section 2.3).

2.1 Partnering: an ideal to move towards

Partnering is a first change strategy for dealing with market and project failures in constructions. It has been stressed since the 1990s as an important component in developing complex construction projects, as innovative techniques were needed in a time of under-investments in public infrastructure. PFIs were one way to bring in private investment in public infrastructure, building on the innovative potential of private contractors. Cooperation was highlighted as a requirement for securing the best from new technologies or new market opportunities (Collins, 1999). Partnering would bring about this cooperation, helping to overcome the adversarial relationships hampering the construction industry from delivering *VfM* projects. Partnering plays a range of functions in projects. Firstly, it enables innovation when the public authority and the private contractor design the project (Section 2.1.1). Secondly, it contributes to a whole-life approach throughout the supply-chain, especially in the performance phase (Section 2.1.2). Partnering cuts across this distinction to apply transversally to the supply-chain during the project design and to the performance of public-private relationships. However, partnering may also cause trouble as it is non-legally binding (Section 2.1.3).

2.1.1 Innovation in planning complex projects

Complex projects require a planning taking into account their specific features in terms of idiosyncratic assets, large investments, risks notably linked to their long duration. Partnering may help in these respects. Project management understands partnering as '*a long-term commitment between two or more parties in which shared understanding and*

trust develop for the benefit of improving construction' (Bybballe et al, 2010, p. 239). Similarly, legal scholarship emphasises that partnership can be defined as follows: '*essentially the relationship is based on trust, dedication to common goals and an understanding of each other's individual expectations and values'* (Mason, 2009, p. 206). In both cases, trust and sharing (understanding or goals) are highlighted. The challenge is to bring these ideas in the relationships between public authorities and their private contractors.

The partnering approach should allow to bringing new ideas, processes or techniques influencing the overall duration of the project, resulting in *VfM* not at one point in time but over the whole-life cycle of the project. Partnering agreements bring about ideas such as fairness, honesty, transparency in how parties deal with each other. Recent project management research calls for caution about the risks involved by partnering (such as wishful thinking, risks of exclusivity, encouraging opportunism) (Bresnen, 2007). Some consensus seems to emerge that more empirical studies on the perceived advantages of partnering and the variety of its formal and informal expressions are needed (Bybballe et al, 2010).

Despite these theoretical uncertainties, partnering seems to answer a genuine need to develop a framework to understand how relationships are managed during the course of a project. Contract law is here not helpful to give some predictability to the parties to the project, especially in the phase preceding and following the actual construction. Hence, partnering has been applied to PFIs, either in general¹ or in specific projects such as Building Schools for the Future (*BsF*) and its 'strategic partnering agreement'. Partnering principles have also been encapsulated in various standard models, such as NEC3, JCT, PPC2000, resulting from practice and project analysis. These documents do not operate alone: supporting mechanisms such as a partnering team or partnering adviser should also be implemented. This results in the principle of behaviour being documented. Parties communicate to each other what their expectations are and their own commitments should problems arise. Agreed norms of behaviour are thus formalised. How does this perform, once partnering principles are incrementally agreed upon?

2.1.2 *Performing partnering*

Originally, partnering was mainly a way to approach litigations crippling construction projects in the performance stage. Partnering is a strategy to tackle risks, in terms of both preventing them and addressing them once they have arisen. It should bring the parties into a mindset facilitating a constructive management of issues, with the benefit of securing successful projects. This mindset needs to be slowly integrated within the project from the start, to find practical applications in risk management.

First, in the design phase, partnering considerations are extended to the supply-chain in two ways. Early involvement of contractors (and their sub-contractors) in designing the project would allow to gaining time, ensuring more certainty about pricing, both in the defining and in potential savings, and bringing a cultural change in the private contractors (Mosey, 2009a). The issue is to find a proper process to ensure this early involvement. One such form is to proceed in two stages: first, to tender a pre-construction services agreement where the private contractor provides preparatory

¹ OGC, *The Integrated Project Team – Teamworking and Partnering, Achieving Excellence in Construction Procurement Guide*, 2005; OGC, *Best Practice, Forming Partnering Relationships with the Private Sector in an Uncertain World*, n.d.

services while the project is being designed. Secondly, the contractor submits a tender for the works to be carried out following the design developed according to public authorities needs/requirements. This two-stages approach may struggle to ensure that competition is properly maintained between the two stages as required in the public procurement regulation (Barber and Jackson, 2010).

Secondly, partnering would provide management solutions for weaknesses in contract law, especially for changing circumstances, resolving issues or need of renegotiating solutions to supervening events. This may have three consequences however. First, partnering may become fairly detailed regarding the various stages and principles to be followed would problems arise. Secondly, if partnering results in changes in scope or price of the contracts, this may again not fully respect public procurement. Finally, partnering operates within a legal framework for construction contracts encouraging adjudication and 'pay now, argue later' principles.¹ However, these techniques may in practice enhance hostility between parties and thus threaten any partnering ideas (Tackaberry, 2009).

Partnering seems to be crucial both between public and private contractors and in the supply-chain. It does not solve all issues however: it only helps to design projects from a benevolent perspective, which should be reflected in how supervening events are addressed.

2.1.3 *Informal reliance, not legal protection*

Partnering revolves around ethical norms of behaviour that partners have expressed and are committed to respecting and developing as the project progresses. It works only as long and as well as partners actually walk their talk when confronted with issues. Here a paradox appears regarding the bindingness of partnering.

On the one hand, the absence of legal bindingness is underlined on a recurring basis.² Partnering does not give rise to any legal rights. It is for this very reason that parties agree to commit themselves to partnering principles, even within a well- documented framework.

On the other hand, this absence of legal bindingness also leaves the partners without any legal protection when the contracting party does not respect its commitments. This explains why recent surveys on the practical implementation of partnering agreements show reluctance to use them (Mason, 2009), despite repeated efforts by public authorities³ and professional bodies⁴ to highlight its benefits.

The partnering paradox lies in its very nature of generating trust in the other party by accepting a soft commitment to behaviour standards. Contract law accepts that managing projects alongside partnering helps find innovative solutions to complex issues. Public procurement does not share this accommodating perspective in tackling market and projects deficiencies.

2.2 Public procurement: formalising information exchanges

EU public procurement frames the second strategy for tackling market and project failures. It aims to develop an efficient market based on principles of transparency and equality. Transparency is strengthened at three levels: first, in the decision-making process and the design of a project meeting public authorities' needs and requirements; secondly, in the information provided to the unsuccessful bidders; and thirdly, both levels are made effective through legal challenges.

This pattern, common to all procurement routes, calls for specific attention regarding major construction projects due to their complexity, reliance on innovation and increased need for efficiency. Public procurement regulations address these points in a tailored way. First, complexity in construction projects has resulted in competitive dialogue (Section 2.2.1). Secondly, innovation in project design triggers questions of commercial confidentiality, to be balanced with the accountability required by taxpayers' money (Section 2.2.2). Thirdly, the efficiency of the market is ensured thanks to market-players supposedly being eager to secure their markets and hence to enforce the rights they have under public procurement (Section 2.2.3). Transparency here works in the relationships between the public and private parties and among all market players. This increases the complexity of already difficult projects.

2.2.1 *Competitive dialogue: designing complex decision-making*

Complex projects require clear framing of the relationships between the procuring authority and all potential bidders. The EU 'classic' directive designs a specific procurement route for complex projects.¹ The key idea is that complex projects involve a range of issues, and public authorities are not necessarily well equipped to decide pre-emptively what would be the best answer. Room needs to be maintained for testing innovative approaches and integrating a range of components into one single operation, encompassing the whole-life cycle of the project. Conversely, the overall decision-making process of public authorities needs to include consideration of how information is communicated to the candidates at all stages of the project's elaboration.

The starting point is the complexity of a project. Complexity involves a range of questions and uncertainty about the most suitable approach to a range of issues. In public procurement, a 'particularly complex contract' is defined as '*a contract where a contracting authority is not objectively able to (a) define the technical means [...] capable of satisfying its needs or objectives; or (b) specify either the legal or financial make-up of a project or both*'.² In the case of such complex projects, competitive dialogue has been devised as a practical solution to the uncertainties linked to the choice between concession/procurement and the applicability of negotiated procedures, each having their own transparency requirements. The ECJ case law on the defining criterion between concession and procurement – the risk allocation between the parties – is not always easy to apply. Furthermore, public authorities do not know before starting the tendering process what may be the best risk allocation, and hence under which legal category the contract will fall, and therefore the tendering route and the level of transparency which should have been followed due to the result. Thus, the choice of process is already a matter of information exchange.

¹ Directive 2004/18 of the European Parliament and of the Council of 31 March 2004 on the coordination of procedures for the award of public works contracts, public supply contracts and public service contracts, art 29.

² *Public Contracts Regulations 2006* (hereafter *PCR 2006*), reg 18(1).

Secondly, competitive dialogue channels information before and after of the negotiations between a limited number of bidders, leaving the actual layout of the negotiations to the procuring authority. Before the formal opening of the dialogue and negotiations, public authorities need to detail the procurement process and the dialogue. Information must be given to potential candidates on public authority's needs and requirements.¹ The various stages of the dialogue narrowing down the number of bidders need to be made public from the outset.² This flexibility is a source of complexity, as public authorities have to predict the issues likely to arise and factor them into the formalisation of their dialogue process. Formalisation also extends to the information which may be exchanged once the dialogue is closed. In this tightly knitted formalisation there are two different pockets of discretion. The first one starts when the dialogue is opened: negotiations are possible on any aspects of the procurement.³ The second one relates to the criterion for awarding the contract: the most economically advantageous tender ('MEAT'). The factors and their weightings need to be made public at the start of the process but the final assessment belongs to the public authority.

Thirdly, this mapping of the competitive dialogue may not leave aside practical issues. Most problematic is for public authorities to design in advance the dialogue and to target the issues to be negotiated to avoid wasting time. Hence, the Treasury questions whether the competitive dialogue should be used as the default procurement route for complex projects.⁴

While complex projects were supposed to be awarded thanks to this competitive dialogue, doubts about the efficiency of this process arose. A key element in any procurement dealing with complex projects is the ways in which information related to public decisions and innovative techniques may have to be disclosed.

2.2.2 *Uncertainty in broadening information duties*

While information has to be directed to all potential market players likely to bid for a contract, specific information on the decision has to be given to the rejected bidders. Justifications have to be given. Debriefing has to be organised. Internal public authority documents may have to be communicated. The exact scope of this duty to provide information depends on the techniques used: either the *Freedom of Information Act* 2000 ('FOI' Act) or the *Public Contracts Regulations* 2006 ('PCR 2006'). A balance between the innovation to be protected (commercial confidentiality) and accountability needs to be struck to safeguard trust – either among the market players or among taxpayers.

First, *PCR* 2006 provide how information may be exchanged during the procurement process and which information has to be communicated to the bidders once the contract is awarded.⁵ During the competitive dialogue, information may not be communicated to some tenderers in a discriminatory way. Awarding authorities may not transmit solutions or confidential information from one tender to other candidates.⁶ Finally, a

² *PCR* 2006 reg (18)(12).

³ *PCR* 2006 reg (18)(21).

⁴ HM Treasury, *Review of Competitive Dialogue*, 2010.

⁵ *PCR* 2006 reg (30) and (32).

⁶ *PCR* 2006 reg (21)(b) and (c).

debrief of the bidders occurs, once the award decision notice sent. It should state full reasons for the decision in choosing the winning bid.¹

Secondly, the *FOI* Act is part of the means to ensure greater accountability on government in general. Any members of the public, including bidders may use it to obtain information regarding the procurement process, even beyond the post-tender phase. In doing so, bidders may gain access to wider information than in relying on the *PCR* 2006 and may unearth irregularities in the bidding process. Commercial information may be protected but the practice suggests that public authorities must show that the risk of prejudice for commercial interests is real (Oonan, 2010).

Thirdly, the extended duties to disclose information conflict with the protection conferred to confidential information, for instance that relating to innovative techniques. The ECJ decided that national review bodies had to strike a balance between the two competing interests.² English courts applied this ruling. In the *Amaryllis* case, the judge decided that some information needed redaction by the parties and he asked that the full documents and the redacted ones would be made available to him, before progressing with the case.³ In another (Scottish) case, the court gave the parties seven days to agree between themselves the safeguards they would find appropriate (e.g. restrictions, undertakings).⁴ Nothing hampers to apply the solution in England (Henty, 2011). Judges recognise thus that parties play thus an important role in shaping the information available.

As the projects are complex, these balances in the duties related to information become highly sophisticated; respecting regulations is therefore increasingly challenging.

2.2.3 *EU remedies, a temporary pain?*

While partnering sought to prevent litigation to foster *VfM* projects, procurement, especially the 'remedies' directive, seeks to foster the availability of legal challenges so that self-seeking rejected bidders will promote efficiency.⁵ There is indeed a paradigmatic shift in English procurement. Traditionally, decisions related to awarding public contracts were only very little challenged. The impact assessment to the implementation of the remedies directive noted that the consequences of this implementation may be uncertain.⁶ Yet, changes were starting to emerge prior to this. For instance, judicial challenges were constrained by tight time limits, which had been successfully challenged⁷ just months before the entry into force of the regulations implementing the 'remedies' directive. Questions now arise regarding how transparency may be influenced by legal challenges, being reinforced or re-directed? How would this affect the delivery of complex construction projects?

The theory is that the whole process of information exchange regarding procurement should allow the rejected bidders to understand public authority's choice and assess whether this decision is regular and if not, on what grounds it may challenge it. Courts

assess what should be disclosed on the basis of what may be needed for the rejected bidder to assess whether it is entitled to a remedy, to challenge the choice in court – hence, to assess if public procurement rules have been followed or not. This means that the aim is not to provide a learning process about the project design as such but about the procurement mechanisms. What made a project most economically advantageous and distinctively successful is not to be disclosed to competitors. Yet, tensions appear here: public authorities are trapped between the need to comply with their information duties under the procurement directives and their duty to keep information confidential.

A breach of transparency requirements may bring such serious sanctions as the court making a declaration of ineffectiveness, rendering the contract unenforceable for the future.¹ In practice, courts adopt a strict approach to transparency requirements, both at the level of principles and in their applications. First, courts start with the principle that regarding the compliance with transparency requirement, public authorities have no discretion or margin of appreciation, while in matters of judgment or assessment of the bids they had such discretion.² Secondly, courts apply transparency to the extent to which criteria, sub-criteria, including the weightings applied to these to assess the MEAT have to be communicated from the outset.³ This resulted in the procurement to have to be started again. When procurement is cancelled and has to be re-run, the public authority may face new difficulties in dealing with increased layers of upset bidders.⁴

This leads to even longer and more complicated procedures: parties have to weigh up whether a claimant has a good chance of winning the case or not before progressing with the complex project and its planning. A possible solution advocated during the implementation of the remedies directive was to incentivise the chosen bidder to ensure that the procurement process had been awarded on a regular basis.⁵ One form of cooperation between public and private partners is thus put forward as a way to safeguard the balance between competition and efficiency in the awarding of complex projects. If this route were to be followed, EU procurement regulations would have had a pedagogic effect on how parties may have to behave to secure successful projects. Yet, it may also extend the timeframe to develop complex construction projects.

2.3 Transition from failing projects to efficient market: multi-layering of public control?

The reasoning based on partnering (Section 2.1) and public procurement (Section 2.2) addresses different issues regarding the parties to relationships and contractual phases. Procurement relates to the horizontal relationships between market players in their race towards the contract. Partnering relates to the vertical relationships between the public authorities and the (would-be) contracting party and supply-chain. Procurement emphasises the elaboration phase as defining the success of the project in the competitive, equal and transparent choice of the contracting party and the long-term contractual modalities. Partnering highlights the importance of giving due attention to performance in the designing of the project, in order to reach *VfM* over the lifecycle of the project. This presentation of the strategies for developing major complex infrastructure projects underlines the role of the public authority tendering the contracts and the private bidders and contractors. However, in practice, two different layers of

⁴ Eg: *Apcoa Parking (UK) Ltd v Westminster City Council* [2010] EWHC 943 (QB).

⁵ OGC, above (n 6) para 34.

pressures are added to the complexity of the projects: first, central processes and institutions; secondly, individual claimants. Both influence how information is channelled and managed between the public and private partners and towards the outside.

First, innovation is seen as a key issue in public procurement that should be addressed with cultural changes and '*long term strategic procurement planning*'.¹ Such planning was started with the public bodies (Partnerships UK, OGC and the Treasury) revolving around PPPs/PFIs. The *Government Construction Strategy* goes further in urging regular updates of the planning of major infrastructures over the next two years, so that the private sector can develop its own planning strategy.² Infrastructure UK is also overseeing the planning of infrastructures across departments. The planning of individual projects is also supported through institutional machinery such as the Gateway Review Process and the Major Project Authority. The latter, located in the Cabinet Office, is now in charge of strengthening assurance and support for major projects over the whole lifecycle of the project.³ The details of these projects would fall within the current transparency agenda, and hence be made available on the Internet. Yet, this overall transparency strategy may leave some bidders wary as publishing on-line schedules including winners' bids may contain innovative techniques (Henty and Mannings, 2011).

Secondly, individuals have been refused standing in public procurement, as rejected bidders looking after their self-interest are supposed to best represent individuals' interests regarding the proper application of public procurement.⁴ Recent case law shows that this principle may be curbed in the future in favour of recognising the standing of individuals who are affected in an identifiable way by non-compliance with public procurement (Bailey, 2010).

Thirdly, individuals may use other legal means to challenge construction projects or get information on their operation than public procurement however. They can act as part of the collectivity (or of the overall system). They have then met with mixed success. The *Veolia* case shows how a decentralised approach to transparent decision-making and control of taxpayers' money is delicate. In this case, a local elector used the *Audit Act 1998* to get access to Veolia accounts relating to the performance of a waste management contract. The local authority was willing to disclose the information, but Veolia challenged the decision on grounds of commercial confidentiality. In first instance, the reasoning was not followed, but the Court of Appeal accepted limiting the *Audit Act 1998* to preserve commercial confidentiality: some of the information would even be protected by the ECHR, and its first protocol (art. 1).⁵

Formalised/institutionalised public control interfaces between taxpayers' money invested in public projects and services provided to end-users. How can this formalisation transform a market failure into a successful market? According to project management, partnering bridges complexity and innovation and is badly needed in complex infrastructure projects. Yet, procurement regulations do not leave any formal space for partnering, assuming that public authorities' discretion should not be trusted.

¹ Science and Technology Committee, *Public Procurement as a Tool to Stimulate Innovation* (148 HL 2010-12) recommendation 8.

² Cabinet Office, *Government Construction Strategy*, 2011, para 2.6.

³ HM Treasury and Cabinet Office, *Major Project Approval and Assurance Guidance*, 2011, 19 p.

⁴ *R (Kathro) v Rhondda Cynon Taff Country BC* [2002] Env LR 15.

⁵ *Veolia ES Nottinghamshire Ltd v Nottinghamshire CC* [2010] EWCA Civ 1214.

This results in a strengthened need for state oversight of infrastructure planning and project organisation from design to implementation. So far, only limited access to the overall emphasis on transparent decision-making about public money in complex procurement has been given to individuals. Furthermore, commercial confidentiality leaves a space open to parties' negotiations once the issue has been submitted in principle to a judge. The tensions in the information flows thus lead to a requirement that private contractors disclose more information to their competitors or to public authorities voluntarily, on conditions that the public does not gain a far-reaching right to proper access. These tensions can interplay differently. Belgian PPPs show how the formalisation of decision-making and extended disclosures of reasons has led to a shift in discretion to judges and experts.

3 Complexity in Belgian PPPs: paralysis in public choices

In England, developing a complex infrastructure project suggests the management of relationships between public authorities and private contractors. These are currently being formalised and institutionalised from the start to the termination of a project. Information exchanges are developed to foster both cooperation and competition, with strategic approaches by the parties on both accounts. This only partially reinforces the needed trust, both between the contracting parties and among the market players in general. The overall process happens the other way round in Belgium. The legal framework limits public discretion, with little space for organising projects creatively. Public discretion appears paralysed.

The procurement of Belgian infrastructure projects is first and foremost a legal matter, before a planning or management one. The starting point for procurement has become highly formalised. High levels of judicial challenges have followed, many based on the violation of the duty to give formal justification of how decisions have been taken. The balance between transparency and commercial confidentiality has given rise to a displacement of discretion from the parties or public authorities to judges and experts. Finally, besides all these highly formalised solutions, cooperation between public authorities and contractors is encouraged around the law itself. The contrast between the two approaches highlights the need to map out the variety of solutions in order for public authorities to tailor procuring major construction projects to their specific challenges.

3.1 Formalism and routine litigations: key-ingredients to planning procurements

Procuring complex projects in Belgium stumbles over a basic choice between concession and public procurement. Concessions require that the private party bear most of the financial risks and because no public money is at stake, only a general principle of transparency applies. Public procurement regulations are used when a public authority pays for the works and services provided by private partners and therefore bear most of the risks. The main issue is that risk allocation is only known at the end of the decision-making process but needs to be anticipated by the public authority so that the proper processes and transparency formalities are applied. Public authorities may be tempted to set the highly detailed Belgian procurement framework aside whenever possible. Yet, the administrative court, the *Conseil d'Etat*, strengthened the rigid legal framework to control narrowly how public discretion is exercised, so as to limit discretion and risky creativity in the contractual relationship. Formalism is imbedded in

the system on three accounts: contractual documentation, available procurement routes and the legal challenges enforcing these.

The first source of formalism in Belgian procurement regards the procurement route. This developed from old practice based on scholarship stressing the risks of possible abuse of their discretion by public authorities (Flamme, 1990). The classic directive opens up the possibility of procuring projects on the basis of open and restricted procedures, competitive dialogue and the negotiated procedure. Each of these routes triggers problems. First, open and restricted procedures do not leave space for the required reciprocal adjustments to the complexity of a construction project. Secondly, the 2006 Belgian statute transposing the classic directive mentions the competitive dialogue as a possible route for complex public procurement.¹ However, the statute is not yet in force due to a lack of the required statutory instruments for developing the bare legal provisions. Thirdly, the negotiated procedure is the last option open. It is especially interesting as it allows for MEAT and is more flexible regarding the tendering process. It is however an exceptional procedure, available under limited conditions. Because of misuses of the negotiated procedure, the *Conseil d'Etat* exercises great scrutiny of it (Durviaux, 2008a). Facing this dramatic situation where the legal framework does not leave much formal space for cooperation, discussions and innovations from bidders during project negotiations, current literature advocates the development of a more flexible legal framework for complex projects (Durviaux, 2010).

The second source of formalism in Belgian procurement revolves around the use of 'mandatory special terms' (*cahier spécial des charges*) and 'general standard terms' (*cahier général des charges*). These apply to contracts alongside the statutory provisions and instruments. General standard terms set the main conditions applicable to the performance of all procurements. Procuring authorities then draft special terms relevant to a particular contract: this is normally at the start of the process, prior to any knowledge of the bids. The general standard terms have become quasi-mandatory and do not allow for much adaptation (Flamme and Flamme, 2006). The special standard terms can only derogate to the general standard terms for issues essential to specific requirements of the project.² The *Conseil d'Etat* closely scrutinises the 'special justification' these derogations require. A rejected derogation will not apply to issues supervening during contract performance. This rigid system does not allow for adjustment to the specific needs of the public authorities, often seeking to embed contractual documents similar to the English PFIs in their general terms. The technique of labelling projects as 'PPP' to justify these derogations is debatable: no legal features in PPPs make them inherently different to other contracts (Rekenhof, 2008-2009, 65; Van Garsse, 2007; Durviaux, 2008b). Scholarship, however, suggests that a legal basis for adapting the public procurement statutes to PPPs would be needed in this respect as well as in the available procurement routes (Durviaux, 2008c).

The third source of formalism and rigidity in Belgian public procurement is the extent to which judicial challenges are legally open and are effectively used. The *Conseil d'Etat* has no jurisdiction to annul a contract but may well strike down any decision taken by the public authority (Mast et al, 2009). Over the course of the decision-making about the choice of contracting party, a range of decisions may be taken. Therefore the question of the timing in challenging these decisions arises. The *Conseil d'Etat* decided that all

¹ Loi (Act) 15 June 2006 *relative aux marchés publics et à certains marchés de travaux, de fournitures et de services* art 27.

² Arrêté royal (*Royal Decree*) 26 September 1996 *établissant les règles générales d'exécution des marchés publics et des concessions de travaux publics*, art 3.

these interlocutory decisions may (but not should) be challenged together with the end-decision. This means that even the specific standard terms, one of the first stages of the whole process, may be annulled. Finally, these judicial avenues are regularly used. For instance, various challenges against a water treatment project in Brussels were brought to the *Conseil d'Etat*.¹ In Belgium, litigation as a process around the procurement process needs to be integrated as a matter of routine into the planning of the procurement process. These circumvolutions may be best illustrated with transparency.

3.2 Transparency on trial: tensions in protected interests

The constraints on the processes followed in public procurement are becoming increasingly formal, narrowing down public discretion. Yet some discretion may emerge as public authorities have to respect conflicting duties such as that flowing from transparency and commercial confidentiality. Belgium, however, illustrates that the discretion to balance these interests is not ultimately borne by public authorities but by judges, occasionally helped by experts.

Belgian public authorities face layers of far-reaching duties. They have to respect general principles of good administration,² a general duty to give formal reasons³ and a specific duty to give reasons in public procurement matters⁴. This last duty applies across EU and domestic procurements. In theory the specific duty to give reasons requires more information to be given to interested persons: however the general duty to give reasons covers possible gaps in the public decisions not covered by the specific duty but still relevant for participants in public procurement in various ways.

Bidders have used these far-reaching duties to give reasons for challenging public decisions. Public authorities are indeed compelled to provide a court file to the administrative judge, to which the claimant has access. The court file has to contain all the information public authorities relied on to arrive at their decision, including thus potential confidential information. This is used to ensure that the claimant can access all relevant information. Yet, this may conflict with the protection of commercially sensitive information in public procurement. The *Varec* case provides a starting point for mapping this conflict. In this case, the *Conseil d'Etat* referred the matter to the ECJ and the Constitutional Court.⁵ These courts arrived at a roughly similar solution. The ECJ⁶ highlighted that public procurement mainly aims to ensure undistorted competition. Public authorities should not disclose commercially confidential information. Furthermore, awarding procurement contracts is 'founded on a relationship of trust' between authorities and bidders. Hence, bidders need to be unafraid that the public authority will disclose commercially confidential information. Yet there is a need to balance these principles with the right to a fair hearing. The review body (in this case the *Conseil d'Etat*) must then have full access to the information required to decide with full knowledge of the facts – commercial information included –.

The *Varec* case has resulted in review bodies having to strike the balance on a case-by-case basis. Typically, the solution has been formalised in a statutory provision without guiding the judge further on how to cope with the matter.⁷ Scholarship draws attention

⁷ Loi (Act) 24 December 1993, new art. 65/26.

to the lack of clarity about the principles mapping judicial intervention here (Gonthier and Vastmans, 2010). Three main options are open: firstly, commercial information is not relevant to the outcome of the case and can be put aside; secondly, information is mildly confidential and relevant to the solution and then the judge has to transmit it to the claimant; thirdly, information is highly confidential and crucial for the solution and the judge may then have discretion over whether or not to disclose it (Bombois et Dubois, 2008). Scholarship approaches the issue from an all-or-nothing perspective, a choice between disclosing or not. The alternatives of partial disclosure, retraction and compensation for confidentiality are not considered, while the Constitutional court had hinted at these.¹ The *Conseil d'Etat* uses procedural tricks to avoid the issue. In most cases decided since *Varec*, such information was deemed not necessary for the *Conseil d'Etat* to decide the case (Gonthier and Vastmans, 2010). However, in at least one case, the *Conseil d'Etat* asked an expert to give his opinion on confidentiality.² Nowhere the solution developed in England of enjoining parties to negotiate suitable protections has been mentioned in Belgium.

Transparency is however a powerful legal weapon in the hand of rejected bidders. They use the argument often. From the *Conseil d'Etat* decisions where the claimant stopped the judicial process and the awarding authority decided to re-run the procurement, one may assume that rejected bidders may convince the public authority of irregularities in the procurement process. In a way, this looks like a form of cooperation in securing the regularity of public decisions.

3.3 Cooperation in the shadow of the law

As explained in Sections 3.1. and 3.2, Belgian public procurement is basically formal. Yet, at the margins of this far-reaching formalisation, cooperation occurs in various forms. Four cases illustrate this practice of cooperation throughout the whole process framing the development of construction projects.

First, the cooperation between public authorities and private contractors starts at the very general level of formalising public procurement rules. Indeed, the statutory instruments implementing EU directives are drafted in a specific body, the *Commission des marchés publics*, with representatives of public and private sectors.³

Secondly, cooperation is acknowledged through codes of ethics, focusing on the behavioural norms civil servants should endorse in carrying their duties. The codes of ethics are currently in a developmental stage, so that the specific modalities of this acknowledged cooperation have to be worked out formally (Judo and Nolet de Brauwere, 2010).

Thirdly, cooperation between public and private entities is also present during the actual development of complex construction projects. For instance, market analysis – or the sounding out of the market before formally launching procurement – is allowed, as it does not fall under the procurement regulation as such. Yet, these market investigations have been detailed in official guidance.⁴ Furthermore, public procurement regulations contain some provisions which can be interpreted as incentivising a lightly cooperative attitude between public and private entities, for instance in the correction of mistakes in

¹ Constitutional court, above (n 5) para B.9.3.

² CE, nr 184.598, 24 June 2008, Siemens.

³ Arrêté royal (Royal Decree) 10 March 1998 *organisant la Commission des marchés publics*.

⁴ Kenniscentrum PPS, *Marktverkenning- en raadpleging door openbare besturen*, 2008, 106 p.

the bids or the procurement documents (Lindemans and Honnay, 2010, disputed in Durviaux, 2010). Finally, public procurement regulations explicitly prevent some types of information (esp. confidential information) being transmitted to bidders. Other types of information may then be part of communication and cooperation between public authorities and bidders.

Finally, cooperation may be traced up to the litigation stages: the decisions of the *Conseil d'Etat* bear the marks of parties using alternative means (phone calls or 'privileged information routes') to get information such as justification for the public decisions.¹

That Belgian public procurement is over-formalised seems obvious. The tight general standard conditions do not leave much space for innovation and creativity. However, these general standard conditions have been incrementally developed to respond to problems of trust in how public authorities may use their discretion in public procurement. However, interactions and cooperation are also present throughout the procurement policy and projects. The over-formalisation of the process does not prevent less formal ways of behaving. Yet, the modalities of these behaviours are not clearly framed, which does not help transparency or trust in how public decisions are made.

4 Conclusions

Comparing the Belgian and English legal systems highlights how competition and cooperation need to be articulated to develop complex construction projects. This articulation stumbles on how trust should be maintained across the market, between the interested parties and from the public. Transparency plays a cardinal role here; yet its modalities, extent and limits lead to the development of alternative mechanisms to compose the trust required from some actors. This middle ground is inhabited by expertise, parties' arrangements and public pressure vary is framed by two levels of tensions: within the actors of the system underlying construction projects and within particular public-private relationships developed around specific projects.

On the one hand, the general logics of the two systems are mirror images of each other. In England, the process tends towards more formalisation and institutionalisation. Cooperation in the form of partnering does not entail legal consequences but is to some extent formalised in one document developed by the parties: partnering agreements are drafted detailing the positions of each party and communicating to the other the basic principles of the relationships and mutual expectations. In Belgium, the process would tend towards de-formalisation. The overall interactions between the public authorities and the private contractors are not formalised. One finds that cooperation or interactions between the public and the private parties are allowed because they are not prohibited, because they do not fall under an interdiction or specific procedures in the public procurement process (e.g. the case of market analysis). Sometimes, the statutory provisions provide steppingstones to cooperation or exchange of information in encouraging bidders to ask for information or clarification. Sometimes, the statutory provision emphasises the need for soft formalisation with a code of ethics setting standards for professional conduct – yet, only encompassing the public officials. This stage is still difficult to implement. The overall picture of Belgian cooperation does not find one single focal point of attention.

¹ Eg: CE, nr. 181.351, 19 March 2008, Dalkia.

On the other hand, there are situations which are to a large extent parallel in the UK and in Belgium. The typical case this paper brings up to illustrate this is the commercial confidentiality issue. Because of the large EU procurement requirements in this area, the basic pattern is similar in terms of the interests in tension: commercial confidentiality vs. transparency and competition. Yet the ways in which the interests are articulated bear the marks of the different legal cultures relating to discretion. In England, the judge recognises that parties have a part to play in working out a solution to commercial confidentiality. In Belgium, the administrative judge carries a wider discretion in shaping the solution. This may bring in an expert which then, on his turn, exercises discretion.

This paper suggests that in mapping the tensions between competition and cooperation tensions arise around transparency and trust. However, questions of priority may be asked in addressing the key issues underlying arguments in favour of full transparency and competition. Both aim at eradicating endemic problems of bad use of public discretion to the detriment of the public purse (and in parallel of an efficient market where players are fully competing). However, there are alternatives to full transparency which may also contribute to reducing these practices or fears. In this respect, a strengthening of ethics within organisations may be at least an important factor. The codes of ethics may help but, taken on their own, they may not be enough, too weak or too recent (the Belgian case). Developing layers of structures with each one supposed to help achieve transparency does not necessarily result in clearly articulated public control: rather, this probably disturbs more than provides the trust that transparency is supposed to bring about (the English case).

This analysis suggests that a legal analysis of complex construction contracts may benefit from a comparative approach, highlighting how these projects are embedded in an institutional context in which project management and ethical norms are more or less acknowledged and welcome. Conversely, as management research seeks to develop a better understanding of partnering, the legal and institutional contexts in which it interacts may need close attention.

Abstract:

Since around the millennium a tendency has been that more and more tendering cases in Denmark are brought to The Danish Board of Complaints on Tendering (In Danish: Klagenaevnet for Udbud). During the last two years there has been a stagnation in the number of cases, but this tendency started already in 2004. Many cases are going to arbitration because the parties in the tendering process do not know how to handle the tendering process in a proper way.

A prior analysis of cases from The Danish Board of Complaints on Tendering from 2000 until 2008 shows that the number of cases which ended up in The Danish Board of Complaints on Tendering were increasing in these years and that the types of topics were fundamental items, among others, assignment criteria.

A new examination going from 2000 until 2010 shows that there is a sort of stagnation in the number of cases in 2009 and 2010, but more and more cases are on topics like purchase and purchasing of service provided. If cases concerning the Building Sector are selected the examination shows that the stagnation in the number of cases already from 2004, which shows that some participants have learnt to use the Danish Tendering Act and the European tendering legislation even when criteria such as interpersonal and technical competencies are used instead of the price.

assignment, tendering laws, building sector, communication

1 Introduction

1.1 History

From 1993 the European Union began to make rules for the tendering process. Before, Denmark had its own special Competitive Tendering Act very different from the EU law. The Danish Competitive Tendering Act was changed in 2001 to make sure that the Danish tendering laws are like the EU tendering law, which means that now European as well as Danish legislation are in force for the process (Fabricius, 2006).

When the European Union in 1993 started making rules about tendering, the Danish Parliament also established The Danish Board of Complaints on Tendering in 1993 to take care of potential complaint cases in Denmark.

1.2 Now

Until the late 1990s the Court of the European Union had only a few cases, but since then the number of cases has increased (Nielsen R. and Treumer, S., 2005). In Denmark the trend is the same (Ussing, L.F., 2008). At the same time it has become more and more normal that instead of using only the price, clients combine other assignment criteria together with price.

In the beginning the rules were not very well known in Denmark, but during the last years nearly everyone know, that EU rules exist, which you have to follow in a tendering process. Therefore The Danish Board of Complaints on Tendering is now generally known as well. So if a bidder finds, that the supplier does not follow the rules, then he will complain.

In the last few years a significant changes can be observed in the topics in the complaint cases. An analysis of cases from The Danish Board of Complaints on Tendering from 2000 until 2008 shows a change in the total number of cases ended up in The Danish Board of Complaints on Tendering where an increase in fundamental topics, such as others assignment criteria appear (Ussing, L.F., 2008).

These topics are still some of the biggest problems, but a new investigation shows a stagnation in cases relating to the building and construction sector, but a big increase in the total number of cases relating to purchase and purchasing of service provided.

2 Literature Review

The references in this article are mainly based on work and results from a PhD project (Faber Ussing, L., 2010) finished in 2010. In this PhD study, a literature study was made, but the findings were that only very little journal articles deal with the EU bidding law and the building sector, but to discuss the analysis and the conclusion in this paper a literature review for international journal articles has been made. The search has been made systematic mainly based on (Pittaway, L., Robertson, M., Munir, K., Denyer, D., Neely, A., 2004) and (Cankaya, A., Lassen, A., Wandahl, S., Poulsen, S., 2010). The search was made in the following database for journal articles: Academic Research Library, IBZ, Emerald and Web of Science. Tendering law was the first search word and this lead to around 450 articles. Following, the search words: building sector and EU were added. Building sector reduced the number of articles to 220 and following, EU to 43. Articles from after 2008 reduced the number of articles to 10. The 10 articles have been studied and 3 are found relevant for the paper, but only 1 deals directly with cases inside EU.

3 Research Methodology

The purpose of this paper is to show the changes in the Danish building sector over time by using facts from court decisions made by the Danish Board of Complaints on Tendering.

The investigation is made by counting all cases conducted by The Danish Board of Complaints on Tendering. Afterwards the cases are dividing into two groups; relating to the building and construction sector and not relating to the building and construction sector.

An investigation is also made of how many cases were submitted to The Danish Board of Complaints on Tendering but in the end withdrawn again, which means that they do not count in the total number of cases.

4 Findings and Discussion

4.1 Decisions taken by the Danish Board of Complaints on Tendering

The main task for the Danish Board of Complaints on Tendering is to investigate complaints in the tendering process. That means all sort of tendering processes in the building sector, but also in other sectors. The Board is not a court of justice but similar, which means that the decisions can with few exceptions be presented to The Court of Justice.

Decisions taken by the Board can have the following rulings: The tender can be annulled. The tender can be made legal. Compensation can be decided and some of the cases can have a delaying effect. (Ussing, L.F., 2008)

4.2 Number of cases from the Danish Board of Complaints on Tendering

An earlier paper (Ussing, L.F., 2008) shows the topics in all cases brought for the Board of Complaints from the beginning of the Board of Complaints until the 16. April 2008. The paper also shows the total number of cases.

The most presented topics are on fundamental legislations items; a tender has to be transparent and treat all bidders equally (Fabricius J. and Offersen, R., 2006). Details from (Ussing, L.F., 2008) show problem with fundamental topics items as e.g. assignment criteria.

The investigation from the paper (Ussing, L.F., 2008) includes all cases, but during the last years more and more cases have been on topic like purchase and purchasing of service provided. Therefore it can be interesting to investigate the cases concerning only the building sector.

A new investigation on the cases from the Danish Board of Complaints on Tendering has been made. It includes all cases from 2000 until the end of 2010 brought before the Danish Board of Complaints on Tendering and ending with a ruling.

4.2.1 Total number of cases conducted at the Danish Board of Complaints on Tendering

Figure 1 shows the total number of cases conducted at the Danish Board of Complaints on Tendering and also the total number relating to the building and construction sector.

The figure shows an increase in the number of cases in total, but when the building and construction sector are selected a stagnation in the number occurs from 2004.

Fig. 1 Number of cases conducted at The Danish Board of Complaints on Tendering (Klagenævnet for udbud, 2011)

The increase from 2000 until 2004 can be explained with the fact that more and more bidders are aware of EU tendering rules and demand the supplier to use the rules in the right way. From 2004 until 2006 a stagnation appears, which can be explained by the fact that bidders and supplier now know the rules and also have learned to use them.

In 2006 the European Commission published the Commission's rendering announcement (2006/C179/02). This announcement means that a public client has to be careful if not following the EU-directives, because in practice this means that the EU-treaty from 1993 at all times is in force and basic rules and principle as free movement / flow of goods and services, no discrimination and equal treatment, transparency, proportionality and reciprocal recognition, also when the project is lower than the threshold values. (Ussing, L. F., Wandahl, S., Bejder, E., 2010)

The European Commission's rendering announcement about the community law can explain the increase from 2006 until now. Suddenly a lot of small suppliers and bidders have to use some rules they did not know before. They have to learn the rules and learn to use them. At the same time a lot of cases relating to purchase and purchasing of service provided are under the thresholds values and therefore not directly covered by the EU directives.

4.2.2 Number of cases conducted at the Danish Board of Complaints on Tendering relating to the building and construction sector

Figure 2 shows the total number of cases in the building and construction sector. You can see the stagnation going from a few in 2000, 2001 and 2002 to 15 cases in 2003 and then a rise to 23 in 2004. After 2004 the number has been nearly stable on 21, 21, 22 and 24, respectively. In 2009 and 2010 an insignificant increase to 28 and 29 cases can be found.

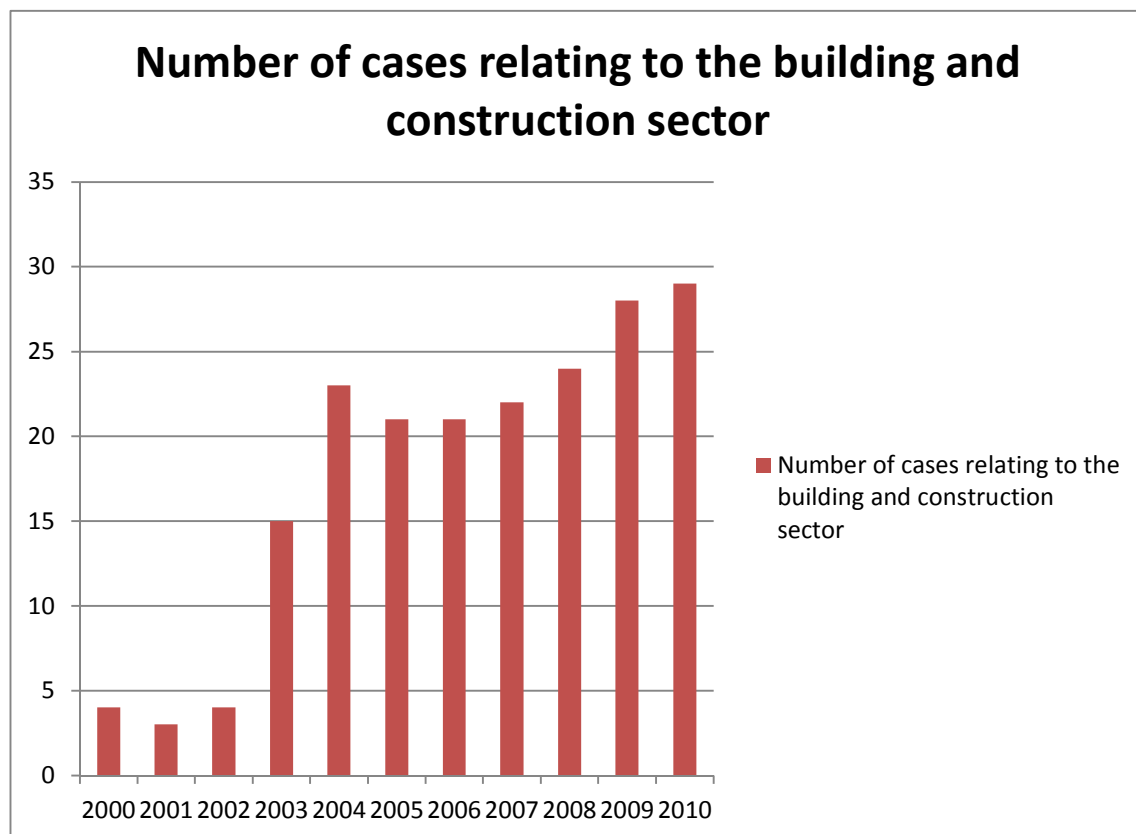

Fig.2. Number of cases conducted at the Danish Board of Complaints on Tendering relating to the building and construction sector (Klagenævnet for udbud, 2011)

The stagnation in 2000, 2001 and 2002 can be explained with that the rules in the late 1990's became well known in the Danish building sector because of the EU case about the "buy Danish clause" on the Storebaelt Bridge. (Konkurrencestyrelsen, 2008)

Because of the case on the Storebaelt Bridge in 2001, the Danish Parliament changed the Danish Tendering Act. The new Tendering Act follows the rules from the European Union, so now almost the same rules have to be followed at all times in Denmark, if you are a public client (Ussing, L.F., 2008), even when you are under the threshold value for the EU directives.

The new tendering act which is valid only for the building and construction sector can be reflected in the increase in the number of cases in 2003 and 2004. Small building projects are suddenly included by the rules, and new players have to learn the rules.

From 2005 the numbers of cases seem to be steady. Two reasons can explain this; in Denmark a building boom happened and all the participants had a lot of work and therefore no time for complaints. Another reason can be that the participants in the building and construction sector now had learned to use the rules properly.

The little increase in 2009 and 2010 can be explained with an overheated market in the building and construction sector in 2007 and 2008 followed by a significant decline in the building and construction activities in 2009 and 2010 (The Danish Construction Association, 2011).

With a decline in activities in the building and construction activities more cases are presented to the Danish Board of Complaints on Tendering. The explanation can be that the bidders have more time to look at the rules, more time to find slips and then complaint. (Faber Ussing, L., 2010)

If the number of cases are examined which have been conducted at the Danish Board of Complaints on Tendering in 2011 until now (15. April 2011), and the year will end as the first part (Klagenævnet for udbud, 2011), a 20% increase in the total number of cases from 2010 to 2011 can be found, but still almost a stagnation in the cases relating to the building and construction sector.

The reason why the number of complaint cases in the building and construction sector seems nearly stable in 2011 regardless of an ongoing crisis in the sector can be that the participants have learned to use the rules.

4.2.3 Number of withdrawn cases submitted to the Danish Board of Complaints on Tendering

Before discussing why the total number of cases increases as the same time as a stagnation in the cases relating to the building and construction sector occurs, it can be interesting to take a look at the number of withdrawn cases submitted to the Danish Board of Complaints on Tendering.

Figure 3 shows the number of withdrawn cases submitted to the Board of Complaints from the beginning of 2004 until the end of 2009. In 2004 there were 9 retired cases, in 2005 the number declines to only 5, in 2006 the number increases to 10, finally in 2007 and 2008 the number increases to 24 and 24 respectively. In 2009 the number of withdrawn cases was as big as 36.

None of the withdrawn cases can be seen in the official list of total number of cases submitted to the Danish Board of Complaints on Tendering. The cases are withdrawn because the Danish Board of Complaints on Tendering estimated them to have no substance for a case, and the parties have settled and therefore was given the permission to withdraw. (Klagenævnet for udbud, 2010)

The increase of withdrawn cases submitted to The Danish Board of Complaints on Tendering can be explained with the total number of cases submitted to the Board of Complaints. When the total number of cases increases it is logical that the graph for withdrawn cases will follow the graph for the total number of cases, and therefore increases too.

Fig. 3 Number of withdrawn cases submitted to the Danish Board of Complaints on Tendering (Klagenævnet for udbud, 2010)

The number of withdrawn cases includes all topics of cases, which gives a little problem. The part directly related to the building and construction sector, may develop differently. But it is not known how many of the cases are related to the building and construction sector, therefore it must be assumed that the graph for withdrawn cases related to the building and construction sector also follows the graph for the total number of cases related to the building and construction sector.

5 Conclusion and Further Research

5.1 Changes in making a public procurement in Denmark

After changing the Danish Tendering Act in 2001 with the last revision in 2007, Denmark has change the procedure for making a public procurement. Before 2001 the building and construction sector was assigned to a tendering law where the only assignment criterion was the lowest price. This changes after 2001 where you were now allowed to use the assignment criterion: economically most advantageous bid. (Nielsen R. and Treumer, S., 2005)

The cases from the Danish Board of Complaints on Tendering have been divided in two parts; cases related to the building and construction sector and cases not related to the building and construction sector. The last part is mainly cases related to purchase and purchasing of service provided.

Before 2001 parties related to purchase and purchasing of service provided outside the building and construction sector were not assigned to any law or rules except the Danish Sale of Goods Act. The result was that they could make agreements nearly in the way they wanted with no involvement.

From 1993 all parties over the threshold value were with the EU directives assigned to the directives. But the Danes did not realise this, because it was small jobs. In 2001,

with the new Tendering Act which is adjusted to the EU-directives a lot more participants were assigned to rules and at a lower threshold value. But the Tendering Act is only valid for the building and construction sector. The result was that everyone else could do as usual. In 2006 when the European Commission published the Commission's rendering announcement (2006/C179/02), it was suddenly serious for the Danes; they all had to follow the EU directives. (Nielsen R. and Treumer, S., 2005)

Before the Danes began using the EU directives, they made a lot of contracts according to; who do we know, and who do we trust? (Ebbesen, R. M. and Ussing, L. F., 2007) This is perhaps special for agreements in Denmark and the other Nordic countries (Camén, C., Gottfridsson, P., Rundh, B., 2011), but the result is that the Danes in a lot of projects use the assignment criterion: economically most advantageous bid (Faber Ussing, L., 2010). Because it fits best the approach: whom do we know, and whom do we trust?

5.2 Using economically most advantageous bid as criterion

When using economically most advantageous bid as criterion some problems arise. You have to make the selection and the assignment to be free movement / flow of goods and services, no discrimination and equal treatment, transparency, proportionality and reciprocal recognition. It is quite easy when you use lowest price as criterion, but when you use economically most advantageous bid, and want to work together with whom you know and whom you trust, it is not easy anymore.

You have to find selection and the assignment criteria as cooperation, personal skills, interviews and organisation. They are not the easiest in the world to make measurable and unambiguous, but it is possible. (Faber Ussing, L., 2010)

5.3 The building sector has begun to learn to use the EU directives

In the last few years more and more suppliers in Denmark use economically most advantageous bid with selection and the assignment criteria as cooperation, personal skills, interviews and organisation (Faber Ussing, L., 2010). It is getting accepted to do the bidding process in that way, but it takes time to learn it.

Therefore the conclusion must be; the building and construction sector has started before the other sectors because of the rules, and the cases conducted at the Danish Board of Complaints on Tendering relating to the building and construction sector are in stagnation. Research shows that the building and construction sector wants to use economically most advantageous bid with selection and the assignment criteria as cooperation, personal skills, interviews and organisation, and it is getting accepted in the field. Those two things must mean that the participants in the building sector have started to learn to follow and use the rules of the EU Laws and the Danish Laws. (Faber Ussing, L., 2010)

The participants related to purchase and purchasing of service provided outside the building and construction sector have, if you look at the total number of cases conducted at the Danish Board of Complaints on Tendering, not learnt to follow and use the rules yet.

5.4 Further Research in cases conducted at the Danish Board of Complaints on Tendering

In the next years it will be interesting to follow the development of the number of cases conducted at the Danish Board of Complaints on Tendering to see if it still increases, declines or gets stable. And moreover to see if it is possible to find out why.

Challenges of Spent Nuclear Fuel Management in Korean Nuclear Plant Construction: Can Pyroprocessing Be a Solution?

Sangmin Shim¹

¹JSD Candidate, Stanford Law School, Stanford, CA 94305, U.S.A.
Republic of Korea

Email: smshim@stanford.edu

Abstract:

This paper explores the extent to which difficulties in spent nuclear fuel management constrain the continued expansion of nuclear plant construction in Korea, and analyzes the legal issues surrounding pyroprocessing, a new method of recycling spent nuclear fuel that makes it extremely difficult to produce weapon-grade plutonium at the end. Whereas nuclear power enjoys renewed attention because of its near-zero carbon emission, cost concerns on disposing of spent nuclear fuel conflict with the prospect of vigorous nuclear plant construction in Korea. Those cost concerns come from the fact that recruiting a geologically stable storage site is confronted with opposition from local population, while reprocessing spent fuel within the Korean territory is not possible without U.S.'s consent under the Agreement for Cooperation between the Government of the Republic of Korea and the Government of the United States of America Concerning Civil Uses of Atomic Energy¹ (hereinafter Nuclear Cooperation Agreement). Pyroprocessing, meanwhile, is potentially an attractive option because it is proliferation-resistant and could in the long run lead to lowering the cost of spent nuclear fuel management compared to reprocessing or transboundary movement of spent nuclear fuel. The question is whether this new technology of advanced fuel cycle also falls under the same rubric of "reprocessing," which is effectively blocked under the current Nuclear Cooperation Agreement. In light of the upcoming negotiations for the terms of a new nuclear cooperation agreement, this paper suggests a balance test in interpreting the relevant treaty provisions, which takes into account both proliferation concerns and potential benefits from continued research on such a new advanced fuel cycle as pyroprocessing. This paper concludes by proposing several applications of the balance test that would allow pursuit of research in that technology along with research sharing between the two countries, in exchange for assumed prior consent on pyroprocessing.

Keywords:

Korea, Spent Nuclear Fuel Management, proliferation, pyroprocessing, balance test, assumed prior consent

1 Introduction

Not many power generation sources receive so much attention as nuclear power, for reasons ranging from nuclear safety to near-zero emission of greenhouse gases. While

¹ Entered into force on 19 March 1973, United Nations Treaty Series, Vol. 911, I-12986.

controversies surrounding nuclear power will intensify in the wake of the Fukushima nuclear accident in March, 2011, nuclear power will likely remain as one of the main sources of power for major economies, and Korea will no doubt be one of them, because of its climate-friendliness, significant efficiency in terms of land to be used (Bryce 2011), and fuels to be spent. In fact Korea is set to increase nuclear power's share in national generation portfolio from around twenty-four per cent in 2008 to forty-one per cent in terms of generation capacity by 2030 (Ministry of Knowledge Economy and Korea Hydro & Nuclear Power, 2009; World Nuclear Association 2010). Considering Korea's commitment to voluntarily reduce greenhouse gas emissions for thirty percent compared to business-as-usual emissions by 2020 (Kang 2009), nuclear power will likely expand even further.

The cost concerns of various kinds may hamper nuclear power's smooth expansion in generation portfolio, however. While there are several cost items related to nuclear generation, the cost concerning spent nuclear fuel management is conspicuous in two ways. On one hand, long-term storage and ultimate disposal of such spent nuclear fuel involves acquiring a large swath of geologically stable land, a requirement that is not easy to meet in many cases. On the other hand, since spent nuclear fuel still contains uranium that can be converted into weapon-grade nuclear material through reprocessing, a careful watch on what to do with spent nuclear fuel is a requisite from nuclear non-proliferation perspectives. This is why reprocessing, which extracts pure plutonium from the spent fuel and makes it usable for a certain type of nuclear reactors (Greenberg 2009; World Nuclear Association 2011), is often looked upon suspiciously because plutonium is useful for military purposes.

As storage and reprocessing will not present themselves as ideal solutions for spent nuclear fuel management in Korea, discussion on "pyroprocessing" gains more traction in the field of Korean academics and policymakers. This technology is relatively free from concerns on proliferation as it will make extraction of plutonium difficult compared with reprocessing, while the end outcome could be fabricated for fuels on a new type of nuclear reactors. If this technology proved to be economically viable, it would work greatly towards solving a difficult question of how safely and cheaply to dispose of spent nuclear fuel.

The biggest legal hurdle facing pyroprocessing in Korea's context is the Nuclear Cooperation Agreement. According to this agreement, the United States' consent is a prerequisite when Korea hopes to reprocess, or alter in form or content nuclear material received from the United States,¹ effectively blocking Korea from reprocessing spent nuclear fuel and subjecting Korea's freedom of action to the United States' political criteria (Hahm 2009). The question relevant here is whether "pyroprocessing" falls under the rubric of "reprocessing", requiring the United States' prior consent on a case-by-case basis. Incidentally the agreement will expire in 2014², and while the Korean government is negotiating with U.S. on the terms of renewal, hopes are high on the Korean side that the agreement will be revised so as to allow Korea more freedom to pursue pyroprocessing without being too concerned about the treaty provisions.

To address this question of whether to allow pyroprocessing under the new Nuclear Cooperation Agreement, one should carefully look at what pyroprocessing exactly means, as well as its potentials and limitations, before jumping into the investigation of

¹ Article 8 of the Nuclear Cooperation Agreement.

² Article 15 of the Nuclear Cooperation Agreement stipulates that it "shall remain in force for a period of forty-one (41) years". Since the said agreement entered into force in 1973, the agreement is interpreted to expire in 2014.

the language in the agreement and coming up with possible solutions. In addition, more information needs to be provided on other methods of managing and disposing of spent nuclear fuel, to put pyroprocessing in perspective with cost concerns duly taken into account. Therefore this paper starts with the discussion on the options of spent nuclear fuel management, which are storage, reprocessing and transboundary movement. It then proceeds to discuss pyroprocessing in more detail, followed by the analysis of the Nuclear Cooperation Agreement with a focus on the provisions governing reprocessing and alteration in form and content of U.S.-origin nuclear material. It concludes with suggestions on how best to interpret pyroprocessing in view of both non-proliferation and nuclear waste management, followed by some possible applications of a balance test that will altogether accommodate due concerns on proliferation as well as on cost control.

2 Spent Nuclear Fuel and Cost Concerns for Nuclear Plant Construction in Korea

Korea has relied much on nuclear energy to power vigorous economic growth in the past three decades, and it plans to build more nuclear power plants in the next few decades or so. However, this rapid expansion of nuclear capacity in Korea generated excessive amounts of radioactive waste material, and spent nuclear fuel is one of them. Since its highly radioactive character, spent nuclear fuel should be put under tight control measures, which will necessarily incur huge costs. This section describes the currently available management options for spent nuclear fuel in Korea, which is on-site and interim storage, and explains why it has to be the order of day over other available solutions.

2.1 Current Approach to Spent Nuclear Fuels: On-Site and Interim Storage

Currently Korea runs a total of 20 nuclear power plants, and the amount of spent nuclear fuels taken out from those nuclear reactors keeps increasing, marking 10,083 tons of spent nuclear fuel in 2008 with an annual increase of 700 tons expected as well (Park 2009). To deal with such a vast amount spent nuclear fuel, Korea has relied on a measure of storing them on each nuclear plant site, using both wet and dry storage facilities. Since their planned storage capacity is almost full, a new work on expanding interim storage capacity for each nuclear plant is under way, so that on-site storage of spent nuclear fuel can continue until 2016 (Ministry of Knowledge Economy and Korea Hydro and Nuclear Power 2009). A recent research finds that by a simple technique of “re-racking,” making storage denser by adjusting the distances among storage racks, the interim storage may continue into 2023.¹ While impressive, such a technique is neither going to be a permanent solution to the problem of spent nuclear fuel management nor so intended. It was simply a precautionary measure just in case finding a location for centralized interim storage becomes difficult or takes longer than expected. Unfortunately this is becoming a reality, given the delay in even starting out on a public discussion of setting out a national policy on spent nuclear fuel management (Hippel 2011).

2.2 Other Options and their Limitations

On-site and interim storage are not the only technical options to deal with spent nuclear fuel. Speaking purely from a technical viewpoint, there are indeed a couple more routes

¹ Interview with Myung Seung Yang, Senior Research Fellow, Korea Atomic Energy Research Institute (Daejeon, 15 March 2011).

available, which are reprocessing within the Korean territory and transportation of spent nuclear fuel to other countries for reprocessing or storage. Each of these methods, however, is subject to certain limitations, which are legal and economical in nature.

2.2.1 Reprocessing

Reprocessing refers to a technique that extracts plutonium from spent nuclear fuel and turns it into a reusable state for fuel fabrication to use for a specific type of nuclear reactor, such as fast breeder reactor. Since this technique requires enormously high level of technical maturity and costs more than simple storage, only a few countries have succeeded in reprocessing spent nuclear fuel, and a much smaller number of countries currently use such technique as a way of disposing of spent nuclear fuel, such as Canada, France, United Kingdom, Russia and Japan (OECD and Nuclear Energy Agency 2005; World Nuclear Association 2011).

A bigger hurdle that reprocessing is confronted with is the possibility that the substance that is produced as a result of reprocessing, especially plutonium, will easily be converted to weapon-grade material. Such a possibility is in direct conflict with the spirit of non-proliferation, which international organizations such as the International Atomic Energy Agency (IAEA) will take very seriously should Korea choose to reprocess spent nuclear fuel. Now that North Korea is under suspicion of having developed nuclear weapons through reprocessing, it would be not advisable for Korea to resort to the technique that clearly has military use. It is also questionable that Korea has secured technology needed for reprocessing. Furthermore, the Nuclear Cooperation Agreement also restricts the extent to which Korea could reprocess spent nuclear fuel, as the article 8 clearly stipulates. At least when it comes to reprocessing U.S.-origin spent nuclear fuels, the United States' prior consent on a specific case is a requisite, which cannot be guaranteed at all times.

For the reasons noted above, reprocessing spent nuclear fuel within the Korean territory will not be a realistic option to pursue.

2.2.2 Transboundary Movement of Spent Nuclear Fuel

If reprocessing within the Korean territory cannot constitute an option for managing spent nuclear fuel, one may wonder if such spent fuel could be shipped out of the country for reprocessing or, assuming that there exist some countries willing, for permanent geological disposal by way of burying it a few hundred meters underground (LaTourrette et al 2010).

There is indeed an international agreement covering this issue, namely the Joint Convention on the Safety of Spent Fuel Management and on the Safety of Radioactive Waste Management¹ (hereinafter Joint Convention). Since Korea is a contracting party in the Joint Convention by means of ratification (Louvat 2006)², it is possible at least in theory that Korea's spent nuclear fuel would be shipped out of the territory for reprocessing or permanent disposal, under a mutual agreement between Korea and the recipient country.³

¹ Entered into force on 18 June 2001, United Nations Treaties Series, Vol.2153, I-37605.

² Korea became a contracting member of the Joint Convention by way of ratification, which took effect on 15 December, 2002. Article 39 of the Joint Convention.

³ Article 27 of the Joint Convention.

The practical importance of such an international convention for Korea is, however, limited at best. First of all, the United States, which supplies most of the nuclear material for generation purposes, will effectively have a final say on whether Korea may ship such nuclear material to a third country, as the United States' prior consent on a case-by-case basis is essential for that to take place (Compton 2009).¹ In addition, the United States has taken the position that it would not take back the nuclear material that it provided to other countries to its own territory (Burkart and Gorn 2008). Part of the reason is perhaps the fact that the United States has not successfully found the site for permanent geological disposal. Even though the U.S. government designated Yucca Mountain in Nevada as a locale for such geological disposal, such decision has not been implemented effectively due to the lawsuits at the courts of various levels (Kessler 2008). The earliest that the Yucca Mountain area should be ready for taking in spent nuclear fuel and other high radioactive waste was projected to be 2017 (Ministry of Knowledge Economy and Korea Hydro and Nuclear Power 2009), but after the Obama administration took office in 2009 such a plan for permanent geological disposal was put on hold (World Nuclear Association 2011).

In addition, there is no guarantee that shipping out the spent nuclear fuel from the Korean territory for other disposal methods will make economic sense. Even if we count out reprocessing in a third country as expensive, since the reprocessing cost itself is deemed as twice as high as direct disposal (Bunn et al. 2003; Orszag 2007), the shipping cost involved, with all the supplementary cost required for safeguarding the spent nuclear fuel until it arrives at a final destination, will easily become prohibitive. If Japan's case serves as an example, the remaining waste after the reprocessing overseas would be returned to Korea, not necessarily helping with reducing nuclear waste (Kusunose 2008; World Nuclear Association 2011). The situation would not be much different if the shipping out were for direct disposal, as it would involve payment per unit of spent nuclear fuel to a country willing to take it inside its territory, aside from transportation costs (Compton 2009).

For these reasons, shipping out spent nuclear fuel for reprocessing or direct disposal elsewhere will not be an appealing option for Korea either.

3 Pyroprocessing: Can It Deliver?

Since neither of the methods in section 2 could represent a long-term solution to the issue of spent nuclear fuel, efforts must be made to seek out other technologically sound options. One such possibility, as often discussed in the Korean context, is pyroprocessing. The following subsections will grapple with pyroprocessing's concept, its potential benefits and limits, and the prospect for the future.

3.1 Spent Nuclear Fuel Question Reframed: Disposed of or Recycled?

According to the conventional view spent nuclear fuel is radioactive waste; discussion will then focus on the safe disposal of such nuclear material, permanently if possible, without envisioning the possibility of reusing it in the future. On the other hand, if spent nuclear fuel is viewed as a still valuable resource containing fission material, then the question turns into how best to take advantage of the spent fuel's potential value, which turns the spent nuclear fuel into an object of recycling (Committee on Science and Technology 2009). With the advance of extraction technology and other supplemental

¹ Article 10 of the Nuclear Cooperation Agreement.

methods, recycling or “advancing fuel cycle” slowly becomes a possibility in the near future, and it is in this context that pyroprocessing is put forward as a future solution for spent nuclear fuel, as it opens the possibility of reusing spent fuel for nuclear power generation.

3.2 Pyroprocessing: Definition

Pyroprocessing is, to put it simply, a way of recycling spent nuclear fuel to use some residual active nuclear material for nuclear generation purposes. It starts with breaking down the spent fuel rods into pieces, eventually made into powder, and then placed in a bath of molten salt. In this an electric current is transmitted, thereby separating radioactive material from the solution of molten salt. The end result of this process is the concentration of actinides – radioactive elements with long half-lives – mixed with plutonium and other nuclear material (Inoue and Koch 2008). This end result can then be used for nuclear fuel fabrication designed specifically for a certain type of new generation reactors, such as fast neutron reactors or sodium-cooled fast reactors that Korea is intent on developing (Song et al. 2010).

3.3 Pyroprocessing’s Advantages, Limits and Prospect for Future

Pyroprocessing’s advantages are twofold. First, since this technology allows spent nuclear fuel to be reused in nuclear energy generation, it will help reduce the volume of highly radioactive nuclear waste. In Korea’s case, all the spent nuclear fuel under the current circumstances would have to be stored somewhere on site or in a centralized interim storage, which will not come in the foreseeable future. Pyroprocessing would, if proven successful, convert a significant volume of nuclear waste into a usable resource, contributing to a complete fuel cycle and efficient use of nuclear energy as well. Second, pyroprocessing is highly proliferation-resistant (Inoue and Koch 2008). With pyroprocessing, it is difficult, although not entirely impossible, to produce weapon-grade plutonium out of the mixture of actinides and plutonium that comes as an end outcome. Therefore it helps mitigating fears of nuclear proliferation that is often the case with reprocessing technology, which produces pure plutonium that could easily be tapped for making nuclear weapons.

However, the level of maturity in this technology is low to say the least. Given the present state of pyroprocessing in terms of efficiently extracting nuclear material from spent nuclear fuel, this technology will at least be decades away from becoming up and running on a commercial basis (Hippel 2011). Another point of weakness in this technology is the fact that the fabricated fuel that comes from pyroprocessing’s end outcome should be used for a specific type of nuclear reactors, such as fast breeders. The pace with which such reactors are researched and developed is also slow, and one should expect such reactors to come fully operational in around 2030 (Hippel 2011). In essence, pyroprocessing is currently not the readily available technology for commercialization, and still is left at the stage of R&D and demonstration. The media hype in Korea surrounding pyroprocessing as if it were a technology of immediate use is, in a sense, misplaced. Such is the case that the potential economic benefits in waste management cost reduction will not become easily established, until a number of sodium-cooled fast reactors with commercial capacity begin running (Chen 2010; Committee on Science and Technology 2009).

This does not mean that pyroprocessing is of no practical value, and one should not dismiss such a promising technology as simply experimental, as it shows a measure of promise for waste reduction and fuel recycle in the future. However, such a prospect

must be qualified with the fact that pyroprocessing has not reached its economic potential, so that a strict assessment of pyroprocessing's value and potential benefits may not be conclusively made at present. It is important in this context that one should not get carried away by rosy pictures of pyroprocessing's potential, but be ready to take a more guarded approach, basing decisions only on the best available scientific evidence and well-structured research on its economic costs and benefits.

4 Negotiations on a New U.S.-Korea Nuclear Cooperation Agreement

The following subsections summarize the background against which pyroprocessing has hit headlines, and also look into the different perspectives by United States and Korea in terms of pyroprocessing. Such discussion on differences of views will lay the groundwork for suggestions to be made in the next section on how to accommodate pyroprocessing in a new Nuclear Cooperation Agreement.

4.1 Background: Prior Consent on "Reprocessing"

The relevant provisions of the Nuclear Cooperation Agreement are article 8 and article 11, respectively. Article 8(C) provides that:

"When any special nuclear material received from the United States of America Pursuant to this Agreement or the superseded Agreement requires *reprocessing*, or any irradiated fuel elements containing fuel material received from the United states of America pursuant to this Agreement or the superseded Agreement are to be removed from a reactor and are to be *altered in form or content*, such reprocessing or alteration shall be performed in facilities acceptable to both Parties upon a joint determination of the Parties that the provisions of Article 11 may be effectively applied." (italics added)

Furthermore, article 11(B) stipulates that:

"B. . . . the Government of the United States of America, notwithstanding any other provisions of this Agreement, shall have the following rights:

. . .

(3) To require the deposit storage facilities designated by the Commission [author's note: United States Atomic Energy Commission] of any of the special nuclear material referred to in paragraph B(2) of this Article which is not currently utilized for civil purposes in the Republic of Korea and which is not transferred pursuant to Article 8 or otherwise disposed of pursuant to an arrangement mutually acceptable to the Parties; "

When interpreted in combination with each other, these two provisions strengthen the proposition that the United States has a strong say in reprocessing or altering in form and content of U.S.-origin nuclear material, and that it even has power to designate storage facilities for spent nuclear fuel. In other words, these provisions require prior consent from the United States when Korea attempts a certain form of "reprocessing" or "alteration in form or content" (Hahm 2009). These provisions may be effectively used against Korea's experimentation with pyroprocessing, if the concerns on nuclear

proliferation outweigh its other potential benefits in deciding upon the United States' negotiation stance.

4.2 Pyroprocessing: Reprocessing or Not?

4.2.1 U.S. Perspectives on Pyroprocessing

Since the official negotiations between Korea and the United States for a new nuclear cooperation agreement began only recently, it will be too early to tell what the United States government will say about Korea's pyroprocessing technology. However, if a recent remark by a U.S. government official serves as any indication, it does not bode well for Korea's hope for gaining a freer hand on pyroprocessing under a new agreement. Richard Stratford, an official from the U.S. Department of State, said in a conference that the U.S. Department of Energy "states frankly and positively that pyroprocessing is reprocessing. Period. Full stop." He even suggested that the key features in pyroprocessing "moved to the point that the product is dangerous from a proliferation point of view. So, for that reason, pyroprocessing is reprocessing, and that's part of the problem" (Horner 2011).

If the view that Mr. Stratford described at that conference should become the United States' official position, then it would be difficult for Korea to persuade the United States to accept pyroprocessing as a technology that would do without prior consent from the United States, as it would still see potential for nuclear proliferation from the end outcome of pyroprocessing, and it would wish to maintain the country's strong say in reprocessing and alteration in form and content of nuclear material, including spent nuclear fuel.

4.2.2 Korean Perspectives: Need for a Long-term Solution on Spent Nuclear Fuel

Korea's insistence on pushing ahead with pyroprocessing is understandable, in view of the political difficulties of securing an interim or permanent nuclear waste storage. The economic value of pyroprocessing is still not established, however, and this technology will not go past the experimental phase until a few decades later. Given the technology's limited potential in the foreseeable future, it may seem strange for Korea to enter into a bilateral negotiation with the United States on such a weak rationale.

Nevertheless, if one takes into account that nuclear power plant expansion in Korea is continuing and will continue even with the recent Fukushima nuclear accident in 2011, Korea's hope of holding onto every possibility of providing a long-term solution on spent nuclear fuel is not to be swept away too quickly. Even if pyroprocessing should take a long period of time to demonstrate its feasibility as well as commercial viability, the related research and development efforts ought to continue, at least to give the technology an appropriate environment to prove itself. The fact that pyroprocessing is highly proliferation-resistant should also serve toward more permissive approach from both the United States and Korean governments, as the technology represents only a minor risk factor when assessing proliferation risks. Considering that Korea is a contract party of the Nuclear Non-Proliferation Treaty¹ and has faithfully complied with many safeguard requirements mandated by the International Atomic Energy Agency (hereinafter IAEA), the concern for Korea's violation of nuclear proliferation duty may be overblown.

Seen from this perspective, pyroprocessing is not to be viewed as reprocessing with a high risk for military purposes but as a form of a peaceful use of nuclear material for

¹ Entered into force on 5 March 1970. United Nations Treaty Series, Vol. 729, I-10485.

civil purposes, with a small potential for conversion to weapon-grade material that could be dealt with by other safeguard agreements with the IAEA.

5 Suggestion of a Balance Test on Pyroprocessing

Summing up the discussion covering the diverse issues related to pyroprocessing, this paper suggests a balance test for assuming the United States' prior consent on pyroprocessing technology, if certain conditions are met. This approach will alleviate the United States' concern on nuclear proliferation that may follow from pyroprocessing, while supporting Korea's effort to refine and further develop pyroprocessing for future applications on reduction of nuclear waste as well as on efficiency increase in nuclear fuel use.

5.1 Balance Test's Guiding Principles

First of all, the balance test should contain a principle that permitting pyroprocessing must contribute to promotion of civil nuclear technology, not of military one. In this context, a constant outside watch on the technical advance of pyroprocessing should be established, in the form of a United States-Korea joint commission combined with Korea's duty to report significant developments or anomalies. In other words, the principle should require that pyroprocessing proceed as long as it would not present an increased risk of nuclear proliferation.

Secondly, an economic test should be attached to assessments of the relevant technology, assuming that such a technology would be wholly devoted to civil purposes. If it turns out that pyroprocessing technology will not make much economic sense in terms of reducing nuclear waste or of advancing fuel cycle, then the said joint commission should be able to debate the usefulness of such technology before deciding upon its continuation. A reduced financial support could also be envisioned as an exit strategy should pyroprocessing fail to show sufficient economic viability.

5.2 Application of Balance Test

5.2.1 Assumed Prior Consent contingent on Proliferation Risk Assessment

As it is likely that the United States will not give up its strong say on many aspects of nuclear cooperation with Korea, the structure of prior consent in nuclear reprocessing and other alterations would better be maintained. Instead, the two sides could agree on certain exceptions related to pyroprocessing, by inserting a clause on "advanced fuel cycle research and development," which would assume the United States' prior consent. To guard against abuse, this clause may be supplemented by a joint periodic assessment on proliferation risk, so that the assumed prior consent could be explicitly withdrawn should the assessment clearly show a significant increase in proliferation risk due to technical developments. This approach will therefore reconcile the need for constraining proliferation risks and the need for providing technological possibility for nuclear waste reduction and efficiency enhancement in nuclear fuel use.

5.2.2 Shorter Expiration Term

Consistent with the above point, the expiration term of the new nuclear cooperation agreement also needs to be shortened. When the agreement first entered into force in 1973, quite possibly the rationale behind the 41 year-term provision was that nuclear technology would not see much change within such a period. Now that such assumption

is arguably no longer tenable, a shorter expiration term for the agreement will provide more opportunities for the two parties to review the technical aspects of pyroprocessing comprehensively, allowing for significant revision of the agreement if situations so require. This shortened term will also mitigate the United States' concern that the assumed prior consent would perpetuate the path toward higher proliferation risk. Considering that most nuclear cooperation agreements remain in force for an average of 30 years, this paper suggests a 15-year expiration term to give both parties a relatively easy access to the review procedure.

5.2.3 Research Cooperation and Sharing

Korea is not the only country interested in pyroprocessing. Several other nations, including the United States, are currently involved in advanced fuel cycle research and development (LaTourrette 2010), although Korea is relatively ahead of other countries in terms of technical maturity and the scalability. If the research outcome from Korea's pyroprocessing research and development could be shared with the United States to the extent that doing so would not severely dilute the intellectual property values from those researches, it may give one more reason for the United States to grant assumed prior consent for pyroprocessing technology.

In fact the Korean Atomic Energy Research Institute (KAERI) recently agreed to conduct a 10-year feasibility study jointly with counterparts in the United States (Horner 2011), which may mark a good start toward research cooperation and sharing in this field. This paper suggests a more inclusive approach, providing possibilities for research sharing in areas that are insensitive to concerns on infringement of intellectual property, such as basic research that are not subject to patent awards.

6 Conclusion

Management of spent nuclear fuel is an area where concerns for nuclear waste and interests in fuel recycling collide. The implications that a successful management of spent nuclear fuel will have on smooth expansion of nuclear plant construction will be enormous. Pyroprocessing, by way of providing a potential for reducing nuclear waste through fuel recycling, can be considered as a prominent technology for the future, while the proliferation-resistant nature also makes it more acceptable than other reprocessing methods. Because of the technology's lack in commercialization records it should not become an immediate solution to the problem of spent nuclear fuel, but it recently received much attention combined with the fact that the Nuclear Cooperation Agreement would expire in 2014 and that the negotiations between the two parties would deal with several outstanding issues, including pyroprocessing. This paper suggested a balance test in reconciling differences between the United States and Korea concerning pyroprocessing, seeking to alleviate concerns on proliferation while ensuring continued research and development in the technology.

While pyroprocessing alone will not completely face up to the challenges of spent nuclear fuel management in Korea's expansion of nuclear plant construction, in the long run it will provide an opportunity for addressing the core problem of cost control in a comprehensive manner. The ideal package of solutions should combine all the necessary measures concerning nuclear waste management, including but not limited to on-site storage, centralized interim storage, permanent geological disposal and continued research on other advanced fuel cycles, among which is situated

pyroprocessing. Then the goal of supplying nuclear power to the Korean economy at reasonable costs would be made more within reach.

Cartels on the construction market in Poland

Maciej Hulicki

Research assistant, Institute of Intellectual Property Law,
PhD Student, Faculty of Law and Administration,
Jagiellonian University,
Krakow, Poland

Email: maciej.hulicki@uj.edu.pl

Abstract:

Antitrust regulations concern mainly two types of actions, which may restrict competition on a particular market: conclusion of competition-restricting agreements, and abuse of a dominant position. The first group of actions infringing competition, includes agreements between competitors, of a cartel nature. It manifests itself mostly by price-fixing, market sharing, and discrimination of specific entities. Recently in Poland, several cartels on the construction market were detected by the Office for Competition and Consumers Protection. The case of price fixing and market sharing by cement producers was particularly famous. Such illicit activity, affects the competition and harms other entities, and indirectly consumers. This paper highlights the issue of cartels occurring on the construction market in Poland. It places especial emphasis on the cement cartel which is a good examples of a prohibited agreement that has drastically limited competition on the construction market. Hence, this paper analyzes the significant decision of the President of the Office for Competition and Consumers Protection in the case of the cement cartel.

Keywords:

cartels, prohibited agreements, cement market

1 Introduction

1.1 The scope of protection of the competition in Poland

The President of the Office of Competition and Consumer Protection (hereinafter “the Office”) aims at safeguarding intact functioning of the competition. If he detects a competition-restricting practice, in his decision he may order abandonment of such practice and impose penalties¹. There are three types of activities which are harmful for competition, and are subject of interest of the Office.

Antitrust regulations concern mainly two types of actions which may restrict competition on a particular market: conclusion of competition-restricting agreements, and abuse of a dominant position. The first group of actions infringing competition includes agreements of a cartel nature, concluded between competitors. It manifests itself mostly by price-fixing, market sharing, and discrimination of specific entities.

¹ See art. 10 and 106 of the Act (Dz.U. 2007 nr 50 pos. 331)

With regard to abuse of a dominant position, *the Act of 16 February 2007 on competition and consumer protection* (hereinafter “the Act”) constitutes that such practices are prohibited. The Act includes also a non-exhaustive list of activities, which are abuses of a dominant position. It consist of such activities as imposition of unfair prices, limiting production, creation of diversified conditions of competition, tying agreements, hampering the development of competition, imposition of onerous terms and conditions, and division. It is significant that legal actions which concern such abuses, are void entirely or in their respective part¹.

Besides the abovementioned practices, the Office has goals also in the area of control of concentrations. It can occur in such forms as merges and acquisitions. Excessive consolidation on a particular market may lead to achievement of a dominant position, what may be detrimental factor for a proper competition. In a situation when statutory conditions are fulfilled, entities which act with an aim of concentration have to report such intention to the Office. President of the Office has significant powers in this matter, also when unauthorized concentration took place².

1.2 Relation between the Polish and EU legislation on competition

With respect to both cartels and abuses of dominant position, Polish legislation is similar to the EU law³. At the EU level corresponding regulations are contained respectively in art. 101 and 102 of the Treaty on the Functioning of the European Union (hereinafter “TFEU”)^{4 5}. These rules were specified in several regulations, and non-binding notices and guidelines of the European Commission (hereinafter “EC”)⁶.

In the field of the EU competition law application, two paths of proceedings exist. Of course when a particular competition-restricting practice may affect the trade between EU member states, the EC can initiate adequate procedure. On the other hand, appropriate domestic authorities can and even have to carry on antitrust proceedings in this area⁷.

Thus, President of the Office can directly apply art. 101 and 102 TFEU. He employs both domestic and EU competition law, and may impose sanctions on undertakings violating these rules. However, according to the art. 5 of the Council’s Regulation 1/2003⁸ and to Court of Justice decision in the case *Tele 2*, domestic antitrust authorities can not deliver a decision finding no infringement of the EU competition rules: *“Empowerment of national competition authorities to take decisions stating that there has been no breach of Article 102 TFEU would call into question the system of cooperation established by the Regulation and would undermine the power of the Commission. Such a ‘negative’ decision on the merits would risk undermining the uniform application of Articles 101 TFEU and 102 TFEU, which is one of the objectives of the Regulation highlighted by recital 1 in its preamble, since such a decision might*

¹ Art. 9 of the Act.

² See Section III (art. 13-23) of the Act.

³ However it should be stated that the interpretation of these provisions may differ. See: K.Kowalik-Bańczyk, *Pojęcie “wpływu na handel” jako kryterium stosowania przez sądy krajowe wspólnotowego prawa konkurencji*, Przegląd Ustawodawstwa Gospodarczego, Nr 2/2008

⁴ Consolidated version of the Treaty on the Functioning of the European Union (OJ C 83, 30.03.2010, p. 47)

⁵ The main source of EU law for mergers is the Council Regulation (EC) No 139/2004 of 20 January 2004 on the control of concentrations between undertakings (OJ L 24, 29.01.2004, p. 1)

⁶ Notices and guidelines are not binding, but serve an important role in interpretation, and in fact set standards which EC applies.

⁷ See art. 10 of the Act

⁸ Council Regulation (EC) No 1/2003 of 16 December 2002 on the implementation of the rules on competition laid down in Articles 81 and 82 of the Treaty, OJ L 1, 04.01.2003, p.1-25

prevent the Commission from finding subsequently that the practice in question amounts to a breach of those provisions of European Union law.”¹.

1.3 Prohibition of the competition-restricting agreements

Cartels are defined as monopolistic agreements between a number of entities, which aim is to restrict or even eliminate all competition on the relevant market. What promotes the formation of cartels is oligopolistic shape of the market². Small number of competing undertakings creates an opportunity for them to enter into conspiracies, harmful for other competitors and consumers. Cartels cause great losses to the economy. Their harmfulness manifests itself mostly in unnaturally high prices, economical inefficiency, and prevention of cost-saving technological advances³.

Regulations concerning prohibition of cartels contain two important elements. First of all, they prohibit such agreements. Secondly, they exclude certain agreements from the general prohibition.

The Act constitutes that prohibited are agreements, which have as their object or effect elimination, restriction, or other infringement of competition on the relevant market⁴. Article 101 par. 1 TFEU was constructed slightly different and broader. According to it prohibited are: “*all agreements between undertakings, decisions by associations of undertakings and concerted practices which may affect trade between Member States and which have as their object or effect the prevention, restriction or distortion of competition within the internal market*”. Of course with respect to the EU competition law, it is crucial that their object or effect may concern the internal market.

Further the Act constitutes that such agreements are entirely or in their respective part void⁵, while art. 101 par. 2 TFEU, that any agreements or decisions prohibited pursuant to it are automatically void.

Regarding the exclusion from application of the rules on prohibited agreements, the Act in art. 7 and 8 provides two such exceptions. First of them concern *de minimis* agreements⁶. Second, agreements which impact technical and economical progress. Four conditions have to be fulfilled for art. 6 of the Act not to be applied. Such agreement has to contribute to improvement of the production or distribution of goods or to promote technical or economic progress. Subsequently they have to allow the buyer or user a fair share of benefits, which result from an agreement. Then they can not impose on the undertakings concerned restrictions which are not indispensable to the attainment of these objectives. And also they can not afford such undertakings the possibility of eliminating competition in the relevant market in respect of a substantial part of the goods in question⁷. Art. 101 par. 3 TFEU contains correspondent regulations.

Both art. 6 par. 1 of the Act and art. 101 par. 1 TFEU contain exemplary enumeration of the prohibited agreements. According to art. 101 par. 1 TFEU, they are:

¹ Judgment of the Court in the case Tele 2 of 3.05.2011, C-375/09

² Kartel, *Encyklopedia Wiem*, available at: <http://portalwiedzy.onet.pl/3340,,,kartel,haslo.html>

³ Cartel (economics), *Britannica Online Encyclopedia*, available at: <http://www.britannica.com/EBchecked/topic/97205/cartel>

⁴ Art. 6 par. 1 of the Act.

⁵ Art. 6 par. 2 of the Act.

⁶ The prohibition does not apply to agreements between undertakings whose market share does not exceed 5% for competitors, or 10% for other entities. See art. 6 par. 1 of the Act.

⁷ Art. 8 par. 1 of the Act.

“(a) directly or indirectly fix purchase or selling prices or any other trading conditions;

(b) limit or control production, markets, technical development, or investment;

(c) share markets or sources of supply;

(d) apply dissimilar conditions to equivalent transactions with other trading parties, thereby placing them at a competitive disadvantage;

(e) make the conclusion of contracts subject to acceptance by the other parties of supplementary obligations which, by their nature or according to commercial usage, have no connection with the subject of such contracts.”

The Act provides two more examples of such prohibited agreements. They are: limiting access to the market or eliminating from the market undertakings which are not parties to the agreement, and collusions between undertakings entering a tender, or by those undertakings and the undertaking being organizer of the tender, concerning the terms and conditions of bids to be proposed, in particular as regards the scope of works and the price.

2 Findings and Discussion

Cartels on the construction market tend to be among the most frequent and biggest ones. In recent years, many cases concerning cartels in the construction industry have emerged, e.g. in the United Kingdom, the Office of Fair Trading imposed huge fines on biggest building companies in the country, such as Balfour Beatty and Kier Group, for bid rigging and cover pricing¹, in South African construction company Aveng faced fines for collusive behavior on the rebar and wire mesh construction markets², while in the EU more than 0,5 bln has been levied from the steel companies for price fixing and market division³. In Poland, collusions of a cartel nature involving construction businesses constituted the largest group of the detected prohibited agreements⁴.

Most of the cases concerning prohibited agreements on the construction market in Poland involved price fixing. In a number of cases, the Office detected cartels on the paints and varnishes⁵, wholesales of doors⁶, ceramic tiles⁷, and carpenter markets⁸. Generally the scheme of detected misconduct was similar. The reselling prices were fixed directly in trade agreements. Similarly on the tile and sandstone market price fixing consisted of an obligation to sell products for the suggested prices, not lower than

those included in the producers' price-list, discounted not more as provided in the distribution agreement¹. In the *Xella* case agreement included a provision constituting prohibition of using prices lower than the purchase price from the products' manufacturer².

However, in this paper I would like to focus on the cartel, which has occurred on the cement market. It was the biggest case, where a record penalty was imposed on the entrepreneurs in collusion. But not only the total sum of the imposed fines demonstrates the importance of this case. It is also a clear example of high level of cartel organization and its effect on the market. Moreover, the case was thoroughly analyzed by the Office and its decision regarding cement cartel presents the standpoint of the Office in numerous issues of competition law enforcement. The conclusions may be therefore relevant for the entire system of protection of the competition in Poland.

2.1 Cement cartel

In its decision nr DOK-7/09 of 8 December 2009, the President of the Office has found that the practices of 7 biggest Polish cement producers (Lafarge Cement S.A., Góraźdże Cement S.A., Grupa Ożarów S.A., Cemex Polska S.A., Dyckerhoff Polska S.A., Cementownia Warta S.A., Cementownia Odra S.A.) were restricting competition on the domestic market of production and sales of the grey cement. Accordingly, the President found that these practices have constituted an infringement in terms of art. 81 of the Treaty establishing the European Community (hereinafter TEC; art. 101 TFEU at present). The President of the Office has ordered infringers to abandon such practices and imposed the heaviest fine possible (10 % of the profits) on them³. Jointly they have paid 414 mln PLN, what makes this fine the largest that was yet imposed⁴, and indicates importance of this decision for the construction market, as well as its significance for the competition protection system.

The proceeding that was pending before the Office concerned such practices as fixing of the prices and other conditions of cement sales, division of the cement production and sales market, and exchange of the confidential information about trade⁵.

2.2 Cement sector in Poland

After the downfall of the communist regime in Poland the cement industry has undergone dynamic transformations. As a result of the process of privatization a number of leading foreign companies have entered the Polish cement market. Afterwards, competing undertakings tried to strengthen their position on the market, what has resulted in restructuring and consolidation in the sector⁶.

In 2006 at least 13 plants were producing cement in Poland. Several of those that were functioning in the '90 were closed, and their production capacity was marginal. On the contrary those which have remained on the market were subject to privatization,

¹ See Decision of the Office nr RKT-35/2009 of 08.12.2009

² See Decision of the Office nr DOK-3/2008 of 04.07.2008. However in this case participants have escaped punishment because they obliged not to use such practices in the future.

³ Lafarge Cement S.A. is an exception. The fines were not imposed on them since they have disclosed relevant facts about the cartel and participated in the leniency procedure.

⁴ See: *Rekordowe kary za cementową zniżkę cenową*, Rzeczpospolita, available at: <http://www.rp.pl/artykul/404118.html>

⁵ Only the first two are specified in particular subsections of the Art. 5 par. 1 of the Act, but the list included in this article does not have an exhaustive nature.

⁶ See Decision of the Office DOK-7/09 of 8 December 2009, point 31

restructuring, and modernization. Currently they are among the most modern in Europe, and their production capacity in longer perspective is growing¹.

Before the regime has changed, all cement producers were associated in the Association of the Cement Producers. This body managed entire production of the cement in Poland, and obviously there were no conditions for competition. After privatization and ownership changes took place, this has changed, and in 1990 a new association has emerged. Currently its aims are very different, comparing to situation before the transformation, and concentrate on development and promotion of cement industry, as well as representation of its interests².

Bearing in mind such structure of the cement market in Poland there are no doubts that a cartel between major undertakings had to negatively influence the competition on this market. Additionally, prohibited horizontal agreements are always harmful for the market, whether by its distortion, restriction or elimination of the competition, and therefore they violate the interest of the general public³.

2.3 Relevant market

It has to be noted that negative effects of a prohibited agreement must have their impact on the market, which is relevant in terms of a particular case. Relevance of the market concerns its subject (products), geographical, and temporary aspects.

Market should be specified narrowly, and defined as market of goods, which because of their purpose, price, and properties, including quality, are treated by their purchasers as substitutes (product market), and are offered on the area, where because of their nature and properties, existence of barriers in the access to the market, consumer preferences, significant differences in prices, and transport costs, conditions of the competition are similar (geographical market)⁴. In the case of cement cartel, which has been subject to the interest of the Office, both the product and geographical market were identical. Often the activity of the cartelists can itself determine the relevant market.

In this case the relevant market is the market of grey cement⁵. It is a homogenous product, for which clinker constitutes common component, and also its basis. Therefore, different types of the grey cement may be used as substitutes. In addition, it is possible to use preparations of the construction chemicals, and still achieve the same product. What is important is the fact that as a result, one can obtain the concrete which strength is the same⁶. There are no substitutes of grey cement, and in particular this applies to specialist products, such as white cement and aluminous cement⁷.

¹ DOK-7/09, points 32-36

² DOK-7/09, points 96-107

³ DOK-7/09, point 370

⁴ See art. 4 par. 9 of the Act

⁵ DOK-7/09, point 376

⁶ DOK-7/09, points 377-379

⁷ DOK-7/09, point 383

The cement price is determined by the amount of clinker in it. The competition between the cement producers is however of a minor significance, since although raw materials used in production may vary, the final product has to meet certain quality level, contained in specific standards¹.

With regard to the geographical market of the grey cement, in this case it was limited only to the Polish territory, forasmuch the cement is definitely a heavy product, and *ipso facto* its transportation expenses are high. It has its reflection in the statistics of import and export of the cement products, which are systematically dropping, and constitute only a few percent of the entire cement market in Poland².

Figure. 1 Cement Plants in Poland. Source: Cement Industry in 2007, http://www.polskicement.pl/3/3/artykuly/13_89.pdf

There is also no local market in this case. Cement plants are localized in the southern part of Poland (as shown in Fig. 1), what is linked with the fact, that there are relevant deposits of natural resources. Areas in close range of these plants, which would normally constitute their basic markets, are overlapping, so cement producers can not ignore reciprocal actions. Their localization indicates also that the costs of transport to the north are similar. Therefore, on such market conditions of competition are also similar³.

An important issue in the determination of the relevant market is the level of precision in its indication. In terms of prohibited agreements, in contrary to abuses of a dominant position and control of concentration, it is not necessary to indicate precisely the relevant market. When a prohibited agreement has as its aim restriction of the competition, it is not necessary to assess its effects on the relevant market. However, if these effects were to be analyzed (because such agreements did not aimed at restriction of the competition), then the relevant market should be precisely specified⁴.

¹ DOK-7/09, points 380-381

² DOK-7/09, points 387-388

³ DOK-7/09, point 390

⁴ DOK-7/09, points 392-394

2.4 Influence on the trade between member states of the European Union

According to the decision of the President in the cement cartel case, this agreement has affected the trade between the Member States of the EU. To assess whether Polish cement cartel has affected the trade between the Member States, the Office has based its findings on *the Commission Notice - Guidelines on the effect on trade concept contained in Articles 81 and 82 of the Treaty*¹.

Regarding the concept of “trade” it should be interpreted broadly, including not only the exchange of goods and services, but also any cross-border commercial activities. It is enough, that such activities can influence the structures of the competition in the EU, and it can occur even when the relevant market has a national or a local range². Strengthening of the market along the borders hinders other entities entering it, and therefore it means that the competitors from other countries are excluded from it³. In this case the aim of the agreement was to stabilize the market situation, particularly in scope of the quantity of shares on the market and level of prices. Members of the cartel wanted to avoid great competition or a “war” on the market, as the Office noted. Their activities were targeted at company that has entered the market – Ekocem Sp. z.o.o., and which could significantly reduce prices, and hence the cartel members wanted to control its sales. As the Office remarked, barriers of market entry caused that in effect the common market could be divided⁴.

The expression from art. 101 TFEU *may affect* should denote the possibility of foreseeing, basing on objective legal or factual premises, that a particular agreement may affect directly or indirectly, actually or potentially on the model of the trade in the EU. Such possibility of foreseeing must have a high degree of likelihood, what means that the nature of the agreement and products in question, and the status of the undertakings have to be taken into account. Again, it is a broad interpretation of the TFEU, since even an indirect and potential impact on the market can be treated as affecting the trade in the EU. Moreover, such influence does not have to necessarily mean that the trade is limited or stopped. It simply means that this impacts the model of trade in a way that it starts to develop differently, even if it related with its increase⁵. In this case the grey cement potentially can be a subject of import and export, although currently such activities are marginal⁶. It should be noted that all members of the cement cartel were related with international capital groups operating throughout the EU. Therefore, the change of the market position of a certain entity in one state would affect the market status of the entire group⁷.

Finally, influence on the trade has to be substantial. Therefore the nature of the competition-restricting practice and the market status of the undertakings participating in a cartel have to be taken into account. In the case of cement cartel in Poland, its members shared almost 100% of the market⁸.

⁶ DOK-7/09, point 411

⁷ DOK-7/09, point 414

⁸ DOK-7/09, points 404-405

2.5 Prohibited agreement in the cartel case

Such an agreement should be regarded as joint plan of colluding undertakings, which limit or can limit their individual commercial activities by specifying the framework of their harmonized activities or self-restraint on the market. What matters is their shared intent of competition-restricting activity, a concurrence of will, regardless of legal form¹. Hence, such agreements do not have to have a written form, contain sanctions, be finalized, or be detailed. On the contrary, they may have a provisional nature and be general². Moreover, such prohibited practices do not have a form of a contract. Also concerted practices are prohibited in terms of the competition legislation. Even when a party has not joined the agreed plan, but is using with an intent collusive devices facilitating coordination of their commercial practices, such a behavior can be treated as a concerted practice and therefore constitute an infringement of antitrust policies³. Often it is difficult to indicate whether specific misconduct has a form of an agreement or concerted practice, since the cartel could have features of both, however not the form is relevant, but the scope of the solutions⁴.

It is required that the undertakings operating on a certain market must act according to its independent policy. Thus, to some extent they have a duty of independent decision making on the market⁵.

Activities of the cement cartel members included price fixing, limitation of the sales, and exchange of the information. They were making decisions on numerous meetings, where they expressed their intention of a specific market behavior, and established a joint plan of activities, creating common framework, and limitation of their market autonomy. As the Office has found, even when a particular representatives were not present at the meeting, such decisions were passed also to them. Therefore, the risk of competition was replaced by practical cooperation between the competitors. Such meetings, talks, and exchange of standpoints led to the conclusions, agreements and concerted practices⁶. Since cartels are unstable, the fact that some of cement producers which were members to it did not complied with its provisions is irrelevant⁷.

It has to be noted that the Office has assessed that in the case of cement cartel there were no grounds for exclusion of such practices from the general prohibition of anti-competitive activities, whether according to the *de minimis* doctrine, or whether as a group or individual exclusion⁸.

2.6 Fixing of prices and other conditions of cement sales

Price fixing is regarded as an example of hard core cartel. It influences the higher prices, and reduction of the supply and consumers welfare. In fact, goods for which there is a demand are not produced⁹. Price fixing can manifest itself in different forms,

¹ It is essential that the agreement between the cartelists is voluntary. See: *Komentarz do art.6 ustawy z dnia 16 lutego 2007 r. o ochronie konkurencji i konsumentów (Dz.U.07.50.331)*, [w:] K. Kohutek, M. Sieradzka, *Ustawa o ochronie konkurencji i konsumentów. Komentarz*, LEX, 2008.

² DOK-7/09, point 422

³ DOK-7/09, point 426

⁴ DOK-7/09, point 443

⁵ DOK-7/09, point 441

⁶ DOK-7/09, points 439-440

⁷ DOK-7/09, point 444, see also: DOK-7/09, point 484, and DOK-7/09, point 485 where the Office noticed that even passive members of the cartel took part in the exchange of the information

⁸ DOK-7/09, points 537-550

⁹ DOK-7/09, point 454. See also: *Communication from the Commission: Guidelines on the application of Article 81(3) of the Treaty*, (OJ C 101, 27.4.2004, p. 97-118)

e.g. fixing equal prices, price formulas, minimal prices, target prices, recommended prices, discounts, and increases in prices¹.

As the Office has found, the scheme of arrangements consisted of two stages. In the primary stage, the cartel members have introduced a complex system of prices in individual districts. Such system included maps, tables, and distances from particular cement plants, which eased the calculation of the transport costs. They also have set regular differences in prices of respective cement types in relation to the base cement².

In the latter part of the cartel activity, its participants have withdrawn the system of district prices, but regular differences in prices of particular cement types were still used. They also have fixed the increases of cement prices and the period of their introduction. This consisted of communications to competitors details about the rise of prices. Therefore other entities knew how they should act in order to keep the market stabilized³.

The dominant aim of the cartel was to secure the status quo the market. Hence, when an undertaking applied an aggressive price policy, what was related with its increase in general sales or to a particular customer⁴, members of the cartel tried to influence such entity. However the goal was not to enforce identical prices, since they knew that those are negotiated individually, and were agreed with reference to general level of prices⁵. The form of such agreements on price levels was evolving according to the current circumstances. Their contacts became more formal, and went beyond simple signalization of price policies, after detecting that one of the members applied more competitive prices than signalized⁶.

The misconduct of the cartel members consisted also of fixing of sales conditions. The cement producers restrained themselves from supplying bagging and mixing plants. Therefore, they have collectively boycotted these companies because such businesses were selling cement for lower prices. Cartelist justified this boycott, claiming that bagging and mixing plants, by selling the cement of a lower quality, committed acts of unfair competition. In the opinion of the Office, even if such was the case, it would be a subject for investigation of respective public authorities, but it can never justify the violation of competition law.

2.7 Market division

Agreements concerning division of a certain market are also regarded as hardcore cartels. They can have numerous forms, e.g. fixing of market shares of particular entities, or allocation of specific territory or customers to them⁷. Division of the market is harmful for the competition because it leads to elimination of the competition on the particular market⁸.

In this case, cartelist fixed the individual shares in the Polish cement production and sales market on the basis of historical shares (before the transformation of the regime).

¹ DOK-7/09, points 455-456

² DOK-7/09, points 459-460

³ DOK-7/09, points 459-460

⁴ When a specific customer was supplied by a number of cement producers, they have fixed prices specially for him

⁵ DOK-7/09, point 461

⁶ DOK-7/09, point 462

⁷ DOK-7/09, points 476-477

⁸ See: *Komentarz do art.6 ustawy z dnia 16 lutego 2007 r. o ochronie konkurencji i konsumentów (Dz.U.07.50.331)*, [w:] K. Kohutek, M. Sieradzka, *Ustawa o ochronie konkurencji i konsumentów. Komentarz*, LEX, 2008.

The emergence of a new competitor on the market, namely Ekocem Sp. z o.o. has change the situation on the market and the cartelists reacted by modification of the shares. Members of the cartel were concerned about potential excessive loses of their shares in the market. Finally, Ekocem Sp. z o.o. was taken over by Górażdże Cement S.A. This acquisition and requests from 2 other entities of increasing their shares, in exchange for limitation of their export to Germany, resulted in stabilization on the cement market, with respect to the shares of particular companies¹.

Cement cartelists had also tools to enforce the status quo in shares on the market. They transferred their clientele to competitors, as a compensation for loses in shares. Furthermore, those who achieved the biggest increase in shares on the cement market were obliged to increase the price in the next period first. Also powerful cement plants made advantageous offers to clients of other undertakings, in order to reclaim the market. The exchange of information and meaningful measures made the stabilization on the market easier².

2.8 Exchange of confidential commercial information

The exchange of the confidential information was not included in the exemplary list of prohibited agreements in terms of competition law. However, if the general premises of these agreements are fulfilled, also such act can be regarded as infringing the rules of competition.

Such actions may be a part of the trade contracts of a cartel nature, or constitute an independent infringement of antitrust law³. Nevertheless, they usually derive from the violation of these regulations⁴.

The Office in its decision in the cement cartel case, invoked the judgment of the Court of Justice in *the Asnef-Equifax*⁵, where it was stated that the agreements concerning the exchange of the information are inconsistent with the protection of the competition, when they limit or eliminate the level of uncertainty about the activity of the certain market.

In the cement cartel, the information that was a subject to the exchange between its members included monthly (sometimes even more frequent) sales results. It aimed at monitoring of the entire market and adaptation of production, what as the Office has noticed, has reduced the level of uncertainty on the market. Further it has noticed, that assessment of such practice on the grounds of accordance with legislation on competition, should not be done *in abstracto*, but basing on the circumstances of the case in question, such as properties of the market, nature of the exchange of the information, their frequency and significance.

The type of the information is relevant in this context as well, e.g. its accessibility for the customers? Also it has to be noted, that only up-to-dated information about the tariffs, transportation capacity and costs, is relevant in this context. For instance

¹ DOK-7/09, points 478-479

² DOK-7/09, points 480-481

³ However in the cartel case the exchange of the information about the price rises, was not an independent infringement because it was used in assistance for price fixing

⁴ DOK-7/09, points 488-489

⁵ See: Judgment of the Court of 23 November 2006 in the *Asnef-Equifax* (C-238/05)

information from one year before was regarded as historical, and therefore irrelevant. In the cement cartel its members exchanged the information with consistency¹.

Such assessment should take into account and predict how the market would look like without this exchange. In this case the exchange of the secret information was used to control the sales, and therefore could have a negative effect on the scope of supply. The level of concentration and quantity of the products should be also bared in mind. The more competitors and diversity of the products there is on the market, the adjustment of prices is more difficult and expensive².

In the cartel case the market was highly concentrated, actually of an oligopolistic nature. The market seemed transparent to a certain extent, since cement companies had numerous regional sales representatives. This facilitated the economic intelligence, but it could only complement the data collected. It could not replace the information about the entire sales market³.

3 Conclusion and Further Research

Although in recent years the Office has detected many cases of cartels on the construction market, the decision made with regard to the cement cartel is of a particular importance. Not only because of the amount of the fines imposed on the cartelists, which was the heaviest levied in the practice of the Office, but primarily because of the structure, scope, and effects of this prohibited agreement for the competition. Particularly, the described scheme of competition law infringement and the level of its organization indicate the degree of negative consequences for the entire construction market (cement is a basic product for most investments). Moreover, the decision analyzed in this paper (DOK-7/09 of 8 December 2009) is significant also for the entire system of the competition protection, since it contains relevant deliberations on some fundamental issues of antitrust law. The comprehension of this case, makes it impossible to describe it in a paper of such size, with all details. Therefore, only most important legal issues and examples of infringement were presented and selected for analysis. However, there are still some issues to be considered and analyzed, especially with respect to the leniency procedure, its fairness, and potential consequences for the market. Also the issue of private enforcement of the competition law is interesting in the context of these case, since the size of harm, that was made to the economy.

Turkey

Email: irlayici@itu.edu.tr; tase@itu.edu.tr

Abstract:

In the Turkish construction industry, KIK standard contract forms, which are published by Public Procurement Authority, are used. Although there is an existence of standard contract forms, they are not sufficient and useful both in scope and content. Due to the lack of the nature of these standard forms, many problems and difficulties arise in the completion of a construction project within the desired time, cost and quality. In order to solve these problems, standard contract forms in Turkey are needed to be restructured both in scope and content. In this context, analyzing other standard contract forms, which are commonly used and accepted throughout the construction industry, is necessary and helpful. In this paper, AIA, FIDIC and JCT standard contract forms are reviewed and compared with the standard forms of contract used in Turkey. The differences between these standard forms are determined with the help of the comparison. The problem areas of Turkish standard contract forms are presented and appropriate suggestions are improved.

Keywords:

AIA, FIDIC, JCT, KIK, standard contract forms

1 Introduction

Construction market is the leading one in which the world's largest scale companies compete. By the help of the increasing numbers of construction project opportunities around the world, operating internationally is rapidly increasing day by day. Turkish contractor firms also operate internationally and undertake private and public projects in international construction market. Furthermore, the process of Turkey's accession to the European Union has a positive effect not only on the business potential of international contractor firms in Turkish construction market, but also on the entries of Turkish contractor firms to the international ones.

With the increase of international construction projects which are executed by different partners from different geographies, participants from different specialties need to work together and use huge amounts of money, materials and equipments in order to reach the desired purpose. In this process, correct and complete documentation is very important such as managerial skills. Correct and complete documentation means to prepare necessary documents in order to manage and control the construction project process by determining the roles and responsibilities of all participants of the construction project, defining the relationships between them and presenting appropriate solutions to the problems encountered. These documents are defined as contract documents in the construction industry. Contract documents need to be prepared by

using clear and explicit statements which are not open to interpretation. Correct and completely designed contract documents are essential and necessary for the successful completion of a construction project within the desired time, quality and budget. In this context, using standard contract forms which serve a common language and common understanding all around the world is necessary and helpful.

The aim of this paper is to review the standard contract forms which are commonly used and accepted throughout the construction industry and to compare them with the standard contract forms used in Turkish construction industry. In order to reach this aim firstly, AIA, FIDIC and JCT standard contract forms are reviewed. The review of these standard contract forms helped to define and differentiate between the Turkish standard contract forms. The differences between these standard forms are determined, the problem areas of Turkish standard contract forms are presented and appropriate suggestions are improved.

2 Standard Contract Forms

The need for a standard form of building contract became apparent in the 19th century at a time when most building work was procured by an approach that has become described as the traditional or conventional method (Hibberd, 2007). In the Latham Report it is recommended that “all parties in the construction process should be encouraged to use standard forms” (Latham, 1994). Because of the complexity of rights and liabilities, it was seen as desirable to use standard forms in order to avoid the expense and problems of bespoke contracts (Furst and Ramsey, 1995).

There are many advantages to using standard contract forms. First of all, using a standard form avoids the cost and time of individually negotiated contracts. As they are written by legal experts, it will be generally more convenient to use a standard form. Therefore, ambiguities and inconsistencies are reduced to a minimum. The rights and obligations of both parties are set out clearly. Because of standardisation owners, architects, consultants and contractors who use a standard form contract become familiar with the rights and obligations. This improves communication and efficiency in contract administration. Especially, it is very important in international construction projects where communication is more difficult and misunderstandings are more likely to arise.

There has been a proliferation of standard forms in the construction industry in recent years, and there are many organisations which publish standard contract forms. Some of the examples of these published standard contract forms are AIA (The American Institute of Architects), AGC (The Associated General Contractors of America), EJCDC (The Engineer’s Joint Contract Documents Committee), FIDIC (International Federation of Consulting Engineers), JCT (The Joint Contracts Tribunal Limited), ICE (Institution of Civil Engineers), NEC (The New Engineering Contract) and ACA (The Association of Consultant Architects). These standard forms are based on similar purposes, applications and provisions and are commonly used and accepted throughout the construction industry.

2.1 AIA Standard Contract Forms

The American Institute of Architects (AIA) was founded in the USA in 1857 by a group of 13 architects. Since then, AIA has been the leading professional membership association that represents member architects and related professionals. The main

approach of this association is to promote the scientific and practical perfection of its members and to elevate the standing of the profession (www.aia.org). Within the framework of this approach, AIA publishes standard contract forms (documents) for the design and construction industry in order to manage the relationships involved in construction projects. The first standardised contract form was published in 1888. Since that time, AIA attempts to revise and update its documents every seven to ten years to reflect trends, changes and developments in the construction industry.

AIA organises its standard contract forms into two main groups. The first group is AIA series, which is based on the use of the document and the parties of the agreement. The second one is AIA families, which is based on the types of projects or particular project delivery methods.

2.1.1 AIA Series

AIA standard contract forms are divided into six alphanumeric series according to document use or purpose and parties of the agreement.

A Series: A series cover owner / contractor agreements. There are 25 different standard owner / contractor agreements and their general conditions in the A series. The most commonly used forms are A101–2007 Standard Form of Agreement between Owner and Contractor and AIA Document A201-2007 General Conditions of the Contract for Construction.

B Series: B series involves owner / architect agreements. There are 38 different standard owner / architect agreements and standard forms of architect's services. The most commonly used agreement is B101–2007 Standard Form of Agreement between Owner and Architect.

C Series: C series cover the other agreements except owner / contractor and owner / architect agreements. In the C series, there are 12 different standard agreement forms.

D Series: D series are miscellaneous documents. There are only 3 standard forms in the D series.

E Series: E series are called as exhibits. There are 2 standard forms which are Digital Data Protocol Exhibit and Building Information Modelling Protocol Exhibit.

G Series: G series cover contract administration and project management forms. In the G series, there are 39 different standard contract forms.

2.1.2 AIA Families

AIA standard contract forms are divided into eight families based on project type or delivery method. Standard forms in each family provide a consistent structure to support the major relationships on a design and construction project.

Conventional (A201) Family: This is the most commonly used family of documents because it is suitable for the conventional (design-bid-build) project delivery method. It is suitable when there are separate contracts for the design and the construction of the project. In conventional family, there are 40 different standard contract forms from A, B and C series.

Construction Manager as Adviser (CMA) Family: This family consists of standard contract documents for the construction projects which are delivered by the construction management project delivery method. There is a construction manager who acts as an independent adviser through the course of both design and construction. In construction manager as adviser family, there are 11 different standard contract forms from A, B, C and G series.

Construction Manager as Constructor (CMc) Family: In this family, the owner employs a construction manager who will complete the construction and also provide construction management services. There are 2 different standard contract forms from the series A.

Design-Build Family: The Design-Build family is used where the project delivery method is design-build. The owner enters into a contract with a contractor who is obligated to design and construct the project. In this family, there are 7 different standard contract forms from A, B, C and G series.

Integrated Project Delivery (IPD) Family: This family concerns integrated project delivery method, which utilizes the talents and insights of all project participants through all phases of design and construction. AIA provides three levels of standard contract forms for integrated project delivery family. These are transitional forms, the multi-party agreement and the single purpose entity. There are 9 different standard contract forms from A, B and C series.

Interiors Family: It is appropriate for furniture, furnishings and equipment procurement services which are combined with architectural interior design and construction services. In this family, there are 5 different standard contract forms from A and B series.

International Family: The International family is for US architects working on projects located in foreign countries. There are 2 different standard contract forms from the series B.

Small Projects Family: This family is used when the project is of simple content, low cost and short duration. There are 2 different standard contract forms from the series A and B.

2.2 FIDIC Standard Contract Forms

The International Federation of Consulting Engineers (in French, Fédération Internationale of Consulting Engineers des Ingénieurs-Conseils, FIDIC) was founded in 1913 by three countries – Belgium, France and Switzerland. It has 86 national member associations representing over 1 million professionals. FIDIC aims to represent globally the consulting engineering industry by promoting the business interests of firms supplying technology based intellectual services for the built and natural environment (www.fidic.org). FIDIC published its first standard contract form in 1957 under the title of Conditions of Contract (International) for Works of Civil Engineering Construction. Since then, FIDIC forms are one of the most widely used standard forms of contract in international construction. Subsequent editions of the Construction contract were published in 1967, 1973, 1977, 1987, 1992 and 1999 respectively. Up to 1999, FIDIC standard contract forms followed the ICE (Institute of Civil Engineers) form of contract. In September 1999, FIDIC updated its standard contract forms by publishing entirely

new standard forms designed to take account of developments in the international construction industry.

FIDIC has a suite of different standard forms of contract, most of which has been ascribed a colour, often referred as the “FIDIC rainbow”.

The Red Book: It is the Conditions of Contract for Construction for Building and Engineering Works Designed by the Employer. The red book is the traditional form for civil engineering construction in which the contractor constructs to the employer's design. This is the most commonly used standard FIDIC form in the international construction projects. The Red Book consists of general conditions, guidance of the preparation of particular conditions, forms of letter of tender, contract agreement and dispute adjudication agreement. In 2006, FIDIC introduced a variation of the Red Book, which is the MDB (Multilateral Development Bank) Harmonised Edition.

The Yellow Book: It is the Conditions of Contract for Plant and Design-Build for Electrical and Mechanical Plant, and for Building and Engineering Works, designed by the contractor. It is intended as its name suggests to be used for design and build contracts and for plant contracts. The Yellow Book involves general conditions, guidance for the preparation of particular conditions, forms of letter of tender, contract agreement and dispute adjudication agreement.

The Green Book: It is FIDIC's short form of contract. It is used when the price for the contract is relatively small (under US\$ 500,000), the construction time is short (less than 6 months), or the work involved is relatively simple or repetitive. It covers the agreement, general conditions, rules for adjudication and notes for guidance.

The Silver Book: It is the Conditions of Contract for EPC (Estimated Prime Cost) Turnkey Projects. The Silver Book transfers more risk onto the contractor than FIDIC's traditional forms. The contractor takes total responsibility for the design and construction of the project. Similarly, the Green Book involves general conditions, guidance for the preparation of particular conditions, forms of letter of tender, contract agreement and dispute adjudication agreement.

The Orange Book: It is the Conditions of Contract for Design-Build and Turnkey. Although it is intended that the Orange Book be replaced by the entirely Silver Book and Yellow Book, it is still used within the construction industry. The Orange Book consists of two parts. The first part is general conditions. The second part gives the guidance of the preparation of conditions of particular application. It also involves forms of tender, agreement and FIDIC model terms for the appointment of a dispute adjudication board.

The White Book: It is the Client/Consultant Model Services Agreement. It is intended to be used in conjunction mainly with FIDIC's Red and Yellow Books. The white book consists of agreement, general conditions, particular conditions and appendices.

The Gold Book: It is the Conditions of Contract for DBO (Design, Build and Operate) Projects. FIDIC introduced the Gold Book in 2008. Its approach is to combine design, construction, and long-term operation and maintenance of a facility into one single contract awarded to a single contractor. It involves general conditions, particular conditions and sample forms.

2.3 JCT Standard Contract Forms

The Joint Contracts Tribunal (JCT) was established in 1931 and became incorporated as a company limited in 1998. For 80 years, JCT has produced standard forms of contracts, guidance notes and other standard documentation for use in the construction industry (www.jctltd.co.uk). The JCT's approach is to produce standard forms that meet clearly defined needs and apportion risk in a way that is appropriate for the procurement approach it reflects. Although the forms were not called as JCT until 1977, The RIBA (Royal Institute of British Architects) formed the first standard form of contract in 1931. New editions of JCT standard contract forms followed in 1939, 1963, 1980, 1998 and 2005. The JCT standard contracts are fundamentally building rather than civil engineering contracts but are used for projects where both building and civil engineering works are involved.

JCT provides a wide range of forms of contract to meet the various and diverse needs of the UK construction industry. The policy of the JCT is to produce a discrete standard form of contract for each type of project or procurement route commonly used in the UK (Griffiths, 2010). The JCT 2005 suite consists of contract families made up of main contracts and sub-contracts. There is a practice note which is prepared by JCT in order to help to decide the appropriate JCT construction contract concerning the choice of procurement and the type of contractual arrangement (JCT, 2009).

Standard Building Contract (SBC): This is the most commonly used standard contract form because it is suitable for the conventional project delivery method. It is appropriate for use on building contracts where the employer appoints an architect to be the interface between him and the contractor. It has 3 main contracts Standard Building Contract with Approximate Quantities (SBC/AQ), Standard Building Contract with Quantities (SBC/Q) and Standard Building Contract without Quantities (SBC/XQ). Under the SBC, there are 2 different sub-contract agreements and conditions document.

Minor Works Building Contract (MW): It is one of the smallest and simplest forms of JCT standard contract forms. It is appropriate on projects where the work is of a fairly simple nature. Another version is the Minor Works Building Contract with contractor's design (MWD). There is also a sub-contract agreement for minor works in the JCT suite.

Intermediate Building Contract (IC): The IC form is more detailed and contains more extensive control procedures than the Minor Works Building Contract (MW) but is less detailed than the Standard Building Contract (SBC). An alternative version is the Intermediate Building Contract with contractor's design (ICD). Similarly, there are 2 different sub-contract agreements and conditions documents.

Design and Build Contract (DB): This form is used where the project delivery method is design-build, where the employer wants a contractor to take on the responsibility for both the design and construction works. Under the DB, there exists a sub-contract agreement and conditions document.

Major Project Construction Contract (MP): MP is suitable for and major projects and experienced users who regularly procure large-scale construction works. In this type of contract the contractor takes greater risk than under other JCT contracts. Similarly, there is a sub-contract form and conditions document.

Constructing Excellence Contract (CE): This form is one of the newer standard contract forms produced by JCT and is used where the project delivery method is partnering. Its format and style are significantly different from the traditional JCT standard contract forms. It encourages collaborative working and the formation of integrated teams. In the CE there is a separate contract for project team agreement.

Construction Management Contract (CM): CM is the main contract for the construction management project delivery method. It is suitable for projects where there is a construction manager for managing the project on behalf of the employer. There are 2 different contracts under the CM, which are construction management appointment and trade contract.

Management Building Contract (MC): This form is used when the management project delivery method is applied. This form is appropriate for use with large scale and complex projects where an early start on site is required and where it is not possible to prepare full design information before the work commences. In the MC there is an agreement and conditions document.

Measured Term Contract (MTC): It is suitable for regular works such as repair and maintenance which normally run for a set period of time. In this contract the employer and contractor will enter into an agreement to carry out an unknown amount of construction work.

Prime Cost Building Contract (PCC): This form is appropriate for projects requiring an early start on site, but where it is not possible to prepare full design information before the works commence. This contract is most often used for alteration works and for urgent repair works.

Repair and Maintenance Contract (RM): It is used when the work involves the repair and maintenance of a building. RM is a single document, comprising both the tender and the conditions.

2.4 KIK Standard Contract Forms

In Turkey today there is only one current standard forms of contract for construction industry. These forms are published by Public Procurement Authority (Kamu İhale Kurumu-KIK) (www.ihale.gov.tr), which is a governmental authority. These standard contract forms are the government contracts which are developed based on the Turkish Public Procurement Law- 4734. The purpose of this law is to establish the principles and procedures to be applied in procurements held by all public entities and institutions governed by public law or under public control or using public funds. Although participants of construction projects are free to use any other contract forms in their private construction works, KIK standard contract forms are compulsory for the public construction works in Turkey. There are apparently absolute rules about KIK standard contract forms should be used in the public construction projects. Standard contract forms that are published by KIK as follows:

Standard Contract for Construction Works: This standard form is the agreement which is used in the public construction works. It is an owner / contractor agreement. This form is the only and common agreement and is used with all project delivery methods. Besides, it is used with all contract types such as lump-sum, measurement and cost reimbursement.

General Specifications for Construction Works: This standard form is the general conditions of the construction contract. The purpose of this standard form is to establish the general principles and procedures that will be applied in performance of the works that are contracted as per Turkish Public Procurement Contracts Law- 4735. There is one and only general condition document and it is used with all types of project delivery methods and contract types.

Administrative Specifications: Administrative specifications are prepared on the basis of the Standard Administrative Specification annexed to the Regulation on Implementation of Construction Works Procurements hereby according to the procedure applicable in the construction works procurement.

3 Comparison of the Standard Contract Forms

The review of AIA, FIDIC and JCT standard contract forms helped to define and differentiate between the KIK forms used in Turkish construction industry. When KIK standard contract forms compared with those forms several evaluations can be made.

First of all, KIK standard contract forms are designed by a governmental authority for public construction works in Turkey. As they are written by government for government, their primary mission is to protect the government's rights. The risk allocation between the parties is not fair. They transfer the risk more onto the contractor. This characteristic makes it impossible to use these standard forms in private construction works or international construction projects.

Secondly, KIK forms do not have a clear language which can be easily understood. The statements and provisions are not clear and explicit, so it is open to interpretation. This makes it difficult to understand the rights and obligations between the parties. Besides, many references to different documents make it hard to follow the content.

In AIA, FIDIC and JCT there are different standard contract forms which are adopted for different project delivery methods such as conventional, design-build, construction management, design-build-operate and partnering. However, in KIK there is only one type of standard form for only conventional project delivery system. Furthermore, in AIA, FIDIC and JCT standard contract forms vary in terms of contract types such as lump-sum, measurement and cost reimbursement. In KIK there is only one type of contract which is used with all contract types.

Moreover, in AIA, FIDIC and JCT rights and obligations of the participants of the construction projects are clearly set out with the help of the different types of agreements. There are many different types of agreements between different parties such as owner, contractor, architect, quantity surveyor, contract administrator, construction manager, sub-contractor and consultant. In KIK, there is only one type of agreement and this agreement is an owner / contractor agreement. There is not any agreement or provision for the other participants of the construction project.

In AIA, FIDIC and JCT there exist general conditions, which serve as the definitive or explanatory document, and supplementary conditions which are amendments and modifications of and additions to statements which are made in the general conditions. In KIK although there is a general conditions document, there is not any supplementary of partial conditions document for amendments. General conditions usually are basic to

most projects, but there is a need of supplementary conditions which enable special and peculiar requirements of a particular owner and project.

Finally, in AIA, FIDIC and JCT there are guidance notes and commentaries which help to clearly understand the contract provisions or help to decide the appropriate standard contract form for the right procurement method. In KIK, there is not any guidance or commentary for the usage of standard contract forms.

4 Conclusion and Further Research

In conclusion, when the Turkish standard contract forms are compared with the AIA, FIDIC and JCT standard contract forms, it can be seen that KIK standard contract forms are not sufficient, comprehensive and useful both in scope and content. There is a need of a new family of standard contracts which provides a wide range of forms of contract to meet the various and diverse needs of the Turkish construction industry.

This new family of standard contracts needs to involve different types of contracts for different project delivery systems. Moreover, it needs to concern different types of contractual arrangements. The rights and obligations are needed to clearly set out for all the project participants.

This paper aimed to review the standard contract forms which are commonly used and accepted throughout the construction industry and to compare these forms with Turkish standard contract forms. It is the first stage in a PhD research project which aims to restructure standard contract documents used in Turkish public construction works. Further research will involve the development of required standard contract documents by proposing a new, comprehensive and up-to-date model for the successfully completion of the public construction works in the Turkish construction industry.

Towards design and application: an investigation into how mediation can complement existing planning practice

Alan McCarten

School of Planning, Architecture and Civil Engineering

Level 3, David Keir Building, Stranmills Road, Belfast, BT9 5AG

Email: amccarten01@qub.ac.uk

Abstract:

The purpose of this paper is to identify issues and foster suggestions for further investigation in considering how mediation can complement existing planning practice. It begins with a short illustration of how globalisation is impacting upon the nature of conflict in planning practice, leading to a discussion on how land-use and development disputes are currently resolved within the United Kingdom (UK) planning system. Taking into account government proposals for planning reform and drawing upon discussions with key informants, the paper outlines opinions as to how mediation may potentially lend itself to planning practice. Attention then focuses on the practices and procedures characterising dispute resolution programs operating in a number of Anglophone jurisdictions, before discussion turns to the investigations already undertaken regarding the use of mediation in the UK planning system. In summarising the issues to drive further investigation, it is suggested that more than one approach will be needed if mediation is to complement existing planning practice.

Keywords:

alternative dispute resolution, environmental dispute resolution, mediation, planning, Anglophone jurisdictions

1 Introduction

Mediation involves “the intervention in a negotiation or conflict of an acceptable third party who has limited or no authoritative decision-making power, who assists the parties to voluntarily reach a mutually acceptable settlement of the issues in dispute” (Moore, 2003: 15). Interest in mediation is gaining momentum but substantial investigation is required to assess how best mediation can be designed and applied to planning practice. In this undertaking it is necessary to consider not only the practices and procedures of established mediation programmes but the challenges for mediation in planning presented by an increasingly pluralist and ever changing society and space. This paper outlines issues emerging for further investigation in considering how mediation can complement existing planning practice in the UK. Conscious of the alignment of mediation to the communicative turn in planning theory and collaborative philosophy this paper outlines current opportunities for stakeholder engagement in planning practice and decision-making process. Through qualitative inquiry with key informants working within the planning profession and those having an interest in dispute resolution discussion focuses on the potential role of mediation in planning practice.

2 Globalisation and Planning

Contemporary globalisation, progressively intense and inherently complex, impacts significantly on planning practice and the role of planners. Murtagh et al. (2008: 43) note how “urban spaces have become more differentiated and contested, in response to technological change, globalisation and social restructuring.” Increasingly planning finds itself enmeshed in a fragmented web of economic, cultural, political and technological attributes that contribute society and space. Globalisation continues to change the dynamics and nature of conflict in planning arenas.

The challenge presented to planning is how to mediate between global and local tensions. As Newman and Thornley (2002: 21) suggest: “pressures on planning come from both the need to integrate city economies with global forces and from the need to integrate fragmented interests within the city.” Moreover, planning must contend with conflict between the regional and the local. In responding to such conflict and the wider impact of globalisation, planning will:

“...need to be more sensitive to [the pressures it faces] and develop a more flexible form of practice. It will need to live with the uncertainties arising from ... multiple forces operating at multiple levels; 20 century forms of comprehensive and rational planning are less likely to work in a globalised context.” (Thornley and Rydin, 2002: 10).

3 Planning in the UK

Significantly different from systems in operation throughout the European Union and largely uniform across its constituent countries, the UK planning system operates within a unitary state. It is subject to ‘a radical distinction between local and central government, and a high degree of centralised monitoring and control’ (McKay, 2010: 116). Variations exist, insofar as Northern Ireland (NI) and Scotland retain separate legal systems and legislation, and Wales, an administration detached from England. Statutory provisions and legislative change in NI largely follow those introduced in England, and powers granted to local government are decided and controlled by central government. Contrary to the administration of planning functions in mainland UK, which remain the responsibility of local councils, planning powers in NI are administered by the Department of Environment (DOE), which has 8 offices spread across 5 planning areas, (see Figure 1).

PLANNING AREAS

- Area Planning Offices
- ▬ Planning Area border

Figure 1. Planning Areas

(Source: DOE, 2011)

Opportunities for public engagement in planning practice are limited by procedural constraints. Largely involved through consultative processes, individuals and communities can: (1) attempt to influence planning policy; (2) comment on development plans for their area and participate in public examinations; (3) comment on planning applications likely to affect them; and (4) report alleged breaches of planning control. The role of facilitating public engagement in mainstream planning falls largely to the DOE and the Planning Appeals Commission (PAC).

The PAC is an independent appellant body established under Article 88(1) of The Planning (NI) Order 1972, and continues by virtue of Article 110(1) of The Planning (NI) Order 1991. Equivalent to the Planning Inspectorate in England and Wales, the PAC has 81 functions in regard to land-use planning and other related matters. In addition to its decision-making appellant role the PAC has responsibility for public examination of development plans, and in conducting and reporting on public inquiries into major planning applications.

At an initial level of engagement, the planner is often positioned between the applicant and members of the public making representations to an application. Many consider the role of the planner to 'mediate' disputes at this level, but during discussions with members of the community and voluntary sector, questions were raised regarding the appropriateness of planners 'wearing two hats', and suggestions made that it is impossible for planners to be mediators and decision makers. Although stepping outside the UK context, a recent report by the Law Reform Commission of Ireland is not without relevance to this issue, and jurisdiction. In considering the role of mediation in

the planning application process, a number of submissions received by the Commission suggested:

“...the informal negotiation process between an applicant and a local planning authority is working sufficiently within the planning application process to resolve many potential issues or disputes and there was no role for mediation in [this] process.” (LRC,2010: 177)

Interestingly these respondents fail to consider individuals making representation to an application and therefore fail to acknowledge their significance to disputes, which has resonance to issues raised during discussion of planning practice in NI. For members of the community and voluntary sector, the concerns of individuals and community were not fully appreciated. Stories relayed the reluctance of planners to meet with the community, yet happy to hold discussions with developers. Members of this sector went as far as suggesting, at best individuals and communities could do little more than constrain the application process, and argue the DOE needs a “culture shift” to account for the needs of individuals and community.

Further, members of the community and voluntary sector expressed opinion, that “planning processes encourage confrontation.” The quasi-judicial character of proceedings before the PAC, arguably do little to quell such assumptions. Although McKay (2010: 122) recognises “the inspector is not a judicial arbitrator but an inquisitor whose role it is to responsibly seek out all relevant information to reach the best possible solution”, the proceedings before the PAC, are not particularly informal. Practitioners within the wider planning field suggest the PAC come from a more adjudicatory background and have substantial knowledge of all aspects of planning, especially planning law. In discussions on the appeals process, practitioners felt there were instances of informal mediation taking place within hearings but suggested an appeal is concerned with investigating the soundness of a decision made before the appeal, and concluded in any event a decision would have to be made. Therein, concerns were raised as to how far mediation could be introduced to the appellants system, and if it is possible for inspectors to combine adjudicatory and mediatory roles, should mediation be introduced as a precursor to appeal.

4 The Changing Landscape of Planning Practice

The reform of the planning system in NI is set within the context of an on-going Review of Public Administration (RPA). The Planning Bill, passed through the Northern Ireland Assembly (NIA) on 23 March 2011, provides a framework for the future of planning in NI. Principally, it provides for the transfer of many planning powers and functions to district councils, whereby decisions on local planning matters will be taken by elected representatives. A key objective of the planning reform agenda in NI seeks to address ‘community participation and involvement in order to allow full and open consultation and actively engage communities’ (DOE, 2010: 103). Offering a largely reactive form of engagement whereby communities have opportunities to respond to initiatives forwarded by the DOE and district council, ‘the Bill provides ... for relatively minor improvements in consultation’ (NIA, 2011a: 10).

In introducing new classifications for development, the Bill establishes a requirement for pre-application consultation by applicants for those proposals classified as a ‘major’ form of development. Both planning practitioners and members of the community and

voluntary sector expressed opinion that mediation could potentially lend itself to this stage of the planning process in which responsibility lies with the developer to consult with the community in advance of lodging a planning application. It was suggested, the Bill offers the opportunity to establish and promote to all parties, the standards and procedures expected to be met in consultation processes but more so that the 'community' would welcome the presence of an independent facilitator in such consultation processes. This, it was argued, would provide the community with more confidence in the process.

Before deciding on major planning applications, the Bill provides for pre-determination hearings where 'the applicant and any person so prescribed' (NIA, 2011b: 16) can appear before a council committee and have their respective cases heard. It is feasible to assume mediation could be incorporated at this stage in the process to help parties express their case but also to identify areas of consensus or help foster agreement on issues that would permit the application to be approved.

Despite being a prominent issue during consultation, the Bill dismisses the introduction of third party rights of appeal to NI; the DOE, having earlier concluded "that further consultation of third party appeals should be deferred until the extensive changes to the planning system under planning reform and the transfer of planning functions have settled down and are working effectively" (DOE, 2010: 5). The Bill also fails to consider provisions currently being proposed in mainland UK under the Decentralisation and Localism Bill, specifically neighbourhood development plans and neighbourhood development orders. As components of neighbourhood planning, it is envisaged these proposals will facilitate the Government's move towards decentralisation of power to the local level, providing local councils, and more specifically communities with responsibility for decisions affecting their area.

Under current proposals, a local planning authority (LPA) must respond to any initiation by a parish council or neighbourhood forum undertaking to produce a neighbourhood plan. Neighbourhood plans are developed by the community, who together, with parish councils or forums formulate priorities for the local area. An important aspect of "neighbourhood development plans is that their contents must have regard to national policies and advice in guidance from the Secretary of State and be in general conformity with strategic policies in the development plan for the area" (Stephens, 2011: 1). The draft neighbourhood plan is submitted to the LPA who arrange for an independent examiner to assess the proposals and make public a report or recommendation, concerning the submission of proposals to a local referendum. If the majority of the local community vote in favour of the neighbourhood development plan, the LPA must initiate it.

Both practitioners of planning and the voluntary and community sector felt mediation may lend itself particularly well in helping communities reach a draft neighbourhood plan. The earlier discussion on globalisation and the changing nature of conflict within planning has particular relevance to mediating between diverse community realities and interests. With increased migration and fractured intra and inter-community relations in many urban areas, difficulties are sure to arise in any attempt to develop neighbourhood plans.

5 The Emergence and Development of Alternative Dispute Resolution (ADR) and Mediation

Mediation is now a feature in many Anglophone jurisdictions, being used in the resolution of labour disputes, employed within the civil justice system and introduced in public disputes involving environmental and land-use issues. The early colonial experiments with dispute resolution reflect to a large extent the situation today in that “models of dispute resolution can be grouped into two familiar categories: either ... ethnocentric and community-based and completely distinct from mainstream adjudicative models, or ... court-connected models to dispose of claims that would otherwise fall to the courts to resolve” (Hanycz, 2007: 178). Models of dispute resolution in the United States (US), Canada, Australia and New Zealand are discussed below before attention turns to investigations undertaken into ‘Mediation in Planning’ in the UK. Not surprising a number of intra and inter-jurisdictional variations exist between dispute resolution programs.

6 ADR and Mediation in the United States (US)

Largely regarded as the founding moment of the modern ADR movement, the American ‘Pound Conference’ of 1976, convened in response to dissatisfaction with the administration of justice. The address by Frank Sander focused attention on the use of alternative ways for resolving disputes outside the courts as a means of reducing judicial caseload. He envisaged a transformation from the courthouse to a “Dispute Resolution Centre where the grievant would first be channelled through a screening clerk ... to the process ... most appropriate to his type of case” (Sander, 1976: 84). As Menkel-meadow (1997: 1616) gathers from Sanders thinking, “different kinds of disputes might require different treatments, and if we could triage ... cases the way that doctors and nurses triage medical cases perhaps the caseload could be better and more efficiently handled.”

Various land use dispute programs in the US approach the resolution of conflict differently; some undertaking to screen disputes in a process similar to that advanced by Sander (1976), others imposing mandatory attempts at mediation, and many offering voluntary mediation, for example:

In Connecticut, parties appealing decisions of the Planning and Zoning Commission must file a statement with the Court stating the appeal can be resolved through mediation before any attempt to resolve the case in this way can be initiated;

Any request for mediation under the Local Land-use Planning Act in Idaho deems the first session mandatory for all parties and thereafter optional;

The Land-use Mediation Program in Maine mandates state agencies to participate in mediation when required by the Court ADR Service;

In the Massachusetts Land Court Program, judges may refer parties to attend orientation sessions where their case is determined to see if referral to a dispute resolution service is appropriate;

In Minnesota disputes are referred to a mediation service provider if the dispute is not resolved after 30 days and then to binding arbitration if it is not resolved after 60 days; and

In Vermont, pre-trial conferences are held to see if mediation is appropriate for the dispute. If so, the judge orders mediation.

More recently, Kitsap County, Washington adapted an ordinance requiring mediation as a pre-requisite to appeal certain land-use decisions (Smith, 2010). The ordinance is codified in Title 21.04.120 of the Kitsap County Code which states “Kitsap County and the hearing examiner encourage the use of mediation where possible to resolve any disputes that arise at any time during the processing of land use applications or appeal...” (KCC, 2010). The Kitsap County land-use mediation process “when successful should result in a disclosable mediation agreement consistent with the comprehensive plan, adapted codes and ordinances, and the general public interest” (KCC, 2010). The Director, during development application review, may offer voluntary mediation, and if accepted, the mediation must commence within 14 days and be completed within 21 days of its agreement. If an agreement is reached the parties sign a mediation agreement which is then forwarded to the appropriate body for approval. Where an appeal is made in respect of Ministerial (Type 1) or Administrative (Type II) decisions, mediation is mandatory prior to being heard by an examiner. In appeals of quasi-judicial (Type III) decisions, mediation is encouraged but not mandatory. Mediation will be paid for by the County “if the parties choose to use the dispute resolution centre of Kitsap County, but parties must share mediation costs if they decide to use a different mediator” (Smith, 2010).

7 ADR and Mediation in Canada

Not dissimilar to the American situation, a number of variations exist between dispute resolution programs in Canada. Principally concerned with civil mediation, the Canadian experience has sought to improve access to justice. In this respect the introduction of court-connected mediation programs are regarded as the most significant development. In Saskatchewan’s Court of Queen’s Bench, the Department of Justice assigns a mediator to the parties in dispute and it is mandatory that all parties attend the mediation session(s) before further steps can be taken. Should a party fail to attend mediation, a Certificate of Non-Attendance can be filed at which point “the court may either order the party to attend mediation, order another mediation with specific terms, or under certain conditions, strike the proceedings of the party that failed to attend” (Keet and Salamone, 2001: 61). If the mediation process is completed however, the mediator will file a Certificate of Completion.

In contrast to the province of Saskatchewan, mediation services under the Ontario Mandatory Mediation Program, ‘are largely provided by practitioners, chosen by the parties to the dispute’ (Winkler, 2010: 237). Under this system, the mediation session must take place within ninety days of the filing of the first defence. A second contrast between Ontario’s procedures and those of Saskatchewan exist in that parties to a dispute in Ontario must submit a ‘Statement of Issues’ in advance of the mediation session outlining the issues in dispute, their position and their interests. A Certificate of Non-Compliance will be issued by the mediator if this statement is not provided or if a party fails to appear, and the matter will be referred to the case management master or judge who will decide what action is to be taken. The master or judge may “convene a case conference and either establish a timetable for action, strike out any document filed by a party, dismiss the action or strike the defence, order a party to pay costs, or make any other ‘just’ order” (Keet and Salamone, 2001: 63).

Whereas mediation is mandatory under the programs operating in Saskatchewan and Ontario, “the process of judicial mediation [in Quebec] is entirely voluntary (...) and is invoked only when parties show they are ready to reach an amicable settlement” (Otis, 2010: 247). Parties in dispute are notified of the possibility of entering into mediation before a statement of defence is filed and again before filing a certificate of Readiness for Trial.

8 ADR and Mediation in Australia

Recently, in Australia, a burgeoning field of ADR and mediation has developed in relation to environmental disputes. Sipe (1999: 1) suggests the history of environmental dispute resolution (EDR) in Australia ‘begins in the early 1990s, when the Australian Resource Assessment Commission considered using mediation in its inquiry process.’ Although the Commission decided not to pursue the process, the Land and Environmental Court (LEC) of New South Wales began to offer mediation. In addition to EDR process being run in the LEC of New South Wales, ADR practices are common in the Planning and Environmental Court (PEC) of Queensland, the Environment, Resources and Development Court (ERDC) of South Australia, the Victorian Civil and Administrative Tribunal (VCAT) and the State Administrative Tribunal (SAT) of Western Australia. As is the case in America and Canada slight variations exist between Australian Court and Tribunal dispute resolution processes. The two most widely recognised programs are those of the LEC of New South Wales and the SAT of Western Australia.

As one of the oldest specialist environmental courts in the world, the LEC of New South Wales has a two-tier structure allowing it to review the merits and decisions of particular bodies and to declare and enforce the law. Further the LEC has a mixed jurisdiction, dealing not only with merit appeals relating to environmental and land-use matters but also with civil and criminal enforcement cases, and judicial reviews. This jurisdiction is divided into 8 classes accruing to subject matter (See Table 1).

Table 1. Classes of the LECs Jurisdiction
(Source: LEC, 2009)

Classes of the Courts Jurisdiction	
Class 1	Environmental planning and protection appeals (merits review appeals)
Class 2	Local government, trees and miscellaneous appeals (merits review appeals)
Class 3	Land tenure, valuation, rating and compensation matters (merits review appeals)
Class 4	Environmental planning and protection (civil enforcement and criminal review)
Class 5	Environmental planning and protection (summary criminal enforcement)
Class 6	Appeals against convictions or sentences relating to environmental offences (appeals as a right from Magistrates in Local Court prosecutions for environmental offences)
Class 7	Appeals against convictions or sentences relating to environmental offences (appeals requiring leave from Magistrates in Local Court prosecutions for environmental offences)
Class 8	Civil proceedings under the mining legislation

Recourse to mediation at the request of the parties or the Courts volition is permissible in respect of Classes 1, 2, 3, 4 and 8 at any stage in the process. Anything said in mediation is confidential and cannot be used if recourse is transferred to court or tribunal, and any presiding judge will not be informed of anything having occurred during the mediation conference. However, if parties reach an agreement through mediation, “they can either have an informal agreement or have it given the force of a court order so that it is binding” (Lyster et al., 2007: 40).

The SAT of Western Australia, established on 1 January 2005 under the State Administrative Tribunal Act 2004, has jurisdiction of town planning review applications¹, with authority to undertake ADR processes. The SAT have developed two types of directions hearing for planning cases; Class 1 directions hearings for “planning review applications involving developments with a value of less than \$250,000, or single houses with a value of less than \$500,000, and subdivisions to create not more than three lots” (Parry, 2009: 3), and Class 2 directions for all other planning review proceedings. In respect of Class 1 directions hearings, the setting is generally relaxed and usually involves an explanation of the planning review process, identification of the issues in dispute and consideration of alternative solutions. The presiding member has the power to convert the directions hearing to a mediation process if it is perceived this will help discussion and effect resolution of the dispute.

Unlike Class 1 directions hearings, the complexity of Class 2 directions hearings – often requiring preparations and wider participation in order to facilitate resolution – mean that such hearings do not normally discuss the merits of the application or alternatives to it. Rather, “to facilitate resolution of the application or issues, there is a presumption that cases will be referred from a Class 2 directions hearing for mediation...” (Parry, 2009: 4).

9 ADR and Mediation in New Zealand

Prior to the use of EDR and particularly mediation in the resolution of disputes within New Zealand, ADR was a feature of Family Courts. Criticism of the handling of family disputes within the legal system gave rise to the Family Court in 1981 in which ‘the process of dispute handling has a three-tiered system which distances disputants from the option of litigation’ (Wilson, 1993: 363) The first of the three tiers in most cases is counselling provided either by the court or through a private agency. Should the parties fail to reach settlement at this stage, the dispute then moves to the second tier in the system during which a mediation conference is held. It is only in extreme cases that parties will be permitted to move to the third tier of adjudication.

Not unlike the criticism against the handling of family disputes prior to the introduction of the Family Court, “the adversarial approach that tended to dominate most [Planning] Tribunal hearings was a source of concern to many who felt that this method of dispute resolution was often inappropriate and not conducive to an efficient or just method of determining many planning and environmental disputes” (Rive, 1997: 206). In the mid-1980s, a comprehensive review and reform process began in relation to New Zealand’s environmental management framework. As part of this process, “the [Resource Management Act (RMA)] policy formulation process of 1988-90 ... [called] for better integration of mediation and other [ADR] approaches into the statutory framework.” (Montgomery and Kidd, 2004: 106).

Rive (1997: 208) describes how the “coming into force of the Resource Management Act 1991 brought with it a statutory recognition of the appropriateness of employing techniques other than the traditional adversarial model of the resolution of disputes coming before Consent Authorities and the Planning Tribunal.” In particular ‘Section 268 [of the RMA] allows mediation ... to be used before or during an Environmental Court² hearing’ (Mitalfe, 2001: 206). Bollard and Wooler (1998: 711) note, “in practice, once proceedings are lodged an Environmental Judge considers the file and determines whether the matter may be suitable for mediation.” If so, the parties are invited by the registry to participate in the mediation process. Should the parties choose to engage a private mediator they are liable for associated costs and expenses, but “if a Commissioner acts as a mediator, the parties would not be required to pay expenses, as the Environmental Court provides mediation as a free service” (Voigt, 2002: 937).

Where parties engaged in mediation fail to settle their dispute, Section 268(2) of the RMA does not disqualify a member of the Environmental Court:

“...from resuming his or her role to decide the matter ... if: (1) the parties agree that the member should resume his or her role and decide the matter; and (2) the member concerned and the court are satisfied that it is appropriate to do so” (RMA, 1991).

In practice, this rarely occurs with Bollard and Wooler (1998: 711) suggesting “the Court’s own approach tends to regard that course as inappropriate – a prime concern being to avoid any suggestion (however) belated that what was said in confidence during the mediation somehow played a part in arriving at the Court’s eventual decision.”

10 Investigations into ADR and Mediation in the UK Planning System (England and Wales)

Heavily influenced by and largely following the emerging debates of ADR in the US, discussions of alternative forms of dispute resolution in the UK began in the 1960s, concentrating on criticism of state institutions and the role of the state, before progressing in the 1970s to a focus on criticism of litigation and the merits of settlement. A further turn of discussion occurred in the 1980s; the result of growing interest in ADR within the legal and academic professions. Such discussions inevitably led to developments in practice with pilot projects and court-connected mediation schemes, along with further investigation into ADR and civil justice reform with the publication of the Woolf Report in 1996 and more recently the Jackson Report in 2010.

Whilst developments of ADR in the civil justice system in the UK have grown considerably since the mid 1990s, investigations of the potential use of ADR and mediation in the planning system have been somewhat slower. In May 1996, “Chris Shepley the Chief Inspector [of the RTPI], proposed that the mediation of planning disputes merited discussion, and speculated there might even be a role for the Inspectorate in organising mediation services” (Harrison, 1997: 79).

Over two years later, a report into the use of ‘Mediation in the Planning System’ was commissioned by the Department of the Environment, Transport and the Regions (DETR), with the aim of establishing the viability of introducing mediation effectively in the planning process and to determine if this would speed up decision making, reduce the pressure on public funds and the number of disputes which might otherwise result in appeals (Wellbank et al., 2000: 6). A study prior to the production of the report included a pilot project of 48 cases and led to the formation of six recommendations. The first three of these recommendations focus on the use of mediation in the planning system, arguing:

the use of mediation should be encouraged on a voluntary basis but under formal arrangements;

in the first instance there are benefits in establishing a mediation service with trained volunteer mediators; and

best practice guidance should be made available on the use of mediation in the planning system.

The final three recommendations relate to proposed changes to the planning system developed from experiences gained in the pilot project, and suggest:

the effectiveness of the existing communication arrangements between parties in the planning system, (i.e. the applicants and planning departments), should be reviewed;

a separate planning application regime for ‘householder’ applications should be introduced; and

there is a need for further study into the use of additional forms of ADR in the planning system, and additional research into the application of mediation to processes in the planning system other than planning appeals.

Following these recommendations the DETR commissioned 'Further Research into Mediation in the Planning System'. Published in November 2002, the report identified five additional recommendations concerning mediation in the planning system, namely:

a National Planning Mediation Service be established;

an Implementation Program for Mediation be launched;

the use of Mediation be incorporated as a Best Value Indicator;

incentives to encourage the use of Mediation be provided; and

the remit of the National Planning Mediation Service be drawn to cover 'stakeholder dialogue' services. (Wellbank et al, 2002: 67-70).

Published in September 2003, the report by the then Office of the Deputy Prime Minister (ODPM) entitled, 'Participatory Planning for Sustainable Communities: International experience in mediation, negotiation and engagement in making plans', called for a move from public participation to participatory planning in which mediation may be used to resolve conflicts and objections to development plans. The paper suggests there is a spectrum of processes within participatory planning: engagement, negotiation, pre-mediation (planning authority-led, seeking to resolve potential disputes between other parties and reach agreements that can be built into the plan), and mediation by a neutral third party when the planning authority is a party to the dispute (ODPM, 2003: 4).

There has been little progress made on the recommendations of the aforementioned reports with Barker (2006: 169) under Recommendation 25 reiterating the Department for Communities and Local Government (DCLG):

“should establish a planning mediation service to act as an alternative dispute resolution mechanism within the planning system [and advancing the Planning Inspectorate] should also explore further means of reducing demand for the appeals system [and suggesting] this should include greater use of powers to charge for unreasonable behaviour leading to unnecessary expenses.”

In November 2008 the final report of the Killan Petty Review “recommended that greater use of alternative dispute resolution should be encouraged at all stages of the planning application process where this can deliver the right decisions in a less adversarial and cost efficient way” (Killen and Petty, 2008: 118) suggesting two options to achieve this. The first argues that steps need to be taken by planning authorities and applicants to identify areas in which recourse to alternative dispute resolution mechanisms during the planning process are possible, and the second suggests further research is required to discover if the costs in introducing a formal mediation scheme outweigh the potential time and cost savings of less appeals.

In response to the suggestion by the Killen Petty Review, urging investigation of the use of ADR in all stages of the planning process, a final report on 'Mediation in Planning', jointly commissioned by the Planning Inspectorate and the National Planning Forum for England was launched on 29 June 2010. The report identified three key recommendations containing in total 10 sub-recommendations:

developing and building a market for mediation to include: developing awareness, assessing the value of mediation, developing practice, selling the idea and assessing the effectiveness.

providing advice and guidance on mediation to include: developing understanding; quality assurance;

developing skills and creating capacity for mediation to include: providing a framework and developing the infrastructure to support the use of mediation, and developing the skills and knowledge of all players in the planning system. (Roze & Powell, 2010: 29).

Whilst welcoming the report Grossman (2010) comments that the planning community is behind in the game when it comes to mediation suggesting

“mediation has been a real, viable and - to a large extent - available option for the last decade and it is time that the planning community caught up with other sectors, both private and public, who have been using it to resolve their disputes and assist in better communications and dialogue.”

He advocates the need to develop a strategy for introducing mediation to the planning system rather than simply taking an exploratory stance.

Although now, no specific provision for ADR and mediation appears in planning policy or legislation, Parmiter & Phillips (2008) suggest “some tools and guidance already exist in the planning system to allow planners to make more use of mediation.” For example Rule 14(1) of the Town and Country Planning (Inquiries Procedure) (England) Rules 2000 requires the planning authority and the applicant to “prepare an agreed statement of common ground and ensure that the Secretary of State [and any] statutory party receives a copy of it not less than four weeks before the date fixed for the holding of the inquiry” (TIE, 2000). Whilst acknowledging this does not always happen, the use of ADR practices may facilitate parties in preparing their agreed statement and limiting the number of issues going to inquiry with Parmiter & Phillips (2008) suggesting “the nature of mediation is ideally suited to identifying existing areas of consensus, which are often surprisingly broad.”

11 Investigations into ADR and Mediation in the UK Planning System – (Scotland and NI)

Whilst there has been no investigation in NI into the potential use of ADR and mediation in the Planning System there have been some investigations in Scotland. In 2003, the Planning Division of the Scottish Executive Development Department produced a Consultation Paper into ‘Modernising Public Local Inquiries’ stating “planning authorities must work harder to reduce the number of objections that reach inquiry, through mediation and negotiation leading to agreed changes to the plan before the inquiry is requested” (SE, 2003: 19).

In questioning if the process of development planning could be improved the paper asked if improvement could be brought by reducing the number of objections to plans through negotiation and mediation prior to calling an inquiry and by adapting a hearing format as the norm for all plan inquiries and applying other relevant improvements. An analysis of the ‘Digest of Responses to the Consultation Paper’ reveals mixed views

from respondents on the use of mediation to reduce the number of objections to the plan, (See Table 2).

Table 2. Views of the use of mediation to reduce the number of objections to plans
(Source: Created by Author from an analysis of responses to the
Consultation Paper on Modernising Public local Inquiries)

	Respondent	In favour of Mediation	Recognised Positives & Limitations of Mediation	Against Mediation
Breakdown of Respondents & Responses	Local Authority (LA)	5	6	1
	Other LA Organisation	0	1	0
	Public Bodies	3	0	0
	Development Industry	1	0	0
	Other Business / Business Group	2	1	0
	Professional Organisation	2	1	0
	Planning Consultant, Architect or Lawyer	1	3	0
Totals number of Respondents		14	12	1

In favouring the use of mediation prior to the public examination of objections, Western Isles Council suggested “it may be worth considering whether there would be a role, either in mediation, or even in a hearing or inquiry, for local environmental courts” (SG, 2003: 206). The sub-committee of the Law Society of Scotland whilst agreeing that there is potential for the use of mediation to reduce the volume of objections, indicated this should not be the norm adding they are very cautious about compulsory mediation in this area. The legal practice of Archibald, Campbell & Harley commented that “all parties to the local plan process should be encouraged to recognise that mediation and negotiation have their parts to play” (SG, 2003: 212) but indicated in practice this may not be easy as too many ‘planning authorities are trapped into defending their plans at all costs’ (SG, 2003: 212).

Later, the Scottish Government produced a guide on the matter in 2009. Entitled ‘A Guide to the Use of Mediation in the Planning System in Scotland’, “the purpose of the guide is to help those involved in the planning system in Scotland to understand how mediation can be used to enhance the planning process” (SG, 2009: 1). The report identified a number of areas in the planning system in Scotland where the use of mediation may be appropriate, including: (1) the consultation phase of national planning projects; (2) the pre-plan and post-draft plan publication phases of the development plan process; (3) the pre-submission consultation stage for planning applications; (4) the pre-decision phase in the planning application process; (5) the post-refusal stage of the application process; and (6) prior to the planning authority undertaking full enforcement measures.

12 Issues Emerging for Further Investigation

The analysis of dispute resolution programs operating in a number of court and tribunal based settings, has demonstrated a number of differences in practice and procedure, both within and between jurisdictions. These differences have identified a number of issues for further investigation in considering if mediation can lend itself to planning

practice in the UK. Notably, it will be necessary to consider how disputes in planning are decided applicable to mediation. Is it the case that this should be left to the parties to file a statement stating their appeal can be dealt with by mediation as is the case in Connecticut, or should parties attend orientation or screening sessions to have their dispute assessed, as suggested by Frank Sander? Some options pre-suppose that mediation is voluntary, others that mediation is mandatory, but which is most appropriate to planning disputes and most applicable to the existing planning system. If mandatory mediation is viable should this be in all cases or for certain types of dispute as identified in the Kitsap County Code? Is it the case, particularly with a back-log of planning appeals that a tiered system can be introduced as exists on Minnesota or the Family Court in New Zealand? Further, who mediates and who enforces mediation agreements? Is there a need to consider the role of environmental courts in the UK?

Both planning practitioners and members of the community and voluntary sector have expressed concern about local authority planning officers and commissioners functioning as mediators and decisions makers. Mediation practitioners, when questioned on this issue suggested the possibility of incorporating in planning, practices similar to that introduced by the NI Parades Commission who facilitate disputes concerning public processions. Under this system, independent 'Authorised Officers' contracted by the Parades Commission work on the ground to mediate public procession disputes and if mediation fails a decision on the matter is taken by Commissioners. This is similar to the system Bollard and Wooler (1998) have shown to operate in the Environmental Court of New Zealand.

Despite this and the use of mediation in courts and tribunals some planning practitioners questioned the appropriateness of introducing mediation in the tribunal system. In expressing that this was their opinion, they did make an interesting suggestion that further investigation on this matter could be undertaken by approaching organisations such as the Industrial Relations and Employment Tribunal who may have different views of mediation in the tribunal setting. Whilst labour models of mediation may be beneficial for appeals and some enforcement disputes, where parties in dispute are easily identifiable, the issues in dispute are easily defined and usually involve legal representatives or experienced negotiators in bilateral negotiations, Susskind and Ozawa (1983: 186) suggest:

“There are strong indications that in the larger realm of public resource allocation disputes, the labour model may prove ... inappropriate.”

The earlier discussion on globalisation and planning practice becomes important in considering that conflict in public sector land-use disputes often involves a number of vague issues held by many different interest groups with un-equal access to resources. For Susskind and Ozawa (1983) the international model of mediation may be more applicable to public sector disputes in that the mediator has a more overt role in the process. How blatant, this role should be is a matter for further investigation, but it may be appropriate to consider moving away from the role of the mediator as an impartial and neutral third party to that of an advocator who takes into account power inequalities of the parties to dispute. Some planning practitioners and members of the community and voluntary sector suggested it may be appropriate for community organisations to undertake the role of mediators in the planning system as much advocacy work is already undertaken by these bodies which often facilitate negotiations between communities and developers regarding land-use activity.

It is apparent that no single approach to mediation can be applied to the nature of conflict within the planning system and whilst procedures and practice drawn from programs used elsewhere may be tailored to apply to the planning system, nuanced approaches to mediation will be required to facilitate the resolution of disputes considered more complex and hindered by diverse interests and contestation.

13 Notes

¹ “‘Planning review applications’ and ‘planning cases’ in the State Administrative Tribunal refer to applications for review of decision of local and state government authorities to refuse to grant approval for, or to grant conditional approval for, development or subdivision applications or strategic planning proposals under planning schemes, and to give landowners and other directions or notices in relation to the carrying out of development or other activities.” (Parry, 2009: 1)

² The Planning Tribunal was replaced by the Environmental Court with the introduction of the Resource Management Act 1991.

The Shared Ownership Lease: Can the Wrong be Righted?

Nicholas Macklam, Susan Bright and Nicholas Hopkins

n.p.hopkins@soton.ac.uk

Abstract:

The Coalition Government continues to support the use of “shared ownership” to provide an affordable route into home ownership. Yet there is a significant problem with the shared ownership scheme; as *Richardson v Midland Heart* [2008] L & TR 31 shows, in the event of the home “owner” falling into rent arrears, he or she may lose not simply his or her home, but also the equity in the property. This paper examines whether there is some way of using existing legal principles to avoid this unjust outcome by either; first, protecting the use value of the home by relying on Convention rights under the Human Rights Act 1998 to prevent termination of the “shared ownership” lease; or, secondly, recouping the investment value of the home by using human rights, public law and private law arguments to enable the home “owner” to retain the equity even if the home is lost.

Keywords:

Shared Ownership, Human Rights, Housing Law

1 Introduction

An Englishman’s home is his (or her) castle. In England the majority of householders live in homes that they own, with surveys demonstrating repeatedly the population’s strong preference for home ownership over renting. Yet rising housing prices have meant that traditional home ownership – the purchase of a home funded through the buyer’s own resources and a commercial mortgage – has become the impossible dream for many. As a result, successive governments have sought to make this dream a reality by filling the affordability gap through Low Cost Home Ownership (LCHO) schemes.

One legal model for such schemes is “shared ownership”, or “part-buy part-rent”. Shared ownership schemes aim to place the purchaser somewhere along spectrum of home ownership, but are in fact a misnomer; there is no sharing of ownership at all. What the purchaser gets in reality is a “shared ownership lease”. This is a lease of a 99-year term (if necessary, purchased using a commercial mortgage); the premium paid for the lease is calculated according to the percentage of the market value the purchaser is able to afford (generally between 25-75%), and a sub-market rent is paid on the “un-purchased share”. The freehold is retained by the housing provider (most typically a housing association).

Shared ownership properties necessarily constitute a dwelling-house which is let as a separate dwelling, as the purchaser’s only or principal home. The shared ownership lease therefore falls within the definition of an assured tenancy under section 1 of the Housing Act 1988.¹ As a result, the lease attracts certain statutory protections, including

¹ As rent is being paid on the un-owned share, the lease will not fall into the exceptions in schedule 1 to the Act for leases in which there is no or low rent.

fetters upon the termination of the tenancy which can occur only by court order and on the grounds provided in schedule 2 to the Housing Act 1988. Crucially, this means that the lease is subject to Ground 8.

Ground 8 entitles the landlord of an assured tenant to a possession order if two months' rent is unpaid;¹ provided that condition is satisfied both at the time notice is served under section 8 of the 1988 Act and at the date of the hearing, the court must make the order. Possession under Ground 8 is thus mandatory, not discretionary.

Use of Ground 8 and its draconian consequences has the potential to turn the ownership dreams of shared ownership tenants into nightmares, exemplified by the following case:

Richardson v Midland Heart [2008] L & TR 31

- 99-year shared ownership lease; Miss Richardson "owned" 50% share of the property.
- House worth £60,000 in 1995 (when the lease was granted).
- By 2005 this has risen to £150,000; the rent payable on the "non-owned share" was approximately £1,500 p/a.
- Miss Richardson subsequently fled the property to a women's refuge; rent arrears began to accrue.
- The housing association successfully applied for possession under Ground 8.
- Miss Richardson tried to recover her 50% "share" of the property. She failed.
- She lost: her home, her share of the uplift of the property's value (£45,000) and her initial premium (£30,000) (although the housing association made an *ex gratia* payment of this amount, less rent arrears).

The injustices:

- Use of Ground 8; albeit that loss of the home was inevitable once the arrears began to mount up.²
- But she also lost the investment value tied up in the home. Is Miss Richardson any different to a standard renter? Where is her "ownership"?
- Do such consequences fundamentally undermine the aim of the scheme to deliver home ownership to those who otherwise couldn't afford it?

This paper looks at ways to avoid these injustices; first, by protecting the "use value" of the property by preventing possession. Three avenues will be explored: using Article 8 of the European Convention on Human Rights (ECHR); using Article 1 of the First Protocol to the ECHR (A1P1); and using judicial review to challenge the decision to seek possession. Secondly, means of recouping the "investment value" of the property will be discussed, to deal with the situation where the tenant is unable to prevent the housing association from obtaining possession and therefore wishes to recoup his or her "share" of the monetary value of the property. Again, three areas will be explored in depth (with arguments of private law also discussed in outline): using A1P1; claiming

¹ The entitlement based on two months' unpaid rent is for rent payable monthly; if payable weekly, the requirement is eight weeks' unpaid rent; if payable quarterly or yearly, the requirement is one quarter's rent in arrears of more than three months and three month's rent in arrears of more than three months respectively.

² A significant feature of the *Richardson* case was that Miss Richardson had not used a mortgage to buy her 50% share, but had paid this sum outright. If a mortgagee had been involved, then it would have intervened to protect the security (eg, by discharging the arrears). But it appears that it is not uncommon for shared ownership leases to be purchased without a mortgage; this happens in around 15% of cases: see Tenant Services Agency, 'Existing Tenants Survey 2008: Shared Owners' (2009) p 25.

under the public law doctrine of legitimate expectations; and making recourse to Ombudsmen.

2 Protecting the use value: Article 8, A1P1 and Judicial Review

This section looks at whether possession can be delayed or prevented in order to give the tenant under a shared ownership lease (“the tenant”) time to sell his or her share in the property and thus recover the money invested.¹ Clearly, this argument can only assist the tenant if it is brought prior to the possession order being granted.

2.1 Article 8

There has been much activity in recent years involving Article 8 being used to challenge possession proceedings brought by social landlords. A sustained clash between the European Court of Human Rights (ECtHR) and domestic courts has finally been brought to an end by the Supreme Court in *Manchester City Council v Pinnock*,² where it was decided that domestic courts must be permitted to examine the proportionality of a possession order in order to comply with the procedural requirements of Article 8 (although in the overwhelming majority of cases, the substantive challenge based on Article 8 will likely fail – unlike Ground 8, some grounds for possession already carry a condition of “reasonableness”; if granting the order is “reasonable”, it is highly unlikely to then be disproportionate).³

*R (Weaver) v London Quadrant Housing Trust*⁴ established that housing associations could be classified as hybrid “public authorities” under the Human Rights Act 1998 (HRA 1998), meaning they would be under a duty to comply with Convention rights through the operation of section 6(3)(b) of the HRA 1998.

Following the principles laid down in *Weaver*, housing associations offering shared ownership leases would appear to constitute a hybrid “public authority” for HRA 1998 purposes. This is because; first, they will most likely be in receipt of social funding in the form of social housing grants; secondly, they provide subsidised housing (a “governmental function”), which has been promoted by successive governments; thirdly, they most likely will have charitable status and therefore have charitable objects and act in the “public interest”; finally, if a housing association constitutes a “non-profit registered provider of social housing”, it will be able to exercise certain statutory powers, such as applying for Anti-Social Behaviour Orders.⁵

It must also be shown that the act of taking possession proceedings under Ground 8 is an act of a “public” nature. Following *Weaver*, it probably is: the act of terminating a social tenancy⁶ is so bound up in the function of providing social housing that, if the latter constitutes a “public function”, the former must constitute a “public act”.⁷

¹ Shared ownership tenants do have alienation rights in relation to the property. However, the lease is structured in a way that encourages the shared owner to notify the housing association that they intend to sell. The housing association then enjoys a period of exclusivity (usually two months) to nominate a purchaser. Only if that period expires without a buyer being found, or if the nominated buyer fails to proceed, is the tenant able to offer the property on the open market.

³ *Pinnock* (n 5) [55] and [56].

⁴ [2009] EWCA Civ 587, [2010] 1 WLR 363.

⁵ Crime and Disorder Act 1998, s 1(1A).

⁶ Housing and Regeneration Act 2008, ss 68 and 70 explicitly classifies shared ownership as social housing.

⁷ See *Weaver* (n 7) [76] to [80]. Although *Weaver* involved termination of an assured tenancy, the argument applies equally to the allocation and termination of low cost home ownership products.

2.1.1 *The substantive challenge under Article 8*

Article 8 reads:

Everyone has the right to respect for his private and family life, his home and his correspondence.

There shall be no interference by a public authority with the exercise of this right except such as is in accordance with the law and is necessary in a democratic society in the interests of national security, public safety or the economic well-being of the country, for the prevention of disorder or crime, for the protection of health or morals, or for the protection of the rights and freedoms of others.

Where a public authority seeks possession of a person's home, Article 8 is engaged due to the interference with the tenant's "home" rights.¹ Any measure which interferes with Article 8 rights must pursue a legitimate aim in accordance with the law by answering a "pressing social need" and the measure used to pursue that aim must be "necessary in a democratic society".

In practice this is now taken to mean that it is necessary to show both that possession pursues a legitimate aim and is a proportionate means of achieving that aim.

2.1.2 *Pursuit of a legitimate aim?*

In *Pinnock* it was said that "there will be no need, in the overwhelming majority of cases, for the local authority to explain and justify its reasons for seeking a possession order."² This view was based on the fact that, in the majority of cases, the twin aims identified in *Pinnock* are satisfactory for Article 8 purposes. The twin aims were: a) vindicating the authority's ownership rights; and b) enabling the authority to comply with its public duties in relation to the allocation and management of its housing stock.

But shared ownership cases are different. Shared ownership operates very differently from the social housing statutory regime under consideration in the *Pinnock* and *Hounslow London Borough Council v Powell*³ cases.⁴ It is clear that in *Powell* Lord Hope places emphasis on the fact that Parliament has already carefully decided who is to have security and who is not under the Housing Act 1985 to reflect the perceived housing management needs of local authorities.

This conclusion does not apply in the same way to shared ownership tenants. First, no particular Parliamentary attention has been given to the way in which shared ownership works. Secondly, shared owners have not been deliberately placed into a class of occupiers for whom there is no security, unlike the occupiers under consideration in *Pinnock* and *Powell*. The absence of security is probably an unanticipated consequence of the legal models used to deliver shared ownership. It is likely that prior to *Richardson* most people would have assumed that termination of a shared ownership lease would be

¹ "The loss of one's home is the most extreme form of interference with the right to respect for the home"; see *Kay v United Kingdom* [2011] HLR 2 [68].

² *Pinnock* (n 5) [53].

³ [2011] UKSC 8, [2011] 2 WLR 287. *Powell* was heard a few months after *Pinnock* was handed down, and was billed in the latter case as providing more specific guidance as to the nature of the proportionality inquiry to be undertaken by the courts.

⁴ The demoted and introductory tenancies under consideration in *Pinnock* and *Powell* were set up to deal with the problem of anti-social behaviour; the licence granted under the homelessness legislation in *Powell* was part of the response to the need for housing authorities to be able to respond flexibly and quickly to homelessness situations.

governed by the usual rules on forfeiture giving the possibility of relief against forfeiture being available.¹ Thirdly, the first aim in *Pinnock* is to do with vindication of ownership – in shared ownership cases, ownership itself is split between the housing association and the tenant.² Fourthly, account should be taken of the aim of shared ownership: unlike rental social housing it is about more than simply providing a roof over one’s head; it is also intended to enable a capital asset to be built up.

2.1.3 Proportionality

Adapting the language from the leading immigration case of *Huang v Secretary of State for the Home Department*,³ the balance required by Article 8 requires consideration of whether the grant of possession, taking full account of all considerations weighing in favour of the occupant, prejudices the occupier’s right to respect for the home in a manner sufficiently serious to amount to a breach of the fundamental rights protected by Article 8.

The onus is therefore on the tenant to demonstrate that possession is, in the context, disproportionate and prejudices his or her right to respect for the home. This presents a significant challenge, because (absent special personal circumstances), the crux of the shared ownership tenant’s case is that it is (usually, not exceptionally) disproportionate because it means losing not simply the use value but also the *investment value* of the home.

However, whilst “home” has an autonomous meaning in the ECtHR jurisprudence and has been interpreted broadly,⁴ it has never previously been argued that it extends to the investment value of the home. Nevertheless, in the particular context of shared ownership, taking account of the policy reasons underlying the promotion of LCHO and the intangible values associated with ownership, the argument could be run that “home” should be understood not simply to cover the roof over the head but all of the other benefits associated with ownership – including the investment value. As Hopkins and Bright have argued elsewhere, home incorporates much more than simply a roof over the head and in the context of low cost home ownership products the ability to build a capital asset (investment) is integral to the meaning of home.⁵

2.2 A1P1

A1P1, entitled “protection of property” reads:

Every natural or legal person is entitled to the peaceful enjoyment of his possessions. No one shall be deprived of his possessions except in the public interest and subject to the conditions provided for by law and by the general principles of international law.

¹ For full details on relief against forfeiture, see K Gray and S F Gray, *Elements of Land Law* (5th edn, OUP 2009) para 4.4.52 and following. Put briefly, there are various statutory grounds through which the tenant can obtain relief from forfeiture, in addition to the residual equitable discretion of the courts; in the case of non-payment of rent the tenant is effectively entitled to relief if he or she pays all arrears and costs.

² For more detailed information on this point, see S Bright and N Hopkins, ‘Home, Meaning and Identity: Learning from the English Model of Shared Ownership’ (2010) *Housing, Theory & Society* DOI: 10.1080/14036096.2010.527119.

³ [2007] UKHL 11, [2007] 2 AC 167.

⁴ *R (Countrywide Alliance) v Attorney General* [2007] UKHL 52, [2008] 1 AC 719, 745, citing *Niemietz v Germany* (1993) 16 EHRR 97 to illustrate that the expression “home” can “... cover premises other than the place where a person lays his or her head at night”.

⁵ S Bright and N Hopkins, ‘Home, Meaning and Identity: Learning from the English Model of Shared Ownership’ (2010) *Housing, Theory & Society* DOI: 10.1080/14036096.2010.527119.

The preceding provisions shall not, however, in any way impair the right of a State to enforce such laws as it deems necessary to control the use of property in accordance with the general interest or to secure the payment of taxes or other contributions or penalties.

Using Article 8 to protect the investment value is a novel argument. It is much easier to show that it comes within A1P1, the ambit of which extends significantly further than simply “home” rights. The protection of “possessions” in the first sentence of A1P1 guarantees, in substance, the right to property.¹ Within its scope fall all rights and interests constituting assets, broadly understood, as explained by the ECtHR in *Stretch v United Kingdom*:

The Court recalls that, according to the established case law of the Convention organs, “possessions” can be “existing possessions” or assets, including claims, in respect of which the applicant can argue that he has at least a “legitimate expectation” of obtaining effective enjoyment of a property right.²

For a claim to succeed, there must be an interference with “possessions” (the “interference” question), which is not “in the public interest and subject to the conditions provided for by law” (the “justification” question); in substance, the justification question leads to a proportionality analysis.

As a preliminary point, it should be noted that the reasoning of the Supreme Court in *Pinnock* and *Powell*, in the context of Article 8, would apply in a similar way to A1P1. In other words, the conclusion in the *Pinnock* line of jurisprudence was that, where Article 8 is engaged, domestic courts are required to consider the effect of making a possession order on the rights guaranteed by that provision; it seems highly unlikely that a different result would obtain in the case of A1P1, or that the ECtHR would take a softer approach in terms of the procedural requirements for compliance with A1P1 as compared to Article 8.³

2.2.1 *The “interference” question*

In practice, the ECtHR has treated A1P1 as containing three rules:

The *first* rule, which is of a general nature, enounces the principle of peaceful enjoyment of property; it is set out in the first sentence of the first paragraph.

The *second* rule covers deprivation of possessions and subjects it to certain conditions; it appears in the second sentence of the same paragraph.

The *third* rule recognises that states are entitled, amongst other things, to control the use of property in accordance with the general interest, by enforcing such laws as they deem necessary for the purpose; it is contained in the second paragraph.⁴

¹ *Marckx v Belgium* (1979) 2 EHRR 330 [63].

² (2004) 38 EHRR 12 [32].

³ It may be the case that the ECtHR would allow a wider margin of appreciation in the case of A1P1, as a less “fundamental” right than Article 8; in other words, states would be afforded a wider degree of discretion in relation to measures which interfere with A1P1 rights. However, that margin of appreciation would very much depend on the specifics of the individual case; the more fundamental the substance of the right claimed, the narrower the margin of appreciation.

⁴ *Sporrong and Lönnroth v Sweden* (1983) 5 EHRR 35 [61] (emphasis added).

The approach of the ECtHR is to classify an interference with possessions under one or more of these three rules. The second rule (“deprivation” of possessions) is said to apply to someone who is deprived of ownership, meaning “the *extinction* of all the legal rights of the owner by operation of law or the exercise of a legal power to the same effect”.¹

In contrast, the third rule (“control of use” of possessions) typically involves the elimination of one of the sticks from the bundle of rights comprising ownership, thus constituting interference with possessions, but not to the extent required under the second rule. Examples of measures which have been held to constitute a “control of use” include import and export laws² and planning controls.³

The analytical value of approaching AIP1 on the basis of three separate rules has been questioned; in some cases, the ECtHR has taken the view that it is unnecessary to decide whether an interference falls within the second or third rules (for example). However, in other cases the classification as to which “rule” the case falls under has been influential on the outcome, because interferences falling under the second rule *may* be subject to a proportionality inquiry of a greater intensity than those falling within the third rule.

The most conspicuous illustration of the difficulties in this area is *JA Pye (Oxford) Ltd v United Kingdom*,⁴ where the Grand Chamber held that the operation of the rules on adverse possession in English law were not in violation of AIP1. One of the reasons for this finding was because the scheme of adverse possession was ruled to constitute a “control of use” of property under the third rule.⁵ This result is highly surprising, and demonstrates the difficult task in drawing the line between the three rules. It has been commented in relation to this case that “it is highly unsatisfactory that an essentially unprincipled classification exercise should have substantive consequences”.⁶

Further difficulties have been seen in domestic case law. First, there are cases where classifications under domestic law are not consistent with those in Strasbourg.⁷ Secondly, there is a potential hurdle for cases involving an apparent deprivation of ownership, which has come about as a result of one of the incidents of that ownership.⁸

¹ See R Clayton and H Tomlinson, *The Law of Human Rights: Volume 1* (2nd edn, OUP 2009) para 18.104, citing *Lithgow v United Kingdom* (1986) 8 EHRR 329 [107].

³ *Pine Valley Developments v Ireland* (1991) 14 EHRR 319.

⁴ (2008) 46 EHRR 45.

⁵ The case was decided on the basis that the proportionality test was satisfied: a fair balance *had* been struck between the interests of the individuals and the community. However, the court was split 10:7, with a dissenting judgment arguing that a fair balance *had not* been struck, in large part down to the absence of compensation for the holder of the paper title. However, the majority was of the opinion that compensation is only an important factor in second rule (deprivation of possessions) cases; the dissenting judgment disagreed. Arguably, then, if the case were categorised as falling within the second rule, the absence of compensation may have tipped the balance in the proportionality inquiry.

⁶ R Clayton and H Tomlinson, *The Law of Human Rights: Volume 1* (2nd edn, OUP 2009) para 18.110.

⁷ For example, English courts have held that the imposition of penalties and taxes falls under the second rule, whereas the ECtHR treats such interferences as falling within the third rule.

⁸ For example, in *Wilson v First County Trust Ltd (No 2)* [2003] UKHL 40, [2004] 1 AC 816, statute had provided that where specific formality requirements were not fulfilled, certain loan agreements were unenforceable. A loan agreement which fell foul of these requirements came before the House of Lords: was the operation of the statute which rendered the agreement unenforceable in violation of AIP1? Lords Hope and Scott held that it was not; the agreement was from the outset improperly executed, and therefore the lender *never* held the rights to enforce the agreement. As those rights were never vested in the first place, there was no deprivation of possessions, and consequently AIP1 was not engaged. In contrast, Lord Nicholls held that AIP1 would have been engaged; on delivery of the chattel which provided security for the loan, the lender acquired a proprietary interest which was extinguished when the court refused to make an enforcement order pursuant to the state. Whether AIP1 was engaged was, according to his Lordship, “a matter of substance rather than form”. The approach of the Court of Appeal in *CA*

This involves a complex idea. The nature of the “possession” owned will often be defined by the contract creating that right and if this contract contains limitations then any termination in accordance with those limitations can (arguably) be said not to involve a “deprivation of possessions”. However, this “inherent limitation” point seems surmountable in the context of termination of leases on statutory grounds, on the basis that from the moment of grant the tenant has all the powers of a leaseholder; it is the legislation which provides the means by which these powers can be extinguished and Ground 8 (for example) is therefore not a limitation inherent to the lease.¹

The termination of a lease using Ground 8 falls either under the second or third rules. Under domestic law, where there has been very little analysis of “control of use”,² the courts have taken a common-sense approach stating (in a context outside of A1P1) “whether a law or exercise of an administrative power does amount to a deprivation of property depends of course on the substance of the matter rather than upon the form”.³ This would seem to indicate that a domestic court would treat the termination of a lease as falling within the second rule of deprivation of possessions; a conclusion supported by the judgment of the Court of Appeal in *Pennycook v Shaws (EAL) Ltd*.⁴

On the other hand, it is difficult to distinguish the Grand Chamber’s decision in *Pye*, where it was held that the extinguishment of freehold title by operation of statute⁵ was simply an exercise of rules which governed the regulation of land use, and therefore fell within the third rule of “control of use” (a point on which both the majority and dissent were in agreement).

2.2.2 The “justification” question

Any interference with the rights protected by A1P1 must be justified. In *Stretch*, the ECtHR explained:

According to the Court’s well-established case law, an interference must strike a “fair balance” between the demands of the general interests of the community and the requirements of the individual’s fundamental rights ...⁶

There are two connected issues here. First, any deprivation must be in the public interest; legislative measures which effect an interference with possessions must be subject to conditions provided for by law and pursue a legitimate aim. Secondly, the interference must strike a “fair balance” between the interests of the community and individual rights. In substance this amounts to a proportionality analysis: the means employed must be proportionate to the aims pursued and not impose an excessive burden on one individual.

Webber (Transport) Ltd v Railtrack Plc [2003] EWCA Civ 1167, [2004] 1 WLR 320 and *Pennycook v Shaws (EAL) Ltd* [2004] EWCA Civ 100, [2004] Ch 296 appears closer to Lord Nicholls’ view (although there are difficulties reconciling the cases with either analysis – see T Allen, *Property and the Human Rights Act 1998* (Hart Publishing 2005) pp 236-237).

¹ This conclusion is consistent with *Pennycook v Shaws (EAL) Ltd* [2004] EWCA Civ 100, [2004] Ch 296, where the operation of a statute to extinguish a statutory right to renew was classified by the Court of Appeal as a deprivation of possessions.

² Although it has followed the Strasbourg jurisprudence in treating adverse possession as a “control of use”, following *JA Pye (Oxford) Ltd v United Kingdom* (2008) 46 EHRR 45.

³ *Grape Bay Ltd v Attorney-General of Bermuda* [2000] 1 WLR 574, 583 (PC).

⁴ See *Pennycook* (n 32) above.

⁵ Limitation Act 1980, s 17.

⁶ (2004) 38 EHRR 12 [37].

Of relevance to the “fair balance” inquiry is the provision of compensation: A1P1 has been read to implicitly require the payment of compensation to render lawful a “deprivation of possessions” under the second rule.¹ The presence of procedural safeguards are also relevant: the ECtHR has stated that A1P1 requires that the individual must be given reasonable opportunity to put their case forward, “for the purpose of *effectively challenging* the measures interfering with the rights guaranteed ...”²

The mandatory nature of Ground 8, which means that the tenant cannot challenge possession except on procedural grounds, is important in this context. Similarly, as the termination of a shared ownership lease may invoke the second rule of A1P1 (a deprivation of possessions), the absence of any compensation means that to grant possession, and thereby terminate the lease, is likely to be found disproportionate. Even if termination of the lease were to be categorised as falling under the third rule, this conclusion is supported by the obiter remarks at the High Court stage³ of the *Di Palma* case.⁴

The landlord has received all the rent and service charge due to it. It can be compensated for any additional expense to which it has been put by her behaviour. What factor in the history of the case can justify a result by which, in addition, the landlord recovers, and she loses an asset worth, on her view, £30,000 and on any view many thousands of pounds?

I regard such a loss as a wholly disproportionate penalty for her to suffer for her delayed payment of the judgment debt and, in effect, for her inability to take reasonable steps to protect and preserve her asset.⁵

Where the heart of the proportionality argument is that the shared owner should not lose the investment value of the property, it may be appropriate to delay possession in order to give the shared owner time to sell the property. Lord Neuberger in *Pinnock* said:

... if domestic law justifies an outright order for possession, the effect of article 8 may, albeit in exceptional cases, justify (in ascending order of effect) granting an extended period for possession, suspending the order for possession on the happening of an event, or even refusing an order altogether.⁶

¹ See *James v United Kingdom* (1986) 8 EHRR 123 [54].

² *Jokela v Finland* (2003) 37 EHRR 26 [45] (emphasis added).

³ *Di Palma v Victoria Square Property Co Ltd* [1984] Ch 346 (Ch). See also *Di Palma v United Kingdom* (1988) 10 EHRR 149. The European Commission of Human Rights found there to be no violation of A1P1, placing considerable weight upon the fact that what had happened was not the result of the state interference but resulted from the private law relationship between landlord and tenant. In this case, there was a particular problem because the tenant had been unable to claim relief from forfeiture due to the limited jurisdiction of the county court (which has since been increased). Although this might appear to flow against the argument being made in this paper it is easily distinguishable from the shared ownership lease under discussion; first, the act of termination was, in *Di Palma*, based on the common law right to forfeit and not a statutory ground for termination; secondly, the landlord was a private individual, not a public authority; and thirdly, human rights law has developed considerably in the intervening years.

⁴ In *Di Palma* a long lease was forfeit because the leaseholder had failed (because she was in a dispute with the landlord) to pay the service charge, amounting to £299.36, together with a bailiff’s fee of £15. The flat, at the time of forfeiture, was worth around £30,000. The leaseholder later paid the sum into court and applied for relief against forfeiture.

⁵ [1984] Ch 346 (Ch) 361-362.

⁶ *Pinnock* (n 5) [62].

His Lordship also noted¹ that this may require certain statutory provisions to be revisited, referring to section 89 of the Housing Act 1980. Section 89 limits the period for which a possession order can be postponed to 14 days, but in cases of “exceptional hardship” can be extended to six weeks. In *Powell* Lord Hope said it is not possible to read down section 89 to extend this period but that as no evidence had been given to show that six weeks was insufficient to meet cases of exceptional hardship, he declined to make a declaration of incompatibility.² When discussing section 89, Lord Phillips noted that the effect of the strict section 89 time limit may “in rare cases” cause a judge to refuse possession when it would otherwise have been granted with a longer postponement.³

Given that more than a six week delay will be needed in order to give the tenant of a shared ownership property time to sell, the effect of section 89 is that the court will need to refuse possession (or issue a declaration of incompatibility under section 4 of the HRA 1998, although this route was rejected by Lord Phillips in *Powell*).

Of course, if the effect of the argument is to prevent possession at all this will mean that the housing association is stuck with an occupier who is not paying her dues. It may be that a time will come in which a court would say that the tenant has had their chance and it is now proportionate to order possession, or that legislative change was needed to deal with this problem.

2.3 Judicial Review

In *Kay v Lambeth London Borough Council*,⁴ Lord Hope explained the grounds on which a tenant could challenge a possession order. These were formally known as Gateways (a) and (b); the former a challenge to the law under human rights law; the latter a challenge using judicial review. The availability of these Grounds was confirmed in subsequent cases, such as *Doherty v Birmingham City Council*.⁵

The recent case of *Pinnock*, whilst focusing upon the availability of a direct proportionality challenge under Article 8 (formerly Gateway (a)), also reaffirmed the availability of public law defences. Lord Neuberger said:

... where a tenant contends that the decision of a local authority landlord to issue, or indeed to continue, possession proceedings can in some way be impugned, the tenant should be entitled to raise that contention in the possession proceedings themselves, even if they are in the County Court.⁶

This allows tenants to raise in the county court challenges to possession on grounds of judicial review that would otherwise be brought in the Administrative Court (provided, of course, that the body seeking possession is amenable to judicial review). These points were affirmed in *Powell*, where it was stated that a public law defence in the county court could challenge any prior decision on which the possession claim was founded

¹ *Pinnock* (n 5) [63].

² *Powell* (n 13) [64].

³ *Powell* (n 13) [103].

⁴ [2006] UKHL 10, [2006] 2 AC 465.

⁵ [2008] UKHL 57, [2009] 1 AC 367.

⁶ *Pinnock* (n 5) [81].

(for example, the decision to serve a notice to quit) as well as the decision to bring possession proceedings.¹

Judicial review in this context will generally only involve a rationality inquiry under the test of *Wednesbury unreasonableness*² but in *Kay and Doherty*, this ground of review was expanded to what was dubbed *Wednesbury plus*.

Wednesbury plus is wider than traditional *Wednesbury* grounds; whereas the traditional approach asks whether the decision at issue was “one which no reasonable person would have made”, Lord Hope in *Doherty* stated that the considerations that can now be taken into account are wider and include, for example, longevity of occupation.³ It seems unlikely that, following *Pinnock* (where compliance with Article 8 was reached via the Gateway (a) approach), the intensity of review would drop back down from *Wednesbury plus* to conventional *Wednesbury* rationality; as Toulson LJ noted in *Doran*, that development in intensity of review was based on general public law principles rather than on the Convention rights.⁴

However, *Pinnock* and *Powell* also emphasise the focus of the judicial review; open for challenge is the *decision-making* process, rather than the specific factual circumstances of the claim which are dealt with by a proportionality inquiry (if an Article 8 or similar defence is also put forward). This makes the potential for challenge under judicial review limited in scope, and as a result any public law defence to a possession proceeding will almost inevitably play second fiddle to challenges based on Convention rights of the type discussed above.

3 Recouping the investment value

The above arguments proceeded on the assumption that the tenant is able to defend the possession claim and thus protect the “use value” of the property, at least long enough to enable her to attempt a sale of the property.⁵ Once the lease has been terminated, and the shared owner has lost the home, is there any way in which the “wrong can be righted” by enabling her to recover the “investment value”?

Intuitively it would seem that the tenant should be able to recover his or her “share” of the property under private law principles. But in *Richardson* the tenant was not able to. The fact that Miss Richardson had bargained for and received a lease presents a significant obstacle to arguments for the creation of additional and informal rights through a trust or estoppel. In the case, the arguments advanced focused on attempts to establish a trust arising in favour of Miss Richardson simultaneously to the grant of the lease. A suggestion that the lease may have been held on trust was withdrawn “under judicial pressure”⁶ while a claim to a trust of the freehold failed. HH Judge Gaunt QC explained, “the relationship of the housing association and Miss Richardson was that of landlord and tenant, not that of trustee and beneficiary”.⁷ Bright and Hopkins have shown that an alternative argument, that new rights in the freehold may arise in favour

¹ *Powell* (n 13) [42]. See J Luba and others, ‘Defending Possession Proceedings’ (2011) Legal Action Group (Online Update), 3, <<http://www.lag.org.uk/files/93674/FileName/DPP7onlineupdateforweb.pdf>> accessed 4 August 2011.

⁵ See (n 4) above.

⁶ *Richardson v Midland Heart* [2008] L & TR 31 [11].

⁷ *Ibid.*

of the shared owner at the time the lease is repossessed, is also unlikely to succeed.¹ The shared owner has made no contribution to the acquisition of the freehold to form the basis of a resulting trust, while the express grant of a lease appears to rule out arguments for a constructive trust based either on a “common intention” or on the failure of an informal “joint venture” to provide a home for the purchaser. A claim to proprietary estoppel meets the evidential difficulty of establishing an assurance of property rights other than the lease.

Therefore, this paper turns once more to arguments of human rights and public law.

3.1 A1P1

For reasons canvassed above, it is arguable that termination of the lease constitutes a breach of A1P1. Therefore, the former tenant should be entitled to a remedy.

Section 8(1) of the HRA 1998 gives broad powers to the courts to (in relation to any act which would be unlawful) award “such relief or remedy, or make such order, within its powers as it considers just and appropriate”. Whilst Section 8(1) does not refer to the ECtHR jurisprudence directly, domestic courts have nevertheless taken it into account, reflecting the approach taken to damages under the HRA 1998.

3.1.1 Damages under the HRA 1998

The current leading case is *R (Greenfield) v Secretary of State for the Home Department*,² where a unanimous appellate committee of the House of Lords held that domestic courts were *not* free to depart from the scale of damages applied by the ECtHR (the argument was run that the courts could use domestic comparators in awarding damages). Section 8(4) of the HRA 1998, which obliges domestic courts to take into account the principles applied by the ECtHR in relation to the award of compensation under Article 41 of the Convention, was drawn upon to support this conclusion.

Therefore, domestic courts now operate a “mirror” approach to assessing damages under the HRA 1998; English courts have sought to ensure that the domestic jurisprudence reflects the approach taken by the ECtHR in terms of how the discretion to award damages is to be exercised, and the scales of damages applied.

This decision is unpopular. The Law Commissions of England and Wales and Scotland have recommended that principles of tort law should be drawn upon when awarding damages.³ Many agree; mainly on the basis that the ECtHR jurisprudence in this area suffers from severe deficiencies.⁴ Aside from some basic principles, the approach of the court lacks consistency, coherence, and principle. The court often gives little or no guidance as to the basis on which compensation has been awarded, other than typically saying it has proceeded on an “equitable basis”. Nevertheless, it continues to reflect the present approach of domestic courts.

⁴ See J Varuhas, ‘A Tort-Based Approach to Damages under the Human Rights Act 1998’ (2009) 72 MLR 750.

3.1.2 *The approach to remedies of the ECtHR*

Article 41 of the ECHR (introduced by the Eleventh Protocol to replace Article 50) reads:

If the Court finds that there has been a violation of the Convention or the protocols thereto, and if the internal law of the High Contracting Parties allows only partial reparation to be made, the Court shall, if necessary, afford just satisfaction to the injured party.

The standard remedy for a violation of Convention rights is a declaration or a finding to that effect. However, in recent years the court has taken a more interventionist approach.

For example, compensation is a discretionary remedy available to the ECtHR, which the court has in recent years began to exercise with (relatively) increased frequency. The Law Commissions' report¹ distilled from the court's jurisprudence the following factors which are taken into consideration when deciding whether to award compensation:

- The other measures taken by the public authority in remedying in the breach
- Whether a finding of a breach can constitute "just satisfaction" without the need for compensation
- Whether the loss suffered is sufficient to render an award necessary
- The seriousness of the violation
- The conduct of the respondent
- The conduct of the applicant

The principle of compensation is *restitutio in integrum* – Article 41 strives to ensure that the claimant is (so far as possible) put back into the situation in which he or she would have been had the violation not occurred.

However, in *Brumarescu v Romania*² the Grand Chamber ordered a restitutionary remedy instead of compensation. That case was similar in nature to *Papamichalopoulos v Greece*;³ the court had previously found that the state's nationalisation of the applicant's house constituted a violation of A1P1 and Article 6; the state had failed to remedy the situation, so the court ordered the house in issue (and the land on which it was situated) to be returned to the applicant (and, failing that, compensation representing the current market value of the house):

The Contracting States that are parties to a case are in principle free to choose the means whereby they will comply with a judgment in which the Court has found a breach. This discretion as to the manner of the execution of a judgment reflects the freedom of choice attaching to the primary obligation of the Contracting State under the Convention to secure the rights and freedoms guaranteed (Article 1). *If the nature of the breach allows restitutio in integrum, it is for the respondent state to effect it.* If, on the other hand, national law does not allow – or allows only partial – reparation to be made for the consequences of the breach, Article 41

¹ See (n 59) above.

² (2001) 33 EHRR 36.

³ (1996) 21 EHRR 439. The court ordered the respondent to return property taken from the applicant in violation of A1P1, where the respondent state had failed to abide by the courts earlier order to pay compensation.

empowers the court to afford the injured party such satisfaction as appears to it to be appropriate.¹

3.1.3 Application to the shared ownership scenario

In the scenario where a tenant has failed to defend the possession proceedings and therefore lost their home, in breach of A1P1, the remedy sought would mostly likely be damages to compensate for the loss of the investment value of the home.

Section 8(3) HRA 1998 provides that damages can only be awarded if, after consideration of:

- (a) any other relief or remedy granted, or order made, in relation to the act in question (by that or any other court), and
- (b) the consequences of any decision (of that or any other court) in respect of that act,

the court is satisfied that the award is *necessary* to afford *just satisfaction* to the person in whose favour it is made.

However following Section 8(4) HRA 1998 and *Greenfield*, domestic courts draw heavily upon ECtHR principles when assessing whether to make an award for damages (and if so, to what amount). Unfortunately the ECtHR jurisprudence is not at all helpful in this area. Looking at the factors cited by the Law Commissions in their joint Report, the most relevant in the shared ownership context would appear to be the nature of the loss suffered (whether sufficient to render an award necessary) and the seriousness of the violation (which, again, could draw upon the disproportion between the amount of the rent arrears and the value of the property). Furthermore, the principle of *restitutio in integrum* requires to be ascertained what the position of the tenant would be had the violation not occurred. This would seem to allow an award for the tenant's share of the market value of the property, less arrears owed to the housing association.²

3.2 Public law: legitimate expectations

In English public law a legitimate expectation is a device used to prevent public authorities from defeating, without good reason, expectations they have created in citizens of procedural or substantive rights. So-stated, the doctrine has clear parallels with private law estoppel, but the courts are keen to cut the Gordian knot between the doctrines. In *R (Reprotech) v East Sussex County Council*, Lord Hoffmann said:

It seems to me that in this area, public law has already absorbed whatever is useful from the moral values which underlie the private law concept of estoppel and the time has come for [legitimate expectation] to stand upon its own two feet.³

Public law legitimate expectations and private law estoppel differ in their rationale, focus, and the relief available. Estoppel prevents the defendant acting “unconscionably” by reneging on a promise of rights judged against the individual circumstances of the case. Once estoppel is found the court has remedial discretion guided by the “minimum equity to do justice” or by what is necessary to counter the unconscionable conduct.

¹ (1996) 21 EHRR 439 [20] (emphasis added).

² This also seems to follow the award in *Brumarescu* (n 62) above.

³ [2002] UKHL 8, [2003] 1 WLR 348 [35].

In contrast, the doctrine of legitimate expectations aims to prevent an abuse of public power by the defendant and balances the individual's expectations against the wider public interest. A legitimate expectation that has been generated can be defeated, but only where it is proportionate for the public authority to do so having regard to a legitimate aim pursued in the public interest. The remedies available are those of public law (for example, quashing the decision). It is not generally a route to financial compensation. Damages are generally only available in judicial proceedings where they could have been claimed in private law at the time the judicial was sought;¹ or a private law claim may arise following a successful judicial review (for example, where the effect of finding a public authority's conduct unlawful is that a tort has been committed).

A potential claim under legitimate expectations would require a tenant to demonstrate that a public authority generated a legitimate expectation which is then defeated. One possible avenue to establish the expectation is through the shared ownership literature, which advertises the "*normal rights and responsibilities of a full owner-occupier*". The argument could then run that this was expectation was then defeated by the loss of the home and the consequent loss of the investment value, which clearly illustrate that the tenant did not have the "normal rights and responsibilities" of a true owner. Potentially, this could be used to quash the decision to use Ground 8 as opposed to seeking forfeiture of the lease for non-payment of rent. However, as noted above, Bright and Hopkins have doubted that Miss Richardson would be able to mount a private law claim to estoppel to establish any rights beyond the lease that would protect her investment interest.² In the light of this, it is improbable that a legitimate expectation claim would succeed, as the threshold for generating an expectation is higher than that for an assurance of rights for estoppel. In *Weaver* the court noted that there must be a "clear, unambiguous and unqualified promise";³ compared to the requirement in estoppel of a "clear and unequivocal" assurance.⁴

If a legitimate expectation was established, the issue would then become one of proportionality, akin to the ECHR arguments discussed above. The question would be whether the housing association acted to pursue a legitimate aim in a manner that is proportionate, balancing the defeat of the tenant's expectations against the wider public interest.

Assuming judicial review is brought before possession has been obtained, a successful claim under legitimate expectations could result in the decision to use Ground 8 being quashed, leaving the housing association to make the decision as to how to proceed against the tenant again. As noted above, it would not provide a route to damages. If proceedings were brought after Ground 8 had been exercised, and the decision to use Ground 8 was the quashed, this would mean that the housing association's possession of the property would constitute a trespass for which damages may be available.

3.3 Public law: Ombudsmen

Public sector ombudsmen have been described by the Law Commission as "a vital 'pillar' of administrative justice"⁵ playing a distinct role from that of courts and

¹ Senior Courts Act 1981, s 31(4).

² *Bright and Hopkins* (n 57) above.

³ *R (Weaver) v London and Quadrant Housing Trust* [2008] EWHC 1377 (Admin), [2009] 1 All ER 17 [87].

⁴ *Thorner v Major* [2009] UKHL 18, [2009] 1 WLR 776.

⁵ Law Commission, *Administrative Redress: Public Bodies and the Citizen* (Law Com No 322, 2010) para 5.2.

tribunals. In addition to investigating individual complaints, public service ombudsmen “are in a privileged position to address systematic failures that occur across the administrative landscape”.¹ If *Richardson* represents the “right” outcome as a matter of law, then does there remain an “injustice” of the sort an ombudsman could investigate? The role of two ombudsmen falls for consideration.

3.3.1 *Independent Housing Ombudsman Service*

The Independent Housing Ombudsman Service (IHOS) was created by section 51 and schedule 2 to the Housing Act 1996. Membership is compulsory for social landlords (including housing associations that are registered providers of social housing) with voluntary membership for private landlords. The IHOS has a broad jurisdiction to settle disputes, even where no maladministration is found. The role of the IHOS is thus explained in broad terms, as being to determine complaints “by reference to what is, in his opinion, fair in all the circumstances of the case”.² The IHOS has no jurisdiction where the complaint “[concerns] matters where proceedings have been issued or they have already been taken to a court or tribunal, *where a complainant will have or has had an opportunity to raise them in the proceedings ...*” or where a complaint concerns matters “where the Ombudsman considers it quicker, fairer, more reasonable, and more effective to seek a remedy through the courts, other tribunal or procedure”.³ But the IHOS could investigate, for example, the decision to seek possession under Ground 8 and the accuracy of information provided by the housing association in respect of a shared ownership scheme, as neither of these matters would be raised in Ground 8 proceedings themselves.

3.3.2 *The Parliamentary Ombudsman*

The parliamentary ombudsman provides redress where maladministration has led to injustice. Neither of these terms is defined by the legislation. The government funding for LCHO schemes, set in its broader policy context as a means by which the government promotes home ownership, raises the question of public accountability for the failure of schemes to deliver the policy promise. But it is questionable whether this can be said to constitute “maladministration”. “Injustice” may be found not only on the part of buyers who, like Miss Richardson, have suffered quantifiable financial loss, but more generally by those who discover that they have not got the “normal rights and responsibilities” of home ownership that they were promised.

But there may be doubts as to whether the ombudsman is the appropriate forum in which to seek redress in these cases.⁴ In particular, as we have shown in this paper, it may be questioned whether the legal issues have yet to be sufficiently resolved.

¹ Law Commission, *Public Service Ombudsmen* (Law Com CP No 196, 2010) para 2.50. The Commission’s final report on public service ombudsmen was published on 14 July 2011; see Law Com No 329, 2011.

² Housing Act 1996, sch 2 para 7(1).

³ Independent Housing Ombudsman Approved scheme, paras 16(e) and (f) – see: <http://www.housing-ombudsman.org.uk/downloads/HOS_Scheme.pdf> accessed 4 August 2011)

⁴ To date (4 August 2011) the Ombudsman Case Digest reports only 5 decisions in which the tenure is described as “shared owner”. These complaints deal with defects and repairs to property, management of a parking scheme and the valuation used to determine the rent payable, rather than any broader questions arising from the position of the shared owner – see: <<http://www.housemark.co.uk/hmkb2.nsf/cdhp?openform>> accessed 4 August 2011).

4 Conclusions

This paper has sought to sketch out the arguments available to a tenant facing possession proceedings against his or her shared ownership lease brought under Ground 8. As should now be clear, this is an area of law where there are almost as many questions as there are answers; each of the arguments under Article 8 and A1P1 offer intriguing hurdles to be surmounted – the meaning of “home” under Article 8; the nature of “deprivation of possessions” and “control of use” of property; the provision of damages under the HRA 1998 and Convention case law. This paper has not attempted to offer a definitive solution to these problems. Indeed, it may be years before these emerge from the jurisprudence of the national and European courts. Nevertheless, there is something intuitively wrong with the draconian consequences of the exercise of Ground 8 on shared owners: people (whose housing prospects are weak by definition) losing not just their home, but also their investment as the “ownership dream” turns into a nightmare. It is hoped that human right law provides the means to right this wrong.

Legal Education in Property & Construction

Construction law on built environment higher education programmes: what should be taught? How should it be taught?

Tim McLernon

School of the Built Environment
University of Ulster, Newtownabbey, BT37 0QB
United Kingdom

Email: t.mclernon@ulster.ac.uk

Abstract:

References to the increasingly litigious nature of UK society are prevalent in the journals and magazines directed at the industries and professions associated with the built environment disciplines. Employers of graduates of those disciplines expect those graduates to have the necessary underpinning knowledge to ensure that their practices avoid formal dispute resolution with its inherent cost and expense. The purposes of this paper are to report on an element of a longitudinal study of methods utilised for teaching Construction Law on higher education programmes in the built environment discipline and to highlight and discuss issues arising from the study with a view to educational enhancement. The content of the paper will draw on current prescriptions from the literature relating to perspectives on pedagogy and practice and will critically compare the rationales for curriculum content and teaching practices across different built environment programmes from two UK universities using data from academic tutors and complementary data from small samples of students. The findings of the study will confirm different but sound rationales for curriculum content and will illustrate a variety of teaching methods used for construction law education. The conclusions of the study generated for this paper are indicative and intended for further discussion at the conference to inform curriculum design.

Keywords:

construction, law, curriculum, design, pedagogy

1 Introduction

Our attention is drawn regularly by the press and the media to the litigious nature of UK society. The construction industry has long suffered from a reputation for being susceptible to disputes in the management of the construction project. Journals, magazines and newsletters associated with the built environment and construction regularly report on matters relating to construction management disputes. A search of the internet using one of the search engines produces a wide-range of sources addressing the issue. Historically, economic recession tends to increase the amount of disputes in the construction industry. A future historical study of the association of disputes in the construction industry and impact of the current recession would be informative. Construction contracts and contractual arrangements have been at the hub of contractual disputes. Construction contracts have, in recent years, been utilised as management tools to aid the smooth management of the construction contract. Recent

developments in standard form contracts such as those in the NEC3 and JCT suites of contract have focussed on dictating practices, procedures and, indeed, attitudes and behaviours that aim for smooth running of the contract with an emphasis on the avoidance of formal disputes. Higher education courses in the built environment disciplines have a duty to ensure that graduates are sufficiently equipped with the necessary knowledge, understanding, skills and attributes to add value in the workplace. Employers of graduates of those disciplines expect those graduates to have the necessary underpinning knowledge and attributes to ensure that their practices avoid formal dispute resolution with its inherent cost and expense. Accelerating Change (2002), a report by the Strategic Forum for Construction, stated that (p 10): “*Our vision is for the UK construction industry to maximise value for all clients, end users and stakeholders and exceed their expectations through the consistent delivery of world class products and services*”. The report went on to say (p 11) “*This vision needs to be supported by an education and training process that incorporates best practice and a systematic approach to continuing professional and personal development*”. This vision, with its emphasis on support through continuing and personal development endures as an appropriate context for the construction law curriculum that ultimately contributes to successful construction and project management. The purposes of this paper are to report on an element of a longitudinal study of methods utilised for teaching Construction Law on higher education programmes in the built environment discipline and to highlight and discuss issues arising from the study with a view to educational enhancement.

2 The Built Environment Discipline?

Discipline is defined by the *Oxford English Dictionary* as "a branch of learning or scholarly instruction." It is contended that the modules that make up a course in the built environment discipline are disciplines in their own right. It was hypothesised for the research design for this paper that the learning of Construction Law may be hindered by the mindset and expectations of students because, in the context of discipline, it differs from the rest of the curriculum of the course in which it resides. The courses associated with the built environment have an express or implied practical association. Construction law is founded in the regulation of human behaviour. Law is a discipline that is different. It is textual in format, necessitating the establishment and communication to students of context to focus their thinking by teaching methods that are different, particularly from those more practically oriented subjects such as construction technology, land surveying and laboratory experimentation. The conundrum is to conceive the optimal teaching, learning and assessment regime that best suits the learning styles of the various students that study built environment courses.

2.1 Disciplinary Differences

Kolb (1981) used his original Learning Style Inventory to collect data (the Learning Style Inventory has undergone significant revisions). The Learning Style Inventory consists of a psychometric test used to determine students' learning styles. From this data, Kolb came to an important conclusion that different subjects were related to different styles of learning. Biglan (1973a) devised a conceptual framework to guide the systematic investigation of diversity in the activities and attitudes of academics. He devised a three-dimensional model which contains eight mutually exclusive clusters of subject matter areas, i.e. academic disciplines. The three dimensions of the model are:

1. The degree to which a clearly delineated paradigm exists; referred to as ‘hard’ versus ‘soft’ areas,
2. The extent of concern with the practical application of the subject matter; referred to as ‘pure’ versus ‘applied’, and
3. The level of involvement with living or organic objects of study; referred to as ‘life system’ versus ‘nonlife system’.

The model is shown in Table 3:

Table 3: Clustering of Academic Task Areas in Three Dimensions
(From Biglan 1973 – Law added by this author)

Task Area	Hard		Soft	
	Nonlife System	Life System	Nonlife System	Life System
Pure	Astronomy Chemistry Geology Math Physics	Botany Entomology Microbiology Physiology Zoology	English History Philosophy Communications	Anthropology Political Science Psychology Sociology
Applied	Ceramic Engineering Civil Engineering Computer Science Mechanical Engineering	Agronomy Dairy Science Horticulture Agricultural Economics	Accounting Finance Economics LAW	Educational Administration and Supervision Secondary and Continuing Education Special Education Vocational and Technical Education.

The dimensions of hard/soft and pure/applied are to be represented as continuums as opposed to bounded categories; i.e. as Becher (1989, p155) describes:

“Along the hard/soft dimension, physics chemistry, pharmacy and mathematics are predominantly hard; biology and mechanical engineering less evidently so. Economics and geography may be classed as borderline disciplines on the other side of the divide; history, modern languages, sociology and law lie firmly at the soft end of the scale...”

The model has been used as a basis for subsequent important studies on disciplinary differences as applied to a variety of research projects by different researchers. The validity of the model and of its three dimensions has, over the years, been substantiated and extended by subsequent studies; e.g. Smart and Elton, (1975; 1982); Smart and

McLoughlin, (1978), Stoeker, J.L. (1993) and Hativa and Marincovitch (1995). Smart and Elton (1982) set out to validate Biglan’s model and their study supported the empirical validity of the model and also provided examples ‘to illustrate how the systematic use of the model could enhance the quality of research on university faculty (*sic*) members and the academic administration of institutions of higher learning’.

3 Research Design and Methodology

The research design took into consideration this underlying hypothesis that construction law may be different as a discipline. Data was collected from two UK universities. The rationale for the use of two universities is set out below. A questionnaire was prepared to find out from students what they thought about construction law, its relevance, the students’ approaches to learning construction law and their thoughts on assessment. The questionnaire was distributed to students, willing to participate, in the classroom setting with provision to discuss and explain any matters arising from the questionnaire. The questionnaire, that predominantly requested short, quantitative and qualitative responses, was completed by students as set out in Table1 and Table 2 below.

Table 1: Students Completing Questionnaire; Institution A

Course	Year	Level	No of Students
Quantity Surveying	1	u/g	15
Building Surveying	1	u/g	15
Construction Engineering and Management	2	u/g	15
Architectural Technology	2	u/g	35
Construction and Project Management		MSc	11

Table 2: Students Completing Questionnaire; Institution B

Course	Year	No of Students
Building Surveying	1	18
Construction Management	1	10
Env Building Construction	1	20
Building Surveying	2	9
Construction Management	2	6
Architectural Technology	2	4

Focus group interviews with groups of three students were held with year 2 students in each university to probe further into their opinions, attitudes and behaviour in relation to the teaching, learning and assessment regime for construction law. In addition, an unstructured interview was conducted with one final year student who was just completing a final year dissertation on construction law. Semi-structured interviews were conducted with the tutors of construction law from each institution.

3.1 Rationale for the Use of Two Universities; Organisational Differences

“Every organized human activity ... gives rise to two fundamental and opposing requirements: the division of labor into various tasks to be performed and the coordination of those tasks to accomplish the activity”. (Mintzberg, 1989).

Porter (2006) highlighted the role that institutional structures and cultures play in how students engage with their studies. Organisations differ by the structures and methods used to accommodate these requirements. Organisational differences can influence student behaviour and learning patterns. Although universities superficially have identical objectives, as organisations, they can differ significantly. The context of the university, the formal and informal structures, the lines of authority and the relative emphasis on key activities, impact on the degree to which objectives are attained. Universities, although subject to government policy and control and, to a large extent, with similar stakeholder interests, are, nevertheless, independent organisations with their own individual management structures and cultures. This study used an institutional comparison in the research to determine if there were any obvious, discernible differences in academics’ practices student approaches, behaviour and attitudes in relation to teaching learning and assessment of the construction law curriculum that were due to institutional differences. In order to assess the influence of institutional differences on academics’ views of their assessment practices, the sample was selected from two different institutions: University A and University B. Both universities were former polytechnics and were each formed by the amalgamation of the polytechnic with other institutions. The ideology and ethos of an organisation diffuses throughout the organization and guides processes, procedures and behaviour. For example, Twale and Place (2005) asserted that:

“(I)deology includes mission, philosophy, and core values including vision statements, goals and objectives, and prevailing philosophy... (T)he more clearly defined the ethos, the easier it is to translate it into meaningful purposes for constituents to follow (e.g., Twale & Schaller, 2002)...”.

The vision of university A is “to be a university with a national and international reputation for excellence, innovation and regional engagement”. One of its five core strategic aims is to “provide excellent learning opportunities that are student centred and client focused”. The core values, set out the Corporate Plan, include:

- See all students and members of staff as individuals with their own needs;
- Provide quality learning and development for students and staff;
- Be creative and adapt to the challenges of change.

The vision of University B is: “to be the enterprise university” It states: “Our vision sets out the type of University we aspire to be. We are already an ambitious, world-class University. By placing enterprise at the heart of everything we do, we will develop an innovative and creative culture that empowers people”. University B also asserts that: “Our core values define our University culture. They guide how we make our decisions, and how our staff, students and stakeholders work with each other. These core values include:

- Transforming lives through knowledge, collaboration and partnership.
- Providing access to research-informed teaching and learning to all who can benefit.

- Championing innovation, entrepreneurship and creativity.
- Pursuing excellence in all that we do.

The structure of the two universities in this study, like other UK universities, are organised around disciplines. Such organisational structure creates fragmentation and compartmentalisation because the disciplines form divisions. The discipline-based approach narrows the focus of the educational régime. The introduction modularisation and semesterisation in UK universities brought with it many educational challenges. The university course is now sub-divided into independent units of study taken over, mainly, one semester of twelve teaching weeks. The credit framework and the individual institutional regulations on the structure of modules and their assessment impact directly on teaching and learning practices. The point being argued in this section is that institutional ethos, emphasis, policies and strategies can directly influence the teaching, learning and assessment régime, the attitudes, emphasis and behaviours of tutors and, ultimately, student behaviour and attitudes. The regulatory framework of the institution should not stifle innovative teaching practices.

4 Engaging Learning

David Boud (2011), giving an address at a teaching and learning event, asserted that time spent on a task by students had a proportionate positive impact on their learning and understanding of the subject matter associated with the task. The timetabling for incorporating the curriculum design, delivering the content and using appropriate teaching practices are governed, to a degree, by such regulations. Umbach & Wawrzynski, (2005) stated that students report higher levels of engagement and learning at institutions where faculty members use active and collaborative learning techniques and engage students. They further stated (p173) that “faculty staff do matter. The educational context created by faculty behaviours and attitudes has a dramatic effect on student learning and student engagement.” Graham *et al* (2007) stated that “a diverse body of educational research has shown that academic achievement is positively influenced by the amount of active participation in the learning process.” Taking account of this research, McKeever and McNamee (2011) conducted a pilot study with first-year law students in which they adopted an educational approach in one module that was designed to encourage student engagement and active participation in the learning process. The teaching method employed the use of films, guest speakers and reports and documentaries. Films were chosen to both demonstrate the various workings of the legal system and to encourage debate in the wider context. Guest speakers were used to give different perspectives on current issues and to introduce a level of controversy. Reports and documentaries were introduced to act as a focus for debate and small group discussion. The evaluation by students and tutors was positive on the whole. For the purposes of this paper, two key points stand out:

1. the active, interested participation of students as a result of the creation and maintenance of a stimulating intellectual environment, and
2. the connection with practice.

5 Data Analysis, Findings and Discussion

The analysis of the data used three preset categories: practice; discipline and institution/organisation. Hypotheses and theories emerged from the qualitative data set while the data collection was in progress and after data analysis started. These

hypotheses and theories were pursued. Despite differing visions and core values, the impact of the institution as an organisation on the teaching practices and the curriculum content was not a significantly, discernible different factor. The organisation did impact on the teaching, learning and assessment regime in both institutions, but in similar ways. It is further suggested that the issues, values, beliefs, processes and procedures are not confined to construction law or, indeed, the built environment disciplines. It may not be confined to UK universities. Evidence from Williams, Sher and Simmons (2010) indicates that construction education in Australia faces issues and challenges very similar to those encountered in this research. They further identified (p108) marked changes in the attitudes and behaviours of cohorts, current at the time of their research, largely designated as ‘Generation Y’ students, i.e. born between 1978 – 1994, characterised by factors such as: absenteeism; being easily distracted by technology; not listening to or learning from lectures; expecting to be ‘spoon-fed’; seeing education as a commodity; not valuing knowledge; being motivated to learn to earn money rather than to gain knowledge; wanting to be entertained; being computer orientated; wanting to do the ‘bare minimum’; and, wanting to complete their degree quickly so they could start work. These same characteristics were apparent in the formal and informal discussions with tutors from both institutions in this study.

5.1 Matters attributable to the organisation and to discipline.

The semi-structured interviews with construction law tutors revealed some common matters attributable to the organisation or ‘the system’ as was the more often used term. Three particular issues are notable. The first related to the relative importance of the subject as compared to other subjects as perceived by ‘the system’. References were made to ‘mainstream’ subjects. Tutor ‘S’ in institution B experienced a pronounced difference when construction moved from an Engineering Faculty to a faculty of Arts. In the Faculty of Engineering, ‘S’ found that construction law was considered as ‘not mainstream’ and not thought important enough to attract or deserve extra resources for trying out new approaches such as additional tutorials. Now in the Faculty of Arts, ‘S’ finds that this Faculty is “*more willing to facilitate new ideas and to give resources (to a degree)*”. The second issue relates to timetabling. Both institutions found timetabling to be an issue and outwith the necessary control of the tutors directly involved. This was indicative through comments such as: “*Timetabling is an issue...*”; “*...tutor has little say...*”; “*The System calls for ‘efficiency’, but...*”. Timetabling and associated rooming was a matter of key concern for students. If students found that they had a lot of downtime between classes and/or only one or two classes in a day, they had a tendency to decide not to attend. The focus group discussions, the individual interview and observant participation revealed that the learning environment is a key component in student learning. Many students commented that the schools and colleges from which they transited have better learning environments than those that they subsequently encounter in university. Cramped rooms, hot/cold conditions, noise, unable to see/ hear and operating to scheduled times at which rooms had to be vacated because another class needed the room, were issues raised by the construction law students. A suggestion from the final year student in institution B pulled together expressed or implied comments from many of the students and from the tutors when he said: “*A base room would be great because we could share ideas, books and have posters; especially if it was properly equipped ... the public spaces are too noisy and cramped...*”. The third issue related to constraints on changes by the organisation. Both institutions profess to be at the cutting edge of educational enhancements. There was a desire amongst the construction law tutors to try out different and novel techniques with students but found that the ‘system’ was not quickly responsive or sufficiently flexible

to accommodate changes. Tutors in both institutions found the bureaucracy associated with curriculum delivery changes to be so “*cumbersome*”, “*time-consuming*” and “*frustrating*”, with “*uncertainty*” associated with being able to introduce new techniques and /or methods that it was “*not worth the bother*”.

5.2 Student Views

The first question on the questionnaire asked students: “*Do you like Construction Law?*” This question was posed to get an overall general impression of the students’ affective considerations. Despite later responses to other questions that would tend to indicate a dislike for the subject, there was an almost unanimous response of 94% of students responding “yes” to the question. When asked in question 4 to rank how much they liked the subject in relation to the other subjects studied on their course, 26% ranked construction law above the mid-point and 74% ranked it below the mid-point, with 17% ranking it as the least liked and 6% as the most liked subject. The second question asked students to briefly articulate their likes and dislikes about construction law. The purpose of this question was to get an understanding of what the students thought about construction law to inform curriculum design and teaching practices. The analysis of this question suggested key common factors. There was a dominating view that they liked the relationship between what was taught to what they envisaged as being ultimately useful in practice. These views were articulated in a variety of ways; e.g.:

- “the relevance of issues brought up will help throughout work life”.
- “vital to being a professional”
- “without construction law people could be taken advantage of and ripped off, + buildings would not be constructed to any certain standard”.
- “having deeper understanding of Construction Law (e.g. contracts). Useful when we get practical examples in the construction industry. Also, the knowledge is useful for future opportunities”.
- “...and how it relates to the construction profession”.
- “example case studies.”

There were several responses that incorporated the words “boring” and “dull” and phrases that suggested the same, e.g.: “... aren’t of great interest...”. Almost as a counterbalance, there were responses that incorporated the words “enjoy” and “like” and phrases that suggested the same. Difficulties in learning emerged with comments such as “confusing language”; “law cases difficult to interpret”; “confusing”; “heavy workload” and “hard topic to grasp”.

5.3 Teaching Practices & Curriculum Content

The tutors of construction law in both institutions were enthusiastic about the subject and had a good rapport with the students. Their practices were informed by educational research and there was a clear concern for the student experience. There was a feeling that there was not the opportunity to experiment with different methods of teaching and learning and that teaching and assessment practices were constrained because of a lack of flexibility in the system and a degree of risk aversion by the institutions. Teaching practices in both institutions were influenced to a large degree by factors outwith the direct control of the tutors and imposed by the internal procedures and processes of the respective institutions. These factors included:

- Timetabling
- Learning Environment (rooms in which class contact took place)
- Numbers in the class
- The format of the class because timetabling demands require early booking of rooms, up to six months in advance in one institution, with a stipulated use; e.g. lecture or tutorial.
- Teaching methods that are dictated either expressly or inferentially because of student demands or interventions by the institution; e.g.:
 - placing lecture slides in advance of a lecture on the virtual learning environment
 - a timetable that stipulates the format of each class activity for the duration of the module.

Students demonstrated a preference for sustained, continuous periods for study. The modular timetabling was not conducive to helping them manage their learning. They found that there was a tendency for “*bunching of assignments*” with periods of little activity and periods of “*excessive activity*”. Curriculum content in construction education in which construction law is embedded is guided and controlled to a significant degree by accrediting bodies such as the Royal Institution of Chartered Surveyors, and the Chartered Institute of Building. Accreditation visits include consideration of employability. Curricula have to align with their respective educational frameworks. The clear preference for students was that the context should be clear and that the curriculum content should prepare them for ultimate practice in employment. Employers of construction graduates encountered at a variety of professional for a voiced the expectation that those graduates have the necessary underpinning knowledge to ensure that their practices avoid formal dispute resolution with its inherent cost and expense. Teaching practices have to be structured to embed in students the necessary preparatory skills and attributes for employment. In both institutions, the construction law curricula were founded on the UK legal system. Whilst this aspect of the curriculum takes a generic approach in both institutions with little reference to the construction industry at this stage, tutors from both institutions observed and commented that most students found this initial aspect of the curriculum to be enlightening because it explained how one’s actions and behaviours are regulated. Students seemed to be interested because they could immediately understand the relevance to real life and the context was clear. The law of contract and the law of tort were universally accepted by students in both institutions as being useful. However, in order to make these subjects clearly relevant, the connection with construction practices had to be emphasised. For example, the law established by key cases such as *Donoghue v Stevenson* in the law of tort, or *Carlill v Carbolic Smokeball Company* in the law of contract have to have explained its significance as it relates to construction. Both institutions included contractual procedures as laid down by popular standard form contracts. Both institutions adopted the approach of using practical examples based on the provisions of the NEC3 (New Engineering Contract, third edition) and the JCT (Joint Contracts Tribunal) suites of contracts. The emphasis at undergraduate level was on the JCT Standard Building Contract. The postgraduate students proposed a greater emphasis to be placed on the NEC3 suite of contracts. These postgraduate students were mainly mature, part-time students currently employed at middle to senior management positions in the industry and, essentially, wanted training in this growing field. The preferred method of teaching this aspect of the curriculum in both institutions incorporated a significant proportion of case studies that required students to offer advice on contractual situations using their interpretations of the designated construction

contract. This connection with practice seemed to motivate students, prompted questions, discussions and argument that assisted in understanding.

6 Discussion

Perhaps the universities and the departments should place more emphasis on, and devote more resources to that element of curriculum design that considers the teaching, learning and assessment regime. Whilst these elements are evidently considered in the design of courses, there appears to be more time and effort ensuring that the content of the course meets the perceived and/or actual requirements of the various stakeholders, that the documentation accords with governance and procedural matters, that a physical 'template' is followed and that there is consistency amongst the course components. Whilst these matters are certainly important ones, I would argue that the starting point of course design should be a foundation constructed on the considered impact on the student experience. Construction law is not necessarily alone in being different in the built environment course curriculum. Other subjects may occupy different areas of the Biglan model. Notwithstanding this observation, construction law should have a teaching, learning and assessment régime that is appropriate to this discipline, and one that connects seamlessly and appositely with the teaching, learning and assessment régime of the course. In addition, it may be appropriate for the institution and/or the department, and or the course, and/or the construction law module, to have an ethos, ideology or philosophy that identifies the characteristics of the associated teaching, learning and assessment régime. For example, it may be that because the understanding of construction law demands a substantial amount of reading of, and reflection on, a wide range of textual material and because information sources are readily and instantaneously available today, the associated teaching, learning and assessment régime for construction law should adopt the heuristic method of teaching by which a learner is trained to find things out for himself or herself. The outcome of such considerations should form the basis of the teaching, learning and assessment régime for construction law.

7 Conclusion

This paper reports on part of an overall study. It has not dealt with a key element of the study and that is the assessment element. It does not give definitive answers but, rather, poses questions, formulates hypotheses and suggests proposals for this conference. The evidence suggests that the built environment disciplines imply a practical orientation to students and their expectations are that the university experience will be significantly practice oriented. The evidence further suggests that students are better motivated when they are set tasks that have a clear purpose, are interesting and are linked to practice and, preferably, require activity. Curriculum design should recognise that we are dealing with students who each have their particular degree of liking for the subject; that some find it dull, boring and heavy. Relating to practice and using actual cases motivates and engages: linking the teaching, learning and assessment regime to practice will help contextualise the learning, will help students understand and will also motivate students to learn because they will be better able to see the point of the subject as it relates to practice. Case studies formulated in conjunction with practitioners, and/or based on actual scenarios work best. Tasks must be relevant and interesting. Appropriate time to be spent on a task by students should be planned, structured and accommodated so that there can be a proportionate positive impact on their learning and understanding of the subject matter associated with the task. Construction law cases offer a ready database of

easily accessible practical issues from which a variety of practice-based tasks can be formulated and structured. Such tasks can have outcomes that emphasise those transferable skills sought after by employers; for example: communication skills, presentation skills, the ability to formulate evidence-based arguments, negotiation skills and self-assessment. Each student is an individual with an individual learning style and with a bent towards a discipline. Disciplinary differences for learning should be recognised and accommodated in curriculum design for construction law. Small group tutorials of approximately 12 students help to consolidate different learning styles, provide the opportunity for students to learn from each other, allow students to recognise their own individual learning preferences *vis-à-vis* their peers and act as a forum for discussion and argument that will ultimately add to the portfolio of skills for employment. It has to be recognised that institutional ethos, emphasis, policies and strategies can directly influence the teaching, learning and assessment régime, the attitudes, emphasis and behaviours of tutors and, ultimately, student behaviour and attitudes. This can be a very positive factor. Careful articulation and communication of the mission, vision and core values of the institution can act as a pedagogic tool to be considered in curriculum design for engagement.

Email: mike.hoxley@ntu.ac.uk

Abstract:

The high referral rate of the professional body prequalification assessment process for building surveyors and other criticisms of graduates have led many to question whether building surveying education is fit for purpose. Previous research on this subject has concentrated on obtaining the views of course providers and employers. The approach adopted for this study has been an on-line survey of recent UK building surveying graduates. A 30% response rate resulted in 806 graduates undertaking the survey. Most graduates had studied a full-time undergraduate course, three quarters had gained some form of placement or work-experience during their studies, the mode of the year of graduation was 2004 and 65% of the sample work in private practice. The survey reveals concerns over non-coverage of some of the professional body's pre-qualification competencies. The most useful subjects studied by graduates were construction technology and building pathology and the least useful was economics. The top two omitted subjects from courses were contract administration and dilapidations – both core areas of work. Skills' development was weaker on postgraduate than undergraduate courses. Those designing HE building surveying courses can refer to the results of this study to ensure that their curricular remain relevant and current to the needs of industry. This study into building surveying education has been undertaken at a time when many UK universities are reviewing their course provision to ensure that they are well placed to survive the massive upheaval imposed by government funding cuts and changes in student finance. This study with its large sample size will be of assistance to those reviewing building surveying courses.

1 Introduction

Within a generation the profession of building surveying has grown from an offshoot of general practice surveying to a professional group of 28,000 members worldwide – growth that has been described as 'rapid and spectacular [and one] that pays tribute to the increasing importance of the building surveyor role' (Sayce, 2010). There are currently about 8,000 Chartered Building Surveyors working in the UK and another 700 working overseas – although nearly half of these are based in Hong Kong (RICS, 2011). There are 27 RICS-accredited BS degree courses in the UK and approximately one-third of graduates applying for BS posts are from postgraduate courses (Gough, 2010). In addition to an RICS accredited degree, Chartered Surveyors are required to pass the Assessment of Professional Competence (APC) which involves a minimum of two years approved professional training and a final professional interview with two or three

assessors who are BS practitioners (RICS, 2006). The first time referral rate for the BS pathway is typically 50% which is higher than for other professional groups. Sayce (2010) suggests that the technical nature of building surveying is the likely reason that APC candidates lack the depth of experience required after two years in the work-place.

The high APC referral rate and general disquiet about the content of academic courses has led many in the profession to question whether BS education is fit for purpose. In a study of large BS employers five years ago Hoxley & Wilkinson (2006) found that there was a concern about the level of construction technology knowledge of BS graduates, and that in teaching contract administration to building surveyors, relevant contracts should be used (principally minor works and intermediate forms). The RICS HE Policy Manager for Education and Qualifications Standards, Nick Evans has recently commented that there has been criticism of HE's role in supporting professional practice – principally over the quality of graduates (Evans, 2010).

As the UK comes out of economic recession there are fears that there will be a shortage in the supply of construction professionals including building surveyors. There were skills shortages following the last two recessions and fewer graduate places are being offered by BS firms because of the decline in activity. Sayce reports that the first generation of building surveyors is nearing retirement and there are concerns about the supply of graduates and recently qualified surveyors to replace them. Between 2007 and 2009 BS APC enrolments fell by over 50% (Sayce, 2010). In the previous two recessions enrolments onto HE courses in building surveying fell drastically as the number of graduate opportunities diminished although there was a lag of several years between what happened in the jobs market and enrolment onto HE courses. This time around there is the added complication of HE applicants rushing to beat the 2012 increase in tuition fees (Browne, 2010) so that numbers on BS courses are likely to remain buoyant for the time being. After 2011, however there may well be a significant decline in applications for HE courses in building surveying. This is a worrying scenario given forecasts from Construction Skills and Asset Skills that there is a long term need for surveyors and other built environment professionals (Hough, 2010).

As the financial implications of the Browne Report (2010) become clearer, many universities are undertaking reviews across departments, programmes and within courses to ensure that their future offerings will enable them to survive. Given the huge upheaval predicted for the HE sector and industry concerns about the quality of BS education, now would seem an opportune moment to consider the content and delivery of building surveying courses.

2 What does RICS-accreditation mean?

The oversight of surveying academic programmes of study by the professional body has undergone change in the last decade. An accreditation visit every 5 years or so has been replaced by an annual partnership meeting. Whereas the visit would typically last a couple of days the meeting is usually over within a few hours. Employers sit on the partnership committees and any new programmes or changes to programmes are considered by these committees. However time pressures usually ensure minimal consideration and discussion of any changes of curricular. Of course universities have their own rigorous validation and review procedures and employers participate in these processes but the reality is that the oversight of curricular of surveying programmes of study has become 'lighter touch' with the move to partnership meetings. It is therefore

incumbent upon individual course providers to ensure that their curricula are current and relevant.

RICS do publish guidance on what should be included in courses. For many years a document written by Professor Trevor Mole was the point of reference for building surveying courses (Mole, 1997). This document known throughout the profession as 'Mind the Gap' suggested that any profession is concerned, ultimately, with the way its members operate in practice and the skills, knowledge and competencies they have. The work was heavily influenced by the work of Eraut (1994) who suggested that the abilities of each professional depend on the particular knowledge and skills of each, as derived from their educational and practice background. Eraut considers this to be a mix of the following:

- propositional knowledge
- personal knowledge, impressions and experiences
- professional knowledge referred to as 'process knowledge', which is based upon professional experience and action
- moral or ethical principles.

Mole's contribution has been replaced by *Keep learning: a framework for building surveyors* (RICS, 2009). This document includes much of the philosophical discussion of the earlier 'Mind the Gap' paper (Mole, 1997) and when considering BS courses suggests that typical modules are:

- Construction Technology
- Law and Responsibility
- Economics and Finance
- Building Pathology
- Planning and Design
- Environmental Science
- Management.

Murray (2010) writing in a special edition of the RICS Building Surveying Journal devoted to education and training suggests that the core subjects to be covered should be:

1. Building pathology (in both traditional and modern methods of construction)
2. Environmental and material sciences
3. Construction technology
4. The law of contract, tort, property, and landlord and tenant.

He goes on to say that Universities could offer separate 'electives' in curtain walling, cladding systems, building contracts options, contract administration, etc.

The general advice that RICS gives all universities offering programmes of study in surveying is that the APC competencies and particularly the 'core' competencies (see Table 1) should be covered by the course. Obviously in some cases this may involve teaching the knowledge that these competencies require even if the skills elements will be delivered as part of the later professional training.

It is well known throughout industry that different building surveying courses have different flavours and indeed some employers make a point of only appointing graduates from one or two particular universities each year. Thus each BS programme of study will be different but what is important, of course, is that each one delivers the core subject knowledge and understanding to prepare graduates for the workplace.

3 Assessing the quality of education

In the UK, the Higher Education Council for England uses an independent national student and graduate survey (HEFCE, 2010) as one of the proxies of quality. As far as surveying is concerned, Lee & Hogg (2009) took a similar approach when considering the education and training of the quantity surveying (QS) profession. They report the outcomes of a survey of 425 early career QSs to rate their own degree of confidence with performing a number of standard QS tasks. Poon et al (2010) followed this example in their study of UK real estate graduate competences. In their study of previous RICS education reform on the BS profession, Wilkinson & Hoxley (2005) surveyed course providers and large employers (Hoxley & Wilkinson, 2006) but the individuals who are likely to have the most clearly focused views about education are those who have recently experienced it and who are now working in the industry. A decision was taken, therefore to carry out a survey of BS graduates.

4 The survey

RICS Education provided the names and email addresses of current and recent APC candidates for the building surveying route (the 'sampling frame'). In conjunction with the RICS BS Professional Group Board an online questionnaire on BS education was developed. Initially the objective was to see how graduates perceived that the course they had studied prepared them for the BS APC competencies. For each APC pathway the competencies are divided into mandatory (that are common across all of the surveying disciplines) core and optional. One would expect all of the mandatory and core competencies to be covered to some degree by BS courses and some but probably not all of the optional competencies. Table 1 lists all of the BS APC competencies.

On 3rd August 2010, 2,910 emails were sent to the sampling frame with an invitation to complete the survey via Survey Monkey. 226 of the emails were undelivered for one reason or another and by mid-October 2010, 806 responses had been received, which represents an overall response rate of exactly 30%. This is a very good response for this type of survey (Hoxley, 2008, p126). In their on-line survey of quantity surveyors, Lee & Hogg (2009) received a response rate of less than 10%. Attention to detail in the design of research instruments is critical in ensuring an adequate sample size. For example in this study, several hours effort was expended to ensure that each of the nearly 3,000 emails was personally addressed to the first name of the recipient.

Table 1: Building Surveying Assessment of Professional Competence Competencies (Source: RICS, 2006)

Mandatory Competencies	Optional Competencies
Data management	Analysis of client requirements
Conflict avoidance, management and dispute resolution procedure	Commercial management of construction
Client care	Conservation and restoration
Sustainability	Contract practice
Health and safety	Design economics and cost planning
Business planning	Development/project briefs
Accounting principles and procedures	Fire safety
Teamworking	Housing maintenance or maintenance management
Communication and negotiation	Insurance
Conduct rules, ethics and professional practice	Measurement of land and property
	Project financial control and reporting
Core Competencies	Quantification and costing of construction works
Building pathology	Risk management
Construction technology and environmental services	Works progress and quality management
Contract administration	
Legal/regulatory compliance	

5 Findings

The sample of graduates included 650 who had studied an undergraduate qualification (and 97% of these had a degree) while 129 had studied either a Masters or a Graduate Diploma. Just under two-thirds had studied full-time, 20% part-time and just under 8% by distance learning. Six-hundred and fourteen (76%) had undertaken some form of placement or work-experience during their studies. The mode of the year of graduation was 2004 and the mode of the year of qualification as a chartered surveyor was 2007. The mean time since graduation was 7 years for UGs and 5 years for PGs. One-hundred and thirty of the graduates work in the public sector while the majority (65%) work in private-practice. The graduates were asked to indicate their main industrial activity and as will be seen from Figure 1, the vast majority (nearly 86%) were almost equally divided into those undertaking professional work, including condition assessment and those undertaking project work.

In interpreting the results, the 'acceptable' threshold of the aggregate view of all the attitude scale questions was taken as '3', that is the neutral response. Above that level the aggregate view was positive and below that level, negative. In determining differences of emphasis between undergraduate and postgraduate responses the non-

parametric Mann-Whitney U test was used and the test was conducted at a one-percent probability level (Dancey & Reidy, 2007).

Figure 1. How would you describe the main type of work you currently undertake?

5.1 APC Competencies

Figure 2 indicates the aggregate response (i.e. means of each variable) for the mandatory competencies of the APC. The variables are ordered (from left to right) by value of their means and as will be seen ‘teamworking’ was the area most covered by courses – a clear indication of the success of group project work. Only half of these competencies were above the neutral response level and the areas where there is cause for concern are with the coverage of ethics, conflict avoidance, business planning, accounting and client care.

On a more positive note all of the core competencies are adequately covered by courses but of the optional APC competencies, insurance, risk management, work progress monitoring, financial control and commercial management of projects had means below the neutral response.

5.2 Preparation for undertaking common tasks

The highest ranked variables in this question were understanding building structures, building defect diagnosis, condition surveys and maintenance scheduling. However graduates felt less than prepared to carry out work involving insurance, dilapidations, submitting statutory control applications and design and tendering for small building projects. This result has similar themes to the responses to the question about what graduates should have studied but did not. The top two responses were contract administration (132) and dilapidations (112). These two activities are core BS work and should be adequately taught on all BS courses.

Please indicate to what extent you agree/disagree with the following statements: My building surveying course prepared me for the following MANDATORY competencies of the APC:

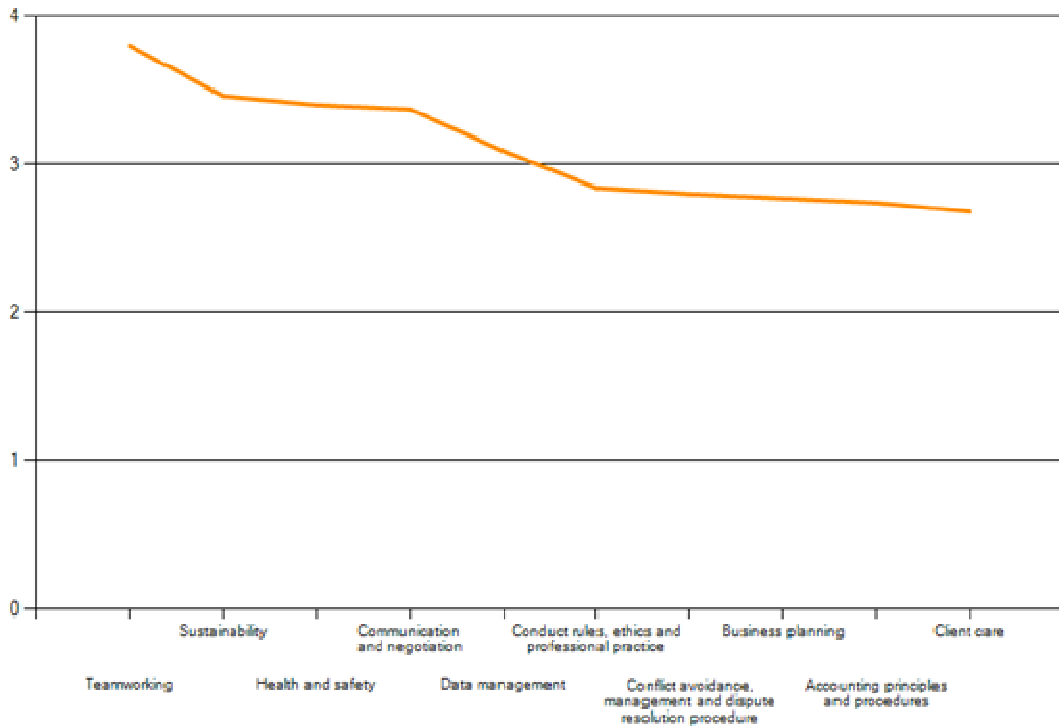

Figure 2: Course preparation for mandatory competencies of RICS BS APC

5.3 The curricular

Table 2 lists the top 6 responses to the questions about the most useful and least useful subjects on their courses. Those designing programmes of study are advised to take these responses into account when deciding upon the curricular of their courses. Clearly there are mixed messages (for example the fact that law appears in both lists) but the over-riding importance of building pathology and construction technology and the apparent irrelevance of economics cannot be ignored.

Table 2: Most useful and least useful subjects studied

Most useful subject studied		Least useful subject studied	
	n		n
Building pathology	281	Economics	170
Construction technology	231	Law	44
Law	83	Management	36
Design	30	Facilities management	33
Contract administration	29	Structures	26
Professional practice module	21	Statistics	25

5.4 Skills' development

In the questions about skills' development and learning, teaching and assessment the aggregate responses were all above the neutral benchmark level. However when the responses were separated by level of course studied there were interesting differences revealed in the skills' question. Figure 3 indicates the differences between the aggregate undergraduate response and that of those who studied a postgraduate programme of study for this question. As will be seen, UGs are much more confident than PGs in this area of their studies and indeed all of the drawing skills on the PG response fall below the '3' acceptable response. The likely reason for this result is related to the length of the respective courses. Whereas there is time to develop these skills during a 3 or 4 year undergraduate course there is far less time available to do this during a 12-month fast-track conversion course. This is an issue that should be addressed by postgraduate course providers particularly as the proportion of PG to UG students shows signs of increasing (Gough, 2010).

Figure 3: A comparison of UG and PG graduates' perception of skills acquisition from their course

(* indicates a significant difference at a 1% probability level)

6 Conclusions and recommendations

At the time of writing this paper there are rumours circulating throughout the surveying education community that the RICS is planning to remove the requirement for trainees to have studied an accredited degree. They would instead be able to complete any undergraduate degree and then train with a surveyor for five years. Clearly this proposal, should it be made, will be in response to fears about the number of students opting to study surveying at university once there has been a significant rise in tuition fees. This additional competition for surveying course providers is even more reason for them to ensure that their curricula are current and relevant. The results of the survey reported in this paper suggest that of the mandatory competencies of the APC, ethics, conflict avoidance, business planning, accounting and client care could be better covered on building surveying courses. Core competencies are adequately covered but a high proportion of respondents believed that they should have studied (and didn't) contract administration and dilapidations. Both of these subjects are central to the work of building surveyors and it is essential that they are adequately taught on BS courses. The optional APC competencies of insurance, risk management, work progress monitoring, financial control and commercial management of projects could be better covered on courses.

Graduates feel less than prepared to undertake the following types of work: insurance, dilapidations, submitting statutory control applications and design and tendering for small building projects. Clearly, this finding does not throw a positive light on the education that these graduates have received. Construction technology and building pathology are the most useful subjects studied while economics appears to be the least useful. Although only 16% of the respondents studied a PG programme there are some interesting differences of confidence revealed, particularly in the area of skills development.

The shortcomings revealed by this survey should be addressed in future building surveying course designs/reviews. This mainly involves strengthening courses by ensuring adequate technical content and including core subjects such as contract administration and dilapidations. Each of these subjects is core to the work undertaken as part of the two facets of building surveying— project work and condition assessment. As evidenced by Figure 1, building surveying is a very broad subject and in the author's view the only way to adequately address the issue of the high referral rate in the APC is to give consideration to allowing BSs to specialise (in professional work including condition assessment OR project work) prior to the APC final assessment. Naturally the profession has reservations about such a development but unless the issue of the high referral rate is addressed, potential BSs will be dissuaded from entering the profession in the first place.

At the end of the questionnaire the graduates were asked if they had any additional comments about building surveying education. Two typical comments about the education they received were 'very out of touch with the industry itself' and 'I left university feeling disheartened and unprepared for my day to day job'. Overall there were more negative than positive comments and if the concerns revealed by this study are to be addressed then course designers and reviewers should concentrate on delivering the core technical subjects that are so clearly valued by graduates.

7 Acknowledgements

The author gratefully acknowledges the assistance provided by RICS Education in providing contact details of recent graduates and the contribution of three members of the RICS Building Surveying Professional Group Board for their input into the design of the main research instrument.

Minerals and waste

Demolition Protocol & Best Local Practice for the Western Australian Construction and Demolition Industry

Andrew Whyte and Nicholas Marshall

Dept. of Civil Engineering,
Curtin University, Perth, WA,
Australia,

Email: andrew.whyte@curtin.edu.au

Abstract:

There is currently no best practice demolition guidance for the West Australia (WA) construction and demolition industry. The work presented here sought to address this need. Development (and subsequent validation) of an optimum, local best demolition practice tool was determined through consideration of: industrial need; environmental impact; and, economic viability, resulting in a resource efficient demolition protocol for WA. The developed protocol was then applied to specific case studies to guide local practice. Primary data generation produced results indicating that both potential environmental and economic benefits are achievable through the application of resource efficient demolition practices. It is concluded that the application of a resource efficient demolition protocol applied to current activities in WA can result in both environmental and economic benefits; translated as significant measureable CO₂ emission reductions (emission benefit of 65,734.2 kgCO₂ per site) as well as an Aus\$14/tonne saving in the processing of arising demolition materials.

Keywords:

demolition-protocol, best-practice, construction, Western-Australia.

1 Introduction

Waste production in Western Australia (WA) is generally designated into three different waste streams (a classification used to describe waste materials that are produced from a particular source): Municipal Solid Waste; Commercial & Industrial Waste; and, Construction & Demolition Waste. Construction and Demolition Waste (C&D Waste) represents the largest waste stream generated locally.

The Construction & Demolition Industry in WA currently produce over 50% of the total waste being sent to landfill locally; the C&D waste stream contributed 2,096,960 tonnes to landfill in 2006/07, accounting for 57% of total landfill in WA (Cardno, 2008a).

Records of C&D material being sent to landfill in WA began in 1995; Figure 1 charts the trend over a twelve year period. C&D material being sent to landfill in the Perth Metropolitan Region has increased periodically despite the two main outliers: 2000/01 and 2001/02 might be attributed to the introduction of the Goods and Service Tax (Cardno 2008b); whilst the decrease in 2008/09 may perhaps be attributed to knock-on competition effects related to the Global Financial Crisis. It is argued that the deviations and outliers indicate strongly that financial concerns impact noticeably upon on C&D

waste landfill disposal; measures that ‘hit-the-pocket’ result in landfill volume decreases.

Whilst recycling of C&D material is increasing in Western Australia, quantities have only been recorded in recent years. The highest amount of C&D material recycled in the Perth Metropolitan Region, recorded to date, was 723,541 tonnes in 2008/09. The quantities of C&D material being both landfilled and recycled in the Perth Metropolitan Region, from 1997 to 2009, are shown in Figure 1.

Figure 1: Total Landfilled and Recycled C&D Material in the Perth Metropolitan Region (1997/98 to 2008/09) (source: Hyder, 2009)

As the Figure above shows there have been gradual increases in the amount of C&D material being recycled over the last five years. Despite trends, the actual extent to which recycling is increasing is minimal when compared to: the amounts being landfilled; as well as, targets being achieved both in the Commonwealth of Australia and overseas (ICE, 2008). A need exists to review and revise the current disposal practices and demolition practices currently undertaken in WA.

1.1 International Lessons Learnt

The potential to utilise demolition waste as recycled products for supply to the construction industry is well recorded; the ICE (Institute of Civil Engineers), in combination with London Remade and EnviroCentre Ltd, produced a Demolition Protocol promoting resource efficiency in 2003 and has since produced a second Demolition Protocol in 2008 to be used in conjunction with the 2003 Demolition Protocol. The application of these protocols has seen significant improvements in resource efficiency in demolition activity in the UK and Europe. WRAP (the Waste & Resources Action Programme), backed by government funding from the United Kingdom, publish a number of case studies highlighting the economic and environmental benefits achieved by applying these protocols. Despite such international advancements, the Australian Industry and in particular the Western Australian Industry has yet to introduce resource efficient processes to guide local demolition practice.

1.2 Western Australian Current Best Practice

There are currently three major inert material recycling facilities located in the Perth (WA) Metropolitan Region: All Earth Group (Maddington); C&D Recycling (Hazelmere); and Capital Recycling (Bayswater). Given demolition material is segregated at source, these recycling facilities provide a relatively inexpensive and resource efficient alternative to landfill disposal in WA. These recycling facilities achieve recovery rates of between 96.6-99.5% for material entering respective facilities.

The best demolition recovery rates experienced in WA, resulting from efficient on-site segregation, range from 80-85%. These rates are achieved by Capital Recycling, StateWide Demolition and, the City of Canning District of Perth, in specific test-case projects; it is argued that these initiatives guide the way forward for local practitioners.

1.3 Western Australian Waste Authority

WA does recognise the need for action and a 2nd Draft Waste Strategy for Western Australia was produced by the Western Australian Waste Authority in consultation with the Western Australian community and was published in March 2010. The document highlights areas of importance relating to the generation of waste in Western Australia. In addition, it provides direction towards dealing with this waste including; government strategies, future regulations and areas of public opinion. The Waste Authority also provide two priority actions directly relating to the demolition industry: they recommend to the government that it require its agencies to take 50% of the current C&D waste stream for use as raw material; and, propose regulations to empower local government to require and implement waste disposal plans before authorising demolition. Although, these strategies suggest the need for a greater diversion of demolition material away from landfill, a means to achieve this end is unspecified; it is argued here that the production and enforcement of a demolition protocol that promotes resource efficiency is needed.

1.4 Existing Specification of Demolition Recyclate in WA

The protocol proposed by this study is somewhat implicitly supported by local initiatives such as the specification of crushed recycled concrete currently within the WA Local Authority's infrastructure body, *Main Roads*' Specification 501 for Pavements. *MainRoads* WA outlines the use of crushed recycled concrete in both sub-base and base-course applications. This specification has been successfully applied to a test pavement section on the new Perth to Bunbury Highway in 2009. Similarly The City of Canning District in Perth has specification suggestions for recycled materials applicable to road-base and has applied these to yet another test section during upgrade activities on the Welshpool Road in late 2007. These new-build and refurbishment applications for recycled material show that a market does indeed exist for the protocol developed here.

2 Methodology

Data collection included secondary and primary research. This study employed a qualitative research method that involved the collection, organisation and interpretation of documented material derived from semi-structured interviews, observations, as well as case study applications to validate the results. Secondary research, providing contextual information and background, laid the foundations for primary research related to confirmation of key variables via semi-structured interviews, alongside case

study applications to measure specific environmental and monetary values (Creswell, 2007).

Semi-structured interviews were conducted in two sessions; one prior to the case study, a pilot study, and one after case study analyses. The initial pilot study session was conducted in order to support, refute or extend the main variables identified via a review of literature. The session after the case study, however, was used to both re-evaluate the industry demand for recyclates and to further validate case study findings (which indicated the viability of applying a demolition protocol to demolition practice within WA).

The selection of participants and subsequent case-studies sought to provide an accurate overall representation of the demolition/recycling industry within WA. Furthermore, the participants involved were all designated in senior positions. The participants/companies interviewed included: the three major local inert recyclers identified above; two demolition contractors; an engineer with extensive experience in recycle specification; and, the President of the Waste Management Association of WA.

3 C&D Waste in WA

The semi-structured interviews, and the resulting analysis, identified explicit local industry requirements.

3.1 C&D Waste Local Variables

The key findings included:

Significant recovery rates can be achieved by the demolition industry in Western Australia.

High recovery rates by recycling facilities can only be achieved through the supply of clean, segregated demolition material.

The existing specifications and proven performance of recycled products within Western Australia should result in increased procurement of recycled products.

The current landfill tax levy within Western Australia should be increased from its current level of \$8/tonne towards a figure of \$28/tonne, to align with other Australian states.

The landfill tax levy cannot be viewed as being the only factor that will influence the disposal practices within Western Australia.

Legislation to make the recycling of demolition materials a requirement will work strongly towards creating a greater diversion of demolition material away from landfill.

Tender specification of recycled products and legislative requirements to use recycled products are needed in order to achieve increased recycled product procurement.

Significant economic savings can be made through the application of on-site segregation.

Pre-Demolition Audits could potentially result in a significant increase in the amount of demolition material being sent to recycling facilities.

3.2 Industry Outlook

In recent times there has been a push towards sustainable practice across the civil engineering/construction industry; despite this push towards sustainable practice, efficient resource recovery has not been applied to the common demolition practice currently undertaken in WA.

The general opinion from the interview responses was that for greater resource recovery from demolition to occur, perceived barriers restricting the recycling industry must be addressed, and that, any increase in resource recovery will continue to remain minimal in WA without market forces that 'hit-the-pocket'. The senior respondent (from Capital Recycling) expressed the view that the industry will see a greater amount of demolition material being recycled in about five years time, but added that a demolition protocol could potentially see an increase in the amount of demolition material being recycled much sooner.

Respondents confirm that the civil engineering/construction industry outlook suggests that demolition activity will seek to employ greater resource efficiencies in the future. An increase in resource efficiency could occur sooner with the introduction of a resource efficient demolition protocol. The continued application of such a demolition protocol across the civil engineering/construction industry would aid significantly the maintenance of desirable demolition recovery rates.

4 Demolition Protocol for WA

A demolition protocol of best practice for the Western Australian civil engineering/construction industry was adapted and modified from secondary research sources such as the ICE Demolition Protocol. The protocol presented here aims to provide a structured procedure that can be implemented by developers and demolition contractors in order to achieve greater resource recovery. The demolition protocol includes key processes, such as: on-site segregation; Pre-Demolition Audits; cost benefit analysis; and environmental benefit analysis.

4.1 On-site Segregation

On-site segregation involves the separation of different structural components into similar waste streams. On-site segregation requires; assessing a proposed demolition on a site-by-site basis, defining different waste streams, and the production of a site design guide to allow for different waste streams. The potential benefit from waste material will be maximised if a structure or built-asset is taken apart systematically, and divided into waste streams such as: concrete; masonry; steel; non-ferrous metals; timber; plastic; glass; and mixed waste.

4.2 Pre-Demolition Audit

A Pre-Demolition Audit is implemented in order to accurately assess the resource recovery potential of a structure. In order to do this effectively, the materials/components of the structure must be outlined individually. These components must then be recorded with their corresponding tonnages, volumes, percentage of recycling/reuse opportunities and potential applications. These components are then

used to create a Bill of Quantities (BQ) as a specific resource production guide for the proposed demolition.

There are three main steps that should be undertaken to improve the efficiency of the Pre-Demolition Audit. These steps include: desk study examining structural drawings; on-site measurement and visual assessment; and quality assessment.

4.3 Cost Benefit Analysis

The most applicable demolition cost analysis to WA industry is the comparison between demolition resulting in landfill disposal and demolition resulting in recycling facility disposal. All factors influencing the total cost benefit of demolition options should be assessed and represented clearly for the client. For demolition resulting in landfill the costs should include: labour/plant, transport and disposal fee inclusive of the landfill tax levy. Similarly, demolitions resulting in reuse/recycling the costs should include: labour/plant and disposal fee.

4.4 Environmental Benefit Analysis

Resource efficiency is an important step towards waste minimisation and greenhouse gas reduction. The application of a demolition protocol will significantly reduce both waste to landfill and CO₂ emissions associated with demolition projects. A recent study undertaken by Life Cycle Strategies Pty Ltd (2010) can be used in determining the environmental costs of disposing recyclable waste from demolition activities in Perth, WA. The study found that recycling activities produced net environmental benefits. The results identify the amount of CO₂ per tonne prevented by recycling as opposed to landfill disposal. These individual material component indicators were applied specifically by this research project to the case study described below.

5 Case Study

The case study undertaken by this research project applied (an international adapted and locally developed) demolition protocol to the demolition component involved in the *Forrest Place Redevelopment* in Perth, Western Australia. The selection of the Forrest Place Demolition for case study analysis was based upon: the site's high recycling potential; site constraint variables; extensive labour/plant requirements; and a central location to provide reasonably indicative urban transportation distances.

5.1 Pre-Demolition Audit

A full Pre-Demolition Audit was undertaken, involving a desktop study examining the structural plans of the existing structure proposed for demolition. The Pre-Demolition Audit carried out by this research project resulted in the creation of a full BQ for the arising volumes of demolition material. These volumes were then converted into the potential recovered tonnages and total tonnages in order to calculate the Demolition Recovery Index achieved, seen in Table 5.1

Table 5.1: Demolition Recovery Index (Case-Study: Forrest Place Demolition Site)

Material	Total Tonnage	Recovered Tonnage
Large/Heavy Concrete	0	0
Small/Rubble Concrete	0	210
Masonry	92.52	92.52
Metals	52.81	52.81
Timber	1.32	0.65
Glass	4.504	4.234
Miscellaneous	54.0	33.75
Total	205.154	393.964
Demolition Recovery Index	97.4%	

5.2 Cost Benefit Analysis

The cost benefit analysis of demolition resulting in landfill disposal as opposed to demolition resulting in recycling facility disposal was undertaken for the Forrest Place Demolition case-study. The labour/plant costs were higher for recycling facility disposal due to the need for on-site segregation. However, this increased labour/plant cost was heavily outweighed by the economic saving made on lower disposal and transport costs associated with recycling facility disposal. The potential financial saving to be made on the Forrest Place Demolition case-study, through the application of on-site segregation and recycling facility disposal is shown below in Table 5.2.

Table 5.2: Potential Economic Benefit achieved by recycling demolition materials arising from the Forrest Place Demolition Site Case-Study

Potential Economic Benefit	
Saving per m ³ of Demolition Material	\$17.70 / m ³
Saving per Tonne of Demolition Material	\$13.91 / tonne
Saving per Semi-Truck Load	\$280.10 / Load
Total Cost Saving	\$14,539.20

5.3 Environmental Benefit Analysis

The total reduction in CO₂ emissions, as well as the landfill capacity saving, achieved by sending the majority of the demolition materials from the Forrest Place Demolition case-study to recycling facility disposal can be seen in Table 5.3. The reductions in CO₂ emissions are calculated from the study outlined previously.

Table 5.3: Potential Environmental Benefit achieved by recycling demolition materials

Potential Environmental Benefit	
CO ₂ Emission Benefit	65,734.2 kgCO ₂
Landfill Capacity Saving	801.6 m ³

The CO₂ emission benefit of 65,734.2 kgCO₂ per site is equivalent to taking 10 standard vehicles off the road for 1 year (based on a “standard vehicle” producing 6,600 kgCO₂/year).

5.4 Conclusion: Benefit Validation

The Forrest Place Demolition case-study presents an accurate representation of both the economic and environmental benefits that can potentially be achieved by applying a resource efficient demolition protocol, which addresses the relocation of demolition materials to recycling facilities as an alternative to landfill disposal, related to demolition activity in WA. The accuracy of the case study results were subsequently confirmed as representative and accurate by interview participants in the follow-up validation procedure; potential economic benefits calculated were confirmed as having a high degree of accuracy while the potential environmental benefits were confirmed and if anything deemed somewhat conservative by the sample study group.

6 Conclusion

This study into Demolition Protocol and Best Local Practice for WA has highlighted the need for reform to the common demolition practice undertaken in Western Australia (WA), in order to improve resource efficiency. To encourage further resource recovery from demolition activities in WA, a structured process in the form of a demolition protocol should be applied to all demolition projects. The lessons learnt from demolition protocols created and applied to projects internationally, is that demolition protocols result in significant economic and environmental benefits; local study indicates a similar potential for benefit.

This study has identified that the application of a demolition protocol to demolition activities in WA has the potential to increase resource efficiency. The case study analysis provides strong evidence that the application of the demolition protocol in WA can provide an economic benefit of \$14/tonne saving on the processing of arising demolition materials as well as significant reductions in CO₂ emissions.

7 Recommendations for Industry

Recommendations for the civil engineering/construction industry in WA with regard to current demolition activities include:

Introduction of legislation making recycling demolition material a requirement, prior to allowing landfill disposal.

Introduction of a demolition protocol as a form of regulation, aimed at greater resource efficiency.

Increase in the Landfill Tax Levy in Western Australia to align with the other Australian states.

Introduction of an annual Landfill Levy Escalator.

Class 1 (Inert) Landfill levy to be charged per tonne.

Greater policing on Inert Landfill sites to monitor and enforce correct disposal.

The inclusion of adequately tested demolition recyclates in Australian Structural Design Standards.

An introduction of legislation requiring the use of demolition recyclates, where feasible, in all new build projects.

Consideration of the introduction of a primary aggregates tax in the future.

Industry/stakeholder (re)education outlining the potential economic and environmental benefits to be achieved by resource efficient demolition practice.

Handling Soundness and Quality to Improve Reliability in LPS – A Case Study of an Offshore Construction Site in Denmark.

Søren Lindhard and Søren Wandahl

Department of productional and mecanical engineering,
Aalborg University, Fibigerstræde 16,

Email: lindhard@m-tech.aau.dk; sw@m-tech.aau.dk

Abstract:

The Last Planner System of Production Control (LPS) is, in today's construction projects, a common used tool to secure a reliable planning. Even though LPS is an efficient system to keep track of the production, and a remarkable increase in productivity has been achieved; the system is not perfect. In order to gain further productivity improvement, elements in LPS have, therefore, been analyzed. This includes both the elimination of preconditions, defects, and quality issues which among others are affecting the time schedule. To determine if defects and low quality is substantial in construction, empirical data was collected and compared with previous studies. This showed that cost and time consumption related to rework, caused by defects and low quality, is significant. Rework is impossible to forecast, and it affects the time schedule, and decreases reliability and predictability. Quality has in LPS only minor direct attention, but in an attempt to increase reliability defects and quality has to be taking into account. In general the construction site is complex, dynamic and uncertain why one wonders why the "health check" when eliminating preconditions only is performed once. Because the soundness of each precondition easily can change, it brings uncertainty into the backlog of sound assignments. An approach to increase reliability is to expand the PPC measurement to include quality and by introducing a "health check" of the buffer as an addition to the conduction of the Weekly Plans.

Keywords:

defects, last planner, precondition, quality, waste

1 Introduction

Through this research there will be a focus on the defects and errors which surfaces during the construction process. The defects and errors consist of problems, inconvenience, mistakes, breakdowns etc. All the mentioned factors are affecting the time schedule, and are decreasing the reliability and predictability of the construction process. By determining the magnitude of defects and errors it can be concluded whether or not these problems are general in construction and if the related extra cost and time consumption are significant. The study reviled that cost and time consumption are significant, therefore, preventive actions have to be carried out, to help the construction industry in handling the mentioned problems.

To prove that defects and errors are a general tendency in construction and not just an isolated incident, previous studies are included. By including other studies the quantity of data is much greater.

The Last Planner System of Production Control (LPS) is a scheduling tool developed to increase the reliability of the schedule and thereby handling errors and defects which occur during construction. Ballard (1994) who introduced LPS also introduced a tool to measure the reliability of the schedule called PPC.

Before Ballard introduced the LPS, he measured the PPC level to be about 50 %, after implementation he recorded the PPC to be at the 70 % level. Furthermore he measured a decrease in non-productive time on 15 % from 50 % to 35 % (Ballard 1999). Here non-productive time only included the loss of productivity which can be assigned to delays and rework

Indeed there is still, both reliability in planning and more essential productivity to be achieved. Still 30 % of all planned activities do not finish as planned and still only 65% of all time is productive. The question is what can be done to improve the LPS, in the handling of defects and errors. Two issues are treated; the making ready process, and the purpose of the PPC.

The making ready process is extremely important; through this preconditions are removed. This is done from every individual assignment and if the making ready process fails, the assignments cannot be executed. But changes in preconditions take place (Love 2002). In this research, a weekly “health check” is therefore proposed to ensure nothing goes wrong.

The reason to introduce the PPC measurement was to measure the reliability of the schedule, to be able to react on variations, and to find and eliminate root causes. By only measuring the observance of the schedule, the quality aspect of the completed work is neglected. Therefore this research proposes that a quality aspect is added to the PPC measurement. The reason why, is that a completed assignment is very depended on quality. Increased quality also means reduced time spend on rework.

1.1 Elucidation of the extends of defects in construction

The costs of defects and errors during the construction process have been a popular objective for research in decades e.g. (Hammerlund *et al.* 1990b). A brief historical view to these studies points out that it is a general problem which usually amount to a considerable part of the total project costs (Burati *et al.* 1992). The costs of defects or errors can be divided into direct and indirect costs. The direct costs are the direct measurable costs attached to a given defect. The indirect costs are not directly connected to correcting the defects or errors and are, therefore, not directly measurable. The indirect cost or consequence of an error is multiple. Peter Love categorizes the consequences of errors into three groups which all attribute to cost at different levels in the company (Love 2002).

- *At the individual level*, stress, fatigue, absenteeism, de-motivation, and poor morale are found to be the primary indirect consequences of rework.
- *At the organization level*, reduced profit, diminished professional image, interorganizational conflict, loss of future work and poor morale are identified as indirect consequences of rework.

- *At the project level*, work inactivity (e.g. waiting time, idle time, travelling time etc) and end-user dissatisfaction are identified as indirect consequences of rework.

Cited from (Love 2002)

The results of the selected studies are presented in the text below.

Back in 1990 Hammalund *et al.* (1990a; 1990b) conducted a study of quality failure costs. The study included one main site which was monitored spanning over a 20 month period. To test the validity, 21 small building sites were monitored in a 3 week period. The study revealed that the costs of correcting the quality failures amounts to 6 % of the total production costs.

Burati *et al.* (1992) monitored the cost of quality deviation from nine construction projects. The collected data did include the direct costs related to rework, and cost of rework associated with design changes. Burati *et al.* found that the costs of rework on the nine projects varied between 0.4 and 26.0 % of the total project costs resulting in an average cost at 12.4 %.

Through studies performed from 1994-1996 Josephson and Hammerlund (1999; 1994) monitored seven different construction projects to ascertain the causes of defects and the related costs. The studies showed that the costs of defects varied between 2.3 and 9.4 % of the total production costs, this only including the direct costs of the defects.

In a research conducted by Abdul-Rahman *et al.* (1996) the costs of non-conformances on constructions sites were measured to be 6 % of the total project costs. Here a single construction site was monitored during a 22 week period. Non-conforming costs include costs of rework, material waste, warranty repairs etc. while conformance costs include costs of training, indoctrination, verification, validation, testing, inspection, maintenance, audits etc. (Love and Li 2000).

Love and Li (2000) studied the courses and costs of rework at two Australian construction projects. This revealed a cost of rework at respectively 3.2 and 2.4 % of project contract value. Even though the study only included the direct costs, Love and Li (2000) stated that the results were not to be considered indicative. This mainly because the costs were significantly lower than indicated by previous studies.

In 2000 Barber *et al.* (2000) measured the costs of quality failures in two major road projects. Only the direct costs of failure were observed. The findings showed that the costs of failure were respectively 3.6 and 6.6 % of the total project costs. To this Barber *et al.* (2000) afterwards added the calculated costs of both delay and work acceleration resulting in a significantly higher loss at respectively 16 and 23 % of the total project costs.

In Denmark Apelgren *et al.* (2005) during a three months period studied the amount of stumbling stones in a housing construction. Where the term, stumbling stones, is defined as: All conditions in the product or process which prevents the entrants in conducting his work as effective and correct as possible – the first time (Apelgren *et al.* 2005). The findings showed that the amount of stumbling stones amount to 7 % of the total contract sum. The result includes both the direct and indirect cost; it is though a conservative estimate to the costs of stumbling stones. This is primarily due to limited

resources to the registration of stumbling stones and to difficulties in determining the extent of the indirect costs. Design changes are not included in the study.

All the mentioned studies include only the direct costs related to rework or errors, this except Apelgren *et al.* (2005) who also have included a conservative estimate to the indirect costs. The direct costs are according to Burati *et al.* (1992) only the “tip of the iceberg”. An study by Love (2002) states that the indirect costs are a significant expense, and have a multiplier effect of the direct cost at between 3 to 6 times. This agrees with Love and Li (2000) which state that indirect costs are a considerable part of the costs. The reason why only the direct costs are included is because it is very difficult to determine the indirect costs (Love 2002).

Wantakorn *et al.* (1999) studied management errors in construction. They concluded that no matter levels of skill, experience or training of the management, they can make errors at any time. Wantakorn *et al.* (1999) identified the following factors as affecting the frequency and severity of the errors: Task complexity, pressures of time and cost of project, and the uncertainty of the management task. They furthermore simulated the probability of management error in consideration of the mentioned factors.

Of course there is conducted more studies than those included in this short review. The included studies confirm that errors do occur, and they provide a basic knowledge to which extent errors occur. Since only the direct costs are included in the above mentioned studies, with the exception of Apelgren *et al.* (2005), the figures gives a very conservative bid to the costs of error in construction. However the studies do show that the costs of error represent a significantly part of the estimated total construction costs.

2 Research Methodology

This case study is in a four months period conducted at an offshore wind farm project in Denmark. The study is conducted in collaboration with the main contractor of the civil works. Because the construction site was placed at sea, the logistics and storage of equipment and materials took place with limited resources. Transportation was done by boat, and depending on the speed and the placement of the foundation, the transport time varied between 20 – 60 minutes.

The purpose of the case study was to A) prove that errors do occur and B) to find root causes to these problems in an attempt to increase productivity. The main research question throughout the study has been: How is it possible to improve reliability in order to increase productivity.

The data collection consists of primary daily observations and experienced problems. Here the observations are focused on problems related to soil surveys and excavations, where there on a regular basis has been contact with the main personnel. Additionally data was collected through unstructured interviews.

Only major problems which had a significant impact on the production were collected. In total 24 problems were registered. The observer was focusing on soil surveys and excavations. It is expected that not all major problems were discovered. Therefore, the survey does not give a complete picture of all experienced problems, but it leaves a good impression of the impact and the significance of problems in construction. Besides observations of problems, the everyday contact to the contractor gave a good insight in difficulties and complications which occur during offshore construction.

The data collection consists of a short description of observed problems. There is made no calculation of expected cost.

3 Empirical evidence

During a four month period, major problems in an offshore construction project were monitored. In total 24 problems were collected, all having influence on among others the time schedule. The problems are described in detail in (Thomsen 2010). There is made no calculation to neither the direct nor the indirect costs of the problems, but an offhand estimate clarify that the costs are significant.

Besides the monitored problems, other factors were having an influence on cost and on reliability. The weather in general had a great impact to the work performed, because it was changing the soundness of the scheduled assignments. This is why bad weather often was the cause to non-productive time, in a normal workweek this composed to, not only hours, but days. The number of bad weather days varied with the season, at summer it was one or two days a week, and at winter it was three or four days a week. The weather was very unpredictable which is why it was an obstruction to the planning and time scheduling. Even local weather forecasts had difficulties in predicting the weather and the time span of bad weather so accurate that scheduling by the hour made sense.

The weather made it with the tools available impossible to conduct a robust and reliable time scheduling. It affected both the working scheme and the duration of the assignments. Bad weather days completely stopped production at the construction site, where only maintaining activities could be conducted. Because of the weather the soundness of the assignments varies, which makes it impossible cf. LPS to maintain a backlog of ready work. Thus the assignments are not following the critical characteristics for a sound assignment cf. LPS (Ballard 2000).

Another factor which complicated the planning was the great distance to the construction site. Material, equipment, machinery, and labour; everything has to be transported by boat. With limited resources the logistics have to be planned carefully, changes in orders made it very difficult and often there was a lack of capacity. Moreover the transport took a lot of time, which besides non-productive time, made the production sensitive. If for instance there is a breakdown on some of the heavy equipment and a repairman or a specific spare part is needed, the transport time gives an increased delay in the production. Furthermore, the great distance made it difficult to follow up on the production, to verify the quality and to follow up on the planning.

Finally the study has revealed that construction managers work with high pressure and stress. The time pressure presses the construction managers to make fast and not thought through decisions. This gives an enhanced probability for the managers to make errors (Wantanakorn *et al.* 1999).

The conclusion after monitoring the project is that the construction process at offshore construction is very complex and chaotic and impossible to predict and plan completely. There is constantly a change in the daily plans which indicate the lack of a more flexible and robust planning.

4 Evaluation of the studies

The great variation in results from previous studies, can among others, be ascribed to the building process, which is complex and chaotic (Bertelsen and Koskela 2003; Bertelsen 2003). This is making it very difficult to register and measure the costs. There are a lot of factors that contributes to the great variation in the findings. Primarily there is a lack of uniformity in the way data is collected; this includes the used sources such as observations, interviews and other documented sources from the site. This non-uniformity is reflected in the huge difference in the factors which are included in the studies. Furthermore, the objective of the studies is often different, some are focusing on measuring the cost of errors some quality failures, some non-conformance and some the amount of rework. Generally there is a lack of guidelines on how to perform the study and there is no given interpretation of which factors there should be included in the studies.

Despite differences in data collection all studies shows that the related cost of errors are significant. Furthermore, there is accordance between the presented theory and the empirical data collected from the case study. Therefore it can be concluded that errors are a general problem in construction.

Errors or rework are directly effecting the conducted planning. The errors cause non-productivity which include waiting, motion, cleaning, rectifying etc. and are thus a main source of time- and cost overruns and chaos (Love 2002). Love and Li (2000) found that rework have a major effect in the time performance. He measured two construction projects and found that rework had an unfavourable effect on the critical path at respectively three and four weeks. Furthermore errors do provoke defects which induce increased costs and decreased quality and productivity.

To avoid delay and daily penalties, time overruns are often handled through accelerated work. Barber *et al.* (2000) pointed out that accelerated work usually is significantly more expensive than work completed at normal tempo. Randolph and Todd (1996) surveyed 129 different electrical contractors to measure the magnitude of inefficiencies due to overmanning. They found an average loss of total efficiency on 29 % which could be attributed to overmanning introduced to speed up production. They also found that the general trend is that the net loss of efficiency increases if the percentage of overmanning increases. The relation between schedule acceleration and losses in efficiency is supported by (Thomas 2000). Thomas surveyed three different construction projects and found that the estimated loss in productivity caused by accelerated work to be 25 %. He furthermore measured the loss in labor efficiency to range between 20 % and 45 %.

Errors are increasing the variation in execution of activities, and cause defects which subsequently lead to low quality. This result in rework which again makes the construction process unpredictable and chaotic. This unpredictability is making it very difficult to especially perform long term scheduling.

5 Improvement of LPS ability to handle soundness and quality

Rework, defects, errors and non-conformances all refers to problems or difficulties which occur at the construction site. And yet difficulties occur; Bertelsen and Koskela (2004) express it severe: "*The plans and schedules present an idealized linear picture*

of what should take place, but not of what actually dos take place. Planning does not reflect reality, but dreams!”

The LPS works with a parameter PPC, which is a measurement showing in percent how many of the scheduled activities which are actually completed. In a typical construction site only half of the activities in the weakly plans, get conducted as planned (Howell and Ballard 1995). According to Ballard (1999) the implementing of LPS has raised the work flow reliability from 30 - 60 % to the 70 %. Though high PPC has been gained after implementing LPS, there is still a need for a more reliable and robust plan (Ballard 2000). To reach PPC at 90 % or higher additional actions are required (Ballard 1999).

According to the LPS theory the soundness of a certain assignment depends on seven preconditions which have to be present for an assignment can be conducted, first presented in Koskela (1999), but widely cited, among others (Bertelsen *et al.* 2006; Koskela 1999). The preconditions are as following:

- Construction design; correct plans, drafts and specifications are present
- Components and materials are present
- Workers are present
- Equipment and machinery are present
- Sufficient space so the task can be executed.
- Connecting works, previous activities must be completed
- External conditions must be in order.

If just one of the seven preconditions is not fulfilled the assignment cannot be conducted. Therefore it is extremely important that assignments do not starve any of the seven inputs. Koskela (1999) continues by stating that “*the realization of tasks heavily depends on flows, and the progress of flows in turn is dependent on the realization of tasks*”. The varying nature of Planning and scheduling can be difficult because these flows often are plagued by missing inputs and varying nature (Koskela 1999).

To secure a more robust scheduling a Lookahead process is introduced in the LPS. The Lookahead process is a plan spanning 3-8 weeks and which purpose is to remove constraints to secure the soundness of the assignments. Only sound activities are later moved to the Weekly work plan or to a buffer to maintain a backlog of assignments which can be performed (Hamzeh *et al.* 2008; Steyn 2001; Ballard 2000).

By securing that only sound activities are selected to the Weekly Work plans the success rate of completed tasks (PPC) is increasing. This entails that the uncertainty of the schedule is significantly reduced (Jang and Kim 2008; Ballard 1997; Ballard and Howell 1994). This increases certainty and honesty in the construction process, where “*we do what we say we are going to do*” (Ballard 1994). Furthermore a reduced uncertainty in the schedule leads to reduced project duration and costs (Ballard 1997).

Based on the case study two aspects of LPS are treated in an attempt to develop and improve LPS and thereby increase the reliability and robustness of the scheduling. The two aspects are first the making ready process with focus on changes in soundness, and secondly the purpose of the PPC measurement with focus on quality.

5.1 Changes in soundness

This process of removing constraints and making assignments sound is very idealistic. The “health check” is only performed once; it does not take in consideration that the

soundness very well can change. A change in just one of the seven preconditions is enough. For instance would design changes, rotten and dwindling materials, illness, breakdowns, unauthorized storage of materials, delay of previous activities, or troublesome weather conditions all give rise to a change in soundness of an assignment. Conclusively every precondition are hereby a variable and compose a possible obstruction for a given assignment to be fulfilled. Still the likelihood of change in a precondition varies. For instance changes in construction design are expected, according to Love. This is because the clients have difficulties with the visualization of the end product that they procure (Love 2002). New 3D tools can help the customer in defining criteria and thereby decrease the number of changes.

According to the PPC problems, with not sound assignments, shall be registered, investigated and the roots afterwards eliminated, this is done to achieve a higher PPC. Firstly the roots can be very difficult to eliminate and control, especially concerning the external conditions such as weather conditions. Secondly, there is no assurance that every non-completed assignment is registered. If for instance a craftsman has to use a buffer assignment, but finds that it at present time not can be conducted. Then the craftsman has a choice; A) report it to management or B) say nothing and find another assignment. If the change in preconditions is more permanent he could without telling choose to put the assignment back in the Lookahead plan.

At extreme construction projects a single or more preconditions can be very uncertain and uncontrollable. This will result in Weekly Work plans which at times contain not sound activities. In such constructions this precondition could be ignored. This could for instance be offshore works which are very dependable of the weather conditions. By ignoring the weather conditions cf. the example; the planning could be conducted as normal, but maybe with an extra focus on having a backlog with sound and weather undependable activities if possible.

The risk of changes in preconditions increases with time. Often many preconditions are fulfilled weeks before the assignment is planned to be conducted, leaving plenty of time for changes. To detect changes in preconditions it is proposed to implement a weekly "health check". Changes in preconditions will now be detected beforehand, which will keep the production running unaffected and thereby increase the reliability and robustness of the schedule. The weekly "health check" can be implemented as essential part of the weekly PPC evaluation.

5.2 Handling quality

One of the central elements in Lean is the focus on product flow and in the elimination of non-transformations or non-value adding activities; in other terms the removal of waste. Ohno (1988) stated that the total capacity of a production system equals the sum of work and waste, he furthermore identified seven different types of wastes, these are showed at the list below; see also (Suzaki 1987). In the list the first five elements refer to the material flow while the two last refer to the human work flow (Koskela 2000).

- Waste of overproduction
- Waste of stock on hand (Inventory)
- Waste of transportation
- Waste of making defective products
- Waste of processing itself (Over-processing)
- Waste of movement

- Waste of time on hand (Waiting)

There are a lot of different reasons to why waste arises. Defects are resulting in waste. When work assignments cannot be conducted as a result of defects, it results in crew waiting time, crew motion and unnecessary transportation of material and equipment. This is reducing productivity and could subsequent lead to delay, and thereby affect the time scheduling. But most importantly defects result in low quality which force rework to take place.

Rework, which is very difficult to forecast, is by Love and Li defined as the unnecessary effort of correcting construction errors (Love and Li 1999). This often induces demolition or removal of the defect or damaged structure. Koskela (1999) states that rework is carried out with minimum preparation and planning. This is often making a ravage to the sequencing of the work, and furthermore there is a risk that it would cause congestions and thereby slowing down or at worst completely stopping the production.

The fact that defects occur and that defects lead to waste implies that a reduction of defects would reduce waste and thereby increase productivity. Nevertheless, LPS is only focusing on the conduction of the schedule and trying to make the schedule itself more reliable. It is not focusing on the end product and not trying to enhance the quality in construction. Therefore, the only measure is the PPC. In worst case the production can be speeded up in order to archive high PPC, but then later witness lots of defects and poor quality, which again lead to waste consisting of waiting, motion, transportation and rework.

PPC is often used as a measure of the performance of the construction site. If quality is not taking into account it gives a disfigured picture of the performance. To restore the picture poor quality and related defects should be deducted from the performance. To secure a consistent judgment of quality the control could either be undertaken by the construction manager or by the crews which undertake the subsequent assignments. Here the minimum criteria for acceptance must be that current standards are followed and that the outcome is correct. If only acceptance is the criteria for quality, the amount of rework can be used as an indicator of quality.

6 Conclusion

This research is based on a case study of an offshore construction site in Denmark. In order to prove that defects and errors are common in construction, a short literature survey was conducted. This was done to compare existing theory with the new empirical knowledge. Through comparison it was found that the conducted research supports existing theory and state that errors and defects are common in construction and that the related cost and time consumption is significant.

Defects and errors in construction lead to an unpredictable and chaotic construction process. The case study revealed two possible ways to increase reliability, both related to LPS. The two aspects are related to LPS ability to respectively handle soundness and quality.

A central element in LPS is the making ready process, which secures that all preconditions are removed. When all preconditions are removed the assignment is moved to a workable backlog, from here the sound assignments are later moved to the

Weekly Work plan. This case study shows that changes in preconditions take place. To detect changes and secure that only sound activities end up in the Weekly Work plans a weekly “health check” is proposed.

To secure a reliable and continuous improving scheduling the PPC measurement was introduced. In order to reduce the number of defects and errors, this research suggests that there should be a focus on the end product. Therefore, this research recommends that quality is implemented as a supplement to the PPC measurement.

Abstract:

Programming and scheduling which are the functions of contractors have significant role to play in the outcome of construction projects. This study evaluates the efforts of indigenous and expatriate contractors in Nigeria on programming and scheduling and their contribution to the outcome of the projects they execute. The objectives are to determine the performance of selected construction programming processes by indigenous and expatriate contractors in Nigeria, its relationship with project outcome, compare the efforts of indigenous and expatriate contractors on construction programming and their influence on project outcome. In order to achieve the objectives, a survey of 86 contractors was conducted. 12 programming activities were selected to represent the efforts of contractors on construction programming. Data were collected using structured questionnaires and analysed using percentage, chi-square and t-tests. The results reveal that overall efforts of the contractors have no influence on project outcome but the performance of the programming processes contribute to project outcome. It is therefore suggested that the two categories of contractors should ensure that the processes are not only done but performed properly using Microsoft project software.

Keywords:

construction projects, contractors, Nigeria, project outcome and project programming.

1 Introduction

The construction stage and indeed contractors are very crucial in project delivery. The activities carried out at the construction stage are known to have major impact on the outcome of projects. Any decision or action taking and any delay at the construction stage are known to have greater implications than when they are taking at the pre-construction stage. This is so because the bulk of the resources of a project are utilised and the works that constitute the project are carried out at the construction stage. The contractor is the major player at the construction stage because he is the party responsible for the execution of the project. In Nigeria, construction contractors are categorised into indigenous and expatriates (Edmonds, 1979; Ogunpola, 1984; Olateju, 1991; Samuel, 1999). Studies (Olateju, 1991; Oni, 2001; Eze, 2004; Idoro, 2004; Okafor, 2005) discovered that Nigerian clients give preference to expatriate contractors in the award of contracts. Several reasons have been adduced for this preference such as clients' lack of confidence in the capability of indigenous contractors (Oni, 2001); clients' negative mentality about indigenous contractors (Eze, 2004); impact of colonial

rule (Idoro, 2004) and low managerial and technical capacities of indigenous contractors (Idoro, 2009). Idoro (2009) discovered that clients' mentality about indigenous contractors and preference for expatriate could change if indigenous contractors improve upon their managerial and technical capacities.

One important aspect of management as far as project delivery is concerned is planning. Planning plays a significant role in the success of construction projects. This is so because construction projects involve the use of numerous and complex resources (materials, plant and equipment, men, labour, time, information, stakeholders, etc) and series of interrelated activities or operations that demand effective planning. Mawdesley (2001) observed that the numerous activities, parties, constraints such as time and cost involved in the construction of a project necessitate careful and proper planning before the commencement of construction work. Faniran *et al.* (1998) classified project planning into two categories namely: pre-construction and construction planning. The former describes the planning that is done prior to construction while the latter describes the planning done during construction. Another important difference between the two is that while pre-construction planning is the duty of consultants, construction planning is majorly the duty of contractors. Although, the two types of planning are important for a project to be successful, pre-construction planning has been the focus of previous studies. Studies conducted by Faniran *et al.* (1998 & 2000), Idoro (2009) were concerned with pre-construction planning. Whereas indigenous contractors in Nigeria can change the negative impression that clients have about them and the preference for expatriate contractors by adopting improved planning strategies, little attention has been given to construction planning in previous studies.

The attempt to ascertain how indigenous contractors in Nigeria fared when compared with their expatriate counterparts prompted this study. This study evaluates the efforts of these two categories of contractors on programming and scheduling and their contribution to the outcome of the projects they execute. The objectives are to compare the extents of performance of selected construction programming processes by indigenous and expatriate contractors in Nigeria, their relationship with the outcome of projects executed by the two types of contractors, compare the efforts of the two types of contractors on construction programming and their influence on project outcome. The achievement of these objectives is expected to assist the two categories of contractors to improve their efforts on construction planning with a view to improving the performance of the projects they execute.

2 Literature Review

2.1 Construction Contractors in Nigeria

Contractors play a very important role in project delivery as the parties responsible for executing the works in any construction contract. The classification of construction contractors in Nigeria into indigenous and expatriates in previous studies has been mentioned. Indigenous contractors refer to construction firms that are fully owned and managed by Nigerians while expatriate contractors refer to construction firms that are jointly owned by Nigerians and foreigners but their management is fully controlled by expatriates. Ogunpola (1984), Olateju (1991), Samuel (1999) and Idoro (2004) discovered that expatriate contractors are few in number, operate on a large scale and execute majority of the contracts in Nigeria while indigenous contractors considerably outnumber their expatriate counterparts; operate on small and medium scales but are responsible for a very small proportion of the value of contracts executed in Nigeria.

These two parties collaborate with consultants to ensure that construction projects are delivered to time, cost and to required quality standards.

2.2 Construction Programming

Planning constitute a considerable part of the process of project delivery such that the first three phases namely: inception, design and construction are sometimes described as planning stage. However, it has been realised that planning is a continuous process in project delivery that has to be done from the opening to the close of a project. Hore *et al.* (1997) and Faniran *et al.* (2000) in separate studies described project planning as the systematic arrangement of project resources in the best way so as to achieve project objectives. Faniran *et al.* (1998) described project planning as the process of determining appropriate strategies for the achievement of predefined project objectives. The process of project planning requires that client's requirements and available resources be defined first, matched to set project objectives, available options identified and evaluated and the most appropriate frameworks, strategies and tactics to achieve the objectives selected. It also involves communicating the objectives and the frameworks, methods, strategies, targets/deadlines to achieve them to persons, parties and organisations concerned with their implementation, monitoring and control. Project planning therefore refers to the process of defining project objectives, determining the frameworks, methods, strategies, tactics, targets and deadlines to achieve the objectives and communicating them to project stakeholders.

Planning is a continuous process and it starts as soon as the decision to invest is taken and does not end until the project is successfully delivered. For this reason, Dvir *et al.* (2003) identified three levels of project planning namely: 1) the end-user level where planning focuses mainly on the functional characteristics of the project end-product; 2) the technical level which focuses on the technical specifications of project deliverables that are needed to support the functional requirements and 3) the project management level which focuses on planning the activities and processes that are needed to be carried out to ensure that the technical work proceed effectively. These three levels of planning refer to project conception planning, project design planning and construction planning.

2.3 Relationship between Construction Planning and Project Outcome

Research studies agree that planning contributes considerably to the final outcome of projects. Since planning is all about how to achieve project objectives, it follows also that the objectives of planning are the same with those of a project. Faniran *et al.* (1998) assertion that the objectives of project planning are to complete a project within a fixed time, at a previously estimated cost and to a specified quality standard implies that project and planning objectives are invariably the same. This assertion also implies that the bases of project performance and planning performance are the same. Naoum (1991), Ling and Chan (2002) and Thomas *et al.*, (2002) agreed with the assertion by regarding project performance as the basis of evaluating the effectiveness of project planning. Naoum *et al.* (2004) described planning as one of the key tools that stakeholders use to ensure that construction projects are delivered successfully. Idoro (2009) opined that the measures of the effectiveness of project planning and the measures of project performance are the same. These assertions show that there is agreement among researchers that planning whether pre-construction or construction contributes to project outcome.

3 Variables of the study

The variables used for the study are classified into four categories namely: construction contractors, construction programming processes, contractors' effort on construction programming and project outcome. Construction contractors in Nigeria are classified into two categories namely: indigenous and expatriate contractors. Twelve processes of construction programming namely: lists, quantities, durations, start and finish dates, production rates, sequences, cash-flow chart, plant, labour and material schedules of project activities and summary of major project phases were identified from the features of the programme of work in Microsoft project software and the preliminary interview conducted during a pilot study and used for the study. Two parameters namely: contractor's level of performance of construction programming process and level of construction programming were derived from construction programming processes and used as contractors' effort on construction programming. On project performance, two parameters namely: time-overrun and cost-overrun were selected. Time-overrun was calculated as the percentage of time-overrun to initial contract period while cost-overrun was calculated as the percentage of cost-overrun to initial contract sum of a project. The understanding of the four categories of variables shows that there is a relationship between them. The two categories of contractors are responsible for the programming of the projects they execute and construction programming involves a number of processes which are described as construction programming processes in this study. Contractors' effort on construction programming is a measure of the number of the processes performed and this is expected to contribute to the performance of projects executed by the contractors. This relationship is expressed in the conceptual framework of the study presented in Fig. 1.

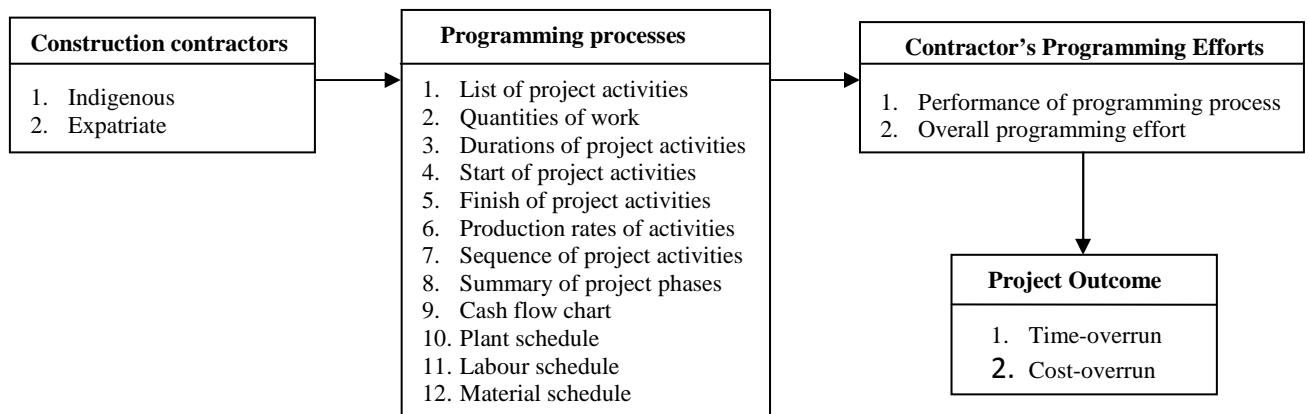

Fig. 1 Conceptual framework showing relationship between contractors' construction planning and expatriate contractors and project outcome

4 Research Methods

A questionnaire survey approach which involved a field survey of 86 construction projects was adopted. A list of 136 recently completed projects made up of 96 projects executed by indigenous contractors and 40 projects executed by expatriate contractors was prepared through a preliminary survey conducted in early 2009 because a reliable list of both on-going and recently completed projects in Nigeria could not be obtained. These projects were used as the population frame for the study. The study sample was selected from this population by stratified random sampling. The population was

classified into indigenous and expatriate contractors' projects thereafter; 86 projects made up 64 projects executed by indigenous contractors and 22 projects executed by expatriate contractors were selected randomly.

Four hypotheses were postulated to achieve the objectives of the study. The first hypothesis states that the differences in the extents of performance of construction programming processes between indigenous and expatriate contractors are not significant. The second hypothesis states that the extents of performance of selected construction programming processes by indigenous and expatriate contractors have no relationship with the outcome of projects they executed. The third hypothesis states that the efforts of indigenous and expatriate contractors on construction programming are not significantly different while the fourth hypothesis states that the efforts of indigenous and expatriate contractors on construction programming have no significant relationship with the outcome of the projects they executed. The results of the first and fourth hypotheses will enable indigenous contractors to compare their efforts on construction programming with those of their expatriate counterparts. The results of the second and third hypotheses will inform both indigenous and expatriate contractors concerning the contribution of their efforts on construction programming to the performance of the projects they execute.

Data were collected using structured questionnaires on the characteristics of the projects sampled. The respondents were also requested to tick whether or not each of the twelve programming processes were performed in the projects and to state the initial and actual contract periods and sums of the projects. The level of performance of each programming process was derived as the percentage of the number of projects in which a process was performed to the number of projects sampled. Contractor's level of construction programming was derived as the percentage of the number of processes performed to the expected number of processes to be performed which is twelve. Time-overrun that is the difference between initial and actual contract period and cost-overrun that is the difference between the initial and final contract sum of a project were derived. The parameters of project performance that is time and cost overruns were derived as the percentages of time-overrun to initial contract period and cost-overrun to initial contract sum. The instrument was administered in mid 2009 on either engineers or builders who were involved in the projects sampled as the heads of contractors' team. The data were analysed using percentage, Chi-square test, t-test and Spearman correlation test.

5 Results of Data Analysis

The results of the analysis of the data collected for the study are presented as follows.

5.1 Characteristics of the Projects Sampled

The characteristics of the projects sampled were investigated. Table 1 contains the results.

Table 1 Descriptive result of the characteristics of projects sampled

Characteristic	N	%	Characteristic	N	%
Project type			Project client type		
Building	72	83.7	Public	16	18.6
Road	14	16.3	Private	70	81.4
Total	86	100	Total	86	100
Project planner			Project contractor type		
Project manager	24	28.6	Indigenous	64	74.4
Architect	14	16.7	Expatriate	22	25.6
Builder	20	23.8	Total	86	100
Quantity surveyor	12	14.3			
Structural engineer	14	16.7			
Total	84	100			

N=Number of respondents

Table 1 shows that both building and road projects were sampled but building projects formed the majority. The two known types of project clients namely: public and private were covered in the study although the majority of the projects sampled were procured by private clients. The two types of contractors in Nigeria namely: indigenous and expatriates were equally covered in the study however; indigenous contractors constituted the majority. The professionals responsible for preparing the programme of work of the projects sampled were discovered to be project managers, architects, builders, quantity surveyors and structural engineers.

5.2 Level of Performance of Construction Programming Processes by Indigenous and Expatriate Contractors

The levels of performance of the selected programming processes by indigenous and expatriate contractors were analysed in order to determine their efforts in construction programming. In the analysis, the 12 processes involved in programming construction projects stated in the variables of the study were used. The performance of each process represents a programming effort therefore; the extents of performance of the processes by the two categories of contractors were analysed. The respondents were requested to indicate whether or not each process was performed in the programming of the projects sampled. The extents of performance of the twelve programming processes were analysed as explained in the research methods. The results are presented in Table 2.

Table 2: Percentages of performance of selected programming processes by indigenous and expatriate contractors in Nigeria

Construction programming process	Total		Not prepared		Prepared		Construction programming process	Total		Not prepared		Prepared	
	N	%	N	%	N	%		N	%	N	%	N	%
List of acties							Summary of phases

	86							86					
	100							100					

N=Number of respondents, Acties=activities, Prodn=production

Table 2 shows that the levels of preparation of lists (84.4%), durations (56.2%), start dates (81.2%), production rates (62.4%), sequences (68.7%), cash-flow charts (53.1%), plant schedules (56.2%) and material schedules (59.4%) of project activities by indigenous contractors are higher than the levels of preparation of lists (81.8%),

durations (54.5%), start dates (72.7%), production rates (54.5%), sequences (54.5%), cash-flow charts (45.4%), plant schedules (54.5%) and material schedules (54.5%) of project activities by expatriate contractors. However, the levels of preparation of quantities (100%), finish dates (81.8%), summary of major project phases (72.7%) and labour schedules (54.5%) of project activities by expatriate contractors are higher than the levels of preparation of quantities (78.1%), finish dates (68.7%), summary of major project phases (71.9%) and labour schedules (31.2%) of project activities by indigenous contractors.

5.3 Differences in Performance of Selected Programming processes by Indigenous and Expatriate Contractors

Further analysis was done to test for significant differences in the levels of preparation of the selected programming processes between indigenous and expatriate contractors. The analysis involved the test of the first hypothesis that the extents of performance of construction programming processes by indigenous and expatriate contractors are not significantly different. The hypothesis was tested using the Chi-square test with $p \leq 0.05$. The rule for the rejection of the hypothesis is that when the $p\text{-value} > 0.05$, the test fails to reject the hypothesis but when the $p\text{-value} \leq 0.05$, the test rejects the hypothesis. The result is presented in Table 3.

Table 3 Results of Chi-square test for difference in the levels of performance of selected programming processes between indigenous and expatriate contractors

Process	N	χ^2	Df	p-value	Decision
Lists of project activities	86	0.079	1	0.779	Accept
Quantities of project activities	86	5.748	1	0.017	Reject
Durations of project activities	86	0.019	1	0.890	Accept
Start dates of project activities	86	0.719	1	0.307	Accept
Finish dates of project activities	86	1.390	1	0.238	Accept
Production rates of project activities	86	0.860	1	0.354	Accept
Summary of major project phases	86	0.006	1	0.939	Accept
Sequences of project activities	86	1.454	1	0.228	Accept
Cash-flow chart of project activities	86	0.385	1	0.535	Accept
Plant schedule of project activities	86	0.019	1	0.890	Accept
Labour schedule of project activities	86	3.803	1	0.051	Accept
Material schedule of project activities	86	0.157	1	0.692	Accept

N=Number of respondents, Df=Degree of freedom

Table 3 reveals that the p-value for the test of difference in the preparation of quantities of works involved in project activities between indigenous and expatriate contractors is less than the critical p-value (0.05), therefore the test rejects the hypothesis. This result indicates that the difference in the levels of preparation of quantities of work in project activities between the two categories of contractors is significant. However, the p-values for differences in the levels of preparation of other processes are greater than the critical p-value (0.05) therefore; the test fails to reject the hypothesis. The results indicate that the differences in the levels of preparation of lists, durations, start and finish dates, production rates, sequences, cash-flow chart, plant, labour and material schedules of project activities and the summary of major project phases between the two categories of contractors are insignificant.

5.4 Relationship between the Extents of Performance of Programming Processes by Indigenous and Expatriate Contractors and Project Outcome

To determine whether or not the performance of each programming process contributes to project outcome, the second research hypothesis that the extents of performance of selected construction programming processes by indigenous and expatriate contractors have no significant relationship with the outcome of projects they executed was tested. The extents of performance of each of the 12 selected programming processes and project time-overrun and cost-overrun were used to test the relationship. The hypothesis was tested using the Chi-square test with $p \leq 0.05$. The rule for the rejection of the hypothesis is that when the $p\text{-value} > 0.05$, the test fails to reject the hypothesis but when the $p\text{-value} \leq 0.05$, the test rejects the hypothesis. The results are presented in Tables 4 and 5.

Table 4 Results of chi-square test of relationship between the levels of performance of selected programming process by indigenous contractors and project outcome

Parameters correlated	N	χ^2	Df	P	Decision
Time-overrun					
Lists of project activities	56	53.548	21	0.025	Reject
Quantities of project activities	56	40.000	21	0.007	Reject
Durations of project activities	56	35.037	21	0.028	Reject
Start dates of project activities	56	37.820	21	0.014	Reject
Finish dates of project activities	56	47.289	21	0.001	Reject

Durations of project activities	54	41.574	24	0.014	Reject
Start dates of project activities	54	42.955	24	0.010	Reject
Finish dates of project activities	54	54.000	24	0.001	Reject
Production rates of project activities	54	48.000	24	0.003	Reject
Summary of major project phases	54	43.586	24	0.009	Reject
Sequences of project activities	54	45.424	24	0.005	Reject
Cash-flow chart of project activities	54	48.600	24	0.002	Reject
Plant schedule of project activities	54	45.989	24	0.004	Reject
Labour schedule of project activities	54	54.000	24	0.001	Reject
Material schedule of project activities	54	44.654	24	0.006	Reject

N=number of respondents, χ^2 =Chi-square value, Df=Degree of freedom, p=p-value

Table 4 reveals that the p-value of the test of relationship between time-overrun and the level of preparation of the labour schedule of project activities is higher than the critical p-value (0.05) therefore; the test fails to reject the hypothesis. The result implies that the extent to which the labour schedule of project activities was prepared by indigenous contractors did not contribute to the time-overrun of the projects they executed.

However, the p-values of the test of relationship between time-overrun and the level of preparation of lists, quantities, durations, start and finish dates, production rates, sequences, cash-flow chart, plant and material schedules of project activities and the summary of major project phases are less than the critical p-value therefore; the test rejects the hypothesis. These results imply that the extents to which the lists, quantities, durations, start and finish dates, production rates, sequences, cash-flow chart, plant and material schedules of project activities and the summary of major project phases were prepared by indigenous contractors contributed to the time-overrun of the projects they executed.

Table 4 also reveals that the p-values of the test of relationship between cost-overrun and the levels of preparation of the lists, quantities, durations, start and finish dates, production rates, sequences, cash-flow chart, plant, labour and material schedules of project activities and the summary of major project phases by indigenous contractors are less than the critical p-value therefore; the test rejects the hypothesis. These results indicate that the extent to which all the twelve programming processes were prepared by indigenous contractors contributed significantly to the cost-overrun of the projects they executed.

Table 5 Results of chi-square test of relationship between the levels of performance of selected programming process by expatriate contractors and project outcome

Parameters correlated	N	χ^2	Df	P	Decision
Time-overrun					
Lists of project activities	18	7.875	7	0.344	Accept
Quantities of project activities	18	**			
Durations of project activities	18	13.950	7	0.052	Accept
Start dates of project activities	18	13.500	7	0.061	Accept

N=Number of respondents, χ^2 =Chi-square value, Df=Degree of freedom, p=p-value, **= value is a constant.

Table 5 reveals that the p-values of the test of relationship between time-overrun and the levels of preparation of lists, durations, start dates, production rates, sequences, cash-flow chart of project activities and the summary of major project phases are higher than the critical p-value (0.05) therefore; the test fails to reject the hypothesis. These results indicate that the extents to which the lists, durations, start dates, production rates, sequences and cash-flow chart of project activities and the summary of major project phases were prepared by expatriate contractors did not contribute to the time-overrun in of the projects they executed. However, the p-values of the test of relationship between time-overrun and the levels of preparation of the finish dates, plant, labour and material schedules of project activities are less than the critical p-value therefore; the test rejects the hypothesis. These results show that the extents to which the finish dates, plant, labour and material schedules of project activities were prepared by expatriate contractors contributed significantly to the time-overrun of the projects they executed.

Table 5 also reveals that the p-values of the test of relationship between cost-overrun and the levels of preparation of lists, durations, start and finish dates, production rates, sequences, cash-flow chart, plant, labour and material schedules of project activities and the summary of major project phases are less than the critical p-value (0.05) therefore;

the test rejects the hypothesis. These results indicate that the extents to which all the programming processes except durations of project activities were prepared by expatriate contractors contributed significantly to the cost-overrun of the projects they executed.

6.5 Difference between Programming Efforts of Indigenous and Expatriate Contractors

To compare the efforts of the two categories of contractors in Nigeria on the programming of the projects they execute, the efforts of the contractors on programming were measured as described in the research methods. For the purpose of the comparison, the third hypothesis was tested. The hypothesis states that the efforts of indigenous and expatriate contractors on the programming of projects are not significantly different. The hypothesis was tested using the t-test with $p \leq 0.05$. The rule for the rejection of the hypothesis is that when the $p\text{-value} > 0.05$, the test fails to reject the hypothesis but when the $p\text{-value} \leq 0.05$, the test rejects the hypothesis. Table 6 contains the results.

Table 6 Results of t-test for difference between programming efforts of indigenous and expatriate contractors

Variables differentiated	N	Mean	SD	t-value	Df	p-value	Decision
Levels of programming efforts							
Indigenous contractors	64	0.61	0.151	-0.210	84	0.834	Accept
Expatriate contractors	22	0.62	0.158				

N=Number of respondents, SD=Standard deviation, Df=Degree of freedom

Table 6 reveals that the p-value for the test of difference in the efforts of indigenous and expatriate contractors on programming of projects is higher than the critical p-value (0.05); therefore the test fails to reject the hypothesis. This result indicates that the efforts of indigenous and expatriate contractors on programming of projects are not significantly different.

5.5 Relationship between Effort of Indigenous and Expatriate Contractors on Programming and Project Outcome

The study also evaluated the contribution of the efforts of the two categories of contractors on construction programming to project outcome. To achieve this, the fourth research hypothesis was tested. The hypothesis states that the efforts of indigenous and expatriate contractors on construction programming have no significant relationship with the outcome of the projects they executed. The hypothesis was tested using the Spearman correlation test with $p \leq 0.05$. The rule for the rejection of the hypothesis is that when the $p\text{-value} > 0.05$, the test fails to reject the hypothesis but when the $p\text{-value} \leq 0.05$, the test rejects the hypothesis. The result is presented in Table 7.

Table 7 Results of Spearman correlation test for relationship between the efforts of indigenous and expatriate contractors on programming and project outcome

Parameters correlated	N	Mean	SD	R	p	Decision
Indigenous contractors effort on programming	56	0.27	0.249	0.215	0.112	Accept
Time-overrun	54	0.07	0.115	0.134	0.332	Accept
Cost-overrun						
Expatriate contractors effort on programming	18	0.23	0.140	-0.309	0.212	Accept
Time-overrun	20	0.08	0.074	0.245	0.297	Accept
Cost-overrun						

N=Number of respondents, SD=Standard deviation, R=Spearman correlation value, p=p-value

Table 6 reveals that the p-values for the test of relationship between the efforts of the two categories of contractors on programming and the time-overrun and cost-overrun of the projects they executed are higher than the critical p-value (0.05) therefore the test fails to reject the hypothesis. The result indicates that the efforts of the contractors on programming had no significant relationship with the outcome of the projects they executed. In other words, the overall effort of the contractors on programming did not contribute to project outcome.

6 Discussion of Findings

The test of the first hypothesis in Table 3 has revealed that the two categories of contractors differ only in the extents to which the quantities of work in project activities are prepared. The analysis of the performance of selected programming processes in Table 2 implies that expatriate contractors prepare the quantities of work involved in project activities more than their indigenous counterparts. The result implies that the only difference in the programming efforts of the two contractors is that expatriate contractors are more concerned with preparing the quantities of work involved in the activities of the projects they execute than indigenous contractors. However, the test of the third research hypothesis in Table 6 shows that the overall efforts of the two categories of contractors on programming of projects are the same. This finding tends to indicate that if construction programming contributes to project performance as claimed by Faniran *et al.* (1999), the contribution is expected to be the same for projects executed by the two categories of contractors. In other words, the advantage of better performance on the part of expatriate contractors discovered in research studies (Idoro, 2004 and 2009) cannot be attributed to better programming of projects.

The results of the second and fourth hypotheses tend to indicate that the overall efforts of the two types of contractors on construction programming do not really contribute to project outcome but the extent to which each process is performed does contribute to project outcome. The test of the second hypothesis tends to indicate that the preparation of all the programming processes except labour schedule will reduce the time and cost overruns of projects executed by indigenous contractors. This result is an indication that the preparation of the programming processes will improve the performance of projects executed by indigenous contractors. The reason for this is not unconnected with the fact that each process often produces information that is useful for the monitoring and control of a project. The effectiveness and efficiency of project monitoring and control processes and the eventual success of a project are based on the available information generated during construction planning. This finding agrees with the findings in the

study conducted by Faniran *et al.* (1999) that construction planning has effect on project performance.

The result of the second hypothesis also indicate that the preparation of the finish dates and plant, labour and material schedules of project activities contribute to the time-overrun and all the programming processes except the quantities of work involved in project activities contribute to the cost-overrun of projects executed by expatriate contractors. This result implies that the preparation of some of the programming processes will improve the performance of projects executed by expatriate contractors.

7 Conclusion

The purpose of the study is to evaluate the contribution of the efforts of indigenous and expatriate contractors in Nigeria on construction programming to the performance of the projects they execute. This was achieved through a survey of eighty-six construction projects. From the findings of the study, it is concluded that first, indigenous contractors in Nigeria compare with their expatriate counterparts on construction planning. The only significant difference in their efforts is that expatriate contractors are more concerned with the preparation of the quantities of work involved in the activities of the projects they execute than their indigenous counterparts. Second, many of the processes involved in construction planning contribute significantly to project outcome whereas the overall efforts of the two types of contractors on construction planning do not. This finding tends to show that the influence of construction planning on project outcome is based on the processes involved in programming.

From the conclusion of the study, indigenous and expatriate contractors need to concentrate their efforts on the processes of construction planning and be concerned with how well the processes are done. They should ensure that the processes investigated in the study are properly carried out in order to monitor and control projects effectively. Since the processes are derived from the features of Microsoft project software, it is suggested that both indigenous and expatriate contractors should adopt the software for the programming of the contracts awarded to them.

Planning Law

Expert Evidence and Expertise in Dispute Resolution

Linda Pearson

Commissioner, Land and Environment Court of New South Wales

Visiting Fellow, Faculty of Law, University of New South Wales

Email: l.pearson@unsw.edu.au

Abstract:

Courts and tribunals determining environmental, planning, and land use disputes routinely rely on expert evidence from a range of disciplines. The decision maker may themselves have expertise which frames the perspective through which expert evidence is viewed. The approach adopted by a particular court or tribunal to the admissibility of expert evidence, and the form in which it is provided, may depend less on whether the dispute resolution process takes an adversarial form than on other factors, including the nature of the issues in dispute and the constitution of the decision-making body. The challenges posed by environmental and land use disputes, including the diversity and complexity of the issues raised, make it imperative that expert evidence is focussed on assisting the decision-maker to reach a sound and justifiable outcome. Specialist environmental courts and tribunals are not unique in seeking more effective ways to elicit and manage expert evidence than have traditionally been adopted in adversarial dispute resolution. Australian environmental courts and tribunals have been active in implementing procedural reforms relating to expert evidence, including court-appointed experts, joint conferencing, and concurrent evidence.

Keywords:

dispute resolution, environmental law, expert evidence, planning law

1 Introduction

The purpose of this paper is to identify the challenges for the provision of expert evidence in environmental and planning disputes, and to consider how reforms to civil procedure have impacted on provision of expert evidence across a broad range of adversarial dispute resolution processes. Australian specialist environmental courts and tribunals, in particular the Land and Environment Court of New South Wales (LEC), and the generalist Administrative Appeals Tribunal (AAT), have adopted many civil procedure reforms relating to expert evidence, including single experts, joint conferencing, and concurrent evidence. There is limited research on whether these reforms have achieved the desired efficiencies in cost and time, and whether they have contributed to an increase in impartiality and value of expert evidence to the dispute resolution process.

2 Expert evidence in environmental and land use disputes

Australia has a well developed system for the hearing of appeals in relation to environmental and land use decisions made at all levels of government, from Commonwealth or State Ministers through to local authorities. In most instances, such

appeals are appeals de novo, where the reviewing court or tribunal is not limited to the evidence before the decision maker, and has the power to substitute a new decision for that of the original decision maker, based on evidence presented to it which may include expert evidence. Such appeals are generally determined at the Commonwealth level by the AAT, established in 1975 and deriving its jurisdiction from a range of legislation.¹ Appeals in respect of decision making at the local, State and Territory levels are heard by a variety of separately established courts or tribunals.² In addition to the review of administrative decisions by courts or tribunals, Australian courts hear and determine environmental civil enforcement and judicial review proceedings, and criminal proceedings, which may also require the presentation of expert evidence.

There is a developing body of literature on specialist environmental courts and tribunals (Pring & Pring, 2009), and a detailed consideration is beyond the scope of this paper. This paper focuses on one such court, the LEC, and a generalist tribunal that hears environmental disputes. The LEC is a specialist environmental court, established in 1980 as a superior court of record.³ Classes 1, 2 and 3 of its jurisdiction include appeals heard de novo and a number of other civil disputes; Class 4 is the civil enforcement and judicial review jurisdiction; criminal prosecutions are heard in Class 5; Classes 6 and 7 are appeals from the local court; and Class 8 is a relatively recently conferred jurisdiction relating to mining matters. The LEC exercises both administrative power and judicial power, depending on the nature of the proceedings and the class of jurisdiction. In contrast, the AAT is a general merits review tribunal which exercises only executive power in reviewing decisions of Commonwealth government officials and agencies. In common with many other specialist environmental courts and tribunals, both the AAT and the LEC include among their members persons with specialist qualifications and expertise in areas other than law; and those members appointed without such specialist qualifications soon acquire through the course of decision making experience and expertise in areas other than law.

In most instances Australian courts and tribunals determining merits appeals are not bound by the rules of evidence. However, the rules of evidence, now codified to some extent in legislation,⁴ provide the framework within which decisions are made as to which evidence to admit and how much weight to give it. Courts hearing civil enforcement, criminal, and judicial review proceedings are bound by the rules of evidence. Those rules prohibit the provision of opinion evidence, subject to some exceptions, including the provision of evidence by a person with "specialised knowledge based on the person's training, study or experience".⁵

The need for expert evidence arises as a consequence of the nature of disputes presented to the courts and tribunals hearing environmental and land use disputes. A major part of the LEC caseload comprises appeals from decisions of local authorities refusing consent to proposed development, or imposing conditions, or making orders directing landholders to do or refrain from carrying out certain activities (such as using premises

¹ The central Commonwealth environmental legislation is the *Environment Protection and Biodiversity Conservation Act 1999*; other legislation conferring jurisdiction on the AAT includes the *Great Barrier Reef Marine Park Act 1975*.

² The Australian Capital Territory Administrative Appeals Tribunal, the Land and Environment Court of NSW, the Planning and Environment Court of Queensland, the Environment, Resources and Development Court of South Australia, the Tasmanian Resource Management and Planning Appeals Tribunal, the Victorian Civil and Administrative Tribunal, and the Western Australian State Administrative Tribunal.

³ *Land and Environment Court Act 1979* (NSW).

⁴ The *Evidence Act 1995* (Cth) is the model which has been adopted elsewhere, including in NSW: *Evidence Act 1995* (NSW).

⁵ *Evidence Act 1995* (NSW) s79.

for a purpose without development consent). Such appeals may require the court (usually constituted by a Commissioner) to decide both threshold legal issues, such as permissibility of proposed development, and issues going to the merits of the application such as whether the proposed development should be approved and on what conditions. Merits issues routinely require consideration of planning issues such as consistency with the objectives of applicable planning instruments, and often include assessment of noise impacts, social impacts (eg in relation to operation of licensed premises), ecological issues (eg impacts on threatened species), bushfire protection, and engineering questions (eg adequacy of drainage). All of these issues are matters on which the Court will usually be assisted by expert evidence. Criminal prosecutions can require expert evidence to assist the Court to determine issues such as whether vegetation cleared allegedly in breach of the applicable legislative prohibition is in fact “native vegetation”.¹ Judicial review proceedings can require the Court to determine, as a jurisdictional fact, whether or not a proposed development is likely to significantly affect threatened species, as part of its determination whether a development consent was validly granted.²

The challenges of environmental and land use dispute resolution include the broad diversity of issues that may require provision of expert evidence; the complexity of some of the issues (such as urban ecology: Taylor & Ives, 2009); a relatively small pool of individuals who might be qualified to give expert evidence in some areas; and simply a lack of reliable data and research.

One example which illustrates the complexity of environmental dispute resolution was a decision of Preston J, the Chief Judge of the LEC, *Newcastle & Hunter Valley Speleological Society Inc v Upper Hunter Shire Council & Stoneco Pty Ltd* [2010] NSWLEC 48, which was a challenge to the granting by the council of consent for a limestone quarry. The issues in the appeal included whether the proposal was likely to significantly affect the White Box Yellow Box Blakely’s Red Gum Woodland (White Box EEC), which was an endangered ecological community, and the habitat of the Squirrel Glider (a threatened species); and whether the limestone on the site was likely to contain caves and other karst features and cave-dwelling fauna, such that the proposal was likely to cause serious or irreversible damage to those karst features and fauna. The Court (constituted by Preston J, assisted by an Acting Commissioner with qualifications in ecology) heard evidence from experts on vegetation and soils in order to determine whether or not the vegetation on the project site comprised the White Box EEC as defined, and in determining whether or not the project was likely to have a significant effect on the EEC. On the limestone issues, the Court heard evidence from experts in geology, concluding:

177 In the present matter, although there is an absence of site-specific information on biota in the limestone, the presence of biota in caves and groundwater in the near vicinity of the site and the increasing number of studies elsewhere that establish the presence of biota in limestone, make it scientifically likely that some form of biota will be found within the limestone on the site. Without being able to predict the particular species which would be present, it is beyond a mere possibility that biota will be present. This scientific likelihood is sufficient to engage the precautionary principle...

¹ *Native Vegetation Act 2003* (NSW) Part 2.

² *Environmental Planning and Assessment Act 1979* (NSW) s78A(8).

178 If there is biota present then, at least within the extraction area, the biota will be harmed by quarrying. Such harm would constitute serious and irreversible environmental damage. There is uncertainty as to the threat of environmental damage flowing from the uncertainty as to the presence of voids and fissures, with available water, to support biota. However, the threat of environmental damage is scientifically likely; there is reasonable scientific plausibility that there are voids and fissures, with available water, to support biota, which would be damaged by quarrying: *Telstra Corporation Ltd v Hornsby Shire Council* [2006] NSWLEC 133; (2006) 67 NSWLR 256; (2006) 146 LGERA 10 at [148].

The Court concluded that an appropriate response to the threat of environmental damage to biota within the limestone was to implement an adaptive management approach through conditions of consent requiring monitoring linked to adaptive management.

3 Requirements for expert evidence

The now common reliance by courts and tribunals on expert evidence from a range of disciplines is a relatively recent development. During the 19th and early 20th centuries the courts were mistrustful of evidence given by scientific experts, who were often perceived to be in support of the cause in which they were embarked, and in favour of the person employing them (Bergin, 2011). As recently as 1963 the NSW Supreme Court referred to expert scientists being "affected in greater or less degree by the kind of unconscious bias which is a well known characteristic of expert evidence".¹

Both the United Kingdom and Australia have made significant reforms to expert evidence procedures in recent years. The UK reforms have their origin in the reports of Lord Woolf in 1995 and 1996 which led to Part 35 of the Civil Procedure Rules 1998 (UK) (CPR). The reforms in New South Wales built on those reforms, and the relevant legislation applicable to NSW courts and tribunals is the Civil Procedure Act 2005 and the Uniform Civil Procedure Rules 2005 (UCPR). These reforms were driven in part by a perceived need to reduce costs and complexity in civil litigation, and also by a desire to improve the quality of expert evidence and its provision.

The threshold question in any proceedings is whether expert evidence is admissible. Expert opinion evidence given by someone with "specialised knowledge based on training, study or experience" can only be given where the opinion of that person is wholly or substantially based on that knowledge.² If a person without experience in the area would be able to form an opinion on the matter without the assistance of a person possessing specialised knowledge, expert evidence is not admissible (Pepper, 2011). The critical issues will be that the expert have specialised knowledge based on their training study or experience; that the field be sufficiently recognised as a reliable body of knowledge; that the evidence be based on that specialised knowledge; that the facts or assumptions on which the opinion is provided are established or are made explicit; and that the reasoning engaged in to arrive at the conclusions is set out (Pepper, 2011).

Australian courts and tribunals share with the UK a reliance on what Dwyer has described as "notions of decent conduct and fair play" (Dwyer, 2008:347): that is, imposing on experts an overriding duty to assist the court, which finds its expression in

¹ *Miller Steamship Co Pty Ltd v Overseas Tankship (UK) Ltd* [1963] NSWLR 737 at 753.

² Section 76, 79 *Evidence Act 1995* (NSW).

express statements in the applicable rules.¹ In NSW expert witnesses are required to agree to be bound by a code of conduct, and to acknowledge that agreement in their written report, failing which their report may not be admitted, and their oral evidence not received, without leave of the court.²

4 Particular issues

There are two distinctive features of environmental and land use dispute resolution in the LEC and the AAT which may impact on the expert evidence provided to, and required by, those bodies.

4.1 Council staff as experts

It is not uncommon in appeals heard by the LEC from decisions of a local authority for the council to lead expert evidence from one of its employees, commonly from planning officers or other officers with engineering or building qualifications. Resource limitations mean that many councils only retain the services of external experts where their own staff have recommended approval of a proposed development and would as a consequence be unable to give expert evidence in support of the council's case in an appeal against refusal of consent. The general proposition is that an employee is not precluded from giving expert evidence; however, their evidence may be given less weight.³ The issue is whether the expert has the required degree of impartiality.⁴ For example, in one matter the LEC rejected evidence from a council officer who had been involved in the proposal for the development and whose report contained not only facts but partisan opinions.⁵ It can be difficult to determine the point at which a council officer ceases to be able to provide impartial expert evidence and demonstrates the degree of connection with the subject matter that precludes them from giving expert evidence.

4.2 Expertise of decision maker

Both the LEC and the AAT are required to consider the question of expertise in constituting the court or tribunal for particular matters. The qualifications for appointment of a Commissioner of the LEC are specified in s12 of the Land and Environment Court Act, and include qualifications and experience in planning, valuation, engineering, and architecture. For members of the AAT, the relevant provision is s7 of the AAT Act which includes a similarly broad range of disciplines and expertise. Section 30(2) of the Land and Environment Court Act requires the Chief Judge to have regard to the knowledge, experience and qualifications of the Commissioners and to the nature of the matters involved in the proceedings in determining the Commissioner or Commissioners who is or are to exercise the jurisdiction of the Court in relation to any proceedings. In Classes 1, 2 and 3 of the Court's jurisdiction a Judge may sit with the assistance of a Commissioner with particular relevant qualifications. A similar requirement to consider the type of expertise that may be relevant applies to constitution of the AAT.⁶ Both the AAT and LEC have

¹CPR r35.3: Dwyer 2008.

²UCPR r31.23.

⁵*Willoughby City Council v Transport Infrastructure Development Corporation (No 2)* [2008] NSWLEC 238.

⁶*Administrative Appeals Tribunal Act 1975* (Cth) s23B.

part time members with a diverse range of expertise: in the AAT, that includes expertise in aviation, engineering, environmental science, medicine, pharmacology, military affairs and public administration (Downes, 2011).

Consideration of how an AAT member or an LEC Commissioner who has specific expertise relevant to the issues in dispute can make use of that expertise has generally been framed in terms of procedural fairness. The parties must be alerted to information derived from that expertise where the decision-maker proposes to reach a conclusion based on their knowledge of a particular fact, or relying on a particular expertise.¹ Beyond this constraint, there appears to be acceptance that a decision-maker appointed because of their expertise should be able to use it in the decision-making process;² the unresolved issues are the extent to which such knowledge should be contestable by the parties (Cane, 2009: 241), and precisely how that expertise is used by the decision-maker. At the least a decision-maker with expertise should be better able to evaluate competing expert evidence, or at least know what questions need to be asked of the expert witnesses. The LEC makes use of the expertise of Commissioners in conciliation of many of the matters that are appealed to the Court (Preston, 2007).

5 Procedural matters

In NSW, the main purposes for the provision of expert evidence are set out in r31.17 of the UCPR:

- (a) to ensure that the court has control over the giving of expert evidence;
- (b) to restrict expert evidence in proceedings to that which is reasonably required to resolve the proceedings,
- (c) to avoid unnecessary costs associated with parties to proceedings retaining different experts,
- (d) if it is practicable to do so without compromising the interests of justice, to enable expert evidence to be given on an issue in proceedings by a single expert engaged by the parties or appointed by the court,
- (e) if it is necessary to do so to ensure a fair trial of proceedings, to allow for more than one expert (but no more than are necessary) to give evidence on an issue in the proceedings,
- (f) to declare the duty of an expert witness in relation to the court and the parties to proceedings.

The LEC Practice Directions set out the requirements for when, and how, expert evidence is provided in each of the classes of the Court's jurisdiction.³ Distinctive features of the LEC's approach to expert evidence include the requirement that the parties first consider whether expert evidence is required on a particular issue; appointment of single experts if appropriate; routine joint conferencing of parties' experts; and provision of oral evidence by experts as concurrent evidence. These are

¹ *Tisdall v Health Insurance Commission* [2002] FCA 97.

² *Gillies (AP) v Secretary of State for Work and Pensions Scotland* [2006] UKHL 2.

³ Practice Directions are authorised by r31.20 of the UCPR. LEC Practice Directions are available at: http://www.lawlink.nsw.gov.au/lawlink/lec/ll lec.nsf/pages/LEC_practicedirections.

discussed in more detail below, however it is worth noting here that the adoption of procedures such as these is entirely consistent with the prevailing trends in civil litigation more generally, both in Australia and elsewhere. Dwyer argues that the changes contained in the CPR are an attempt to provide more efficient use of resources, both state and party, through more active case management, and that the significant change in the use of experts under CPR Pt 35 and the nature of expert roles is a reflection of broader changes in the culture of civil procedure (Dwyer, 2008: 210). That is consistent with the NSW experience, where the Civil Procedure Act states as the overriding purpose of the Act and the rules as being “to facilitate the just, quick and cheap resolution of the real issues in the dispute or proceedings”.¹ This statement of overriding purpose is supplemented by a legislative statement of the objects of case management (s57); and directions that the court act in accordance with the dictates of justice (s58), eliminate delay (s59), and implement procedures with the object of resolving the issues between the parties in such a way that the cost to the parties is proportionate to the importance and complexity of the subject-matter in dispute (s60).

5.1 Single experts

The LEC Practice Directions provide that parties must first consider whether expert evidence is genuinely necessary to resolve the issues in dispute.² Where expert evidence is necessary, the Practice Directions encourage consideration of whether a single expert is appropriate, by reference to:

- (a) the importance and complexity of the subject matter in dispute in the proceedings;
- (b) the likely cost of obtaining expert evidence from a parties’ single expert compared to the alternative of obtaining expert evidence from individual experts engaged by each of the parties;
- (c) the proportionality of the cost in (b) to the importance and complexity of the subject matter in (a);
- (d) whether the use of a parties’ single expert in relation to an issue is reasonably likely either to narrow the scope of the issue or resolve the issue;
- (e) the nature of the issue, including:
 - (i) whether the issue is capable of being answered in an objectively verifiable manner;
 - (ii) whether the issue involves the application of accepted criteria (such as Australian Standards) to ascertainable facts;
 - (iii) whether the issue is likely to involve a genuine division of expert opinion on methodology, or schools of thought in the discipline; and
 - (iv) whether the issue relates to the adequacy or sufficiency of information provided in the development appeal application;

¹ *Civil Procedure Act 2005*, s56(1).

² *Practice Note Class 1 Development Appeals* at [42]; *Practice Note Class 1 Residential Development Appeals* at [53]; *Practice Note Classes 1, 2 and 3 Miscellaneous Appeals* at [30]; *Practice Note Class 3 Valuation Objections* at [34].

(f) whether the evidence of the parties' single expert involves the provision of aids to assist in the assessment of a development appeal application (such as shadow diagrams, view lines or photo montages).

(g) whether the parties' single expert would be required independently to obtain further information or to undertake monitoring, surveys or other means of obtaining data before being able to provide expert evidence;

(h) whether the parties are prepared at the time to proceed to hearing on the basis of a parties' single expert report about the issue and no other expert evidence about that issue;

(i) whether the integrity of expert evidence on the issue is likely to be enhanced by evidence being provided by a parties' single expert instead of by individual experts engaged by the parties; and

(j) whether the Court is likely to be better assisted by expert evidence on the issue being provided by a parties' single expert instead of by individual experts engaged by the parties.

The parties may agree on an expert ("parties' single expert") or the court may decide to appoint a "court appointed expert". The Court must be satisfied that it is practical to appoint a court appointed expert, and that it is in the interests of justice to do so.¹ The parties require leave of the Court to adduce evidence of another expert on an issue where a single expert has been appointed to provide evidence on that issue.

A single expert (whether engaged by the parties or court-appointed) may not be appropriate where the relevant discipline recognises that there may be more than one school of thought on an issue and where a single expert may employ only one method of analysis (Pepper, 2011). Appointment of a single expert may not assist in reducing time and associated costs for the parties if the parties engage their own experts to "shadow" a single expert (Livingstone, 2008: 47). The use of single experts in the LEC, whether parties' single experts or court-appointed experts, has declined in recent years: while between March 2004 and April 2005 there were 171 court-appointed experts in the LEC, in 2010 there were only 5 parties' single experts and no court-appointed experts (Pepper, 2011). That may be because the LEC routinely utilises Commissioners with expertise in certain areas (Pepper, 2011); or it may reflect concerns that there are more fundamental limitations with this mode of expert evidence, including concern that it is not possible to test whether the views provided in this form are correct in the absence of evidence to the contrary (Livingstone, 2008: 48; Rackemann, 2011).

5.2 Conferencing

A routine feature of litigation in the LEC is a requirement for joint conferencing of experts, with the provision to the Court of a joint report which "must specify matters agreed and matters not agreed and the reasons for any disagreement".² The LEC's further requirements for a joint report are:³

¹ UCPR r31.17(d).

² UCPR r31.26(2).

³ *Practice Note Class 1 Development Appeals* at [54]; *Practice Note Class 1 Residential Development Appeals* at [61]; *Practice Note Classes 1, 2 and 3 Miscellaneous Appeals* at [42]; *Practice Note Class 3 Valuation Objections* at [46]; *Practice Note Class 4 Proceedings* at [46].

If experts are directed by the Court to confer, experts are to ensure that their joint conference is a genuine dialogue between experts in a common effort to reach agreement with the other expert witness about the relevant facts and issues. Any joint report is to be a product of this genuine dialogue and is not to be a mere summary or compilation of the pre-existing positions of the experts.

Lawyers are not permitted to attend a joint conference, or be involved in the preparation of a joint report, without the leave of the Court.

Joint conferencing may not necessarily reduce time and costs to the parties (Livingstone, 2008: 57). Reservations have been expressed as to whether joint conferencing improves the quality and impartiality of evidence, in particular whether the process can be hindered by entrenched or inflexible views, hostility between experts, or domination of the process by more senior or experienced experts (Livingstone, 2008: 55). There is an added difficulty where an expert later withdraws or modifies agreement reached in the joint conferencing process, and in identifying when it is appropriate to grant a party leave to adduce additional evidence from another expert (Livingstone, 2008: 56). On a more practical level, joint conferencing is of limited assistance where the experts fail, or refuse, to engage with each other to identify areas where agreement can be reached.

5.3 Concurrent evidence

There is some debate as to its origins (Bergin, 2011; Livingstone, 2008), however concurrent evidence (or “hot tubbing” as it is sometimes referred to) is now an accepted aspect of the provision of oral evidence in the course of proceedings in many Australian courts, including the LEC, and in the AAT. The earliest use of concurrent evidence in the AAT was in 1994 (Administrative Appeals Tribunal, 2005). The LEC commenced routine use of concurrent evidence in March 2004 (Administrative Appeals Tribunal, 2005), and the LEC’s Practice Notes assume that where expert evidence is given from more than one expert in the same discipline it will be given concurrently unless the hearing Judge or Commissioner orders to the contrary.¹ There is no express reference to concurrent evidence in the UCPR, and in the LEC the procedure is as directed by the Judge or Commissioner hearing the matter. The procedure was described by McClellan J in *BGP Properties Pty Ltd v Lake Macquarie City Council* [2004] NSWLEC 399:

121 The issues which were ultimately defined in the proceedings required resolution of the different views of experts in relation to a number of significant matters. As will become commonplace in proceedings in this Court, the oral testimony of the experts was taken by a process of concurrent evidence. This involved the swearing in of the experts with similar expertise, who then gave evidence in relation to particular issues at the same time. Before giving evidence, the experts had completed the joint conferencing process, which enabled the court to identify the differences which remained and which required resolution through the oral evidence. Each witness was then given an opportunity to explain their position on an issue and provided with an opportunity to question the other witness or witnesses about their position. Questions were also asked by counsel for the parties. In effect, the evidence was given through a discussion in which all of the experts, the advocates and the Court participated.

An example of an appeal in the AAT involving concurrent expert evidence was *The International Fund for Animal Welfare (Australia) Pty Ltd and Ors and Minister for*

¹ For example, *Practice Note Class 1 Development Appeals* at [56]; *Practice Note Class 4 Proceedings* at [48].

Environment and Heritage and Ors [2005] AATA 1210, a challenge to the Minister's decision to grant permits for the import of eight Asian elephants (listed in the Convention on International Trade in Endangered Species of Wildlife, Fauna and Flora (CITES)) to two Australian zoos.¹ The issues requiring determination included whether the elephants were being imported "for the purposes of conservation breeding or propagation"; whether the zoos were "suitably equipped to manage, confine and care for the animals, including meeting the behavioural and biological needs of the animals"; and whether the importation of the elephants would "be detrimental to, or contribute to trade which is detrimental to ... the survival ...or ...recovery in nature of" Asian elephants. There were 17 expert witnesses, with qualifications and expertise in areas ranging from veterinary science, ecology, to animal behaviour. The means by which the evidence was provided is described as follows:

43. The means by which most of the evidence was taken was the process now frequently used in the Tribunal which the Tribunal has called "concurrent evidence". All of the witnesses prepared reports or made affidavits. The reports and affidavits were admitted without objection except as to relevance. Prior to giving evidence witnesses whose evidence related to similar areas of expert knowledge conferred with one another. This process involved up to four witnesses at a time. Legal representatives were not present. Sometimes the meeting was wholly or partly by telephone including international telephone calls. Witnesses who gave evidence on more than one area of expert knowledge were involved in more than one meeting. The witnesses who took part in this process included the chief executive officers and other employees of the zoos. The chief executive officers were also cross examined conventionally on non expert issues. During their meetings the experts were asked to isolate the matters on which they reached agreement and the matters on which they continued to disagree. They were asked to reduce this to writing. So far as the Tribunal is aware this process took place without any intervention from the legal representatives except, perhaps, in the provision of typing facilities.

44. Each group of witnesses took an oath or affirmation to be truthful. They sat alongside one another. Not all witnesses were in the hearing room. Some were overseas. They joined the concurrent evidence session by video link. In one case (Mr Kumar) the evidence was received by telephone. Dr Atkinson and Dr Stevenson gave evidence concurrently from the United Kingdom by video link. At the time they were in separate parts of the country.

45. At the beginning of each session the agreed statements were received in evidence. The witnesses were then asked, in turn, to state succinctly what they wished to stress as the essential parts of their evidence. Some of the witnesses accepted this opportunity. Others did not. They were then asked, in turn, whether they wished to ask any of the other witnesses questions or to comment on what the other witnesses had said. Counsel for the parties were then invited to ask questions of any of the witnesses. During all this time members of the Tribunal asked questions when they thought it was appropriate.

The hearing ran for seven days; it is not possible to determine how many days might have been required for more traditional presentation of the expert evidence.

¹ Another case involving a large number of experts of different areas of expertise in the AAT is *No Ship Action Group Inc and Minister for Sustainability, Environment, Water, Population and Communities and State of New South Wales (Joined Party)* [2010] AATA 702, a challenge to the Minister's decision to grant a permit for the scuttling of a former navy frigate in the coastal waters off New South Wales.

The benefits of concurrent evidence are said to be that it enhances the quality of the court's decision by identifying the fundamental issues and providing the material necessary to resolve them, and that it saves time;¹ and that it helps to narrow the issues in dispute (Pepper, 2011). There is disagreement as to whether concurrent evidence assists the less articulate expert in presenting their evidence. McClellan J when Chief Judge of the LEC was of the view that it does, and thereby both assists communication between the experts and assists the court in deciding which expert to accept (McClellan 2005); however Davies J was not persuaded that it would prevent the court being unwittingly convinced by the more articulate or authoritative personality (Pepper, 2011). There is dispute as to whether it reduces the likelihood of adversarial bias. Edmond, for example, doubts whether simply allowing experts to respond during the same session rather than a day or week later can produce a demonstrable change in behaviour (Edmond, 2009:172). On a more fundamental level, Edmond questions whether adversarial bias is deliberate or necessarily detrimental - after all, experts may be selected by the parties because they already adhere to particular assumptions or commitments, and experts do not enter into disputes without some professional, institutional or ideological "baggage" (Edmond, 2009:173). It may be impossible for the decision maker to determine whether an expert's reluctance to agree with others is because of legitimate professional differences, or simply because of a desire to advance the cause of the party engaging them (Edmond, 2009:174).

At its minimum, there seems to be agreement that concurrent evidence enhances communication and comprehension in court. As Edmond notes (2009: 174):

If nothing else, concurrent-evidence procedures require the experts to meet and talk, they enable expert witnesses to give longer explanations using their own words, they encourage experts to comment directly on the testimony of others, and they provide a forum where judges are less restricted in their questioning of witnesses and enable fact finders to observe the interaction between experts.

Edmond cautions, however, that there are no guarantees that concurrent evidence can narrow disagreement or encourage co-operation, or make decision-making easier, less controversial or more accurate (Edmond, 2009: 174-5). It also needs to be noted that whatever the benefits of the concurrent evidence model for adducing evidence at trial, it should not be considered a substitute for appropriate pre-trial management to obtain the benefit of expert discourse at an earlier time (Rackemann, 2011).

There has been limited empirical research into concurrent evidence. That which has been conducted suggests that concurrent evidence is supported by judges and tribunal members (Livingstone, 2008: 50-51), less so by legal practitioners and by expert witnesses (Edmond, 2009:182-185; Rackemann, 2011). The AAT reviewed its use of concurrent evidence in 2005, finding that tribunal members considered that concurrent evidence enhanced the decision-making process by identifying areas of contention, distilling issues and making technical issues easier to understand (88.1% of tribunal members), and that it had improved the objectivity of evidence presentation (73.7%). However, tribunal members considered that while in approximately 30% of cases the experts spent less time giving evidence and the hearing was shorter, in approximately 50% of cases it was about the same, and in 20% of cases it was longer (Administrative Appeals Tribunal, 2005). Edmond's study based on interviews in 2007 and 2008 (which included practitioners and experts appearing in the LEC) found that lawyers disliked

¹ *BGP Properties Pty Ltd v Lake Macquarie City Council* [2004] NSWLEC 399 at [122].

idiosyncratic implementation of concurrent evidence procedures, and that experts, while generally favourably disposed toward concurrent evidence were more ambivalent about the pretrial joint conferences (Edmond, 2009). It is worth noting that Edmond's study was conducted not long after concurrent evidence became the norm in the LEC, and it may be that attitudes have changed with more familiarity, and hopefully more consistency in practice.

6 Value of expert evidence

The suggested benefits of joint conferencing and concurrent evidence include that they enable experts to engage directly with each other. A joint report, or questioning during concurrent evidence, may lead to the expression of agreement for example as to methodology, modelling, or the relevant criteria to be applied, or it may lead in a more fundamental way to agreement as to outcome. Sometimes all that can be agreed is that adoption of a particular methodology (rather than another) will lead to an agreed outcome, while adoption of another methodology will lead to a different (agreed) outcome: the decision-maker will still be required to decide which (or whose) methodology is the appropriate one to adopt. Lack of willingness of experts to engage with each other and make appropriate concessions may relate both to personal and professional factors, and to the adversarial context within which court and tribunal processes are framed. The recent decision of the Supreme Court of the United Kingdom to abolish the immunity previously enjoyed by expert witnesses may add another factor, at least in the UK (there being no suggestion at this stage that the Australian courts are likely to follow suit).¹ Professional reputation, and perhaps a desire to continue to be engaged by litigants, may have a more significant impact on an expert's willingness to make concessions in the course of conferring.

The courts and tribunals which have adopted procedural reforms such as joint conferencing and concurrent evidence have done so in the belief that this may help counter adversarial bias, improve efficiency of court and tribunal hearings, and enhance both the quality of the expert evidence and the ultimate decision. There is clearly a need for empirical research, based on the now substantial experience in the LEC and the AAT, into whether these procedural reforms have promoted better decision-making.

Urban Planning Legislation in New Zealand: Resource Management Act Stage Two Reforms

Lydia Kiroff

Department of Construction, Faculty of Technology and Built Environment,
Unitec Institute of Technology, Auckland
New Zealand

Email: lkiroff@unitec.ac.nz

Abstract:

The Resource Management Act (RMA) 1991 is a major piece of legislation underpinning urban development in New Zealand and is considered as a fundamental legal framework governing the built environment. The Act is administered by the Ministry for the Environment and has the intention “to promote the sustainable management of natural and physical resources”¹ in the country.

The purpose of this paper is to examine the current RMA Stage Two Reforms, a process that began in 2010 with the appointment of two Technical Advisory Groups (TAGs), the Urban TAG and the Infrastructure TAG. Both bodies were commissioned to produce independent reports for the Minister for the Environment and advise on the viability of further reforms of the RMA. In October 2010 The Ministry for the Environment launched a Discussion Document *Building Competitive Cities: Reform of the urban and infrastructure planning system*³ building on these two reports. New legislation will be introduced by the Government as a consequence of the two expert reports and the public, individual and group submissions. This paper analyses the recently launched Discussion Document and evaluates some of its major recommendations to address planning coordination and process efficiency in relation to the urban environment.

The paper concludes that the main focus of the new Discussion Document should be on the urban environment, which until now has been completely unrecognised in the Act. Some of the proposed initiatives offer potential to significantly improve planning and urban design outcomes.

Keywords:

planning legislation, Resource Management Act, urban planning

1 Introduction

The Resource Management Act (RMA) 1991¹ is a major piece of legislation underpinning urban development in New Zealand and is considered as a fundamental legal framework governing the built environment. The Act is administered by the Ministry for the Environment and has the intention “to promote the sustainable management of natural and physical resources”¹ in the country.

The purpose of this paper is to examine the current RMA Stage Two Reforms, a process that began in 2010 with the appointment of two Technical Advisory Groups (TAGs), the Urban TAG and the Infrastructure TAG. Both bodies were commissioned to produce

independent reports for the Minister for the Environment and advise on the viability of further reforms of the RMA. In October 2010 The Ministry for the Environment launched a Discussion Document *Building Competitive Cities: Reform of the urban and infrastructure planning system*³ building on these two reports. New legislation will be introduced by the Government as a consequence of the two expert reports and the public, individual and group submissions. This paper analyses the recently launched Discussion Document and evaluates some of its major recommendations to address planning coordination and process efficiency in relation to the urban environment. In addition a summary of the official submissions of two key professional bodies, the New Zealand Institute of Architects (NZIA) and the New Zealand Planning Institute (NZPI) are also included in the paper to illustrate some of the feedback provided to the Ministry for the Environment.

2 An Overview of the Resource Management Act (RMA) 1991

The RMA 1991 is a major piece of legislation underpinning urban development in New Zealand and is considered as a fundamental legal framework governing the built environment. The Act is administered by the Ministry for the Environment and has the intention “to promote the sustainable management of natural and physical resources”¹ in the country. At the time of its inception the RMA “was hailed as a world first for its freedom, flexibility and focus on effects-based environmental management” (Oram, 2007, p.11), “as an innovative, brave attempt to devise a planning system capable of delivering sustainable development” (Barton, 1998, p.453) and a “pioneering example of legislating for sustainability” (Jackson & Dixon, 2007, p.107).

The scope of this national legislation is quite wide as it integrates previous pieces of legislation dealing with a diverse range of fields: land use planning and control of the built environment under the Town and Country Planning Act 1977 (TCPA); management of certain natural resources from the Water and Soil Conservation Act 1967 and Geothermal Energy Act 1953; and environmental regulation functions of the Clean Air Act 1971 and various other acts regulating hazardous materials. For example, Part 3 of the Act, “Duties and restrictions under this Act”¹ has separate sections dealing with land, coastal marine area, river and lake beds, water, discharges, and noise.

Part 2 of the Act, “Purpose and principles”, section 5¹, provides a definition of “sustainable development [which] means managing the use, development, and protection of natural and physical resources in a way, or at a rate, which enables people and communities to provide for their social, economic, and cultural well-being and for their health and safety”¹. The same section identifies three key conditions that enable sustainable development defined by the Act: sustaining the potential of natural and physical resources to meet the reasonably foreseeable needs of future generations; safeguarding the life-supporting capacity of air, water, soil, and ecosystems; and avoiding, remedying, or mitigating any adverse effects of activities on the environment.

2.1 The RMA and its Amendments

The eighteen subsequent amendments to the Resource Management Act 1991 that were introduced over the past twenty years, from 1993, 1994, 1996, 1997, 2002, 2003, 2004, 2005, 2007, 2008 and 2009, have strived to improve existing practices and ultimately the overall quality of the urban environment in New Zealand. Some of the main amendments deal with a diverse range of issues. The 1993 amendment, No 65, introduced changes to a number of administrative and process issues regarding

subdivisions. The 1996 amendment, No 160, covered areas such as marine farming, coastal occupation and a range of technical issues. The 2003 amendment, No 29, was concerned with streamlining RMA processes at all levels including the development of National Policy Statements. Furthermore, Regional Policy Statements and Regional and District Plans were required to reflect those. The six 2004 amendments, No 2, No 5, No 46, No 77, No 94 and No 103 were limited in scope and scale to energy and climate change issues and had a large impact on Regional Policy Statements. The 2005 amendment, No 87, was considered the most significant as it intended to improve various management processes such as national leadership, decision making, local policy and plan making as well as Environment Court operations.

Whether the particular planning aims and intentions of the RMA and its eighteen amendments have been achieved over the past two decades remains highly debatable. Oram (2007) argues that while the RMA works well for “small, local consents ... it is inadequate for dealing with wide area, long-term and strategic issues of urban development” (p.3). Overall “the RMA does radically shift the weight of planning legislation towards sustainable resource management” (Barton, 1998, p.454). Jay (1999) identifies some of the major problems with this piece of national legislation whose primary focus is “on the effects and impacts of development rather than on the nature or scale of development” (p.468). As sustainable management seems to take precedence over the process of sustainable development and biophysical issues play a central role, “this places the Act at a significant distance from issues of urban planning and development (Hunt, 2008, p.9).

An additional problem is presented by “the exclusion of social and economic matters” (Jay, 1999, p.468) which is believed to have been dictated by the prevailing market forces in New Zealand central government circles. “The RMA carefully stresses the physical variables, leaving social variables, including equity in resource distribution, largely to look after themselves” (Barton, 1998, .454). As a consequence “the reduced emphasis on socio-economic effects within land-use development plans has impeded the promotion of sustainable spatial development strategies” (Jackson & Dixon, 2007, p.107). The “market forces emphasis remains at odds with processes that deliver high quality urban design outcomes” (Hunt, 2008, p.2). In summary, the powers vested in the RMA become seriously compromised when it comes to “control over the nature or scale of resource use, provided that detrimental effects on the biophysical environment are avoided, remedied, or mitigated” (Jay, 1999, p.468). Barton (1998) concludes that the RMA “does integrate in one compendious Act a host of environmental legislation ... and it does display, in the text at least, a naive idealism which can inspire respect” (p.453).

2.2 The RMA and Functions, Powers and Duties of Central and Local Government

The introduction of the RMA in 1991 was accompanied by changes at central and local government levels. Part 4 of the Act is dedicated to the “Functions, powers and duties of central and local government”¹. Section 24 defines the functions of the Minister for the Environment, who is in charge of issuing National Policy Statements and making of National Environmental Standards. Section 28 defines the functions of the Minister of Conservation, who is in charge of the preparation and recommendation of New Zealand Coastal Policy Statements and the approval of Regional Coastal Plans.

On a local government level New Zealand has a two-tier system that consists of 12 regional councils and city or district councils. Section 30 (a) defines the functions of the regional councils, who are in charge of “the establishment, implementation, and review of objectives, policies, and methods to achieve integrated management of the natural and physical resources of the region”¹. In general, the regional councils were given responsibility for managing water, soil, air, coasts, natural hazards, and hazardous-waste mitigation, the discharge of contaminants, and land-transport planning. They are also required to produce Regional Policy Statements, a Regional Coastal Plan and a Regional Plan. Section 31 (a) defines the functions of the territorial authorities, who are in charge of “the establishment, implementation, and review of objectives, policies, and methods to achieve integrated management of the effects of the use, development, or protection of land and associated natural and physical resources of the district”¹. The territorial authorities or the district and city councils are in charge of district planning, noise control, hazard mitigation, and land subdivision and are required to produce District Plans under the RMA.

2.3 The RMA and Planning Practice in New Zealand

All proposals for the use and development of land in New Zealand fall within the jurisdiction of the RMA 1991. Every proposal not identified as permitted activities in the relevant District or Regional Plans requires the lodgement of a resource consent application at the local district or city council. The local territorial authorities (TAs) are responsible for developing District Plans based on the guidelines provided in Part 5 of the RMA “Standards, policy statements and plans”¹. Section 72 states the purpose of the District Plans: “The purpose of the preparation, implementation, and administration of District Plans is to assist territorial authorities to carry out their functions in order to achieve the purpose of this Act”¹.

As “the 1991 New Zealand Resource Management Act established an effects-based planning system intended to safeguard the biophysical resource base” (Jackson & Dixon, 2007, p.107), one of the functions of the TAs under the Act as stated in Part 4, Section 31 (1) (a) is “to achieve integrated management of the effects of the use, development, or protection of land and associated natural and physical resources of the district”¹. The types of zones developed in the District Plans “are related to the types of effects generated by activities, rather than types of uses” (Jay, 1999, p.468). Similarly Miller (2000) agrees that “the emphasis was very clearly on the control of the effects on the environment rather than the activity itself” (p.129). Overall, an examination of District Plans reveals a consistent reliance on rules and regulatory instruments (Miller, 2000).

Planning practice in New Zealand requires the local councils to check resource consent applications to establish compliance with the District Plan rules. If the proposal is deemed to have no significant detrimental environmental effects and if the assessment of potential environmental effects is satisfactory, then resource consent is granted. One major deficiency of this generally rigorous process is the complete lack of consideration of the proposed activity with its associated aesthetic characteristics. As long as a proposal is perceived as harmless and having only a minor environmental effect, this guarantees the favourable outcome of the resource consent application. Hunt (2008) contends that traditionally, analysis of effects has focused on biophysical effects, and issues of design quality have not been considered which “highlights the limited basis on which visual effects have typically been assessed under the RMA” (p.5). The need to shift the focus and include urban design issues when evaluating resource consent

applications led to the establishment of the Urban Design Panel at Auckland City Council in 2003. Although this was a non-statutory initiative, the role of the Panel is mainly to ensure high quality urban design of large scale central city developments and make recommendations included as part of the resource consent process.

There are three major options when evaluating resource consent applications. The first and most straight forward one is when the proposed activity complies entirely with the District Plan rules. The second option can be a non-notified resource consent which requires the signatures of all affected parties in the cases when there is some degree of deviation from the District Plan rules for that particular area. The third and most time-consuming option is a notified resource consent which requires public notification and the opportunity for members of the public to make submissions.

Hunt (2008) poses the question whether the District Plans based on the requirements of the RMA 1991 are able to accommodate measures that will ultimately lead to quality urban design and development. In the absence of city by laws and the fact that the RMA is a piece of national legislation governing all urban development in the country, any urban design initiatives that sit outside this legislation remain non-mandatory. In recent years the need to introduce statutory measures has become more compelling which has led to the RMA Stage One and Two Reforms.

3 The RMA Stage Two Reforms

The latest Resource Management (Simplifying and Streamlining) Amendment Act 2009 No 31² was passed by the Government in 2009 to improve some of the aspects of the resource consent process. This Amendment Act constituted the Stage One Reforms undertaken by the Government. Currently the Stage Two Reforms is underway, a process that began in 2010 with the appointment of two TAGs (Technical Advisory Groups), the Urban Technical Advisory Group and the Infrastructure Technical Advisory Group. Both bodies were commissioned to produce independent reports for the Minister for the Environment and advise on the viability of further reforms of the Resource Management Act. In October 2010 The Ministry for the Environment launched a discussion document *Building Competitive Cities*³ building on these two reports. The intention was to invite feedback from various professional bodies as well as the general public, a process, which had a deadline by 17 December 2010. New legislation will be introduced by the Government as a consequence of the two expert reports and the public, individual and group submissions.

3.1 Building Competitive Cities: An overview of the Discussion Document

The document has a clear structure and consists of five sections: 1. Introduction; 2. Problems with the planning system; 3. Options for change: Planning and urban design; 4. Options for change: Social and economic infrastructure development; and 5. Consultation process³. The current problems with urban planning and infrastructure are clearly identified in section 2. The suggested possible solutions are listed in two separate sections: section 3 is dedicated to options for change in planning and urban design and section 4 deals with possible options for change in social and economic infrastructure development.

The purpose of the document is clearly stated in the Introduction section: “to improve our knowledge and understanding of the issues facing planning and urban design and infrastructure development in New Zealand” (p.1)³. The document seeks feedback on

the options for reform and how they could improve the status quo. As 85 per cent of New Zealanders live and work in urban areas³, it becomes even more important to build attractive and competitive cities that will contribute to the country's economic growth. Being the largest city in New Zealand, Auckland plays a special role in the country's economy with an average productivity, which is 45 per cent greater than the rest of the country (Mare, 2008). Hence the focus of the suggested changes in the planning system as well as in social and economic infrastructure is on Auckland first. One example is the spatial planning currently taking place in Auckland as a result of the amendments to the Local Government Act (LGA). Similar spatial planning principles could also be applied to other New Zealand cities and towns.

3.2 Problems with Urban Planning and Infrastructure

The New Zealand urban planning system is complex and is guided by three different pieces of legislation: the Resource Management Act (RMA) 1991, the Local Government Act (LGA) 2002 and the Land Transport Management Act (LTMA) 2003. In addition the Historic Places Act 1993 also plays a role in certain urban areas. The three major pieces of legislation governing the urban environment have "different legal purposes, processes and criteria, which were not actively designed to work together" (p.5)³. The Government has identified four potential problems with urban planning due to current legislation and practice that hinder the process of building competitive cities.

The first problem with urban planning is the inadequate recognition of urban environment in the RMA³. This major piece of national legislation deals primarily with effects-based management of the natural environment and has limited capacity to assess the value-adding capabilities of potential urban developments. The achievement of long-term urban planning goals and good urban design outcomes is hindered by the existing legislation leading to the intrusive sprawl of ad hoc developments driven by quick return motives. The second problem with urban planning comes from the complex planning system that consists of the three separate Acts mentioned above and their complete lack of alignment and connection³. As a consequence there is a complete lack of consistency in the decisions that have been made, which constitutes the third problem of the urban planning system³. The multiple participants and decision-makers aggravate further the problems already identified: local and central government, the private sector, infrastructure providers, communities and various non-government organisations. Agreements reached among the participants operating within a single Act are not simultaneously integrated with agreements reached within the other Acts. The fourth problem with urban planning is the barriers to effective implementation: inconsistent implementation of national objectives and standards in plans; cost and time associated with preparing and changing plans; and the potential problems with various tools in practice³.

Separate from the problems with the urban planning system, the Government has identified five problems with the infrastructure development in New Zealand. The first problem is the lack of clarity and consistency of national objectives and standards, such as National Policy Statements (NPS) and National Environmental Standards (NES). Due to the specific nature of large infrastructure projects, which often cross regional and local boundaries, NPSs and NESs become increasingly important to "articulate national priorities, provide national direction and facilitate consistency and certainty in the way resource management issues will be addressed" (p.12)³. The second problem refers to the mixed access to designations, which are special provisions in the District Plan which allow a public work, such as schools, airports, etc to be developed without the need for

land-use resource consent from the territorial authority³. The complex and inflexible approval processes constitute the third problem with issues ranging from the level of detail required for new designations to the multiple approval processes and appeal routes³. The fourth identified problem with the infrastructure development is the lack of robust and integrated decision-making and the fifth one is the inefficient and inadequate land acquisition which deals with issues when land is acquired for public works and compensation provisions are required³.

3.3 Proposed Changes for Urban Planning and Design

The third chapter of the document *Building Competitive Cities* proposes specific changes in the urban planning system that are structured around the problems identified in the previous chapter. The recommendations are outlined in four categories corresponding to the relevant problems. The first category deals with the recognition for the urban environment in the RMA framework. Ensuring a stronger focus on the urban environment necessitates the modification of two definitions: of “environment” to specifically include the urban environment and of “amenity values” to put more emphasis on the quality of the urban environment³. The second category of proposed changes addresses issues of greater national direction and clarity³. The feedback received when the NPS on Urban Design was introduced in 2008 suggests that the NPS needs to include principles of good urban planning that result in a quality urban environment on all levels from cities and towns to individual spaces and buildings. The option that is put forward suggests extending the scope of the proposed NPS to require local authorities to provide an adequate supply of land to meet future urban growth demands and include policies considering housing affordability. The third category of suggested options is dedicated to spatial planning. The new Auckland Council that came into being on the 1st November 2010 as a result of the merge of the seven Councils in the Auckland Region has been charged with the task of developing a spatial plan for Auckland “to provide an overarching vision for Auckland” (p.21)³. The 2010 Amendment to the LGA defined the requirements for Auckland spatial plan. Careful consideration has been given to the possibility of applying the spatial plan tool to other areas in New Zealand and also to be given “an appropriate level of statutory influence” (p.24)³ on RMA, LGA and LTMA plans. The fourth category of suggested options deals with the improvement of tools to develop and maintain a quality urban environment: introduce a national standardised template for local and regional plans, developed by central government; produce a single document with a combined NPS and NES as a clear expression of national direction; establish a National Urban Design Panel and a Government Architect to improve the quality of urban design; and improve land assembly to create large areas of land in specific places that require regeneration³.

3.4 Proposed Changes for Social and Economic Infrastructure Development

The fourth chapter of the document *Building Competitive Cities* proposes specific changes addressing infrastructure issues that are structured around the problems identified in the previous chapter. The recommendations are outlined in six categories corresponding to the relevant problems. The first category deals with the recommendation for greater national direction and consistency through the systematic use of NPSs and NESs that will outline the Government’s priority areas of economic, social and environmental significance under the RMA. The second category includes recommendations for changed access to the designation system by extending eligibility for designations to a broader range of infrastructure types, such as ports and electricity generation. The third category deals with improved approval processes. Some of the detailed recommendations specify the eligibility criteria for concept designations and

define the level of detail required with applications. Integrating current multiple approval processes into a single process and removing duplicated processes is seen by the Government as an efficient way to streamline approval processes. The fourth category is dedicated to the enhanced decision-making framework with the aim to make decision-making more independent, transparent and integrated. Under the current system, decisions on different infrastructure projects are made by different decision-makers in isolation from each other. The fifth category of proposed changes describes an efficient compensation process under the Public Works Act (PWA) 1981 in the cases of land acquisition from private property owners. The suggested options outline a reasonable list of compensation measures for land acquired under the PWA. The sixth category of recommendations deals with transitional provisions which may be needed to manage the change and to ensure that investment in existing infrastructure is maintained and continued.

3.5 New Zealand Institute of Architects (NZIA) Submission on Building Competitive Cities Discussion Document

NZIA's submission summarises the strong views of the architectural profession of the complete lack of recognition of the urban environment in the current version of the RMA 1991. As discussed above, this major piece of national legislation which defines the legal framework governing the built environment in New Zealand focuses predominantly on planning coordination and process efficiency and remains completely ignorant to the fundamental changes in New Zealand's urban environment and infrastructure over the past twenty years. The Stage Two Reforms and the launch of the *Building Competitive Cities* Discussion Document are seen by the Institute as an opportunity for an adjustment of the RMA to reflect the urban reality in the country. NZIA's submission suggests six initiatives to significantly improve planning and urban design outcomes (NZIA, 2010).

3.6 Explicitly Recognise the Urban Environment in the RMA (NZIA, 2010)

The NZIA provides its strong support to the adequate recognition of the urban environment in the RMA framework. The Purpose of the Act may be extended to include recognition of the built environment, and consider both the beneficial and adverse effects on it. Another area where the Institute feels strongly that improvements can be made is "amenity values"¹. New Zealand cities and towns have undergone major transformations over the past twenty years since the RMA was first introduced in 1991 and yet the concept of "aesthetic coherence"¹ has not, still providing little guidance as to how desirable design outcomes can be achieved. The possible inclusion of other qualities relevant to amenities, such as "sense of place, contribution to vitality and social interaction" (NZIA, 2010, p.1), are seen by the Institute as having the potential to overcome past and current urban design and planning issues resulting from the inadequacies in the current version of the RMA.

One major concern expressed by the Institute is the differentiation between the natural and urban environment. While the RMA seeks to actively protect the natural environment by minimising the adverse effects on it, a major characteristic of the urban environment is its constant change and development. This characteristic needs to be considered by the revised RMA to encourage good urban development on a national scale.

Another recommendation of the Institute is the formulation of a new definition of heritage either within the RMA or as a supplementary document outside the RMA.

New Zealand is a young country and requires recognition of its modern heritage, which is different from the historic heritage connected to the history of the country, which “is thinly spread in our young country” (NZIA, 2010, p.1).

3.7 Ensure the Spatial Plan for Auckland replaces the current multiple overlapping planning processes and guides a Unitary Plan (NZIA, 2010)

The proposed Auckland Spatial Plan must integrate the Regional Policy Statement and the Regional Land Transport Strategy in order to be effective according to the NZIA. Under the current legislative system a suite of District Plans, based on the RMA, are in operation. Before the 1st November 2010 when the new Super City in Auckland came into being, there were seven Councils in the Auckland Region (Rodney, North Shore, Auckland Central, Waitakere, Manukau, Franklin and Papakura) using their own District Plans. The necessity to introduce a single Unitary Plan with a single set of definitions, policies and controls that apply across wider Auckland is strongly supported by the Institute. While the role of the Spatial Plan is seen as providing “vision for the city, lower order plans, including a Unitary Plan, should be consistent with it, rather than being required to give effect to the Spatial Plan” (NZIA, 2010, p.2).

3.8 Establish a National Policy Statement on the Urban Environment (NZIA, 2010)

The formulation of a National Policy Statement (NPS) is seen as a “simple means of setting expectations for the planning and design of the urban environment and ensuring their consistent application nation wide” (NZIA, 2010, p.3). The scope of this NPS is quite wide including diverse areas, such as: intelligent growth management that integrates transportation and land use; response to local conditions and context, distinctive sense of place, ecological responsiveness, mix of densities and network of connections to and within an area, mixed use areas and achieving high quality public realm and great places to live.

3.9 Establish a National Urban Design Panel (NZIA, 2010)

The NZIA believes that the establishment of a National Urban Design Panel (NUDP) will assist “better, higher value design outcomes” (NZIA, 2010, p.3). It should be administered by the Government Architect and work with regional and local panels. The Urban Design Panel at the former Auckland City Council had an advisory role and made recommendations that were not mandatory. Similarly, the new proposed NUDP will not be a decision-making group but the recommendation is that its findings should have standing in RMA related processes.

3.10 Establish a Government Architect (NZIA, 2010)

The NZIA believes that establishing a position of Government Architect “would assist New Zealand in achieving a level of design excellence and sustainability performance in the built environment that will enrich the lives of all New Zealanders” (NZIA, 2010, p.3). The New Zealand architectural profession has been under severe criticism over Auckland’s urban environment and the almost complete lack of urban planning considerations. Although well understood, good urban design principles seem to remain an enigma for urban planners in Auckland, resulting in the ubiquitous proliferation of mediocre architecture and urban spaces. “... Auckland lacks a collective sense of creative energy and focus; ... has poor urban design and planning; and ... is developing with little attention to aesthetic considerations” (p.9)⁴.

The argument that NZIA puts forward is that “Government plays a vital role in shaping our built environment” (NZIA, 2010, p.4) through the erection of various social and institutional buildings, such as town halls, museums, schools, hospitals, courts and the Parliament buildings, hence the necessity to lead by example.

3.11 Ensure efficiencies in the planning and resource consent process are achieved (NZIA, 2010)

The NZIA places more emphasis on the resolution of conflicts at a planning and design level thus avoiding the involvement of legal mechanisms that prove to be costly and time consuming. Ensuring efficiencies is seen through a range of measures: the establishment of the National Policy Statement on Urban Development; the introduction of a Unitary Plan in Auckland in order to simplify and coordinate the planning process; and the establishment of a National Urban Design Panel in conjunction with regional and local panels, whose recommendations become an integral part of consent processes.

3.12 New Zealand Planning Institute (NZPI) Submission on Building Competitive Cities Discussion Document

The NZPI’s submission is structured around the questions posed in the official feedback form prepared by the Ministry for the Environment. The Institute provides detailed answers to twenty out of the twenty three questions in the form.

3.13 Urban Planning System and Infrastructure Development

The NZPI strongly agrees that the current planning system “is unduly complicated” and there is “a lack of consistency in decisions and some barriers to effective implementation” (NZPI, 2010, p.4). The view on the infrastructure development is somehow vague and rather short calling for “stronger alignment of strategic goals and governance structures from the national to regional and local entities” (NZPI, 2010, p.4). More surprisingly, unlike the NZIA submission, which strongly supports the adequate and explicit recognition of the urban environment in the RMA framework, the NZPI takes the stance that the current legislation recognises the “environment” and its various aspects: social, cultural and economic. The argument that is put forward is that the existing concept of “environment” already incorporates the concepts of “urban environment” and “amenity values” and that the proposed amendments to their definitions would not necessarily lead to good urban design and planning. The view of NZPI is that the RMA “does not require alteration to give greater recognition to the urban environment” (NZPI, 2010, p.6). What is suggested instead is the further refinement of the “various mechanisms and tools available to the planning community to address the urban or built environment” (NZPI, 2010, p.6).

According to the NZPI the current problems arise from the interpretation and implementation of the various statutes and rules in the current legislation, which is permissive and allows for variations in the “practice of planning” (NZPI, 2010). The submission does not distinguish though between the natural and built environment, which are two separate components in the context of any town or city. According to the NZPI the provision of guidance notes to aid planning practice could help improve the quality of future urban developments. The possibility to put in place special mechanisms or urban panels to help urban planning practice is not perceived as necessary (NZPI, 2010).

The NZPI also believes that “it is not possible to legislate for good planning” and suggests “stronger leadership, direction and guidance at a national level” (NZPI, 2010,

p.6). As the current RMA 1991 is concerned mainly with assessing the effects of a potential development and minimising the harm to the natural environment, it remains unclear how maintaining the status quo can solve the massive urban design and planning problems in Auckland. The reality is that the magnificent natural setting seems to have been wasted with developments driven primarily by greedy property developers trying to make a quick return. Such developments of non-descript nature all seem to lack aesthetic qualities and vision.

3.14 Spatial Planning in Auckland

Similarly to the views of the NZIA in their submission, the NZPI supports incorporating the Auckland Regional Land Transport Strategy (RLTS) and Auckland Regional Policy Statement (RPS) to avoid inconsistencies between the two and encourage integrated transport and land use planning. As there is certain criticism towards the existing RMA plans in Auckland, associated with the lack of consideration to growth, economic development, transport or environmental outcomes, the NZPI recommends the development of plans in close collaboration with communities, individual citizens, organised groups and other government agencies. Similarly to the NZIA, the NZPI also supports the development of a single Unitary Plan “from the perspective of best practice” (NZPI, 2010, p.8). The Institute believes that the effectiveness of the Auckland Spatial Plan could be improved by giving it an appropriate level of statutory influence and by achieving a level of consistency with other pieces of national legislation, such as the Resource Management Act (RMA), Local Government Act (LGA) and Local Transport Management Act (LTMA). It also needs to be developed in close consultation with all the stakeholders in the Auckland area, such as central government agencies and departments (NZPI, 2010).

3.15 Greater National Direction and Consistency

The NZPI's view that a strong National Policy Statement (NPS) should be prepared to clarify national direction on urban planning is similar to the NZIA's one. Central government should direct the content of plans through this NPS and associated National Environmental Standard (NES). The NZPI believes that the development of a national template would be useful in achieving alignment and at the same time facilitating the inclusion of local and regional interests and needs. The purpose of the NPS is seen as a mechanism that ensures the seamless integration of district and regional planning with local planning, which is usually broader by nature (NZPI, 2010).

4 Conclusion

The *Building Competitive Cities* Discussion Document launched by the Ministry for the Environment in October 2010 is a long overdue adjustment of the Resource Management Act (RMA) 1991. The document sets out four problems with urban planning and five problems with the infrastructure development in New Zealand and provides a number of options to address the identified issues. Three of these topics directly relate to urban design: recognition of the built environment in the RMA; National Policy Statement on urban design; and additional tools aiming at the provision of more direction on the content of plans, increase government involvement in urban design through the appointment of a government architect and improve the ability for councils to acquire and assemble land.

The Discussion Document outlines four options aiming at specific changes in urban planning and urban design and six options for change in the social and economic infrastructure development. Some of these proposals put forward will definitely make a positive change in the urban environment but the fairly limited extent of these changes suggests that they might play only a small role in the process of making cities more sustainable, competitive and economically successful.

Is capturing the “unearned increment” in land value still a viable idea? A cross-national analysis*

Rachelle Alterman

The Klutznick Center for Urban and Regional Studies,
Technion – Israel Institute of Technology, Haifa 32000, Israel

Email: alterman@technion.ac.il

Abstract*

The financial aspects linked to planning regulation impact the built environment. The idea that the public should reap the “unearned increment” or the “plus value” of land is by no means new. The underlying rationale is that much of the value of real property is created not by the landowner’s work, but by government policies that grant development rights or by broad economic and social trends.

Drawing on the author’s comparative research on the laws and practices in 13 advanced-economy countries around the world, the paper addresses the degree to which recapture of the “unearned increment” is indeed a useful approach that policymakers should adopt for financing or incentivizing the delivery of public services and affordable housing.

The idea of value capture in its pure form has failed to catch on widely among advanced economies, but the basic idea has not died away. In recent decades, several “mutations” of this idea have been gaining popularity in many countries, but in widely different forms and degrees.

Keywords:

betterment tax, development control, planning law, real-property taxation, value capture

1 Introduction

The built environment is shaped not only by the direct regulatory instruments that planning law provides, but also by the ancillary financial aspects. These deserve more attention. Few issues in land-use planning are as universal as the bipolar relationship between planning regulation and property values. This issue carries deep economic, social, and distributive-justice implications. Do governments have the right to reap some of the increment in value attributable to planning decisions? And the corollary: Do governments have an obligation to compensate private landowners for value decline due to land-use

* A somewhat different and expanded version of this paper is *forthcoming* (2011) under the title: “Land use regulations and property values: The ‘Windfalls Capture’ Idea Revisited”. Chapter 33, pp. 755-786 in: The Oxford Handbook of Urban Economics and Planning, edited by Nancy Brooks, Kieran Donaghy and Gerrit-Jan Knaap

regulations? Two American scholars have whimsically tabbed this issue as “windfalls” and “wipeouts” (Hagman and Misczynski 1978). This topic has trailed planning policy

for a long time, yet is no closer today to being resolved in a politically or legally sustainable manner.

This paper revisits the upward side of the land-value coin: How relevant is it today around the world, and especially among advanced-economy countries? The idea that landowners should share some of the increased value of their land with society encompasses a wide range of situations and policies. I will first address the issue broadly and then focus on one specific type of value capture—where the rise in property values is due to land-use regulations or public works. This topic has not benefited from enough comparative research.¹ By analyzing the experiences of a large sample of advanced-economy countries, this paper seeks to contribute to knowledge sharing on this important issue.

2 The Idea of Land-Value Capture

The idea that the value of land is created by society and should therefore be reaped for the public is by no means new. The brief survey reported here first looks at the evolution of the notion of the “unearned increment” in land in general, and then specifically at the idea of capturing increments created by land-use regulation.

2.1 Henry George and the “Single Tax” Idea

In 1879 the American thinker Henry George famously proposed the “single tax” idea in his book *Progress and Poverty*. He argued that if the rent from land alone (without the buildings and other “improvements”) were to be paid to the government authority on an ongoing basis, it would suffice to finance the entire set of society’s public needs (Andelson 2000, xxii -xxiv). A tax on land would avoid causing the kind of economic turbulence that taxes on labor and mobile or financial capital inevitably create. This latter view is supported by many economists (Ingram and Hong 2007; England 2007; Netzer 1998). George (1962) argued that public capturing of land values represents “a takings by the community, for the use of the community, of that value which is the creation of the community” (421). At the time, his proposal did not link value capture with land-use regulation because he wrote the book long before these were established in their modern format.

The “Georgian movement” still draws dedicated followers around the world (as well as many critics; see Andelson 2004).² (as well as many critics; see Andelson 2004). However, as attractive as the Henry George theory may be, 130 years after he published his seminal book, the “vote” around the world is clear: “no” to the single-tax idea, with

¹ Despite the ubiquity of the land-value issue, it has not benefited from much systematic comparative research. The only major academic work that looks at both sides of this issue comparatively is the seminal book by Hagman and Misczynski (1977). It surveyed five English-speaking countries (the United States, Canada, Australia, New Zealand, and England) and contributed considerably to the theoretical framing of the issue. Another book, by McCluskey and Franzsen (2005), focuses mostly on developing countries. The “wipeouts” side—called “regulatory takings” in American lingo—has recently benefited from greater comparative attention. My recent book (Alterman 2010) presents an in-depth comparative analysis of the laws and policies of thirteen countries. Alexander’s 2006 book analyses four countries in depth.

² For an example of one of the movement’s organizations, see <http://www.henrygeorgefoundation.org/>. See also <http://www.earthrights.net/wg/wg1.html>.

a few small local exceptions. Yet the underlying rationale of the Georgian argument is still compelling to many. It is often cited in support of the idea that the added value specifically created by land-use regulation decisions should be shared with the public.

2.2 Value Capture and Land-Use Regulation: The “Betterment Capture” Idea

Historically, Britain led the way in the world discussion about the nexus between planning regulations and property values. The phrases that the British coined for the issue—“betterment and compensation” or “betterment and worsement” (or “worsenment”)—date back to the late nineteenth century (Baumann 1894). In 1909 a British prime minister made the following eloquent statement when introducing a national betterment capture levy as part of the world’s first national planning act (Housing, Town Planning, Etc. Act 1909 (c. 44)): “It is undoubtedly one of the worst evils of our present system of land that instead of reaping the benefit of the common Endeavour of its citizens a community has always to pay a heavy penalty to its ground landlords for putting up the value of their land.”¹

The failure of this British experiment cannot be attributed to lack of enthusiasm. Unlike the United States, Britain has had a long tradition of legislative responses to both sides of the property value effects. Subsequent legislation tried various other formulas, and these ideas were exported to many of the colonies (McAuslan 2003; Home 1997). However, neither side ever worked satisfactorily (Grant 1999), as discussed in section 4.

Since World War II the betterment and compensation sides have been decoupled in Britain. During the height of the war, the British government appointed the Expert Committee on Compensation and Betterment to guide the government in the laws and policies it should adopt for postwar reconstruction. The influential *Uthwatt Committee Report*² introduced two important concepts—“shifting value” and “floating value” (Replogle 1978; Tichelar 2003).

“Shifting value” assumes that the demand for any given type of land use in a particular region is finite. Land-use restrictions in one municipality (or in one part of a city) may cause downward value changes, but at the same time may increase the value of land in another locality where the regulations do permit development. “Floating value” refers to the speculative nature of potential land values. Landowners tend to assume that if only planning regulations did not stand in their way, a lucrative type of development would “land” on their own plot of land. However, the notion of shifting value implies that even if land-use regulations were to be abolished, not all landowners would benefit from development (Moore 2005, 3). The assumption that landowners are entitled to compensation for reduction in development rights was thus shaken, while the justification for capturing the added value was reinforced.

Based on this thinking, the UK Town and Country Planning Act of 1947 reformed the entire system. It discarded the idea of “development rights” granted by plans years in advance and substituted a system whereby each development is approved “case by case” through a “planning permission” (Booth 2003). Local government must prepare local plans, but their function is to guide decisions, not to grant development rights. Thus, the

¹ *Hansard* (1909).

² The *British Expert Committee on Compensation and Betterment*, Cmd 6386 (1942). This report is known by the name of its chair, as the *Uthwatt Report*. Its importance in shaping British recovery is recognized not only by planners and lawyers but also by historians of British history. See Tichelar (2003).

very notion of entitlement to compensation was abolished (Purdue 2010). At the same time, the other side of the coin—capturing the betterment value—was fortified. For several decades hence, the United Kingdom seemed to have “volunteered” to serve as the world’s laboratory for testing the betterment capture idea, as detailed in section 4.

2.3 Is There Symmetry between Windfalls and Wipeouts?

The UK story brings to mind an obvious question: If landowners are required to share the windfall derived from land-use decisions, should they also have the right to compensation for decrease in property values due to such regulations? And the converse: If landowners are allowed to keep the windfalls, then symmetry of logic would hold that they should absorb the wipeouts and not be eligible to compensation from the public purse.

However, my recent thirteen-country comparative analysis has produced some counterintuitive findings: In most countries, the two sides of the coin are not symmetric either in law or in practice (Alterman 2010, 3–5). The lack of symmetry is usually not even a public or legal issue, except as a teaser by proponents of one side of the debate who wish to highlight the other side’s ostensibly faulted logic. In all but two among the sample countries (Poland and Israel), the two sides of the land-value coin are currently disassociated. Thus real-life laws and policies do not operate according to the axioms of pure logic.

The following sections take a closer look at specific instruments for value capture, with a particular focus on those directly targeted to capturing value created by land-use regulatory decisions.

3 Three Types of Value Capture: Macro, Direct, and Indirect

Despite considerable scholarly literature, *value capture* remains an open-ended term, variously defined and used. Some use the generic term *value capture* to cover any type of policy or legal instruments whose purpose is to tap any form of “unearned increment,” regardless of the cause of the value rise. Others use the same term to denote only the policy instruments targeted at value arising directly from land-use regulation or public works. The most direct term available to denote the latter type of value increase is *betterment*—a word that originated in British English and still has no specific American English counterpart.

There is also considerable vagueness in the literature on whether a policy should be classified as value capture based on its *purpose* or its *outcome*. Some policies not primarily or overtly intended to reap the unearned increment do in fact exact from landowners or developers monetary or money-equivalent contributions. To provide a more level field for research and knowledge exchange, I propose a distinction among three sets of policy instruments that relate to value capture: (1) *macro*, (2) *direct*, and (3) *indirect* instruments.

3.1 Macro Value Capture Embedded in Broader Land Regimes

Macro value capture instruments are not freestanding. They are embedded in some overarching land policy regime, motivated by some broader rationale and ideology. These regimes are assumed to provide a better land and development policy than a market regime. Four major types of land policy regimes have value capture embedded in them—at least in theory. Some authors regard these macro land policies as value

capture instruments (e.g., Smolka and Amborski 2007). The four are: 1. Nationalization of all land and direct government control over its use; 2. Substitution of private property by long-term public leaseholds; 3. Land banking; 4. Land readjustment. Because these macro land policies don't feature value capture overtly, they will not be discussed further in this paper.

3.2 Direct Value Capture

Direct instruments for value capture are policies that seek to capture all or some of the value rise in real property under the explicit rationale that it is a legal or moral obligation for landowners to contribute a share of their community-derived wealth to the public pocket. As a wealth redistribution instrument, direct value capture is often regarded as a tax and requires legislative authority. Direct instruments do not need to seek any additional rationales—for example, they do not need to show that the funds are necessary to mitigate negative impacts of the project, or that the properties that generated the funds will also benefit from the services financed by them. The rationale for direct value capture stands in its own right.

Direct value capture may be divided into two subtypes, and the second subtype is further divided into two subtypes:

- a. Capture of the unearned increment:** Where the value rise is not linked to a specific government decision but rather to general economic or community trends.
- b. Capture of betterment:** Where the value rise is due to a specific government decision directly caused by specific types of land-use regulatory decisions or by the execution of public infrastructure.

The betterment levy, too, may be further divided into two subtypes. Confusingly, both are often denoted by the same term: *betterment*. I propose to dedicate specific terms for these two types:

- b1. Development-rights-based betterment:** Where the value rise is due to a planning or development-control decision that applies directly to the land parcel in question and raises its value.
- b2. Infrastructure-based betterment:** Where the value rise is due to positive externalities from a government decision to approve or execute public infrastructure, parks, or other services.

Capture of the unearned increment type may take many forms, including a capital gains tax on land or real property, an “unearned increment” tax upon transfer of title, sometimes time-adjusted to curb speculation, or an annual property tax that is closely tuned to the rise in property values. Taxation of the unearned increment is found in several countries. Americans know the examples of Vermont and Pennsylvania (Daniels, Daniels, and Lapping 1986 and by Gihring 1999). In the Far East reported cases are Taiwan (Lam and Tsui 1998), Hong Kong, and Singapore (Hui, Ho, and Ho, 2004) . . .

This paper focuses on the second subtype—capture of betterment arising from government land-use decisions. In sections 4 and 5 I will report on the international experience.

3.3 Indirect Value Capture

The rationale of the indirect instruments differs from the direct ones. The indirect instruments do not seek to capture the added value for its own sake, because it is “unearned,” but in order to generate revenues (or in-kind substitutes) for specific public services. Indirect instruments are usually practiced on the local government level. The objectives behind the indirect tools are usually more pragmatic and less ideological than the objective behind either the macro or the direct capture instruments. To survive legal and political challenge, the indirect instruments usually need the “cover” of other rationales beyond the desire to capture the unearned increment. It is easy to confuse the indirect instruments with the direct ones because both types harness the same source of wealth—the additional value of real property derived from government land-use and development decisions.

Unlike the direct instruments, indirect value capture is an ever-evolving category of policies that varies greatly among countries and localities. This topic merits its own comparative research. In section 6 I will discuss this topic only to contrast it with direct value capture.

4 Betterment Capture: The International Experience

How prevalent is direct betterment capture around the world? In this section and the following one I report on my international comparative research that focuses on betterment capture practices among advanced-economy countries (with a small detour to South America too).

Many types of government land-use or development decisions could serve as grounds for direct value capture.¹ These vary from country to country and possibly also from one municipality to another. Infrastructure-based betterment levies are historically the earliest form of betterment capture. I will discuss this type first and then proceeding to focus on development-rights-based betterment capture instruments.

4.1 Infrastructure-Based Betterment Capture

The oldest types of the betterment capture instruments are “infrastructure-based.” They focus on value increase to neighboring properties caused by public infrastructure. Public works are a government function that preceded land-use planning laws by centuries. When the British enacted the first town planning act in 1909, they instituted a 50 percent levy on infrastructure-based betterment—an instrument that predated that act. This instrument migrated to many of the British colonies and protectorates but experienced many failures (Peterson 2009, 36–38; Grant 1999; Alterman 1982). Apparently, linking value rise to the execution of public works is not easy. The reasons may include difficulties of proving the causal relationship to the infrastructure works; difficulties in determining the geographic range of impact; and difficulties in levying the charge at a time frame reasonably close to the execution of the public works (because the windfall is usually not realized at that point in time).

¹ In theory, other types of government decisions unrelated to land use could also be the cause of land value increases—for example, a new trade treaty that will influence a border town. However, these have not generated a significant body of law or scholarship and are not discussed here.

Yet this idea resurfaces from time to time. For example, in 2004 the Scottish government commissioned a report on whether betterment could be captured from value increase directly due to new transport facilities. Peterson (2009), writing for the World Bank, and Medda (2010) for the UN report on similar initiatives in both developing countries and advanced economies. These initiatives usually stand alone, unrelated to capture of development-rights-based betterment.

4.2 Development-Rights-Based Betterment Capture

Betterment capture policies may target a variety of land-use planning and development-control decisions. I do not know of any country or locality that has ever implemented value capture instruments to tap all the possible “stations” along the planning-to-permitting procedures. The international experience shows that only a few of these stations have ever served as grounds for this type of betterment capture.

As part of a large research project on compensation for value decrease (Alterman 2010), I also looked at the value capture side. The sample of countries encompasses fourteen advanced-economy and democratic jurisdictions (thirteen nations and an additional U.S. state). This sample constituted about 40 percent of the thirty-four members of the OECD in 2010. In alphabetical order the sample countries are Australia, Austria, Canada, Finland, France, Germany, Greece, Israel, the Netherlands, Poland, Sweden, the United Kingdom, and the United States (with additional focus on Oregon). The sample was selected to represent a variety of legal and geographic contexts: large and small countries located on four continents; federal and unitary jurisdictions;¹ common-law as well as civil-law countries with varying degrees of constitutional protection of private property;² countries belonging to the EU and those outside it; different cultural and language backgrounds, and so forth.

A finding that may surprise many is that most of the sample countries do not practice *direct* betterment capture today. There are only three countries in this sample with significant experience in direct betterment capture instruments: the United Kingdom in the past, and Israel and Poland currently. These countries applied a variety of capture policies, so cumulatively their experiences contain a wealth of potential lessons from which other countries may learn.

4.3 Britain: The World’s Former “Laboratory” of Betterment-Capture Instruments

Britain’s vicissitudes with various types of betterment capture policies make it the world’s most distinctive laboratory. Between 1909 and the early 1980s, Britain exhibited pendulum-like shifts in policies about compensation and betterment as power changed hands between Labor and the Conservatives (Tories; Cox 2002; Tiechelar 2003; Lichfield and Darin-Drabkin 1980, 144–145). These shifts were accompanied by ideological debates and significant public exposure.

¹ The United States, Canada, Australia, Germany, and Austria are federal jurisdictions.

² The United Kingdom, Ireland, Canada, United States, Australia, and Israel have a common-law tradition (Israel is regarded as a mixed system, but in the area of planning and property law it resembles other common-law systems with former British influence). For an analysis of the constitutional protection of property in these countries, see Alterman (2010, 26–35).

The various policies adopted and repealed represent a large range of rates of recoupment: the 1909 Housing, Town Planning, Etc. Act and its successors imposed a 50 percent levy on betterment arising from the approval of a land-use plan (called “scheme” and functioning similarly to zoning). The British exported this instrument too to many of their colonies around the world. It too proved to be almost inoperable due to difficulties in exacting the levy from landowners at the time of approval of the scheme (Peterson 2009, 36–38; Grant 1999; Alterman 1982).

After World War II and the rethinking brought about by the Uthwatt Commission, Labor enacted the 1947 Town and Country Planning Act that imposed a 100 percent “development charge” on the full extent of betterment. The revenue was to go to central government (Grant 1999; Lichfield and Darin-Drabkin 1980, 136–142). The tax was ineffective (Williams and Hallett 1988, 119), but scholars remain divided about whether it might have succeeded with time (Lichfield and Darin-Drabkin 1980, 142–144). In 1953 the Tories abolished the act.

When Labor returned to power, it enacted the 1967 Land Commission Act along with a new far-reaching plan: in the long run the national Land Commission would assemble a large national land bank by compulsorily purchasing all land coming in for development. In the short run, a 40 percent betterment levy was imposed on all land transacted on the open market, and the levy’s rate was to go up gradually. The revenues were to go to the central government. However, this act too was repealed by the Tories, who came back to power in 1971 (Grant 1999; Lichfield and Darin-Drabkin 1980, 144–145; Tiechelar 2003).

Labor’s last attempt (so far?) to institute a direct tax on the betterment value was made in the linked acts of 1975 and 1976. The 1975 Community Land Act was a local-government-based version of the Land Commission Act. It would have ultimately made it mandatory for local authorities to purchase all development land (Cornfield and Carnwath 1975; Lichfield and Darin-Drabkin 1980, 169–191; Tiechelar 2003). In the interim, the 1976 Development Land Tax Act (DLT) instituted an 80 percent charge on the betterment value. This time the municipalities were allowed to keep some of the tax revenues, but most still went to central government. A team of researchers commissioned to evaluate the DLT in “real time” found that its partial implementation was due to the lack of financial incentives for local governments to administer the tax effectively (Barrett, Bobby, and Stewart 1979; McAuslan 1980, 118–142).

The Tories kept the DLT in the books for a few years, making it the longest-surviving postwar betterment tax in Britain. However, the Tories broadened the exemptions clauses so much that the tax gradually became ineffective and was formally abolished in 1985 (Denyer-Green 1998, 274–275). Since then, Britain’s policy has so far said “no” to betterment capture.

However, the issue is by no means dead. In 2004 the Labor government commissioned the Barker Report, which recommended reintroduction of a mandatory national betterment levy to be called the Planning Gain Supplement. It would have captured 20 percent of the increase in land values resulting from the grant of planning permission. This proposal was rejected, partially because developers feared that the indirect value

capture would continue in addition, and partly because local governments would not have been the direct recipients of the proceeds.¹

Instead of going dramatically back to the tradition of direct betterment capture, the Labor government preferred a hybrid type of levy—a graft of direct and indirect value capture called the Community Infrastructure Levy (CIL). Ironically, the new levy was to commence on April 6, 2010, on the eve of the national elections. The levy would be discretionary, based on a preset formula that reflects the additional floor space allowed by a planning permission rather than the property's additional value. There is flexibility in the types of infrastructure that may be financed by the levy, and the geographic range is broad. However, the new levy specifically excludes affordable housing, to continue to be delivered by means of “planning obligations” negotiated with developers—a well-established type of indirect value capture extensively used in the United Kingdom (Crook et al. 2002; see also section 6 of this paper). The Conservatives who gained power in the May 2010 elections had declared all along that they would abolish the levy, and the new cabinet decided to review it.² Will the fate of the CIL be even more short-lived than its historic predecessors?

With this history, no direct betterment recapture policy (meaning, no Labor government) has yet lasted long enough for evaluation research to provide evidence for future policy makers. Since all betterment policies were adopted by Labor yet were altered by Labor itself at the next opportunity, it is clear that none were deemed good enough for re-adoption. Nevertheless, the British experience does provide some tentative lessons about why betterment capture policies may not work, to be summed up in section 5.

4.4 Israel: A Sustainable Betterment Levy

Israel's experience with betterment capture is the longest-lasting current policy among the sample countries (or reported in the international literature). The betterment levy dates back to the 1930s during the British administration over the region. Like many other former British colonies and protectorates, Israel imported unworkable notions of a betterment tax similar to the old British laws. But in 1981, an extensive revision to the betterment tax was enacted that sets out clear and workable rules for levying the net betterment derived from land-use decisions. The law also provides several types of socially based exceptions, including deprived town and neighborhoods, urban regeneration areas, and individually built homes of modest size.

All local planning commissions are obliged to levy 50 percent of the real increment in land value, to be assessed parcel by parcel. Three types of planning and development-control decisions are the legal grounds for the levy: approval of a local or detailed plan, approval of a variance, and approval of a nonconforming use. A bill submitted to the Knesset in April 2010 would add approval of a subdivision plat. The law wisely separates out the grounds from the occasion for levying so as to avoid the mistakes of the old British legislation. The levy is paid upon the sale of the property or application

¹ UK Department for Communities and Local Government (2008). ;

² Report to Cabinet Title: Community Infrastructure Levy Regulations (CIL) – (Proposals to Replace S106 Planning Agreements) – Update Following Government Consultation,

May 27, 2010, http://www.rbwm.gov.uk/public/meetings_100510_peosp_community_infrastr_levy_regs.pdf.

for building permission. Importantly for a country where nationally owned land is more prevalent, the levy applies to both private land and public land on long-term leases (which in Israel function almost like freehold land; Alterman 2003).

In addition to the compulsory betterment levy, Israel also imposes a 25 percent unearned increment tax upon sale of a property to tap the added value in general (not necessarily linked to land-use decisions). Sale of a private residential unit is usually exempt. When both the betterment levy and the unearned increment tax apply, the two are offset against each other.

The Israeli betterment levy is an important though highly fluctuating source of income for local governments. Its success is partly due to the fact that the municipalities keep the full proceeds. However, this type of levy is not free of distributive-justice issues. On the intermunicipal level, the levy is inherently uneven because the opportunities for development are a matter of “luck,” depending on a town’s location, past development patterns, and vacant land. Any betterment such levy of this type would be inherently regressive because the revenues per unit of land will be higher in localities where land values are higher. The revenues are also intrinsically uneven over time because land reserves deplete whereas urban regeneration is slow to occur.

The success of the Israeli betterment levy has several additional reasons: its rationale is clear; the appraisal is plot-specific and provides for fair procedures; the rate is uniform, nondiscretionary, and high enough to justify administrative costs; there are reasonable socially based exceptions; and the revenues may be used for an open-ended set of public services. The levy has never become a major issue in national or local electoral campaigns. In addition to the betterment levy and unearned-increment tax, Israeli planning bodies also practice indirect capture mechanisms (exactions) in varying degrees (Alterman 1990, 2001, 2007). The Israeli example thus shows that, where the real estate market is vibrant, land values may be able to tolerate cumulative layers of value capture mechanisms.

4.5 Poland: A Nonoperational Betterment Levy

Poland too currently has a direct betterment capture mechanism. In the 1990s, after the demise of the Communist regime, Poland legislated a new planning law that introduced a levy on the betterment value created by the approval of an area plan. In view of the strong private property ideology that prevails in Poland, the adoption of the betterment levy at that junction was not a trivial decision. However, the levy as instituted was in fact destined to be barely operational. The legislators should have looked more closely at other countries’ experiences in order to avoid repeating mistakes.

Some aspects of the Polish levy are potentially robust. It taps only the real value increase by requiring parcel by parcel appraisal, and the local governments in charge of collection are also allowed to keep the revenues. But several factors weaken the Polish levy. First, the Polish legislature anchored the levy in the approval of a local land-use plan even though such plans did not exist at the time, and still cover only a minority of the country. Most development decisions are granted by means of ad hoc development permits to which the betterment levy does not apply. Second, the law provides for a discretionary rate of between 0 and 30 percent, which may vary even within a single plan. Thus a fairness criterion among landowners is not built in. If a rate lower than 30 percent is applied, the administrative costs may be too high. Third, the law leaves gaping “escape loops” for landowners. The Polish legislators repeated the mistakes of

the British Town and Country Planning Act of 1932 by adopting the occasion of sale of the property as the only tax collection point and by stipulating a maximum number of five years beyond which the authority to tax would expire (Gdesz 2010).

Therefore, direct betterment levies in Poland exist largely on paper. When a legal framework is weak, there is room for differential application (not to say favoritism and corruption). There is currently some discussion in the Polish government about major revisions to the law.¹

4.6 The Spanish Tradition and Beyond

Spain is another OECD country that, although not in my sample of countries, merits a quick look at its plus-value capture policy because the Spanish tradition, like the British one, has been influential beyond its borders. The Spanish Constitution of 1978 enshrines the betterment capture principle: “The community shall have a share in the benefits accruing from the town-planning policies of public bodies” (section 47). The rate of the operative levies is about 10 to 15 percent—much lower than those of the three countries discussed earlier in this paper (Calavita and Mallach 2009; Calavita et al. 2010; Gielen 2008). Unlike Israel and Poland, in Spain the betterment levy is not necessarily assessed parcel by parcel and may not reflect the real value increments of specific plots. In addition to direct betterment capture, Spanish law obliges developers to finance a wide range of public services as well as to dedicate land to the municipality.

The importance of Spain extends to South American countries, most of which are not OECD members. In these countries, the discussion of the “plus value” as it is called in Spanish, often occupies a high place in both political and scholarly discourse. Legislated instruments of various types have been enacted (Furtado 2000; Smolka and Furtado 2001, 2003; Smolka and Amborski 2007). However, the evidence shows that actual implementation is weak due to the rampant informal development and other administrative and governance weaknesses. Smolka and Amborski’s (2007) comparative assessment of South America and North America leads to the conclusion that the former is very strong in rhetoric about direct value capture, while the latter shuns direct value capture but is strong on indirect value capture mechanisms.

What about the other advanced-economy countries not included in my sample? Because the sample of OECD countries is large and varied, my tentative assessment is that not many other OECD countries practice direct betterment capture. In developing countries, where public administration is often weak, even where such levies are on the books (perhaps as relicts from former colonial status), they are unlikely to be effective in practice.

5 Distilling Lessons from the International Experience

Why have most countries avoided adopting direct betterment capture policies? Unless each country insists on making its own mistakes, the experiences gained by Britain, Israel, and Poland should be mined to draw out the relevant lessons. In the absence of any comparative empirical research on outputs, outcomes, or impacts of betterment

¹ Based on personal conversations with Polish government representatives during two visits as a guest of the Polish government in spring and summer 2009. Based also on ongoing conversations with Dr. Miroslaw Gdesz, an administrative court judge in Warsaw.

capture policies, I shall rely on the tentative observations based on the analysis presented earlier. Here are some observations:

- The rationale for plus-value policy is not as easy to “sell” to politicians and voters as may seem from the logic of the argument. The British experience is a real-life laboratory of how the absence of political support can lead to the rise and demise of betterment capture policies along with shuffles in the ruling parties. To adopt a successful betterment-capture policy, proponents must be able to package a rationale that transcends party ideologies. This of course is no easy task, but it is a *sine qua non*. In the Israeli and Polish cases, the betterment tax has not been a party-political issue and thus has escaped the tug-of-war that its British counterparts have experienced.
- One of the arguments used against direct betterment-capture policies is that they may raise real-property prices because the price of land component would rise. If that were true, it would erode some of the justification for recapture policies. The British experience has not generated much evidence on this issue despite the experimentation with a broad range of tax rates. All of Britain’s direct value capture policies installed between 1909 and the mid-1980s were too short-lived to enable systematic evaluation. Nor has the Israeli experience delivered reliable empirical evidence because the 50 percent rate has been uniform over time and place (unless exceptions apply). Thus there has never been a “control group” to analyze. The scholarly literature on related taxes and exactions indicates that their effect on property values depends on a variety of extraneous market and contextual variables (Skaburskis and Qadeer 1992; Evans-Cowley and Lawhon 2003). Empirical research has shown, for example, that the impact may differ between raw land and built-up areas and that these may offset each other (Ihlanfeldt and Shaughnessy 2004). Since the authority to tax must usually be derived from primary legislation and applied equally, policy makers have little flexibility to adjust the level of the levy and its grounds to accommodate market fluctuations. In considering betterment capture it is important to conduct as much prior economic modeling as feasible (see also Vickars 2003).
- The British experience also teaches us that in order to sustain a betterment capture policy; there should probably be a direct link between the government authority charged with collecting the tax and the one that benefits from the revenues. Research evidence conducted in “real time” during the life of the last British recapture policy in the latter 1970s indicates that when local governments had a lesser interest in the revenues, collection was not robust enough. In the Israeli and Polish cases, the levy is administered and kept by the local governments, and they have been its major watchdogs.
- In order to retain public support, the legislation should determine in advance which public services may be financed by the levy and should expose this to the public. However, there is built-in tension between this objective and the need to maintain flexibility to accommodate changing needs for public services or changing public perceptions about what services merit public support. The traditional services such as linear infrastructure and educational facilities may compete with newer items on the list such as environmental conservation, historic preservation, or affordable housing. There are always many mouths to feed, while the potential income from a betterment levy is finite. It is difficult to “square the circle” and resolve this inherent tension between earmarking and flexibility.

- Developers are likely to argue that the revenues should be reinvested in public services for the benefit of the project that generated the funds. This argument should be resisted because it turns betterment recapture into an indirect value capture instrument with a rationale based on mitigation of negative impact or on indemnification of a burden on public services. If so, this type of value capture policy should be designed from the start as an indirect value capture instrument with an impacts-based rationale at its forefront.
- To retain its rationale, the betterment levy should be assessed parcel by parcel so as to capture only the real rise in value, as successfully applied in Israel (and potentially in Poland). However, this raises the administrative costs significantly. To allow a reasonable net yield, the rate of the levy must be relatively high. Public agencies might be tempted to simplify the levy by adopting a preset charge based on some easy formula (such as per built-up area or per assumed average increase). This type of quasi-betterment levy was briefly proposed in Israel in 2006 but discarded following protest by the Association of Local Governments. Some scholars have recommended similar formula substitutes (Ihlanfeldt and Shaughnessy 2004; Gdesz 2005 for Poland). Such shortcuts gnaw away the very rationale of direct value capture and, with time, might lose the value capture justification and become just another tax.
- Direct value capture poses a tough distributive justice dilemma. Adoption of a uniform rate for all landowners and locations is fair in some ways but not in others. Although the rate may be ostensibly equal, the opportunities for revenue are never equal across place and time. Betterment levies also have inherent regressive attributes. Well-off towns where property values are usually high or where land reserves happen to be available will be able to reap higher revenues than less-advantaged or just historically unlucky towns. Thus an equal assessment rate by no means ensures equal revenues—by whatever indicator chosen.
- Finally, a similar ethical dilemma applies to the distribution of the revenues. On the one hand, the desire for local voter support justifies retention of the full revenues at the local level. But on the other hand, distributive justice considerations justify redistribution. Localities with high revenues do not necessarily need or merit the revenues most. Calibration of funds among municipalities could be done by means of the national or regional governments on the basis of various criteria. Two of the British postwar policies as well as the 2005 rejected proposal did incorporate a national-redistribution policy. However, these policies are deemed to have failed partly because they paid a price in lost local public support and in reduced efficiency in tax collection. This dilemma faces issues of both ethics and feasibility, and there is no sure and tested way to resolve it.

The fact that most countries have not adopted a direct form of betterment capture indicates that the shortfalls and dilemmas noted here are not easy to resolve. There are many built-in catch-22s and very little international experience from which to learn. Meantime, the indirect value capture instruments have been flourishing.

6 Indirect Value Capture

Even though direct betterment capture is not prevalent, the idea that government should reap the unearned increment on land has not died away; it has simply undergone various mutations. The need for innovative funding sources for public services has in fact

increased in recent years. There are three well-known reasons for this increase: growing voter reluctance to pay higher taxes, higher costs of many services, and—at the same time—voters’ expectations for amplified services (Alterman 1988b; Altshuler and Gomez-Ibanez 1993, 1–4; Callies and Suarez 2003; Rosenberg 2006; Nelson et al. 2008, iv–xiv; 1–3).

Local governments therefore increasingly need to conjure up financial instruments that are less visible to voters than direct taxes or levies. The alternative is to leverage local governments’ authority to regulate land use, and solicit from landowners or developers money, land, or construction services in exchange for an affirmative decision or fast-track processing. But instead of doing so through the front door of direct betterment capture, local governments in many countries increasingly adopt a smorgasbord of indirect value capture instruments.

6.1 A Variety of Terms and Instruments

Indirect capture instruments vary from country to country and locality to locality. They are known by a variety of terms. A general term proposed by Alterman and Kayden (1988) is *developer obligations*. In the United States indirect value capture instruments are generically called *exactions*. In the United Kingdom they are known as *planning gain*, or, more recently, *planning obligations*. In France the term is *participation*. (Renard 1988). If based on preset formulas indirect instruments may be called *impact fees* in the United States or *development charges* in Canada (Slack 2004). In the Netherlands the term (as translated into English) would be *cost retrieval* or *cost allocation*.¹ The term *incentive zoning*—born in the United States but of recent international spread—refer to two-tier discretionary instruments whereby the developer may choose to grant the desired good or obtain lesser development rights.

6.2 Alternative Rationales for Indirect Value Capture

How do indirect value capture instruments relate to the direct ones? The same generator propels indirect and direct value capture—the increase in land values due to land-use decisions. However, the unearned-increment rationale remains only in the background. Under some legal regimes, such as the United Kingdom, to survive legal scrutiny, users of an indirect instrument may even have to prove that they are *not* motivated by the desire to recoup “betterment by stealth.”² Alternative rationales must be conjured up. I propose the following classification (compare Healey, Purdue, and Ennis 1993):

- Indemnification of direct public costs of public services generated by the particular project (“cost recovery”). In cases where cost recovery is capped by the amount of betterment, the instrument becomes a hybrid between direct and indirect value capture.
- Need for public services, infrastructure, housing, or ecological services that are not met by the market or by existing funding sources.
- Internalization of negative externalities such as noise, radiation, or pollution.

¹ These are the official terms in the English translation of the Dutch Land Development Act that came into effect in July 2008. Available at <http://www.vrom.nl/docs/internationaal/Land%20Development%20Act.pdf>.

² The official UK government circular on “planning obligations” states in section B7: “Planning obligations should never be used purely as a means of securing for the local community a share in the profits of development, i.e. as a means of securing a ‘betterment levy.’” (July 2005 Circular 05/2005, Office of the Deputy Prime Minister).

- Mitigation of impacts on the natural environment or on historic buildings.
- Mitigation of perceived social injustices such as social exclusion or higher housing prices.

In practice, a mixture of these rationales may serve as the legal or public-policy ground. Real-life application of indirect instrument often contains ambiguities about which of the alternative notions is being applied in a particular case. Indirect instrument also vary in how the contribution is delivered: some are in money, others in kind whereby the developer constructs a public service, delivers mitigating technologies, supplies land, or builds housing.

6.3 An International View of Indirect Value Capture

Among the sample of thirteen OECD countries, all except Sweden and the Netherlands have decades-long experiences with shifting the costs of public services onto developers. Since the 1990s Sweden too has been gradually joining the group. The Netherlands is the last in the set to adopt indirect capture instruments, formally enabled for the first time by the 2008 Land Act. So even the Netherlands—with its uniquely strong tradition of direct government action in land purchase and development—must now rely more and more on land-use regulation and private developers as a source of financing for public services (Needham, 2007, 176–177).

Indirect instruments differ from direct ones in the way they emerge. Direct capture instruments are usually enacted or otherwise adopted “top down,” often for an entire jurisdiction. This is because in well-governed countries, authority for direct value capture may entail special enabling legislation (at times even constitutional amendments). By contrast, indirect instruments often emerge “from the bottom,” by dispersed locally grown policies. If the instruments are viewed as successful and survive legal challenges, they are likely to be copied by other localities. The United States has been an especially rich breeding ground for a wide variety of innovative value capture instruments that are recently being “exported” overseas (Alterman 2005; Spaans, van der Veen, and Janssen-Jansen 2008, 17–22).

Because the indirect instruments are usually locally determined and may not require explicit legislation, they have several advantages over direct betterment capture:

- They can more easily go “under the radar” of party-political debates and can therefore better survive changes in party ideology and voter resistance to new taxes.
- They can more easily be justified to the project’s consumers and to the general public if they are linked to the burden that the project would have otherwise placed on the public.
- They are more flexible for financing changing public needs because they are usually applied only when development is ripe.
- They can be fine-tuned to be politically more acceptable when sociopolitical positions change in the community
- They may be adjusted to accommodate the changing economics of real estate so as not to drive away development.

Yet, indirect capture instruments are not a panacea. They are often applied case by case, without ensuring equality among landowners. These instruments are therefore open to political and legal challenges regarding bias and favoritism. The value of the financial

or in-kind resources delivered by developers is often unpredictable because it depends on uncertainty about estimates of anticipated impact or on the success of negotiations. The extent of financial gains to the community may vary even among parallel projects. There is some evidence that the financial gains to the public may represent only a few percent of the unearned increment (Alterman 1988a).

6.4 Some Preconditions for Adoption of Indirect Value Capture

Indirect value capture policies are likely to expand and intensify around the world. Because of the complexity of these instruments, there is great need to exchange knowledge between jurisdictions, so more systematic comparative analysis is necessary. I hypothesize four preconditions for reasonably successful application of indirect modes of value capture:

- Governments should have well-trained professionals (planners or real estate experts) to negotiate with the developers or to develop preset formulas of impact assessment. The professionals need to be savvy in real estate economics to be able to assess the limits of how much may be exacted from the developer without “killing” the projects.
- Local government should conduct good monitoring of fluctuations in land prices in order to be able to challenge developers’ arguments that the exactions in fact raise the cost of housing or other products. This type of argument—not necessarily true in specific market situations—may generate public opposition.
- There should be enough transparency in negotiated exactions to help withstand legal challenges (yet full disclosure is often not possible in order to protect the legitimate economic interests of the developers).
- Countries or local authorities known for high levels of corruption should refrain from adopting value capture instruments with discretionary elements. A reasonable good level of trust in government is a precondition for their successful operation.

7 The Future of Direct and Indirect Value Capture

An obvious issue is the interrelationship between the two categories of value capture. In those few countries that do practice betterment capture, does it in fact replace the need for indirect capture instruments? The state of current knowledge does not provide empirical answers to this question, and the body of law is also skimpy. However, the underlying logic of the two modes leads me to conclude that they are not mutually exclusive. The indirect capture instruments are often open-ended and evolving, and they possess the capacity to “fill in the holes.” So long as governments have insufficient resources for public services (as they often do) and so long as they have the authority to refuse permission to develop, indirect value capture, especially its negotiated modes, is likely to be practiced to some extent.

The experiences of the United Kingdom and Israel shed some light on this issue. In Israel, negotiated exactions are sometimes applied over and above the 50 percent betterment levy, and case law has not ruled them illegal. In the United Kingdom, negotiated planning gain (today called “planning obligations”) likely existed to some extent in parallel to the various direct betterment capture modes exercised until the early 1980s. The current debate surrounding the 2010 Community Infrastructure Levy illustrates the difficulties of drawing a solid boundary between the two modes of value

capture. Although the policy statement makes an effort to restrain double charging, developers and the new Tory-led government are not yet convinced.

The bottom line is that the rationale for direct betterment capture may be convincing on paper, but it has not caught on widely across the world. At the same time, indirect value capture tools have proliferated. As counterintuitive as it may seem to those who have not walked through this paper, these instruments—with their “messy” rationales and exposure to legal challenges—hold the more realistic potential for funding public services than their elegant direct-capture siblings.

Professional Liability & Ethics

Just how smart is “smart regulation”: evolving architectures in the governance of regulation?

Timothy Eccles¹ & John Pointing²

¹School of Surveying & Planning, Kingston University, UK

²Barrister and Kingston University

Abstract:

Government endorses the idea of “smart regulation”, seeing it as an attractive wrapper for a business-friendly approach to regulation that could make savings to the public purse whilst offering improvements in consumer protection. The result is to bring the regulation of commercial providers of goods and services closer to previously privileged concepts of professional self-regulation on the basis that it offers “cost-free” regulation.

This paper examines whether smart regulation is just another manifestation of a “fictional commodity” enabling producers to cloak their activities in a favourable light. Alternatively, smart regulation could result in greater transparency, giving legitimacy to the providers of goods and services and better protection for consumers. The drama of smart regulation in disarray in the financial sector since the 2008 “crunch” provides one perspective, but the authors argue that now is the time to formulate a theory of regulation and governance that better captures recent developments.

Having published separately on disparate issues of regulation (including food law, statutory nuisance, professions, service charge management and financial accounting), the authors draw these together here. Our model is based on Gunningham’s (2009) concept of regulatory “architecture”. This has been developed further into a “Triptych” of regulatory processes that better describes the relations between regulator and the regulated.

Keywords:

smart regulation, regulation, self-regulation, governance, nuisance, building control

1 Introduction

The professions and business refer to, generally accept the need for, and may even promote regulation. The key issues are: who regulates and who pays? Self-regulation has the official support of government in the form of the Better Regulation Executive (BRE), an arm of the Department for Business, Innovation and Skills (BIS), whose brief is to lead the regulatory reform agenda across government as a whole. This apparatus could be seen as the swansong of a Labour Government profoundly discredited by the failure of regulatory institutions to regulate the financial sector effectively, so contributing to the “crunch” of 2008. But its roots go back to the 1990s and it has survived - at the time of writing (May 2011) - a year of centre-right Coalition Government.

Self-regulation provides an alternative to direct regulation by the regulator. It is closely linked to “smart regulation” which provides the focus to this paper. Smart regulation has its origins in the broader principles of deregulation, risk analysis and no-cost regulation - a process that has been exhaustively examined by a number of writers over the years. It is a somewhat broad concept: “used to refer to an emerging form of wide-angled regulation that seeks to harness not just governments but also business and third parties to provide policy alternatives that include, but also go beyond, direct regulation” (Gunningham 2009: 200).

These are very broad and ambitious claims. Smart regulation was originally developed in the context of environmental regulation in developed economies, in part as a response to the failure of state agencies to regulate pollution effectively, or to prevent exporting the collateral damage of industrial pollution to developing economies (Black 2007). Its smart characteristics are rooted in its flexibility and diversity as distinct from “single instrument or single party approaches” (Gunningham 2009: 200). The overall purpose, then, is for smart regulation to:

...allow the implementation of complementary combinations of instruments and participants tailored to meet the imperatives of specific environmental issues, and will result in a more flexible, efficient and effective approach to environmental regulation than has so far been adopted in most circumstances (Gunningham 2009: 200).

The problem with attributing such broad aims and general applications to smart regulation is that it becomes a bit too vague, flexible and all-embracing. An advantage is that it provides a way of stepping back from the detail to examine the underlying structures of regulation. Gunningham’s analysis applies to changes in environmental regulation over time. It provides a useful way of understanding processes across national and regional boundaries as well as for evaluating changes in policy. But it also has a wider application for analysing changes within occupational and business structures. Thus, the modernising thrust of smart environmental regulation is to:

... embed environmental values and processes within corporate culture in such a way that it becomes self-regulating, relying on oversight from local communities and perhaps third-party auditors, to supplement or even replace direct regulation (Gunningham 2009: 202).

This framework invites comparison with other areas of regulation and in this paper we will examine an example of professional self-regulation and the Primary Authority Scheme for local authority enforcement. Both these examples reveal that high expectations are placed on making improvements to the process of regulation. Whether regulation is smarter as a result is in issue; if present, it needs to be specified what this actually entails.

1.1 Background to Deregulation

The background to deregulation has been extensively analysed and talked about. There is basic agreement that in the course of the 1980s and 1990s a crisis emerged in the developed economies over the role of the state and its executive agencies as regulator (Braithwaite 1999, 2008; Black 2007). This was accompanied by a strongly

deregulatory rhetoric that included attacks by economically liberal politicians on the costs of over-regulation for businesses (Hutter 2005).

The legalism and inflexibility of regulators were singled out for castigation. Sometimes this amounted to verbal abuse. For example, in the UK, Neil Hamilton, the Deregulation Minister, in addressing the October 1994 Conservative Party Conference, famously described the proper role of local government enforcement officers as “handmaidens of business – helping them to comply – rather than the local branch of the Gestapo” (Andrews 1998: 21). Interestingly, soon after the Deregulation and Contracting Out Act 1994 became law, section 37 was criticised for giving ministers dictatorial powers to use regulations to repeal legislation without requiring scrutiny by Parliament (Williams 1995).

The type of regulation that was castigated here was derived from “command and control”, where the system is based on the regulator making frequent inspections, with reliance on formal methods of enforcement, and showing a readiness to resort to prosecution for infringement of regulations (Hawkins 2002). The reality was somewhat different and the practice of state regulators, at least since the 1980s, has been to rely heavily on persuasion and encouragement to comply with regulatory requirements, with formal enforcement powers – particularly prosecution – being used only as a last resort (Hawkins 2002). But the underlying purpose of the Deregulation Minister’s jibe was to promote the superiority of techniques developed in the private sector. These were (and still are) very attractive to politicians, their advisers from business and to ministers’ policy advisers. Providing credibility to the deregulation agenda has been assisted by academics, who from the late-1990s were being nurtured by rich sources of funding drawn from both central government and business as a source of intellectual support to the ideology. The key private sector virtues incorporated into the regulatory agencies have included: the setting of explicit standards and measures of performance; a stress on private sector styles of management practice, including hands-on professional management; and an emphasis on greater discipline and parsimony in resource use (Hood 1991: 4-5).

1.2 Professionals and Deregulation

Professions face particular problems in the ideological battle over regulation since they are the dominating example of a powerful elite allowed to self-regulate in anti-competitive and monopolistic forms. Therefore, theirs is a different experience to that of the wider business community. Whilst smart regulation does have similarities to self-regulation, this difference in experience creates a very different environment for professions. We have adopted the concept of late modernity to explain this context and the paradox it creates. The idea is taken by Reed (1996) in his discussion of expert power, where he describes professions as not only engaged in a battle to retain occupational control, but that they are losing (see for example Muzio 2004 on the legal profession). The rise of the knowledge-based economy and its new classes of worker are seen as a fundamentally new paradigm in social, political, economic and market contexts (see for example Evetts 2003a, 2003b) and are destroying traditional forms of occupational control.

Late modernity is drawn from the work of Lord Giddens (1990, 1991, 1994). He devised the concept to refer to the various ways in which a culture of radical scepticism and uncertainty has penetrated deep into the social fabric of everyday life in modern societies. The knowledge that underpins professions becomes submissive, provisional

and abstract, rather than a body of expertise. Late modernity is characterised by uncertainty, powerlessness and the loss of determining authority.

There are no authorities which span the diverse fields within which expertise is claimed – another way of repeating the point that everyone in modern systems is a lay person in virtually all aspects of social activity (Giddens 1991: 195).

Organisations permanently monitor and control all operations and the application of knowledge through a process of institutional reflexivity. From this others have created the concept of a “post-bureaucratic” or neo-bureaucratic” state (for example Farrell and Morris 2003), which further strengthens the view of the expert as a servile functionary. What generates smart regulation is destroying self-regulation since it is not based upon expertise as much as a desire to engage as a collaborator with other parties on creating ‘safe’ goods and services.

Late modern, therefore, is used in this work to represent the erosion of traditional forms of respect together with a growing scepticism regarding the idea of an elite. It reflects the increasing orthodoxy towards deprofessionalised and managerialised professions, of fundamental technical changes within occupations that undermine the control of expertise and which traditionally form the foundations for the social superiority of the concept of profession. Giddens (1991) points to common themes of powerlessness, uncertainty and commodification within modernity. Whilst “smart regulation” provides an opportunity to create, or recreate, occupational control and establish a determining authority, reinforced and recognised by the State, it is also a threat. Whilst this is particularly an issue for professions, all forms of expertise are similarly affected and the concept of late modernity provides a useful background in which to explain the events discussed here.

1.3 Smart-regulating the Professions: the Case of Building Control

The particular problems faced by professions derive from the very meaning of a profession. Professions exist because they have created an occupational jurisdiction (Abbott 1981, 1986, 1988, 1991) recognised by clients and the State. Professional work requires the establishment of difference, of distance between professional and client (see, for example, Johnson 1972) and the creation of a fictional commodity (Larson 1977). The resulting dialogue of professional versus charlatan provides a particularly illustrative example of the importance of regulation to the concept of profession. It helps maintain occupational control, an authority that is swept away by internationalising modernity (see, for example, Giddens 1991) and, potentially, by smart regulation.

Building control was the very first profession to face directly the introduction of what we now know as smart regulation. The 1984 Building Act and the statements set out within the Building (Approved Inspectors etc) Regulations 1985 proved a key piece of legislation in developing the deregulation agenda within the building industry. It removed building control from within the domain of public sector Building Control Officers to a market-orientated competition between public and private sector provision. Government application of the Deregulation and Contracting Out 1994 Act led to the acceptance of approved private sector inspectors as clarified in the Building (Approved Inspectors) (Amendment) Regulations 1996. This removed the specialist nature of building control from its previously prescribed body of public sector professionals and opened the way to other operatives. Those seeking to operate as such must apply to the

Designated Body, which the legislation created to ensure the maintenance of inspection standards. This body is currently the Construction Industry Council (CIC).

The particularly interesting development within building control is that the CIC awards the status Building Control Body (BCB) to those deemed worthy of carrying out building control work. The first body to be given approval was on 11th November 1985 to NHBC Building Control Services Ltd. As part of NHBC they obviously had prior experience of this line of work given the nature of the NHBC guarantee and their long experience of carrying out inspections. The legislation was originally intended to apply only to individuals since the Building (Approved Inspectors etc) Regulations 1985 required any corporate bodies seeking approved inspector status to apply directly to the Secretary of State for the Environment, Transport and the Regions, rather than to the CIC. An indication to revise this was given in a written response by Construction Minister, Nick Raynsford (DETR press release 1998: 188/ENV) on 11th March 1998. By this time, the number of inspectors had risen to seven companies and 30 individuals, increasing by July 1999 to 12 companies and 35 individuals.

Within building control and the general enforcement of Building Regulations there has been a consistent drive since the Building Act 1984 came into force to avoid the need (and expense) of inspecting building work. This led to the search for so called competent persons whose work is of a high quality that does not need checking and may be self-certified (DETR 1997). DETR (1999a: 3) places emphasis on cost, that “building control must also be efficient, to minimise cost and delay for those carrying out the building work.” The result was that membership of a professional body was deemed appropriate to qualify the expertise and regulate competence of building control service providers (DETR 1999a, 1999b). Of course, this returns to professions as regulators. Not exactly self-regulation, but close enough at the time to appease the wider professions whose private sector members saw business opportunities at the expense of their public sector colleagues. Similarly, the Royal Institution of Chartered Surveyors saw the opportunities for itself and its members in becoming the dominant professional authority under this new regulatory paradigm.

1.4 Self-regulation of Businesses

The Local Better Regulation Office (LBRO) sits in the vanguard of change in the relationship between local authority regulators and businesses. The Office was established under the Regulatory Enforcement and Sanctions Act 2008 as a public body accountable to the Department for Business, Innovation and Skills (BIS) through the Better Regulation Executive (BRE). The LBRO launched the Primary Authority scheme in April 2009, the essential objective being for local authorities and companies to reach agreements about how their regulatory relationship should operate (LBRO 2010). Instead of companies with many outlets having to deal with various local authority regulators, implementation of the agreement would simplify and centralise regulatory activity by funnelling advice and enforcement action. As a result, only one local authority acting as the Primary Authority enforces environmental health, licensing, health and safety, and trading standards law. The aim is that enforcement is carried out consistently by the primary authority with respect to many, if not all, of the activities of the company subject to regulation by local authorities. If successful, the regulatory model presaged by the Primary Authority Scheme produces benefits in terms of rationality, legitimacy and effectiveness; and savings in the costs of regulation can be hoped for too.

The building up of a relationship of trust between the regulator and company is anticipated to mean that more of the regulatory burden is managed willingly by the company. The nature of the burden is legitimated, so that a climate is induced that allows self-regulation to flourish. The role of regulation thereby changes, with the regulator taking a less direct, more supervisory role, so resulting in cost savings. This process has been described as “meta-regulation” in which:

The role of regulation ceases to be primarily about inspectors or auditors checking compliance with rules, and becomes more about encouraging the industry or facility to put in place processes and managerial systems which are then scrutinised by regulators or corporate auditors

(Gunningham 2007: 190-91).

All this “regulatory goodness” contrasts favourably with the vagaries that may ensue when individual local authorities are left to their own devices. Without the guidance and support provided by enlightened officials, such as those employed by the LBRO, local councils become liable to corporate drift, such as may occur when there is a mismatch between the agendas of local cabinets and the practices of council officials. Councils may be powered by inconsistent political agendas; they are structured as separate corporate entities and have a margin of discretion to formulate enforcement policies. These forms of particularism are not removed by the Better Regulation Agenda; and the Primary Authority Scheme has not been imposed by central Government, only promoted and led by the LBRO.

The Better Regulation Agenda calls for the regulator to change its behaviour – by operating more like a private company – and for the company to cooperate and become a party to the regulatory endeavour. This way of thinking goes back to the *Enforcement Concordat* (1998) which:

Signified an agreement between government, business and local authority regulators over the use of a risk-based approach to enforcement which was designed to be more business-friendly and in line with the prevailing deregulation ideology (Pointing 2009: 595).

The Better Regulation Agenda is very appealing to those wanting to change the ways local authorities have traditionally gone about their business. Responses to the Primary Authority Scheme have also been positive. Judging from published responses by key professional bodies, such as the Chartered Institute of Environmental Health (CIEH 2008), there seems to be wide support for smarter, risk-based models of enforcement as a better alternative to “command and control” (Hawkins 2002: 13-16) and other forms of direct regulation.

The benefits appear to be “win-win” for all concerned. With cooperation and partnership the gate is opened “to simpler, more successful local regulation, based on a new relationship between businesses and local authorities (LBRO 2010: 2). Better regulation is directly equated with better relationships:

Better relationships between the regulated and the regulators mean better regulation. Primary Authority can increase the prosperity of businesses and communities, and offer protection for vulnerable consumers and traders facing unfair competition (LBRO 2010: 3).

Consistency in regulatory approach, better relationships and simplicity in dealings are the key watch words. The central state acts as the referee in this process, with the LBRO presiding as a helpful, enabling “Dutch uncle” who ratifies a successful relationship brokered between the regulator and firm. Should the need arise it even provides a dedicated dispute resolution service (LBRO 2010: 3).

2 “Better” Regulation?

Despite the intentions of government to free businesses from the burdens of over-regulation and all the talk about it, there has been little winding back of regulation in the longer term (Braithwaite 2008: ch 1). Indeed, Braithwaite (2008, Foreword) argues that there has been an explosion of regulation going back to the dark age of Reagan and Thatcher. This phenomenon has profoundly changed the structure of social relations, amounting to a paradigm shift towards “regulatory capitalism”. Such changes go beyond the “regulatory state” not least because non-state regulators have proliferated not just ones deriving authority from governments.

Stepping back from the wider picture, in the environmental sphere, claims made in the 1990s that negotiated agreements would reduce administrative burdens have not been made out (OECD 2000:131). It is still too early to judge whether the agreements brokered by the LBRO will increase or decrease the amount of regulatory activity. But even if relations do improve between regulator and company this is not necessarily in the interests of the wider public. Better relationships, as distinct from better regulation, could result because the regulator has been “captured” by the company, perhaps dazzled or over-awed by the corporate power imbued in the company.

Sometimes the relationship between regulator and company becomes very fraught. An instance of this can be found in the case of *Derrick Barr and Others v. Biffa Waste Services Ltd* [2011] EWHC 1003(TCC). Here, the company did make initial attempts to engage with local residents and to keep them better informed about its land-fill operations which were causing a nuisance. The relationship deteriorated over time between the company and the regulator (the Environment Agency) and between the residents and both the EA and Biffa. Difficult nuisance problems to do with landfill sites, waste disposal facilities and sewerage works have a tendency to drag on for years. An acceptable solution to odour, noise and dust problems from such sites can be elusive, leaving one or more stakeholders dissatisfied, perhaps irreconcilably so.
