Mr Justice Coulson heard the case over an 18-day period in the High Court. His Lordship was concerned about many aspects of the case in which Biffa were denying that any actionable nuisance had been caused from their operation of the waste site. The company asserted that they were entitled under the doctrine of statutory authority to operate the site as they wished, provided they did not do so negligently and acted in accordance with the terms of their waste licence. The case is a particularly interesting one because it reveals the drama of deteriorating relationships. His Lordship was “particularly troubled” by Biffa’s confrontational stance towards the Environment Agency (para. 570), finding that the company’s “unnecessarily aggressive approach”

spilled over into the trial itself and created an “unfortunate impression” (paras. 572-3). On the other hand, the “pusillanimous attitude of the EA” came up for criticism, his Lordship finding that they “should have been much more forceful with Biffa” (paras.579-80). Over time, co-operation between the EA and Biffa was in “very short supply” (para. 580) and the interests of the public were hardly served at all. Indeed, the quality of relationships fell to just about the lowest point imaginable in a civilised society.

The judgment is a salutary lesson regarding the idealisation that permeates the Better Regulation Agenda when being promoted by government agencies. The notion that better relationships between regulators and businesses are closely linked to improvements in the system of regulation is an untested assumption, and possibly one that is simplistic and flawed. Further, the possibilities for self-regulation depend very much on the type of problem subject to regulation and on the nature of the business. A waste operation can be run by a highly organised, properly licensed, competent and professional company (one like Biffa). On the other hand, there are people running waste companies illegally, without a licence, who could be better described as serial fly-tippers than as businessmen. Obviously, the approach taken by the regulator towards these extremes will need to be different, with recourse to prosecution coming very early on in the relationship with the latter. A regulator may be operating in accordance with smart regulation principles, but just because it decides to prosecute a fly-by-night waste operator promptly for illegally depositing regulated waste does not mean there has been a paradigm shift back to “command and control”.

There are also substantive limits to the extension of Better Regulation methods which may be established in legislation. For example, section 80 of the Environmental Protection Act 1990 places a duty on a local authority to serve an abatement notice on the person responsible for causing a statutory nuisance in its area (Malcolm & Pointing 2011). The Act requires an opinion to be formed about whether a statutory nuisance exists, or is likely to occur or recur, before the notice can be served. Such an opinion is made on behalf of the council; if it is to be made properly that opinion should be reached by an environmental health practitioner. The principle enshrined in the legislation is for the regulatory decisions to be made locally, not by another local authority under the Primary Authority Scheme. The Environmental Protection Act 1990 was deemed to come within the scope of the Primary Authority Scheme when the government published its consultation document (BERR 2008). The specifically local enforcement implications of the statutory nuisance regime may not have been fully appreciated by those who drafted this document.

3 Towards an Architectural Triptych

The model we are proposing for testing the smartness of regulation takes into account differences in the capacity of businesses or professional entities to engage with the regulatory process. It also takes on board the policies and modes of regulation being pursued by the regulatory body. The model has to accommodate differences in the capacities of the regulated entity to understand, relate to and accept the legitimacy of the regulatory process. Underpinning the model is the work of Gunningham (2009), in particular the concept of “shifting architectures”. This term is useful for putting changes over time into perspective. It also incorporates the trend towards indirect regulation in which the responsibility for, and costs of, regulation is increasingly internalised by the business or professional organisation.

Our model identifies three stages comprising a “trptych”, a term indicating that these stages are linked. Implicit within the dynamics of the triptych is that regulated entities will move through these levels.

Neophyte

All entities seek to self-regulate in some way, particularly when starting up. Neophytes need encouragement rather than penalisation, and will often seek guidance, advice and help from the regulator. Neophytes may be enthusiastic, but often lack confidence and skills. The approach of the smart regulator is to assist in providing neophytes with a path to the next level. Not all neophytes will want or be able to engage with this process. Some will be incompetent, dishonest, or even running criminal businesses that are “beyond regulation” (Pointing 2005:49).

Self-Improvers

The second stage recognises that firms will learn and develop given appropriate support, guidance and help from the regulator. Recourse to intrusive types of enforcement – disciplinary action, serving of formal notices or prosecution – should not be necessary and smart regulators will use their powers sparingly and as a last resort. This is a transitional stage, not an end result. Businesses and professional entities are assumed to be striving towards the next stage. This can be seen as a form of professionalization whereby firms are in the process of a transformation.

Champions

This is the ultimate end to the regulatory process. The steady-state stage of the model is that businesses and professional groups seek to establish themselves as self-regulating paragons. To reach this stage, the costs of regulation are largely met by the body being regulated; the regulator can adopt a removed, supervisory relationship that is only rarely visible. Professional associations reflect this ideal, but trade associations aim to reach similar status. Business champions can demonstrate a clear “difference” between themselves and their less competent competitors. This allows them to create a “fictional commodity” (Larson 1977) – incorporating branding and competitive advantage.

4 Conclusions

The paper identifies the philosophical (Late Modern) and legislative environment driving the ideas of smart regulation, concluding with a “Triptych” modelling the agents upon whom it acts. We overviewed two examples, one as the first example of the “smartening” of regulation (Building Control) and one that offers insight into its current form (the role of the LBRO).

Our adoption of Late Modernity allows us to draw attention to the competing authorities seeking to dominate legislation, whilst recognising that there is no single, determining authority. Government (local and national) is increasingly unable to “command and control” and traditional professional expertise is unacceptable for legitimising a right to self-regulate. Whilst it is tempting to describe LBRO as a determining authority, it is exactly the opposite, depending upon voluntary adoption and a willingness to learn from mistakes – rather than a determination to enforce and punish. Late Modernity offers intriguing insights into self- versus smart regulation.

Our Triptych emphasises the role of the regulated rather than the enforcer. It illuminates the role of encouragement, negotiation and an acceptance that mistakes happen. One obvious area for further development is those entities “beyond regulation” since the model presumes some degree of engagement and a willingness to comply. This requires consideration of the dynamics of change and the basis of the desire to self-regulate.

There is a need for empirical data to flesh out both the model and the principles of smart regulation. Objectively, is smart regulation “better” and/or cheaper, or is it a surrender of independence to vested interests? Is cost-free to the consumer actually a cheaper option? Such questions will be the subject of future work as we develop our ideas and create data to test them.

One case study identified for further work concerns Somali shop owners in Hayes, whose encouragement is derived from an engaged local authority and local community champion. In the case of trade associations, whilst some are little more than “badge associations”, others engage their membership in moving through the Triptych. This process by which trade associations “professionalise” through a variety of actions (enforced CPD and PII, for example) as well as regulatory control provides a particular organisation as the driver of change.

Whilst professional firms might be expected to be champions within the Triptych framework, due to professional regulation this possibility is inconsistent, as shown by recent work into service charge management (see, for example, Eccles and Holt 2009). This shows the need for the model to engage with a wider secondary literature, such as Di Maggio and Powell (1983) on why firms change and the role of smart regulation in inducing change. Equally, the grounded theory being developed must be taken into the real world of the specific, and tested and fleshed out against empirical studies. This is our next endeavour.

Professional Liability of the Construction Professional as an Expert Witness in the Spanish Legal Framework

Federico Garcia Erviti¹ and Gema Maria Ramirez Pacheco¹

Email: federico.garcia@upm.es; Gema.Ramirez@ua.es

Abstract:

Inside COBRA 2011 RICS International Research Conference, the present paper is linked to analyze the liability of the construction professional in his practice as a expert witness in the Spanish legal framework. In a large number of legal procedures related to the building it is necessary the intervention of the expert witness to report on the subject of litigation, and to give an opinion about possible causes and solutions. This field is increasingly importantly for the practice of construction professional that requires an important specialization. The expert provides his knowledge to the judge in the matter he is dealing with (construction, planning, assessment, legal, ...), providing arguments or reasons as the base for his case and acting as part of the evidence.

Although the importance of expert intervention in the judicial process, the responsibilities arising from their activity is a slightly studied field. Therefore, the study has as purpose to think about the regulation of professional activities raising different aims. The first is to define the action of the construction professional-expert witness and the need for expert evidence, establishing the legal implications of this professional activity. The different types of responsibilities (the civil, criminal and administrative) have been established as well as the economic, penal or disciplinary damages that can be derived from the expert report.

Keywords:

expert report, expert witness, law of evidence, professional liability

1 Introduction

In a large number of judicial processes relating to the building is required the intervention of a Expert witness to report on the subject of litigation, giving an informed view on possible causes and solutions (Sido, 2005). An expert can only bring to the attention of the judge matters of fact, so dominant that can only be issued by anyone who is trained in a particular branch of knowledge, whether scientific, artistic, technical, or a particular practice. The expert provides the judge the knowledge he is not required to master (building, planning, valuations, legal architecture, ...), providing arguments or reasons for the building of his trial thus acting as a test. Expert intervention is used as a means that can be used in court to assess the facts (Xiol, 2002). The survey will be made based on the mere knowledge of an expert, or rather the application of such knowledge in evaluating a particular test. The expert may be appointed judicially or

proposed legal action by one or both parties. He may exercise the same influence on both the trial and his performance making his task indispensable in the investigation phase and the probative value on the course of proceedings.

This field is increasingly important for the professional practice of architects and other professionals related to construction, which requires significant expertise. The Civil law procedure (Article 340) defines the need. The same law states that experts should be legally qualified (article 457) by holding a university degree attesting to their expertise or not (Xiol, 2002), despite not having the same, proving to be versed in the speciality. According to Royal Decree 25/12/1977, of June 17 expert opinions are part of the professional work of the architect.

In spite of the importance of expert intervention in the judicial process, the responsibilities derived from his activities are a scarcely studied field. The responsibility can be defined as demand for compensation in case of damage or harm resulting from an act done freely (Gamble, 1987). Therefore, from the legal point of view, there must be accountability first, the course of damage, and secondly, personal conduct which could be attributed to the former. That is, there must be a causal or cause-effect relationship between a specific behaviour and the damage caused by it. This damage can result from breach of any law or any contractual obligation of the bond created by the free agreement of the parties to a contract. Therefore, to prove the causal relationship between a particular breach and expert performance it is essential to define the responsibility of the expert.

Both situations action-damage provide a third element of responsibility, which involves the duty to indemnify or compensate the damage caused. The way in which it materializes depends on the origin of responsibility. Legally there are, broadly, three types of responsibilities, civil, penal and administrative, describing their nature and their damages (Gillardin, 1989).

2 Civil responsibility

2.1 Nature of civil liability

Expert's civil liability starts on voluntary or involuntary acts or omissions linked to his activity (Farr, 2005). These result in damage or harmful outcome which could have been avoided having acted diligently. This negligent conduct may occur in the content of the opinion, as the way to such issue (for example, the delay in the issuance) in operations involved in expert performance as the recognition of places (art. 345 LEC) or where appropriate, the assistance in the trial for oral ratification of the dictum. (art. 347 LEC).

Therefore the civil responsibility occurs within the scope of the activity of the experts in their individual relationships with the parties involved in the process. The judicial interpretation of such responsibility is based on the so-called 'theory of cost-benefit'. It states that anyone who takes advantage of an activity (in this case, which involves the provision of services as an expert), takes full responsibility in consequences resulting therefrom. Therefore the offended party does not need to prove the guilt of the perpetrator, but only the relationship between the damage and the conduct of the perpetrator. This theory is fully applicable to the professional activity of the expert.

From the practice of the whole profession we get enforcement of the *lex artis*, i.e. rules or obligations established for the exercise of a profession. Therefore, there is liability if there is damage or harm to the author of the commissioning of expert dictum or other persons resulting from a breach of those duties and standards. In any case, the expert's responsibility is not linked to the fact that the result of expertise is the cause of damage, but the latter is a consequence that the expert did not put the necessary means to obtain this result. This means performance rather than results:

"It is, in short, an obligation in the means used in the activity, not outcome, since it is not bound to the success of the action being taken but to exercise it appropriately (SSTS 8 June 2000 and 28 December 1996), it has been said that the provision of these professionals is the provision of means rather than result, therefore, for the obligation to be fulfilled, it is required stating that the practitioner has provided means to achieve the desired result, and these have been made in accordance with the *lex artis*, although the desired outcome has not been achieved (STS 7 February 2000) "(SAP Vizcaya of May 27, 2005)

Therefore, for the expert to be held responsible it is necessary to prove that the damage is caused directly by his activity as such (Font, 2000). However, in the event that it was so, the damage is caused by a judicial ruling against the interests of the affected party, issued on the basis of expert opinion. If the court assesses the valuations according to the rules of sound criticism (art. 348 LEC), it is questionable whether the lack of a direct relationship between the report and the damage (by the mediation of the sentence, when it has been called the "judicial filter"). This would prevent the allocation of liability to the expert, since the damage is caused by the judicial decision and not an erroneous or false opinion, although that was based on the latter. However, the Supreme Court has shown that the responsibility of the expert is independent from the evaluation of evidence by the court:

"The powers of the court under the law in order for the assessment of expert evidence, made in civil proceedings for a declaration does not exempt (...) of responsibilities to an expert opinion issued by the act in which he must act, according to their knowledge and belief, as the margin of discretion that the subjectivity of the expert with the legitimate claims and discrepancies with those of others who come, but always with the diligence of a good professional in knowledge, art or craft concerned and therefore subject to the *lex artis* of the profession he exercises, without making intention or negligence "(STS 16 October 1985)

2.2 Assumptions of civil responsibility

The general principle underlying the civil responsibility is determined by Article 1902 of the Civil Code (CC), it states: "Whoever by act or omission causes harm to another, intervening fault or negligence, is obliged to compensate the damage caused. "This principle governs the so-called 'contractual liability' (Xiol, 2002). There is also a 'contractual liability' determined by Article 1101 CC, which occurs when the damage comes from the breach of the terms of a contract.

In practice, the difference between the two types of liability, contractual or tort, is defined primarily by the various periods of prescription for action to demand accountability (Gillardin, 1989). The limitation period is the period of time the affected party legally exercises the right to claim for damages. This period begins to run from the time of manifestation of the damage (Article 1969 CC).

The Civil Code, Article 1968, states that the limitation period is one year if the tort liability incurred in nature. On the contrary, if the responsibility is contractual, it is charged under Section 1964, which states that personal actions have not been identified, special term of prescription expires after fifteen years. Thus, once defined the contractual or tort, the time to bring in proceedings will be 1 or 15 years from the date on which the said damage has been manifested.

Contractual liability cases are linked to the expert's report commissioned by one of the parts of the process, the expert being forced to do his job with due diligence, including the completion of the dictum within a reasonable time. Therefore, any loss or damage caused by breach of these commitments, intentionally or in bad faith, negligence or default (i.e, delay fault in compliance with agreed period or default delay (i.e, in the implementation of agreed at a reasonable period), is a breach of the terms of the contract.

"(...) regardless of official duties imposed by the position of the expert and public nature of the role, as is the case with lawyers or attorneys that link the relationship with your client or expert who is appointed from acceptance of the assignment, has a contractual nature, namely leasing of services by providing the required, according to their profession (...) "(STS 16 October 1985)

Part of the doctrine also esteems that there is contractual relationship between the expert appointed by the Judge and the parties involved in office. In this case, the expert voluntarily joins the listings of professional associations that he presents to courts and tribunals (art. 341.1 LEC), is appointed at the request of the plaintiff or defendant (art. 339 LEC). According to art. 342.3 LEC, the court-appointed expert may apply for funding on account of the final settlement of their fees, and all are satisfied all the requirements for the existence of a tenancy agreement for services as provided in Article . CC 1544.

However, for another sector of the doctrine, the liability of the court-appointed expert is not contractual in nature, but tort. In defense of this thesis argues that the acceptance and oath of office does not create any legal relationship between the expert and the parties, it remains possible that they require compensation or want amends of the damage caused, based on an inexistent contract.

Finally, we can extend to the intervention of experts STS, 1^a, 16.12.1996 (RJ 8971) which deals with the tort activity of the lawyers. According to this the tort liability is reserved for those cases where their conduct falls outside the orbit of the contract by action, not under an onerous contract, but by relation of friendship or kinship, no consideration.

2.3 Damages or consequences of civil liability

Civil law seeks to redress the damage by paying monetary compensation or repair the damage. It is common practice by the expert from the obligation to indemnify a third party for damages caused by reason of the exercise of professional expert activity is covered by a policy ensuring civil liability expert (Gamble, 1987).

Contract guarantees are excluded, in general, the responsibilities arising from (Farr, 2005):

1. Intentional crimes criminally prosecuted for being established

2. Fines and penalties of any kind.

3. Inexcusable disregard of the rule book of good construction, rules and regulations related to the environment, town planning, building or safety, in this case, applied to the activity of the insured as an expert. Understood as 'inexcusable' deliberately violated that involves awareness of the harm likely and reckless acceptance without valid reason.

3 Penal responsibility

3.1 Nature of penal responsibility

Criminal liability arises from the breach of any legal or contractual obligation regulated in the Penal Code in relation to expert testimony. Note that the Penal Code (CP), approved by Law 10/1995, of November 23, amended by Law 15/2003 of 25 November-regulates crimes and offenses that are defined (Article 10 CP) as fraudulent or negligent omissions punishable by law is considered willful act or omission that is committed with intent to cause harm. On the other hand, it is considered reckless omission of a duty of care or safety precautions needed to avoid harm, without any, in this case, intent on action.

The criminalization of the act or omission as a crime or offense provided for in Article 13 CP in terms of penalties, as provided in Article 33, amended by Law 15/2003- with those who are punished. Establishing the criminality in felonies, lesser offenses and offenses. The impact on the offense hits its limitation period, according to art. CP 131.

Penal law does not seek financial compensation to the injured, but social disapproval or punishment by penalizing the liable party. However, CP article 116 states that every person criminally responsible for crime or misdemeanor is also civilly liable if any damages arise. That is, criminal liability involves the liability of the person responsible, resulting in additional obligation to provide compensation for damages caused to the person or persons aggrieved by their professional performance. That it is determined by the lack of criminal responsibility does not imply, however, the absence of liability, but only the lack of criminal jurisdiction of the court to rule on it, in which case the injured party may initiate a lawsuit against the expert for recovery of civil damages.

3.2 Assumptions of penal responsibility

3.2.1 Crimes against the Administration of Justice

Title XX of the Criminal Code regulates crimes against the administration of justice and Chapter IV, relating to perjury, referring to the punishable acts of experts during the exercise of their profession. This rule has been interpreted by the Supreme Court warning that, to fall into the offense up for failure "to the truth maliciously" on the expert opinion is necessary:

- In objective terms, the sentiments expressed in the opinion or ratification be contrary to reality, not sufficiently motivated or alter the facts verified
- In subjective terms, conscious awareness and deliberately not telling the truth.

So says a ruling by the STS February 18, 2009.

"But if the designated document can not objectively prove the falsity of the defendant's expert report, much less can it prove that the alleged misrepresentation was malicious, willful and deliberate, that is, awareness and willingness to present as true and correct, as mentioned, is the subjective element of the crime charged. "(STS of 18 February 2009)

Overall, the doctrine of this provision is contained in the following Judgement:

"Under the doctrine of this Court (See SSTS de2-11-2005 [RJ 2006, 2556], no 1483/2005 of 30.1.1998 [RJ 1998, 388] and, 28/05/1992 [RJ 1992, 4392]) the actus reus of art. 459 (RCL 1995, RCL 3170 and 1996, 777) requires that the expert's statement be false, meaning that there is contradiction between the statements and reality, discrepancies and opinions are insufficient, as expressed in art. 459.

The basic element of the criminal activity listed in that provision (cf. STS 03.01.2005 [RJ 2005.3615], no. 265/2005 consists of missing the truth maliciously in the expert opinion given in court cases, so that the falsity must be apparent or manifested by the rest of the evidence. But along with this objective element, it requires the concurrence of a subjective element, the fraud, since this offense under the current Penal Code, is eminently intentional, excluding the reckless mode. The fraud in this type of crime is reflected in the intentional delivery of a statement or report forgers. The reported crime rate has an inherent fraud that doesn't require anything more than cover the legal injury that may occur consciously and voluntarily, for the intentional characteristic of this crime, actually reach, without requiring additional intention of causing a particular injury in the Administration of Justice. The sentence of this Room of 5.5.1995 (RJ 1995, 4539) confirms this thesis, without requiring the author of these facts act with a special animosity or intent to injure any of the parties in dispute. The crime of perjury is a conscious and deliberate falsehood or lie of the witness's statement or a malicious lack of truth in the expert's report. But it requires not only the lack of objective truth in the statement or in the opinion but also the direct intent, consisting of discovering the falsehood and willing to express it. (STS of 15 June 2007).

3.2.2 Crimes against Public Administration

Among the offenses against public administration, the Penal Code includes the crime of bribery, that article CP 422 expressly extends to experts. The crime of bribery applies to those who "benefit for oneself or a third party, requests or receives, either directly or through intermediaries, gift or present or accept an offer or promise to perform in the exercise of his office an act or omission constituting crime "(art. 419 CP) This reference to experts should be considered extensible not only to the designated court, but also to those appointed by the parties, since the LEC equates to two (Article 335.1)

3.3 Damages or penalties resulting from penal liability

Criminal law, unlike civil law, seeking social disapproval of the individual whose conduct is covered or an offense under the Penal Code . The Code regulates various crimes or offenses that may be penalized by the imposition of sentences of imprisonment, disqualification from office of an expert, or the imposition of fines.

The offense is punishable by a penalty proportionate with the nature of the act or omission. In the case of expert testimony, the penalty can range from imprisonment (imprisonment and personal liability for unpaid fines subsidiary) to the deprivation of rights (specific disqualification from employment, public office or profession, in this

case, his tenure as an expert) and the fine. The penalties to be imposed according to the offense would be the following:

- Felony. In the case of the expert it never happens because it is not accounted for in the penal code, prison terms of more than 5 years or total disqualification from office.
- Misdemeanour. In expert performance, the imprisonment of six months to six years to twelve years disqualifications and fines of more than three months.
- Faults. For the expert, the fine of ten days to two months, applicable for cases where the fines are proportional to the amounts defrauded.

In the case of economic damages (Article 50 CP, as amended by Organic Law 15/2003) they will be applied by the system of "day-fine", whose extension, in general, is at least 10 days and a maximum of two years, the have a minimum daily fee of 2 euros and a maximum of 400 euros the amount takes into account the economic situation of the defendant. In the art. CP 459 it establishes the penalties imposed "to experts and interpreters who alter the truth maliciously in its opinion or translation." These penalties are given by the upper half of those in the art. 458.1 (imprisonment for six months to two years and a fine of three to six months), also "punishable with the penalty of disqualification from a profession or occupation, employment or public office, for a period of six to twelve years."

Moreover, Article 460 CP introduces a notion of false testimony (in this case calls the doctrine as "partial" or "improper"), establishing fines for six to twelve months and, where appropriate, suspends the expert in charge for six months to three years for certain cases: "When a witness, expert or interpreter, without failing substantially to tell the truth, alters reluctantly, inaccuracies or silencing relevant facts or data that were known, shall be punished with a fine of six to twelve months and, where appropriate, suspension of employment or public office, profession or occupation, six months to three years. "

For the crime of bribery, the offense is punished with imprisonment from two to six years, a fine of three times the value of the donation and disqualification from office for a time of seven to 12 years without prejudice to the punishment for the crime committed because of the gift or promise (in this case, the false testimony of the arts. 459 and 460 PC). Art. 420 governs cases in which the wrongful act for which the expert receives compensation doesn't constitute a crime, reducing the penalties to be imposed.

4 Administrative responsibility

4.1 Nature of administrative responsibility

Administrative responsibility has, in the case of expert testimony, a disciplinary character. It is caused by the infringement of legal provisions established both by the Administration of Justice and the professional bodies or organizations to which it is built by the expert. In general, the failure of the rule is penalized by a fine whose amount is imposed in each case depending on the seriousness of the violation or disciplinary action regarding the disqualification of the expert to exercise that capacity. This responsibility is entirely compatible with those of civil and criminal referring to the same event.

4.2 Assumptions of administrative responsibility

4.2.1 Liability for breach of disciplinary rules in the Administration of Justice

Organic Law 6 / 1985 of 1 July, the judiciary, regulates in Article 193-1 (and, by reference to this, Article 192) to impose disciplinary measures to the experts who act incorrectly in the view and judicial acts. It establishes the possibility of expulsion from the room or fine when the consideration, respect and obedience due to judges, prosecutors, clerks and other personnel working for the Administration of Justice is not observed (Cristensen, 2004).

Within the civil and criminal jurisdiction it establishes the penalties applicable to the expert who breach their duty to appear before the judge. In addition, the Criminal Procedure Act allows damages for breach of certain duties by the expert. The expert must abstain from participating, and therefore does not accept the appointment by the courts, as specified in Article 105 of the LEC, when the circumstances indicated to the disqualification of expert witness in Section 124, which refers also to Article 219 of the Judicial Power Organization Act. The expert will be penalized if he accepts an appointment with prior knowledge that inconsistency is incurred for attending any of the circumstances:

- Technical failure to do the dictum
- Incompetence or favouritism manifested
- Assignment of responsibilities.
- Expressing oneself on matters not related to the object nor direct relationship to them.

The experts appointed by the parties may only be subject to reproach for the reasons and in the manner provided for in Articles 343 and 344 of the LEC, but they can never be challenged by the parties, as provided in paragraph 2 of Article 124). On the other hand, you cannot provide expert opinion in everyone who has been offended.

4.2.2 Liability for breach of professional school rules

The Rules of Professional Conduct ethical standards of the Architects of CSCAE establishes certain assumptions applicable to professional architects and experts involved. Certain items are extended to the expert performance as part of the architect's own professional activities:

Article 12. The architect shall act with honesty and sincerity in all professional activities. When acting on a mission of experts, expert witness or juror, or where in any of its fields of activity, be issuing any kind of certification, support its discretion in those proven facts so warrant.

Article 23. No architect may violate professional obligations, and shall assume legal responsibility not only derived from their performances, but also those of occupational responsibilities inherent in accepting the job. Without prejudice to the legal liabilities that may incur, will also respond before the professional school for the damage that may be caused by incompetence, negligence, error, lack of foresight, risk, lack of adequate commitment or failure in its performance.

Furthermore, Article 51 may apply to the expert critical analysis that he is required to do, both in his own dictum and in the statements made in the ratification of other opinions into the process and have been drawn up by architects (art. 347. January 5 th LEC) in conjunction with the formal content of such analysis:

Article 51. Every architect should be objective in his criticism of the works of his colleagues and accept criticism with the same objectivity. The architect must refrain from making statements that are personally offensive to their colleagues or to the profession. Shall, however, notify the school of any breach of professional duties that may arise.

4.3 Damages or penalties resulting from administrative responsibility

Therefore, damages or penalties resulting from administrative responsibility are economic or disciplinary action. As stated in Articles 192 and 193 of the CP, the expert may be sentenced to a fine of up to two months if he disrespects judges and other members of the Administration of Justice.

In turn, the Civil Procedure Law states in Article 292.1 of fines that will fall on the expert for breach of the obligation to appear at a hearing. Violation of this duty is punishable, upon hearing for five days, a fine of 180 to 600 euros (writing as RD 1417/2001)

In Article 420 CC states that if the expert resists to declare what he knew about the facts that might be asked he does not fall within the exemptions of the above items and will incur a fine of 200 to 5,000 euros, and if he persists in his resistance will be taken before the presence of the investigating judge by the agents of authority, and persecuted for the crime of obstruction of justice crime under article 463.1 of the Penal Code (cited below) In the second case he will also be pursued for serious disobedience to authority. The fine will be imposed when the breach is detected or done.

In Article 464 states , despite the expert being the offended party in the procedure, went ahead with the report without putting expert report before the judge who had appointed him he will incur a fine of 200 to 5,000 euros, unless the act produces a criminal liability. With respect to citations of experts in CP Article 175 establishes the obligation to attend the first appeal, under penalty of 200 to 5,000 euros, or longer if the second does occur, the to attend on pain of be prosecuted as liable of the crime of obstruction of justice crime under article 463.1 of the Penal Code (writing under Law 38/2002 of October 24). In turn, Article 463 of CC indicates that if referred to in legal form, fails to appear voluntarily without just cause, before a court or tribunal to convict in criminal proceedings on remand, causing the suspension of the trial, shall be punished with imprisonment for three to six months or a fine of six to 24 months. In the fine of six to 10 months will incur which, having been warned, do it for the second time in a criminal case without defendant in prison, has caused or not the suspension. (Writing under Law 15/2003 of 25 November)

Moreover, the breach of the Rules of Professional Conduct ethical standards of Architects for professional expert witness may incur lower Experts List to periodically move the competent bodies such as professional associations to different courts. Before agreeing to be granted forced down the person concerned a hearing within 10 days for claiming in his defense as it sees fit. This will require you petition the competent judicial body prior to the Board of Governors, who's moved to the Ethics Commission or the complaint filed against the former directly by any party interested in the opinion

or some college as it deems have been unfairly prejudiced by the expert's report. The law will be effective at the time that the penalty becomes final.

5 Conclusions

The professional who acts as an expert before the court intervenes as an expert in his discipline, so a lot is expected of him in the technical aspects related to the issue which prompted review. On the other hand, the technical opinion of the expert will form part of a process in which the judge must rule on the facts in accordance with the rules of law. The expert should be knowledgeable of the procedure that regulates his intervention before the court of law, whether they had been appointed by the judicial organ or his opinion had been brought to the process by the parties. And this responsibility takes place both in the field of criminal justice, civil and disciplinary, as in all of them may incur as a result.

Abstract:

Cost and schedule overruns are norm in offshore hydrocarbon projects. With increasingly complex commercial and contracting arrangements, technical challenges, changing local economic and regulatory conditions and a shift toward project's being undertaken in peak oil frontier regions, the risks of overruns increase. A major factor contributing to such overruns is rework. Twenty three in-depth interviews with leading oil and gas industry practitioners were undertaken to acquire knowledge of their experiences of rework causation in offshore projects. Analysis of the dialogue and narratives obtained enabled a nomenclature for rework causal factors to be classified as *People*, *Organization* and *Project* for different types of offshore structure. The determination of rework causal factors provides the foundations for appropriate risk management strategies in future projects to be determined.

Keywords:

errors, change, sensemarking, offshore projects, rework

1 Introduction

The catastrophic failure of offshore structures such as Piper Alpha, Sleipner A, Petrobas-36 and Ranger I resulted in an intense period of introspection that resulted in major changes to safety, reliability and engineering assessments and standards (e.g., Moan, 2009). Detailed investigations and subsequent analysis of these accidents have attributed the causes of failure to be associated with an array of human and organizational errors (Bea *et al.*, 2010). Such errors not only have been found to contribute to system failure and accidents, but also cost and schedule overruns in projects (Love *et al.*, 2009). Between 1993 and 2003 one in eight major offshore developments with a capital expenditure (CAPEX) ranging from US\$1 million to US\$3 billion were deemed to be a financial disaster. These projects exceeded cost and/or schedule growth by 40%, or within the first year of operating were producing less than 50% of production capacity (Merrow, 2003a,b). Furthermore, more than 40% of capital

offshore projects in excess of US\$1 billion overran budget by more than 10% (Morrow, 2003a,b). More recently, it has been estimated that the average cost overrun for offshore construction programs is 35% and average delays total seven months (Eriksen, 2010). The most common factors contributing to cost overruns in offshore projects are (Eriksen, 2010):

- the placing of orders before engineering is completed;
- the implementation of new technology without qualification;
- insufficient engineering with regard to operational robustness and maintainability;
- problems with component deliveries and documentation when transferring fabrication;
- fabrication yards having to build competence and resources during the project, and
- poor interface management.

Complex commercial and contracting arrangements, increased technical challenges, changing local economic and regulatory conditions, and a shift toward projects being undertaken in frontier regions (e.g., Bangladesh, Ecuador, Kazakhstan, and Peru) are increasing the risk of overruns, failures and accidents.

Failure to deliver megaprojects on budget and on schedule often generates negative publicity in the national and international news, thus adversely impacting stakeholders' perception of a company's ability to meet commitments. Poor project performance is not acceptable when capital markets are looking for predictability and strong returns (Love *et al.*, 2011a). Projects that underperform, perhaps due to rework, are often explained away as being an isolated instance of unfortunate circumstance and considered not to be a part of normal practice (Love *et al.*, 2009). Put differently, rework in such circumstances may be analogous to being a 'Black Swan' (Taleb, 2007); an outlier event within projects. In spite of its outlier status, explanations and justifications for its occurrence, after the fact, are often made by organizations in an attempt to make the event explainable and predictable (Taleb, 2007). The quandary is that many organizations are reluctant to admit to problems that may exist within their systems and processes for fear of being judged irresponsible by their stakeholders. To reduce the probability of cost and schedule overruns, failures and accidents, rework risks need to be identified and classified before they can be assessed, managed, and mitigated. A series of unstructured interviews with leading industry practitioners was undertaken to acquire knowledge about their experiences with rework in projects that they had been involved with. The dialogue and narrative derived provide valuable insights that enabled 'sensemaking' of rework causes to be identified for various different types of offshore structure.

2 Rework and Latent Conditions

Rework has been defined as "the unnecessary effort of redoing a process or task that was incorrectly implemented the first time" (Love, 2002:p.18). It has been identified as a problematic issue in construction and engineering projects and a major contributor to cost and schedule overruns (Hwang *et al.*, 2009). Rework, on average, contributes to 52% of a total cost overrun incurred and can increase schedule by 22% (Love, 2002). Rework costs have been found to range from 5 to 20% of contract value in construction

and engineering projects (Love *et al.*, 2011a). To date, there is limited knowledge available about rework costs and its causes in offshore projects.

Rework has been attributed to latent conditions that reside within the organizational and project systems (Love *et al.*, 2009). Reason (1997) states that “latent conditions are to technological organizations what resident pathogens are to the human body” (p.10). For example, at an organizational level this may include insufficient training, resourcing levels and lack of a quality management focus. At a project level, lack of supervision, competitive tendering, and contracting strategy have been found to provide the conditions for errors to manifest (Love *et al.*, 2011a). In effect, latent conditions lay dormant within a system until an error comes to light. Invariably, they arise as a result of strategic decisions taken by senior management, government, regulators, designers and key decision-makers. The impact of these decisions spreads throughout an organization and project, shaping their culture and creating error-producing factors within individual workplaces (Reason, 1997).

Errors can take the form of violations, mistakes, slips and lapses (Reason, 1990). Violations arise to due aberrant behaviour and are analogous to omission errors, though they may not always result in an error being made. Violations are deliberate deviations from practices deemed necessary (Reason, 1990). Before errors become apparent, participants often remain unaware of the impact upon project performance that particular decisions, practices or procedures can have (Love *et al.*, 2009). Until errors are identified or a failure occurs they remain in a state of incubation and become an integral part of everyday work practices (Reason, 1990). If an error is identified, then rework can be undertaken. If schedule pressure becomes a problem during the rectification of the error, then there is a potential for safety to be compromised and accidents to occur (Goh *et al.*, 2011).

Active failures are unsafe acts committed by people who are in direct contact with a system. They are often difficult to foresee and cannot be eliminated by simply reacting to the event that has occurred. When latent conditions combine with active failures, then the error consequences that arise can be significant (Reason, 1990). Active failures, such as those identified above, have an immediate impact and are committed at the human-system interface (Reason, 1997). Latent conditions provide an environment for increasing the likelihood for active failures to occur by creating the local factors that promote an individual to commit an error or violation (Reason, 1997). Through proactive management latent conditions can be identified and remedied before an adverse event occurs (Goh *et al.*, 2011).

2.1 Project Complexity and Uncertainty

The management of errors in offshore operations has been extensively examined from a human and organizational perspective (Ren *et al.*, 2008). Such research has been initiated by accidents and catastrophes that have occurred. While considerable advancements in the ability to reduce and predict their likelihood, errors have been made and still continue to prevail. A possible explanation for this can be derived from Tversky and Kahneman (1974) research on judgment and uncertainty. People are guided by their previous experiences and therefore will be inclined to underestimate irregularities in the future. Thus, they will plan for fewer contingencies than will actually occur. Tversky and Kahneman (1974) have suggested that people are influenced by the representativeness and availability of heuristics that are available to them. When people rely on individual representative heuristics they are likely to judge

causality on the basis of perceived similarities between the cause and effect of events they have experienced, or to their knowledge. If people rely on the availability heuristic then they will predict the frequency of an event, or a proportion within a population, based on how easily an event can be brought to mind. This is also compounded if a person believes that a given event has only one underlying cause (Nisbett and Ross, 1980). Love *et al.* (2011a) suggest that the causes and effects of committing errors are not unidirectional or linear, but are reciprocal or looped in their relationships. Understanding how such relationships emerge and interact with one another is necessary in the pursuit of error and rework reduction. The ideal error reduction approach is to view errors as symptoms of underlying problems, and in so doing, they become information sources that help explain how systems work. While underlying events may be similar in nature, the dynamic and chaotic nature of projects may produce large variations in system behaviour if a shift or deviation from initial conditions arises. Such a phenomenon is referred to as *sensitive dependence* (Hilborn, 2004).

Another issue that may explain why projects continue to experience cost and schedule overruns is the use of conventional project management within chaotic environments. Classical Newtonian scientific philosophy is somewhat akin to conventional project management and implies that order should be imposed from above (leading to top-down command and leadership) and that structures should be designed to support decision-makers. As projects have become more complex in nature, this philosophy to managing projects is deemed ineffective in reducing failures and assuring successful outcomes. Inherent within complex projects are unintended consequences and counterintuitive outcomes due to the structural complexity and uncertainty that prevails. According to Williams (2002) structural complexity is derived from the interaction between the number of elements that form the project and their interdependence. Uncertainty is derived from a lack of clarity concerning project goals and an absence of appropriate means with which to achieve those goals (Williams, 2002). The result is that project elements interact in complex and unpredictable ways, which can increase the likelihood of rework occurring (Love, 2002). This situation is further exacerbated when activities are undertaken concurrently due to issues associated with schedule pressure.

In an effort to meet a project's schedule completion date, additional resources may be employed, however such action may lead to a contradictory effect (McConnell, 1999). By pushing beyond the limits of concurrency, complexity increases and tasks are delayed, particularly when revisions, repairs and rework occur (Love, 2002). Paté-Cornell (1990) suggests that schedule pressure not only increases the probability of errors occurring but also decreases the chances that they are detected using regular procedures. Design errors that may be deemed minor in nature are likely to be overlooked due to the time that it would invariably take to correct them (Paté-Cornell, 1990). An 'escalation to commitment' may prevail if any ambiguities are identified and invalidate efforts of the initial design and engineering that has been undertaken (Paté-Cornell, 1990:p.1214). The inherent uncertainty that prevails within offshore projects can result in planning being problematic, especially when information is unavailable. Faced with high uncertainty, there is an over reliance on scope changes to solve problems that may arise during construction, installation and commissioning.

3 Research Methodology

An interpretative research approach was adopted to determine the systemic nature of rework. A similar approach has been advocated by Goh *et al.* (2011) who examined the systemic causes of organizational accidents. As limited research has addressed rework in offshore projects 'subjective idealism' was adopted (Farrell, 1996). In this instance, subjects construct their own views and opinions on the phenomena to be investigated based upon their experiences; an inclination to truth and pragmatism is deemed to prevail. This approach is similar in nature to Weick's (1988) 'sensemaking' where meaning is given to experience, dialogue and narratives about events that have occurred through a process of retrospection.

3.1 Data Collection

Twenty three in-depth interviews were conducted over a four month period with a variety of personnel including operations managers, project managers and engineering managers who were working for a major international oil and gas operator. The sample consisted of: operations managers (3), project manager (10), structural engineer (3), procurement manager (2), mechanical manager (2) and Engineering Manager (3). Interviews were chosen as the primary data collection mechanism as they are an effective tool for learning about matters that cannot be observed (Kvale, 1996). The firm was selected as the research team had a direct contact point within the organization that had an interest in understanding 'why' and 'how' rework emerged in projects. For reasons of commercial and individual confidentiality, specific details about the organization are not presented. Personnel involved with the procurement of projects within the organization were invited to participate in the research and interviews were conducted at the offices of interviewees for their convenience. Interviews were digitally recorded and transcribed verbatim to allow for finer nuances of the interview to be documented.

The interviewees' details were coded to allow for anonymity, although all interviewees were aware that it might be possible to identify them from the content of the text. The format of the interviews was kept as consistent as possible following the themes associated with rework identified from the literature. The interview commenced by asking individuals about their experience within industry, and their current role within the organization. Interviewees were then asked to select a completed project they had been involved with and identify a particular rework incident that had taken place. The interviewee was then asked for their perspective how and why they thought it arose. Phrases such as 'tell me about it' or 'can you give me an example' were asked when further information was required. The open nature of the questions allowed for avenues of interest to be pursued as they arose without introducing bias in the response. Interviewees were asked to identify the main sources of rework that occurred in offshore projects that they had been involved with and to suggest strategies could be used to prevent it from reoccurring in the future. Notes were taken throughout the interview to support their digital recording to maintain validity. Interviews varied in length from one to three hours and sought to stimulate conversation whilst simultaneously breaking down any interpersonal barriers that may have existed between the interviewer and interviewee. Each interview was transcribed and a copy given to each interviewee for comment to check overall validity and accuracy. In conjunction with the interviews, documentary sources for each of the projects were provided.

4 Findings and Discussion

Each interviewee held views as to the reasons rework occurred in projects that they have been involved with, though a high degree of consensus emerged as to the underlying causes and risks that needed to be taken into account to reduce its materialization in projects. When rework in a project was deemed to be equivalent to a series of ‘anaphylactic shocks’ that destabilized a projects’ performance, though the severity of its impact cost and schedule performance depended upon where and when an error was identified and how it was addressed. Narratives from completed projects that interviewees had been intimately involved with from different parts of the world were described. This led to a rich representation of the dynamics and risks associated with rework to be attained. The sharing of dialogue and narratives is pivotal for learning, though there is a proclivity for it to occur at different levels within organizations.

4.1 Rework Costs

Intuitive estimates of rework costs for projects were provided by interviewees. These ranged from 3% to 25% of CAPEX. Such costs are not measured even though they can contribute to increased project costs. Using an Engineering Procurement Construction (EPC) contract strategy, a 10% cost growth, with 5% due to rework, was deemed to be acceptable considering the uncertainty and complexity associated with offshore projects. Taking into account the potential for optimism bias (i.e. over estimating the likelihood of positive events and under estimating the likelihood of negative events), the actual rework costs could be considerably higher.

Cost overruns were deemed to be the norm. Having to undertake rework as a result of errors and omissions was an issue not *formally* recognized during the concept design and Front End Engineering Design (FEED) risk management processes that were in place within the organizations where interviewees had been employed. Despite the use of post mortems from completed projects being used as a formalized learning mechanism for future projects, the inclusion of any form of risk assessment or even acknowledgment of rework was eschewed: it is a ‘taboo’, its costs buried within a project’s contingency sum. To the interviewees knowledge rework is not measured; it exists and occurs regularly, but is hidden deep within an organization’s subconsciousness until a major incident arises. Then, as one engineering manager commented “the blame game begins and the contract comes out, and all hell breaks loose”. An unwillingness to admit that rework was a problem was clearly evident from the opening statement made by a project manager who had more than 15 years experience working in offshore environments who initially stated “we don’t have rework in our projects”. This shielding comment was not the voice of the individual, but that of the organization they were representing. The mere recognition that errors occurred could potentially jeopardize the organizations corporate image and possibly the value of their ‘shares’. As the interview unfolded, the voice and experience of the individual began to surface. It was clear that rework was indeed a costly issue in many projects that they had been involved with.

If rework costs of 5% of CAPEX are an acceptable norm, there is a danger that this ‘norm’ will insidiously creep up further and settle in at an uncomfortable level, particularly as demand for energy and hydrocarbons increases. If rework repeatedly occurs within offshore projects, it may become invisible or viewed complacently as being a necessary evil of doing business. The percentage increase in rework will undoubtedly be added to an organization’s overall costs. If rework accounts for 5% of

regular work of an organization, this would lead to everything being increased by 5%: supervision, cycle time for administrative procedures, answering requests for information, and so on. The time element obviously translates into costs, which are then buried in what would be considered ‘normal’ operating costs. History suggests that those who fail to learn from their mistakes are invariably condemned to relive them again. Insight gained from previous mistakes or oversights made in projects can be gainfully employed in preventing future repetition. Learning from mistakes is difficult, but continuing to make the same ones is far harder and certainly more costly.

4.2 Narrative: Remember the Shareholder

In this narrative, the deck, hull and mooring system were constructed (fabricated and installed) by three different contractors simultaneously and importantly, contracts were let before the detailed engineering had been completed. This posed a problem during hull and Topside fabrication as the number of risers was not determined due to the uncertainty of the hydrocarbon well. In describing this issue a project manager stated:

“We started the engineering of the Topsides when we’d not completed the reservoir simulation works. We were running before we could walk! We over designed on the number risers and wells that were going to be needed. Those assumptions turned out to be wrong. We kept going round in circles because we’d not finished the reservoir works. We were designing for too many uncertainties and complexities. Mistakes were made; we were under considerable pressure to get the project up and running. We always have to remember though that we have shareholders who expect dividends”.

The fabrication process was staged until the number of risers could be finalized and detailed engineering completed. This staging inadvertently delayed the project’s schedule, but it was still expected that the installation process would meet its original schedule. Any delay to the final completion date would adversely influence gas production and the company’s share prices. Audits and reviews of the detailed engineering were undertaken, but this was seemingly done in a haphazard manner due to the imposed schedule pressures. It was not until the platforms components were being installed that engineering and fabrication errors began to materialise. While three-dimensional clash detection exercises had been undertaken during engineering, extensive clashing of pipe work occurred on-site during the installation of the deck and hull systems. A structural engineer revealed that an up-dated software version was used, but unfortunately several engineers were not completely familiar with the ‘nuances’ of the new application. An engineering manager stated:

“We’re experiencing a severe skills shortage. We just can’t get people who have the skills and experience needed. The entire resource sector is experiencing a shortage of labour. We’re just getting who we can and try to train them on the job – I don’t know what we’ll do if and when we get more work. We don’t have time to train people. Sadly, it has to be done on the job. You only have to look at the quality of work undertaken by the contractors and their subcontractors. We have to hold their hands”.

Evidence of this inexperience became apparent when the platforms components were being installed; poor quality materials and workmanship were prevalent. For example, issues related to weld contamination, and mismatching material grades were identified.

During Topside installation, it was observed that material grades had been ‘mixed up’. Type II steel had been used where only Type I had been specified. This was a major concern as the Topside’s structural integrity was brought into question. The Type I steel was subjected to rigorous testing and it was found that it achieved the performance level equivalent to that specified for Type II steel. A simple colour coding system in the fabrication yard would have eliminated these errors. There were instances where a weld had been contaminated by the inclusion of dissimilar materials. Pressure testing of pipe work and equipment during the fabrication process to ensure the integrity of the welds, revealed carbon steel particles had become engrained within a stainless steel weld. Once this happens the weld adopts the function of an anode to the stainless steel cathode, thus accelerating the process of corrosion. A structural engineer suggested that during fabrication the same grinders and steel brushes that had been used on the carbon steel were probably also used on stainless steel and copper nickel pipe work; a clear indication that the contractor did not implement stringent QC procedures. Minor works were undertaken, but the weld’s integrity needed to be constantly monitored.

4.3 Narrative: The Push for Production

In this next narrative, rework costs were estimated to be 3% of CAPEX, which according to the estimates identified above were below the level considered to be a ‘norm’. Like the aforementioned project, the determination of the hydrocarbon reservoir was identified as a problematic issue. A project manager project stated:

“It’s very difficult determining in the size of a hydrocarbon reservoir. There are so many variables we have to take into account, though with the technology we have today you’d expect some degree of accuracy. When you’re dealing with Mother Nature you never know.”

Failing to assess the reservoir capacity impacted on the engineering and procurement of the Topside facility. The deck, hull and mooring system were constructed (fabricated and installed) by three separate contractors. The same contractors that had been involved with the project presented above were involved with this project, and therefore were familiar with the client’s eagerness to push ahead with the project to satisfy shareholder confidence. Again, contracts were let before the detailed engineering had been completed. Recognizing that a tight schedule had been established, the number of risers required was anticipated based upon preliminary forecasts of the reservoirs capacity and incorporated into the engineering design. Contractors began to fabricate based upon the original engineering design but changes to the design were required to accommodate for an increased production capacity. This resulted in significant changes to the platforms component parts. Fortunately, the rework required was undertaken in the fabricating yard and not on-site. During fabrication the internal side of a caisson and riser guides were found to be unpainted. This was not noticed until they had been installed. Concerns over accelerated corrosion were raised due to water movement within the annulus casing and the removal of the corrosion product, which would have otherwise acted to protect the uncoated surface. It was deemed impractical to coat the internal caisson and riser guides through the small annulus gap. At such uncoated locations, corrosion can be exacerbated and therefore the caisson required continual monitoring; an unnecessary maintenance cost was created.

5 People, Organization and Project

Sensemaking of rework through dialogue and narratives provided by the interviewees revealed high degree interdependency existed between rework events. In Figure 1 the relationship between the nomenclatures of people, organization and project is identified. Apart from the organizational and project related influences, erroneous decisions during FEED can occur due to impaired human cognition. An individual's cognitive *ability* (i.e. measured by aptitude tests) and *style* (i.e. the way an individual thinks, perceives and remembers information) influences their ability to learn. The majority of errors that arise are due to human action or inaction by virtue of cognitive failure (Busby, 2001).

Cognitive failure can be defined as cognitive-based errors on simple and often replicative tasks that a person should normally complete without fault; these mistakes include problems with memory, attention or action (Reason, 1997). The inability to engage and sustain attention is seldom a direct consequence of boredom. Boredom is often described as an adverse affective or cognitive state, but is arguably more fundamentally an inability to engage and sustain attention (Wallace *et al.*, 2002). Decisions taken by senior managers at an organizational level, which are often influenced by the demands imposed on them from their environment, can determine the extent that policies and procedures are adhered too as well as the resourcing capacity for a project. Decisions that are made by individual organizations can increase or decrease the likelihood of rework. Each participating organization has differing goals, objectives and learning capacity, which may further exacerbate problems that become embedded within project systems and processes. The contracting strategy adopted for a project therefore needs to ensure that goal alignment can be ensured. The current use of an EPC contracting strategy inhibits goal alignment between participating project organizations, especially when competitive price determination becomes a driver for the selection of their services. Instead, alliances with an in-built learning capability and performance incentives should be used to establish a project culture that is able to drive the behaviour of organizations to achieve a successful project outcome (Love *et al.*, 2011b).

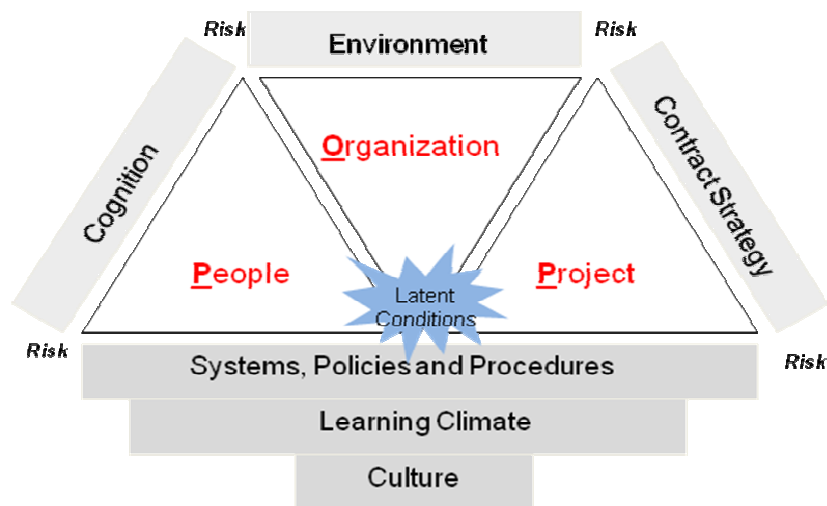

Figure 1. Relationship between people, organization and project

An organization's culture influences its ability to learn, particularly in the context of rework reduction (Love *et al.*, 2000). A culture conducive to learning is necessary for stimulating innovation, as it enables an organization to anticipate and adapt to the dynamics of a changing environment. An organization where a learning culture exists is characterized as one where all its members value learning and strive for high performance through its application to innovative work (Love *et al.*, 2000). A culture adept at learning emphasises open exchange of information and ideas in ways that facilitate exchange and dissemination of knowledge. Culture is based upon the beliefs that are shared within, whereas climate is based upon what an individual's senses about its organizational environment. In the context of a learning climate, it is not the work environment, but the way in which employees are encouraged to respond to it. According to Koppelman *et al.* (1990) it is the 'perceptual medium' through which culture and other work environment factors influence job-related attitudes and behaviours.

It would appear 'learning' is not given the priority that is needed by organizations as excessive cost and time overruns are regularly experienced. The same mistakes are being repeatedly made. Implementing strategies to maximize production capacity and profit to increase 'share price', by unnecessarily accelerating activities, can lead to safety and the environment being jeopardized. Such a strategic risk can cause not only a significant 'ripple effect' throughout the owner and operator's organization, but also other participating organizations in a project as they strive to meet the demands and constraints imposed upon. Mismanagement, mostly made by people with no training in managing risks has been identified as a basic condition contributing to the collapse of BP's Deepwater Horizon (Bea *et al.*, 2010). There is an explicit expectation that BP should have learnt lessons from the incidents that occurred at its Grangemouth Complex in 2000 (HSE, 2003), Texas City refinery accident in 2005, and collapse of the Thunder Horse platform in the Gulf of Mexico in 2006 (Bea *et al.*, 2010). Lack of training, poor communication, poor supervision and fatigue have been identified as contributors to BPs accidents. These findings are not dissimilar in nature to those reported in this paper contributing to rework. A notable difference, however, pertains to the interrelationships

that have been identified from the dialogue and narratives obtained and extrapolated to the nomenclatures of people, organization and project.

6 Conclusion

The increasing demand for and rising costs of energy has stimulated the need to extract and produce greater volumes of oil and gas. Consequently, a large number of offshore projects have been commissioned or built. Many have experienced significant cost and schedule overruns. A significant factor contributing to such cost and schedule overruns is rework, which arises due to errors, omissions and changes. Such rework arises as there is an underlying pressure to complete the project and commence production as soon as possible. If rework occurs, it is explained away as being an unfortunate event. Surprisingly, cost and schedule overruns are expected; a 5% of CAPEX cost increase due to rework is considered acceptable, if it occurs. If rework is anchored at such a level, then the likelihood for accidents and perhaps even loss of life significantly increases. It is only when a major failure, accident or catastrophe occurs that an investigation reveals design, managerial and organizational flaws have occurred. The determination of rework causal factors provides the foundations for appropriate risk management strategies in future projects to be determined.

7 Acknowledgments

The authors would like to thank Dr Nurica Forcada, Professor David Edwards and Professor Zahir Irani for their contributions to this research.

Abstract:

The Ugandan Economy is one of the fast developing economies on the African continent with the Construction Industry contributing close to 10% of the Gross Domestic Product for the last couple of years. The Volume of construction work has steadily increased over the years due to the increased foreign investment into the Country. However, despite the positive trend, the industry faces a number of challenges one of the major ones being cost overruns on Construction projects. A review of existing literature on the subject revealed that this is majorly due to the ineffectiveness of the Project cost estimation method used in the industry. The study investigated the manner in which contingency sums included in the entire project cost were determined on twenty projects with a contract sum above 1m USD. The study further examined how the cost of those projects was managed during construction revealing the cost overruns for the different elements of the works; assessed the factors that determine the accuracy of the contingency sum included and as such the realistic project cost required for each individual building works. Finally the study proposed a new approach to determining close to accurate contingency sums of the individual construction works elements.

Keywords:

construction, cost, estimation, management, Uganda

1 Introduction

The cost performance of construction projects is a key success criterion for project funding agencies. Projects require budgets to set the sponsor's financial commitment and provide the basis for cost control and measurement of cost performance during the design process as well as during construction. Uganda is one of the African countries that had a very nasty past full of political instability and turmoil. Because of this the country and its infrastructure deteriorated so much till up to 1986. However since that time and for the last more than 20 years the country has experience peace and this over time has won the confidence of investors. With the inflow of investments, the construction industry has seen a great boom that has never been in history. Construction projects of various scales are taking place. However notwithstanding the boom, the Industry faces a several challenges one of which is the fact that most of the projects carried out are finished at a cost between 25-35% of the initial project cost at that start

of the project. This is rather a disturbing phenomenon among the professionals in the industry as well as the Clients.

In Uganda, cost overrun in especially public construction projects has been pointed out for a long time and no consistent and in-depth research has been carried out. Accordingly completion of both private and public construction projects within the pre-set budgets have been challenging issues for the Ugandan construction industry. It should be highlighted that achieving the objectives of a building contract is very important to the satisfaction of the parties involved particularly the Client. In construction projects, plans and cost estimates are usually drawn to ensure that the work is carried out to the desired quality, within agreed contract time and within the contract sum. However, the Ugandan construction industry there are several invariably unforeseen items and events in the execution of a building project such as the unstable dollar to Uganda shilling rate that affects the price of the imported building materials; the rather low level of professionalism and skill among the workers in the industry etc.

In Uganda, while preparing the cost estimate for a project, a contingency sum is included in the cost to cover up for the potential unforeseen circumstances that may lead to increase in the cost of the project. Contingency is usually defined as the budget that is set aside to cope with uncertainties during construction. The main objective of contingency is to prevent a project from experiencing cost overrun. The effectiveness of this contingency is dependent on adequate consideration given to those factors that are responsible for the changes in plan. Any realistic contingency must serve as a basis for decision-making concerning financial viability of the variations.

A key component of a project budget is cost contingency. Project cost contingency has been a part of projects and project management for at least fifty years and probably much longer. Most textbooks on project management and in particular project cost management invariably contain some reference to project cost contingency. Despite the ubiquity of project cost contingency in the theory of project cost management, there has been little empirical research into project practitioners' understanding of the concept, its intended scope, methods of estimating or management. There has been a recent resurgence into researching cost contingency, (e.g. Mak et al 1998, Aibinu & Jagboro 2002, Williams 2003) which may be a reflection of growing interest in project risk management over the past decade and the realisation that cost contingency is in fact an important risk management notion. An appreciation of risk aspect of contingency may encourage greater use of quantitative risk analysis techniques for its estimation.

Contingencies are often calculated as an across-the-board percentage addition on the base estimate, typically derived from intuition, past experience and historical data (Mak et al, 1998). It is considered an arbitrary method of contingency calculation that is difficult for the estimator to justify or defend (Yeo 1990, Newton 1992). Thompson & Perry (1992) claim that all too often risk is either ignored or dealt with in an arbitrary way and Baccarini simply adding a percentage contingency onto the estimated cost of a project is typical. Furthermore, the percentage addition results in a single-figure prediction of estimated cost, which implies a degree of certainty that is not justified (Mak et al 1998). The percentage addition indicates the potential for downside risk and does not indicate any potential for cost saving opportunities and may therefore mask poor project management (Mak et al, 1998). It also does not encourage creativity in estimating practice, promoting a routine and mundane administrative approach requiring little investigation and decision making, which may propagate oversights (Yeo 1990, Mak et al 1998). The traditional allocation of contingency in construction projects using

percentage addition method has been challenged and criticised leading to evolution of analytical and scientific methods.

David Baccarini in his paper *Understanding Project Cost Contingency – A survey* (Baccarini, 2005) highlighted several shortcomings in the understanding of the concept of project cost contingency that can have significant repercussions for effective project management. He concluded that the lack of sophistication in the estimation of project cost contingency by practitioners is reinforced by poor management practices in term of reviewing the accuracy of contingency and the limited existence of policy and good management practices. Overall, this suggests there is significant room for improvement in the understanding, estimation and management of project cost contingency.

Notwithstanding the inclusion of the contingency on most projects in Uganda, the projects end up with cost overruns. This was the underlying reason why this research was undertaken – to investigate how the project cost estimates are made at the start of the project; how the amount of the contingency sum is established; how the cost is managed during construction and then finally to evaluate the effectiveness of the method used to determine this contingency sum.

On examination of how the cost of those projects was managed in Uganda particularly during the construction period, it was revealed that there are various cost overruns for the different elements of the works that make up the overall construction project. The research revealed the factors that determine the accuracy of the contingency sum included and as such the realistic project cost required for each individual building works. Finally the study proposed a new approach to determining close to accurate contingency sums of the individual construction works elements.

2 Literature Review

Contingency has been defined as: "An amount of money or time (or other resources) added to the base estimated amount to achieve a specific confidence level, or allow for changes that experience shows will likely be required" (AACE 2000: 28) "The amount of money or time needed above the estimate to reduce the risk of overruns of project objectives to a level acceptable to the organization" (PMI 2008: 199). The key attributes of the concept of project cost contingency are: *Reserve* - Cost contingency is a reserve of money (AACE 2000). *Risk* – The need and amount for contingency reflects the existence of risk in projects (Thompson and Perry, 1992). Contingency covers for two categories of risks – known unknowns and unknown unknowns (PMI 2008; Hillson 1999). Contingency caters for events within the defined project scope that are unforeseen (Moselhi 1997; Yeo 1990), unexpected (Mak *et al*, 1998), unidentified (Levine 1995), or undefined (Clark and Lorenzoni, 1985; Thompson and Perry, 1992). *Risk Management* – There is a range of risk management strategies for risk in projects such as risk transfer, risk reduction, and financial treatments for retained risks e.g. contingency (Standards Australia 1999). So contingency is used in conjunction with other risk treatment strategies.

Bello and Odusami, 2007 in their paper *'the Practice of contingency allocation in construction projects in Nigeria'* found the conventional allocation of a lump sum amount and percentage addition to the base estimate to be the methods used by quantity surveyors in estimating contingency on construction contract despite the awareness of the scientific methods by a good number of them. They concluded that the importance

of forecasting an accurate and effective construction contingency is sine qua non to client's satisfaction on the estimated final construction cost and hence, the construction contract delivery. The factors considered in setting an arbitrary contingency should be tailored to the use of scientific methods of contingency estimation; the outcome of such would go a long way in assessing the performance in the construction industry. If percentage addition is to be used; a proper assessment of the project could indicate a prescribed percentage among those developed from scientific methods. The government establishment can also develop a scientific method of estimating contingency that can be used as a benchmark for effective performance of construction contingency, this is the practice in United Kingdom and Hong Kong.

Clark and Lorenzoni, 1985 defined contingency as "a specific provision of money or time in an estimate for undefined items which statistical studies of historical data have shown will likely be required." Therefore, any realistic contingency must serve as a basis for decision making concerning financial viability of the variations, and a baseline for their control (Akinsola, 1996). Touran, 2003b identified project size, type of construction, difference between low bid and owner's estimate among factors that affect project cost overrun. Project size, type of construction, type of client, method of procurement, percentage of design completed before tender, adequacy of information, and number of subcontractors used were identified by Akinsola, *et. al*, 1997.

In estimating for contingency, major project factors or variables considered are: project cost data and duration with their variabilities. It becomes more difficult to determine overall estimate reliability because some sections of a project may be completely defined at the time of estimate, and others only sketchily defined. Contingency estimation has been described as subjective and deterministic based on intuition (Moselhi, 1997; Hogg, 2003 and Baccarini, 2005).

A review of the existing literature on contingency sum estimation for construction projects revealed that there are a number of methods that have been proposed. The methods are primarily traditional algorithmic methods (Moselhi, 1997). Some of the methods are deterministic and others are probabilistic accomplished by either expert opinion or statistical methods.

The Lump sum Amount Allowance: Hogg, 2003 reported 'intuitive perception' as the most adopted method of assessing the amount of contingency whereby the consultant quantity surveyor allows a single figure for risk that reflects the overall perception of the project. Other researchers reported this method but Hogg, 2003 distinguished it from percentage addition in his findings.

Traditional Percentage Addition: This is a subjective method of percentage addition on the base estimate derived from intuition; gut feeling, past experience and historical data. This method has been described as "Crystal ball" (Moselhi, 1997); 'across-the-board' percentage addition (Baccarini, 2004). It has been considered arbitrary (Ahmad, 1992; Thompson and Perry 1992) and criticized by researchers. In fact, it is the criticism of this method that led to different methods and techniques proposed for contingency estimation as this method has several weaknesses (fully described in Thompson & Perry, 1992; Mak *et al*. 1998, Mak and Picken, 2000; Karlsen and Lereim, 2005). Generally, the contingency estimated with this approach ranges from 1 to 5 percent and rarely exceeds ten percent (Moselhi, 1997).

Cost Item Allocation: A contingency percentage is allocated to each cost item (Moselhi, 1997) in the work break down structure (Karlsen and Lereim, 2005) or several work packages (Ahmad, 1992) and the project overall contingency is then estimated as a weighted average. According to Ahmad (1992) each work package can be treated as a risk centre, and the amount of contingency to be allocated to each will be different.

Probabilistic Itemised Allocation: This method is similar to 'cost item allocation' method but it uses Pareto's law – known as the 80/20 rule that is the law of significant few and insignificant many (Moselhi, 1997). For the estimation of contingency, it means that 80% of the risk will be associated with 20% of the cost items and it examines closely each item being considered significantly and allocate for each item a probability value, rather than percentage contingency, for not exceeding its estimated cost. Touran (2003a) also developed a probabilistic model for the calculation of project cost contingency by considering the expected number of changes and the average cost of change orders.

Programme Evaluation Review and Technique (PERT): The method calls for some judgment about the probability density function, which describes each cost item as a random variable taking on values between its estimated lowest and highest costs. Yeo (1990) suggested using formulae similar to PERT according to a 5-95th percentile. Three estimates of cost are needed for each item being considered: lowest cost (optimistic), highest cost (pessimistic) and the most likely cost (modal value). The three estimates of cost can be made base on judgment and experience and or base on data collected from previous project.

PERT with modified variance: This is a direct probabilistic method like PERT but can model any correlation that may exist among the project cost items (Moselhi, 1997). Based on probability distribution used for each cost item, the mean of the project cost is the sum of those calculated for the individual items as in PERT and the variance of the project cost is calculated in a manner different from that used in PERT. Moselhi (1997) reported that this method is accurate and reliable.

Monte Carlo Simulation: The Monte Carlo technique is a process for developing data through the use of random number generator. This technique was developed a number of years ago and has become one of the most popular probabilistic risk analysis techniques (Smith, 1999). It was introduced as an improvement over and as an alternative to PERT (Moselhi, 1997). In this approach, a simulation model is created. The model is basically a cost breakdown structure (Karlsen & Lereim, 2005) or work package (Ahmad, 1992) where each cost item in the structure is a single point estimate.

3 Research Methodology

The research sample selected was guided by typical cases of a population that can provide the requisite data and information among professionals in the construction industry. Purposive sampling was used in selecting projects as the research intended to study only projects with a contract sum above USD 1million and on which the researcher was directly involved on from inception to handover. This was basically to ensure that accurate data is used in the research, as not many consultants in Uganda are willing to release this confidential information to non-project team members. The primary data for this study were obtained through structured questionnaire administered to experienced professional and practising quantity surveyors in majorly

Government/Public and Private consulting firms. This was in the bid to guide the respondents to providing direct answers that can finally explain in detail how the contingency sums are determined and how the cost overruns relate to the contingency sums allowed for on a project. Most of the organisations had projects across the country hence, were representative of, according to Asika (2005), what obtains in the entire population of the study.

Archived data was reviewed on ten projects handled by the author in the last 10 years of practice. These include a wide spectrum ranging from some of the biggest construction projects in the Industry with contract sums amounting to USD 65 million to multi storied commercial facilities. The benefit obtained in use of data where the author was part of the consultancy team was the fact that he saw the project from conception; preparation of the very first preliminary cost estimates, the engineer's estimate at tender and then the final contract sum obtained by competitive tender; involved in the supervision of the construction works and therefore able to track the trend of the estimated costs vis-à-vis the final cost on completion of the project.

The research methodology should clearly discuss the approach and/or the research design, data collection, and data analysis adapted or to be adapted in the research. One of the most important issues to be discussed here is the appropriateness of the selected methodology, i.e. the justification of why this particular methodology (consists of research approaches, tools, and so on), is the most appropriate choice compared to other alternatives. This is the opportunity for the authors to demonstrate their awareness and understanding (appropriate for the level of study) of the research tools commonly used in their field and how this knowledge is used to inform them in constructing a robust methodology to tackle the research problems/questions.

4 Findings and Discussion

The research established that the process of determining the cost of a Project in Uganda is done using a document called Bills of Quantities (BOQ). It is a document generated by the Quantity surveyors (QS) using detailed drawings from the Architects and Structural/civil Engineers showing detailed specifications of the Project in their respective specialties. Works in this document are divided into two major parts – the civil works and the Electrical mechanical (EM) works. The BOQ is made usually of 6 major components i.e. the Item or number or reference of a particular component of the works; the description of the works to be executed; the Unit of measure e.g. m, m², m³, kg etc; the Quantities as measured by the QS from the drawings; the Rate charged for the execution of one unit of measure; the cost which is the product of the rate and the quantity. In the BOQ all the works to be done on the Project are described in a systematic manner usually in the most likely order they should be logically executed i.e. starting with the foundations etc. It is meant to be a comprehensive document as it is used as a reference for the generation of any payment certificates for the Contractor during the execution stage of the Project.

Another vital component of the BOQ is what is known as the Contingencies. It is meant to cater for any unforeseen changes in the works as it is executed. They are spent only with the prior permission of the Architect. If not spent at the end of the Project this remains the Client's money. This is usually done as a percentage of the total derived cost of works. It is usually in the range of 5-12% of the cost of the Project. The cost of the Project is dependant on the Quantities amounts and their description. It should be

noted that in this method of determining cost the safeguard is in the use of a contingency sum. It is estimated that the contingency sum can be used to cater for any changes and variations in the project. In Uganda determining the amount or percentage required on the Project contingency is through the experience of the QS.

From the extensive literature review and the practical experience of the author, it was revealed that the unforeseen that the contingences are meant to cater for show up in a wide variety of ways and affect different parts of the Project. It is therefore not justified to give a summary contingency percentage on the overall as if all areas of the Project are affected the same way by the changes. Some changes are due to unforeseen site conditions like in Uganda the underground services are difficult to locate as there isn't an up-to-date services layout master plan for the City and yet there have been new lines laid in the last couple of years. This justified the researcher's approach to divide the building into several parts and then study independently the effects on these different parts during the execution of the Project.

The proposal is that the contingency sum of each of the parts should be embedded and made as a percentage of the individual portions and not of the final cost. This will have a cumulative effect on the total amount of contingency available on the Project and also allow for individual use of the said amount during the execution of the Project. It is agreed that different parts are affected but then another question arises affected to what extent so as to deem a high or low percentage of the contingences. The research revealed four major factors that affect the accuracy of the cost of a particular element of the construction works.

The practical work experience of the author revealed four major factors that determine the required contingency sum for particular elements of work of a project. Experience has it that the different works on the Project are designed and their quantities (volumes) can be ascertained with less effort than other works. For instance any works that are under the ground level are deemed to have a high level of uncertainty in defining the works and their quantities involved during the stage of tender especially if no detailed geotechnical investigations are made which the research revealed is the case on most projects in Uganda. This can be explained by the fact that these are specialised services and only few firms provide this service which leads to it being expensive. So the first parameter of measurement is *Level of uncertainty involved* on a particular set of works on the Project. The higher the level of uncertainty, the higher the required contingency percentage.

Research has revealed that one of the major holdbacks on the effectiveness of Tenders in Uganda is a result of incomplete drawings at tender stage. One Architect explained that design is an on-going process and so often continue even up to the execution stage of the Project. Notwithstanding the fact that this is true, not all parts of the building design are left uncompleted at tender stage. Here we derive the second parameter – possibility to have the design and detailing of that portion of the building completed, or in other words *the level of incompleteness of the part* at tender stage. If it is high then it calls for a higher contingency as it is bound to alter the quantities more during construction than other parts of the building.

A construction project is a rather complex assignment which is made of so many varied parts which should be clearly and in detail described to the contractor in order to ensure a clear understanding of the same and therefore give it a viable and corresponding rate while pricing for the works. It can be agreed that not all parts are of the same

complexity. The QS is meant to describe the parts in a clear and usual construction language. Many projects have had court cases due to the misunderstanding and therefore misinterpretations of the specifications of the different parts of the building. So the *level of difficulty to achieve clarity* of the works definition by the Architect and QS will definitely affect contingency sum required for the works.

Contingences are taken to be the safe haven to run to in case of any variations on the Project. Experience testifies that most contingences rarely cope with the level of changes made on a project and are therefore depleted even before the mid of a construction project time. Again it should be remembered that not all parts of the building are susceptible to variations to the same extent, and so it is not justified to have the same percentage of contingency attached to those parts. So the forth parameter is the *probability that a variation will occur to that part* of the building.

The next stage of the research reviewed the cost overruns for the ten projects worked on by the researcher to reveal first the contingency allowed for and second the final cost overrun attained at the end of the project. In Uganda the Building works particularly the new works are usually divided into *Sub-structure works (foundations and all works below the ground level); concrete frame and roofing; External and Internal walling; Openings (windows, doors, curtain walling etc); Finishes (internal & external); Electrical and Mechanical Installations*. Table 1 below shows the results received from the detailed review of the archived information.

Table 1. Cost overruns in percentage of the different building works to the Overall cost overrun
(Source: Author's findings)

Project no.	01	02	03	04	05	06	07	08	09	10	AV.

5 Conclusion and Further Research

The results from the table above give ground for a more practical approach to the management of Construction projects cost in Uganda. First analysis is made on all the areas that have HIGH as the rated index. These are the combinations of the type of effect that must have a thorough mechanism for monitoring of the Project Cost. For instance Finishes on the Building should be closely monitored by ensuring the following; The Architect developing a comprehensive schedule of finishes of the building early on in the Project; discuss and agree with the Client on the same so as to bring the effect of the index probability of variation into the range of Medium or even low, so as to save on the 12% contingency included in the Cost.

Because finishes have a high level of complexity and difficulty to describe, with the detailed schedule the QS will find it easier to describe the finishes better for the

contractor. A vital point here is the fact that the materials market for finishes is changing pretty fast, with better sometimes more cost effective in the long run coming onto the market. This leads the Client and even the architect to want to make a variation for the good of the Project. This justifies the 12% contingency sum of the cost of the finishes.

The proposed new method for determining the individual contingency sums of the various elements of the project needs when applied needs to be reviewed in the various circumstances surrounding each individual project. Further research should be made in revealing the most effective ways of managing the contingency included in the project cost.

Critical-Chain Project Management in Western Australia: Towards Construction Project Duration Reduction

Andrew Whyte¹ and Andrew Crew¹

¹ Dept. of Civil Engineering,
Curtin University, Perth, WA,
Australia

Email: andrew.whyte@curtin.edu.au

Abstract:

Given that one in three infrastructure projects in (Western) Australia were completed over-time, project management of the building process requires re-examination; Critical-Chain Project Management (CCPM) is presented as a way to address unsuccessful, over-time delivery of projects for the local construction industry. CCPM is an application of the Theory of Constraints to establish procedures to better manage human behaviour and more efficiently allocate resources required to complete tasks. CCPM is presented as a means to improve upon the Australian construction industry's more commonly used Critical Path Method. The research work described uses a qualitative methodology to assess the extent to which stakeholders in WA might be able to implement this alternative scheduling technique to incorporate risk assessment. Findings are presented which suggest that whilst industry appears resistant overall to the implementation of CCPM, utilisation of the technique may be suitable for disaster-mitigation community-asset-reinstatement.

Keywords:

critical-chain, project-management, civil-engineering/construction, Western-Australia.

1 Introduction

According to the Australian Constructors Association Report entitled 'Scope for Improvement', which surveyed over 200 industry professionals during 2005, one out of every three infrastructure projects in which the survey participants were associated with were completed over time (ACA, 2008). Western Australian (WA) professionals identified significant Liquidated Damages associated with projects conducted in their unique home-state (Western Australia is comparable in size to Western Europe, has a population of 2.3 million, with the world's most isolated mainland city, Perth).

This paper explores the possibility of using a new paradigm of project management, namely Critical Chain Project Management (CCPM), to address the problem of unsuccessful delivery of projects on time within the WA construction industry.

1.1 Critical Path Method (CPM)

Currently within the Australian construction industry Critical Path Method (CPM) is the most frequently used time-scheduling technique and is a mathematically based algorithm for scheduling a set of project activities. A CPM schedule is developed in the form of a graphical model known as a 'network', this network is a visual representation

of activities linked together in a logical sequence to create a map of relationships and dependencies between activities, and identifies the project's critical path/s (Uher, 2003). The project's Critical Path is defined as the longest chain of dependent activities, referred to as critical activities, whereby any delays in these critical activities will delay the entire project's schedule.

1.1.1 Shortcomings of the Critical Path Method

Advocates (Goldratt, 1997) of Critical Chain Project Management (CCPM) attribute a range of project failure rates to CPM's inability in dealing with three important factors:

Fundamental Project Uncertainties Causing Delays

Resource Dependencies Between Activities

Human Behavioural Factors

Project uncertainties are accounted for in CPM schedules through the allocation of contingency time to activities' duration estimates, based upon the planner's perception of risk to which the activity is exposed (Uher, 2003). It is recognised by CCPM supporters that planners will estimate according to their worst past experience of that activity type leading to excessive safety time being allocated, which in turn seldom motivates the performance of a respective project team (Goldratt, 1997). In addition it might be argued that the insertion of respective contingency time(s) into each activity's scheduled duration makes it very difficult for the project team to monitor project progress along the schedule. This can be argued to prevent the accurate estimation of a work path or project's expected completion date by the project team, unable to effectively intervene to accelerate progress in order to protect committed completion dates.

Efficient allocation of a project's committed resources is an important aspect of successful project management; however, CPM schedules do not largely require activity resource allocation. Omission of some resource dependencies is likely to result in unexpected delays, as activities await the resources required.

It is common within the WA construction industry for payments to be paid based on the achievement of milestone progress points. This form of progress measurement can be argued to result in an environment of somewhat short sighted project management, where the project team in an effort to appear successful push to achieve these milestone payments at the expense of other works. Although this form of progress measurement is not specifically required by CPM, CPM seldom provides any relevant guidance.

2 Critical Chain Project Management (CCPM)

Critical Chain Project Management (CCPM) is the application of the Theory of Constraints (ToC) to the project environment. CCPM establishes procedures and introduces techniques to plan and manage projects in any industry, attempting to better manage human behaviour and more efficiently allocate resources required to complete tasks. It is a structured way to increase project flexibility, allowing advances in the programme to be capitalised on and providing additional feedback loops for management to base intervention decisions upon.

2.1 Implementation of CCPM in Order to Minimise Project Durations

2.1.1 Cutting Estimated Task Durations

The first stage of CCPM is to address (effectively cut) the safety/contingency time from activity durations estimated within the project schedule. The amount of time to be trimmed from each activity duration estimate should reflect the amount of uncertainty embedded in its tasks. Goldratt argues for significant cuts to activity durations, suggesting in many cases opportunities for the halving of a 'reasonable' task duration estimated by an experienced scheduler using CPM (Goldratt, 1997). This proposed new expected duration is subsequently deemed to reflect the median safety-free duration of works, free of any inbuilt safety time allowing for delays which may occur. However contingency time remains required to deal with uncertainties and delays, in CCPM this time is installed into the programme in the form of buffer periods.

2.1.2 Buffer Period Installation and Management

There are three types' of buffer periods used in CCPM, as outlined below:

Project Buffer: half of the time cut from critical activities are compounded (summed together) and inserted into the schedule at the end of the Critical Chain. Goldratt argues that the estimated activity duration is to be cut by 50% and half of the time which has been removed is placed in the project buffer; meaning that the overall activity duration estimation calculation including safety time is approximately up to 75% of the original projected duration using traditional CPM scheduling methods.

Feeding Buffers: calculated using the same techniques as the Project Buffer above. The difference between Feeding and Project Buffers is that Feeding Buffers contain safety time for each non-critical work path opposed to the Critical Chain, inserted into the project schedule where the non-critical work path feeds into the Critical Chain; as such there is more than one Feeding Buffer within the project schedule, whilst there is only one Project Buffer.

Resource Buffer: unlike the Project and Feeding Buffers, it is not a summation of safety time to account for delays but rather a rouse (wake-up-call) in the form of a notice, given to the relevant subcontractor one week and again one day prior to a particular plant or personnel being required to undertake a critical activity. These Resource Buffers are inserted into the project network in the form of Resource Dependency arrows between activities. A requirement of CCPM project network development is that each activity is allocated the resources required for its completion, allowing resource allocation priorities to be developed.

Monitoring of the Project and Feeding Buffer's consumption is to be done on a regular basis (perhaps even daily) through routinely updating the project schedule, with delays in activity completion to be subtracted from its corresponding buffer. Once delays have been subtracted the buffers so-called Burn Rate requires to be calculated. The Burn Rate is defined as 'the ratio of the percentage of buffer consumed to the percentage of work completed along a particular work path' (Srinivasan, 2007). The Burn Rate acts as a feedback mechanism for the project team; once a work path produces a burn rate ≥ 1 , intervention is required from the project team to bring the work-path back on schedule to protect its expected completion date.

2.1.3 Updating Project Schedules

In order for buffers to be managed effectively CCPM advocates a significant increase in project progress reporting. Regular (ideally daily) on-site subcontractor supervisors will be required to submit a 'Subcontractor Daily Progress Report' or SDPR to a contractor representative, to update them on progress made on activities throughout the day and predict expected activity completion dates (Maylor, 2002). Based on the submitted SDPR each activity which is underway should be updated on the working project schedule to reflect the situation on-site. Once each schedule has been adjusted it is to be passed onto the project manager who is tasked to combine all work schedules into a summary schedule showing percentage progression of each work-path. Based on the projected dates, corrective action can be taken by the project management team to protect committed completion dates. CCPM also calls for an increased openness between the contractor and client, brought about by allowing the client access to this working schedule. Therefore once the schedule is updated it needs to be posted on a pre-agreed online forum to which the client and client's representative have access.

2.1.4 Monthly Progress and Cost Reports

Somewhat by definition no matter how quickly you complete non-critical activities the project cannot be completed any sooner than the time it takes to complete those which are critical. Therefore by measuring the progress of a project by its progression along the Critical Chain, a true estimate of progress can be made and payments made accordingly. CCPM calls for progress payments to be paid as a percentage of the total quoted price of the project based on the percentage of the Critical Chain completed (Goldratt, 1997). Therefore the Progress and Cost Report must include a detailed breakdown of Critical Chain activities and the progress that has been completed along it to date. The information required to ensure the accuracy of these monthly reports is to be taken from the updated schedules outlined above.

3 Assessing Opportunities for CCPM in WA

It was considered that enquiries into opportunities for utilisation of CCPM locally were best achieved by the use of the qualitative method of research. This method allowed analysis of the variables related to critical chain project management to be investigated in terms of understanding the circumstances in which study participants address issues in scheduling (Creswell, 2007).

Pilot study data collection occurred in the form of four semi-structured interviews with senior civil engineering project management professionals locally. Interview participants were identified using 'purposeful sampling' with a view for 'maximal variation' (Creswell, 2007). On this basis participants company profiles varied in size, nature (client/consultant/contractor) and sector (public/private). All participants were high-rank personnel with extensive knowledge of scheduling practices.

3.1 Late Project Completion in WA

From the responses given in the structured interviews, problems do exist within the WA construction industry in delivering projects on time. Time-blowouts were recorded on 25-50% of projects within the remit of the sample-group.

3.1.1 Establishing the Negative Financial Impact of Liquidated Damages

Three-quarters of the respondents had encountered the application of very harmful liquidated damages, which resulted in the contractor ultimately losing money on the project in all cases. The high level of harm caused by liquidated damages within the WA construction industry indicates a greater level of uncertainty than was contractually expected from the builder/contractor. CCPM advocates contractors and subcontractors to take on larger liquidated damages contractually, therefore exposing them to more risk, in exchange for larger profit margins. CCPM enables the project team to better understand and deal with delays by providing additional feedback loops, minimising uncertainty and making harmful liquidated damages less likely.

3.1.2 Establishing the Cost Competitiveness within the WA Construction Industry

The structured interviews identified that there is a general trend of cost competitiveness increasingly within the WA construction industry, especially in the lower tier building sector. For larger contracts the sample identified that competition is not placing significant downward pressure on profit margins within Western Australia. Since CCPM calls for large financial incentives for its implementation, large infrastructure projects would be most feasibly able to offer these incentives.

3.1.3 Establishing if the Milestone Progress Payment System is Affecting Negatively Project Durations

All project managers in the sample interviewed identify the practice of pushing for milestone payments at the expense of other works as common within the WA construction industry; however respondents deny doing it personally. This practice increases the risk of delayed works being neglected until they become critical and potentially delaying project completion.

3.1.4 Problems Due to an Increase in Activity Progress Reporting

As identified in the structured interviews, subcontractors within the WA construction industry independently allocate resources to their activities and job sites. This means that daily progress is not necessarily consistent, and generally subcontractors allocate resources only once an activity has become critical. Confirming the CCPM assumption that adding safety time to activity durations does not help in delivering projects, but rather that ‘an activity will expand to fill the time available’ (validating secondary research suggestions identified by Maylor (2002) et al). Without consistent progress or subcontractors being able to accurately predict the finishing dates of activities, the updated schedule will not help in planning future works.

3.1.5 Payment Based upon Critical Chain Progress

It was found that if payments are made based upon the progress along the Critical Path, the cost of works to the contractor will not correspond to the value of work. Meaning in some cases that the contractor will need to pay more than they are expected to earn for the works, especially in a ‘services heavy’ project, these costs could bankrupt smaller contractors. If however finance was obtained by the contractor, all additional costs due to interest owed, would most likely be passed onto the client and result in the cost of the project to increase. It was also confirmed through the structured interviews that contractors aim to make additional funds by remaining cash-positive throughout the project and reinvesting this additional money. It was identified by both Senior Project Managers and Contracts Administrators interviewed, that any cash flow problems experienced by the contractor due to insufficient payments from the client, would result

in delayed or withheld payments to subcontractors and suppliers, which could impact very negatively upon cash-flows or indeed prevent them agreeing to participate in CCPM projects. Another problem related to systems of payment was the ability to incorporate any change in scope or change in Critical Chain/Path (notwithstanding contractual claims mechanisms); argued by the sample as leading to a delay in payments to the contractor which will be passed onto subcontractors and suppliers.

3.1.6 Reduced Activity Duration Estimation

Accurately estimating durations to reflect the safety-free median activity durations was described by sample project managers interviewed as a 'major resourcing issue'. Yet all also recognise that Target Programmes, developed by contractor representatives and used on-site to drive subcontractor performance, estimate 'unrealistic activity durations' which assume 'a best case scenario' (much like the activity durations called for in CCPM); however it was also recognised during the interviews that if CCPM installs larger liquidated damages into subcontracts, the high level of subcontractor interdependence and interfacing will significantly increase the risk to subcontractors, making them less likely to contractually commit to CCPM projects. Further research into the installation of liquidated damages within CCPM contracts is recognised as an area for further research.

3.1.7 An Increase in Staff and Plant Idleness

The structured interviews identified that 'starting non-critical activities earlier than required in order to keep resources onsite and absorb excess capacity' as a common practice in the WA construction industry. Yet CCPM calls for a structured progression through the schedule in an effort to complete works sequentially and prevent multi-tasking. Discipline will be required by the contractor not to push ahead with future works if the required management resources are not available to the contractor on-site, requiring an understanding and belief in the ideals of CCPM brought about through the continual training of the contractor's project team.

3.1.8 Training Required

For a contractor to implement CCPM, significant continual investment will have to be made in training of staff members and auditing procedures. This investment in people poses significant problems due to the relatively high staff turnover experienced in the WA construction industry as identified through the structured interviews. In the Australian construction industry during the year 2002 there was a 13% mobility rate within the industry and 4% exit rate from the industry (CSRM, 2003), where a mobility rate refers to employees leaving one company for another within the construction industry.

3.2 Aspects of CCPM already in use in the WA Construction Industry

3.2.1 Target Programmes

The Project Programme generally will have much contingency time installed into it since programmers often have a less than clear understanding of the project constraints, site conditions, activity methodologies and other details specific to the project being undertaken. Therefore contractors develop their own programmes which take into account many of these previously unknown variables. These more accurate Target Programmes assume a best-case-scenario, as expressed in the structured interviews, meaning contingency time is not installed into the (updated) activity duration estimates.

This means that the Target Programme is the contractor's version of a CCPM programme without the installation of buffers. The purpose of these Target Programmes is to accelerate subcontractor performance by setting 'unrealistic activity durations', therefore subcontractors constantly believe they are running late. However the development of these Target Programmes is individual to each project manager with the time cut dependent on their unique perception and experiences of uncertainty. Instead of buffers being installed and managed in a structured way, contingency time is cut from the schedule and it is hoped that the difference between the Target Programme and Project Programme will account for uncertainties and delays. The problem with this method of management is that the criticality of each delay is not identified by the project team, and thus the effect that each has on the project completion is not fully understood or appreciated by stakeholders.

3.2.2 Subcontractors Committing to Approximate Start Dates

CCPM calls for subcontractors to commence activities directly after the completion of the preceding activity, and as such has been compared to a baton-relay-race (Maylor, 2002). This requires subcontractors to commit to durations for works rather than set dates, and also requires them to commence works upon instruction. The practice of giving subcontractors rough starting dates to begin works is identified through the interviews as common within the WA construction industry; whereby the Project Programme is recognised as guide only and dates are generally confirmed during meetings closer to the commencement date.

4 Conclusions: Opportunities to Reduce project Durations in WA

Given perceived logistical problems with CCPM implementation and the lack of competition within the industry, the investment required to successfully implement CCPM would significantly outway the potential benefits provided by CCPM in securing tenders and increasing profit margins for a construction contractor within the WA construction industry. However partial implementation of CCPM techniques in the development and management of Target Programmes as outlined above will increase the control of these programmes, through providing a framework in which to establish activity durations, monitor progress and manage buffer periods. Additionally in the case that the economic climate within the WA construction industry worsens significantly, CCPM implementation would become more feasible, providing an alternative to the client in a highly competitive environment.

4.1 Clients with Multiple Projects Running Simultaneously

CCPM seeks to provide the client with the up-to-date working schedule as discussed above, which shows the impact of delays in responding to contractor questions on the project's overall duration through a colour coordinated buffer management system. In the case of a client with multiple construction projects running simultaneously, as generally is the case for the government's public works department, this ability of CCPM to give the client an easily recognisable feedback loop in which to prioritise decisions could provide significant benefits in reducing delays experienced by all projects.

4.1.1 Projects with a Known Amount of Resources

Inconsistent resource allocation, as is argued generally by respondents to be the case within the WA construction industry, means regular monitoring of progress is unlikely

to give an accurate feedback mechanism to judge progress and estimate completion dates. Monitoring, ideally daily, might be argued to elicit pre-emptive action on behalf of the project management team, potentially causing delays and straining relations between the two parties. Therefore projects with a known amount of resources, such as infrastructure projects or on building contracts where no sections of work are subcontracted, would be two project types most able feasibly to utilise CCPM monitoring and buffer management techniques.

4.1.2 Projects with Relatively Large Liquidated Damages

The changes necessary for a contractor to undertake /implement CCPM, requires a lot of time, investment and understanding to be successful. In order to make this large level of investment feasible, sufficient financial incentive needs to be provided contractually by the client based upon the real cost to the client whilst the infrastructure is not operational. Therefore projects with relatively large liquidated damages are best suited to CCPM, as they are better able to provide the large financial incentives and bonuses required to make CCPM implementation financially viable.

4.2 Industry Conditions Suited to CCPM Implementation

4.2.1 High Level of Competition

By implementing CCPM and advertising its potential benefits in reducing project completion durations, contractors offer an alternative to the client, with an estimated project completion date significantly shorter than that offered by traditional CPM. It might be argued that this shorter duration is likely to be balanced by a somewhat higher project price. In the case of a significant increase in industry competition for projects, (private sector market-troughs perhaps) this alternative scheduling tool and the investment required for it, might prove viable for consideration/implementation.

4.2.2 Emergency Relief

In an emergency situation shortening project durations becomes the primary project success criteria in order to minimise impact by restoring vital infrastructure. It can also be assumed that the maximum amount of resources available will be utilised, therefore the resource pool is known. Both these conditions make emergency relief construction works (and perhaps more pertinently, the somewhat longer-term re-establishment of essential residential and community amenities) well suited perhaps to CCPM techniques (notwithstanding the requirement to understand/apply the underlying ethos). Higher contractor profit margins might realistically perhaps be balanced with political and humanitarian incentives in delivering and completing projects as quickly as possible. It might be argued that any organisation predisposed to, and experienced in, emergency relief construction works could potentially benefit most from the implementation and offer of works scheduled by CCPM.

5 Recommendations

Full implementation of the Critical Chain Project Management scheduling tool is not recommended generally for the currently buoyant WA construction and civil engineering industry; however, it can be argued that Target Programmes used onsite might indeed benefit from development and management according to CCPM principals. Development of such Target Programmes, including activity duration estimations and resource dependencies in accordance with CCPM techniques, whilst

requiring additional reporting of progress through Subcontractor regular/Daily Progress Reports and complementary contractor schedule management, can be argued as being potentially advantageous; programme scheduling might be addressed explicitly, towards mutual benefit, within local standard forms of construction contract, such as clause 32 of Australian Standards (AS) 4000. Similarly opportunities may exist for stakeholders associated with disaster mitigation and related community re-establishment projects to gain from an implementation of CCPM techniques (and its incorporation into selection criteria for awarding such re-construction contracts), to address/reduce project duration/delivery times.

Abstract:

Suggestion systems have been used by organisations for centuries to elicit employee ideas and improve organisational performance. They have started gaining popularity in the middle-east in the last decade. This paper presents an analysis of different challenges associated with implementing suggestion systems in the Middle-east construction sector. Among the major issues highlighted that affect the implementation are high upfront cost and lack of lifecycle costing models, varying educational levels of employees, high employee turnover, different expectations for rewards and need for detailed feedback.

Keywords:

suggestion systems, idea management, and innovation

1 Introduction

Competition in today's business environment is so fierce that companies are recognizing innovations and creativity by its workers as an important element in sustaining competitive advantages. By having more innovations companies can find new ways to optimize how work is done and reduce cost and can bring new products to market and more profit to the shareholders. Many organizations have means to collect workers ideas from the classical suggestion box to state-of-the-art IT systems. Nevertheless, organizations (and suggestion systems) can be different but a common issue effecting suggestion systems is how to make them work effectively. This paper elaborates on the idea of employee suggestion system and discusses some major challenges in implementing them in construction organisations in the middle-east.

2 Background

Creativity is a fundamental human capability found to some extent in everyone (Fairbank and Williams, 2001). However, in a civilized society, people themselves need to volunteer ideas, it cannot be forced out of them in distress (Pluskowski, 2002). Suggestion systems primarily consist of administrative procedures and infrastructure for collecting, judging and compensating ideas, which are conceived by employees of the organization (Van Dijk and Van Den Ende, 2002). In addition, suggestion systems have

the capability of being all inclusive by being able to focus on capturing ideas from all workers, working in a range of professions (Fairbank and Williams, 2001).

Suggestion systems are not new at all. In 1721 Yoshimune Tokugawa, the 8th Shogun, placed a box called “Meyasubako” at the entrance of the Edo Castle for written suggestions from his subjects. Although the mechanism and associated rewards of this suggestion system are not known, it is one of the earliest ever known suggestion systems. The first industrial suggestion system known to us is the one established by William Denny in his shipyard in Glasgow in the year 1880 (Dickinson, 1932). Research in the area of suggestion systems is also not new, as one of the references found in the review of literature is Dickinson, which was published as far back as 1932. People have analyzed different aspects of suggestion systems, their success factors and barriers. We have come a long way from the days of suggestion boxes to sophisticated computer-based suggestion systems. Nevertheless, irrespective of the difference in types, and technological complexities of suggestion systems, one common issue affecting them is how to make them work effectively. However, for these suggestion systems to work effectively, they should attract sufficient numbers of suggestions. Research indicates that several suggestion systems fail to attract sufficient participation (Fairbank and Williams, 2001; Dijk and Ende, 2002; and Turrell, 2002).

The following section presents the review of literature in the area of suggestion system lifecycle and the drivers for suggestion systems. It is followed by a section on challenges faced by companies in the middle-east in implementing suggestion systems and is followed by a section on conclusions.

3 3 Literature Review

3.1 3.1 Suggestion System Life Cycle

Frese et al (1999) have highlighted three process variables that are deemed to be important while making a suggestion system work. The first one is the process of having ideas. The second one is a mechanism and associated administrative processes for submission of ideas. The third one is the feedback and associated reward in order to encourage high quality ideas to be submitted. As Grant and Ashford (2008) suggest “The key criterion for identifying proactive behavior is not whether it is in-role or extra-role, but rather whether the employee anticipates, plans for, and attempts to create a future outcome that has an impact on the self or environment”. This impact they are referring to could be the impact on the work environment in terms of the value that is generated or it could be the impact on the job prospect and the associated reward and recognition for himself/herself. Suggestion systems establish formal procedures to actively solicit voluntary value added ideas from employees (Verworn, 2009). This process promotes continuous improvement, and enables the whole workforce to develop ideas instead of relying on a handful of specialists (Fairbank et al, 2003; Verworn, 2009). Suggestion system exploits the reservoir of ideas in employees that would otherwise remain dormant in the absence of this system. These ideas that the employees come up with could be either a recombination of existing materials or an introduction of new materials to the organization (Baer et al, 2003). There are three important elements of suggestion systems as specified by Robinson and Schroeder (2004); the first one is the actual submission of suggestions and ideas by the employees. The second major element is the process of evaluating the suggestion for the value they generate, the process followed and the amount of transparency. The third major element is the

evaluation of reward and communication of the feedback. For the whole suggestion system to be successful, it is important that all three of these elements be analyzed.

The process of submission of suggestion encompasses the publicity and solicitation process for ideas, making them document and submit it, and also helping them make a case for the amount of value added by the implementation of the idea. So it all starts with the promotion of employee innovation. The innovation here is more of interactive process perspective, (Edwards, 2000) where we are consider innovation activities as an interaction between individual determinants and organizational characteristics (Lee et al, 2006). Therefore, in order to generate valuable ideas from individuals it is important that organisations form a support system that encourages employee innovation and submission of more suggestions (Recht and Wilderom, 1998). It is also important in the case of suggestion system to consider attribution theory. Attribution theory states that

“a person who perceives the cause of success for a task to be out of his/her control may lose motivation to perform the task” (Hultgren, 2008). Through soliciting these suggestions, the point of attribution theory is reinforced and employees feel that their suggestions contribute to the success of their organisations which is a big boost to their confidence and sense of being.

The second major element in a suggestion system lifecycle is the process followed. Hultgren (2008) lists some key variables that affect the overall success of the suggestion systems and most of them are related to this part of the cycle. The variables are: simplicity of submission, evaluation and reward system, evaluation bias/unbias-ness, feedback quality and promptness, ability to monitor progress, rapid evaluation and a safe environment that does not penalize the employee for rejected suggestions.

The third element of a suggestion system is the reward and feedback. The rewards of suggestion system and the perceived value could be both financial and non-financial. Imai (1986) established almost two and a half decades ago that there is a debate of culture when it comes what works in terms of value and reward. American suggestion systems were very financially-driven, they stressed on economic benefits and provided monetary rewards; whereas the Japanese stressed the morale-boosting benefits of positive employee participation (Recht and Wildrom, 2008). The impact of financial regard and they being not one of the key drivers was further highlighted by Robinson and Schroeder (2004). However, what is important is to have some sort of reward mechanism that is transparent and acts as motivator. The reward could be merely recognition (Robinson and Schroeder, 2004).

3.2 Suggestion System Drivers

Creativity is basic human capability (Fairbank and Williams, 2001), However, ideas cannot be forced out of people, they need to be volunteered (Pluskowski, 2002). Employee Suggestion System which can be defined as administrative procedure for collection, judging and compensating ideas, which are conceived by employees of the organization (Van Dijk and Van Den Ende, 2002). In addition, suggestion systems are systematic and should focuses on capturing ideas from all workers, not just ideas from identified few smart workers (Fairbank and Williams, 2001). An average benefit of 13 \$ for every 1 \$ spent on the system administration (including rewards) was identified (Shair, 1993). Also it is estimated that net savings of over 7000 \$ are collected on average from every idea (Verespej, 1992). Suggestion systems were used since the sixteenth century in the British navy to stimulate workers to provide their ideas (Turrell,

2002). Since that date the concept of suggestion systems has matured toward what is called idea management. Idea management is concerned with collecting “focused” business ideas, developing them and measuring performance (Turrell, 2002).

Many studies that evaluated the success of suggestion systems revealed that encouraging workers to share their ideas through the suggestion system was a common difficulty. Fairbank and Williams (2001) noted that motivating participation is common weakness in suggestion systems. In addition, a Research Study conducted with 50 companies in the UK between 1996 and 1998 found that the majority of programs failed to meet initial expectations (Turrell, 2002).

A large amount of literature is available on the role of work environments to encourage and enhance creativity, the aim here is to try to link this general literature to how organizational support can help workers use suggestion systems more often. As the subject of environment support is very wide, focus will be on the role of supervisors and colleagues to enhance system usability because of their importance. It is well established that management interest in employee suggestion system is very important in its success (Farnham, 1994). However, ability to recognize and exploit creativity is a primary challenge confronting today’s managers (Hamel 2000). In addition, having senior management chair evaluation committees can comfort workers that evaluation is going to be fair (Fairbank and Williams, 2001).

One of the most famous studies on the field of creativity, which is often cited in research relating to the subject, is that done by Harvard Business School professor Teresa M. Amabile where for over 30 years she was mainly focused on the role of work environment on creativity. Her work, without going into much details, support our model in that both supervisor and work group support are very important factors for workers creativity (Amabile et al 1996). Many other researchers also identified that organizational climate has much effect on innovation where supervisors are key players in it (Abbey and Dickson, 1983). The evidence of the importance of supervisors (and management) support is explained by Cherry Hudson (2004) when he said “Programs lacking good management support will exist, but will not thrive”. Supervisors must realize that they can create a work climate where it acts as a source of pressure for directing workers toward using the suggestion system (Pritchard and Karasick, 1973). Supervisors through their hierarchical rank in companies can orient workers toward creativity and using suggestion systems. Supervisors have many means to influence workers like frequently reminding them in group meetings and recognizing those who submit ideas. Supervisors should also try to establish good relationships with their subordinates as Basu and Green (1997) suggest that a positive leader-member relationship enhances exchange and *innovative* behavior. Negative attitudes and prejudices towards workers can severely reduce system usage (Wilms et al. 1994). Frese, et al (1999) Suggest that supervisors can encourage participation by removing hindrance and encouraging participation. Supervisors can control many hindrances because in many suggestion systems they have considerable power as they act as an initial filter for ideas and can influence the committee decision of accepting it. As mentioned above, it can be summarized that supervisors can enhance system usability because they can encourage the worker to hand in suggestions (Oldham and Cummings, 1996). A life example of the positive role of work environment on increasing participation is found in many Japanese work environments, where environment is a key element as to why some Japanese suggestion systems have much higher participation rate than the American ones. In many Japanese systems a sense of belonging and

shared fate fosters employee commitment; consequently, they are willing to interchange knowledge without restrictions (Recht and Wilderom, 1998).

Support of colleagues and work group is also an important factor in increasing system usability. Rogers (1954) suggested that the cohesiveness of a work group determines the degree to which individuals believe that they can introduce ideas without personal censure. Others have suggested that collaborative effort among peers is crucial to idea generation (Amabile et al, 1996). Participation can increase because workers can compete on who raises more suggestions. In addition, work mates can help new comers and first time users to use the suggestion system. Also discussions of ideas can take place where premature ideas can be enhanced and workers can be encouraged to submit their ideas. Also by collaboration workers are more exposed to creative ideas, which can lead to “set workers mind” to think creative (Amabile, et al, 1996).

There is not much literature that focused on the suggestion system ease of use. No researchers advocate the use of IT based systems to make suggestion systems easy (Turrell, 2002; van Dijk and Van den Ende, 2002). However, IT systems do have limitations particularly at the first stage when entering data is required. Not everybody is comfortable in using an IT application especially older people. Also accessibility is important where the system should be made available for all workers including contractors and even visitors. Accessibility can be enhanced by distributing suggestion forms in strategic locations around an organizational location like the employees cafeteria. Having the forms displayed in, holders can actually stimulate workers “and remind” them to generate ideas. If an IT suggestion system is used, workstations can also be distributed to allow workers with no computers to participate (and can be made easy like the informational touch screen PCs found at airports). Accessibility can also cover how easy it is to hand in a suggestion where a requirement of attendance in person can hinder participation and the ability to send suggestions by mail should be available.

Rewards to increase participation has been and still is a key element in suggestion systems. The majority of research on the subject supports that financial prizes are not very important (when compared to intrinsic motivators) in improving participation in suggestion systems (Fairbank and Williams, 2000). Motivation can be separated into extrinsic rewards like bonuses and gifts or intrinsic motivations which arise from performing the task itself. Intrinsic motivation is the drive to perform a task for its own sake rather than for any external reward received in exchange for performing the. Frese et al, (1999) found in their experiments that the motive to get a reward was only slightly related to submitting ideas and suggested that companies should not attempt to increase participation in suggestion systems by paying more money. Also, comparing large and small companies, Carrier (1998) found that even that incentives are 10 times higher in large companies; the results are not better than small companies. In addition, while in the US the average payment awarded through suggestion systems was US \$ 602; in Japan it was only a mere US\$ 2.20 (Recht and Wilderom, 1998). This huge difference in prize amount did not translate into a higher suggestion participation in the US companies which received around 1% of the number received by Japanese companies (Van Dijk and van den Ende, 2002). Convincing evidence shows that the reliance on extrinsic motivation limits participation to typically 10-15 percent of the employees, as opposed to 70-80 percent when no reward systems is used, or when recognition is kept to a symbolic level. (Stenmark, 2000). Another disadvantage of financial reward is that it makes people focus on the financial compensation rather than on being truly creative,

and it also makes people more reluctant to share ideas or seeds for ideas with others (Stenmark, 2000).

Rewards must be scrutinized to ensure that they promote extrinsic motivation without extinguishing intrinsic motivation (Fairbank, 2003). Stopping extrinsic motivators like money prizes can lead to user dissatisfaction. Fairbank, (2003) explains that while intrinsic motivation elicits and promotes the generation of creative ideas, it may be much less effective than extrinsic motivation at encouraging employees to go to the effort to actually submit their ideas. It should be noted that rewards will only motivate behavior if the rewards are valued by workers. Different prizes can be offered so that workers select prizes that suit them best. Rewards can be even used to foster collective ideas where a reward can be spent on the group for a joint activity (Recht and Wilderom, 1998).

An important element in the success of suggestion systems is to give timely and detailed feedback to workers on their suggestions. To improve participation, the organizational culture must offer a safe environment in asking for feedback to avoid sense of failure (Fairbank and Williams, 2001). If feedback is not received, workers will not know if their suggestions were accepted or just ignored. Long waiting causes frustration and can reduce usability because when time passes, the worker's enthusiasm for the suggestion will drop and he / she might not participate again. Turrell (2002) identifies that many companies have a backlog of suggestions of more than a year and suggests using a web-based system to collect ideas and speed the process of feedback. Responding to suggestions will be difficult if the company does not align its policies and mission statement with encouraging creativity because of the time needed to be devoted for providing feedback. Linking feedback to intrinsic motivation, Hackman and Oldham (1976) suggested that workers would look do for doing activities that provide feedback. In addition, jobs that provide feedback can promote creativity (Fairbank et al, 2003). Thus, if the feedback of the system is structured effectively (like publishing good feedback or putting them on a special certificate) usability will be increased because workers can attain satisfaction from the feedback and the way it was administered.

If negative feedback should be given (i.e. idea can not be implemented), careful management is essential (Fairbank et al, 2003). If feedback is viewed as criticism, it can reduce creativity, but if it is given as information, it can be used to improve the quality of the creative output (Amabile et al, 1996). The speed of feedback can be improved by using a web-based system where feedback can be viewed immediately after it is posted. A web-based system can also help tracking the suggestion and also post suggestion and feedback online which can increase usability and group participation. Also fast feedback can improve perceptions of management support (Axtell, 2000) and workers will believe that the organization treats suggestions adequately and fairly (Frese, 1999).

To provide prompt and reasonable feedback suggestions evaluation should be done by a committee with different disciplines (Fairbank and Williams, 2001). The committee members have the duty to be transparent and provide clear feedback on suggestions, which can remove the mystery surrounding the process and might reduce the perception that the process is political (Fairbank et al, 2003). If the members of the committee are not selected carefully, some good ideas may be prematurely rejected due to the

committee's limited cognitive capacity, the proposal's poor communication skills, bad timing, or being proposed in the wrong context (Stenmark, 2000).

Scope defines what kind of ideas an organization is seeking from its workers. Ideas can be either big or small and participation can be open to all workers and contractors or just restricted to R & D divisions. Van Dijk and van den Ende (2002) define the scope as the net that the company throws to collect ideas. Having a big net by widening the scope will happen only with small ideas (Stenmark, 2000; Turrell, 2002). Robinson and Schroeder (2004) are big promoters of small ideas and they claim that it is impossible to achieve excellence without the ability to pay attention to details which come with small ideas. Also small ideas are important in suggestion systems because they are usually situation-specific and can not be copied by competitors, so they improve competitive advantage more than big ideas which can be easily identified and copied (Robinson and Schroeder, 2004). Small ideas can accumulate overtime and open the door for big ideas especially if they were open for discussion, where they can trigger other workers to build on them to achieve even better improvements. Widening the scope to include small ideas can improve (and increase) usability because logically, on average, people have more small ideas than big ones and thus the flow of ideas to the system should be more. By encouraging small ideas the suggestion system make advertisement for itself similar to a department store doing discounts, where the price limit is set lower and thus more people are able to buy (participate). On the other hand, if the suggestion system scope only focuses on radical and big ideas, many people will be excluded especially blue-collars. This is not suggesting that blue-collars can not have radical ideas but, for example, if a chemical plant wants only improvement in the chemical process, many people would be excluded instantly like HR, finance and many laborers because the area requires specific academic background plus experience. A well documented evidence of the role of small ideas to enhance system participation is in the performance of many Japanese suggestion systems which emphasize small ideas compared to the US companies which look for big and radical ideas (Recht and Wilderom, 1998).

Another support for small ideas comes from Axtell, et al (2000) who studied the contribution of shop floor suggestion systems for workers and suggests that lower level employees are much more likely to be able to contribute in this domain (i.e. small ideas) than to come up with radical new ideas. The more responsible the workers feel about their work, the more they take of charge of change (Axtell, et al, 2000). Responsibility can be linked to small ideas because the majority of workers in any company have specific jobs and don't often look at the larger company picture like managers. This suggests that the workers feel more responsible about their specific areas and usually small ideas are the only ideas that cover that area.

Van Dijk and Van Den Ende (2002) suggest that high accessibility and a broad scope will cause a sudden and sharp increase in the number of suggestions that will have negative feedback. As the number increases, the feedback will be slower. They recommend having dedicated workers to avoid this negative relationship.

Small ideas can affect another element in our usability model which is the satisfactory experience. Small ideas are most likely to be implemented fast, and so workers can see their ideas in reality which will encourage them to generate even more ideas because they can witness the system working and their confidence in the system increases.

4 Challenges Faced By Middle-East Construction Organisations

There are several challenges faced by construction organisations in the Middle-east in implementing these suggestion systems. The first one is the amount of resources needed to develop and administer the system. In order to operationalise an effective suggestion system, it is important to have dedicated people, systems and processes in place. It can be argued that the return from a suggestion system will pay for itself in the long run, but still there is an upfront cost associated with starting the system and it may take a few years to start delivering results. Since a majority of construction companies operating in the region are SMEs, it is difficult for them to justify the initial cost and start a suggestion system. Lack of accurate lifecycle costing models also is a problem in making a case to implement a suggestion system.

The second problem is the educational level of workforce. Most of the construction labourers are from the Indian subcontinent, who do not know how to read or write. This creates a problem because someone actually has to sit with them and write down their ideas on a piece of paper or feed it into a computer system. With limited education, it is entirely possible that these individuals might think they have a good idea but since they have a limited outlook on operations of the company, they might not be able to make a business case to support their ideas. Their ideas might be too crude and a significant refinement and investment of resources might be needed to make a case. On the other hand the same company might also have highly educated employees involved in design, engineering and project management who would be more articulate in expressing their ideas. These employees would be very comfortable with computers and would be easily able to express their ideas in an IT- based system. Therefore, a company will have to create multiple channels for entry of the data that can accommodate both the workers on construction sites and their more educated colleagues. This will again result in a higher cost for the system.

Another issue is the high turnover of employees. Most of the companies in the middle-east face the problem of high turnover. Most employees do not last long enough in a company to actually settle down and think of creative ways to improve their jobs. But it is possible that the high turnover of employees can be reduced if employees feel that their ideas are being used in the organisation and they are a more integral part of the success of the organisation. This can be done by implementing suggestion system. High turnover also means that employees bring ideas from other organisations into their new organisations. These ideas about different ways of operating can actually be used by their new organisation to develop new capabilities and enhance efficiency. So suggestion systems can actually provide a forum to bring external ideas into the organisation and explore new ways of doing work for the organisation.

One more significant issues is the reward system and mechanisms. A discussion on extrinsic and intrinsic motivational factors has been presented earlier. In the case of middle-east construction organisations, both of them are important. Most of the laborers in middle-east construction are paid very low wages, and therefore for them extrinsic reward in the form of cash would be highly motivating. However, cash rewards are usually based on the proportion of benefit delivered by the idea. The ability to measure long term financial benefit for project based organisations is difficult. One mechanism could be just a fixed reward for good ideas irrespective of the returns. For people in the middle and senior management intrinsic rewards might be more motivating. Recognition would be a better reward. Therefore, the suggestion system needs to have multiple types of reward mechanisms for ideas depending on the type of employees.

One issue that has been mentioned in the literature review is feedback. The feedback cannot just be an “accept or reject” process. It needs to recognise that the idea evaluation and feedback is an iterative process. The first idea might not be implementable, but a second or third step refinement might result in a much better and implementable idea. This would mean that the idea evaluation process is comprehensive and provides detailed feedback on how improvements can be achieved either for that idea or in future ideas. This again implies a wider involvement of people from different departments in order to comprehensively analyze and assess ideas which translates into higher resource commitments by the organisation.

5 Conclusions

This paper discussed suggestion systems, their life-cycle and the major drivers that lead to their success. This chapter also highlighted some of the major issues with implementing suggestion systems by construction organisations in the middle-east. The first issue was the resource commitment in starting and managing a suggestion system effectively. Lack of accurate lifecycle costing models and a higher upfront cost is definitely big barriers for organisations who want to implement suggestion system. The second issue was the educational level of employees. In most construction organisations there are laborers who are not educated and who cannot even read or write, and then there are people in management positions who are quite dextrous in using all kinds of computer systems. The suggestion system needs to provide appropriate mechanisms to elicit and gather ideas from both types of employees. This would mean someone actually going to construction sites and sitting down with employees who have ideas, noting them down and submitting on their behalf. For more educated employees there needs to be an easy to use computer based system that they can use to submit the idea. This multi-channel system will also translate into a higher cost for the companies.

Construction organisations in the middle-east also have a high employee turnover. This means that employees don't work with an organisation long enough to actually proactively start engaging in process improvement. On the other hand, this can also be viewed as an opportunity to elicit ideas that they have brought into the organisation from outside.

Reward systems and differences in expectations between management level employees and laborers have been regarded as another significant issue that needs to be addressed by organisations implementing suggestion systems. The reward has to be extrinsic for site labours and intrinsic for management level employees. This dual reward system is needed for successful implementation of the suggestion system. The last issue that was discussed was the need for detailed feedback. The system should help the employees improve their ideas and work with them to make sure that good ideas can be implemented.

Using a Process Framework for Large Developments

Dr Richard Moore

Anglia Ruskin University (University of Queensland)

Email: richard.moore@anglia.ac.uk

Abstract:

The possible translation of large mixed-use precinct delivery processes and their assessment into a conjectural integrated management, planning and design framework is a major goal. Due in part to the improvements sought in the ecological performance of the Development Industry. If these are to be achieved process based outcomes in particular are crucial to the Industry given its fragmented structure. The framework needs to help clients, stakeholders and professional advisors particularly managers achieve a range of integrating objectives linked to increasing pressures not least those arising from sustainability demands. With an optimum integrative delivery framework a more rigorous and innovative route map based on whole systems, approach results better places developers and managers when determining how best to delivery project goals, aims and objectives within a sustainable development agenda. This will aid in achieving reductions in pre planning timescales and give greater certainty in actual performance delivery and outcomes. The paper provides an overview of a contextual framework that evolved out of the interrogation and evaluation of the process and outcomes of several large mixed-use precinct case studies. Crucially its engagement aligned with developments that were undertaking a sustainable development assessment of their planning, design and operational management outcomes by an internationally recognised independent assessment process.

Keywords:

assessment, certification, framework, integration and process,

1 Introduction

The translation of mixed-use precinct delivery processes and assessments into a conjectural integrated management, planning and design framework is a major goal. If improvement in ecological performance outcomes is to be achieved an integrative process is crucial to the Development Industry given its fragmented structure. The framework needs to help clients, stakeholders and professional advisors particularly managers achieve a range of coalesced objectives (Emmitt, 2010) linked to increasing pressures not least those arising from sustainability demands. By building this optimum delivery framework a more rigorous and innovative development route map based on a 'Whole Systems Approach' (Stasinopoulos, et al., 2009) for mixed use precincts can be proffered. This should better place developers and their process managers when determining how best to deliver a project's own goals, aims and objectives within a sustainable development agenda. It will aid in achieving reductions in pre planning timescales and give greater certainty in actual performance delivery and outcomes.

It is a prime consideration that the principles of sustainability allow early identification of opportunities and constraints. Clearly statutory authorities require land and property

developers to address the issue of (and ensure) the protection of social, economic and ecological environments when submitting supporting material for development applications. How and in what form they do this is paramount. The notion that meaningful assessment undertaken at an early stage minimises the risks associated with inadequate consideration of social, economic and environmental values is crucial. It also provides the possibility of ensuring sustainable development outcomes whilst still achieving particularised project objectives.

Any framework must be applicable, comprehensive and independent regarding the whole of a project delivery process. Without this, it will not be effective in assuring compliance with local and international legislative requirements and called for corporate social responsibility imperatives. If these factors alone were not met, it would be unable to provide independent conformity via auditing and certification of sustainability and associated environmental risk mitigation for all stakeholders. Such failure will also mean that those opportunities such as the saving of costs by expediting planning approvals and embedding cost effective green design criteria in the projects would be lost as well. This is because when seeking to achieve ongoing uniformity and consistency of environmental and broader sustainability criteria for the whole of a project (from inception and design through to building delivery, operation and maintenance) the process is highly dependent on establishing objectives early particularly regarding planning and legislative obligations. Accordingly, such a framework needs to identify the encompassing criteria into an ongoing precinct project and its interrelated phases. This incorporating of principles however cannot simply limit itself to the development specifications and details of design, construction and operational aspects. It will crucially be required to determine the impacts of a project over in many cases considerable timescales.²

2 Review of Mixed Use Development – A pragmatic and positive solution

Increasingly as noted by Moore (2010) the Development Industry has responded to long held concerns over the shortage of developable land supply and growing disquiet regarding the degradation of the built and natural environment (ODPM, 2001, Brikeland, 2008) with medium to large mixed-use developments. They are also a commonly accepted means of accommodating the beneficial objectives linked to the rising discipline of urban design (Carmona, 2004). The resultant and diverse projects are an increasingly important and popular (Rabianski Et al, 2009) feature of the Industry's response when considering the continuing growth of challenging political and economic conditions that have always commonly attached themselves (Coupland, 1997, Wheeler, 2004) and now sustainability pressures to increasingly complex development circumstances.

Yudelson (2008) suggests that medium to large mixed-use precincts will continue to grow in importance, primarily because cities are actively encouraging such developments and assisting private developers with planning and zoning decisions, incentive programs, and in some cases the assembling of land (NAHB, 2008). A USA Industry survey cited by Yudelson (2008) noted that amongst large national development organizations that these types of projects accounted for some 25% of members' activity with some 35% stating that these types of mixed-use schemes accounted for more than half their business. It is likely that these figures are repeated elsewhere i.e. Australia and the UK where, as with the USA land prices have steadily

risen along with a growing wish to integrate the key roles of homes, work, and leisure activity into lifestyle choices.

Of note is that this form of undertaking has long been a largely pragmatic land management (Barton, Davis and Guise, 1995) and functional planning response (Hoppenblower and Louw, 2005). They have become predominant in the real estate landscape (Rabianski, 2009) and are increasingly popular where localized pressures require comprehensive resolution (Nguo and Armitage, 2008). The range of related issues they seek to resolve include population growth, declining economic performance linked to regeneration of inner city, industrial areas and brownfield sites. A further manifestation is in areas where developers are creating opportunities for themselves (BCO, 2005) through promotion of professed environmental, social and economic gains linked to new precincts or extensions of existing townships. Of crucial importance is the argument that mixed-use precincts offer an ideal opportunity for achieving sustainability and meaningful ecological improvements given the scale of development and land areas normally involved (Hyde, Ed., 2007). These factors along with extensive built environments, associated infrastructure and wide social and economic activity can create positive development outcomes despite the somewhat complex and dynamic relationships and considerable timescales involved. Conversely it is a paradox that research from the UK (Williams and Dair, 2007) and Australia (Moore, Ed. 2009) suggests that large scale precincts appear to fall short of a fuller implementation of sustainable environmental, social and economic best practice or better.

These increasingly seen projects offer enormous opportunities in searching for improvements in the ecological performance of not only the development itself but also the related development and construction industries. This is due in part to the scale of such schemes, which may incorporate a wide range of facility i.e. residential, retail, education, commercial, travel and tourism facilities, transport, roads, footpaths, cycleways and structural landscape infrastructure. The potential pursued emanates from the 'economies of scale' and the ability to achieve meaningful win-win outcomes. This provides opportunities to explore innovative alternatives regarding management, design, technology and demand and supply services (Koebel Et al, 2004). These inevitably master-planned undertakings afford, particularly where residential tenure is a main element, the prospect of richly textured areas and environments comprising a mix of provision, uses and activities (Carmona, Et al., 2010).

2.1 Closely Aligned Processes and Considerations

Closely aligned to these project features are sustainability benchmarking and performance assessment. These increasingly involve independent third party certifications of the development's planning, design and operational management processes. This reflects an implicit awareness of the key roles they have to play in resolving, or at least mitigating, many of the conflicts that mixed-use developments may generate. Governments and a growing number of developer organisations have regulations and policies in place to tackle universal themes such as water and energy conservation, waste reduction, social inclusion and equitable economic outcomes. Some go further and seek to assess impacts and outcomes in terms of total ecological success. They have considered it crucial where predicted and/or actual performance assessment feature in a precinct development processes to translate this necessity into an integrated management, planning and design process based framework (Moore, 2010). This is due to the problematical question of how to deliver sustainable development agendas consistently on what are complex procedural undertakings. Of equal importance is what

the framework looks like and what models and tools to employ within its boundaries when recognizing sustainability as a dynamic progression or journey.

Another framework consideration involves the need to identify fully the critical activity of managing the total development process. In doing this it should help the Development Industry, its clients, stakeholders and many professional advisers particularly the Development Manager, achieve goals brought on by ever increasing 'sustainability' demands and actual delivery pressure (Moore, 2010). The significance of these propositions flows from growing calls for developers, who ever they are, to reflect greater degrees of 'sustainability' (Brikeland, 2008) and the related and highly desirable 'Quality of Life' (Moore, 2006) in their developments. Crucially the associated agendas of these primary areas are recognized by many national and local governments (and importantly existing and new communities impacted on or created by development) as being crucial to their long-term implementation success.

The creation of a program framework that seeks to reconcile all the possibilities and encourages equitable resolution of the inherent conflicts of development is an advancement of existing processes. Viewed in essence as a means by which it becomes easier to recognize how the planning, construction and operable life of any precinct will have environmental, social and economic consequences. These complex and interrelated outcomes will inevitably place demands on natural capital (Hudson, 2005) and as such it is important that the resultant impacts are either fully mitigated or at least kept to a minimum (Bokalders and Block, 2010).

However, mitigation is only likely to come about if there is a willingness to undertake innovative, responsible and committed approaches on developments. As such, the framework approach will require a multi disciplined and highly directed assemblage of actors and processes. This objective if achieved will secure the engagement of those able to provide the skills, tools and solutions needed in the securing of sustainable futures for developments (Battle and MaCarthy, 2001).

3 Primary Questions, Research Methodology and Major Areas of Interest

3.1 A Primary Question

In responding to this search for an innovative approach the resultant enquiry sought to consider whether the delivery processes involved (including ecological assessment) on large mixed-use precincts would benefit from an integrated management, planning and design process based framework. The aim is to help the Development Industry, its clients, stakeholders and its many professional advisers particularly the Development Manager, achieve goals brought on by ever increasing 'sustainability' demands and actual delivery pressures. Of particular interest is would the framework manage a perceived gap currently found at the crucial pre development point of delivery at the level of precincts.

In doing so, it may be able to surmount the many economic, social and technical barriers that presently prevent the Industry delivering sustainable development projects as a norm rather than the exception (Keobal Et al., 2004, Wales and Mead, 2006, SGSR, 2009). There is also the possibility that use could gain the sought after recognition and possible reward for achieving best practice by those involved in pursuing innovative development processes when seeking to deliver enhancing ecological performance

agendas. In responding to the resulting questions, a crucial methodology employed was the engagement of the framework with actual primary and comparative case studies (Moore Ed., 2009).

3.2 Case Studies

Research involved the interrogation (Swanborn, 2010, Thomas, 2011) of several large mixed-use precinct case studies from Australia, the UK and the USA. The primary case studies were all master planned development undertakings of a similar scale and mix. They reflected the total development process at various stages of their evolutionary cycle. The schemes chosen (including the comparative ones) also engendered large multi-disciplined teams lead by a client based project manager. Whilst there is significant difference between location, geographical variance and actual stage in the delivery process, this did not impede the gathering of information and data. Quantitative and qualitative methodologies (Walliman, 2011) collected key area performance and sector benchmarking indicator data (Bell and Morse, 2010). This aided in assessing (Kelly, 2004) the ecological sensitivity and management of the precincts planning, design and actual construction. Information gathered also helped evaluate the ongoing operation some of the precincts in terms of their performance regarding environmental, social and economic outcomes. The findings when matched with a number of similar comparative case studies (Moore, Ed, 2009, Nichols and Laros, 2010) show that developers are responding to the now established demand (Pitts, 2004, Williams, 2009) that they plan, design and manage precinct infrastructure provision in a sustainable manner.

Crucially many of the developments studied measured their immediate and broader impacts and eventual total performance outcomes. This reflected awareness by these developers and their teams that by describing and monitoring a range of situations better assessment of available management options were possible. Crucially this provides a means to evaluate the outcomes of actions taken. Also of significance is that all the major parties involved in the processes of the primary case studies recognized and acknowledged that with the ensuing data, critical decisions made regarding sustainability had some certainty of success. Of importance is their concurrent recognition that when challenging business as usual process norms entailing broad ecological agendas there are considerable resource inputs. Additionally the primary case studies along with others confirm that in specific locations the implementation of innovative delivery strategies is fundamental. They also confirm the critical need for ongoing involvement between initial development progressions and associated long-term operational management practices adopted by facility managers.

Recognized are the limitations and implications of single case study research however as noted these case studies are part of a number of related parallel investigations into the management, planning and design and operational processes of precinct development. The ensuing analysis of these actual case studies provides insights into their conception, evolution, construction and eventually management. The case studies utilized serve as a broad evidentiary base (Kathan, 2008) to compare the outcomes noted later. The use of multiple case studies as noted by Hines (2007) generates a cross case analysis which is both descriptive and covers explanatory topics.

This option recognizes that whilst each of these developments has its own context and perspective the numbers studied accommodate and overcome the uniqueness and artificial conditions surrounding comparative case studies (Jensen and Rodgers, 2001).

Crucially they are able to provide a means to access highly pertinent information and understanding of real life phenomenon (Yin, 2003 and Lamnek, 2005)). The outcomes recorded promote constructive observations and support the actual implementation of viable processes better formulated to aid future developments. The originality and value of this offers a unique analysis of the correlations between desired development outcomes through increased cooperation, and actual process behaviour in terms of planning, design, construction and operational procedures.

Review of processes and extensive documentation, analysis of the information and data collected from members of their development teams, participation in team meetings and a large number of site visits and interviews with key stakeholders were the range of sources utilized and interrogated. This unlocked an array of crucial insights into the goals, aims and objectives of the parties involved and of the developments themselves. Also exploited was material originating from a large number of similar undertakings selected from related international sources. The comparative case study approach element identified an extensive number of crucial demand variances regarding location factors such as culture, economic and environmental capabilities. The framework needs to accommodate this feature.

A major area of interest was the use, particularly timing, of third party assessment and certification models and tools employed on many new developments to assess the sustainability and ecological performance outcomes of the resultant planning, design and operational management of precincts. The extensive technical reports flowing from these accreditation bodies provide considerable insights into the delivery of sustainable development. Consideration of the multifaceted principles of sustainability and sustainable development in the early phases of a proposal allows for swift identification of substantial opportunities and constraints (Yudelso, 2009).

Concurrently most statutory authorities will require land developers to address and ensure protection of social, economic and ecological environments when providing supporting material for development applications. Assessment undertaken at an early stage minimizes the risks associated with inadequate considerations of environmental values and provides an opportunity to ensure sustainability outcomes while still achieving project objectives. The increasing difficulty for developers is the ability to predict the potential outcomes of a project and to identify the opportunities for incorporating sustainable planning and design, construction and operational aspects in a way that reduces impacts. Guidance from certification bodies that provide benchmarking and assessment is a growing feature. Some of these organisations have created guidelines and checklists that include sector indicators to help tackle development issues faced by developers (at the master planning and early development delivery phase) who wish to raise their ecological performance and profile. The adoption of these tools also offers potential rewards and recognition not least of which, may include early authority approval, a result of the confidence that some assessment agencies place in these independent certification bodies. Crucial to project success is their accommodation in the framework.

Of importance regarding the use of possible outcomes and findings from the preceding is how best to deliver sustainable development agendas on these precincts. The contextual framework provides the necessary process based program and overall inputs to result in a consistent means to delivery sustainability and the highly prized 'Quality of Life'. Concurrently the significant matter of what measures are required to overcome the many barriers particularly the high degree of fragmentation that besets the

Development Industry and the allied Construction Industry should also manifest itself when using the framework.

3.3 Contextual Issues

The first consideration was to seek to identify those matters affecting the efficiency of the Development Industry regarding the delivery of sustainable development and 'Quality of Life' on precincts. There is a significant gap in the delivery processes at the mixed-use precinct level. This gap is a result of the highly fragmented nature of the Development Industry and related Construction Industry. This fragmentation is a result of ongoing traditional responsibility transfer, investment inertia, developer priority, statutory inflexibility and professional inimitability (Egan, 1998; Marsh, 1997 and Myers, 2011). These and other factors conspire in preventing the Development Industry in particular to overcome major barriers regarding its crucial role in responding to growing environmental, social and economic agendas flowing from ever increasing government and community demands. Resolution of this malaise is critical to the achievement of sustainable development and ultimately improved 'Quality of Life' for all stakeholders involved with or affected by a project. There is a substantial industry responsibility and imperative in seeking answers to the vexed questions surrounding the failure to resolve its shortcomings.

A major objective of the research has been to seek to resolve the issue of integration of the many parts and participants in the process of delivery. Determination is paramount due to the increasing numbers of actors and their influences on the process. Of significance will be if the integrating program based framework created offers high performance outcomes on this type of development. Equally, can it also secure measurable improvements in the management of the total development process? Linked to these two outcomes would be the gains seen in high quality urban planning and design, improved infrastructure and individual building performance particularly post construction and most crucial of all occupation and community evolution.

The contextual settings of development and its management, urban planning and design, architecture, sustainability, sustainable development and 'Quality of Life' are critical elements in this process. Of critical importance are the relationships and impacts these have with and on a developer and a development manager. An initial point contemplated regards the skills set and continuing professional progression needed by these two central figures. Further reference to the need for ecological and Triple Bottom Line assessment and reporting is also crucial. To meet this need the case studies show an increasing range of third party models and tools employed on them and aimed at delivering improved sustainability outcomes. Evidence of the effectiveness of these aids and their acceptance and proficiency manifested itself from several workshops held as part of the research program. However many attendees appear to hold some reservations regarding support of the models and tools in overcoming the known deficiencies of the current system (Moore Ed. 2009).

3.4 The Search for Definition

To achieve the stated goals and objectives of delivering mixed-use precincts as described earlier there needs to be a coherent transformation of the many resultant definitions into measurable framework success. In this lies a major problem. Observations show that an extensive range of interpretations existed regarding what is a precinct. The result of there being no workable definition and/or understanding of how to integrate it into a precinct delivery process is critical for the primary participants i.e.

the Developer and Development Manager when undertaking such developments. These parties normally engage with the total delivery process of schemes and therefore normally accept the prime responsibility for achieving success. The measure of this success will need to be a reflection of what it is that they are creating hence the need for definition clarity. To resolve the issue it is felt that there are two basic considerations needing resolution when giving regard to the meaning and contexts of precincts. Firstly, the importance of determining what constitutes a precinct. Secondly, what are the main characteristics that need addressing within the debate regarding sustainable development? From the answers the creation of precinct sustainability agendas and 'Quality Of Life' plans will flow.

The US Green Building Council (USGBC, 2007) identifies that whilst no strict definition exists for what comprises a precinct there is research on the topic. They note that *'in simplistic terms, a precinct or neighborhood is an area of dwellings and/or work places and their immediate environment that residents and/or employees identify within terms of social and economic attitudes, lifestyles, and institutions'*. In seeking to offer some further clarity they cited some time ago the Charter of the Congress for the New Urbanism (1996) which rather simplistically defined a neighborhood and therefore for the purposes here a precinct as being a place that is compact, pedestrian friendly, and mixed-use. These rather limited concepts when expanded on by Dover and King (in Doug Farr's Sustainable Urbanism, 2007) define a precinct as the basic increment of town planning. This observation allows the use of the idea that a single precinct can stand alone or together as two or more interconnected precincts, that will not be limited in common sharing of specialized areas, hubs or main streets of a town or possibly a region. This last point is important because the case studies show that some precincts can be of such a scale that they rival small villages and towns in terms of population and facilities. In some urban extensions, they can enlarge existing communities or engulf them to such an extent that they in essence become the new community (Moore, Ed. 2009).

The search for definition is critical given that currently most refer only to a political or legal boundary. These whilst important regarding the administrative operation of localized facilities and services are less than adequate regarding its true nature or complexity. In addition, the limitation of this defining will not offer a means by which integration of a precinct into a broader area, regional or national context can take place. Without broader designation and matched characterization, it is likely that attempts to coordinate actions towards greater efficiency in resource usage for example will not take place. The outcome of which is likely to be continuing tensions between national goals, community expectations and development industry delivery. The definition is also crucial regarding the ultimate delivery of sustainability and 'Quality of Life'. Determining what a precinct is should provide clearer understanding of the agendas needed to deliver these two key elements of sustainable development.

3.5 Principles and New Approaches

It is recognized that the Developer and the Development Manager will need guidance in creating the conditions within which a precinct may flourish and become a great place to live, work and grow. In considering how best to deliver the critical features of a truly sustainable community the evolving framework advocates the use of guidelines and checklists. These tools are practical applications for trying to implement multifaceted aspects of the complex relationships between physical and holistic concepts many of which are untested at present.

It is contended that 'decision making for sustainable development in the built environment requires new approaches that are able to integrate and synthesise on all the dimensions of an urban system (or a building) and different points of view, in a holistic manner' (Brandon and Lombardi, p.75 2005, citing Mitchell, 1999 and Deakin, et al. 2001). This accords well with the view that currently other than ecological problems i.e. environmental impacts there is only limited integration or focus on the wide number of connected development factors. The narrowness of this approach consistently seen in statutory requirements has led to the relegation of equally important dynamics such as social, economic and cultural issues to the periphery of decision making by developers in particular. A further consequence has been the lack of contemporary analytical tools development aimed at handling such areas more rigorously. Brandon and Lombardi (2005, citing survey's by Deakin between 2001 and 2003) note that only life cycle assessment is being used to augment environmental capacity with consideration of equity, public participation and futurity. Even on the case studies, very little evidence existed of systematic usage of pre-development tools other than those required for EIA requirements.

The failure of even established tools to penetrate the Industry is primarily due to many of them not truly reflecting or being able to respond to the growing complexity of institutional structures and a range of stakeholder interests commonly seen on many developments. Most of the analysis models employed in strategic planning are only useful for systematic and analytical evaluation of alternative courses of action. Some advocate that to overcome this failure Life Cycle Costing (LCC) and Life Cycle Assessment (LCA) need linking into a Life Service Model (Bell, 1998). Whilst this may seem simply and a primary requirement for developers few have the expertise to use these evidence hungry tools correctly at the initial stages of a development where there is the greatest uncertainty.

Consequently, the case studies show that many developers are more likely to use internally created tools aimed at specific organisational needs and reflecting in-house skills. The issue here is their efficacy when compared with third party models. It is highly unlikely that any useful company tools that prove efficient will become commercially available to others. This is understandable given the already suggested complexity and limitations of assessments methodologies such as Life Cycle Cost Analysis (Rebutter and Hunker, 2003). There is also likely to be a reluctance to release what may be methodology that provides market advantage to competitors. This aspect of project reality is fundamental because to be effective the analyses must be carried-out early. This presents an issue for the Industry and the resultant framework regarding how early and at what stage of the development process are they most effective. Many schemes have complex time issues for example some projects are responses to existing planning determinations facilitated by highly regulated policies and strategies. These may force the developers onto an already established and structured pathway that is less open to change and innovation.

Irrespective all precinct schemes have to respond to market driven vagaries that are extremely time sensitive and very difficult to impact assess. Predictability therefore is a constant problem given the timescales that are involved and the highly volatile nature of financial markets and consumer sentiments. To accommodate these tensions many tools adopt a primary objective of choosing the best alternatives to the employment of scarce resources. They follow such a course of action because they need to review the entire life of the project and not some arbitrary time span. However, they all find difficulty in determining the correct course of action to undertake. This is because firstly there is

likely no single defining course when viewed against the known difficulty of determining development programs. Secondly, existing tools do not reflect all the issues or possibilities prevalent in development. With such lack of definition and without an available all encompassing model accurate assessment and performance prediction remains elusive.

There is an absolute pre-requisite for constant review and long-term commitment by the parties. Without this there is little guarantee of success. When considering the preceding a common technical problem arises regarding the effective use of these models and the ensuing information. To have an unfettered confidence in decisions flowing from the findings there can be no omission or misinterpretation of data. Any analysis must take place in a systematic structure using estimating techniques that are not prone to being wrong or misused. There is a heavy reliance on a concentration of correct and significant facts and meaningful assessments of uncertainty. Crucially there is also an imperative that constant checking takes place that they do not estimate the wrong items and they use correct and consistent escalation data. It is more than a truism to contend that these features do not feature consistently in the Development Industry. Therefore, the framework would need to be robust enough to accommodate the variation in the Industry's developers and their management capabilities. It must also provide a means by which limited resources do not mean responses that are not fully coherent with the challenges of integration of a wide range of agendas one being sustainability.

4 Findings and the Framework

4.1 Needs and a Theoretical base

There was no intention in the research for fully tackling the theoretical base for such a framework. This is because several works have comprehensively provided outlines that offered a sound base and pragmatic approach to formulating the nature and content of the conjectural proposal. Brandon and Lombardi (2005) use a holistic and integrating 'modality' based mechanism and framework structure. This approach helps to underpin a decision making process aimed at bringing together the diversity of interests involved in sustainable development. It also provides the means to overcome other major problems such as lack of language commonality and systematic methodology in the approaches of the many actors and disciplines already identified. Their propositions are an outcome of using the fundamental but according to Nijkamp (2005) somewhat neglected scholarly work of the Dutch philosopher Dooyeweerd (1968 and 1979). The resultant theory has been adapted into a proffered holistic approach that provides a basis for understanding complex dynamic realities. It employs the fifteen modalities of Dooyeweerd so that they may be seen as irreducible aspects or dimensions that altogether make up a holistic pattern where a list of dimensions can be used to '*understand the functioning of a complex system or entity such as the built environment or local community*' (Brandon and Lombardi, 2005 p.78) hence its appropriateness.

Brandon and Lombardi (2005) maintain that by using Dooyeweerd philosophical basis it helps to understand the complex trade-offs in sustainability. It also goes some way in coping with the multidimensionality of evaluating new possibilities for future sustainability in the built environment. The 'modalities' have been adapted by them to reflect the built environment into fifteen descriptions which they suggest will help decision makers classify and quantify sustainable development issues. These classifications supported by scientific criteria and a number of questions will aid and guide the user in handling the evaluation of a planning and design proposal. They

should be able to facilitate collaborations aid consultation and improve communication between the parties involved.

The adapted modalities are an overview for sustainable development decision making. They represent the beginnings of criteria requiring consideration at the start of the development process. In support of 'modalities' work by Thorburn, Jakku and Webster (CSIRO, 2003) who have investigated the use of decision support systems (DSS) was used. Their work has been to search for the means by which scientific knowledge incorporation can be in a form that industry stakeholders are able to use in assisting their management decisions. This closing of the loop in particular by designers is a means to enhance processes and possibly offer more innovative ways of increasing design reliability along with reducing ecological footprints (Vallero and Brasier, 2008). The search prompted by the need to understand the growing number of complex interactions that now exist between a range of environmental, social and economic factors (Thorburn, Jakku and Webster, 2003). A complexity clearly mirrored in medium to large mixed-use precincts and the development processes employed.

4.2 Into a Project Management Process

It is pertinent to develop a specific development framework process using familiar development, project and operational management techniques given the inconsistencies in the Industry's skills base. This reasoning also responds to the fact that most developers and many of the stakeholders involved desire the management and completion of projects in a timely and cost effective fashion. This means that the framework needs to reflect at least in the short-term existing developer and consultant abilities and resources with additional expertise coming from external or internal third party sources. This has profound implications for the objectives and methodology resulting from this viewpoint.

The benefits that derive from a 'total lifecycle' view starting from initial planning through operation and disposal of a facility are highly relevant to decision making. As the case studies show many promoters are now concerned with a project from the cradle to the grave. This involvement requires proficiency or at least understanding of a much broader range of activities. Many not normally encountered by single-phase organizations such as architects and constructors. It also means that certain costs, i.e. construction will represent only a small portion of the overall life cycle costs of a development. Accordingly optimizing performance at one stage of the process may not be beneficial overall if additional costs or delays occur elsewhere in the total process. For example, saving money on the design process will be a false economy if the result is excess construction and operational costs.

Fragmentation of development and project management among different specialists is common and may be necessary though is best avoided. This is due in part to the disadvantage caused by the challenges of integrating specific disciplines into the various parts of a process (Vallero and Brasier, 2008). Good communication and coordination among the participants becomes even more essential in accomplishing the overall goals of the development where specialism diversity is prevalent. It is here that the integration of the process and the flows of information become crucial. New information technologies can be instrumental in this process, especially the Internet and specialized Extranets.

Productivity improvements are always of importance and value if they provide improved results. As a result, introducing new management approaches, design tools, materials and automated construction processes is desirable as long as they are cost effective and consistent with desired performance outcomes. Quality of work irrespective of whether related to design, physical or operational performance is critically important to the success of a development due to it being the Developer and stakeholders that live with the result. This in essence gives to motivation for adopting the focus on developers and their development manager. The concentration of attention is because cost effectiveness of total facility development falls on these two rather than the competitive provision of single services by the other various participants to the process.

However while the framework is primarily targeting development management it is not solely intended for the Developer and their direct representatives. By understanding the entire process, all participants can respond more effectively to the Developer and other critical stakeholder's needs in their own work, in marketing their services, and in communicating with other participants. In addition, the specific techniques and tools discussed in context of this framework (such as social and economic evaluation, management information systems, benchmarking and certification) readily apply to any portion of the process. Because of the concentration on the effective management of the entire development, a number of novel organizational approaches and techniques become of interest. Primarily the incentive is to replace confrontation and adversarial relationships with a spirit of joint endeavor, partnership and accomplishment. For example, the appropriate means to evaluate risks and the appropriate participants to assume the unavoidable risks associated with constructed facilities.

Scheduling, communication of data and quality assurance have particular significance from the viewpoint of an owner, but not necessarily for individual participants. The use of computer-based technology and automation also provides opportunities for increased productivity in the process. Presenting such modern management options in a unified fashion should be a major objective. This unification viewpoint of the entire process of project management differs from other views regarding the subject. Most treat special areas or problems, such as cost estimating, from the viewpoint of the particular participants such as construction managers or contractors.

This once again reflects the fragmentation of the construction process amongst different organizations and professionals. Even within a single profession such as Civil Engineering, there are quite distinct groups of specialists in planning, design, management, construction and other sub-specialties. Fragmentation of interest and attention also exists in nearly all educational programs. While specialty knowledge may be essential to accomplish particular tasks, participants in the process should also understand the context and role of their special tasks.

4.3 The Conjectural Framework and Realms of Influence

The framework seeks to provide a means for achieving what some (Newman and Jennings, 2008) describe as long term visioning based on sustainability, intergenerational environmental, social, economic and political equity whilst respecting the drivers of individuality. Interestingly whilst this convergence view of Newman and Jennings (2008) is for a city, it translates readily into the starting point for the conjectural framework. Its focus with appropriate amendments provides a catalyst from which to launch the drawing together of the disjoint parts of the process that is

development. Holding a long-term vision is the starting point for positive changes that leads to sustainability. The vision must reflect the distinctive nature and character of the place. It should also express the shared aspirations of all who are seeking to make the development more sustainable. These aspirations need matching by an addressing of equity giving equal access to both natural and manmade resources. This sharing must also bring with it responsibilities regarding resource preservation for future generations.

Therefore, a sustainability vision must offer an opportunity to align and motivate a range of development participants around common purposes, which offer a basis for developing a meaningful strategy linked to action plans and the processes needed to achieve such a vision. For a precinct to be truly successful, its developer and development champion must operate within a prescribed but flexible framework. Figure 1 provides a proposed conjectural framework that is seeking to define for developers and their advisors the total process, critical influences, crucial phases, likely direct management actions needed and timings for the use of models and tools involved in the creation of a precinct. The framework is an aid in the achievement of sustainability goals. It offers a picture of the elements necessary to meet regulatory requirements, provide realistic outcome predictions modeling and identifies the use of independent third party assessment and certification. A further aspect is the continuing flexibility and adaptation reflected in the open and overlapping systems nature of the process, phases and management linkages. It identifies crucial matters that encompass a whole systems view of a precinct development that there are considerable opportunities to integrate a range of input tools. Of particular interest will be those that have evolved to deal with the operational and community phases. It is this phase that is most impacted upon by the aim of improving ‘Quality of Life’.

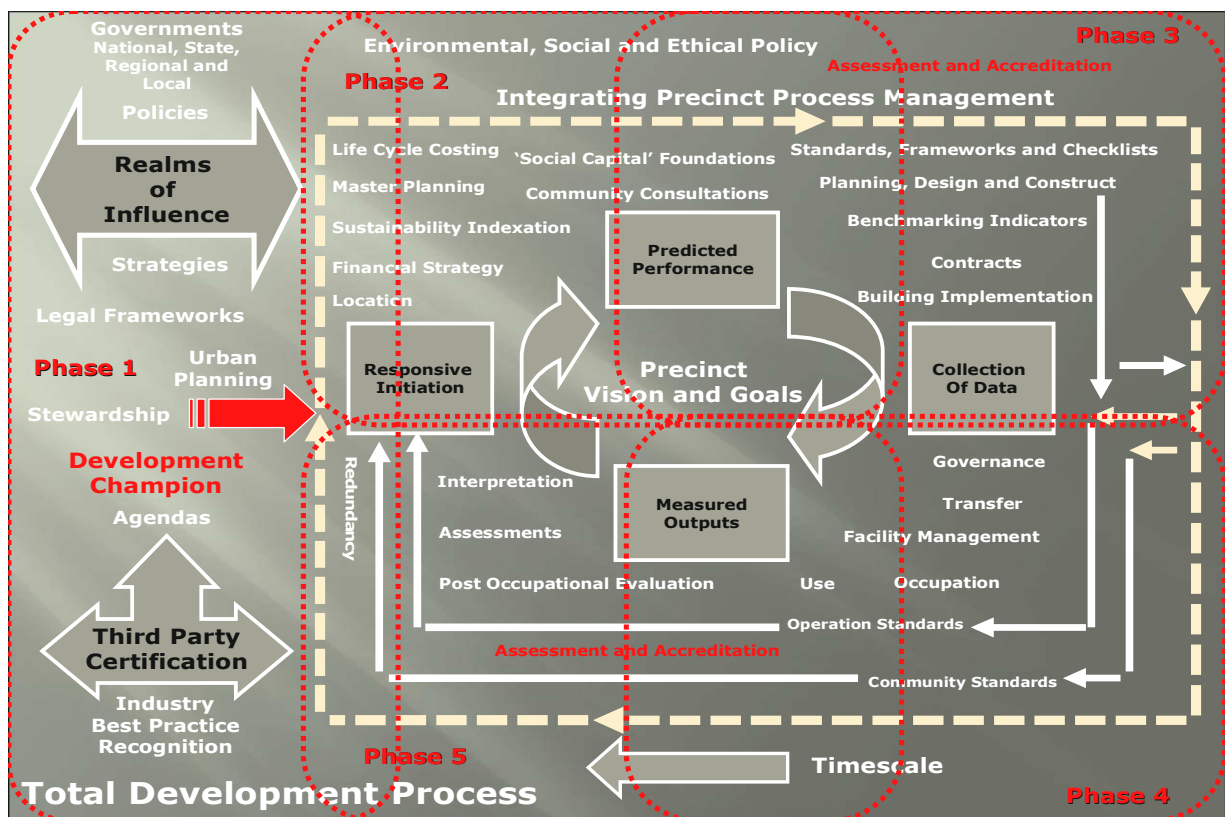

Figure 1: A Conjectural Framework for Delivery of a Mixed Use Precinct

The framework vision and its structure however will need to reflect and respond to the reality of a development process. The direction a project takes will be subject to a considerable range of pressures. In seeking to establish sufficient understanding of these there is a critical need within the framework to determine what are the 'Realms of Influence' that exert authority and in some cases control the responses of the development if not challenged. These influences best determined by an early analysis of factors. These refer to the nature, type of timing of what may be positive manipulations of inputs. Others it is possible to contend are unnecessary burdens or at worst are barriers to the delivery of a sustainable development.

A further framework consideration regards the fact that whilst considerable effort has gone into achieving and, measuring project success against time, budget and deliverables many have failed in the attempt. Major causes of this failure, are noted by Henrie and Sousa-Poza (2005) who cite several sources (Meadows, 1996, Ollila, 2002, Faulconbridge and Ryan, 2002 Kerzner, 1998 and Cleland and Ireland 2002 respectively). These include poor requirements definition, Selection of the wrong person as project manager, misused management techniques and inadequately applied project management principles and processes. Henrie and Sousa-Poza (2005) contend that there is a common theme to all project management successes or failures, which revolves around the people involved. This notion and the preceding stated reasons for failure supports firstly an argument for clearly defining the vision (or requirements) of the Precinct. Second is the importance of selecting the right Project Leader or Champion to manage the total process. Thirdly, management of the wide range of inputs and outputs that make up this complex system will be dependent on the correct choice of techniques and tools. Lastly but as critical will be the application of sound management principles at appropriate times commensurate with the needs of the process. All these factors will need to be present in the framework structure with support at each phase as to what mechanisms are required to be in place to ensure success. Importantly the factors relate strongly to the common issue surrounding all projects, which is the influence of cultures. Already noted are the professional barriers brought on by educational and practice imperatives. Institutional factors are more opaque but are still the result of 'people' either individuals or collective groupings. The issue primarily involves astute awareness. It is also fundamental for all to be fully aware of what culture dominates the undertaking. This awareness requires equally matching with an appreciation of how many cultures a development team may need to accommodate.

Recognition is a crucial factor in the encouragement or mitigation of positive and negative impacts respectively. Undertaking this analysis is a primary function of project leadership. Therefore early selection of the correct key person or organization (who has been termed 'Development Champion') for the framework stewardship role is essential. On filling the position, interpretation of the influences should take place immediately. This early interventionist framework approach attempts to more accurately predict potential outcomes of the influences on the project. It seeks to determine without bias as to what are likely consequences when responding to or challenging them. It is important that the analysis is done within the contexts of all phases of the process giving due regard to timescales.

5 Ongoing Work and Conclusion

The proposed conjectural framework representation is by nature broad based and requires to be further developed. The continuing evolution is considering each phase to

show more succinctly critical influences and possible processes, models and tools that when used achieve the outcomes proffered earlier. There is already interrogation of the five phases identified on the primary case studies and some comparative ones. This distinguishing at each phase of particular parties, their roles and inputs is essential. Of these, the most influential regarding the process itself group into several major factions. The most obvious are the regulatory bodies, the Developer and his team, the Community and third party external organizations. The ongoing phase charting of the total development process uses these groupings as the basis to determine what designated role and influence each has in the process.

The primary case studies reflect strongly the use of predictive modeling linked with third party certification bodies. They in the main were targeting environmental, social and economic commitments as the crucial dimensions of improved ecological performance. Early indications are that others have utilized tools noted on the primary studies, in the development process stakeholders. Many of those found and incorporated into the evolving framework become potential tools that a developer may wish to engage by negotiation with for example a local planning authority.

An early introduction of these tools may provide the non-aligned professional guidance needed regarding process development linked to sustainable development. Additionally it may also introduce into the regulatory system the idea of benchmarking and assessment transparency regarding predicted ecological performance and in particular 'Quality of Life'. Other tools used in delivering particular aspects of a development are noted. Whilst more specific in role i.e. value engineering, these tools suggest the willingness of some developers to use a wide range of aids. Comment is required on the efficacy of these more specialized tools. This may point to the reasons for their limited penetration of the total development process. Crucially all the models and tools identified so far are able to single out opportunities for incorporating sustainable planning, design, construction and operational factors into a project.

The charting seeks to identify crucial areas where the Developer and managers require strategies for responding to and influencing possible outcomes. As noted earlier the functional quality of any model or tool and their efficiency when employed is paramount. The framework will not be commenting upon particular ones currently in use. This is because currently charting aims are more to do with identifying particular types and where they should engage with the process. However if a common and proven model or tool is available it will be identified for reasons of clarity. This clarity is prudent because there is a significant range of models and tools currently being researched (and in some cases used) to meet the sustainability challenge. Brandon and Lombardi (2005 p.123 citing Deakin, 2002) identified '*at least 61 methods available for evaluating the planning, design, construction and operation of the sustainable urban development processes*'. Crucially they restrained their chart to only showing the most commonly used ones. Whilst the charting attempts to provide some form of hierarchy of models and tools readily available at the development activity level there are already noticeable gaps particularly in preliminary site selection analysis. Also in, attempting to offer a listing it is important to recognise that some of the new (and even the more established) models and tools employed by the development industry are not universally available. Further, the charting will reflect the Industry practice of in-house tools use a feature clearly seen on all the case studies. Wide variants of similar tasked tools (albeit individually constructed or commercially available though modified) exist in a large number of developer organizations. This aspect is important because the conjectural

framework is not about excluding any particular tool. However whilst each has its own merits because of limited industry exposure, there has been no rigorous testing.

The ongoing research seeks to translate all the preceding input (and more) found into the broad conjectural process based performance framework with discrete phases that integrate crucial concepts along with pragmatic models and tools. The primary aim is to offer the route map toward the destination of sustainable development and improved 'Quality of Life'. It seeks a theoretical but highly practical basis on which to formulate the framework, mapping the sustainability journey through the interlocking phases of total development. Of note, are the crucial references identified from case study examples and extra inputs as to what aspects are fundamental to successful outcomes. However for the framework to be successfully applied other factors will be needed. It is but a part of a broader missive one that will require further inputs from those involved in the Development Industry.

Abstract:

The client's satisfaction of construction project is not always at the forefront of contractor's interest especially in the quest for more project and profit therefore undermining the client reason for the project which in turn creates a wide deviation from what the client expects thus contributing to the client not been satisfied in the performance of the project. This is an important challenge towards the contractor's performance and successful projects delivery. The primary objective of this paper is to identify the current levels of client satisfaction in Lagos state and to examine the important criteria for assessing contractor's performance. An opinion based questionnaire of fifty in number were distributed randomly to the respondents, 36 were retrieved and used for the analysis. It implies a descriptive research survey and the population entails clients which include public and private clients and his representative in an on-going and completed projects. The data collected were analyzed using descriptive and average index. The study shows that Clients in Lagos state, Nigeria, are slightly satisfied with contractor work performance having expressed satisfaction with only five (5) out of the forty five (45) important contractor work performance criteria surveyed. The top priorities of clients for contractor work performance in Lagos state, given in order of importance include: adequacy of as-built (finished product), quality of workmanship and identification/ correction of deficient work in a timely manner. In conclusion clients are satisfied with quality of overall service, Organization of current documents and records and agreement about changes of contractors' work performance in Lagos state.

Keywords:

client, contractor work, performance, project success, satisfaction

1 Introduction

Satisfaction can be defined as a person's feeling of pleasure or disappointment resulting from comparing the perceived performance of a product in relation to expectations. If performance matches the expectations, the customer is satisfied. If performance exceeds expectations, the customer is highly satisfied or delighted. If performance falls short of expectations, the customer is dissatisfied (Comite europeen des responsables de la

cartographie officielle (CERCO) working group on quality 2000; Kotler 2000). Satisfaction will occur when a client's needs are matched with an organisation's product or service (Besterfield *et al.*, 1995). Previous definitions of customer/client satisfaction have referred to it as a buyer's cognitive state of being (Howard and Sheth, 1969) an evaluation or judgement of an experience (LaBarbera and Mazursky, 1983; Cadotte *et al.*, 1987); a summary attribute phenomenon coexisting with other consumption emotions (Oliver, 1992); an evaluation summary psychological state emotion (Oliver, 1981); an outcome an emotional response (Halstead *et al.*, 1994); an evaluative response (Day, 1984; Tse and Wilton, 1988) and a response pertaining to a particular focus determined at a particular time (Giese and Cote, 2002). Products and service have attributes which affect customer satisfaction; attributes such as performance attributes, threshold attributes and excitement attributes (Besterfield *et al.* 1995). In the construction industry, there is an absence of a generally acceptable operational definition and measure of customer satisfaction (Torbica and Stroh, 1999), but, however, it has been defined as the extent to which a physical facility (product) and a construction process (service) meet and/or exceed a customer's expectations (Karna, 2009) i.e. how well a contractor meets the client's expectations (Karna *et al.*, 2004; Yang and Peng 2006); or the satisfaction with the constructed facility, the contracting facility and the contracting service (Yasamis *et al.*, 2002). Performance measurements and criteria used for determining project success initially have relied upon the traditional factors of time, quality, cost (Pinto and Rouhiainen, 2001; Jafaar *et al.*, 2006; Karna, 2009) and safety, but recently subjective measures such as client satisfaction have been included as a criterion for measuring performance (Chan and Chan 2004; Center for construction Innovation, 2004) even as time, cost and quality have been deemed as insufficient (Toor and Ogunlana, 2009). Client satisfaction with contractor work performance is however a subjective assessment (Masrom and Skitmore, 2010; Cheng *et al.*, 2006) influenced by individual perception, orientation / experience and expectations of the client, which will differ for different individual clients, but nevertheless remains an indication of the success of delivery or the ability to execute and complete a project within the required expectations of the client (Construction Industry Development Board (CIDB) construction industry indicators summary results, 2009).

According to Soetanto *et al.* (2001), satisfactory performance of project participants is a must for a harmonious working relationship and assessing client satisfaction will help to provide information for participants to help improve their performance.

Few construction firms in Lagos state carry out a process of self audit geared at improving performance and client satisfaction, but the greater focus has been on profit and more projects. A wide deviation from what the client expects in terms of actual cost, schedule control and quality of completed work is what obtains today and this constitutes an important challenge to successful project delivery and contractor work performance in the construction industry. The satisfaction of the clients who drive construction projects are often side lined in this drive for profit by construction firms, who do not seek to understand and focus on the individual needs of clients or who do not have an understanding that different clients will have different needs when defining client-contractor relationships. According to Pratt (2004), the construction industry is not known for focusing on customers'/end users' needs. Disputes and litigations and delay in payment are some of the negative results that arise from this practice. This research intends to examine the level of client satisfaction with contractor work performance and to identify the important criteria for assessing contractor's work performance in Lagos state.

2 Client expectation factors and contractor performance

Karna (2004) explained that a customer's expectations in construction are a function of several factors: the customer's past or direct experiences with the contractor and similar contractors, word-of-mouth information about the contractor, and the customer's personal needs. In addition, a customer's expectations are affected by a contractor's marketing activities and image, and the customer's own investment in the project and the relationship. The customers' expectations play an important role in the evaluation of contractor's performance. According to Kärnä (2009), at the project level, the customer assesses the contractors' performance in relation to three comparisons, all of which impact customer satisfaction as shown in fig 1. They are:

1. Comparison – between the quality of the building, the customer's expectations and the adjusted goals for the building.
2. Comparison – between the quality of the construction process and the experiences, which have emerged during the process.
3. Comparison – between the customer's expectations and experiences.

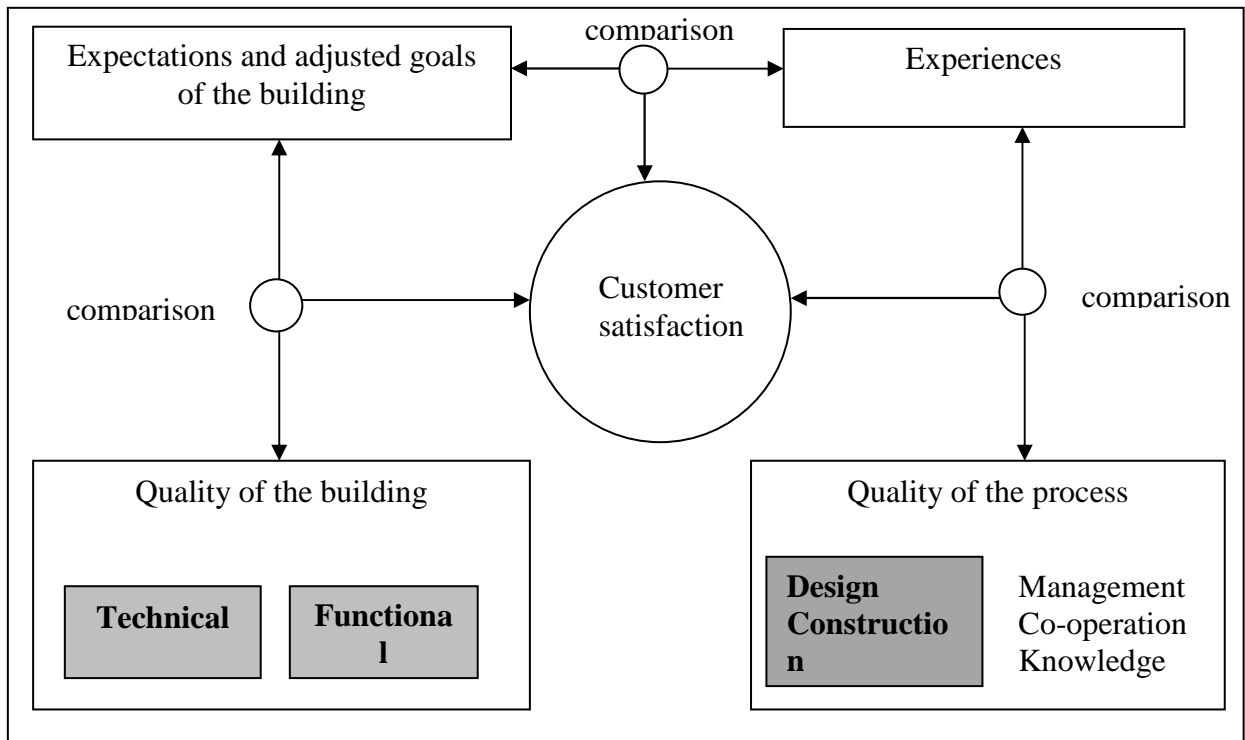

Fig 1: Interrelationships between customer satisfaction and quality at project level (Karna, 2009)
According to Blumenthall *et al.* (2000), clients of the construction industry want their projects delivered: on time, on budget, free from defects, efficiently, safely and by profitable companies.

Regular clients expect continuous improvement from their construction team to achieve year-on-year reductions in project times and cost. And according to Latham (1994) the owner's wish will normally include: value for money, pleasing to look at, free from defects on completion, delivered on time, fit for the purpose, supported by worthwhile guarantees, and reasonable running costs and satisfactory durability.

The client's needs can be given as satisfaction of function, achievement of economy, control of programme time and creation of aesthetics conditions (Turner, 1995). Needs such as timeliness of completion, aesthetics, cost of the project and safety of production are part of project schemes and should be satisfied by building teams (Alinaitwe 2008). Bowen, *et al*, (1997) and the study by Kometa, *et al* (1994) as cited in Alinaitwe (2008), construction industry clients are largely misunderstood, dissatisfied and critical of the performance of their consultants and contractors. Client satisfaction can be achieved by getting client constructional needs translated into a design which specifies technical characteristics, performance criteria and quality standards and enabling the project completed within time, cost and quality standard.

3 Research methodology

A descriptive research survey was used for the study. The population consists of both public and private client of recently commissioned and ongoing projects who are randomly selected. Convenience sampling technique method was used. A total of fifty (50) self administered questionnaires were randomly distributed and thirty-six were retrieved and used for the analysis for this study. Statistical packages for social sciences (SPSS) were used for analyzing the data collected using descriptive and average index rating to calculate the level of importance. The formulae is shown below

Importance index calculation:

$$5n_1 + 4n_2 + 3n_3 + 2n_4 + 1n_5$$

Where:

$$\frac{\quad}{n_1 + n_2 + n_3 + n_4 + n_5}$$

n_1 = Very important; n_2 =Important; n_3 = Neutral; n_4 =slightly important; n_5 = Not important;

The extent of the range as used in the importance index analysis rating scale was calculated given that the difference between the lower and upper ends of the five point scale =4.00, from 5.00 – 1.00 and that since there are five points thereon, 4.00 was divided by 5 which gives 0.8, which determines the extent of each range and hence the importance index analysis rating scale is as given in Table 1

Table 1: Importance index analysis rating scale

Range	Category
$>4.20 \leq 5.00$	Very important
$>3.40 \leq 4.20$	Important
$>2.60 \leq 3.40$	Neutral
$>1.80 \leq 2.60$	Slightly important
$>1.00 \leq 1.80$	Not important

Satisfaction index was calculated from:

$$7n_1 + 6n_2 + 5n_3 + 4n_4 + 3n_5 + 2n_6 + 1n_7$$

$$\frac{\quad}{n_1 + n_2 + n_3 + n_4 + n_5 + n_6 + n_7}$$

Where: n₁= Very satisfied; n₂=Satisfied; n₃=Slightly satisfied; n₄=Neutral; n₅= Slightly dissatisfied; n₆= Dissatisfied; n₇= Very dissatisfied.

The extent of the range as used in the satisfaction index analysis rating scale was calculated given that the difference between the lower and upper ends of the seven point scale =6.00, from 7.00 – 1.00 and since there are seven points therein, 6.00 was divided by 7 which gives 0.86, which determines the extent of each range and hence the importance index analysis rating scale is as given in table 2

Table 2: Satisfaction index analysis rating scale

Range	Category
>6.16 ≤ 7.00	Very satisfied
>5.30 ≤ 6.16	Satisfied
>4.44 ≤ 5.30	Slightly satisfied
>3.58 ≤ 4.44	Undecided
>2.72 ≤ 3.58	Slightly dissatisfied
>1.86 ≤ 2.72	Dissatisfied
>1.00 ≤ 1.86	Very dissatisfied

4 Findings and Discussion

4.1 Analysis of general information

Table 3 shows that the profession of architect (frequency of 14 or 38.9%) was the largest amongst respondents surveyed (others refer to respondents who are not professionals of the construction industry but who nevertheless engage in construction activities as either project coordinators, financiers etc). As shown by the table under the **role** played by respondents, the role of client’s representative featured highest with a frequency of 15 (41.7%). Under **organization**, respondents from public/government bodies formed the largest number of clients surveyed with a frequency of 15 (41.7%). The large number of public infrastructure projects being handled by contractors at both local and state government level and the position of government as a regulatory body make this population a significant one. Repeat/continuing clients under **frequency of construction activities** had the highest proportion of the respondents’ evaluated (frequency of 27 or 75%) and the satisfaction of this group is a major factor in determining client satisfaction owing to their wealth of experience. Respondents who were involved in building construction projects formed the largest percentage in project category as shown by Table, with a percentage of 63.9% and a frequency of 23. Under **contract sum**, respondents involved in projects with a contract sum higher than N10,000,000 (greater than USD 66,666) have a greater population and this goes to show that the survey will adequately cover the major and well established contractors in Lagos state.

Table 3: Analysis of general information

Respondent's general information	frequency	percentage(%)
Profession		
Architect	14	38.9
Builder	7	19.4
Quantity surveyor	2	5.6
Civil engineer	1	2.8
Others	12	33.3
Total	36	100
Role		
Client/owner	8	22.2
Project manager	13	36.1
Representative	15	41.7
Total	36	100
Organisation		
Private company	10	27.8
Public/government bodies	15	41.7
Private individual	8	22.2
Total	33	100
Frequency of construction activities		
One-off	9	25.0
Repeat/continuing	27	75.0
Total	36	100
Project category		
Building	23	63.9
Civil engineering	13	36.1
Total	36	100\

Analysis of general information

General information	frequency	percentage(%)
Contract sum		
#1000000-#10000000	4	11.1
Above #10000000	32	88.9
Total	36	100

4.2 Important contractor work performance assessment criteria and client priorities

Table 4 shows clients response to the importance of the surveyed contractor work performance criteria. Clients were neutral or undecided on three (3) out of the forty eight (48) surveyed contractor work performance criteria given as: conducting regular meetings to explain safety programme (mean, 3.33), discussing safety at owner-contractor meetings (mean, 3.31) and correction of noted deficiencies in safety programme (mean, 3.39). Thirty one (31) contractor work performance criteria were seen as important as shown in table 4 while the mainly fourteen (14) contractor work performance criteria had a response of very important. Fourteen (14) contractor work performance criteria were seen as very important. Table 4 also shows the ranking of surveyed contractor work performance criteria and topmost in order of importance include: adequacy of as-builts (finished product) (mean, 4.61), quality of workmanship (mean, 4.56) and identification/ correction of deficient work in a timely manner (mean, 4.50)

Table 4: Clients' response on importance of contractor work performance criteria.
 VI=Very Important; I=Important; N=Neutral; SI=Slightly Important; NI=Not Important. R*=Level of Importance; R**= Ranking

S/N	Contractor work performance criteria	Frequency					AI	R*	R**
		5	4	3	2	1

4.3 Client satisfaction with contractor work performance

Table 5 shows the response of clients as to the satisfaction level with the important contractor work performance criteria or factors. Clients according to Table 5 were slightly satisfied with forty (40) of the forty five (45) important contractor work performance criteria. However clients expressed satisfaction with only five (5) contractor work performance assessment criteria which are given as: quality of overall service (mean, 5.44); adequacy of as-builts (finished product) (mean, 5.47); quality of workmanship (mean, 5.33); agreement about changes (mean, 5.33); organization of current documents and records (mean, 5.36). The overall satisfaction level which gives the current state of client satisfaction with contractor work performance in Lagos state according to Table 5 is a rating of “slightly satisfied (overall mean, 5.05).

45. Level of defects at handover	1	4	25	4	2	0	0	178	4.94

5 Discussion of findings

The results indicate that clients of the construction industry in Lagos state, Nigeria are slightly satisfied with contractor work performance having indicated to a very large extent, slight satisfaction with important contractor work performance assessment criteria surveyed and to a very minimal extent in comparison, expressed satisfaction with the important contractor work performance assessment criteria surveyed. Forty (40) of the forty five (45) important contractor work performance assessment criteria had a response of slightly satisfied and only five (5) had a response of satisfaction

Clients identified forty five (45) out of the forty eight (48) surveyed contractor work performance assessment criteria as being of importance to them and also to varying degrees of importance and the topmost ranked three (3) priorities of clients for contractor work performance in Lagos state, given in order of importance are: adequacy of as-builts (finished product), quality of workmanship, and identification/ correction of deficient work in a timely manner.

6 Conclusions

There is a need by contractors in Lagos state to improve on all the aspects of contractor work performance as identified in this research in order to ensure greater levels of client satisfaction. A slightly satisfied client can easily become a dissatisfied client and this could lead to great implications for future patronage in terms of repeat business, client loyalty, referrals, image and hence economic growth of construction firms and this improvement can be done by meeting client expectations in all the aspects surveyed with a particular focus on delivering clients' top priorities identified in this study and given in order of importance to include: Ensuring adequacy of as-builts (finished product); Ensuring good quality of workmanship; and Identifying and correcting deficient work in a timely manner.

United Kingdom

Email: o.h.motaleb@rgu.ac.uk; m.kishk@rgu.ac.uk

Abstract:

The construction business has been at serious risks to the recent global economic recession. In the Middle East, the investments in this business have reached US\$1.8 trillion in 2008, which is forming about 25% of the construction volume worldwide. The financial crisis in the late 2008 has braked up the economic development in many infrastructure sectors. Consequently, the investors unable to keep their confidence in the construction business. The delay in the construction projects is one of the highest risks versus the project success criteria. The three traditional elements of time, cost, and quality are not sufficient since the construction projects are more complex by a change of business environment. The objective underpins this research is to conduct a literature review to identify additional effective measures for controlling the potential delay risks to maximize the opportunity of success in construction projects. Thirty-six scholarly research studies published between 2000 and 2011 have been surveyed to identify related measures for delay control (MDC). The literature survey revealed that 60% of the studies are related to decision-making, performance, risk management variations, and poor management knowledge of stakeholders, whereas 20% are in the Middle East. 25% of the studies are related to lacking of financial risk by stakeholders, which represent 14% in the Middle East. The knowledge gap has been identified in project performance, stakeholders' management, and risk management as significant measures of success criteria in controlling project delay.

Keywords:

measures of delay control, risk management, project management, stakeholders, Middle East

1 Introduction

Construction delay is ubiquitous in the Middle East construction business, as well as considered as one of the highest risks to the project success. This phenomenon is largely owing to its overlapping with the roles and interests of the project stakeholders in a multicultural society. The stakeholders have long been involving in the construction projects as either individuals or organisations; moreover, their interests might be affected positively or negatively according to the success or failure of the project completion. (PMI, 1996). Mitchell et al (1997) argued that a project manager should have to understand the characteristics of the power and authority of the stakeholders that largely affect the project environment and outcomes. Therefore, it would be significant to carry out the identification and management of the stakeholders throughout the running project since their nature and numbers could vary with the life-cycle of the project (Moodley, 2002).

Accordingly, the stakeholders should update their respective commitments and satisfaction, and hence the project success.

Risk management is the most crucial practice in the management of any project to warrant its successful completion. Royer (2000) expressed the importance of risk management experience, as “*Experience in the risk management must be of critical concern to the project managers and the like in the project network since ill-managed risks are one of the primary causes of project failure*”. Unfortunately, many project stakeholders and contributors have not realized yet the need for risk assessment knowledge, which is a key element in the risk-management process; whereas some of them believe that, the risk identification comes by trial and error experience. However, the trivial risk knowledge is usually cascading as a common term among the construction community of the stakeholders.

Artto et al (2008) defined risk from project management perspective as “An uncertain event or condition (favourable or unfavourable) that results from the network form of work, having an impact that contradicts expectations. An event is at least partially related to other actors in a network”. Referring to this definition, four risk-source categories have been identified based on the project sub-contractors’ interrelations with i- other sub-contractors, ii- clients, iii- external competitors, and iv- non-business actors such as municipality and other area authority (Artto et al, 2008). On the other hand, lack of professional managerial knowledge and skills might cause unavoidable risk management failure (Klemetti, 2006). The risk of construction project cancellation and delay in the Middle East, particularly in Dubai has evoked many worries on the investors to go further in construction business (Wilson, 2010).

Project delays would be a major negative impact on the stakeholders whose economic activities have been overwhelmed. In the Middle East, the situation is notably dissatisfied. The stakeholders are being criticised as they are not dynamically and coherently of delay control, which requires an important approach to the project success. The risks of the project delays have been investigated in many Middle Eastern countries such as Jordan (Odeh and Battaineh, 2002; Sweis et al, 2008), Kuwait (Koukshi et al., 2004; 2005), Saudi Arabia (Assaf and Al-Hejji, 2006), the UAE (Faridi and El-Sayegh, 2006; Motaleb and Kishk, 2010), Oman (Al-Nuaimi et al. 2010), and Iran (Khoshgoftar et al., 2010). These studies focused entirely on the delay causes and effects rather than on the control aspects. On the other hand, the recent global financial crisis has braked up the construction boom leading to postpone and cancellation of running construction projects. This financial situation created a great dilemma of project delay and shortage in cash liquidity leading the stakeholders to delay the payments to the developers of the real estates (Khamis and Senhadji, 2010).

The key objective of the delay control management is to minimise the risk versus maximise the opportunities of successful completion of a project. If the target of success is going to be maintained by the stakeholders’ management and satisfaction, it would be interesting enough for those responsible in formulating projects, as well as for those who initiating projects for the first time. In this study, a number of significant measures for delay control (MDC) were picked out from thirty-six scholarly studies published between 2000 and 2011, with special concern on those studies treated the effects of the recent global financial crisis on the situation of construction projects. We hope that this study to encourage further comprehensive research in the future. The paper is organised as following: Section.2 discusses the stakeholders’ management and satisfaction beyond the traditional criteria. Section.3 outlines the adopted research methodology, which is

seeking to improve the stakeholders' management in a positive way, as well as to identify a number of measures for delay control (MDC) to bridge the knowledge gap in the traditional criteria of time, cost and quality. Section.4 discusses the findings to provide a constructive conclusion and recommendation for further related studies in Section.5. A list of the cited references is appeared in Section.6.

2 Beyond the Traditional Criteria and Stakeholders Satisfaction

Although a widely accepted of the traditional criteria on project success the last couple of decades, the construction project management is slowly departing from the traditional criteria (time, cost and quality) measures to a rather effective measures, since criticisms on the traditional criteria and featured by the heterogeneous, while the criteria meeting resources constrains, the components of time, cost and quality are one thing, and to meet specifications is another (Shenhar et al., 1997). Alarcon et al. al (1998) criticised the criteria as well as not appropriate for long term improvement and arrive too late to correct actions to justifying the ability of effective quality. In addition, no longer can project success be restricted by the traditional criteria only (Low and Chuan, 2006); it is lacked of efficiency when Dweiri (2006) looked crucially at the basic criteria as internal measures of project management efficiency.

It is noted to approaching the efficiency, the projects should be measured by the degree of managing risks, since the stakeholders conflicting interests has different views in project success perception and satisfaction (Bryde and Brown, 2005), considering the state of the stakeholders and their degree of influence in the project. Besides, the significant knowledge in which area the stakeholders are willing to accept risks, this could help the risk response strategy (Mulcahy, 2005), as well as managing and register, risks in an innovated framework will help a continuous building of stakeholders' knowledge (William, 2008).

2.1 Significance of MDC and Project Success

The most important outcome that should be observed on the success criteria of the project is the degree of influential variables that related to the performance, decision-making and variations by stakeholders. Performance mainly stands as a motivated measure into the traditional components, cost benefits saving (Beathamet al., 2004), early completion (Chan and Chan, 2004), improve quality (Ling et al., 2009) when conflicts are often due to stakeholders dissatisfaction of poor quality of work.

According to the changing of buildings functions and demands, the performance is one of the most important in project management and should be tailored and innovated for every project (Toor and Ogunlana, 2010). The satisfaction of project performance is a strategic stance in a world of hyper-competition, this has been considered since construction projects suffer from delay and budget overrun. Moreover, powerful of construction organization should compete to win the market place and create values for their stakeholders (Shenhar, 2004). Studies should be concentrated in more depth of stakeholders' performance, management and perception of risk assessment. Landin (2000) considered to gain long-term of construction project performance, the stakeholders' satisfaction is crucial. As well as effective communications management (Bakens et.al, 2005 and Young, 2006).

Empowerment of stakeholders' decision- making was encouraged previously in different environment in project management, but it is limited under project

management authority. It is more valuable for stakeholders to set their goals and keep inventories, such managerial function and plan innovation come from motivated stakeholders or teams that impact on the decision-making effectiveness. Moreover, affect completing projects on time, budget and within specifications (Barber and Warn, 2005). A significant historical information and knowledge has been used to improve decision-making and the outcome of project control (Albinoet, al., 2002) as well.

Variations/change orders have enhanced projects delays by clients, contractors or other stakeholders that emerged for number of reasons such as user change orders in Jordan (Al-Momani, 2000), excusable delay by clients and consultants (Memon, 2004), excessive client change orders in UAE (Motaleb and Kishk, 2010), change orders in Oman by the client and consultants (Alnuaimi et al. 2010), the most effect are the schedule delay, stakeholders conflicts and cost overrun. Some efforts by Arain (2005) have secured the base of knowledge management during the earlier stages of a project life cycle, mean that the greatest requirement for effective variations management.

In addition, the financial measure as a loss of potential revenue, it can be contributed by any of stakeholders, clients (Al-Khalil and Al-Ghafly, 1999; Assaf and Al-Hejji, 2006). The client's payment delay, contractor poor cash flow (Ahmed 2003, Harris and McCaffer, 2003, Construction Industry Working Group on Payment, 2007). As well as bankers, quantity surveyors, architects, consultants and other constructions parties may affect direct or indirect in the process of payment claim, the invalid contractor's claim, certification delay by consultants, poor work valuation and insufficient documents as well as involving too many stakeholders for honour certification process and heavy works on consultant to work on evaluations. Besides, influences of financial crisis (2008-2010) on the Middle East. Constraints of the cash flow that led to delay of payments (Arabic institutions for strategic researches, 2009).

Inflations, and financial market instability lead to cash flow issues (Ahmed, 2003), lack of funding programmes (Adul-Rahman, 2006). That is what happened in the Middle East where the financial resources are affected by the recent Global financial crisis, difficulties to get and approve loans (Khamis and Senhadji, 2010). Similarly, the impact of crisis on the GCC real estate markets, stakeholders (developers) in financial bodies are among the largest openly scheduled companies in Arab markets, and both were adversely affected by the recession. In addition, increasing of real estate prices in the Middle East had ended by 2008 and the average inflation has estimated to decline from 10.8% in 2008 to 3.7% in 2009 (Habibi, 2009). In turn, speculations decreased in mortgage payment, and as a result, many banks came under financial distress.

3 Research Methodology

A literature review has been undertaken for identifying the gaps in delay control and project success. Thirty-six published research studies have been surveyed, which appeared in scholarly and refereed journals in construction projects areas. Some non-conventional documents have also been surveyed such as dissertations, technical reports, working papers, as well as from authenticated websites as listed in Table.1. Excel spread sheet was used to analysing the data observed.

Table (1) Measures for delay control (MDC)

No	Studies/Country (Region)	MDC Tools	Research method	Causes and effects of delay	Impact on stakeholders
----	-----------------------------	-----------	--------------------	--------------------------------	---------------------------

1	Ng, et. al ,2000/ Hong Kong (Asia)	A Conceptual Case- Based Decision Model for Construction Delays Mitigation (Group 1)	Quantitative	Slow-decision by contractor	increase knowledge-good for inexperience planner-
2	Odeh and Battaineh, 2002/Jordan (Middle East)	Contract performance development (Group 1&2)	Quantitative (Questionnaire)	Owner interference, inadequate contractor, financial , labour productivity slow decision-making	minimize owner interference , labor and finance
3	Aibinu and Jagboro, 2002/Nigeria (Africa)	Acceleration of site activities,&contingency allowance(Group3)	Quantitative (questionnaire)	Client related delay	Eliminate time overrun-
4	Shenhar et al., 2002 (N/A)	Risk Identification ,probabilistic risk &trade off (Group 1)	Quantitative (100 projects)	Time overrun,	Improve Risk management
5	Fernie et al, 2003	Knowledge sharing (Group1)	Quantative (observations)	Knowledge problematic	Leason learned
6	Nguyen, 2004/Vietnam (Asia)	Comfort, competence and Commitments (COMs)(Group 1)	Quantitative (questionnaire)	Complexity of projects (many factors)	Improve knowledge in project handling-

4 Findings and Discussion

Typical results of the study are summarised in Table.1. It can be seen that the MDC was 3% in 2000, 8% in 2002 paced back in 2003 and 2004 by 3%. In 2005-2006, measures have improved by 14% and 16% respectively; and decreased again by 6% in 2007, and 3% in 2008. Effort of attractive studies was clearly improved in 2009 and 2010, by 19% to 31%, respectively, as illustrated in Figure.1:

The MDC has been grouped; Group 1 includes decision-making, performance, variations and risk management, Group 2 for the financial risks and Group 3 for the traditional measures, time, cost and quality.

About 60% studies (2000-2011) are related to stakeholders' management and knowledge in variations, decision-making, but very limited in risk management and performance issues (Group1), 30% was pointed out in (2008-2011).

Group 2 is about 25% related to financial risk; one-fifth in (2008-2011) was coincided by financial crisis, which is not satisfied by this phenomenon.

The rest of 15% implicates the third group that related to the traditional criteria (time, cost, quality).

Geographically, it is noticed that in Figure.2:

About 60% studies have been focused on the level of stakeholders' management (Group1) in Global including the Middle East, 25% in the Middle East.

25% are indicated measures related to Group2. Financial risk in Global including the Middle East experienced about 14% exclusively in the Middle East, and 15% for the traditional measures in Global.

As a result:

The highest rank of MDC issues of construction project are related to stakeholders' lack of management and knowledge in risk management, performance, variations and decision-making, ordered from higher to lower priority followed by the financial risk, as illustrated in Figure.2.

In general, top gap of knowledge in risk management and performance has showed that the stakeholders have to think beyond the traditional measures particularly in the Middle East region. The research suggests that Fig.3 should be considered as a new model of MDC and project success. There are three levels at which the MDC should be looked at: Issues related to the stakeholders management in more depth of knowledge for satisfaction and conforms to approve success in traditional criteria (time, cost and quality). It is a possibly questionable when the project is assigned to be successful, it does offer i- stakeholders satisfaction, ii- quality of performance, and iii- advanced knowledge in risk assessment and management. Similarly, it is unlikely to control the project delay if the stakeholders' management is not ensured in the traditional criteria. On the other hand, the mind-set of the performance management should be transformed from the functional to strategy focused, and this should be improved by governmental organisations such as Municipalities.

From the authors' point of view, additional measures may formulate a good dependency of relationship and interaction; predict changes in early stages can minimize the disruptive/risk effects. Moreover, save time for risk assessment to be identified from the source, it helps the project team in decision-making and consequently develops the project performance. Consequently as a result, conforms to stakeholders' expectations.

5 Conclusions and Further Research

A critical literature review has been carried out to identify gaps in handling construction delays. The research gaps are identified as:

The risk management factors that might affect the success of stakeholder management have not fully developed yet. Most of the studies were focused largely on the stakeholders' management concerning control risk of delays. However, a few studies were dealt with the stakeholders' perception of risk assessment as a source that generates possible events and responses, and the principals of delay control in risk management measure.

A range of practical approaches such as in- depth investigation and integration has to be used for the quality of project performance but has not yet fully considered.

A framework was proposed for structuring effective measures for delay control by conducting effective risk management, stakeholder management and project performance gap of knowledge. The findings provide empirical evidence on the context-specific feature of construction delay in the Middle East, particularly in the value of project nature and objectives. These findings help to take the scope of the research one step up along the pathway towards understanding of project success process in different environment although limitations in past studies implicate improper validation of delay control measures.

This study reflects the general view, but needs in-depth investigation in the primary stage. In future, similar studies could be conducted in other regions to validate and compare with the preliminary finding in this paper.

A conducting research of a PhD is on progress to managing the risk of construction projects delays effectively in the United Arab Emirates.

Abstract:

The need for relational contracting in the construction industry is high because of the barriers arising from its highly fragmented nature. While relational contracting principles are less difficult to apply in private sector projects, it is not known if public sector projects can enjoy the full benefits of relational contracting. This paper aims to provide answers to this question. Difficulties of implementing relational contracting principles in public construction projects were firstly discussed. A theoretical framework including a basic model, an integrated stakeholder network, and three categories of measurement items were then identified. Although the theoretical framework and accompanying hypotheses are still required to be tested by a following survey, the proposed findings would guide the application of relational contracting in public projects, thus contributing to better relationships in the construction contracting environment, and thereby boosting project outcomes.

Keywords:

relational contract, public construction project, network embeddedness, relationship

1 Introduction

The relationships between contracting parties in a construction project include formal liaisons and relational links. Formal contracts set out the rights, responsibilities and liabilities of the parties. But in a formal contract, contracting parties act in an atomized manner, looking out for their own interests (Williamson, 1975). Formal contracts do not support contractual incentives or flexibilities that are required in ever-changing construction scenarios, and in the face of uncertainty and complexity (Rahman and Kumaraswamy, 2002). Barriers also arise from the highly fragmented industry and business nature, where there is dichotomy between design and construction. This lack of integration gives rise to adversarial relationships. The need for relational contracting in the construction industry is hence high.

Relational contracting principles may be mobilized to offer contractual incentives/flexibilities, improve relationships among contracting parties, and lubricate any transactional frictions. Relational contracting is based on recognition of mutual benefits and win-win scenarios through more cooperative relationships between contracting parties, and underpins various approaches, such as partnering, alliance, joint venturing, long term contracting, joint risk sharing mechanisms and other collaborative working arrangements (Rahman and Kumaraswamy, 2004a). Relational contracting allows mutual future planning and considers contracts to be relationships among the parties, in the process of projecting exchange into the future (Macneil, 1974).

While relational contracting principles are less difficult to apply in private sector projects (Kumaraswamy, 2010), it is not known if public sector projects can enjoy the full benefits of relational contracting. This is because public clients are not in a position to offer any future relationships, since most projects must be procured through competitive bidding (Rahman and Kumaraswamy, 2004b). Public clients also cannot be seen to have a 'hand-in-glove' relationship with other contracting parties from the private sector, since this may imply cronyism. The possible side-effects of closer relationships include perceived break-down of carefully crafted contractual checks and balances, and dangers of sliding from partnering-type collaboration to corruption (Rahman and Kumaraswamy, 2004a).

According to a survey by Construction Institute of ASCE, it was found that cost estimating is usually a much bigger problem in public construction than in private construction (Minchin et al., 2010). The problem is that the lack of possible relational contracting approaches in public projects may have contributed to projects being completed above budget, behind schedule and to unacceptable level of quality. Yet, public projects are highly visible, and need to achieve the basic triple project goals because tax payers' money is involved. The knowledge gap in how public projects can capitalize upon and adopt relational contract principles is therefore seen. This paper directly address this issue by drawing heavily on 'network' considerations in developing a conceptual framework for managing transactions in public sector construction projects.

2 Features of Public Construction Projects

Clients in public construction projects could be differentiated into clients who have a regular requirement for construction work and infrequent purchase clients. There are usually two ways to develop public projects. The first way such as in Beijing is that the client departments, who want to build their own office building for example, engage consultants and contractors to develop, design and construct the building by themselves. In this scenario, the client departments could be defined as "one-off" clients. They may be "on-off" clients who periodically build a new building. One-off or on-off clients would neither need nor be able to be experts in construction project management and develop future relationships with contractors and consultants. Another common way like in Hong Kong is that the client departments request the relevant work departments to design, call for tenders from private contractors to construct or to design and build the facility. In this case, the work departments could be defined as "ongoing" clients, who have the construction project experience and will have future projects to be constructed. They may have less difficulty to offer future relationships with private contractors. Relational approaches may hence be possible with a long-term relationship founded on regular spending process (Tookey et al., 2001).

Unlike private organizations, government organizations are strictly constrained by many rules and regulations. Even those public organizations that genuinely wish to change are often restricted by standing orders, public accountability and probity constraints (Palaneeswaran and Kumaraswamy, 2000; Chan et al., 2001; Minchin et al., 2010). These preset regulations restrict public officials in some activities and perpetuate a behavior pattern that militates against any kind of trusting relationships with other contracting parties. This pattern pushes both parties back toward a traditionally adversarial approach (Rahman and Kumaraswamy, 2004b). For instance, the public sector has more stringent procedures to follow whenever variations or deviations from contracts occur (Chan et al., 2008).

Organizational boundaries within government departments are typically rigid and impermeable. The departments have well-defined jurisdictions, responsibilities, and a hierarchy of authority. This traditional bureaucratic system of organizing must be overcome to allow public organizations to be partnered effectively (Crowley and Karim, 1995). There is also a lack of communication among such clients. Common knowledge sharing platforms (both internal and external) in public organizations are rare (Palaneeswaran and Kumaraswamy, 2000). This is especially critical in China as the lack of appropriate mechanisms to inspire the different government departments to communicate actively has reduced the efficiency of project approval (Tai et al., 2009).

Public sector is also burdened by a tedious stepwise decision-making system that often slows project delivery. Hence transforming industry enthusiasm into action for relational contracting in the case of public sector clients is not as easy as with private sector clients (Rahman and Kumaraswamy, 2004a).

The private companies had closer relationships with their suppliers than public clients. The public sector was not active to participate in appointing their own suppliers and left this entirely to the contractor, while by contrast, the private companies played a part in the appointment of their suppliers (Gibb and Isack, 2001). This could be explained by the organizational culture of public bodies. Public organizations are usually restrained by an inertia that may arise from beliefs such as ‘that is not our responsibility’ (Palaneeswaran and Kumaraswamy, 2000).

The bid behavior in public construction projects is usually under stricter legal regulations. Taking Hong Kong for example, competitive bidding is always required in a public project, while negotiation is more commonly adopted in the private sector (Rahman and Kumaraswamy, 2004b). In theory, some common key procurement principles for public construction projects are public accountability, value for money, transparency (open, equitable and fair competition), propriety/integrity/probity, and confidentiality. Objectives considered in public sector construction contractor selections include proper delivery of good products and/services, minimization of risks and maximization of value for money (Palaneeswaran et al., 2003). However, in practice, public owners usually continue to select the same procurement route as they are in the habit of. They do not consider what procurement route suits each project best, and therefore they do not select the route according to best practice (Lædre et al., 2006). Furthermore, public clients are also restrained by beliefs like ‘there is no need to change current approaches/practices that are good enough (or even better than others)’, or a ‘not invented here’ syndrome (Palaneeswaran and Kumaraswamy, 2000). This limitation usually means that a well-performing contractor may not improve its chances of winning the next contract, even with the same public client (Weston and Gibson, 1993).

To sum up, the issues discussed above may be considered as difficulties to successful implementation of relational contracting in public construction projects as presented in Figure 1.

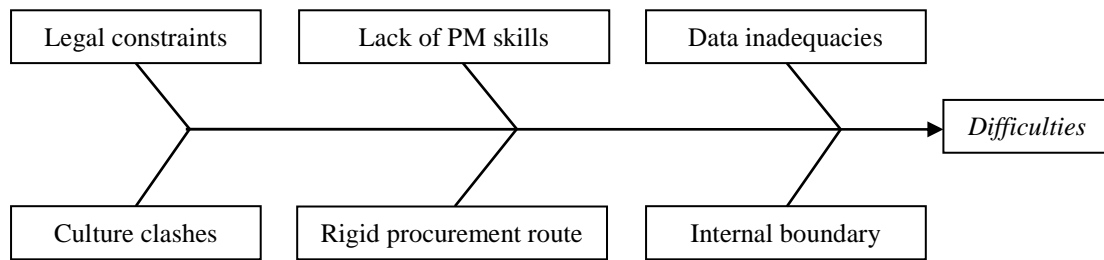

Figure 1: Difficulties of implementing relational contracting in public construction projects

3 In Search of a Paradigm

3.1 Pragmatic Paradigm in Practice

Following the increasing complexities of construction projects, there has been a range of initiatives across many countries to introduce an intensive self-examination and widely publicized reform agenda to the construction process in order to improve performance. Initiatives towards deeper collaboration have played a central role in complex projects, such as the UK “Continuous Improvement” programme (Kumaraswamy et al., 2010) and Australia Alliance Contracting (Clifton et al., 2004). However, there have been improvements, yet these seem not to have been continuous (Anvuur et al., 2011). Taking the UK ‘Continuous Improvement’ programme as example, the 30 percent overall project savings targeted by Egan (1998) have yet to materialize and initiatives have tended to be project-specific (Smyth, 2010). Therefore, this again reinforces the importance of this research.

3.2 Theoretical Underpinning

There are some companies in the construction industry that attempt to maximize their economic profit. They may be keen in participating in public construction projects with the intention of increasing the revenue. They usually prefer to adopt formal contracts, which contain fairly explicit stipulations of proscribed and prescribed behaviors. Contracting parties in a formal contract are adversarial in nature. This type of organizational strategy choice is therefore governed by rational choice theory (Becker, 1976). The basic idea behind rational choice theory is that people do their best under prevailing circumstances (Green and Shapiro, 1996). It therefore usually represents preferences with a utility function and seeks for the utility maximization. Rational choice theory presumes that the individual decision maker’s interest is known and that he/she pursues his/her interests rationally (Becker, 1976). Williamson (1975) stated that in a relatively pure market, parties engage in transactions with minimum interdependence and little expectation for future interaction. The market is operated by ‘economic men’ who exhibit self-interested behavior, are rational, and are affected minimally by social relations. These ‘economic men’ make rational choices in transactions involving formal contracts. They rely on institutional arrangement to guard against trouble, select who to transact with based on pure economic motives, ignoring the identity of and past relationships with the individual actor.

However, risk in a construction project is inherent and difficult to deal with. It is difficult for the partners to completely predict the potential problems and outcomes, and have all essential information. The basic assumptions of expected utility maximization under conditions of uncertainty are especially problematic (Machina, 1987). Contracting parties may also be mutually suspicious of each other as each pursues its profit maximization goal. Instead, Granovetter (1985) argued that most behaviors are closely embedded in networks of social relations. Non-rational behavior will be thereafter quite sensible when situational constraints, especially those of embeddedness, are fully appreciated. It is then noted that the decision making aims not only at economic goals but also at sociability, approval, status and power, which however are rarely seen as rational by economists (Hirschman, 1977). In other words, the objective of the behaviors is therefore not only to maximize utility but also to take into account other social goals (Granovetter, 1985).

Jones et al. (1997) proposed that four conditions promote embeddedness among parties: demand uncertainty with stable supply, complex tasks under time pressure, customized exchanges high in human asset specificity, and frequent exchanges among parties embedded in the network. Construction projects are always characterized by high risks, complex tasks, tight schedule, and long period. It is understandable that participants in the contractual structure of a construction project are usually closely embedded in a social network of relations. There is hence a possible governance mechanism among construction firms and the government embedded in a network.

The Relational Contract Theory was originally developed by Macneil (1974, 1978, 1980, 1983). The theory states that informal agreements and unwritten codes of conduct exist among contracting partners, and these are sustained by the value of future relationships (Macneil, 1978). It allows mutual future planning and considers contracts to be relationships among the parties, in the process of projecting exchange into the future (Macneil, 1974). Macneil (1983) summarized ten common contract behavior norms: (1) role integrity; (2) reciprocity; (3) implementation of planning; (4) effectuation of consent; (5) flexibility; (6) contractual solidarity; (7) the restitution, reliance and expectation interests; (8) creation and restraint of power; (9) propriety of means; and (10) harmonization of the social matrix. Norms applicable to the ends of the relational/discrete behaviors are not simple mirror images. It is worth noting that contractual relationship is not absolutely relational or completely discrete, but exists on a spectrum, which ranges from relational to discrete. Moving a contractual spectrum ranging from relational to discrete does not just give greater or less emphasis to some of the norms, but also transform them (Macneil, 1983; Blois, 2002). The five norms of enhanced importance in ongoing contractual relations are role integrity, preservation of the relation, harmonization of relational conflict, propriety of means, and supracontract norms.

4 Relational Contracting Framework for Managing Public Projects

Two arguments can be drawn from the foregoing discussion. Firstly, public bodies should be differentiated from private companies due to the identified issues presented in Figure 1. Secondly, the two variations in strategic focus will reflect the variations in contracting pattern, i.e. pursuing economic profit only leading to formal contracts and pursuing the balance of economic and social goals leading to relational contracts.

4.1 Network Considerations

In light of the first argument, Figure 2 therefore illustrates how typically multifarious stakeholders in a public construction project need to be integrated. The client body/department/organisation that commissions the built facility and other relevant functional departments like financial department, legislative department, and consulting department are considered in one network; while private contractor, sub-contractors, consultants and suppliers would form another network.

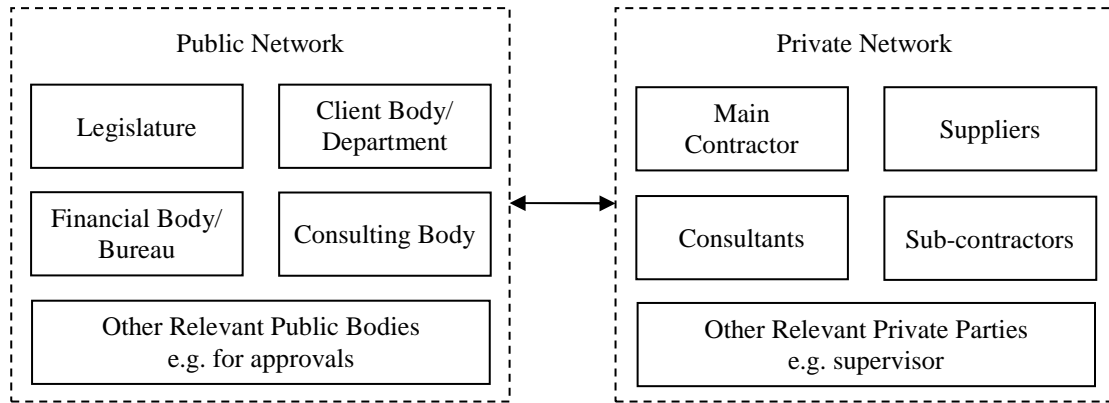

Figure 2: Integrated stakeholders in public construction projects

It is more appropriate to develop two separate networks so that the client department could avoid providing a mistaken impression of having a “hand-in-glove” relationship with private companies. In cities with adequate public accountability and transparency, the difference between relational contracting behaviors and cronyism/corruption is obvious. However, in those cities where public accountability and transparency are not apparent, resistance from the public to adopt relational contracting principles may be encountered.

In addition, one-off or on-off client departments are considered to have less project management knowledge and experience. They therefore need help of other members in the public network, especially the consulting department, to learn about the capability and past performance of bidders in order to choose a reputed contractor. Taking Hong Kong for example, a qualification certificate system is usually adopted in public construction projects such as the List of Approved Contractors for Public Works and the List of Approved Suppliers of Materials and Specialist Contractors for Public Works. In Singapore, the Building and Construction Authority also has a system to register contractors to undertake public works. This is in addition to licensing contractors to undertake large and complex projects. Given the rich project experience of on-going client departments, they can procure the project via competitive bidding and choose any appropriate private partner so as to introduce competition and prevent the “egg-chicken” problem (i.e. a new contractor needs to complete more projects to be reputed but needs to be reputed first to win a contract).

4.2 Basic Model

Based on the second argument, it is expected that the strategic focus will reflect the organizational governance and hence the project performance. Here organizational strategy refers to an attempt for pursuing solely economic goal or a balance between economic and social goals. Pursuing economic profit only (that is interpreted by rational choice theory) would lead to formal contracts, while pursuing the balance of economic

and social goals (that is interpreted by network embeddedness theory) would lead to relational contracts.

In addition, existing literature suggests a positive relationship between organizational culture and project performance (Denison, 1990; Zheng et al., 2010). Organizational culture refers to shared assumptions, values, and norms (Schein, 1985), which are held consistently and enable the organization to have the ability to alter behavior, structures, and systems in order to survive in the wake of environmental changes (Denison and Mishra, 1995). This study focuses on a narrower concept of organizational culture on relationship.

To summarize, Figure 3 presents the basic model. To limit the scope of this research, organizational strategy and culture are both studied from the issue of relationship only.

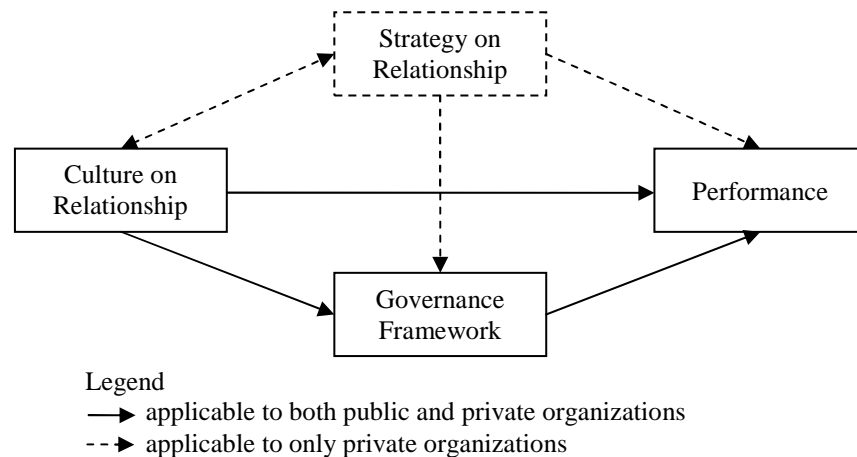

Figure 3: Basic theoretical model

It is worth noting that the objective of public clients in public projects is always not to pursue a maximum economic profit, but instead a maximum value for money towards a balance of multi dimensions. Therefore, “Strategy on relationship” is not a variable to public clients and hence is presented in dashed lines, which means it is only a variable to private construction organizations. More specifically, it is envisaged that:

Hypothesis 1: Private organizations supplying goods/services in public projects that strive towards a relational contracting strategy will achieve better performance than those that pursue economic profit only.

Hypothesis 2: Construction organizations that hold a culture more towards relational contracting behavior will achieve better performance than those that hold a less relational culture.

In the proposed basic model, variables “Strategy on Relationship” and “Culture on Relationship” are both at organizational level, which are in need of a long period to establish. “Governance Framework” is a project-based variable, which includes many other specific constructs like trust and communication and will be further explained in the following section.

4.3 Relational Governance Constructs

To develop a relational governance framework, a literature review is required to identify the elements and success factors of relational contracting approaches, which will be integrated to form relational governance constructs together with the five contract norms of relational contract theory (i.e. role integrity, preservation of the relation, harmonization of relational conflict, propriety of means, and supracontract norms). Based on the (precedent and subsequent) relationships among constructs, a preliminary governance framework could be thereafter derived.

Measure items relating to success factors and elements of relational contracting approach were identified and presented in Table 1. It is worth noting that these items are divided into three categories, i.e. practices by each contracting party, practices between two of contracting parties, and practices among contracting parties. This means of classification provides the possibility to evaluate the practices by different parties and to develop the public and private networks if necessary.

Table 1: Measure items under three categories

Category	Measure Items
Practices by each contracting party	Level of innovation/creativity
	Commitment of resources to the project
	Effort in implementing relational contracting practices
	Acceptance of relational contracting practices
	Culture fit to relational contracting practices
	Financial capacity
	Flexibility when situations change
	Knowledge level about project processes
	Long term commitment level to other parties
	Previous experience in relational contracting approaches
	Readiness to compromise on unclear issues
	Reputation in the industry
	Specific inputs on construction methods, materials, etc before they are formally appointed
	Team working attitude
	Top management support for relational contracting practices
	Attitude to continuous improvement
Practices between two of contracting parties	Familiarity/previous relationships
	Mutual trust
	Mutual understanding
	Open and effective communication
	Level of inter-personal relations/cultural harmony (individual level)
	Sharing of project information
	Ongoing social relationship (eg. “guanxi”, social ties and kinship outside of this project)
	Level of reciprocation/face-saving gesture
Practices among contracting parties	Clarity of division of responsibilities among contracting parties
	Acceptance of performance appraisal mechanism for the project
	Alignment of objectives of different contracting parties
	Collective/combined responsibility by a pre-selected group comprising one person from each major party
	Joint coordination and monitoring plans among contracting parties
	Clearly defined equitable risk sharing arrangement among contracting parties
	Flexible/adjustable contracts to address uncertainties

Category	Measure Items
	Commitment level of contracting parties to joint problem solving
	Presence of conducive learning climate/environment
	Acceptance of dispute resolution mechanism for the project
	Clarity of contract conditions (eg. scope of contract, duties & responsibilities)
	Real gain-share/pain-share among contracting parties
	Effectiveness of team building events used in the project

A questionnaire survey will be conducted, as the second stage of this research, to request public clients, private consultants and contractors to rate the extent to which each of the measure items in Table 1 were present, observed, practiced or emphasized in a past project. Respondents will be request to answer the questions based on one specific completed public construction project which they have been involved in. The questionnaire will include three main parts: i.e. background of the selected project, extent of the activities in the selected project, drivers and obstacles in the selected projects.

The respondents will also be requested to evaluate the performance of the project. The data collected will be analyzed to test the basic model, to identify relational contracting constructs with strong impact on the project outcomes, and then to develop the preliminary governance framework. Following the questionnaire survey, the research will validate the theoretical framework and elaborate on the findings by conducting case studies.

The survey will be conducted in the following cities: Singapore, Beijing, Hong Kong and Sydney. As the funding comes from MOE, Singapore is the natural choice to study. Singapore developers, contractors and consultants are predominantly Chinese by race. How Singapore-Chinese carry out relational transactions will be investigated. To move the study beyond Chinese Singaporeans so that the findings have more international application, this study proposes to investigate how indigenous China-Chinese undertake relational transactions. The research will focus on the capital city, Beijing (as it has a significant number of completed public projects after the recent Olympics). Recognizing that Beijing is not truly representative of China, Hong Kong is chosen to contrast contract practices in the capital and a SAR. To check whether the findings are unique to Chinese when compared to western practices, study will be conducted in Sydney to contrast the findings obtained from Singapore and China. Sydney is chosen because it adopts western project management practices. In addition, more Singapore firms are likely to benefit from an Australian finding as they may also export their services to Australia, and less likely to export their services to UK and US.

5 Concluding Remarks

It is found that contractual relationship is not absolutely relational or completely discrete, but exists on a spectrum, which ranges from relational to discrete. The search for a pragmatic paradigm such as project alliance framework in Australia (which although didn't bring in continuous improvements yet) indicates that relational contracting principles are also applicable to public construction projects. There is hence

a possible governance mechanism among construction firms and the government in a public construction project. A theoretical framework including a basic model, an integrated stakeholder network, and three categories of measurement items were identified in this paper. The framework will be subsequently tested by the fieldwork using a structured questionnaire survey to ascertain its relevance to boost public construction project outcomes.

6 Acknowledgements

The research is made possible by Singapore Ministry of Education's Academic Research Fund Tier 2 funding support (Grant number: MOE2009-T2-2-067) for the project entitled 'Boosting public construction project outcomes through relational transactions'.

Abstract:

Social housing organisations have a privileged position to implement changes on the quality of the housing stock, as they are the owners of a large stock of dwellings. In recent years energy efficiency has become one of the main focuses of their renovation processes. However, the financial capacity of these entities is rather small and limits considerably their opportunities to improve the quality of their housing stock. Moreover, as they offer a public or semi-public service, commonly they have to work with strict regulations.

The current energy renovation processes of social housing organizations from four European countries have been analysed: Belgium (Walloon region), France, the Netherlands and United Kingdom. From this qualitative analysis several problem areas have been identified: strategy, work organization, design decisions, tendering and contracting, knowledge and influence on tenants behaviour.

Moreover, possible alternatives have been proposed aiming to increase the energy performance by improving the coordination and cooperation of the different actors involved in the process. As for example: the use of energy consumption parameters to define the renovation strategy, the involvement of construction and maintenance companies during design phase or the use of selection and award criteria in tendering procedures.

This analysis is the first step of a long-term project. Part of the alternatives highlighted in the paper will be implemented by different housing associations in their renovation processes on the next years.

Keywords:

energy renovation, integrated design, social housing, public procurement, supply chain integration

1 Introduction

In recent years energy efficiency in the built environment has become one of the main focuses of European policies (Uihlein and Eder, 2009). In order to achieve broad energy savings in the existing housing stock social housing organisations (SHOs) have a privileged position, as they are the owners of a large housing stock. However, the financial capacity of these entities is rather small and, as they offer a public or semi-public service, they are commonly under a strict regulation. Public procurement rules

and traditional working methods limit the opportunities to find innovative solutions with the participation of the different actors present in the renovation process.

An integrated design approach seeking for the improvement of communication, coordination and cooperation among the different actors can offer alternatives to the current energy renovation processes.

1.1 Research question

This paper aims to propose alternatives for the current energy renovation processes in social housing. The research question is: How can SHOs improve the energy efficiency of their renovated dwellings and how can they reduce conflicts among actors involved in the renovation processes?

Next the research method is described, followed by the characterization of social housing energy renovation and its processes, the definition of the existing problem areas, the presentation of possible alternatives and conclusions.

2 Research method

Energy renovation is considered to be renovation works resulting in a significant improvement of the energy performance of the building and an extension of the service life of the building. In order to characterize renovation processes, to identify the problem areas and to propose alternatives, SHOs from four European countries: Belgium (Walloon region), France, the Netherlands and United Kingdom have been analysed. The SHOs voluntarily participate in two different research projects.

A total of 33 semi-structured in-depth interviews were carried out among employees of four SHOs participating in an European research project called ‘Shelter¹’ and other actors involved in their renovation processes (e.g. architects, construction companies, maintenance companies). These SHOs are: Walloon Housing Association for Belgium, Logirep and Dynacité for France and Black Country Housing Group for United Kingdom.

For the Netherlands results were used from in-depth interviews and workshops held within the research project ‘Supply-chain integration in housing renovation²’. In this project seven dyads consisting of a SHO and a construction company share knowledge and experiences that they obtain while carrying out a renovation project with an integrated supply chain.

Part of the alternatives proposed in this paper will be tested on the on-going pilots for both research projects.

3 General characteristics of social housing renovation

Dwelling renovation in social housing is shaped by national social housing policies, energy regulations and market regulations. The characteristics of these three elements per country are presented in this chapter.

¹ Shelter. <http://www.shelterproject-ieee.eu> Intelligent Energy Europe project.

² In Dutch: Ketenintegratie bij woningrenovatie, a project initiated by the Lectoraat Vernieuwend Vastgoedbeheer, University of Applied Sciences Utrecht.

3.1 Social housing renovation policies

Among the four analysed countries, two different main goals in the national social housing renovation policies have been identified. Belgium (Walloon Region) and United Kingdom focus on improving health and safety in social housing while France and the Netherlands have in recent years specified their focus on reducing CO₂ emissions. Commonly, the first approach has an effect on energy efficiency too; however, there is not such a specific energetic target as in the second approach. In all cases the renovation policy is being promoted with a different type of funding programs. See Table 1.

Table 1. Main national social housing renovation policies and implementation tools.

Country	Main goal of national social housing renovation policy	Implementation
Belgium (Walloon Region)	Improve health and safety	Exceptional Investment Program
France	Reduce CO ₂ emissions	Law Grenelle
Netherlands	Reduce CO ₂ emissions	Covenant Energy Saving
United Kingdom	Improve health and safety	Decent Homes Standard

In Belgium (Walloon Region) there is an Exceptional Investment Program for renovation purposes that is managed by the Walloon Social Housing Society, umbrella organization for the Walloon SHOs and depending on the Walloon government. The program is subsidizing the renovation of 33% of the social housing stock of Wallonia (Schutter and Mureau, 2009).

In France the generalist environmental Law Grenelle to reduce CO₂ emissions is being implemented by different plans. In the Building Plan the social housing sector has funding incentives through eco-loans. The *Caisses de Dépôts* offers them loans at low interest rates for renovation projects aiming to improve energy efficiency of dwelling rated D or lower by French energy certification standards (Plan Bâtiment Grenelle, 2010).

In the Netherlands SHOs federation Aedes, tenant federation Woonbond, and the national government have signed an Energy Saving Covenant (VROM, 2008) for the housing sector. The covenant has no legal status but defines the common agreement for achieving a certain goal; in this case upgrading the energy performance of all social dwellings to reach energy label B or at least to improve their performance in order to raise the energy label by two degrees.

In 2000 the UK government defined the Decent Home Standard and a Decent Home Program to achieve this standard in all UK social housing stock by 2010. In 2010 10% of the stock was not yet at the standard level. Nevertheless, there has been a large improvement in the health and safety parameters. The program had a Housing Revenue Account managed by the local authorities that offered subsidies for this purpose. At present, UK is defining the goals of a new social housing renovation policy (House of Commons, 2010).

3.2 Energy regulations

The Energy Performance of Buildings Directive, EPBD, has been introduced in all European countries (EPBD CA, 2011). In the four analysed countries it is now mandatory to obtain an energy certificate for the dwelling in case it is being sold or

rented. Therefore, it is not necessary for SHOs to obtain the energy certificate of all their properties. However, as the national policy of certain countries has related the available funding to achieving a certain energy label, the SHOs of these countries have certified the whole stock in order to make energy performance one of the decision fields within their strategic asset management. See Table 2. Among the analysed countries this approach is the case of France and the Netherlands. Belgium (Walloon Region) is already in the process of applying a similar approach (SWL, 2010).

Table 2. Introduction of EPBD score of dwellings in SHOs property register

Belgium (Walloon Region)	France	Netherlands	United Kingdom
Planned to start general implementation next year	Generally implemented	Generally implemented	Not implemented

3.3 Market regulations

SHOs have a different entity status in the European Union that can be categorized mainly in two types: public entities or private non-profit entities. In France and the UK both types of entity exist, whereas in Wallonia all SHOs are public and the Netherlands all SHOs are private non-profit organisations. See Table 3.

European public tendering rules for services (also including design) and works apply to public and private SHOs that use public funds: Belgium, France and United Kingdom. Moreover, national public procurement rules apply under the European thresholds for public entities in Belgium and France (Global Legal Group, 2011). In the Netherlands SHOs are not classified as bodies governed by public law, therefore public procurement rules do not apply to them (Jong and Carnier, 2011). The differences in implementation of public procurement rules and the limitation that they cause to the entities subject to them are currently under discussion at the European Commission (European Commission, 2011).

Table 3. Types of SHOs and Public Procurement Rules applied to SHOs

	Belgium (Walloon Region)	France	Netherlands	United Kingdom
Types of SHOs	Public	Public Private (Non -profit)	Private (Non -profit)	Public Private (Non -profit)
Public Procurement Regulation	EU PPR + Belgium PPR for all SHOs	EU PPR + French PPR for public SHOs	Not applied to SHOs	EU PPR

The fundamental principle of public procurement rules is that the contracts with a budget higher than a defined threshold must be opened up to a nation-wide or EU-wide tender. The conditions of the tender must be published in official EU or national media, depending if national or EU tendering rules apply (Grelier, 2009; Thiel, 2010). The process must assure the equality of treatment among all the candidates.

SHOs can organize an open or restricted procedure. In an open procedure the candidates apply directly with an offer. In restricted procedures the candidates are pre-selected by certain selection criteria related to economic and financial standing and technical or professional certificates. Public procurement rules offer other kinds of procedures, but these are not applied to renovation projects in social housing.

In the case of restricted procedures it is possible to define a framework agreement that allows using the same pre-selection of companies for certain type of contracts for a

maximum of four years. In all restricted procedure a minimum number of companies must be pre-selected (Office of Government Commerce, 2008).

The contract can be awarded to the “lowest price” or to the “most economically advantageous offer”. In order to define the “most economically advantageous offer” a set of criteria needs to be defined beforehand by the SHOs. These award criteria can take into account among other parameters total cost of ownership, delivery date, running costs, cost effectiveness, technical merit, sustainable solutions and after sales-service (Global Legal Group, 2011).

4 Current energy renovation processes

In order to improve the dwellings to current standards, several elements of the dwelling could be replaced; e.g. kitchen, bathroom or the electrical installation. Among the works performed some effect the energy consumption; e.g. insulation of walls and roof, double-glazing of windows, introduction of assisted ventilation, new heating system and, less applied, installation of renewable energy systems.

The SHOs in this research adopt two main types of renovation processes: major renovation and planned maintenance.

4.1 Major renovation

Considering the renovation process from inception until exploitation it can be divided in four phases: planning, design, construction and maintenance. See Figure 1. During this process seven main types of actors are present:

- Tenants
- Social Housing Organisation
- Investors: Bank, Municipality, Regional Government, National Government, Energy Companies.
- Designers: Architects, Engineers, Consultants.
- Construction companies (including installation companies)
- Maintenance companies
- Manufacturers

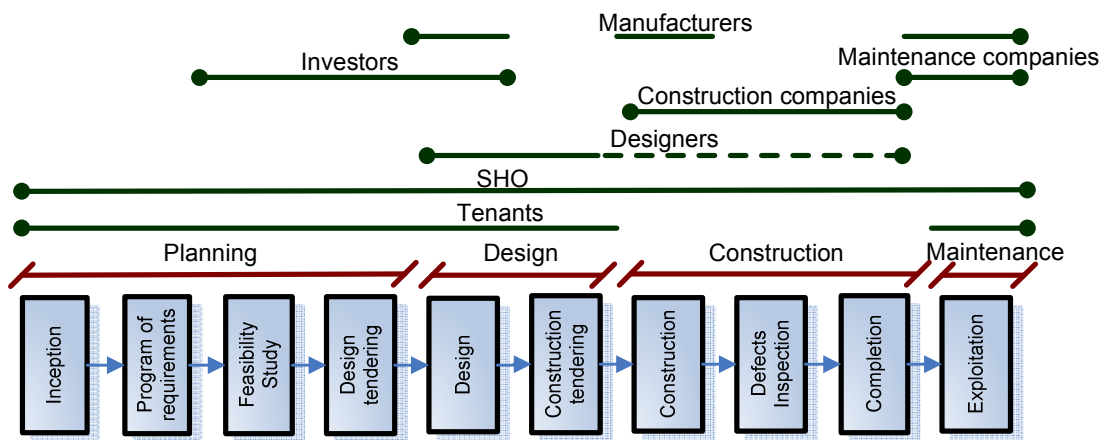

Figure 1. Major renovation process; phases and actors present in every phase.

Major renovation takes place mainly in empty properties, and the tenants have commonly a minor possibility to participate in the design decisions. In effect, only the

SHOs and the designers participate in the designs decisions. Construction companies and maintenance companies get involved into the project once the design is completely defined. The communication between designers, construction companies and maintenance companies is mainly by technical reports.

4.2 Planned maintenance

Planned maintenance can be considered being a renovation strategy in the case that after execution of a long-term maintenance plan the condition status of the effected building components are the same than after a major renovation.

In planned maintenance the different interventions, e.g. replacement of the kitchen, replacement of the heating system, insulation of walls and roofs are done independently in different moments of time. See Figure 2. Thus every action takes only a few days and commonly the dwellings stays occupied while the intervention takes place. Moreover, as standard technical solutions are applied, commonly designers are not involved in the process.

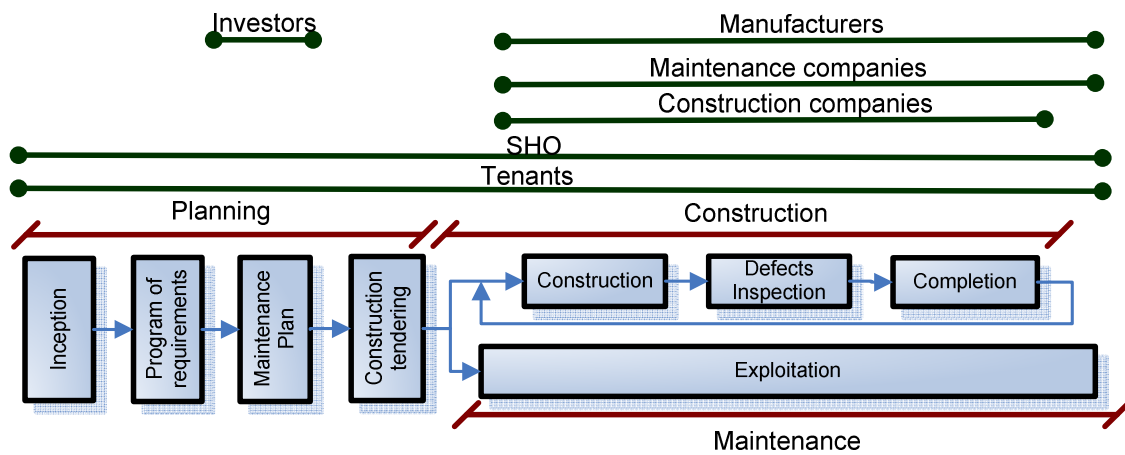

Figure 2. Planned maintenance process; phases and actors present in every phase.

5 Problem areas and possible alternatives to current energy renovation processes

Six different main problem areas have been identified while analysing the SHOs participating in the projects: strategy, work organization, design decisions, tendering and contracting, knowledge and influence on tenants behaviour. In this chapter the problem areas will be presented as well as the possible alternatives to avoid them.

5.1 Strategy

In Belgium (Walloon region) and United Kingdom the renovation strategies don't have improvement of energy performance as one of the main decision making parameters.

Possible alternative

The SHOs could use an energy consumption parameter, e.g. the energy certificate, in the diagnosis and planning phase of their strategic asset management. This solution has already been implemented in two analysed countries, France and the Netherlands, and has allowed taking into account energy performance while prioritizing the renovation of the housing stock. Nevertheless, currently there is discussion about the accuracy of

energy performance certificates as reliable energy consumption indicators (Entrop et al., 2010). In the four analysed countries the energy certificate score is obtained by simulation. Therefore, it is an estimation that does not take into account the real energy use and tenants' behaviour.

5.2 Work organization

If SHOs use planned maintenance methods for energy renovations commonly there is no design phase. Therefore standard solutions for the replacement of specific elements are applied. Moreover, as the different actions (e.g. replacement of heating system, insulation of the walls or double-glazing of windows) are performed in different periods in time, they cannot be part of an integrated solution. Therefore, while using planned maintenance methods there is less room for innovative energy saving solutions.

Possible alternatives

Planned maintenance is defined by different independent components to be renovated. A possible alternative is to integrate them by defining a standard design per dwelling typology. Thus, there will not be a design phase for every dwelling, but it will be a design phase for all the dwellings of a certain typology. Therefore, it is possible to foresee positive and negative interactions of the different elements to be renovated.

5.3 Design decisions

Commonly only the designers (architects, engineers and consultants) and the SHOs are active during the design phase in major renovations. . This means that the practical knowledge gathered by construction companies and maintenance companies is not used properly, that may effect in needless costs, as the costs for modifications of a construction project increase in time, see Figure 3 (Uher and Loosemore, 2004).

Figure 3. Major renovation process. The impact of decisions in design stage on project outcomes. Adapted from (Uher and Loosemore, 2004).

Possible alternatives

An alternative is to involve constructors and maintenance companies in the design phase of a renovation project. However, this simple solution is not easy to implement as the majority of SHOs are under restrictions imposed by the public procurement rules. Moreover, the level of these restrictions is quite different among the different analysed

countries, as shown in chapter 2.3. Thus, two different options for this collaboration during the design phase are possible.

- Use a design-renovate-maintain contract
- Invite maintenance companies as consultants during the design phase

The most complete, is to tender design-renovate-maintain in one single contract. Therefore, the consortium awarded with the contract will be working together from the start of the project. The consortium is formed by a group of companies like an architectural firm, technical consultants, a construction company and a maintenance company. Moreover, as the operation phase is part of the contract, the responsibility in case of a mistake can not be avoided. Even more, this kind of contract can take the maximum profit of performance-based specifications (see chapter 5.4).

Design-renovate-maintain contracts are nowadays not possible for institutions under public procurements rules in some European countries, like Belgium (Walloon region). The first experiences for design-renovate-maintain contracts in the social housing sector are currently being implemented in France (Marote, 2010), some have already been implemented in United Kingdom and in the Netherlands some SHOs started to use design-renovate contracts in the year 2008 (Woonwaard, 2008). These experiences have highlighted two main possible dangers of this kind of contracts: rarely SME's apply for this type of contract as the risks associated are too big for the size of their company (European Commission, 2008); and the architect can lose his role of independent advisor for the SHO, having a contractual link with the construction company (Heller, 2008).

The second option is to involve the maintenance companies as consultants during the design phase. Commonly SHOs have 3 to 10 years contracts with maintenance companies responsible for responsive maintenance of (parts of) their dwelling stock. Therefore, these companies have a good practical knowledge of the properties and could participate as consultants during the design phase.

5.4 Tendering and contracting

The selection and award criteria used in tendering and contracting, the type of specifications (descriptive or performance-based) and the contract's volume can change the relation among actors involved in the renovation process and can even change the structure of the process.

Even though European public tendering rules promote the use of award criteria, currently numerous SHOs are still awarding the contracts by selecting the lowest bid, without valuing the quality of the services offered. Moreover, the tenders and contracts mainly use descriptive specifications. This reduces the opportunities for innovation by the construction companies and makes it difficult to define responsibilities in case of mistakes (Sexton and Barret, 2005).

There is a trend for contracting all renovation works in one single contract. Therefore, only general contractors can apply. This method reduces administrative and supervision tasks for the SHOs. However, there is less control by the SHOs of specialist works that will be subcontracted to other companies and it is more difficult to facilitate the participation of SME's.

Possible alternatives

In order to take into account other parameters rather than price while awarding the contracts there is a need to implement award criteria in all tendering procedures organized by SHOs. To facilitate the implementation of this procedure it is advisable that national and European institutions define a list of recommended award criteria.

The use of performance-based specifications in place of descriptive specifications allows the contractor to get involved in proposing possible alternatives (Straub and Mossel, 2007). Moreover, performance-based specifications allow defining clearly the responsibilities if the requested performance is not being achieved. However, the utilization of performance-based specifications requires that designers and contractors get used to these types of criteria. Moreover, it is needed to define evaluation methods to check the performance-based criteria after construction.

In the cases that SHOs make single contracts for renovation works it is possible to increase the control capacity over specific works maintaining a low profile of administrative and supervision tasks if SHOs, by dividing the contracts in two lots. The first lot includes most part of the work addressed to general contractors, the second lot is for specific works, as it could be the heating installation.

5.5 Knowledge

Construction projects require the participation of professionals with the necessary knowledge. In the case of energy renovations specific knowledge is needed for the designers, constructors and maintenance companies. Unfortunately, this is not always the case as the energy renovation sector is confronted with a constant evolution of building and system products. Moreover, public procurement rules (except for the Netherlands) force SHOs to tender every project separately, limiting the learning curve of the renovation projects of a SHO.

In the cases that works are contracted to a general contractor, commonly some specific works are subcontracted. The subcontracting will be done by the general contractor. In this case, the SHOs must trust the criteria of the general contractor as it does not have the possibility to identify if the subcontracted companies have the required knowledge and competences.

Possible alternatives

In order to assure that all actors participating in the renovation process have the required knowledge it is possible to use selection and award criteria in the tendering procedures. Selection criteria are used in the pre-selection of candidates in restricted procedures. Currently they are mainly used to test the economic and financial standing of the companies, but it could be used also to require certain official certificates about technical and professional competences. The implementation of certificates at European level that assure the professional quality can facilitate the selection of professionals with the required knowledge for the task to perform (ADEME et al., 2011). Moreover, as mentioned before, while awarding the contract among the pre-selected candidates a set of awarding criteria can be used to value the quality of the offer.

In case of works awarded to general contractors, SHOs can require to have a meeting with the designers and all the participating subcontractors in order to identify possible technical knowledge gaps among the participants and look for solutions to solve them.

5.6 Influence on tenants behaviour

The potential energy savings of energy renovations in social housing can be jeopardized by the inappropriate behaviour of the tenants; for example by the opening of windows at winter time to ventilate still being a common action in renovated buildings equipped with mechanical ventilation with heat recovery systems. Or by the increase of tenants comfort standards; for example by heating all the rooms of the apartment. SHOs commonly inform about the appropriate use of the dwelling installations after renovation to their tenants. Nevertheless, the influence on their behaviour still seems to be rather small.

Possible alternatives

In order to influence tenants behaviour is it possible to implement actions that make a direct link between their actions and the cost of the energy bill. These can be implemented by the use of smart meters and individualized energy advice to reduce the costs. Depending on the set up of the energy services, individual or common, different strategies can be implemented to use the savings obtained by the reduction of the energy costs to pay for the meters and the advice offered.

6 Conclusions

European SHOs, represented in this study by four different countries, have an enormous potential for energy saving through the renovation of their dwelling stock. Unfortunately, they are limited by the availability of funds and by the rigidity of the public procurement rules.

In this paper an overview of the alternatives existing in the current system for energy renovations in social housing has been presented covering six identified problem areas: strategy, work organization, design decision, tendering and contracting, knowledge and tenants' behaviour. The most important recommendations are:

- Introduce energy efficiency as one of the main parameters in the energy renovation strategy of SHOs.
- Define a standard design by dwelling typology for SHOs that use planned maintenance as renovation strategy.
- Involve construction and maintenance companies during the design phase in energy renovation projects.
- Define lists of recommended award criteria for contractors selected for energy renovation projects.
- Make use of performance-based specifications.
- Define separate contracts for specific works in energy renovation projects.
- Implement professional certificates at European level.
- Implement actions that make a direct link for the tenants between their behaviour and the energy bill.

Part of the proposed alternatives will be implemented and tested in posterior phases of Shelter and "Supply-chain integration in housing renovation" projects.

Project governance as a means to enable project coordination and communication: a BSF case study project

Ndoni, Doubra Henry and Elhag, Taha. M. Salih

Bartlett School of Construction and Project Management,
University College London, London, UK

Email: d.ndoni@ucl.ac.uk

Abstract:

This paper intends to illustrate the significance of project governance as an approach to align all construction supply chain activities to facilitate information exchanges within project coalitions. The coordination of construction supply chain activities and communication within construction project networks are widely considered as areas that requires improvement to enable efficiency and effectiveness in the construction industry. A major impediment identified for managing task interdependencies and project teams' integration is that a number of construction organisations use centralised models for organising and coordinating design, construction and the whole supply chain. It implies that the traditional approach is not adequate to control construction supply chain as such there is need for supportive approaches.

The integration and connectedness of project partners is necessary to foster condition for knowledge sharing and enabling condition for innovative approaches. The key purpose of governance is to allocate resources, to coordinate and control actions across project networks. In this study, the paper investigates how governance structure affect project teams information exchange relationships and coordination in the course of delivering a construction project. As such data is gathered from the exchange relationships between project actors of a BSF project in the United Kingdom. All the information exchanges are analysed with UCINET 6 software to investigate the varied relationships.

The results indicate that a good mix of project governance influences project actors exchange relationships and cooperative activities. Furthermore, the study also suggests that governance ensures service outcomes are realised but if well defined and guided.

1 Introduction

The construction industry has seen significant changes in forms of procurement systems been used to procure services. The procurement systems used are for varied reasons amongst them are: project complexity, to enable competitive advantage and to transfer project risks. According to Tookey et al., (2001) the choice of procurement method is dictated by the requirements of the client, cost, quality and time. Winch (2000, 2002) described the procurement reforms that took place in the United Kingdom. The systems

include: craft system, trade system, general contracting and professional system. (1) The craft system – relies on the appointment of a master craftsman who employs the services of tradesmen on daily basis to accomplish the job. (2) The trade systems - refers to where the architect took on the task of coordinating the building crafts. The system witness the designation of actors to separate functions such as ‘conception and control’ on the one hand and ‘construction’ on the other; (3) General contracting - refers to a group or single contractor that undertakes the sole financial responsibility for entire works (construction, renovation or demolition of a building, road or other structure) in a single contract; and (4) The professional system – its most distinctive features are the separation of the conception and control functions, together with a reinforcement of the construction function.

In spite of the reformation the industry have gone through it is claimed that the procurement systems are still fashioned to segment the various construction delivery processes of which it affects coordination and communication within the functional delivery teams. As such the approaches are still believed to still follow the methods of the trade system (Winch, 2000, Masterman, 2001, Langford and Murray, 2004). This problem was earlier identified by Higgins and Jessop (1965) and Tavistock Institute (1966) as a setback for effective communication and coordination between members of building teams in the industry. As such project team integration was seen as an appropriate or necessary solution to solve interdependence, uncertainty and complexity of the industry. Green et al., (2004) referred to the fragmented structure of the construction industry as a significant hindrance to the diffusion of ideas. These issues had already attracted widespread publication for example Latham (1994) and Egan (1998) introduced the concept of partnering relationship as a means to improve the working processes of the UK construction industry. Subsequent studies have advocated the principles of integrated supply chain management (ISCM) as an appropriate means for the integration and management of the construction supply chain (Holti et al., 2000, NAO, 2001, Nicolini et al., 2001, Venkataraman, 2004).

In a similar vein, the fundamental challenge for large infrastructure projects is system integration but project governance was found to be an appropriate means to assume the responsibility for project partners’ integration and to lead the temporary project coalition (Davies et al., 2009). It is also found to be significant in aligning all project resources (Robinson et al., 2010) but there appears to be no compelling argument for industry-wide adoption of new working practices (Green et al., 2004). Accordingly, the functional segregation and clustering of construction processes inhibits efficient knowledge creation and organisational learning. The implication is such that knowledge sharing and learning opportunities are reduced or neglected (Gann and Salter, 2000, Ingirige and Sexton, 2006). The crux of this paper in relation to the BSF scheme is based on Sunand Prasad’s (Royal Institute of British Architects - RIBA, President) argument at RIBA (2008) event in Manchester that the BSF procurement process inhibits core relationship between architects and teachers, resulting in below-par schools. One important approach to improve this is through encouraging recurrent interaction with all partners of which it will lead to an expectation of behaviour superior to that of an untested partner (Gulati, 2008).

This paper is set out as follows: in the first section, the paper will attempt to review relevant literature on construction project coordination and communication in the construction industry to build the research problem of this study. In the second section, the concept of network perspective is presented. Third, the research methodology is presented. In the fourth section, a case study project is presented procured under the UK

BSF scheme to investigate the significance of network governance in project actors' exchange relationships. It will discuss significant factors that construction organisations need to promote to enable communication. Finally, the conclusion will examine the implications to the construction industry.

2 Project coordination and communication in the construction industry

According to Hossain (2009a) construction process requires a high level of coordination mechanisms to align all the professionals and trade persons within the construction delivery process from project design to the construction site until the project is completed. Grandori and Soda (1995) identified 10 coordination mechanisms organisations can employ to sustain cooperation within inter-organisational networks as follows: a) communication, decision and negotiation; b) social co-ordination and control; c) integration and linking –pin pole and unit; d) common staff; e) hierarchy and authority relations; f) planning and control systems; g) incentive systems; h) selection systems; I) information system; and j) public support and infrastructure.

These mechanisms can be employed in: a) social networks (collaborative arrangements); b) bureaucratic networks (contractual arrangements); and c) proprietary networks. Social networks are specifically based on interpersonal relationships of which does not need to be formalised into external and internal contracts in order to achieve effective and efficient coordination. Bureaucratic networks emphasize formal contractual agreements between collaboration partners of which are never complete. Proprietary networks are conceived as bureaucratic formal contractual agreements based on financial or property rights. Bureaucratic networks need a wider mixture of co-ordination mechanisms depending on the type of network arrangement. The coordination mechanisms employed for differentiated and integrated type of complex projects such as design and construction projects requires a wide mix of mechanisms such as inter-firm planning, mutual control systems, and penalty systems. Although, for proprietary networks there is need to use 10 of the coordination mechanisms to ensure high level of integration (Grandori and Soda, 1995, Grandori, 1997). A good example of such is the BSF programme which has multiple contractual relationships.

However, project partners' coordination and their integration across project networks are critical for effective construction and project management. Most significantly, sharing information is a key component or outcome for tight integration to optimize the chain-wide performance of the project team (Titus and Bröchner, 2005). Similarly, Edum-Fotwe et al., (2001) have pointed out that information in construction supply chain is a strategic resource that drives both the processes and competitiveness of the companies in the chain. In a similar vein, based on research findings by Hatmoko and Scott (2010) their study suggest that delays in: a) material flow; b) labour flow; c) information flow; and d) plant, equipment and temporary work flow can impact on project performance. In an earlier study, Dainty et al., (2001) found that lack of trust over the motives behind supply chain management practices and negative attitudes hinder successful construction supply chain integration to facilitate cooperative behaviours. The implication of these findings suggests that managing the construction supply chain is significant to facilitate effective and efficient knowledge/information exchange relationships.

Concerning communication, Thomason (1988) defined “communication as the lifeblood of any system of human interaction as without it, no meaningful or coherent activity can take place”. Therefore, to facilitate effective communication within project teams requires early establishment of clear lines of responsibility and clear problem resolution process within the integrated team (Ochieng and Price, 2010). Cheng and Li (2004) suggest that for a successful partnering relationship a series of mechanisms should be taken into consideration such as communication mechanism to sustain the collaborative relationship. However, considering the nature of construction delivery process, information sharing can be hindered where the project is one-off or a temporary project coalition (Turner and Müller, 2003, Ingirige and Sexton, 2006). Hossain and Wu (2009) suggest that organisations should consider structural position in a network in designing and mapping coordinated groups. This implies that centrality have a profound effect on project coalition coordination in construction projects (Hossain, 2009b, Hossain, 2009a). This is helpful but to support and strengthen coordination and communication, project governance is highly significant because it can align project resources and as well enable information flow. However, there has been little research to date investigating the impact of project governance on project partners’ information exchange relationships in the construction industry. However, the significance of governance in project-based organisations has been acknowledged as a means to support project teams in the management of projects (Turner and Keegan, 2001, Abednego and Ogunlana, 2006, Müller, 2009). To support this claim, Robinson et al., (2010) suggested that the establishment and development of project governance within project organisations ensures the proper flow of information.

3 Application of social network analysis in construction

The use of social network analysis (SNA) tools in construction to explore project coalitions or multiple project network relationships is increasing. Notable studies conducted using the concept includes: Loosermore, (1998) who used social network analysis to explore the social and behavioural phenomena within the management of construction crises. Kratzer et al., (2010) also investigated different structural aspects of social networks of teams and their creativity within two multinational product development programs. It implies that SNA can be used to study ‘project teams’ structure and relationships’.

It has also been used as an analytical tool for the identification and classification of procurement and project coalitions (Pryke, 2004a, Pryke, 2004b, Pryke, 2005, Pryke and Pearson, 2006). Similarly, using same approach Hossain and Wu (2009) and Hossain (2009b, 2009a) explored the correlation between actor centrality and project-based coordination using social network analysis software.

In addition, Chinowsky et al., (2008) integrates classic project management concepts with social science variables to improve knowledge sharing as the foundation to attain a high performance team to achieve project outcomes based on social network concept. In a similar vein, a study was conducted using SNA to gain insights of the performance of individuals (workgroup) in geographically distributed knowledge-intensive work environments (Chung and Hossain, 2009). Also, from another viewpoint but still focusing on performance, Park et al., (2009) studied a variety of collaboration patterns and their impact on performance using social network analysis. The findings demonstrates that collaborative networks are developed in order to realise improved performance when project conditions are risky

Finally, from another standpoint based on a case study conducted by Ndoni and Elhag (2010), that focused on the benefits of collaborative network. A network perspective was proposed because it provides the benefits of optimizing relationships to achieve economies of scale and to enable the management of multiple contractual relationships within project organisations.

Overall, this section demonstrates that social network analytical tools, especially UCINET 6, can be applied or employed to study and understand the structure of project organisations and their multiple relationships. However, there is yet to be a study as this paper is aware of that has investigated the impact of 'project governance' on information exchange relationships of project teams within project-based organisations using SNA. This is a significant contribution to project management literature.

4 Research methodology

A case study research approach is preferred to substantiate the paper's proposition using social network analysis software. The case study project is a UK Building Schools for the Future (BSF) scheme. The name of the scheme is withheld for confidentiality reason. The rationale for selecting the BSF project as a case study is based on the nature of the BSF programme. Overall, the project team comprise: a) the client (Local City Council); b) the design organisations (two design organisations); c) the construction teams (ICT, Mechanical & Structural, Cost consultants and the led construction organisation); and d) facilities management organisations.

To achieve the objective this paper a project questionnaire was designed in a format that data collected can be transferred into UCINET 6. Subsequently, the developed questionnaire was distributed amongst the defined project team. For validity and reliability of the research results, respondents were mainly senior executives from the respective project organisations. The following questions were asked respondents: From whom do you receive information which helps you carry out the project? From whom do you send information which helps you carry out the project? Twenty-one (21) respondents were involved in the information exchange relationship.

It provides a good means to study the flow of information between project partners. In addition, most significantly the project organisations developed a governance framework that is focused on aligning people, roles, processes, standards, tools and mechanisms for project compliance (Robinson et al., 2010).

Social network analysis is appropriate for 'relational data', and this are contacts, ties and connections relating to one person to another (Scott, 2001). Relational measures capture emergent properties of social systems (or social structures) that cannot be measured by simply aggregating the attributes of individual members (Knoke and Kuklinski, 1982). The visualization in KrackPlot format is relevant to the construction industry in terms of providing a means of communication that construction practitioners and student can relate and understand (Pryke, 2001).

5 Discussion on the project organisations' project governance structure and network analysis

Fig 1.1 presents the BSF consortium governance structure. The governance structure shows different lines of relationships within the project network as such it explains how

the whole project delivery team has been monitored and coordinated to achieve expected project outcomes.

As illustrated in Fig 1.1, the Scrutiny and Approval strategy of the consortium refers to the approaches used to coordinate and control the multiple contractual relationships within the project network. These includes: a) NPAP, Strategic Partnering Agreement, the Executive Boards and the LEP. By examining the governance structure it is obvious that the lines of communication are clear to enable the delivery of the BSF programme.

A critical examination of the governance structure reveals an overlap of the 'Scrutiny and Approval' approaches adopted for the BSF scheme with the 'Strategic Approach' to deliver the BSF programme. It illustrates effective lines of contact between the Local Authority, the LEP and the integrated project team to ensure that detail contractual agreements are achieved for the overall school projects. The fact is that the governance structure seems to encourage the frequent interactions between all the project delivery organisations. In addition, it also seems to be a significant approach for the partnership to learn and transfer knowledge within the BSF programme. This is a fundamental benefit of having a governance structure because it ensures the effective planning of projects and proper flow of information (Müller, 2009, Robinson et al., 2010).

Finally, it evidence that the governance structure provide for lines of communication to enable the effective management of the BSF programme. In examining the governance structure there is a clear linkage between the client (local authority), the project organisations and the various schools and stakeholders. The lines of interactions can be vital to enable better understanding of the respective schools authority's vision for learning environments.

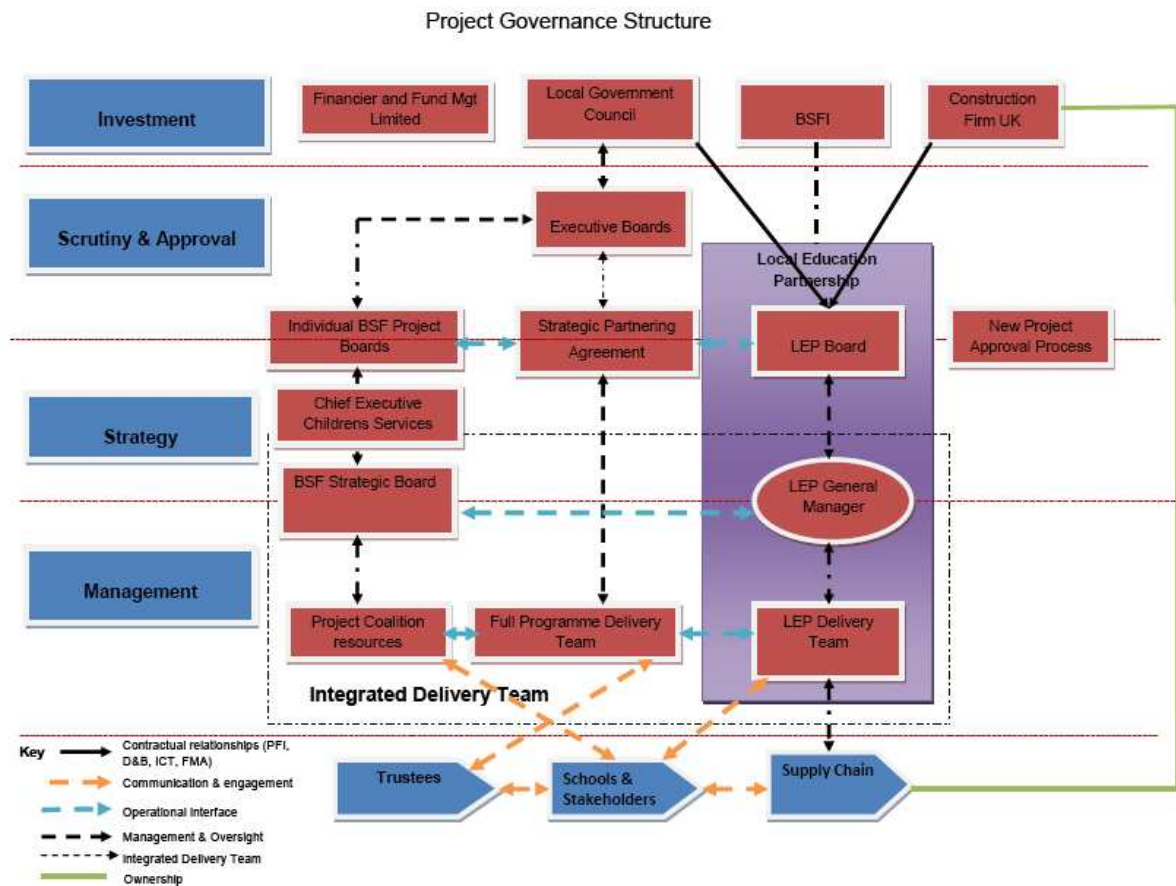

Fig 1 the BSF delivery project governance structure

The governance structure has been able to align project resources, control and co-ordinate all project activities at the project level of the BSF programme. The implication is that it facilitates accountability and transparency within the BSF delivery framework. This is significant for PPP/PFI projects because efficiency is encouraged and the project supply chain is integrated through the governance structure.

ARC1	Architectural firm	0.354	0.345
ARC2	Architectural firm	0.313	0.299

Fig 2 and Table 1 shows information exchange network of project actors and their centrality values. The values of each project actor in the exchange are relatively moderate in centrality. A closer look at Fig 2 shows extensive information exchanges between project actors within the project network. It also illustrates a well connected project team. The connectivity of actors in construction supply chain has been argued to be vital (Nicolini et al., 2001) for information flow. Hence, 'degree centrality' was used to observe the information network to see how connected project actors are to each other. Degree centrality measures network activities. Furthermore, to further calculate the centrality of actors in the project delivery network a measure referred to as Hubs and Authorities centrality was used. It measures how connected an actor is to the well connected. There are two scores for each actor, a hub and an authority. A high hub actor points to many good authorities and a high authority actor receives from many good hubs (Borgatti et al., 2002).

A significant inference from this network analysis is that notwithstanding the separation of design, construction and other project activities within the network information sharing was not hindered. One significant factor for this is that the governance system enhanced cooperation and diminished behavioural uncertainty. As such the ties formed facilitated the exchange of information. The data analysis also demonstrate that client and project teams' interface is important to successfully manage BSF/PFI projects (Pryke and Smyth, 2006, Smyth and Edkins, 2007). It implies that project governance structures that bind and bond team members together are an essential approach to generate knowledge. Although, the case study is based on a single case study it might be concluded that the project governance structure contributed to project actors' coordination and communication within the integrated delivery team.

6 Conclusion

So far the social network analysis has shown that the connectedness of project partners is highly significant in facilitating knowledge sharing in construction and engineering projects. The development and establishment of a governance system in projects can assist in aligning the resources and independencies of project partners. However, to support this assertion the findings of Johnston and Gudergan (2007) provide important lessons for organisations and PPP/PFI practitioners of the importance of project governance to improve project performance. The research revealed that to a greater extent the failure of the projects they examined was attributed to weak governance structure.

Therefore, the ability to plan and to manage the technical components of construction projects such as the tasks and resources; and the ability of project partners to effectively develop into a high performance team (Chinowsky et al., 2008) may depend on how the project governance is framed taking into consideration the characteristics of the project.

Overall, the BSF projects are delivered through project consortiums or Special Purpose Vehicles (SPVs). The project network structure can as well have significant influence on the exchange relationships of project partners. The project organisations are mutually dependent on each other to achieve the BSF programme objective. The implication of the dependencies is that it binds project actors' to continually interact to share knowledge/information to enhance the project delivery process. As illustrated in Fig 2, the information network has strong connections that link the various teams. Therefore, the point this paper is conveying is that project governance is highly significant and should be an integral part of the BSF delivery process. In addition, SNA can be used by project-based organisations to monitor their information exchange relationships. For example if the outcomes of SNA suggests that the project teams' information exchange relationships are weak, the project-based organisation may introduce supportive mechanisms to improve interaction between project actors.

Abstract:

This research aims to develop a framework to explore the conditions of trust between the ALT and AMT relationship within project alliancing. This research also aims to develop a robust trust framework which can improve the understanding of the theory to support trust in alliancing, in particular the ALT and AMT relationship to improve project success factors. Research in trust within the construction industry has not yet examined how the relational signals within the five situations in the normative framework identified by Siegwart Lindenberg affect the level of trustworthiness between partners. More research is necessary to explore potential frameworks that can be used as the basis for future research in trust. Data from previous research in the performance of alliance has been used to verify the proposed framework. The framework will be developed in the ALT and AMT relationship to improve project success factors within the alliance. The originality of this research is trying to understand trust in the context of project alliancing in Australia as there are an increasing number of construction projects using the alliancing procurement method. Additionally, this research is examining the conditions of trust from the ALT and AMT teams specifically formed for the collaboration of project alliancing.

Keywords:

project alliancing, procurement, trust

1 Introduction

Research on project alliancing in Australia have revealed that communication and trust between the Alliance Leadership Team (ALT) and Alliance Management Team (AMT) was a major issue that impacted on the effectiveness of the alliance (Mills & Harley 2010). The precondition for project alliancing to be successful is to develop a trust framework that allows the ALT and AMT to deliver superior project management coordination.

An empirical study (Smyth, 2005) of construction projects demonstrated that performance derived from trust was related to individuals rather than project factors. Conditions of trust have been examined for clients/consultants and contractors and

results have found (Wong *et al*, 2003) that trusting behaviours on behalf of contractors has a significant correlation with the trust level of contractors as perceived by client/consultant. Contractors are more cautious towards trusting behaviours by the client which means that contractors trust less than the clients therefore research should concentrate on building trust from the contractor perspective to improve the client relationship.

Furthermore, other results (Smyth, 2005) have indicated that clients do not have extremely high expectations but this does not translate that they are satisfied with the service delivered by the contractor (Smyth, 2005).

This research aims to develop a framework to explore the conditions of trust between AMT and ALT relationship within project alliancing. This research also aims to develop a robust trust framework which can improve the understanding of the theory to support trust in alliancing, in particular the AMT and ALT relationship to improve project success factors. The results will demonstrate the conditions of trust which affect cooperative attitude under the five situations identified by Siegwart Lindenberg (2000) which affect the levels of trust and how these conditions of trust that can be embedded in the ALT and AMT teams for project alliancing are impacted.

1.1 Nature of Relationship contracting

Two influential reports on the review of the construction industry of U.K. was published in 1994; *The Latham Report-Constructing the Team* and *The Egan Report-Rethinking Construction* (Cheung, 2007). The Latham report recommended that contracts should be founded upon principles of fairness, mutual trust and teamwork rather than mistrust and confrontation (Latham, 1994). The Egan report identified fragmentation as an issue to procurement practice and suggested that partnering and collaborative efforts should be used to resolve problems (Egan, 1998).

The paradigm for cooperative contracting has continued to evolve from traditional procurement to partnering and now to project alliancing. Each of the procurement contracting models is a risk management strategy and an attempt to mitigate adversarial attitude between project participants. In the traditional model, owners try to transfer as much of the risk as possible to others (Ross,1999).

Moore (1999) suggests that partnering is about management of relationships that are trust-based. Successful partnering requires mutual trust, effective communication, commitment from senior management, clear understanding of different parties' roles, consistency of objectives and flexibility to change. Factors which hinder the successful use of partnering are: non-compromising tendering process, poor perceptions of the partnering process, lack of knowledge and skill to adopt partnering as well as non-commitment of parties (Cheung *et al*, 2003). Unbalanced risk allocations in traditional contract provisions create adversarial relationships between project participants (Cheung *et al*, 2003). Contract provisions are often rigidly interpreted without taking into account of parties' needs and construction difficulties (Cheung *et al*, 2003; Piper, 2001). When liability is uncertain, responsibilities are allocated to parties on the basis of administrative conveniences which can hinder problem solving and the tendency for parties to revert to their contractual positions (Cheung *et al*, 2003). For the reasons stated partnering may not be the best procurement option due to the inherent conflicting objectives of the contracting parties (Cheung *et al*, 2003).

Project alliancing is used to deliver large complex projects in the field of resources, infrastructure and building (Ross, 1999). Complex projects have higher uncertainty in risks, diverse stakeholder interests, changing business, political influence and rapid technological change. These circumstances cannot be smoothly dealt with by the traditional risk-transfer contracting models including Public-Private partnerships (PPP) (Ross, 1999).

1.2 Nature of project alliancing

The Construction Industry Institute Australia (CIIA 1996) and Larson and Drexler (1997) suggested that developing trust was pivotal to the success of project partnering. Project alliancing in relational contracting is similar to partnering in that an entity is formed for the purpose of achieving mutual goals in the delivery of the project but this method is mainly used for infrastructure and mega projects where there is high level of complexity as well as opportunity for innovation therefore, more research is needed to explore how trust affects the AMT and ALT teams which are formed specifically for the purpose of project alliancing.

In alliancing each alliance member places their profit margin and reward structure “at risk” this the entire alliance entity either benefits together or lose all (Walker *et al*, 2002). This then creates a motivation to collaborate and cooperate within the alliance relationship. Alliances work on the principles of mutual trust, commitment and communication to reduce conflict and enhance productivity and overall performance (Lee & Cavusgil, 2006).

Project alliancing differs from partnering in that it achieves unity of purpose between project teams. In an alliance, the project price is developed by a pool of professionals through innovation in design with agreed risk and reward sharing arrangement (Walker *et al*, 2002). Cost savings are expected from improved value for money through the leverage of skills and expertise of the alliance partners in innovative construction from project conception through to project delivery. The idea relies on a “best value” outcome rather than least expensive cost or quickest project outcome (Walker *et al*, 2002).

The agreed project price is determined only when the alliance partners have been selected. Contract variations from scope changes does not substantially arise due to the alliance’s work in pre-planning and defining the project scope before agreeing the risk and reward arrangements (Walker *et al*, 2002). Variations that do occur must demonstrate substantial changes in the project scope and on site variations are managed by the alliance team.

There are two teams which are formed in an alliance: The Alliance Management Team (AMT) in charge of the operation of the project and the The Alliance Leadership Team (ALT) team which are in charge of the strategic decision making of the project as well as supporting the AMT team (Mills & Harley, 2010). The ALT team includes the client and determines the Turn Out Cost (TOC), which is the agreed amount the building would cost to deliver (Walker *et al*, 2002). The AMT would include a personnel from the contractor’s side. Both AMT and ALT teams would have representatives from both the client and contactors’ side to facilitate equity, knowledge as well as collaborative spirit in decision making.

A base target cost is established from an agreement on a risk and reward formula where an open-book accounting approach is undertaken to determine cost reimbursement

together with agreed and verified site management costs (Walker *et al*, 2002). The firm's profit margin (determined from audited figures over an agreed period) is placed as an "at risk" component to ensure the agreed project costs are met. Bonuses are shared by all parties to encourage further innovation (Walker, *et al*, 2002).

Purcell and Ross (2005) consider that project alliancing is generally suitable for projects which are complex, high-risks, have strict time lines, myriad of stakeholders issues and external threats.

Infrastructure projects involve a high degree of integration between design, construction and operations groups (Mills & Harley, 2010). The intense integration of the alliance members require excellent communication skills at a personal, business and operational level (Walker *et al*, 2002). Research on project alliancing in Australia have revealed that communication and trust between the Alliance Leadership Team (ALT) and Alliance Management Team (AMT) was a major issue that impacted on the effectiveness of the alliance (Mills & Harley, 2010). The precondition for project alliancing to be successful is to develop a trust framework that allows the ALT and AMT to deliver superior project management coordination.

2 Trust in Construction Procurement

Construction is a highly risky activity where there are high levels of trust and distrust occurring simultaneously due to uncertainties in the time restraint, resource investment and complexity of the design and build of each project (She, 2008). External factors such as escalating prices of raw material, changes in building legislations and regulations, community protest, adverse weather conditions as well as macroeconomic changes in the financial market (interest rates) can affect the original plans of the project (She *et al*, 2010). In addition, internal interruptions such as management restructuring, industrial relation disputes, site issues, personnel changes, significant documentation changes or errors, incompatibility personality classes between contractor and consultant resulting to conflicts can also create delays, disputes and obstacles to the timely completion of the project within the specified quality, agreed cost and any other criteria which may have been documented in the contract (She, 2008).

The nature of construction activity as well as industry dynamics forces everyone involved in the project to make shrewd calculations on potential gain versus loss and this calculation is largely dependent on the belief of ones' own judgment of the other party's behaviour in the collaboration under risky situations as discussed above (She, 2008). In another words, trust for construction personnel is a psychological construct which is in a constant state of change depending on the circumstances that arises therefore, it is naive to postulate that trust between parties without any element of mistrust suspicion occurring at the same can be possible in the delivery process of the project (Rousseau *et al*, 1998; Lindenberg, 2000).

2.1 Definition of trust

Trust has been defined by different scholars over the years as predictability on human behaviour (Cheung *et al*, 2003). For the nature of the construction industry as discussed above, the following definition of trust by Robinson's (1996) is most applicable to this research which is investigating the stability of trust within the ALT and AMT relationship in project alliancing.

“ Trust is “one’s *expectations, assumptions, or beliefs* about the *likelihood* that another’s future actions will be beneficial, favourable, or at least *not detrimental to one’s interest*” (Robinson, 1996).

Robinson’s (1996) definition of trust isn’t the most optimistic outlook but it implies that even if parties are not absolutely considerate of each other’s interests at least their actions will not be detrimental to the extent that it would break the partnership of shared goals. This allows legitimate inherent mistrust to co-exist with trust and so it is the stability of trust at any given point of time or situation that can be measured to determine the intention of future behaviour.

There are several advantages of trust in construction project relationship. According to Karlsen & Mssaoud (2008), the advantages of having trust are time saving, solving problems informally, encourage motivation for cooperation, openness between parties in sharing knowledge, being honest, predicting more accurate risks within the project as well as allowing direct speech to occur.

2.2 Volatility of trust in five situations of any cooperative project (Lindenberg, 2000)

A normative frame is important for trust in a business relationship. It largely suspends opportunistic behaviour when interests are aligned. Legitimate mistrust is the perceived likelihood that a potential or actual transaction partner’s interests are not aligned with one’s own interests and that the partner’s actions are driven by a salient gain frame such that relational and normative considerations are pushed into the background (Lindenberg, 2000). Mistrust is different from distrust. Scholars understand distrust to be the “expectation that others will not act in one’s best interests, even engaging in potentially injurious behaviour (Govier, 1994; Lewicki & McAllister, 1998) and the ‘expectation that capable and responsible behaviour from specific individuals will not be forthcoming (Barber, 1983; Lewicki & McAllister, 1998).

Distrust is when a party has a negative reaction towards another party’s action or transmitted message regardless of the actual intention of the party as it is doubting someone’s honesty. Mistrust is when there is lack of confidence or doubt as there may be a hidden agenda but not necessarily imply that there is serious malicious suspicion. Mistrust can occur in a positive state of a relationship and may even assist in the building of trust as parties may communicate more openly regarding potential issues before the commencement of the partnership but distrust is a negative attitude and signifies that there is an issue or conflict that needs to be resolved in a trustworthy manner or else all endeavours to build trust within a relationship would be rendered ineffective.

In the highly adversarial construction industry, there are currently high levels of distrust beyond legitimate inherent mistrust. It is distrust which is hindering trust building. There are five situations identified by Siegwart Lindenberg (2000) which ask for sacrifice for the relation. These situations are:

2.2.1 Common good situation:

both parties will contribute to the common good even if one party could freeride (the minimal amount of contribution expected for solidary behaviour varies in terms of money, effort and time etc

2.2.2 *Sharing situation:*

if there are joint divisible benefits and costs and if one party is the one who can divide them, that party will not seek to maximise what he gets from the benefit and minimise what he gets from the costs but take his “fair share” of both (what the “fair share” is varies).

2.2.3 *Need situation:*

one party will help the other party in times of need (what constitutes need and how much help is minimally expected for solidary behaviour varies)

2.2.4 *Breach temptation:*

one party refrain from hurting the other party even at a cost to himself (the minimal amount of cost expected for solidary behaviour varies)

2.2.5 *Mishap situation:*

acts can be intended solidary but factually turn out to go against the expectation of solidary behaviour. In that case, one party will show that he meant to act differently, that he feels sorry that it turned out that way, and he will make amends if the mishap has caused damage to others. Also if that party knows in advance that he will not be able to keep to the agreement, he will warn others in advance, so that they can mitigate the damage.

People in a normative frame want to act “appropriately” therefore, they want to follow the norms that are appropriate in these situations and act according to these norms (Lindenberg, 2000).. This way, they will always come to the same expectations in each of the five solidarity situations. Behaviour in these five situations is important for the relational signals it gives off. If all these signals are positive, the normative is stable and the partner is trustworthy (Wielers, 1993). Partners can monitor other behaviour via these relational signals and reduce monitoring costs.

In an empirical research that has been conducted by Mills & Harley (2010) examining the perception of alliance performance in public sector infrastructure, a range of factors has been identified where AMT and ALT performed above and below expectations. Overall, the respondents were more critical of the performance of the ALT with more than two thirds of respondents believing that the ALT did not perform above expectations. The results found that ALT need to perform not only at strategic levels but also be proactively involved in project issues and providing supportive operational environments to delivery successful project management (Mills & Harley, 2010). It would be beneficial to examine the specific issues under the five situations in light of the inherent mistrust issues which co-exists in each case.

2.3 **Conditions of Trust- Performance trust, permeability trust, System Based trust and Relational Bonding trust**

Wong *et al*, (2004) used fourteen attributes (conditions or criteria) of trust to determine the four factors (categories) of trust which affected partnering projects in Hong Kong. The survey was sent out to private and public sector developers, consultant firms and contractor firms. Results from this study demonstrated that 3 of the 4 factors were important to Developers/Consultant/Contractor; namely performance trust, permeability trust and system based trust.

2.3.1 Performance trust

(performance and permeability can build trust but is dependent upon change in attitude in system-based trust). Competence trust defined to be based on one's perception of the other's capacity to perform (Zaghloul & Hartman, 2003) can also be known as performance trust.

The trust attributes or trust conditions according to Wong *et al*, (2005a) which determine performance trust are: competence, problem solving, unity, alignment, respect.

2.3.2 Permeability trust:

openness to sharing information. Can also be known as integrity trust which is found upon one's perception of the other's attitude to act ethically and be motivated not to take one's advantage (Wong & Cheung, 2004).

The trust attributes or trust conditions which determine permeability trust according to Wong *et al*, (2005a) are: communication, openness, information flow and financial.

2.3.3 System-based trust:

(most important). Can also be known as institution-based trust legal systems, conflict management and cooperation, systems regulating education and professional practice were suggested as tools to sharp trust in institutions (Rousseau *et al*, 1998).

The trust attributes or trust conditions which determine system-based trust according to Wong *et al*, (2005a) are: Adopt ADR, reputation and satisfactory terms.

2.3.4 Relational trust:

(less relevant to the construction industry): trust arisen by continual interactions between individuals. Emotions and personal attachments are also influential to the trusting relationship (Rousseau *et al*, 1998).

The trust attributes or trust conditions which determine relational bonding trust according to Wong *et al*, (2005a) are: compatibility and long- term relations.

It would be beneficial to examine the level of these four types of trust under the five situations identified by Lindenberg (2000). The results would demonstrate the strength of the three type of trust and highlight the prominent conditions of each type of trust. This will assist project managers to predict the likely future behaviour of their project partners as well as team colleagues with an understanding of *why* a behaviour or reaction has or will occur under the condition of trust or mistrust.

3 Research aims

This research aims to develop a framework to explore the conditions of trust between ALT and AMT relationship within project alliancing. This research also aims to develop a robust trust framework which can improve the understanding of the theory to support trust in alliancing, in particular the ALT and AMT relationship to improve project success factors

3.1 Research objectives

- Find the conditions of trust from the perspectives of the ALT and AMT teams of project alliancing which encourage cooperative attitude under the five situations in the normative framework identified by Siegwart Lindenberg (2000).
- Develop a trust framework that demonstrates the how the conditions of trust can be embedded in the ALT and AMT relationship to improve project success factors performance whilst allowing inherent mistrust to co-exist.

4 Research Methodology

Yin's (2003) model of assessing which methodology is best appropriate for the research questions investigated suggests that if a question is endeavoring to find out how or why of a particular phenomenon and there is no need for the control of events but there is a focus on contemporary events then a case study approach is the best method for research. For this research, case study approach will be the best approach to examining the perceptions of trust in relationships as project alliancing is unique in nature, scope and particularise so generalisation from quantitative analysis would not justify the benefits of qualitative research, particularly in complex situations some of the critical factors which may have an impact on the conditions of trust and confidence in relationships. Case studies can also highlight the preconditions which are important when interpreting the results.

The Soft System Methodology (SSM) Approach will be used to develop a trust framework. There may be some inherent mistrusting behaviour which would always co-exist with trusting behaviours therefore the issues relating to trust may not be easily defined as different stakeholders would have very different views on what constitutes a problem in construction. This makes the soft system approach an appropriate methodology to explore trust issues within relationship as SSM treats the notion of a system as an epistemological rather than an ontological entity meaning that there are different ways of understanding what is going on rather than defining which descriptions are right or wrong (Checkland & Poulter, 2006).

5 Development of trust framework based on Lindenberg (2000)

The factors of trust which are relevant to this research are: Performance trust, permeability trust and System based trust. Additionally, the conditions of trust identified by Thompson (1997) are also relevant namely, receptivity, promise-fulfilment, consistency/experience, integrity, loyalty, fairness, openness, competence, discretion, availability.

Using the issues that has been identified in Mills and Harley (2010) report on the performance of Project Alliancing, the trust classifications and the levels of trust which follows in the following four tables:

Table 5.1 Classification of ALT's below average performance areas into trust types and situation as identified by Siegwart Lindenberg (2000).

Situation as identified by Siegwart Lindenberg (2000)	Trust types	ALT performing BELOW expectations
Mishap situation	Performance trust	Bogged down in detail-not enough strategic thinking
Need situation	Performance trust	Not necessarily wanting to get involved in the micro management issues that were impacting on the function of the AMT
Common Good situation	Performance trust/ Permeability trust	Areas of improvement include risk management, forecasting and earned value reporting, schedule recovery during construction, safety
Need situation	Performance trust	The ALT provided very little real/material leadership or onsite support to the AMT. The AMT had to consistently seek out members of the ALT for support and assistance, with little proactive response back from the ALT
Breach Temptation situation	System based trust	Governance

Table 5.1 demonstrates that for mishap and need situation, performance trust is the trust that requires further understanding and improvement from the ALT team within the alliance relationship. For common good situation, both performance trust and permeability trust require improvement and under breach temptation situation, system based trust require further improvement.

Table 5.2 Classification of AMT's below average performance areas into trust types and situation as identified by Siegart Lindenberg (2000).

Situation as identified by Siegart Lindenberg (2000)	Trust types	AMT performing BELOW expectations
Need situation have	Performance trust	Capacity to appropriate Change control resources on board when needed
Common Good situation	Performance trust	Community stakeholder management
Mishap situation	Performance trust	Setting safety standards in regard to protection of citizens on and around construction site
Sharing situation/ Common Good situation	Performance trust	Improvement required in the area of cost control
Common Good situation	Performance trust	Lack of in-house schedule programming skills
Mishap situation/ Breach Temptation situation	System based trust	Too caught up in Alliance behaviour and not concentrating on the contract and its relationships
Sharing situation/ Breach Temptation situation	Performance trust / System based trust	Verification model for the D&C stages
Common Good situation/ Mishap situation	Permeability trust	Improving information flow to the ALT

Table 5.2 demonstrates that for need and sharing situations, performance trust requires further understanding and improvement from the AMT team within the alliance relationship. For mishap situation, performance trust, permeability trust as well as system based trust require improvement. For common good situation, both performance trust and permeability trust require improvement and under breach temptation situation, system based trust is the issue.

Lindenberg's (2000) framework with the five situations is reflected in the above two tables which demonstrates that a theory can be developed regarding the role of trust within the ALT and AMT relationship. The issues identified by Mills and Harley (2010) demonstrate that performance and system based trust are the main type of trust that require further understanding and improvement for alliancing projects. It is interesting that performance trust affects all five situations. Trust is vital for the effectiveness of Alliances. Little research has been undertaken in this area therefore Lindenberg's framework can convey deeper insights into the complexity of trust and mistrust.

6 Limitations

This research will rely on in-depth investigation of small sample size of case study projects specific to Australia only with a focus on public sector infrastructure projects.

7 Conclusion

This paper introduces a conceptual trust framework to examine the trust between ALT and AMT teams for project alliancing based on Siegart Lindenberg's (2000) five situation normative framework. Data from previous research in the performance of alliance has been used to verify the proposed framework. This research is trying to understand trust in the context of project alliancing in Australia as there are an increasing number of construction projects using the alliancing procurement method. The framework will be developed to improve project success factors within the alliance.

Project Leaders' Assessment of the Contribution of Contractors to Delay in the Delivery of Federal Government Projects in Nigeria

¹Godwin Iroroakpo Idoro and ²Babatunde Okhemehimi Okun

Department of Building, University of Lagos, Akoka, Lagos, Nigeria.

E-mail: [1iroroidoro@yahoo.com](mailto:iroroidoro@yahoo.com); [2tunde_okuns@yahoo.com](mailto:tunde_okuns@yahoo.com)

Abstract:

Projects developed by the Federal Government of Nigeria (FGN) are very crucial to the economy of the nation. The failure of contractors to deliver them on time has serious negative implications on the growth of the Nigerian economy. This study investigates the factors that affect contractors' contribution to delay in the delivery of FGN projects. The objectives are to evaluate the relative effects and significant difference in the effects of selected factors that affect the contribution of indigenous and expatriate contractors to delay in the delivery of FGN projects. To achieve these objectives, a field survey involving a sample of 78 project leaders was conducted. Data were collected using structured questionnaires and analysed using percentage, Relative Effect Index (REI) and t-tests. The results reveal that the effects of the factors that affect the contribution of indigenous and expatriate contractors to delay do not differ. It was equally discovered that material management problems, Plants and Equipment (P&E) management problems, poor construction planning and scheduling, poor communication and coordination, delay in mobilising to site and inadequate provision of required utilities on site which are contractor related rank high in factors that contribute to delay in FGN projects. The major conclusions are that the effects of the factors on delay in projects executed by the two categories of contractors are the same and that several contractor-related factors found in previous studies to be responsible for project delay still persist in the delivery of FGN projects. The main suggestions are that the contractors should adopt effective and efficient material and P&E management strategies, effective communication, construction planning and scheduling, avoid delay in mobilising to site and ensure the provision of essential utilities on site.

Keywords:

expatriate contractors, federal government of Nigeria projects, indigenous contractors, project leaders and project outcome.

1 Introduction

Both governments and private organisations commit substantial fund into the development and maintenance of construction projects annually because of their importance and contribution to the development, growth and the achievement of the objectives of every organisation. In developing economies, studies have shown that government is the major financier of construction projects. Wong (2003) maintained that government spending is one of the three major factors that influence the growth of the construction industry in Malaysia. Okpala and Aniekwu (1988) opined that the biggest customer of the construction industry in most developing countries is the government. In Nigeria, the dominance of government as the main promoter of

construction projects is highly pronounced as the private sector even depends on government expenditure. The Federal Government of Nigeria (FGN) according to the Nigerian constitution is made up of three arms namely: Executive, Legislative and Judiciary (Federal Government of Nigeria, 1999). The FGN Appropriation Acts from January 2000 to December 2008 showed that the sum of N5.036 trillion (43.5%) was appropriated for capital expenditure while the sum of N6.545 trillion (56.5%) was appropriated for recurrent expenditure (Federal Government of Nigeria, 2009). The figure indicated that the development of construction projects depends mostly on public sector funding.

The rate of completion of these projects falls considerably below the rate at which they are conceived. Dlakwa and Culpin (1999) opined that the main cause of this phenomenon is the delay experienced in the delivery of the projects. The importance of time in construction projects cannot be over-emphasised. Scott (1993) opined that the completion of construction projects within prescribed time scale is an important measure of project success. Studies (Frimpong *et al.* (2003), Williams (2003) and Luu *et al.* (2003) described time as one of the three common and most important criteria for project success. Studies conducted by Okpala and Aniekwu, (1988) and Assaf and Al-Heiji (2006) showed that time-overrun is an existing phenomenon and a major problem in the delivery of construction projects. Mansfield *et al.* (1994) found excessive time-overruns in completed projects executed by the Federal Ministry of Works and Housing (FMWH) the ministry responsible for the implementation of FGN projects. Elinwa and Uba (2001) equally found that in Nigeria, time and cost overruns were regarded as the most important causes of project abandonment and contractors' failure.

Delay in project delivery has been acknowledged as a global phenomenon. Studies on the problem are focussed on the causes and have identified several causes of the problem (Okpala and Aniekwu, 1988; Dlakwa and Culpin, 1999; Mansfield *et al.* 1994; Odeyinka and Yusif, 1997; Kaming *et al.* 1997; Radujkovic, 1999; Odeh and Battaineh, 2002). Some of these studies (Aibinu and Odeyinka, 2006) recognised the role of the parties to the delivery of projects on the problem by categorising the factors according to the parties responsible. The notable parties identified are client, consultants, suppliers and contractors. Among these parties, the contribution of contractors is significant because the party is the major player at the construction stage of a project where the works are executed and delay has serious cost implications. A study conducted by Ogunlana *et al.* (1996) showed that the blame for most project delays was laid on contractors. Another study conducted by Abd-Majid and McCaffer (1998) showed that 50% of the delays can be categorised as non-excusable delays for which contractors were responsible. The findings of these studies tend to confirm that contractors are major contributors to project delay and that the problem of project delay in the industry could be solved by focusing on the factors that affect contractors' contribution to project delay.

Several studies (Iyagba, 1999; Oni, 2001; Eze, 2004; Idoro, 2004 & 2007; Okafor, 2005) have found that Nigerian contractors are classified into two groups namely: indigenous and expatriates. Indigenous contractors refer to construction firms that are fully owned and managed by Nigerians while expatriate contractors refer to construction firms that are jointly owned by Nigerians and foreigners but their management is fully controlled by expatriates. Ogunpola (1984), Olateju (1991), Samuel (1999) and Idoro (2004) found that expatriate contractors are few in number, operate on a large scale and execute a major proportion of the value of contracts in Nigeria while indigenous contractors considerably outnumber their expatriate

counterparts; operate on small and medium scales but are responsible for a very small proportion of the value of contracts executed in Nigeria.

These two categories of contractors are responsible for the execution of projects procured by the FGN and their activities contribute in no small measure to the problem of delay in the delivery of FGN projects. However, there are several factors that are responsible for the contribution of the contractors to delay in the delivery of the projects and their identification is the first step in the effort to solve the problem of delayed delivery of FGN projects. Chan (2002) opined that the first step when addressing a problem is to identify its causes thereafter, corrective actions can be taken. This study therefore attempts to examine how indigenous and expatriate contractors contribute to delay in the delivery of FGN projects by investigating the factors that affect their contributions to delay in the delivery time of the projects. The objectives are to evaluate the relative effects and significant difference in the effects of selected factors that affect the contribution of indigenous and expatriate contractors to delay in the delivery of projects procured by the FGN.

2 Contractors' Contribution to Delay in Project Delivery

It has been established in studies that contractors are major contributors to project delay. Al-Khalil and Al-Ghafly (1999) identified contractors' performance as one of the most important and common causes of delay in public utility projects in Saudi Arabia. Several factors make contractors to contribute to project delay. In a study, Chan and Kumaraswamy (1997) identified poor supervision on the part of contractors as one of the principal delay factors. In another study, Kumarawamy and Chan (1998) found poor site management and supervision, low speed of decision making involving all project teams and inadequate contractors' experience to be three of the six common significant factors that caused delay in both building and civil engineering projects. Kaming *et al.* (1997) identified poor labour productivity, inadequate planning and resources which are contractor-related factors as two of the major causes of project delay. Late delivery of materials was found to be one of the seven factors responsible for delay in 106 out of 130 public projects surveyed. Odeyinka and Yusif (1997) also identified contractors' financial difficulties, material management problem, planning and scheduling problem, inadequate site inspection, equipment management problems and shortage of manpower which were traced to contractors as the major the major causes of delay in the delivery of housing projects in Nigeria. The study by Aibinu and Odeyinka (2006) supported this claim when it found that contractors financial difficulties, planning and scheduling problem, equipment breakdown and maintenance problem as some of the high ranking causes of project delay in Nigeria. Other causes of project delay for which contractors are responsible include shortages of materials (Mansfield *et al.*, 1994), choice of construction method, management of construction resources, schedule management, supervision and control, and communication (Meeampol and Ogunlana, 2006).

3 Research studies

A questionnaire survey design approach was adopted in the study. In the approach, a field survey involving projects procured by the FGN located in the 36 states and the Federal Capital Territory (FCT) in Nigeria in 2008 fiscal year was carried out in early 2009. A preliminary survey was first conducted from which 115 projects made up of 69 projects executed by indigenous contractors and 46 projects executed by expatriate contractors were identified and adopted as the population frame of the study.

Two categories of variables namely: construction contractors and project delay factors were used in the study. The two categories of contractors in Nigeria namely: indigenous and expatriate constituted construction contractors. Twenty-two factors namely: delay in procurement and delivery of materials, shortage of materials, use of inferior materials, lack of utilities (water, electricity, telephone, etc) on site, poor communication and coordination by contractors, Plant & Equipment (P&E) breakdown, shortage of P&E, low productivity of P&E, delay in mobilising to site, ineffective planning and scheduling, delay in sub-contractors' work, poor communication with other parties, poor site management, inappropriate construction methods, use of unskilled workers, conflict between contractor and consultants, use of unqualified technical staff by contractor, shortage of labour, low productivity of labour, accidents during construction and rework due to errors in construction were used. The factors were identified from previous studies and an interview with the respondents conducted during the preliminary survey.

Two hypotheses were postulated in the attempt to achieve the objectives of the study. The first hypothesis states that the ranks of the effects of selected factors on the contribution of indigenous and expatriate contractors to delay in FGN projects are not significantly different. The second hypothesis states that the effects of selected factors on the contribution of indigenous and expatriate contractors in Nigeria to delay in the delivery of FGN projects are not significantly the same. The two hypotheses were postulated to ascertain whether or not the effects of the factors are the same in projects executed by the two categories of contractors.

Data were collected on the project characteristics (ownership, project, contract, procurement and contractor types) and the respondents' assessment of the effect of 22 factors on the level of contribution of indigenous and expatriate contractors to delay in the delivery of the projects. The respondents' assessments were measured on a 5 point Likert-type scale: nil, low, moderate, high and very high. The ranks were scored 1, 2, 3, 4, and 5 respectively.

The data were collected using structured questionnaires which were administered on engineers and builders who were the heads of contractors' site staff on the projects. From the population frame, 78 projects made up of 48 projects executed by indigenous contractors and 30 projects executed by expatriate contractors were selected by stratified random sampling to form the study sample. The sampling option was adopted to ensure that the two categories of contractors were covered in the study. Data collected on the characteristics of the projects sampled were analysed using percentage. The relative effects of delay factors were analysed using Relative Effect Index (REI) which is similar to Relative Importance Index (RII). REI was derived as the total score or sum divided by the number of respondents. The hypotheses of the study were tested using Chi-square test and t-test.

4 Results

The results of the analysis of data collected are presented as follows:

4.1 Descriptive results of the characteristics of projects used for the study

The characteristics of the projects sampled were investigated. For this purpose, five project characteristics namely: project ownership, type, contract type, procurement type and contractor type were analysed. The results are presented in Table 1.

Table 1 Descriptive results of the percentage distribution of the projects used for the study

Project characteristic	N	%	Project characteristic	N	%
Project Ownership			Project Type		
Executive	62	88.6	Building	56	73.7
Judiciary	6	8.6	Road	12	15.8
Legislative	2	2.9	Water	4	5.6
Total	70	100	Electricity	4	5.6
Contractor Type			Procurement Method		
Indigenous	48	61.5	Design-Bid-Build	60	78.9
Expatriate	30	38.5	Design-Build	12	15.8
Total	78	100	Direct Labour	2	2.6
Contract Type			Labour-only		
Fluctuating sum	28	36.8	Labour-only	2	2.6
Lump sum	26	34.2	Total	76	100
Fixed sum	22	29.0			
Total	76	100			

N=Number

Table 1 reveals that projects procured by the three arms of the FGN namely: executive, legislative and judiciary were covered in the study however, projects procured by the executive arm of FGN constituted the majority. Table 1 shows that four types of projects namely: building, road, water and electricity projects were covered by the study. However, building projects constituted the majority.

The results in Table 1 reveal that the projects sampled were executed by three types of contract namely: lump sum, fixed sum and fluctuating sum contracts however; fluctuating sum is the most used contract type, followed by lump sum contract and fixed sum contract. The projects sampled were procured by four methods namely: design-bid-build, design-build, direct labour and labour-only options however, majority of the projects were procured by traditional or design-bid-build method. Projects executed by the two categories of contractors in Nigeria namely: indigenous and expatriate contractors were covered by the study but majority of the projects was executed by indigenous contractors.

4.2 Factors affecting the Contribution of indigenous and expatriate contractors to time-overrun in FGN projects

The factors that affect the contribution of the two categories of contractors to delay in the delivery of projects procured by FGN were investigated. For this investigation, twenty-two factors listed in Table 2 were selected from delay factors identified from literature and suggested by the respondents through an interview with them during the pilot survey. The respondents were requested to indicate their assessment of the effect of each factor to their contribution to the delay in the projects sampled using 5 point Likert-type scale: nil, low, moderate, high and very high. The ranks were scored 1, 2, 3, 4 and 5 respectively. The Relative Effect Index (REI) similar to Relative Importance Index (RII) of the score of each factor was analysed. The results are presented in Table 2.

Table 2 Ranks of the Relative Effect Index (REI) of factors affecting the contribution of contractors to time-overrun in FGN projects

Factors	Expatriate contractors				Indigenous contractors			
	N	Sum	REI	Rk	N	Sum	REI	Rk
Delay in procurement of materials	30	74	2.47	5	48	140	2.92	1
Lack of utilities on site	30	64	2.13	16	48	136	2.83	2
Poor communication and coordination	30	66	2.20	12	46	128	2.78	3
Delay in delivery of materials to site	30	82	2.73	2	48	128	2.67	4
P&E breakdown	30	80	2.67	3	50	130	2.60	5
Material shortage on site	30	68	2.27	10	48	114	2.48	6
Delay in mobilising to site	30	66	2.20	12	50	124	2.48	6
Ineffective planning & scheduling	30	76	2.53	4	48	118	2.46	8
Delay in sub-contractors' work	30	70	2.33	8	46	112	2.43	9
Shortage of equipment	28	64	2.89	1	50	120	2.40	10

N=Number of respondents, P&E=Plant & equipment, REI=Relative Effect Index, Rk=Rank

Table 2 shows that the twenty-two selected project delay parameters vary in effect among the two categories of contractors. While some parameters rank higher in their effects on the contribution of indigenous contractors to project delay than expatriate contractors, others rank higher in their effects on the contribution of expatriate contractors to delay than indigenous contractors. Delay in procurement of materials ranks 1st among the factors affecting the contribution of indigenous contractors but it ranks 5th among the factors that affect the contribution of expatriate contractors to delay. Lack of utilities such as water, electricity, telephone, etc ranks 2nd among the factors that affect the contribution of indigenous contractors while it ranks 16th among the factors that affect the contribution of expatriate contractors to delay. Poor communication/coordination with other project team members by contractor ranks 3rd among factors that affect the contribution of indigenous contractors while it ranks 12th among factors that affect the contribution of expatriate contractors to delay. Delay in delivery of materials to site is discovered to rank 2nd among the factors that affect the contribution of expatriate contractors but it ranks 4th among the factors that affect the contribution of indigenous contractors. Similarly, equipment breakdown ranks 3rd among the factors that affect the contribution of expatriate contractors to delay while it ranks 5th among the factors that affect the contribution of indigenous contractors.

Material shortage on site and delay in mobilising to site rank 6th among indigenous contractors but they rank 10th and 12th among expatriate contractors. Ineffective planning and scheduling of project and delay in subcontractors' work rank 8th and 9th

among indigenous contractors while they rank 14th and 15th among expatriate contractors. Shortage of P&E ranks 1st among expatriate contractors while it ranks 10th among indigenous contractors. The productivity of P&E ranks 11th among indigenous contractors while it ranks 18th among expatriate contractors. Poor communication with other parties and poor site management rank 12th and 13th among indigenous contractors while they rank 17th and 16th among expatriate contractors. The use of inappropriate construction methods ranks 14th among indigenous contractors while it ranks 16th among expatriate contractors. The use of unskilled workers and inferior materials rank 15th and 16th among indigenous contractors but rank 20th and 21st among expatriate contractors. Conflict between contractor and consultants ranks 8th among expatriate contractors while it ranks 16th among indigenous contractors. Low productivity and shortage of labour and the use of unqualified technical staff by contractors rank 18th among indigenous contractors but they rank 12th, 19th and 22nd among expatriate contractors. Delays caused by accidents on site and rework caused by errors in construction rank 21st and 22nd among indigenous contractors but rank 12th and 11th among expatriate contractors.

4.3 Difference between the Ranks of the Effects of selected Factors on the Contribution of Indigenous and Expatriate Contractors to Delay in FGN Projects.

In Table 3, it is discovered that the ranks of the selected factors differ among the two categories of contractors. This finding suggests that the effects of the factors on the contribution of the two categories of contractors to delay in the delivery of FGN projects vary. Further investigation was carried to determine whether or not this variation is significant or not. This investigation involved the test of the first hypothesis which states that the ranks of the effects of selected factors on the contribution of indigenous and expatriate contractors to delay in FGN projects are not significantly different. The ranks of the effects of the selected factors on the contribution of the two categories of contractors to delay in the delivery of FGN projects in Table 3 were compared in the test. The hypothesis was tested using rank correlation with $p \leq 0.05$. The rule for the rejection or non-rejection of the hypothesis is that when the t-calculated $>$ t-table, the test fails to reject the hypothesis but when the value of t-calculated \leq t-table, the test rejects the hypothesis. The results are presented in Table 4.

Table 4 Results of rank correlation test between the effects of delay factors on the contribution of indigenous and expatriate contractors to project delay

Parameters correlated	R_s	t-cal	t-table	p-value	Decision
Ranks of effects of delay factors on indigenous & expatriates contractors contribution to delay	0.465	2.32	2.09	sig \leq 0.05	Accepted

R_s =Rank correlation value; t-cal= value of t-calculated.

Table 4 shows that the value of t-calculated is higher than t-table therefore, the test fails to reject the hypothesis. The result implies that the ranks of the effects of the factors on the contributions of the two categories of contractors are not significantly different.

4.4 Difference between the Effects of selected Factors on the Contribution of Indigenous and Expatriate Contractors to Delay in FGN Projects.

Further investigation was carried out to determine whether or not the factors have the same effects on the contribution of the two categories of contractors to delay in the delivery of FGN projects. This involves the test of the second research hypothesis which states that the effects of selected factors on the contribution of indigenous and expatriate

contractors in Nigeria to delay in the delivery of FGN projects are not significantly the same. Data collected on the respondents' assessment of the effects of the factors were used for the test. The hypothesis was tested using the t-test with $p \leq 0.05$. The rule for the rejection or non-rejection of the hypothesis is that when the $p\text{-value} > 0.05$, the test fails to reject the hypothesis but when the $p\text{-value} \leq 0.05$, the test rejects the hypothesis. The results are presented in Table 5.

Table 5 Results of t-test for difference between the effects of selected factors on the contribution of indigenous and expatriate contractors to delay in FGN projects

Factors	N	t-value	Df	p-value	Decision
Delay in procurement of materials	78	1.766	76	0.081	Accept
Lack of utilities on site	78	1.549	76	0.126	Accept
Poor communication and coordination	76	0.535	74	0.592	Accept
Delay in delivery of materials to site	78	-0.272	76	0.787	Accept
P&E breakdown	80	-0.280	78	0.780	Accept
Material shortage on site	76	0.722	74	0.461	Accept
Delay in mobilising to site	80	1.120	78	0.266	Accept
Ineffective planning & scheduling	78	-0.278	76	0.783	Accept
Delay in sub-contractors' work	76	-0.667	74	0.507	Accept
Shortage of P&E	78	0.389	76	0.698	Accept
Low productivity of P&E	80	1.161	78	0.249	Accept
Poor communication with other parties	76	-0.207	74	0.837	Accept
Poor site management	72	-0.437	70	0.663	Accept
Inappropriate construction methods	76	0.210	74	0.834	Accept
Use of unskilled workers	80	1.606	78	0.112	Accept
Use of inferior materials	74	0.844	72	0.401	Accept
Conflict between contractor & consultants	76	-1.544	74	0.127	Accept
Unqualified technical staff by contractor	76	0.135	74	0.893	Accept
Shortage of labour	78	0.438	76	0.662	Accept
Low productivity of labour	76	-1.873	74	0.065	Accept
Accidents during construction	78	-1.846	74	0.069	Accept
Rework due to errors during construction	72	-1.904	70	0.061	Accept

N=Number of respondents, Df=Degree of freedom, P&E=Plant and equipment

Table 4 reveals that the p-values for the test of difference in the effect of all the selected factors on the contribution of the two categories of contractors to delay in the delivery of FGN projects are higher than the critical p-value (0.05) therefore the test fails to reject the hypothesis. The results imply that the factors have the same effects on the contribution of the two categories of contractors to delay in the delivery of FGN project.

5 Discussion of Findings

The results of the test of the first research hypothesis has established that the ranks of the effects of the selected factors on the contribution of indigenous and expatriate contractors in Nigeria to delay in the delivery of FGN projects are the same. The implication of the result is that although the ranks of the effects of the factors affecting the contribution of indigenous contractors to delay in the delivery of FGN projects are different from those of expatriate contractors, the differences are insignificant. In other words, the extents of the effects of the factors on the contribution of the two categories of contractors to delay in the delivery of FGN projects are the same. The results of the

test of the second research hypothesis also supports this ascertain by revealing that the effects of all the factors on the contribution of indigenous and expatriate contractors to delay in the delivery of projects procured by the FGN are not significantly different. This finding shows that efforts at reducing delay in the delivery of projects procured by FGN should be equally applied whether or not a project is executed by indigenous or expatriate contractor.

The results in Table 2 indicate that material management related factors rank among factors that have the highest in effect on the contribution of the two categories of contractors to delay in the delivery of FGN projects. Delay in procurement and delivery of materials to site and shortage of materials are discovered to be some of the factors that have high contribution to delay in the delivery of projects among the two categories of contractors. This finding shows that material management problems such as shortages and late delivery of materials found in studies conducted by Mansfield *et al.* (1994), Odeyinka and Yusif (1997) and Al-Momani (2000) still persist in the delivery of FGN projects. It indicates that improvement in the management of materials is one of the measures required to minimise the contribution of the two categories of contractors to delay in project delivery. P&E management related factors are also discovered to rank high in effect on the contribution of the two categories of contractors to delay in the delivery of FGN projects. Shortages and breakdown of P&E are discovered to be among the ten highest ranking factors that affect the contribution of the two categories of contractors to project delay. This finding supports the assertion that the problem of delay in delivery and effective maintenance of P&E found in studies conducted by Odeyinka and Yusif (1997) and Aibinu and Odeyinka (2006) still persist in the delivery of FGN projects. The finding indicates that early procurement and prompt delivery of the P&E required for the execution of projects procured by FGN are some of the measures that can reduce the contribution of the two categories of contractors to delay in project delivery. Furthermore, the finding shows that the use of P&E that are in good condition and their effective maintenance can also reduce the contribution of the contractors to delay. Poor planning and scheduling of projects by contractors is also discovered to be among the ten high ranking factors that affect the contribution of contractors to delay. This factor is discovered to rank 8th among indigenous contractors and 4th among expatriate contractors. This finding suggests that the problem of inadequate planning and scheduling earlier identified by Kaming *et al.* (1997), Odeyinka and Yusif (1997) and Aibinu and Odeyinka (2006) is still a major cause of delay in the delivery of FGN projects. It also suggests the need for improvement in construction planning among the contractors as a way of minimising their contribution to delay.

Lack of utilities such as water, electricity, telephone etc, poor communication and coordination and delay in mobilising to site are some of the factors that rank high in effect on the contribution of indigenous contractors to delay. Supervision, control and communication have been identified as major factors that determine success in project time performance by Meeampol and Ogunlana (2006) therefore, the result of the study indicate that the problem still persist in the delivery of FGN projects. This finding suggests that indigenous contractors do not communicate effectively with other project members and they do not mobilise to site promptly to start work after the award of contract and these inadequacies contribute to delay in the projects they execute. The result also suggests that inadequate provision of required utilities on site which before now has not been the focus of research is major delay factor in projects executed by indigenous contractors. The implication of the finding is that indigenous contractors need to ensure adequate provision of the required utilities in their project sites, embark

on effective communication with other project team members and ensure prompt mobilisation to site to start work as soon as contracts are awarded to them in order to minimise delay in the delivery of the projects they execute.

Poor communication with other project parties, poor site management and conflict between contractor and consultants are discovered to rank among the ten highest factors that affect the contribution of expatriate contractors to project delay. Considerable information is generated when executing a project that need to be communicated to all project participants. This finding indicates that ineffective communication of project information to project participants and poor site management by expatriate contractors contribute to delay in the delivery of FGN projects.

6 Conclusion

The main aim of the study is to determine how indigenous and expatriate contractors contribute to delay in the delivery of FGN projects by investigating the factors that affect their contributions to delay in the delivery time of the projects. This was achieved by conducting a survey of 78 heads of contractors' project site staff drawn from both indigenous and expatriate contractors in Nigeria that executed FGN projects in 2009. In the survey, 22 contractor related factors were assessed by the respondents to determine their effects on the contribution of the two categories of contractors to delay in the delivery of FGN projects that they executed. The main conclusions are that first, the extents of the effects of the factors on the contribution of the two categories of contractors to delay in the delivery of FGN projects are the same. It was discovered from the results of the two research hypotheses tested in the study that the respondents' assessment of the effects and the ranks of the effects of the factors on the contribution of the two categories of contractors to delay in the delivery of FGN projects are significantly the same. This shows that measures aimed at reducing the effects of the factors will minimise the contribution of the two categories of contractors to delay in FGN projects.

Second, the findings of the study confirm that several contractor-related factors found in previous studies to be responsible for project delay still persist in the delivery of FGN projects. These include material management problems, P&E management problems, poor construction planning and scheduling, poor communication and coordination and delay in mobilising to site. Third, inadequate provision of required utilities such as water, electricity and telephone on site is one of the major causes of the inability of the contractors to deliver FGN projects on schedule. Efforts of the two categories of contractors at addressing these factors will go a long way to ensure that the contractors deliver the projects to time.

It is therefore suggested that both indigenous and expatriate contractors that execute FGN projects should adopt more effective and efficient material and P&E management strategies, embark on effective communication, construction planning and scheduling, avoid delay in mobilising to site as soon as contracts are awarded and ensure the provision of essential utilities on site in order to minimise delay in the delivery of FGN projects. The task of managing FGN projects effectively cannot be left for contractors alone. Clients and their consultants should support contractors in this task by ensuring that adequate planning is done before construction and this should be used as one of the criteria for contract award. Furthermore, adequate fund should be provided in the budgets of FGN projects for the provision of essential services on site.

Conflict Resolution in Labour Only Contracts in Nigeria

Ogunde, Ayodeji Olubunmi

Department of Building Technology,
Covenant University, Canaanland, Ota. Ogun state, Nigeria

E-mail address: ayodejiogunde1@yahoo.com

Abstract:

In recent times of ailing economy, the Construction Industry now employs more the use of labour-only procurement method in executing both private and public projects. This has resulted in dramatic increase in conflict and consequential adversary relationship between the clients and the contractors. The study therefore investigated the causes of conflicts in labour only contracts and recommended ways of resolving them from time to time. The study identified some of the major factors causing conflicts in labour only contracts as poor communication between project participants, ambiguous contract document, lack of trust between the client and the contractor and no provision for Alternative Dispute Resolution (ADR) mechanism in the contract. It was also found out that the inter-relatedness of the factors causing conflict is significant as it explains why conflicts and disputes occur in some projects and not in other projects of the same procurement method. It also found out that abandonment of project is the most severe consequence of conflict as it invariably results in prolongation of duration (time overrun) and increased cost (cost overrun) of the project. It is recommended that clients should proactively endeavour to limit or reduce contract in-completeness and attenuate the opportunities inclinations of the contractors by incorporating Alternative Dispute Resolution (ADR) mechanism in the contract to minimize the incidence of conflicts during and after construction.

Keywords:

Alternative Dispute Resolution (ADR), claim, conflict, labour only procurement method

1 Introduction

Labour only contract is one of the project procurement methods used in the construction industry in Nigeria, which principally involves the client and the contractor. The labour only contract requires the client to provide all the materials required for the project while the contractor provides the labour force and he is equally paid for the cost of labour including his overhead and profit by the client. (Ogunsanmi and Bamisile, 1997). Due to down-turn in the economy, with the resultant lean economic resources has forced employers (clients) to expand the scope of work of labour only method of construction to include construction of new projects as a means of saving cost as a means of providing needed facility. For survival, indigenous contractors whose amount of remuneration for construction works is not commensurate to their effort/input to the industry may agree to engage in labour only contract instead of the traditional based on long term or open ended employer-employee relationship. (Adenuga, 2003)

Dispute between men are inevitable in any business transaction (labour only contract inclusive), their religions etc social status, level of education notwithstanding, the

parties must therefore either anticipate them in advance or expect to litigate them later (Derr 1998). Misunderstanding and dispute often occur between parties in business transaction on a variety of matters. Such disagreements may relate to the validity or terms of contract between them no matter how meticulously worded. Performance schedule, completion period, insurance claims for loss or damage or the issue may be what legal provisions determine the liability of insurer. The issue may also concern force majeure, which has delayed or frustrated a contract and what the consequence should be (Taiga, 1998). Not only does the incidence of conflict vary from project to project but also seemingly similar circumstances (and sometimes even the same design or construction team) lead to conflict in the project but not on another.

Nevertheless, it is generally believed that detailed contracts tend to prevent dispute because most issues that may give rise to disputes have been anticipated from the onset with adequate dispute resolution clauses, but unfortunately this is not the case as there appears to be a wide field for conflict in construction industry most especially in labour only contracts (Diekman et al., 1995). Conflict and disputes do exist at all levels in the contractual chain client/consultant, client/contractor, contractor/subcontractors, subcontractor/subcontractor and so on. The study therefore sought to find out the causes of conflict in labour only contracts between the client and the contractor and also to recommend methods of resolving them when they do occur.

1.1 Aim of the study

The aim of this study to find out the root causes of conflicts in labour only contracts and proper solution on how it can be resolved so as to reduce conflict and litigation in the execution of labour only contracts.

1.2 Objectives of the study

The research objectives are as follow: -

1. To find out the causes of conflicts in labour only contracts
2. To investigate the interrelated nature of the causes of conflicts in labour only contracts
3. To find out way of resolving conflicts in labour only contracts.
4. To determine the consequences of conflicts in labour only contracts.

Research questions

- What are the causes of conflict in labour only contracts?
- Are the factors causing conflict in labour only contracts interrelated?
- Does detailed contract document prevent conflict in labour only contracts?
- What are the methods used in preventing and resolving conflict in labour only contracts?
- What are the consequences of conflict in labour only contracts?

Research hypotheses

To achieve the aim and objectives of the study the following hypotheses were set up as a guide to test the validity of the data obtained.

1.2.1 Hypothesis I (H_i)

Conflicts in labour only contracts are not caused by the following factors: Ambiguous contract documents; Poor communication between project participants; In-adequate contractor's management, supervision and co-ordination; Overly complex construction processes; Mistakes of the in- experienced contractor and client.

1.2.2 Hypothesis II (H_{ii})

The factors causing conflicts are not interrelated.

1.3 Delimitation

The study is limited to Lagos-State, being a former state capital with a lot of economic activities and housing development projects. The study focused on clients, consultants and contractors based in Lagos State using labour only procurement method for executing their projects in different parts of the country, Nigeria, with the aim of examining the factors which adversely cause conflicts in the execution of these labour only projects.

1.4 Justification of the study

The construction industry is now employing more the use of labour only procurement method in executing both private and public projects and this has resulted in increase in the incidence of conflicts disputes, and related litigation without precedence in our history. It most often leads to adversarial relationship between the clients and contractors. Conflicts and disputes also result in a substantial dilution of effort and diversion of capital from what should be the goal of the industry (i.e creation of works and structures to serve the public).

Consequently, the study of the causes of conflicts in labour only contracts will help to improve the working relationship of the parties to the contract and will lead to the development of preventive measures and methods of resolving conflicts without bitterness through the use of Alternative Dispute Resolution (ADR) mechanism.

1.5 Conditions upon which Labour Only Contract Procurement Method is based:

These are availability of labour, availability of plant and machinery, design must be modified to suit labour only contract, good management technique.

2 Review Of Literature

2.1 The problem of conflict in labour only contracts

Great concern has been expressed in recent years regarding the dramatic increase in conflict and dispute in the construction industry most especially in labour only contracts, and the attendant high cost in terms of direct costs (lawyers claims, consultants management time, delay to project completions etc) and indirect/consequential costs (degeneration of working relationships, mistrust between participants, lack of team work and resultant poor standards of workmanship). The multi-organizational structure of a construction project accounts for the high levels of conflict. Loosemore et al (2000) is of the opinion that conflict is an inevitable byproduct of organizational activity. "Each firm has conflicting aims. The management of each firm has to consider the short and long term goal of their firm against the

objectives of the management teams of each of the projects they are working on”. There is need to make distinction between functional and dysfunctional conflict in the construction industry. Loosemore et al (2000) there are merits in positively encouraging functional conflict “because it is a door way of opportunity to organizational learning and creativity”.

Godfrey (1996) stated that the construction industry was and is, experiencing a growth in claims and related litigations that is without precedent in our history. All too often an adversarial relationship between the owner and the contractor is not only expected but is considered natural and even acceptable, companies and consultants are emerging from every nook and cranny to either create a claim situation or to help an owner mitigate claims. Disputes result in a substantial dilution of efforts and diversion of capital from what should be the goal of the industry which is basically the creation of works and structures to serve the public.

Ridgway (1994) addressed the theme of moral degeneration and argues that the cause of conflict and disputes “may lie in the venality of the people’s character and lack of ethics in the building industry. Uher (1994) is also of the opinion that construction industry is characterized by lack of trust between the participants. “The party in the best bargaining position at the time, take advantage of the position. The disadvantaged parties bid their time and wait for the cycle to change for their turn to get back and take advantage”. The culture is win-lose. Contractors look for loopholes in the documentation and structure tenders to take advantage of the construction documents. The client and especially architects see the contractor as an adversary. Professional litigators and claims experts here appeared in the industry to prey on the win-lose nature of project stakeholders Uher (1994).

The construction process involves multi organizational activity. Conflict and disputes can therefore exist at all levels in the constructional chain; client/consultant; client/contractor; contractor/sub contractor: subcontractor/subcontractor and so on. Disputes however are seen as an affliction in the construction industry because of the multi organizational activities of the industry. A conflict exists, where there is an incompatibility of interest. It would appear that a conflict occurs at the same point in time as when a notice of a claim is given, and exists until the claim or disputes resolved. A claim, which is not resolved, becomes a dispute when either party gives written notice to that effect. Yate and Hardcastle (2003)

Types of conflict arising from this contractual arrangement can be summarized into three categories.

1. Time related (i.e. claims from the contractor for extensions of time for completion of the project)
2. Money related (i.e claims from the contractor for payment of the values of variations and / or reimbursement of loss and expense)
3. “Quality related (i.e assertions by the client of defective materials and workmanships. Claims from the contractor can be categorized according to three main types:
 1. Claims for additional payment or “loss and expense” (i.e “money” claims)
 2. Claims for “extension of time” (i.e time claims)
 3. Routine measurement and valuation of variations (i.e “variation” claims)

Wilson (1982) who identified as the more common causes: -Misunderstanding and poor communications, personal and cultural values and professional ethics, diverging interest and personality of individuals. Ridgevev (1994) attributed the causes of conflict and disputes to the venality of the people's character and the lack of ethics in the building industry" In his view, greed, lack of commitment and lack of responsibility are reflected in claims and disputes. "A man's word is given but not trusted" "A contract is studied for legal opportunity not for common benefit". Boland (1997) attributed the high levels of conflict and disputes to the demise of the general contractor "structure" of the industry and the "indiscipline" of calling tenders based on partially completed designs and the consequent high incidence of variations.

Reva (1992) in a study is of the view that the most frequent causes of claims, which can be traced back to clients "misguided" desire to save money at the wrong "end" of the project. These are: Inadequate site and /or soil investigation prior to starting the design; Starting design efforts too late and / or unduly limiting the cost of engineering /designs; Calling for bids with an incomplete set of drawings; Endeavouring to complete the design through shop drawing review; Introducing untimely design revisions without allowing commensurate time extension for the completion of the project or without recognizing the contractor's right to impact; Interfering both with the sequence and the timing of construction (e.g to compensate for the delay in the delivery of owner supplied equipment /materials) and Continuing to introduce changes under the disguise of correcting deficiencies.

The Centre for Public Resources Inc. (1991) in its publication "prevention and resolving construction Disputes" suggested that the ten most common specific causes of construction disputes are: Contract provision, which unrealistically shift project risks to parties who are unprepared to cover those risks; Unrealistic expectations of the parties particularly employers who have insufficient financing to accomplish their objectives; Ambiguous contract documents; Contractors who bid too low; Poor communications between project participants; Inadequate contractor management, supervision and coordination; Failure of participants to deal promptly with changes and unexpected conditions; A lack of team spirit or collegiality among participants; A "macho" or litigious mind set on the part of some or all project participants; and Contract administrators who prefer to buck a dispute to a higher level or to lawyers rather than take responsibility for resolving the problem at the source.

Most importantly, Omotosho (1999) stated that labour only contract is faced with a lot of management problems arising from improper definition of duties and responsibilities at the implementation stage. The contractor finds it difficult to harness the other production resources provided by the building owner with the labour resources provided by him for the execution of the project. His site operational plan is always shrouded with the quest to at least break even through the relatively low overhead and profit occurring from the labour. For a labour only contractor to make any headway in his operations his appraisal/analysis of the labour resource has to be very thorough and sound. He must be able to properly determine the number of operations for a particular activity, the duration and cost. Above all, he must have on in-depth knowledge of vital management functions.

According to Cooke (1984) at the pre-contract planning stage, it is necessary to assess for effective management the contract requirements regarding: the provision of labour requirements; key material supplies; allocation of plant and equipment and key commencement date for subcontractors and nominated suppliers. Also, Wilson (1982),

“today’s construction project is a complex effort requiring the support of many design professionals along with a variety of construction talent. The construction disputes which can develop from such a complex project are no less complex and require a battery of attorney, and consultants to resolve the issues”.

One of the causes of conflict in building construction project is professional negligence. When a professional holds himself out as qualified in a particular professional discipline, he hereby indicates that he is competent to render a service commensurate with his skill and expertise. Hence, failure to meet this performance criterion, which occasions any loss, renders the professional liable for a breach of contract or negligence, which causes dispute. An in- experienced contractor (due to poor training or lack of experience) will have some problems, dealing with the owner and may not be able to satisfy the owner’s construction requirements. The lack of construction experience will make the construction process inefficient and will lead to improper project execution.

2.2 Conflict prevention techniques in labour only contracts

Prevention techniques are more useful than resolution techniques because their successful application renders resolution techniques unnecessary. Diekman and Girard (1995), stated that three prominent conflict prevention techniques used in labour only contracts are Equitable contractual risk allowance; Use of contractual incentives and Use of long term partnering/project partnering.

2.3 Conflict resolution methods in labour only contracts

Kangari (1995) explained that despite growing criticism arbitration is becoming more preferred alternative to litigation for resolving disputes in the labour only contracts between the client and the contractor. Other alternative dispute resolution methods such as negotiation, conciliation (Mini trial) and mediation are equally gaining ground. Keinfeld (1989) and Taiga (1998) defined Alternative dispute resolution (ADR) as “a broad range of mechanisms and non judicial procedures processes designed to assist parties in resolving differences”. These alternatives mechanisms are not intended to supplant court adjudication but rather to supplement it. These include Arbitration, Negotiation and re-negotiation, Conciliation and mediation and Litigation.

3 Research Methodology

The population of the study is the construction firms, client’s organization, and consulting firms domiciled in Lagos State but are involved in the execution of labour only projects in Lagos State, other parts of the country, Nigeria. Twenty (20) construction companies with qualified site/project managers were randomly chosen from both indigenous and multinational firms based on Federal Ministry of Works register, twenty (20) clients and twenty (20) consultants were selected for the study. Both primary and secondary data were used for this study. 18, 16 and 16 questionnaires were filled and returned by firms, clients and consultants respectively (see Table1). The information obtained covered the following variables: background information of the respondent; causes of conflict; techniques/strategies employed in preventing and resolving conflicts; consequences of conflict; and design.

To facilitate the research, the following hypotheses were formulated.

3.1 Hypothesis I (H_i)

Conflicts in labour only contracts are not caused by: Ambiguous contract documents; Poor communication between project participants; In-adequate contractor's management, supervision and co-ordination; Overly complex construction processes; Mistakes of the in- experienced contractor and client.

3.2 Hypothesis II (H_{ii})

The factors causing conflicts are not interrelated.

4 Method Of Data Analysis

The returned questionnaires were coded into a coding sheet and with the help of the SPSS package and the responses were analyzed. For Hypothesis 1(One): Inter correlation matrix and Multiple regression analysis were used. The dependent variable was Conflict while the Independent variables were poor communication between project participants; Ambiguous contract documents; Mistakes of inexperienced contractor and client; Overly complex construction processes; Inadequate contractor's management, supervisor and co-ordination. For Hypothesis 11(Two): Inter-correlation matrix; Multiple regression analysis and Anova were used.

4.1 Data Presentation, Analysis And Discussion Of Findings

The data computation was carried out using the Statistical Package for Social Scientists (SPSS) and the following presentation shows the background and characteristics of the respondents.

3.2.1 Respondents Characteristics

Out of the sixty (60) questionnaires administered on the respondents, that are twenty (20) for the contractors, twenty (20) for the clients, and twenty (20) for the consultants, a total of fifty (50) completed set of questionnaires could be-retrieved. This represents a total of average of 83% of respondents which is good enough to draw inference on this study.

Table 1 Respondents characteristics

Respondent	Questionnaires served	Questionnaires received	Percentage received	%
Contractors	20	18	90	
Clients	20	16	80	
Consultants	20	16	80	
Total	60	50	83	

The above Table 1 shows that 90% of the contractors returned the questionnaires and 80% response from the clients and consultants respectively. The average total is 83%. This is a very high response.

3.2.2. Educational Attainment

Figure 1: Educational attainment of the respondents

The figure 1 above shows that twenty five (25) respondents have at least HND/BSc, twenty one (21) respondents have Msc and higher qualifications, while only four (4) of them possess WASC/OND. It shows that most of the respondents are highly qualified educationally.

3.2.3. Years of experience of the respondents

Table 2 Years of experience of the respondent

Period	Number of Respondents	Percentage (%)
1 – 10 yrs	14	28
11 – 20 yrs	26	52
21 – 40 yrs	8	16
40 yrs and above	2	4
Total	50	100%

The above table 2 shows that seventy-two percent (72%) of the respondents have more than ten years of working experience in the construction industry and twenty percent (20%) have more than twenty years of experience. It can therefore be assumed that the respondents have good understanding of construction processes.

3.2.4 Staff strength of the respondents firms

Table 3 Staff strength of the respondents firms

Employed	Number of Respondents	Percentage (%)
1-50	32	64
51 – 100	12	24
101-200	3	6.0
>200	3	6.0
Total	50	100%

3.2.5. Categories of projects undertaken by the respondents firms

Table 4: Categories of projects executed by respondents

Project type	Number of Respondents	Percentage (%)
Building	24	48.0
Civil	15	30.0
Mechanical/Electrical	7	14.0

Heavy Engineering	4	8.0
Total	50	100%

The Table 4 above indicates that respondents are mostly involved in building projects (48%) and civil engineering projects (30%) while the remaining respondents (22%) are involved in either mechanical or electrical (44%) or heavy engineering projects (8%).

3.2.6 Types of procurement methods employed by the companies

Table 5: Types of procurement methods

Procurement	Number of Respondents	Percentage (%)
Traditional method	11	22.0
Design and build	3	6.0
Management contracting	2	4.0
Project management	2	4.0
Direct labour	2	6.0
Labour only	29	58.0
Total	50	100

Table 5 above shows that most of the respondents (58%) use labour only procurement method to execute their projects, while very few respondents (4%) use management contracting and project management respectively. The remaining (6%) use direct labour.

3.2.7. Categories of project executed using labour only

The nature of projects executed by the respondents using labour only shows that out of all the projects executed by the respondents using labour only 50% were new projects, and the rest were 26%, 24% respectively for refurbishment and both respectively.

3.2.8. Contract sums of labour only projects

Table 6: Categories of labour only projects

Contract sum	Number of Respondents	Percentage (%)
N1m – 20m	30	60.0
N21m – 40m	14	28.0
N41m – 60m	6	12.0
N110m – 200m	-	-
N201m and above	-	-
Total	50	100%

Table 6 above shows that labour only contracts executed by the respondents less than N20m are 60% and those contracts above N20m are 40%. It means that labour only is commonly used for small size projects.

3.2.9. The intensity of conflict experienced in labour only contracts

Table 7: The intensity of conflict

Intensity	Number of Respondents	Percentage (%)
Less intense	12	24.0
Intense	26	52.0
Most intense	12	24.0
Total	50	100%

The above table 7 shows that conflict is intense in (52%) of the projects executed by labour only while 24% of the projects are most intense in conflict. There is 76% cumulative percentage in the degree of intensity.

3.2.10. The nature of conflict

Table 8: The nature of conflict

	Number of Respondents	Percentage (%)
Between client and contractor	30	60.0
Between contractor and consultants	13	26.0
Between client and consultants	7	14.0
Total	50	100%

The above table 8 shows that the conflict between the client and the contractor is the highest (60%) while the conflict between the client and the consultant (14%) is the least.

4.2 Testing Of Hypotheses In Respect Of Stated Objectives

The data obtained are arranged and discussed in sequence with the manner in which the specific objectives have been presented.

4.2.1 Objective one:

To find out the causes of conflicts in labour only contracts.

Research Question:

What are the factors causing conflicts in labour only contracts?

Hypothesis 1

Null Hypothesis (Ho): Conflict in labour only contacts are not caused by the following factors: Ambiguous contract document; Poor communication between project participants; Inadequate contractor's management supervision and coordination; Overly complex construction process; Mistakes of inexperienced contractor and client;

Alternate Hypothesis (H₁): Conflict in labour only contracts are caused by the following factors: Ambiguous contract document; Poor communication between project participants; Inadequate contractor's management supervision and coordination; Overly complex construction process; Mistakes of inexperienced contractor and client;

The descriptive statistic below shows the ranking of the factors causing conflict in their order of significance.

Table 9: Ranking of causes of conflicts
(Source: fieldwork 2007)

Factors	Mean Item Score (MIS)	Rank	Comment
Lack of communication	4.26	1	Strongly agree
Ambiguous contract document	4.15	2	Strongly agree
No Alternative Dispute Resolution	4.03	3	Strongly agree
Lack of trust between client and contractor	3.97	4	Strongly agree
Delay in procurement of materials	3.34	5	Agree
Poor communication between project	3.24	6	Agree

participants				
Improper management of site resources	2.80	7	Agree	
Late payment for work	2.75	8	Agree	
Low bidding by contractor	2.66	10	Agree	
Unrealistic contract duration	1.53	11	Disagree	
Clients who cut corners in design	1.28	13	Disagree	
Project construction complexity	1.26	14	Disagree	

The above Table 9 shows that the most significant factor is lack of communication between client and contractor (4.27), delay in procurement of materials for the contractor by the client is important(3.34), while the least important factor is Project construction complexity (1.26) in labour only contracts.

It means that complex construction process is the only factor among the above listed factors in the hypothesis one that is not significant enough to cause conflict. This is in agreement with Null hypotheses (H_0), while the remaining factors are in agreement with the alternate hypothesis (H_1).

4.2.2 Objective two:

To investigate the interrelated nature of the causes of conflicts in labour only contracts.

Research Question:

Are the factors causing conflict in labour only contracts interrelated?

Hypotheses H(ii)

Null Hypothesis (H_0): The factors causing conflicts are not interrelated.

Alternate Hypothesis (H_1): The factors causing conflicts are interrelated.

Table 10 Correlation matrix on the factors causing conflict.
(Source: fieldwork 2007)

Variables	Code	Lack of communication (S20A)	Project construction complexity (S20B)	Ambiguous document (S20 C)	Inadequate contractor's management (S20D)	Inexperienced contractor (S20E)
Lack of communication	S20A	1.0000				
Project construction complexity	S20B	-.1471	1.0000			
Ambiguous contract document	S20C	.3273	.2935	1.0000		
Inadequate contractors management	S20D	.0289	-.3340	.3311	1.0000	
Low bidding contractor	S20E	0.245	-.0607	.0748	.0231	1.0000
Inexperienced contractor	S20F	-.0530	.1241	-.0607	-.1126	.2908
Late payment	S20G	-.1686	.5059	.0341	-.1927	.2164
Clients who cut corners	S20H	.1463	.2041	.0271	-.1147	.5036
Poor communication	S20I	-.1051	.4030	.1204	.1116	-.0390
Delayed procurement	S20J	-.0941	-.0791	.0958	.1142	.6471
Improper site management	S20K	.0349	-.2178	.2132	.5365	.0478
Lack of trust	S20L	-.0560	.2407	.1650	-.0097	.0786

No provisions for alternative dispute resolution	S2OM	.1909	.0761	.3750	.2649	.1371
Failure to deals with changes promptly	S2ON	.0180	-.3924	-.1509	.3379	-.2523

The above table 10 shows some negative values, meaning that the factors are negatively significantly related. For example S20D and S20B are. -3340 i.e S20D (the inadequate contractor’s management supervision and coordination) is negatively significantly related to the S20B (complex project construction process). Whereas those positive values mean that the factors are positively significantly related. For example S20k and S20D value is 0.5365. It means, S20k (Improper management of site resources by the contractor) is positively significantly related to S20D (Inadequate contractor’s management supervision and coordination).

4.2.3 Objective three

To determine methods of preventing and resolving conflicts in labour only contracts.

Research Questions:

- What are the methods used in preventing conflict?
- Are the prevention and resolution techniques employed able to eliminate conflict in labour only contracts.

The prevention strategies and resolution techniques were analyzed by the use of descriptive statistics and the result are presented in table 11 and table 12 below.

Table11: Conflict prevention strategies

Conflict prevention strategy	Mean In Score (MIS)	Rank	Comment
Equitable contractual risk allocation	3.91	1	Strongly Agree
Use of contractual incentives	3.35	2	Strongly Agree
Prequalification of contractors	2.54	3	Agree
Long-term partnering /project partnering	2.53	4	Agree

The above table 11 shows that the most effective strategy for preventing conflict is the use of equitable contractual risk allocation (3.91) while the least is the use of long-term partnering/project partnering (2.53).

Table12: Conflict resolution techniques

Conflict resolution techniques	Mean In Score (MIS)	Rank	Comment
Negotiation	4.12	1	Strongly Agree
Conciliation and mediation	3.75	2	Strongly Agree
Arbitration	3.33	3	Agree
Litigation	2.75	4	Agree

Table12 above shows that conflicts are most easily resolved by negotiation (4.0) than by the use of conciliation (3.75) arbitration (3.33) and litigation (2.75) being the last resolution technique when others fail.

4.2.4 Objective four

To determine the consequences of conflicts in labour only contracts.

Research Questions:

- What are the consequences of conflicts in labour only contracts?
- What is the effect of conflict in duration (time) and cost of the project?

The consequences of conflicts in labour only contracts are analyzed below by the use of descriptive statistics.

Table18: Consequences of conflicts

Variables	Mean (MIS)	In Score	Rank	Comment
Project abandonment	4.06		1	Strongly Agree
Cost overrun	3.87		2	Strongly Agree
Time overrun	3.82		3	Strongly Agree
Loss of cohesion among project team	2.80		4	Agree
Poor workmanship	2.51		5	Agree

Table 18 above shows that project abandonment (4.06) is the most severe consequence of conflict while poor workmanship (2.51) is the least consequence of conflict in labour only contract.

5 Discussion Of Findings

5.1 Factors causing conflicts in labour only contracts

From the analysis and the result of hypothesis one (1), in Table 9, The most important factor is lack of communication between the client and the contractor while delay in procurement of materials by the client is equally important as delay in procurement of materials by the contractor will make his labour force redundant and consequently erode his profit margin. This may lead to conflict and dispute between the client and the contractor .Most of the respondents interviewed also agreed that all the factors earlier stated in the hypothesis one (1) are significantly important except for the Project construction complexity.

5.2 To investigate the interrelated nature of the causes of conflicts in labour only contracts

The result of hypothesis two (II) in Table 10 revealed that some factors are positively significantly related e.g Improper management of site resources by the contractor is positively significantly related to inadequate contractors management supervision and coordination while some factors are negatively significantly related e.g. Inadequate contractors' management supervision and coordination is negatively significantly related to complex construction process. The fact that some factors are significantly related and others are not significantly related, explains why conflicts exist in one project and not in another.

5.3 To determine the methods of preventing and resolving conflicts in labour only contract

The result of descriptive statistics used in determining the methods of preventing and resolving conflicts shows that equitable contractual risk allocation, contractual incentives, prequalification of contractors and long-term partnering can prevent conflict provided the client and contractor are willing to abide by the conditions of the contract. Also the introduction of Alternate Dispute Resolution (ADR) mechanism in the contract can be used to resolve conflicts when they occur during and after construction but cannot totally eliminate conflicts. The interview conducted also showed that conflict in any human endeavour is inevitable but it can only be minimized but not eliminated.

5.4 To determine the consequences of conflicts in labour only contracts

The results of the descriptive statistics revealed that conflicts can lead to project abandonment, time overrun and cost overrun depending on the severity of the conflict. The most severe consequence of conflict is project abandonment while the least severe consequence is poor workmanship.

6 Conclusions

The investigation on the conflict resolution in labour only contracts revealed the following:-

1. That the major causes of conflicts in labour only contracts are Lack of communication between the client and the contractor; Ambiguous contract documents; Inadequate contractor's management, supervision and coordination; Poor communication between project participants; Lack of trust between the client and the contractor; Delay in procurement of materials by the clients; Late payment for work and the contract, which does not provide for Alternate -Dispute Resolution (ADR) mechanism for resolving conflicts during and after construction.
2. That the factors causing conflicts in labour only contracts are significantly inter-related either positively or negatively. This explains why conflict and disputes occur in some projects and not in others of the same procurement method.
- 3 That the onus of purchasing materials is now on the client, there could be increased cases of cases of theft. It could also create logistics problems for the client which may lead to delays and consequently conflict between the client and the contractor.
4. That conflicts may lead to increase in project duration (time overrun) and increase in Cost (cost overrun) depending on the severity of the conflict which is in agreement with the recommendation of Adenuga (2003).
5. That project abandonment is the most severe consequence of conflict in labour only contract. It can therefore be concluded that conflicts have serious consequences on labour only contract

6.1 Recommendations

The problem of conflict and dispute in the execution of labour only contract is inevitable, it can however be minimized by the following recommendations: -

- 1 The client should proactively endeavour to Limit or reduce contract incompleteness and attenuate the opportunistic inclinations of the contractor.

- 2 Experienced, reputable and capable design consultants should be selected (particular attention should be paid to the design and coordination of the building services)
3. Contractors should be selected based on quality including reputation and experience as well as price and From the sociological point of view, any procedure such as Partnering and Value Engineering, which brings people together at the early stages of the project will have a positive effect on the working relationship and teamwork.
- 4 That contract documents should be prepared by a team of professionals including a lawyer and Alternative Dispute Resolution (ADR) mechanisms should be introduced into the contract to minimize the incidence of conflict during and after construction
5. Government should enact a law that will forbid quacks from engaging in the execution of building projects, most especially, in labour only projects and also enact a law that would facilitate early settlement and resolution of conflicts and disputes in the court of law. For labour only contracting system to be more successful workers welfare should be should be given utmost priority.

5.3 Suggestion For further studies

A study should be conducted on the causes of conflicts between the contractor and the nominated supplier in the labour only contracts.

Project scheduling a review through literature

Vacharee Tantisuvanichkul¹ and Moray Kidd¹

Abstract:

Project scheduling is very attractive for researchers and has recently attracted considerable attention because of the high cost of capital and the significant effect of the time value of money. There has been a vast majority of the project scheduling methodologies developed with the objective of minimising the project duration subject to precedence and other constraints. Recent efforts have focused on the maximisation of the net present value (NPV) of the project. If financial aspects taken into consideration of particular interest to project management, the maximisation of project NPV then decided as the more appropriate objective. In this paper we review the fundamental approaches for scheduling the problem as well as to summarise and categorise the model that have been proposed and presented in the literature. It was found that many researches focus has been on metaheuristics such as Genetic Algorithms and Tabu search which have been the most popular strategies for both objectives. It was also observed that the new propose techniques contain more components than earlier procedures.

Keywords:

project scheduling, NPV maximisation, project duration minimisation, Net Present Value

1 Introduction

This paper will focus on *project scheduling* that is the subset of project management. Project scheduling is the process where the various activities that need to be undertaken during a projects lifetime should be scheduled. Project scheduling is concerned with the techniques that can be employed to manage the activities that need to be undertaken during the development of a project. It is primarily concerned with attaching a timescale and sequence to the activities to be conducted within the project. Materials and people needed at each stage of the project are determined and the time each is to take will be set. There are ranges of activity management tools that are commercially available. Programme Evaluation and Review Technique (PERT) and Critical Path Method (CPM) are helpful scheduling techniques only when the project deadline is not fixed and the resources are not constrained by either availability or time.

Constructing a feasible project schedule that satisfies the above constraints is an easy task. The difficulty, however, arises when improved schedules are desired to optimise or nearly optimise a stated objective function. These objectives include minimising project completion time or duration, levelling the mean resource usage, and maximising project net present value(NPV). When significant levels of cash flows are present in the project, in the form of expenses for initiating activities and progress payments for completion of parts of the project, the NPV criterion is a more appropriate measure of project

performance. This criterion generates a cost-critical path and schedule of activities, in contrast to the time-critical path and schedule obtained by the make-span objective.

Net present value (NPV) is being used in many investment-planning problems. Some people might think that the time value of money is not an important issue for evaluating such “short” projects. For instance Six Sigma projects which are typically targeted for 6 to 12 months for implementation. However, this would be an erroneous conclusion because, even though the implementation time may be short, the useful project life can be much longer. The financial analysis of projects should be based on the useful life or a long-term view of the project. This is why it is important to apply expected NPV analysis even to “short” projects (Flaig, 2005).

2 Literature Review

The vast majority of the projects scheduling methodologies presented in the literature have been developed. Past research has examined various objectives. These objectives include minimising project completion time or duration, levelling the mean resource usage, and maximising project NPV. Although different objectives have been examined previously, the primary goal of undertaking any commercial project is to maximise the monetary value of the project (Yang *et al*, 1995).

While majority of the past research has focused on minimising project completion time, the primary goal of undertaking any commercial project is its potential profitability. The most pragmatic project objective is, therefore, to maximise project NPV (Yang *et al*, 1995).

Scheduling problem can be distinguished into two categories; the unconstrained project scheduling problem, which occurs when no constraints on resource usage are imposed such that the activities are only subject to precedence constraints, and the resource-constrained project scheduling problem (RCPSP). However, this paper focuses more on project scheduling problem subject to NPV maximisation.

2.1 Unconstrained resource

2.1.1 Project duration minimisation

This problem can be solved by a simple forward recursion procedure, where each activity is assigned its earliest precedence feasible start time (Kolisch *et al*, 2006).

2.1.2 NPV maximisation

A.H. Russell (1970) was the first to introduce the objective of maximising the NPV of cash flows in a network. Russell deals with the unconstrained problem where both positive and negative payments occur as events in the project are completed.

Russell's objective function is to

$$\text{maximise NPV} = \sum_{i=1}^n CF_i \exp(-\alpha T_i) \quad (1)$$

where $\exp(-\alpha T_i) = \beta$, the discount factor.
CF = Cash Flow

For uniformity of expression, the criterion Eq. (1) is sometimes rewritten as:

$$\text{maximise NPV} = \sum_{i=1}^n CF_i \beta^{-T_i} \quad (2)$$

Russell transforms the nonlinear objective function from Eq (2) into a linear one by approximation using the first term of the associated Taylor series expansion.

He does not report computational results with his procedure apart from two small example problems, although reference is made to a computer programme being developed to solve this problem. Because of the development of fast and efficient network computer codes since the publication of this paper, there do not seem to be any theoretical obstacles to implementing his approach. His research showed that the cost-critical path is quite different from the time-critical path when monetary objectives are considered.

Grinold (1972) transforms the unconstrained problem formulated by A. H. Russell into an equivalent linear programming problem. This problem is exploited by the solution procedure that determines the optimal solution by exploring the set of feasible trees on the project network such that all activities have zero slack. This procedure is also used to illustrate, with an example, the trade-off between NPV and project duration He does not provide extensive computational results for his procedure.

Elmaghraby and Herroelen (1990) critique both Russell's and Grinold's formulations to develop a simplified algorithm that gives the optimal schedule for the project scheduling problem with NPV objective. They show that, in general, it is optimal to schedule events with associated positive cash flows as early as possible, and events with net negative cash flows as late as possible subject to restrictions imposed by network structure. They also illustrate that net cash flows are dependent on the time of realisation of cash flow nodes and in the absence of a project deadline, if the NPV is less than zero, the project will be delayed indefinitely.

Demeulemeester *et al.* (1996) have proposed a new optimal algorithm that performs a recursive search on partial tree structures that utilise the concept of scheduling activities early if they bring in payments and delaying those activities that incur expenses. Computational tests report encouraging results in comparison to the Grinold procedure.

2.2 Resource constrained

The RCPSP, which as a generalisation of the *job-shop* scheduling problem is *NP-hard*, has been extensively studied in the literature.

To solve RCPSP, previous research is categorised the procedures as either an optimisation or heuristic solution method. Optimal procedures have been termed *exact* or *analytical* procedures because they usually involve some form of mathematical programming or other rigorous analytical procedure. Heuristic procedures involve the use of some rule-of-thumb or *heuristic* in determining priorities among jobs competing for available resources. However, these two methods consist of procedures which aim at producing the best possible schedule.

2.2.1 Project duration minimisation

Optimisation approaches

With optimal procedures, an initial sub-categorisation can be made according to the

type of mathematical technique employed in the search for the best possible solution. Existing procedures are divided according to whether they utilise some form of integer linear programming, a variation of some enumerative or other technique. Examples are *branch and bound* (Davis and Edward, 1973). The methods applied so far for the exact solution of the resource constrained project are dynamic programming, zero-one programming, and implicit enumeration with branch and bound.

Heuristic approaches

Heuristic procedures can be broadly classified into Priority rule based scheduling and metaheuristic approaches; Genetic Algorithms; Tabu search; Simulated Annealing. The idea behind heuristic algorithms for resource constrained project scheduling is to rank the activities by some rule, this may be managerial priority, earliest start times, and to schedule the activities in that ranking order ensuring that the resource limits on the project are never exceeded. Thus activities considered to be important in some sense are scheduled as soon as possible.

From Kolisch's review, heuristic techniques for the resource constrained project basically involve four different solution methodologies: (1) priority-rule-based scheduling, (2) truncated branch-and-bound, (3) disjunctive arc concepts, and (4) metaheuristic techniques.

2.2.2 NPV maximisation

Optimisation approaches

Doersch and Patterson (1977) were the first to study in the context of the resource-constrained max-npv problem. They introduced a binary integer programming approach to the NPV project scheduling problem. This model included a constraint on capital for expenditure on activities in the project such that the available capital increased as progress payments were made. The objective function also included the cash flows associated with the completion of activities and any penalties incurred for late completion. The model was solved to optimality for projects involving 15–25 activities. The results indicated that at high cost of capital or long project duration, it is important to evaluate bonus/penalty and capital constraints while scheduling activities. However, detailed computational results are not provided.

Smith-Daniels and Smith-Daniels (1987) extend the Doersch and Patterson zero-one formulation to accommodate material management costs. The NPV of the project was maximised subject to material and capital constraints and solved to optimality on small problems. They concluded that not only do ordering and holding cost force activities with common requirements to start at the same time or close to each other, the additional constraints also result in lowering overall project cost even though they may cause activities, and hence the project, to be delayed.

Tavares (1986) proposed a new dynamic programming formulation and solution method, where the optimality conditions were derived using calculus of variations for a set of interconnected projects (Kolisch *et al*, 2006). The objective function to be maximised included a net of the discounted sum of the benefits generated along the programme, the discounted sum of the cost of project expenditures, and a term to penalise the variation in expenses over time. This programme was applied successfully to a large railway construction project in Portugal.

Patterson et al. (1990) presented a zero–one programming model and a backtracking algorithm to maximise the NPV of the constrained project scheduling problem. It is unique in that it can also be used to minimise project duration. The solution methodology utilised the fact that the minimum duration problem is easier to solve than the max NPV problem and used it as a heuristic to generate starting solutions on which right-shifting of cash flows was applied to improve NPV. 91 problems, ranging from 10 to 500 activities, were tested on both objectives using MINSLK and random rules, with optimal solutions found only for the smaller problems. The MINSLK rule generated higher NPV than the random rule.

Baroum and Patterson (1999) proposed a branch and bound procedure directly designed to solve the project scheduling problem with NPV objective.

Icmeli and Erenguc (1996) also developed a branch-and-bound algorithm for the RCPSP with cash flows which used the minimal delaying alternatives concept for branching.

Since optimisation techniques have not been successful in solving this limited resource problem and are impractical to compute for large-scale projects, another method is proposed.

Heuristic approaches

- Priority rule based scheduling

Smith-Daniels and Aquilano (1987) compared the duration and NPV of a late-start critical path schedule to that of an early-start critical path schedule. It was assumed that cash outflows occurred at the beginning of the period and a single project payment was received on completion of the project. Their assumptions were tested using the 110 Patterson problems. An improved average NPV and lower average duration can be found for late-start schedules than early-start schedules.

Smith-Daniels and Aquilano (1987) also considered the resource constrained max-npv problem. They concluded that a heuristically determined right shifted schedule yields a higher NPV and lower average duration than schedules derived with heuristics that schedule each activity as early as possible.

Ulusoy and Özdamar (1996) presented an iterative scheduling algorithm with the objective of improving both the project duration and NPV. The consecutive forward/backward scheduling passes made by the iterative algorithm result in a smoother resource profile, which, along with right-shifting of activities, improves both the project duration and NPV. In the cash flow model assumed here, activity expenditures occur at their starting times and payment is made on completion of the project. The algorithm was tested on two sets of problems from the literature. The results demonstrated that under the assumed cash flow model, the iterative scheduling algorithm improved both criteria.

Baroum and Patterson (1996) evaluated several heuristic approaches used by project and contract managers involving single- and multi-pass procedures. Their single-pass procedures used priority weights based upon cumulative future cash flows for all successor activities. Multi-pass procedures were enhancements to improve upon the

single-pass solution obtained. A full factorial experimental design was used to assess the performance of the heuristic procedures. The computational results demonstrated the efficiency of the discounted cash flow, positional weight heuristics over more traditional methods.

- Metaheuristics

Icmeli and Erenguc (1994) applied a tabu search procedure to a starting feasible solution generated using a simple single-pass algorithm. The initial solution was improved over several iterations by moving each activity one time unit early or late from its current completion time, with the restriction that the resulting completion time should not violate earliest and latest completion times for the activity. They also investigated the use of long-term memory within tabu search to further improve the results. Computational results on 50 problems from the Patterson set indicated that these procedures were both efficient and close to optimal.

Zhu and Padman (1999) applied distributed computing concepts to the RCPSP through the use of an Asynchronous Team (A-Team) approach. An A-team is a software organisation that facilitates cooperation amongst multiple heuristic algorithms so that together they produce better solutions than if they were acting alone. They embedded several simple heuristics for solving the RCPSP within the iterative, parallel structure of A-Team which provides a natural framework for distributed problem solving.

3 Findings and Discussion

Past research (Baroum and Patterson, 1996; Padman et al., 1999; Russell, 1970) has developed many different deterministic, single-pass heuristic decision rules for maximising project NPV. A limitation of these single-pass rules is that they only generate a single solution or schedule for a problem. Many researches focus has been on metaheuristics. Genetic Algorithms and Tabu search have been the most popular strategies for both objectives. The activity list has been the most widely used representation. It has usually been employed in its classical form, while a few researchers have extended it. A general observation is that the new propose techniques contain more components than earlier procedures (Kolisch *et al*, 2006). Considering the advantages of representations like the activity list, one may in fact wonder why some recent metaheuristics still employ the direct schedule representation with operators that are very likely to produce infeasible solutions. Hence, even if a good solution has been found, a more intensive search around the proposed solution is likely to yield an improved solution. Investigating the use of an improved solution procedure for the project scheduling problem is, therefore, a worth while endeavour.

4 Conclusion and Further Research

This paper has summarised approaches of the project scheduling problem. Conclusion and further research directions are indicated as following. First, while minimising project duration and maximising NPV have been the dominant objectives of much of the research to date, there are considerable opportunities in investigating other objectives that combine these with cost, leveling resources, and so on. Many of these problems, being difficult combinatorial optimisation problems, require heuristic approaches for solving problems of practical size and optimal approaches for validating, comparing and benchmarking the solutions given by heuristics.

Second, considering the development during the past years, metaheuristic approaches have recently attracted more attention than priority rule-based methods.

Third, new techniques tend to more components than earlier one. Many methods consider both scheduling directions instead of only forward scheduling, more than one type of local search operator, or even more than one type of metaheuristic strategy.

Finally, recombining merely existing ideas occasionally seems to be less creative than developing new ideas, some of the integration efforts have put well-known techniques into a new and promising context, and the results have often been encouraging (Kolisch *et al.*, 2006).

Abstract:

Snagging is common practice for new and existing buildings in the housing sector in the UK. However the snag reporting process is yet to be fully developed in New Zealand. Whilst inspections for defects and repairs are mostly carried out for old and existing residential buildings, very little is being done to capture snags in new builds in New Zealand. This paper reports on research which is being undertaken in New Zealand to investigate the magnitude of the snagging problem and to identify means by which snag reporting can be introduced within the house building production process. The primary source of data will be the record of defects collected from well established developers and building inspectors and a semi-structured questionnaire administered to new homeowners. The results from the data analyses will be validated through a verification exercise involving subject matter experts. It is hoped that the result of the research investigations will be beneficial to homeowners, developers and the wider construction industry in New Zealand and thus serve to improve quality performance in residential housing construction.

Keywords:

defects, New Zealand, quality, residential building snagging

1 Introduction

Quality and its achievement continue to generate interest in the building sector and the wider construction industry. This is because the building and construction sector is crucial for economic performance and prosperity. The housing sector is one of the most important sectors in the national development agenda of every country (Mohd and Buang, 2010). In New Zealand, the sector contributes 5% of Gross Domestic Product (Building and Construction Sector Productivity Taskforce, 2009). The residential property sector alone has a total market value of between NZ\$450 and NZ\$500 billion making it the largest asset class in New Zealand (DTZ New Zealand, 2004). Because of the importance of the residential sector and how it supports the economy, the current study is motivated by the belief that improving quality achievement levels in new residential buildings will impact positively on the performance of the overall construction sector. This study hopes to improve quality performance by first capturing

the magnitude of snags that occur before or after handover of new buildings and the effect it has on new homeowners. Then an investigation will follow to determine the potential for introducing snag reporting into the New Zealand building production and house buying process.

Snagging items are quality failure items that are identified near the completion stage of a construction project by an individual who could be termed as ‘the snag identifier’, while the process of identifying and rectifying these quality failures is known as snagging (building inspection) (Sommerville, Craig, and Bowden, 2004). Snagging is a modern term for a quality failure which is not commonly used within the New Zealand construction environment. The common terminology for ‘snags’ is ‘defects’ while a ‘snag identifier’ will mostly likely be referred to as a ‘building inspector’ in New Zealand. Building inspection appears to be common practice for new and existing buildings in the housing sector in the UK although in New Zealand at present, inspections for defects and repairs are mostly carried out for old and existing buildings and inspection has become almost a standard pre-sale clause for older residential buildings. However this practice is uncommon for new residential buildings, thus capturing defects that occur before or after handover on new residential buildings is rare in New Zealand. This study therefore intends to create awareness for improved snag reporting in new residential buildings in New Zealand.

2 Literature Review

2.1 The quality problem in residential buildings

The design and construction of new housing is today becoming more complex partly due to project owners’ increasing demands and expectations. Consequently building products and systems are becoming more innovative (e.g. complicated elevations, cladding types, parapets and balustrades, and innovative resource inputs) to meet the demands of owners. Newer and innovative procurement processes bring about challenges which constructors need to manage effectively while delivering value to the project owner. On another hand, the time taken to build an average house has decreased in spite of these complexities and invariably this may mean that quality achievement could be compromised on construction projects.

Sommerville’s (2007) study of the UK construction industry showed that its residential construction sector is continually experiencing low quality performance with a significant record of defects in new builds. Several studies have shown that the quality failure problem exists in other countries as well (Auchterlounie, 2009; Craig, 2008; Ilozor, Okoroh, and Egbu, 2004; Mills, Love, & Williams, 2009; Sommerville and McCosh, 2006). Sommerville and McCosh (2006) studied defects in 1700 new homes in the UK and they found that the scale of snags peaked at 389 for a single property. Their study showed further that there is a direct relationship between the size of properties and the number of snags identified. Another study conducted by Sommerville and Craig (2005) on 2202 new buildings in the UK over a period of four years had observed similar quality failures. The initial analysis of 55,000 out of 130,000 snagging items captured in Sommerville and Craig’s study estimated that 68% of the defects were attributable to poor workmanship and 14% due to omission. Sommerville and Craig therefore concluded that there is a gap between a buyer’s expectation and what the industry delivers in the way of functional quality. In the same vein, Auchterlounie (2009) confirms that customers’ satisfactions do not correlate with technical defects and performance issues.

Similar poor quality achievement is reported in the Australian construction industry. An unpublished Masters thesis by Georgiou (2000) analysed 1772 houses constructed between 1988-1996, of which 1002 were houses built by their owners and 770 by registered builders. Georgiou's data was used to determine the severity of defect occurrences and the location of the defects within each house type. The results reveal that a mean of 2.74 defects per house was recorded in houses built by owners while a mean of 2.3 defects per house was recorded for those executed using registered builders. Georgiou's research shows that houses that were less than one year old were found to have a significant proportion of defects. Further, there is no significant difference in the quality of homes built by the two types of builders. Ilozor *et al.*, (2004) conclude that framing and roofing were major defects that complicate other quality problems in new residential buildings, which could be mitigated by focussing on these two major defects. More recently Mills *et al.*, (2009) reveal that one out of eight residential buildings have defects in Australia, and that the estimated cost to rectify these defects was 4% of the construction contract value.

From the foregoing, it would seem that quality failures are rampant in new residential buildings in other countries. Examining the situation in New Zealand is therefore relevant. Particular emphasis is given to the magnitude of defects that are recorded at handover of new residential buildings to their owners.

2.2 Current quality situation in New Zealand

As observed, defects are common features of most new residential buildings, and there is evidence to suggest that New Zealand has similar quality problems. The common quality failure in New Zealand housing sector is the weather tightness problem. This problem is mainly confined to buildings constructed with monolithic external cladding installed over untreated timber framing and without a drainage cavity between the cladding and the external wall (PWC, 2009). Studies that have been carried out on the weather tightness problem in New Zealand are extensive. For example, the overview group that was commissioned in 2002 by the Building Industry Authority, New Zealand, to examine the problem of weather tightness, had amongst its terms of reference, the following: (a) to determine the nature, extent, and effect of the weather tightness problem, (b) to evaluate the potential contributing causes of regulatory systems and (c) to determine if failures could be attributed to deficiencies in the Building Act. The report of the overview group (referred to as the Hunn report) concluded that though the extent of problem is not fully known, urgent, corrective and preventive measures were needed to solve the problem. The Hunn (2002) report came up with a series of recommendations which contributed to the review of the 1991 version of the Building Act. Of note is the mandatory inspection regime for all new buildings at different stages during construction work. The inspection regime varies for different building types but is specified in the development consent that is issued before any building can be constructed.

Conservative estimates for the annual cost of rectifying the weather tightness problem was put at between NZ\$12-24 million by the Hunn report. The report confirms the result obtained by an earlier study by Porteous (1992) that evaluated and classified building failures in New Zealand. Porteous found that about 1% of 25,000 new houses constructed annually fail within the first few years of their commission and these failures are mostly due to water ingress.

The water ingress problem affects between 22,000 to 89,000 dwellings, with a consensus forecast of 42,000 PWC (2009). The repair cost for this consensus forecast of 42,000 buildings is estimated to be NZ\$11.3 billion (in 2008 dollars). New residential buildings are particularly vulnerable with homeowners having to bear the burden of snags and latent defects. The weather tightness problem is not the focus of the current study, nevertheless it is a useful reference point to quality problems in buildings in New Zealand.

Page (2011) in a more recent survey, found that 60% of new homeowners have had to call their developers back for defects rectification in New Zealand. This is the most recent evidence that new homeowners are still faced with quality failures in their new homes. These abysmal quality performances continue to bring disrepute to the construction industry, particularly its residential building sector. One would expect that, when a new home is purchased, it will be of the highest quality, considering the inspection regime introduced by the Building Act in 2004. Thus an effective and efficient quality management process that will identify and rectify defects is required to improve quality achievement levels in new residential buildings in New Zealand. The quality management process will impact building production and the house buying process. Snag reporting (building inspection) is proposed as a quality improvement system in the current research programme.

This research will provide an insight into the problem of defects in new builds in New Zealand with a view to suggesting means by which the problem can be minimised or eradicated. It is anticipated that the research would provide data that could be compared to trends in related construction industries such as the UK and Australia (highlighted previously). Advanced knowledge on defects identification and rectification held by the UK residential sector could become a benchmark for quality improvements in New Zealand. Similar improvements in the New Zealand house construction sector will be encouraged; and may well be a solution to the weather tightness problem that pervades this local industry.

2.3 Protection mechanisms for homeowners in New Zealand

To purchase a home has always been at the heart of the New Zealander's dream and it is often the largest investment in their lifetime. Unfortunately these dreams are not completely fulfilled when their quality expectations are not met. Quality assurance should be the top priority considering the scale of investment and personal commitment involved in home ownership (Pfahlert, 2002). Because the ordinary homeowners are not so well informed, they rely on the provisions of the building code and the diligence of the Building Act (BA) when defects arise (CIC, 2009). This has traditionally led to claims against the BA when defects are evident. But homeowners find the state system restrictive, bureaucratic, flawed and under-resourced while the court system is perceived as being too expensive, benefiting lawyers mainly and resulting in little money being left for rectification works (Gibson, 2010). Homeowners are therefore not fully protected.

There are initiatives in the Building Act 2004 to support homeowners' quality expectations through the provision of statutory warranties that are implied in all building contracts for household units (Section 396-399). These warranties cover technical items that could affect the structural integrity of buildings. However the warranties are only useful where there is someone who is responsible to make good any

breaches and is prepared to rectify the building work to the quality levels originally anticipated (Kaye, 2011).

The Consumer Guarantee Act 1993, the Fair Trading Act 1986, the Sales of Good Act 1903, and the Companies Act 1993 also provide some form of protection to new homeowners. However these Acts have limited application in the house building sector. For example the Consumer Guarantee Act 1993 does not apply to a contract for the sale of a whole building attached to land which is designed for residential purposes, while the Fair Trading Act does not offer much protection in the case of a newly built home (Laxon, 2002). The Sale of Goods Act is also limited to consumers who had particular contractual agreement with builders and subcontractors.

There are other protections available to new homeowners in New Zealand. For example those provided by registered Master Builders. This is in the form of guaranties to cover residential building work with a contract price of above NZ\$25,000. The three types of guaranties provided by the registered Master Builder in New Zealand are the 10 years premium guarantee, 10 years classic guarantee and 7 years guarantee. It is worth mentioning that these guaranties only take effect when the correct documentation is completed and that the guaranties are not automatic upon hiring a Registered Master Builder. The Master builder guaranties are limited to defects occurring within 2 years of construction (and 5 years for structural elements) and are capped to a maximum of \$100,000 (Kaye, 2011).

Some further amendments are being proposed to the Building Act 2004, which could provide more incentives for builders to 'build right, first time'. For example it is suggested that homeowners commissioning building works of NZ\$20,000 or more are to have a written contract with their builders, which will specify performance expectations, warranties, and remedial measures. Builders would be expected to rectify any defect reported by the homeowners within 12 months of commission on top of existing obligations to put things right for up to 10 years (Williamson, 2010). These amendments will help homeowners to be able to hold their builders to account and get defects to be rectified more quickly and cheaply though defect warranty periods may be ineffective if the developer/builder goes bankrupt. Homeowners may still have to fix the defects themselves, except if the developer/builders are members of a professional body (Ong, 1997).

The fundamental issues, as the authors see it, is being able to get the builders back to rectify defects and for the buildings to have been checked by qualified building inspectors at handover, so that any rectification can be done within these guarantee periods. Although the proposed revisions to legislation and policy documents could encourage quality achievement in house building production, engaging the service of building inspectors to identify defects could ensure that owners' expectations are met and consequently enhancements to their satisfaction levels.

2.4 The house buying process and inspection regime in New Zealand

There are three common ways by which new houses can be purchased in New Zealand. The first is to buy a completed building that has been built by a developer or builder who may or may not be professionally registered. Another way by which new houses are purchased is by negotiating and buying a house that is under construction. In this case, the purchaser enters into an agreement to purchase the house upon its completion. In this house buying process the potential homeowner could influence the design and

construction, depending on the construction stage reached. Thirdly houses could be purchased as what is referred to as a complete package (land and house) from a developer/builder. The designs may be bespoke using the owners own designers or from prototypes offered by the developer/builder. Management of the building production could be by the designer (on behalf of the owner) or by the developer/builder. Early involvement of the homeowner in this process may allow for performance that meets the owners' quality needs.

Whichever of the above processes are used, it is important that the quality needs and expectations of the homeowner's are met. The more the checks and inspection on building performance, the more probable the final build will meet the required quality standards. More so with the growing number of new residential buildings in New Zealand, a good quality management system is required to cope with these demands. Performance improvement schemes are needed within the residential sector to ensure that the sector maintains its capability to build better quality homes. In this light the building consents granted by an approving authority (Building Consent Authority), before the commencement of construction works, contain compliance requirements which are necessary for the proposed building work.

Building consents specify the inspection requirements for building works based on the submitted plans and specification. The purpose of the inspection is to ensure that building works comply with consent documentation. If the council inspector finds work that does not comply with the building consent during the inspection regime, a notice will be issued to rectify all defects. The inspection regime concludes with a final inspection of the completed build after which a Code Compliance Certificate (CCC) is issued. The CCC confirms that the work has been done in accordance to plans and specifications approved in the building consent. Sales and purchase contracts are often conditional on the issuance of a CCC (Gibson, 2010). Building inspection is usually carried out at specific stages corresponding to building progress but typically, council inspectors' inspect residential buildings at six 'key stages' of construction. Council inspectors may not visit the construction site for a number of weeks between stages and random spot checks during the building process are rare.

It is common for new homeowners to carryout visual inspection before finalising the purchase of their new homes, although this visual inspection may not identify all defective works because of the homeowners' lack of construction knowledge. It is therefore reasonable to engage an expert (building inspector) to undertake in depth inspection on behalf of the homebuyer. Holder (2002) advocates quality audits (snagging) by homeowners that will enable the identification of defects that may not be visually detectable and for which ordinary council inspections may not highlight. Similarly Cossar (2003) encourages checking and inspecting buildings before any decision to buy. Craig (2008) asserts that high quality builds cannot always be achieved by relying on the performance of construction parties. Although inspection is variously suggested, it is rarely carried out, especially with new builds in New Zealand.

3 The Research

3.1 The research questions

From the literature reviewed it is clear that there is a current and indeed pressing need to examine quality performance of new builds in the residential building sector in New Zealand. It is in this light, that the research on which this paper is based asks the

important question: *How could zero snags and defects be achieved so that the quality of new residential buildings is enhanced in New Zealand?* Addressing this research question will help to improve the quality of new residential buildings in New Zealand, and subsequently improve the confidence that new homeowners can have in their developers.

Some of the research sub-questions that relate to snag reporting are listed below. These sub-questions were formulated in order to achieve the main research objectives which are outlined in the next section.

What is the magnitude of snags/defects in new residential buildings?

What are homeowners' views on snagging as a means of ensuring quality achievement in new residential buildings?

Can snagging be encouraged for quality achievement in residential construction?

3.2 The research objectives

Specific objectives which relate to the itemised research questions above, to be pursued include the following:

- a) To identify and categorise snagging problems in residential buildings in New Zealand through an analyses of developer's and building inspector's defect records.
- b) To determine the importance of snag reporting from a homeowner perspective. This will be achieved through an opinion survey administered to new homeowners within three major cities in New Zealand.
- c) To suggest improved quality achievement processes that will be beneficial to residential homeowners, developers and the wider construction industry.

3.3 The research design and methodology

The methodology for data collection and analyses that will lead to suggestions for improving existing house building practice in New Zealand is explained in the research framework presented in Figure 1. The research framework contains four key phases. The first phase covers problem recognition and research scoping. This is achieved by an extensive review of relevant literature and the researchers' interaction with external faculty (located in the UK) to gain knowledge on the research area. Clearer research objectives will be formulated based on new levels of understanding in the subject area

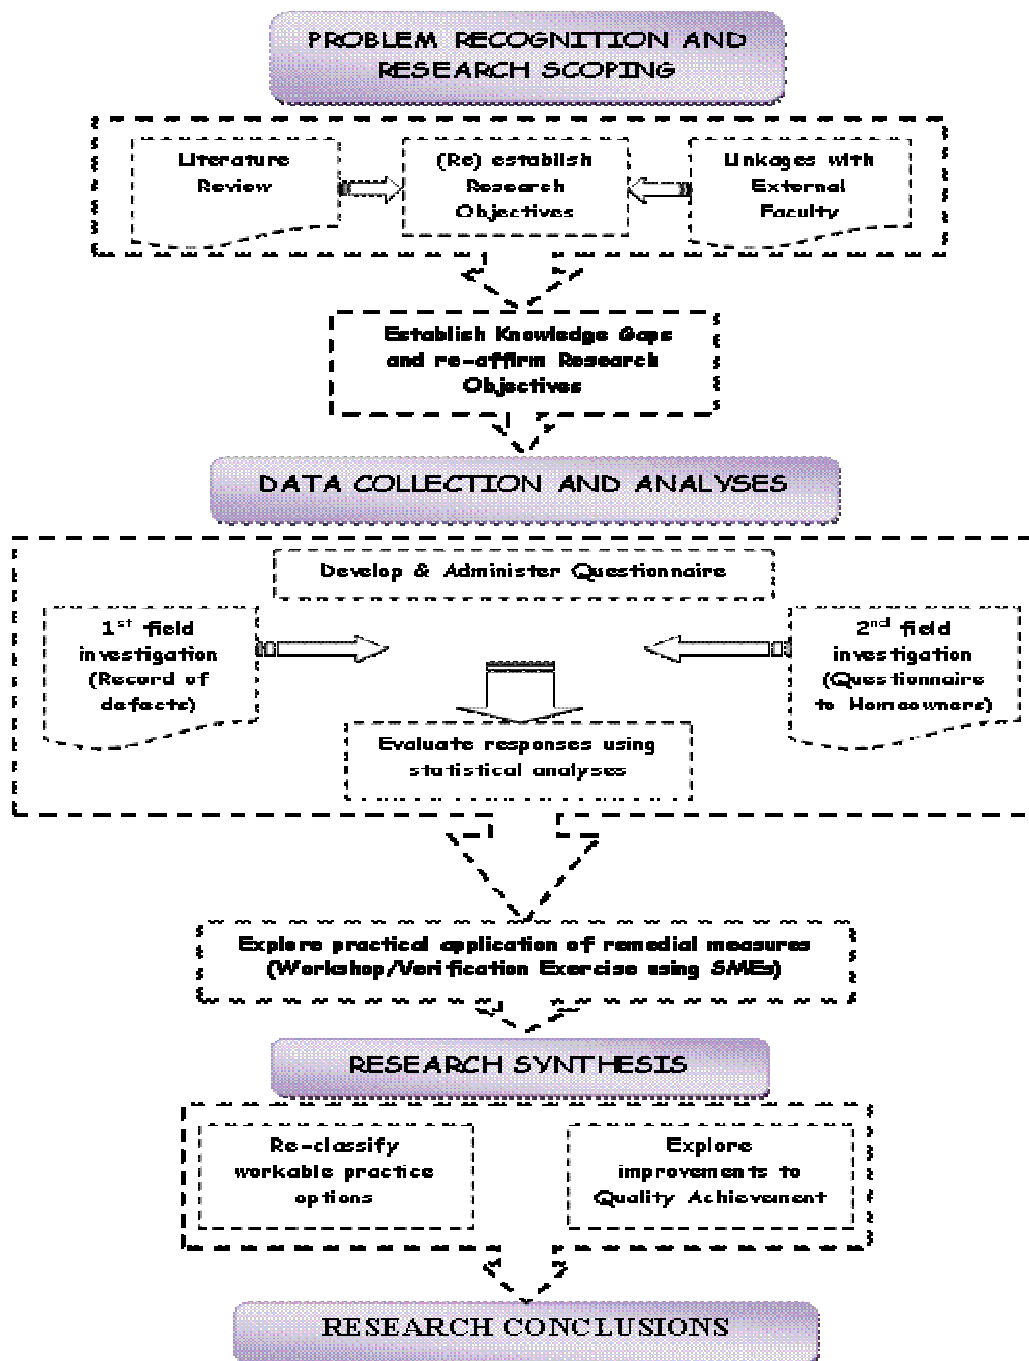

Figure 1 - The Research Framework

The second phase is the data collection and analyses phase. Two data collection tools will be developed, to collect information from two key research participants. The first set of information will be extracted from developers' and building inspectors' defects records, to capture the magnitude of defects in new residential buildings in New Zealand.

While the second set of information will be obtained through the administration of a semi-structured questionnaire to new homeowners. This will determine their satisfaction levels with their new homes and their experiences with quality performance by their developers. The survey will also determine the prospects for snagging new residential buildings for defects before or after handover. Data collected will be analysed using

simple statistical tools. A verification exercise involving subject matter experts will be conducted to validate the results from the analyses.

The third phase involves the synthesis of the research findings, re-classification of workable practice options that could improve quality achievement levels. While the last phase will conclude the research and give necessary suggestions for improving the house building process in New Zealand.

Given the nature of the current research problem and the different research methods available, it is appropriate to employ a mixed method approach. Mixed research method is chosen for the study because the research objectives and questions will benefit from a combination of different approaches for the purposes of triangulation, complementary, development, initiation and expansion. Methods to be used include content analyses, surveys, and interviews to establish the current quality performance in the residential building sector and to suggest improvements that will benefit every stakeholder in the house building sector in New Zealand. The chosen methods will utilise the strength of both the qualitative and quantitative research method. According to Amaratunga *et al.*, (2002) the combination of the strength and weaknesses of both the qualitative and quantitative research approaches can focus on the relevant strengths.

The analysis of the data will be via coded entry into SPSS and Excel as appropriate, and thereafter with its manipulation utilising ANOVA and correlation testing. The analysis would aim at determining the significance of snags; differences and correlates of information amongst research participants. It is fully expected that other highly useful measures of performance will emerge during this analysis phase, along with discontinuities and irregularities that will have to be addressed through other means. Simple interpretive and descriptive methods of presentation will be adopted so that the findings could be communicative and understandable to readers. McQueen and Knussen, (2002) explain that descriptive statistics are used to describe, illustrate and summarise information in three ways viz: forming numbers into tables, generating charts and diagrams from the numbers, and then calculating general statistics.

4 Potential Benefits of the research

At present insufficient data exists regarding current New Zealand quality performance in order to take forward the driving down of quality failures and defects rectification costs. The research will provide essential data for future industry improvement initiatives in reducing residential building defects at handover. This study contends that the snag reporting methodology would provide to companies participating in the research survey, and the building industry some significant benefits. The main likely benefits include:

Comparison and benchmarking of performance – improved snag reporting processes will allow more detailed assessment and auditing of quality achievement within the building industry. The result of those assessments will indicate high, medium and low performers and may provide a benchmark for good practice. It is anticipated that there will be substantial scope for international benchmarking of performance, since preliminary contacts have been made with organisations in the UK who have already undertaken this type of research and are willing to share data.

Improved image and reputation – the building industry is highly competitive and survival may be dependent on a good image of quality achievement by a firm. Quality

differentiates a firm from its competitors. It is not unlikely that long term players in the construction industry are those who have acquired a reputation for meeting their clients' needs for quality through consistently lowering numbers of snags. Companies developing their capabilities on the back of the data generated will be able to significantly increase their performance.

Improved service delivery – A quality conscious firm with reduced defects and less cost of rectification is likely to benefit from increased efficiency in its operations and ultimately the product/service that it delivers.

Growth in turnover – An expanding client base will follow from an increase in the satisfaction rate of clients. Turnover therefore increases and an organisation's financial profile is enhanced.

Increased profit margins - A good quality management system should reduce the 'cost of non-conformance' while the 'cost of conformance' stabilised or reduced in the long run.

Overall the research will benefit the wider construction industry through increased productivity coming from a reduced labour cost compared to the value of the constructed product.

5 Conclusions and Further Research

The pursuit of quality should be a never ending journey of continuous improvement. Improved quality management systems should help the constructor to look at the right ways of delivering buildings to facilitate doing the right things right, rather than simply doing things right. Doing the right things require a system that monitors the production process so that defective works are quickly identified and rectified. Presently snag reporting (building inspection) is mostly carried out for old and existing residential buildings, but little is being done in new builds in New Zealand. As a key objective of the research (reported in this paper), the magnitude of the defects at handover is investigated and the means by which snag reporting can be introduced within the house building production process will be identified.

It is hoped that by the completion of this research, mandatory building inspection will be incorporated into the house buying process in New Zealand. New homeowners can therefore fully utilise the 12 months defects warranty period proposed as an amendment to the Building Act 2004. Checking new builds for defects before or after handover would enable developers to rectify potential defects before they become burdens for homeowners. Homeowners want completed products that are defect-free and worth the utmost value for their investment. Builders should make these a performance criterion and should view the meeting of customer requirements a way of gaining competitive advantage in today's harsh market environment. Ultimately there would be increased confidence on developers by new homeowners on the quality of their new homes. If new builds are to stand the test of time, it is important that the production process do it once and do it right.

Property Law

A pub, a field and some signs – a case study on the pragmatics of proprietorship and legal cognition.

Luke Bennett

Department of the Built Environment,
Sheffield Hallam University
Sheffield,
S1 1WB

Email: l.e.bennett@shu.ac.uk

Abstract:

This paper uses a case study on the management of the grounds of a city-fringe pub to explore land and premises owners' perception of, and responses to, the legal requirements and risks of public access to their property. The paper examines how an *approximate* lay notion of occupiers' liability is acquired and used from an actor's 'internal point of view' (Hart 1994).

The study set out to empirically explore the suggestion (e.g. Jones 1984; Bennett & Crowe 2008) that landowners' expressions of concern about potential occupiers' liability for visitor injuries may function as a polite and acceptable proxy for a more visceral (and less publically expressible) sense of proprietorship but actually found something more prosaic. In the case study the 'liability risk' theme was invoked through copious cautionary signage by a premises manager who showed little overt anxiety about liability or safety and no strong proprietorial orientation towards his land.

To make sense of this conundrum the paper develops a theoretically informed interpretation of the case study which draws upon Bourdieu's notion of the guiding hand of 'habitus' (2005), Mutch's (2000, 2001 and 2003) and Pratten's (2007 a, b and c) work on the constancies and changes within UK pub management, Berger & Luckmann's (1971) concept of the 'sedimentation' of knowledge, Delaney's (2010) call for holistic, multi-disciplinary, 'nomospheric investigations' when studying spatio-legal behaviour, Sack's (1986) notion of the 'space clearing' function of territoriality and Altman's (1975) highlighting of the importance of express normative declarations for ambiguous 'secondary territories' that are neither wholly public nor private.

Through this synthesis insight is given into how a form of thinking and acting about law, liability and proprietorship can become embedded and replicated without needing at any stage a consciously developed self-understanding of that action. The paper considers the implications of this for land and premises management and the study of legal cognition within lay professional communities.

Keywords:

habitus, occupiers liability, land management, legal cognition, public houses

1 Introduction

This paper is a continuation of my recent research projects (Bennett, 2009, 2010, 2011, Bennett & Gibbeson, 2010) in which I have sought to examine the processes by which the abstract conceptual doctrines of the law are translated by lay communities such as cemetery managers or tree owners and applied into their day to day management of their physical environment. These studies have centred upon investigating the ‘common sense’ lay interpretation of the Occupiers Liability Acts 1957 and 1984 and specifically, how important that legal cognition actually is in land and premises management practice.

This journey started in the summer of 2008 when my colleague Lynne Crowe and I were commissioned by member agencies¹ of the Countryside Recreation Network² to conduct a scoping study to identify any existing research on the question of whether landowner anxieties about public liability towards recreational visitors affected the extent to which they allowed (or tried to curb) public access to their land. The study also involved 21 semi-structured interviews of predominantly public sector landowning bodies.

The literature review found only a few existing studies on this issue, and these mostly related to the North American experience (e.g. Teasley et al (1997), Gentle et al (1999), Wright et al (2002) and Henderson (2007)). Our interviews suggested that, for large pro-access public landowners at least, the risk of liability for any injuries sustained by recreational visitors was something viewed pragmatically, and to be taken ‘in their stride’ by those managers and their organisations. Our scoping study (Bennett & Crowe 2008) thus found no direct evidence of a withdrawal of access to private land as a result of fears of Britain’s so called “compensation culture” (Williams, 2005).

In our report we conjectured that the strength of, and effect of, such fear might be greater for smaller organisations, particularly those with no vested interest in facilitating access. We wondered whether away from the calming influence of the mutual support bodies like the Visitor Safety in the Countryside Group (VSCG, 2005) anxieties and misperceptions about the risk of liability for any eventualities that might afflict recreational visitors to their lands might have more power and effect.

This conjecture chimed with commentators who had previously noted that whenever changes are proposed to the legislative frameworks by which access rights are imposed upon property owners (most recently in England in the form of the coastal path right of access under the Marine and Coastal Access Act 2009) anxious landowners and their representative associations raise the spectre of civil liability towards injured recreational visitors as a key concern, and justification, for opposing the legislative change as presented to them. We found ourselves in agreement with Jones (1984), who, writing on the eve of implementation of the Occupiers Liability Act 1984³, surmised that:

“The refusal of access by country landowners probably has more to do with the depredations inflicted by the uncaring public, or an unbridled sense of proprietorship, than the fear of potential liability for accidental injuries” (726).

¹ The Forestry Commission, the Scottish Government, Sport Northern Ireland, and the Northern Ireland Environment Agency.

² <http://www.countrysiderecreation.org.uk/>

³ Which introduced a qualified duty of care to be owed to trespassers, in addition to the duty imposed by the 1957 Act for the protection of lawful visitors.

This paper reports on some of the further steps that I have taken to explore the relationship between landowners' perceptions of their duties and liabilities and their approach to public access to their land and premises. In doing so it will touch on the related themes of territoriality and proprietorship and delve deeper into the pragmatic and performative aspects of lay legal cognition. After briefly reviewing existing studies I will turn to consider a single-site case study warning signage at an urban-fringe pub. This empirical example raises some counter-intuitive questions (and possibly insights) into these processes.

2 Existing studies of occupiers' liability perception and exclusionary territoriality

The North American studies alluded to above (e.g. Teasley et al (1997), Gentle et al (1999), Wright et al (2002) and Henderson (2007)) centred their empirical enquiry around why, given that legislative concessions have already been made in order to insulate landowners against occupiers' liability for injuries sustained by recreational trespassers upon their land, landowners continue to express high levels of fear about potential liability. I do not have space to review this research in detail (see Bennett & Crowe 2008 for more), however Gentle et al's (1999) investigation of whether the different political and cultural heritage of various US States influenced landowners attitudes towards provision of access can help in summary. Gentle et al found no clear patterns other than a general finding that:

"Landowners are much more comfortable with the use of their land by friends and family, rather than by strangers." (Gentle et al 1999, 57)

and that a history of "unpleasant experiences with recreationists"(62), rather than socio-economic differences or differences between rural and urban fringe settings, were the most important influencing factor in landowners' decisions on whether or not to prohibit access to their land. Meanwhile Teasley et al (1997) found respondents giving a variety of reasons for prohibiting access to their land, many of which could be grouped under a collective heading of "keeping land private", with only 28% agreeing that their decision was in whole or in part "to protect me from lawsuits".

There has been little research in the UK upon the role of fear of liability in shaping landowners' attitudes to access and the ways in which they express their proprietorship. The limited UK research evidence found did suggest that fear of liability may be a much lesser influence than perceptions of privacy and control, for example a study of woodland owners' attitudes to access in the South East of England for the Forestry Commission (2005) found that one third of private non-forestry business owners felt that their woodlands were important for personal privacy, with over 75% of this group reporting a perceived "loss of control" if public access was allowed. These privacy and control issues (which I take to be the core of 'proprietorship') showed more strength of feeling than whether liability for visitors was perceived as a factor of significance. In this regard none of the respondents reported "insurance claims" as a "very severe" problem, with 77% of the respondents reporting "no problems" in relation to this factor.

Our 2008 study explored the apparent disconnect between a prevailing public discourse that claims landowners to be fearful of the alleged compensation culture and landowners failing individually to rate fear of liability as a significant influence upon their land

management practices in these studies. It appeared from the US studies that a more general anxiety related to proprietorship was being presented in public as a fear of liability, because that was a more publically acceptable discourse. Furthermore, we noted that the existing studies and anecdotal examples from access policy changes in the United Kingdom and New Zealand all suggest that expressed anxieties about landowner liability risk appear to amplify at times where the landowner community is experiencing the threat of change to access regimes (and/or other uncertainties).

Our study also highlighted the *approximateness* with which liability issues are perceived and invoked by landowners, and the ways in which other preoccupations and anxieties appeared to weave into their stances on access control. Understanding landowner liability perception therefore appears to require an understanding of this wider fear/anxiety and the circumstance specific nature of each landowner's understanding of, and response to, his legal obligations.

A number of commentators (for example Landry (2005), Bauman (2006), Philippopoulos-Mihalopoulos (2007)) point to the contemporary dominance of what might be called 'anticipatory fear' – a future focussed, risk assessment shaped, attempt to prescribe for the adversities of the (near) future. Commentators also note the ways in which such anxieties are (at least in part) constructed by those who suffer them (Wildavsky & Dake, 1990). For example, whilst a landowner may describe that which he fears as external to him and (and imposed upon him) there is a willed, selective, dimension, at least as regards the actor having decided either "*this is what I need to worry about*" or "*this is how I will explain my feeling of unease about public access*". In short, the likelihood is that if you get a landowner to think about access issues he will do so within a narrative framework that makes sense to him in terms of his wider anxieties and tends towards telling you what he thinks you want to hear.

Accordingly, it may be no surprise that respondents to a survey by the Country Landowners and Business Association (CLA, 2007) aimed at raising landowners' concerns about the feared impacts of the Marine and Coastal Access Act's coastal 'right to roam' paraded the following colourful illustrations of contemporary folk devils: feared liability for burglars, doggers (and also dog walkers), paedophiles, vandalism, unexploded bombs, errant golf balls and the perils of coastal erosion. This list of worries testifies to the diversity of rural (and coastal) landowners and the myriad ways in which anxiety about a change in access legislation may be expressed in, amongst other things, the language of safety and liability fears.

The majority of our 2008 interviewees were large, pro-access landowners. A minority of bodies representing small and/or private landowners were included. The respondents largely said (in effect) "*we're not worried about liability; we take it in our stride. We manage the risk*". They then volunteered the following suggestions on what might make smaller landowners more susceptible to liability fears and consequential access restricting behaviours:

- 1) **Isolation and fear of liability.** It was felt that the more a landowner was connected into a support network in which a 'reasonable' approach to the understanding of liability risk could be collectively set and defended, the less the level of anxiety likely to be stirred up by sensationalist sources (e.g. the general media and its 'compensation culture' focus);
- 2) **Marginal survival.** That liability anxieties might be expected to be at their greatest where the business was (due to other pressures) struggling to survive,

- and access would be seen as ‘something else to worry about’. In particular landowners with single site operations may be particularly vulnerable as they will not have the experience of adapting abstract legal requirements and applying them to the (inevitably) different physical circumstances;
- 3) **No gain from access.** That landowners with no direct (or indirect) benefit from the public and their access to their land might be less likely to feel comfortable;
 - 4) **Something valuable to protect.** That landowners would be more concerned about access control in situations where the land or premises comprises valuable assets which could be stolen or damaged by visitors; and
 - 5) **A prior history of bad experiences with public access.**

In the case study that follows I will refer to these collectively as ‘the Five Traits’.

Scholarship to date has observed a fairly rigid distinction between rural and urban investigations, with empirical studies of the control of recreational access to the countryside on the one hand and more theoretically inclined studies of urban enclosure processes on the other. In contrast to the land management focus of the countryside research, the urban studies have tended to focus either on “bunkerization” (Trigg 2008: 554) by homeowners or the grievances of those excluded from the land in question. The urban studies have not directly enquired into the legal cognition of non-residential landowners. Such studies have tended to focus on ‘gated’ residential communities and access control to shopping malls with these studies pointing towards that enclosure being driven by urban fears of crime and ‘others’ (see for example Low (2003), Sandercock (2005) Minton (2005; 2009) and Layard (2010)) rather than an owners’ fear of potential liability for the injury of members of the public who may access his land.

In reality much land lies between the extremes of rural idyll and dense city block. Indeed, as Farley and Symonds-Roberts (2011) note, the greatest level of contestation over day to day access to land may actually lie in the ambiguous “edgelands” – the car parks, urban-fringe fields and woodlands, wastelands and ruins at which neat and stable classification of such spaces as unquestionably ‘rural’ or ‘urban’ or exclusively ‘public’ or ‘private’ will often prove unworkable.

This paper therefore seeks to contribute towards breaking down this polarisation by studying a city-fringe premises, part of the grounds of a pub, as its case study point of focus and by drawing from both from the empirical tradition of the rural studies and the theoretical sophistication of the urban investigations in the following analysis.

3 Is there actually any story to uncover? – a case study

Our 2008 report recommended further research to specifically enquire into the ways in which individual landowners interpret occupiers’ liability law and apply that interpretation to their day to day management of their land. This work is ongoing, focussed around individual sites and their owners.

The remainder of this paper will present a case study of one urban/rural fringe plot of land and its owner. The case study appears to question the Five Traits conjectured above. Whilst this paper cannot postulate rules or generalisations from one case study, an attempt will be made to interpret (and theorise) the case study’s findings.

Looking back on our 2008 study I was conscious of the limitations of interviewing senior executives about their organisation's land management practice and decided that the follow-up work needed to be more 'micro' level and interpretive in its empirical focus. I need to understand how lay individuals come to understand the principles of occupiers' liability law and render them workable for themselves. In my view this (for present purposes at least) requires an open, exploratory research methodology, essentially a hermeneutic approach in which the researcher tries to see the world through the respondent's eyes, at least in so far as that is relevant to understanding how his perception of risks, liability and recreational visitors shapes his land management practices.

As part of my search for case studies in this vein I decided to approach and interview the owner-manager of an urban-fringe countryside pub which I have been aware of for eight years, and which during that time has passed through a number of different owners. This pub has a grassed area (which I will call "the Field"¹). It comprises a small wooden fenced plot bordering the pub car park. It is generally level and contains a couple of old but functional wooden picnic tables. There are no obvious hazards in the Field. Yet I have observed that over the years each successive owner has sought to discourage the pub's clientele from using this area. During this time I have noticed ever-more cautionary signage appearing on the fence and gate that demarks the boundary between the pub car park and the Field beyond (Figure 1).

Through my existing observational knowledge and face to face exploratory interview I hoped to explore with the current owner-manager (hereafter "the Landlord") why had he adopted the cautionary access strategy, his own understanding of occupiers' liability risks and what he based those views on.

¹ It was described by the Landlord as "the Paddock", although no horses have been there for at least 10 years.

Figure 25 - entrance to the field showing six cautionary signs affixed to fence and gate (April 2009)

Having regard to the ‘Five Traits’ I thought that the Landlord would be able to provide a conscious explanation of the signage – perhaps by recounting a previous accident in, or complaint about, the Field area which had set the whole process off. I also thought there might be some indication, in the Landlord’s account, of safety/liability fears presenting as a proxy for a deeper set of proprietorial concerns (e.g. privacy and/or fear of loss of ‘control’). I also anticipated that his approach towards the management of space at his pub would be consciously conditioned by external requirements derived from law (in particular premises licence, planning and insurance requirements).

4 So what was the story of the Field?

Well, there didn’t appear to be a clear cut story so far as the Landlord could account. Whilst he echoed contemporary ‘common sense’ discourse about the self perpetuating nature of safety regulation and by expressing the view that we live in an era of increasing (and spurious) compensation claims he did not appear fearful of any such claims. He had had no personal experience of such regulatory intervention or claims, and appeared confident in his ability to manage people and situations through his own ‘good host’ nature (rather than stating an affinity for forms, barriers or notices). Neither ‘insurer requirements’ nor even the requirements of his premises licence appeared to have much effect upon how he shaped his approach to management of the Field. The Landlord did not appear to be haunted by a fear of his patrons and what they might get up to around his pub. Indeed he appeared to have a particularly optimistic worldview, appraising the likely behaviour of those who may come into the vicinity of his pub by reference to his own behaviour and dispositions.

Figure 26 - customer's eye view of fence signage (April 2009)

Yet despite all of this the Field was plastered with cautionary signs and disclaimers and gave every appearance of it being a place into which the public was not invited (Figure 2) and the

Landlord's best account of his actions in 'closing' the Field was that the area was "untidy" and not somewhere that he would use himself at the moment. The signs were "just a risk assessment...just health warnings".

The following extract from my interview with the Landlord shows the inchoate nature of the Landlord's vague exclusionary territoriality over the Field. After describing the picnic tables in that area and its occasional use for themed events like Halloween and Bonfire night (the interview took place in February 2009), the interview continued thus (the numbers in brackets denote length of pause):

Interviewer so - you haven't got a problem with people going into that area?

Landlord well I do have, at the moment, because it's, erm (0.2), it's (0.1) it's not how I want it (0.2)

Interviewer in what sense?

Landlord it's a bit untidy...because it's overgrown (0.2) and there's like pieces of wood about and it's not really ideal for, especially from this, especially from this time since Bonfire night, in the Winter, it's not really - I probably wouldn't use it...

Interviewer so what about your signage up there, you've got quite a lot of signage up there?

Landlord yeah, it's just a risk assessment, it's just health warnings, 'cause I don't really want like (0.2) anyone on there really, 'cause it's not (0.3) it's not ideal, I don't think, at the moment, well it's untidy, and it's not really ideal, I don't feel (0.1) and I'd rather use that, as and when it's like (0.2) as everything's perfect (0.2).

5 Interpreting the story

It became clear in the interview that the Field is an area of the Landlord's pub that is not at the forefront of his mind or the forefront of his plans for his business. He would turn his attention to that area someday. Until then he'd written it off in his mind as "untidy" and not somewhere that he would want to go if he were visiting this pub as a customer. I felt that he regarded it as a "non-place" (Augé, 1996), in his mind, focussed as it is on building a viable business at this rather marginal location, it was (or at least he wanted it to be) 'out of mind', and because it was meaningless space to him he could not comprehend that anyone else might properly find that space desirable *at the moment*. Yet, for some unarticulated reason he felt compelled to reinforce the abandonment of that space by recourse to signifiers of risk and liability.

How can we account for this behaviour? If we reflect on the 'Five Traits' mapped out above the Landlord does not score particularly highly. The Landlord presented himself as a relatively laid back landowner, someone confident in his 'people skills' and steeped in the publican's service ethos. He had had no unpleasant experiences with public access in the past and the Field is of little current use to him (so his actions are not seemingly borne of a defensive urge). Yet, without conscious sense of exclusionary purpose, the Landlord has been routinely adding ever greater layers of cautionary signage to an unremarkable small grassed field.

I believe that the answer to this lies in the power of what had become *conventional* at this place. At a number of points in the interview the Landlord mentioned the inevitability and/or the business advantage of taking things on as they are - and not seeking to change everything from the start; for example:

"...Here you've got to be kid friendly where we are, in like the Tap Room you've got to be dog friendly: because **that's how it's always been**...so it's easy for me to come and say "I'm not having any dogs in there" - but it's not; **its part and parcel of this, the history of the pub I suppose**" (emphasis added)

This, in the spirit of Bourdieu (1987; 2005), suggests a form of *habitus*, an embedded physical manner of use of a place by its owner and its patrons which it is difficult - or unadvisable - to change. In business parlance this could be called 'goodwill', it is embedded history and knowledge that makes the place what it is. In that sense it is *cultural*, laying down a normative order to a place and encounters within it.

The story of the Field, such as there is one, may well be that the signified conditions of the Field (the signage and appearance of exclusion) have been inherited circumstantially from previous owners via the existing manner of physical arrangement of the property. There is no great thought behind it. It exists, remains and is added to because there has been no event or cause to alter that status quo or challenge its appropriateness.

At this pub this habitus appears primarily encoded and transmitted between successive owners through the physical arrangement of the place, for there was minimal induction of the Landlord by the previous owners on hand-over). The Landlord thus appears, via a process of “sedimentation” (Berger & Luckmann 1971, 85), to have added his extra layers of signage, recycling, repeating or adapting phrases inherited from his predecessors' notices (see Figures 3 & 4).

Figure 27 – Sept 2007 (before the Landlord's reign)

Figure 28 – Nov 2008 (during the Landlord's reign)

In this regard it is worth noting that the signs observed in 2007 (before the Landlord took over) are worded remarkably similarly to those installed in the era of the Landlord and furthermore that those signs, in 2011, still remain at the entry to the Field despite the departure of the Landlord and the arrival of yet another owner, who – presumably because he also has other more pressing things to think about – passively perpetuates the exclusionary effect of this accumulated layers of warning signage (Figure 5).

Figure 29 - May 2011 (after the Landlord has gone)

6 A pub's habitus; a publican's habitus

For Bourdieu habitus can reside in both places and people, and in both cases habitus is at least partially external to the local situation. Wider socio-economic (and other normative) influences will play their part in setting the *appropriate* dispositions for those people in that place.

If we return to the 'Five Traits' for a moment we can find in the socio-economic (and normative) context of the pub some potential pointers to factors that may have contributed towards this Landlord's dispositions regarding signage and the Field.

The recent history of the pub industry is one of rapid (and externally imposed) structural change as Mutch (2000, 2001 and 2003) and Pratten (2007a, b & c) show. In 1913 95% of licensed properties were brewery owned (Pratten 2007a, 336) but during the twentieth century this domination progressively declined. The process accelerated following a Monopoly & Mergers Commission investigation in 1989 (MMC 1989) that led to large brewers being forced to cease brewing or release from purchasing tie half of the pubs that they owned over a national allowance of 2,000 each by November 1992.

This wave of divestment prompted the creation of new, smaller pub portfolio owning groupings ('Pubcos'), many funded by investors from outside the brewing industry. As Pratten (2007c, 614) notes, since the early 1990s the pub sector has been subject to multiple waves of ownership change as banks, venture capitalists and entrepreneurs have regularly traded Pubco portfolios. The rising market share of supermarket alcohol sales and waves of legislative change such as the 2007 indoor smoking ban and the

liberalisation of the hours of pub opening over the last decade have also contributed to the atmosphere of constant change within the sector.

Set against this sea of externally imposed change publicans have struggled to keep their pubs open. The restructuring of the 1990s and first decade of the present century saw marginal pubs either close or float out into independent, owner-run, 'Free House' status¹.

We may conjecture that the co-ordination offered by an area and regional management structure for brewery owned or tied pubs may have operated in the past to reduce anxiety about liability risks within their outdoor zones and/or that, based on experience, publicans and their patrons did not need to be told what was and was not safe or acceptable use of the pub's environs. However due to the intercession of Pubcos and increased Free House ownership, owners and managers drawing from their prior experience outside the pub industry may have imported standards (or a sense of liability anxiety) characteristic of other industries, culminating in the installation of warning signs like those now visible at the case study pub and now embodied in this pub's ongoing habitus.

Mutch's work can also help us to think about the ways in which a *publican's* habitus is formed. Mutch's work confirms the Landlord's own biography and viewpoint – namely that publicans tend to come from publican families, they are likely to have little if any formal training for the job, some supervision may be exercised where the pub is owned by a brewery or similar but even in those parts of the trade the degree of directional supervision has been in decline. The modern way is to control (and incentivise) employed managers via their financial accountability rather than mandating controls over the spatial arrangement of the pub and its surroundings. Thus the trend has been towards leaving managers to make their own sense of what they must do to manage their pub.

However, the publican's freedom of action is tempered by the habitus of the pub itself. As Cavan (1966) and Pratten (2007 a) each show, a pub is a complex set of ordained spaces – often with distinct designated bar areas (the 'public bar', the 'tap room' and the 'lounge') each customarily assigned different decor, physical arrangement, customer expectations and behavioural norms. Add to that the temporal and activity-regulating aspects of the Licensing Acts and it becomes clear that running a pub is all about knowing how to respect and reproduce the 'expected' designation of times and spaces, and the control of activities and uses, within that place. Perhaps not surprisingly, the first place a new manager will look for guidance on what he must do, is the material culture and existing arrangement of the pub itself, as an embodiment of those normative codes and expectations.

So, in terms of the Five Traits, we find an industry sector built firmly upon habitus. An industry framed in unwritten tradition and an expectation of the publican 'learning on the job' yet now under siege from cumulative waves of recent externally imposed change and competition. Once understood in this light it will come as no surprise to reveal that the Landlord spent a lot of the interview alluding to difficulty he was facing in making his business venture a success. Talking about the Field, and asking him to account for how he was perceiving and managing liability risk for this 'non-place' must

¹ A 'Free House' is an establishment that is not 'tied' to a brewer and contractually obliged to purchase stock only from that sole brewer. The pub featured in this case study was, at the time of the interview, a 'Free House'.

have felt perplexing to him. Despite my dogged line of questioning the economic pressures and uncertainties continually interrupted during the interview. Within months of the interview the Landlord's venture was at an end, and the pub had new owners.

However, and in testament to the inertial power of the pub's habitus, this change of ownership wasn't easy to spot. The incoming owners made no changes to the physical arrangement of the place, the brasses, the games box, the tables, the ancient photos of the pub in times past, along with the Field's signage, all remained there, unaltered. In this pub, the owners come and go but the place, courtesy of its habitus, lives on unchanged.

7 What can this case study tell us about legal cognition?

Both the 2008 interviews and case study presented here were intended to illuminate the extent of (and techniques by which) landowners acquire and apply their lay understanding of occupiers' liability law. The outcome of these studies suggests that it would be dangerous to assume (as lawyers might well by training be tempted to do) that all landowners have a coherent understanding of occupiers' liability law and/or base their action upon it.

H.L.A. Hart (1994) sought to promote a 'sociological jurisprudence' which would pay serious attention to the effect of law as internalised by those subjected to it, an approach which sought an understanding of law's interpretation from the actor's internal point of view. This case study leaves me wondering whether Hart's rationalist view of the role of legal cognition in the shaping of lay pragmatic action in 'the real world' is too optimistic. For upon empirically enquiring into legal cognition and the law's subjectively received 'internal aspect' it becomes something rather nebulous, approximate and – to the lawyer's consternation – not as important as we like to think in the shaping of spatial activity.

As Andrews (2000) has noted (in relation to the ritual behaviours comprised in company directors' compliance with their disclosure duties under UK Company Law) what may actually be driving apparent compliance is a learned performativity, a ritualised behaviour, rather than an internalisation of the law itself. Thus just as company directors learn how to remember to fill in the appropriate forms, so landowners learn how to perform adherence to the conventional behaviours of territorial demarcation and risk management, but this is borne more of ritual than deep understanding of the law's conceptual doctrines.

Thus, when we look, we may find that law's concepts and symbols are deployed in day to day discourse in a distinctly approximate and incidental way. I find support for this viewpoint in two related strands of socio-legal scholarship.

First, the study of 'legal consciousness' in the work of Ewick & Sibley (1998) and Sibley (2005) which emphasises the dangers of assuming too close a correspondence between the law as extolled in juridical concepts and textbooks and the public appreciation of, adaptation to and application of, 'the law' in the everyday world. For them, law is an available schema, likely to be drawn upon pragmatically by citizens in order to make sense of their everyday lives, but it does not present a singular controlling code of living. Upon investigation law is commonly encountered as subordinate to other normative (and situational) influences shaping conduct.

Secondly, recent work within the ‘Law and Geography’ collaborative field, influenced as it is by the socio-spatial theorising of de Certeau (1988), Lefebvre (1991) and others, emphasises that ‘the legal’ and the spatial (and the socio-cultural milieu) are co-productive and that the focus of that production is pragmatic action. Thus territorial behaviour is a co-production of the actor’s engagement with (and constraint imposed upon him by):

- i) the physical reality of the specific space;
- ii) the habituated and/or expressly known legal and other normative structures available to govern that space; and
- iii) the purpose of that action – it’s circumstances and contingencies.

Delaney (2010) in support of this ‘intertwined’ reading of the production of places within human action, calls for “nomospheric investigations”(48) that strive to read the factors contributing to this co-production in a way that does not (through the conventions of rigid disciplinarity) privilege one contributory factor over any other. In short, the role of the law in this is important, but not omnipotent. It is in this spirit that I have sought to make sense of this case study. Hogg (2002, 34) encapsulates the required reorientation of the angle of analysis thus:

“if we were to take the spatiality of legal practices seriously ...we should cease to look upon law as a closed, formal and acontextual system and see it instead as an assemblage of heterogeneous elements, discursive, social and technical. These elements include distinctive physical structures, spatial arrangements and rituals as well as texts and rules.”

8 Why do the signs invoke the language of risk and danger?

This paper has sought to focus upon understanding the landowner’s role in restricting access, and the possible ways in which the discourse of liability, risk or danger may be being invoked as a publicly acceptable proxy for proprietorship. The case study has taken us away from that question and has suggested that, in this pub at least, neither fear of liability nor proprietorship are the main drivers of this behaviour. We can, though find some insight into the role of a risk and liability discourse within the chosen signage.

Scollon & Wong Scollon (2003) and Delaney (2005; 2010) both seek to show the indexicality of expressions of territoriality. Delaney (2005, 30) shows how a ‘no trespassing’ sign alludes to, draws upon, and “implicate[s] complex relations of power” in that the sign invokes the apparatus of legal rights to which the landowner may potentially have recourse (not necessarily cheaply or with certainty) in order to control access to that territory. Yet the widespread persistence across the UK of exclusionary signs incorrectly declaring that ‘*Trespassers will be prosecuted*’ (trespass is not generally a crime in the UK and thus is more commonly a civil wrong for which the transgressor might be sued in the civil courts, rather than prosecuted in the criminal courts) is testimony to the approximateness of that invocation of the formalities of the law. Such signs create (and defend) territory as much by their normative appeal to moral and habitual (i.e. learned) notions of public and private space than to those signs’ (correct or incorrect) appeals to the authority of the law.

Such signage (and the appearance of exclusionary intent) also has an inferential dimension for the public. For signage to work successfully as an access control the public in the vicinity of such land must choose to take the warning signs in a conventional way, and not put the landowner to proof of their legal efficacy. The sign's audience must have either a habituated pre-understanding of how it is appropriate to respond in the face of such signs or alternatively those signs must spell out the rules explicitly. Thus the habitus of pubs shapes the way in which these places, and encounters in and about them, are likely to play out. The signs will be noticed, but not normally read. In that sense it often doesn't matter what the signs actually say. Such notices are probably only attentively read by 'nomospheric technicians' (Delaney, 2010, 158) such as legal scholars with an over developed interest lay understanding of occupiers' liability law or claimant lawyers following an accident (Figure 6).

Figure 30 - How many customers would actually read this sign? (June 2008)

But why do the signs not simply say “keep out”?

Well, this may seem too brutal (or total) a prohibition given the ‘welcoming’ context that a pub will generally be expected to provide. Moore & Bottomley (2007) note the trend away from physical exclusion within city centre ‘privatised’ spaces, towards a more collaborative ‘governance’ based approach. Governance here is a term derived from Foucault (Lupton, 1999), which notes that the modern way of governing subjects is increasingly less achieved through barriers, official violence or even direct imposition of law, but rather relies upon processes by which subjects are conditioned to respond to

ever more subtle cues of control. The discourse of risk is a particularly ascendant ‘disciplining’ discourse (Landry, 2005). In short, using the language of risk and danger may be a particularly contemporary, polite and effective way to achieve access control.

The fundamental point with the Field is that the landlord cannot currently conceive of any *other* usage for that space. He would not want to go there (as a customer), he is not currently ‘providing’ that space (in the sense of offering it as part of his commercial realm). It is presently meaningless to him (but has the potential for meaning in the future). He needs to symbolically nullify it, to take it out of the picture and to deal with it ‘later’. Yet he expresses that in the ‘modern way’ via the language of risk allocation and the persistence of inappropriate or mutated signs, that testify to a general deterrence, rather than a specific warning / thing of danger or an outright foreclosure of this space.

This process reveals an aspect of territoriality that may not seem obvious – something that Sack (1986) describes as ‘space clearing’. Sack describes this form of territoriality in rather abstract terms, but with the case of the Field we can see that territory can be a willed nullity. The Landlord has no current use for the space. Perhaps he can see some potentiality in it, but for the time being it is surplus to requirements.

As Sack (1986) notes, territoriality may be a relatively cheap and effort free approach to managing a spatial problem (in this case a spatial surplus). It is easier to deter the public from an area by affixing a few mildly unwelcoming signs than spending the time to render it “tidy”. And to extend the analysis here, it is easier to for the Landlord to deter via a sign that invokes law, risk and danger (because people are more likely to take notice of that sign) than it would be to erect a sign that says (as might have been more accurate):

“Please don’t enter this area because I’ve not had chance yet to get it how I want it to be, and I’d prefer it if you would use and enjoy the other parts of the pub that I have spent time and effort getting to a state that I’m proud of and I want you to enjoy”.

Remember here that the Landlord appears not to have any particular danger in mind other than ‘untidyness’. For him (if conscious at all) the role of the signage is to help keep the Field off his list of things to worry about. It needs to be symbolically declared a ‘non-place’ *for the time being* whilst he focuses on trying to develop the pub’s core spatial zone (the pub’s bar rooms and its contiguous courtyard). The Field now lies beyond that spatially shrivelled core, it’s ageing picnic tables a legacy of a previous expansionist era at this pub, an era during which – these remnants would suggest - an unsuccessful attempt was made to commercially colonise this marginal zone.

Here we see the creation of *waste-land*, a process of neglect underscored by a low-thought, low-cost, low-effort technique for declaring it empty and (in a commercial sense) not currently part of the pub. Yet, all the Landlord has to do is declare it a temporary ‘Beer Garden’ on special occasions and it springs back into being as a willed part of the pub. Moore & Bottomley (2007) have noted the increasing blurring of any rigid distinction between ‘public’ and ‘private’ space – instead spaces become multifunctional. Thus the Field is neither ‘private’ nor ‘public’ in any static sense, instead it fluctuates and the borders that it sets up are porous because of the commercial imperative (and potential of the Field on occasion, and perhaps more so in some

indeterminate future) to be a space of commerce. In such situations the Field can become (both physically and symbolically) ‘opened for business’.

Altman (1975) defines such places as ‘secondary territories’, places characterised by the ambiguity of their access status, due to their being neither for all time nor in all circumstances unequivocally ‘private’ nor ‘public’ space. These are places into which the public may enter *sometimes*. The rules of *sometimes* are complex and may need spelling out in notices and declarations of express conditions of access if the habitus of the place does not create clear normative guidance. Yet, perhaps ironically (as we have seen) the signs themselves can – via sedimentation - subsequently become ‘locked’ within the pub and publican’s habitus, they become part of the ‘normality’ of the pub and its physical arrangement.

Significantly, at this place, the local habitus does not appear to provide a clear framework for the *removal* of this signage. Instead it is left to accrue and the visitor must make their own sense of these notices. Most will vaguely notice these ambiguous signs, but will not stop to read them. They will ascribe to them a general prohibitory intent and not venture into the Field. This seems to be consistent with what the Landlord wants – but (as we have seen) his sense of proprietorship over this area is currently weak and this space is controlled by circumstance, rather than by conscious direction on his part. There is no cynical exclusionary strategy here. Instead the process plays out by default. Here these signs themselves control space, control visitors and – in the sense of habitus explored above – also appear to exert some control over the successive owners of this place.

My best guess is that this process was set in hand a number of years ago under an earlier owner’s initiative. When I first became aware of the Field in 2002 there were vestiges of a rather rudimentary ‘adventure playground’ in the Field. The ‘take care for your children in this place’ trope may have been, at that time, specifically directed to then non-standard feature of this space (and reflect the anxiety and legal interventions around child safety in playgrounds that was at the fore in the late 1980s as chronicled by Ball (2002)). The sign shown in Figure 7 may therefore represent the ‘root’ meme (Dawkins 1989: 192) of this now rather self-perpetuating semiotic rash, for this (long broken) printed sign suggests a more specific and slightly institutional origin than the ‘home-made’ paper offspring now accompanying it.

Figure 7 - The root meme? (Nov 2008)

9 Conclusion

My experience of trying to interpret this case study has forced me to examine the limitations of a traditional ‘legalistic’ approach to investigating both proprietorship and legal cognition.

A visit to the pub would give the impression that the Field is a small area in comparison to the footprint occupied by the pub building and its courtyard. But in preparing this paper (and trying to find out what had happened to the Landlord) I obtained a copy of the title plan from the Land Registry and was surprised to see that the Field is almost exactly the same size as the pub and its courtyard. As Korzybski (1933: 58) has noted in a different context: “The map is not the territory” but it does usually capture at least part of its essence. The title plan shows that both areas are held under the same registered land title, and subject to the same covenants. Yet for the Landlord one part of the title (the pub building) is the anxious commercial focus of his working life whilst the other (the Field) is a surplus, ‘non-place’ barely noticed by him. A conveyancer reading these title documents would get no sense of the differential level of dwelling with which these two parcels are currently invested. The symbolic manipulations of the Field and its flip flop in and out of an actively possessed and enjoyed state registers little, if at all, at this formal level of title.

Yes, physical possession via occupancy and use is an important feature of proving and sustaining ownership, but as Gray and Francis-Gray (1998) and Grear (2003) note, the notion of ownership at common law is conceptually muddled and the legal rules of possession would pay little heed to the subtle totems of nullification and non-place

making identified in this case study. For these are matters of something non-legal: differential degrees of dwelling (in the sense of a space being loved and thought about, or not).

To understand proprietorship – and its effect upon access control - we have to take a more holistic approach and follow Delaney (2010), Hogg's (2002) and Trigg's (2005) exhortations, and move away from interpreting land use solely through the disciplinary gazes of either law or spatiality, because focus on only one dimension will miss some of the story. Instead, Delaney recommends a holistic scholarship that should seek to study how:

“...nomic traces are provisionally inscribed and anchored to segments of the world. Participants in social situations, whether routine or extraordinary, avail themselves of such traces as they see pragmatically relevant to the tasks at hand (the right to exclude *in order to...* the right not to be excluded *in order to ...*). Traces such as rules or rights are not simply free-floating bits of discourse. They are spatialized signifiers that may be deployed as reasons or justifications for acting this way or that, one way or another.” (Delaney 2010: 60 – emphasis in original)

The accumulated signs at the perimeter of the Field are such “nomic traces” (Figure 8). In part they perpetuate because of the inertial effect of the pub's habitus and the dispositions that that engenders in successive publicans (and patrons) who come to the site (and this may be amplified by structural adversity such as recent history of the pub industry). On occasion they are the results of actively willed behaviour, whether deployed pragmatically towards specific ends by the landowner (e.g. declaration of Beer Garden events) or are imposed by some external event or requirement (e.g. playground safety standards or the indoor smoking ban).

But in all of these circumstances the shaping influence of the law is enacted (it is performed by a succession of owners and their respective patrons) via approximate and intertwined notions of law and liability, territoriality, proprietorship, embodied custom (i.e. habitus of the place, its owner and patrons) and feelings and dispositions about a place. This is a complex cocktail that requires us as lawyers¹ to step into a wider frame of analysis if we are to understand lay perception (and pragmatic use of) the law and the contribution of the law in shaping how premises are used and managed.

Clearly, a single case study cannot prove or disprove that a conscious anxiety about liability haunts other landowners, or that such behaviour is really a mask for a rawer sense of proprietorship, but it is hoped that the analysis set out in this paper offers some pointers to techniques, levels of analysis and disciplines to be engaged in the pursuit of this question.

¹ Similarly (and following Delaney 2010) the geographer (or other social scientist) reader should equally take heed not to ignore the important constitutive role of the law in the construction of the pub, the publican and his patrons via matters of title, leasehold and planning obligations, premises licences, brewery ties, anti-monopolistic restructuring, public health controls, fire ordinances, occupiers' liability, insurer requirements and employment legislation to name but a few.

Figure 8 – Decaying signs left as nomic traces, legacies of prior action yet still operative (May 2011)

Email: Divya.Suwasini@gmail.com; Shreyabose15@gmail.com

Abstract:

The right to property has often been derided as the "least defensible" right in a socialist democracy. It is very absorbing to note that Right to Property has induced the most number of amendments to Indian Constitution and has formed the core from which some commendable and historic decisions have emerged from the Indian judiciary. It delves into the intricacies of the transition of "the right to property" from a "fundamental right" to a "legal right". The research shall be grounded in numerous cause célèbre; landmark decisions as well as large number of amendments shall also be analyzed. The researchers would strive to critically examine the development and interplay between important articles like 14, which states the rule of equality before the law and other important articles such as 19(1) (f), 31 and 300, which are critical to the debate on property rights in India. The study highlights the importance of property rights in a person's life as well as the extreme and innovative means he/she could come up with to defend it. The second part of the paper discusses the social restrictions placed on the right in the form of Land Acquisition Act and its controversial provision dealing with "public purpose". In conclusion, the researchers suggest mechanisms to counter the gross violation of fundamental rights in this field of property rights by analyzing different bills.

Keywords:

constitutional aspect; Indian perspective; Right to Property.

1 Introduction

"One will excuse the murderer of his own father but not the person who will take away his property" said the great Machiavelli. These words best describe the poignant state of affairs of landless masses of the nation. 'Property rights' expose the bedrock of Indian socialism propounded by the great Jawaharlal Nehru, the first Prime Minister of the nation. The conflicting views of the legislature and the judiciary over this subject led to the experience of judicial review during the last fifty years and the vicissitudes of judicial activism in the realm of property. The colonial Land Acquisition Act, 1894 (hereinafter referred to as 'the Act'), a legal instrument devised to acquire land, stipulated only monetary compensation at market rate¹, ignoring local self-governments, communal property rights and the environment. It allowed the government to forcibly acquire land from private landholders for projects of 'public purposes'².

¹ Land Acquisition Act 1894, s 23

² Land Acquisition Act 1894, s 3(f)

This paper delves into the transition of the status of right to property from that of a 'fundamental' right guaranteed by the state to its citizen, to that of a 'statutory' right where land could not be acquired save by authority of law. It traces such transition and its outcome which led to the 'tragedy of commons'¹ in the form of mass displacement of the poor and illiterate under the garb of acquisition of land for the purposes of 'development'. The unique economic policy of liberalization caused a furor as the government permitted acquisition of land based on the archaic Act. The Amendment Bill² proposed by the government contains the skewed 70:30³ ratio of acquisition. It shall persist to aggravate the poor living conditions of the hapless farmers and landless laborers as the government shall continue to 'grab' their land for industrial purposes. The existing Act has witnessed maximum litigation by the poor asserting their right to property and demanding the restoration of the original status of the right to property. Needless to say, those evicted were deprived of their basic human right and social security.

2 Tracing the historical background of Land Rights in India

2.1 Pre-Constitutional Position

The Constitution of India derived its foundation largely from Section 299 of the Government of India Act, 1935. It secured the right to property and contained safeguards against expropriation without compensation and against acquisition for a non-public purpose. In "Constituent Assembly of India, Constitutional precedents (Third Series)" (1947), it is stated, "Broadly speaking, the rights declared in the Constitutions relate to equality before the law, freedom of speech, freedom of religion, freedom of assembly, freedom of association, security of person and security of property. Within limits these are all well recognized rights."

2.2 Post- Constitutional Developments

A scrutiny of the relevant provisions of the Indian Constitution as they stood on January 26, 1950 is necessary for a holistic understanding of the developments to this controversial right. They are Articles 14, 19(1)(f), 19(5), 31, 32, 39(b) and (c), 226 and 265. The gist of the said provisions may be briefly stated thus: *Every citizen has the individual right to acquire, to hold and dispose of property. A duty is implicit in this right, namely that it should be so reasonably exercised as not to interfere with similar rights of other citizens. The exercise of it, therefore, should be reasonable and in accordance with public interest.*⁴ The Directive Principles of State Policy⁵ laid down the relevant principles through which the State was directed to secure the ownership and control of the material resources of the community for the common good. It also specified that the operation of the economic system should not result in the concentration of wealth and means of production to the common detriment.

< www.ccsindia.org/interns2002/25.pdf > accessed 30 May 2011

⁵ The Constitution of India 1950, Part IV

The conflict between the citizen's right and the State's power to implement the said principles were reconciled by putting limitations both on the right and the power. The said fundamental right was not absolute.¹ It was subject to the law of reasonable restrictions in the interest of the general public. The State's power was also subject to the condition that the law made by it in so far as it infringed the said fundamental right should stand the double test of reasonableness and public interest. Thus, it vested in the State the power to acquire the land of a citizen for a public purpose after paying compensation along with the power to impose taxation on a person for his property. We rejected the Russian theory of Socialism² but accepted the doctrine of individual right to property subject to the laws of social control. These laws of social control were restrictions imposed on the absolute "right to property" of individuals. The Government implemented these laws through the Land Acquisition Act, when dealing with cases of public purpose. The right to property was conditioned by the social responsibility. The higher judiciary was made the arbiter to maintain the just balance between private rights and public interests. After the Constitution of India came into force, the following agrarian reforms³ were introduced as follows:

- (1) *Intermediaries were abolished*
- (2) *Ceiling was fixed on land holdings*
- (3) *The cultivating tenant within the ceiling secured permanent rights*
- (4) *In some states, the share of the landlord was regulated by the law*
- (5) *In one state, the tiller of the soil secured cultivating rights against the absentee landlord, and in some states, the rural economy was re-adjusted in such a way, that the scattered bits of land of each tenant were consolidated in one place by a process of statutory exchange.*

Thus, these reforms implemented the Directive Principles of State Policy and socialist Nehru enacted the aforementioned ceiling legislations to confiscate lands following the socialists' objective to attain economic equality by robbing Peter to pay Paul.

2.3 Judiciary v. Legislature: The Trouble Begins

Parliament and the Supreme Court clashed on their interpretations of the provisions on the right to property. Although the Constituent Assembly had taken utmost care to avoid judicial interference in the program of economic reforms to which the Congress Party had been committed since the days of the National Movement, the courts did hold the laws authorizing changes in property relations unconstitutional. The First Amendment Act, 1951 introduced Article 31-A and Article 31-B which spawned the saga of legislative manipulation of right to property. Article 31-A defined "Estate" and continued by further amendments to extend its meaning so as to include practically the entire agricultural land in the rural area including waste lands, forest lands, lands for pasture or sites of buildings. Under the said amendment, no law providing for acquisition by the state of an estate so defined or any rights therein of the extinguishment or modification of such rights could be questioned on the ground that it

accessed 31 May 2011

was inconsistent with or took away or abridged the right to equality contained in article 14, right to various freedoms contained in article 19, and the right to property contained in article 31¹.

The subsequent amendments introducing Article 31-B and the Ninth Schedule were an attempt to usurp the judicial power. It was an innovation introduced in the Indian Constitution which was unheard of in any other part of the democratic world. The legislature made void laws offending fundamental rights and included it in the Ninth Schedule, which were later extended from time to time as per the whims and fancies of the ruling political party. Article 31-B declared that none of the acts or regulations specified in either the Schedule or any of the provisions thereof shall be deemed to be void on the ground that they are inconsistent with Part III, notwithstanding any judgment, decree or order of any court or tribunal to the contrary. A further amendment disclosed a cynical attitude towards the rule of law and autocratic power of legislature was thus sustained by democratic processes. The amendments in the realm of property substituted the Constitutional ideology with totalitarian ideology. This totalitarian ideology was articulated by the deliberate use of amendments to add more and more laws to the Ninth Schedule. Originally 64 laws were added to the Ninth Schedule and more acts were added by the 4th, 17th and 29th Amendment Act; the 34th Amendment added 17 more Acts. The 66th Amendment added 55 Acts raising the total number of laws excluded from the purview of judicial review to 257. The 76th Amendment Act, 1994 added the Tamil Nadu Act² providing for 69 percent reservation for backward classes under the Ninth Schedule. This was a clear misuse of the Ninth Schedule for political gains as the object of the Ninth Schedule of the Constitution was to protect only land reform laws from being challenged in court.³

The Supreme Court held in a series of decisions viz. *State of West Bengal v Mrs. Bella Banerjee*⁴, *W.B v Subodh Gopal*⁵ and *State of Madras v Namasivaya Muralidar*⁶ that Article 31, clauses (1) and (2) provided for the doctrine of eminent domain⁷ and under clause (2) a person must be deemed to be deprived of his property if he was “substantially dispossessed” or his right to use and enjoy the property was “seriously impaired” by the impugned law. According to this interpretation, the two clauses of Article 31 dealt only with acquisition of property in the sense explained by the court, and that under Article 31(1) the state could not make a law depriving a person of his property without complying with the provisions of Article 31(2).

It was the decision in the *Bella Banerjee* case which induced the government to resort to the Fourth Amendment. In this landmark case the Apex Court insisted on payment of compensation in every case of compulsory deprivation of property by the state. It was held that clause (1) and (2) of Article 31 dealt with the same subject of deprivation of private property. Further the court held that the word “compensation” meant “just compensation” i.e. just equivalent of “what the owner had been deprived of.”⁸

Such form of judicial activism was met with attempts to curb the power of the courts as well as access to them.¹ Various indirect methods, adopted by the legislature to discipline the judiciary included the supersession of judges² and the transfer of inconvenient judges³.

2.3.1 *The 'Locus Classicus' that saved the Constitution but murdered the right to property*

*Keshavananda Bharti v State of Kerala*⁴ has been a milestone in the history of Indian legal jurisprudence. The judgment was handed down by a panel of thirteen judges, the largest panel created for any judicial hearing in India. This cause célèbre had the petitioners challenge the validity of Kerala Land Reforms Act 1963 during the pendency of which the impugned Act was amended in 1971 and placed under the Ninth Schedule by the 29th Amendment Act. The question that arose was the extent of the amending power conferred by Article 368 of the Constitution.⁵ The Government of India claimed that it had the right as a matter of law to change or destroy the entire fabric of the Constitution through the instrumentality of Parliament's amending powers. Ironically, seventy years earlier, Hitler had asserted and exercised such a right by invoking the amending power of the German legislature, and there were no judicial pronouncement to restrain that dictator. Such was the emotive power of this case that the judgment witnessed the retirement of six senior judges of the Supreme Court (Chief Justice S M Sikri, a day after the judgment was delivered; Justices J M Shelat, K S Hegde and A N Grover who were superseded to the office of the Chief Justice of India for choosing to abide by their conscience and Justices P Jaganmohan Reddy and A K Mukherjea) who had held as follows:

Firstly, the Parliament's amending power was limited. While Parliament was entitled to abridge any fundamental right or amend any provision of the Constitution, the amending power did not extend to damaging or destroying any of the essential features of the Constitution. The fundamental rights are among the essential features of the Constitution. Therefore, while they may be abridged, the abridgment cannot extend to the point of damage to or destruction of their core. *Secondly*, article 31C was void since it took away invaluable fundamental rights, even those unrelated with property.

Whereas Justices A N Ray, D G Palekar, K K Mathew, M H Beg, S N Dwivedi and Y V Chandrachud held the power of the Parliament to amend to be unlimited and article 31C to be valid. Out of the thirteen judges six decided the case in favor of the citizen and the other six in favor of the state. Justice H R Khanna did not completely agree with any of these twelve judges and held that (a) the power of amendment is limited; it did not enable Parliament to alter the basic structure of the Constitution⁶; (b) the substantive provision of Article 31C, which abrogated the fundamental rights, was valid on the ground that it did not alter the basic structure of the Constitution; and (c) the latter part of Article 31C, which ousted the jurisdiction of the Court, was void. He went a part of

accessed 31 May 2011

the way along with judgment in favor of citizens and thus this constituted the majority view of the Supreme Court. It became law of the land.

Khanna J, spelt catastrophe to 19(1) (f), when he held that Right to Property could not be a part of the basic structure of the Constitution. Thus, this demonstrated to the people of India that their Parliament was in reality *property friendly* and not *people friendly*¹.

2.3.2 *The Forty-fourth Amendment Act, 1979: the final blow*

The Janata Party which attained majority at the Centre sought to remove the contentious property rights by introducing this act. The Forty-Fourth Amendment Act removed the right to property from the Part III (Chapter on “Fundamental Rights”) by deleting Articles 19(1) (f) and Article 31² along with subsequent amendments, and inserted in Part XII the following new chapter: “Chapter IV (Right to Property), Article 300A which stated: “Persons not to be deprived of property save by authority of law—no person shall be deprived of his property save by authority of law.” It is pertinent to note the contents of the aforementioned amendment:

3. *“In view of the special position sought to be given to fundamental rights, the right to property, which has been the occasion for more than one Amendment of the Constitution, would cease to be a fundamental right and become only a legal right. Necessary amendments for this purpose are being made to Article 19 and Article 31 is being deleted. It would however be ensured that the removal of property from the list of fundamental rights would not affect the rights of the minorities to establish and administer educational institutions of their choice.*

4. *Similarly, the right of persons holding land for personal cultivation and within ceiling limit to receive market compensation at the market value will not be affected.*

5. *Property, while ceasing to be a fundamental right, would, however, be given express recognition as a legal right, provisions being made that no person shall be deprived of his property save in accordance with law.”*³ This controversial amendment witnessed the ‘right to property’ being asserted not by the rich but by the poor. Now it is being asserted by the evictees whose lands have been acquired by the State in the garb of ‘development’ by using the archaic Land Acquisition Act, 1894.

3 Land Acquisition, the law of social control

Land acquisition, the core of politics of property in India is the process by which government expropriates private property for public purpose, different from just market purchase of land.⁴ The discretion of the state to forcibly acquire land is expressed as “eminent domain”⁵. Conventionally it denoted that the state was permitted to use the property of the citizens only in cases of extreme necessity and in furtherance of public utility. Thus, legitimizing sovereign intervention in relation to private rights, this principle evolved into Article 39 of the Constitution, in the Directive Principles of State

⁵ Supra Note 20

Policy, commanding the state to direct its policy towards securing ownership and control of the material resources of the community keeping in mind that distribution which best sub-serves the common good. Land Acquisition in India comprises three crucial features that allow the government to legitimately steal land from the poverty-stricken farmers. Firstly, the farmers that are forcibly evicted have no title over their land, secondly a feeling of insecurity permeates into the lower strata and finally the amount paid as compensation is meager and arbitrary.

3.1 Land Acquisition Act, 1894

The archaic Land Acquisition Act 1894, formulated in the British era, was meant to further their colonial commercial interests.¹ The primary complaint of the civil society against this legislation was that it allowed arbitrary acquisition in the name of ‘public purpose’ without clearly defining it, thus augmenting the scope of its misuse. The ambiguity of the phrase attracted political discord and litigation. The Supreme Court recently held that “*Public purpose is bound to vary with times and prevailing conditions in the community or locality and, therefore, the legislature has left it to the state (government) to decide what is public purpose and also to declare the need of a given land for the purpose. The legislature has left the discretion to the government regarding public purpose. The government has sole and absolute discretion in the matter.*”²

The negative impact of such discretion can be exemplified by the ‘Tata Motor-Singur’ controversy. The Supreme Court had earlier admitted that the expression ‘public purpose’ was incapable of having a precise definition and had no rigid meaning³ as the issue underlying each case was whether the acquisition was in the general interest of the community as distinguished from the private interest of the individual. As per the Apex Courts judgment in *Babu Barkya v State of Bombay*⁴, public purpose is any purpose in which “*even a fraction of the community may be interested or by which it may be benefited.*” Yet, in *Satya Narain v District Engineer*⁵ it was elucidated that a pure business undertaking though run by the government cannot be classified as public service.⁶ If the activity entailed the possibility of being carried on by a private individual, then it would not qualify to be termed as ‘public purpose’. However some of the common grounds considered as ‘public purpose’ are the provision of land for planned development from public funds in pursuance of any scheme of the government, provision of land for a corporation owned and controlled by the state and provision of land for any other scheme of development sponsored by the government, or with the prior approval of the appropriate government, by the local authority.⁷

Initially the concerns were raised over the fact that citizens could not question the purpose of acquisition, only the compensation and the route taken to compute the market value fixed for the land. However, with time, increasing governmental interference and subjective compensation became the chief worry. Similarly in the

⁷ Land Acquisition Act, 1894, s 3(d)

instances of Special Economic Zones¹ land had been usurped from property owners, using the Act, at prices lower than the alleged market value of the properties. This had snowballed into local protest movements against the State Governments. It was also argued that, even in the case of projects which were undertaken genuinely for public purposes, there was a considerable difference between the market value of the property and the value which the land acquisition officer ultimately paid the land owners.

Unfortunately projects for construction of golf courses and commercial complexes had also been termed as public purpose'.² The exasperating issue continues to be the extent to which the government shall continue to stoop in order to fulfill the objective of industrialization masked behind altruistic development policies? The case in example is the 'Tata Nano-Singur' project³, a prominent controversy that garnered international media attention, when Tata Motors decided to construct a factory manufacturing \$2,500 car at Singur. The Communist Party of India-Marxist ruled State Government of West Bengal used the doctrine of eminent domain to capture 997 acres of fertile farmland.⁴ The justification offered by the government for acting as brokers for private companies was that West Bengal being an industrial graveyard, a morass of economic stagnation, needed fresh investment to revive its economic solidity. They conceived it as an immediate fulfillment of the electoral promises and an initiation towards an escalation in industrial growth rate. However the site allotted was the most fertile and agriculturally productive areas of West Bengal.⁵ Thus law as a tool of legitimized oppression provided the state to take over land for public purposes in the guise of developing private businesses. Even though the Kolkata High Court declared the acquisition prima facie legal, it conceded to the illegality of purpose behind this acquisition. The land earmarked was fenced off by the state administration to prevent protestors from entering and the large contingents of policemen guarding the site were accused of raping and pillaging the villagers, burning them to death. Further the landless labourers and farmers were given inadequate compensation, evicted, and the housing facilities offered were delayed. The population of the subjugated was approximately 15,000 while only jobs for 1000 would be created, most expected to go to outsiders.⁶ The suspicious behavior of the State Government came under scanner when the Chief Minister furnished false information in the Legislative assembly. The concessions given to Tata Motors were not publicly revealed, while false claims of land being acquired through voluntary consent of the owners without the use of force were made.

3.2 Land Acquisition Bill – Boon or Bane?

The Land Acquisition (Amendment) 2007 Bill, along with Rehabilitation and Resettlement Bill, 2007 was designed to address compensation and resettlement of the displaced persons and all such concerns associated with land acquisition. Superficially,

the Bills seem to be advantageous, *but on further examination* the numerous fallacies and uncertain provisions in the Bills that needed to be rectified are identified.

In the case of the Land Acquisition Amendment Bill, the erasure of all references to companies creates a false impression that any acquisition by the state for private parties is being abolished. The original Act is worded “*for a public purpose or for a company*”; the new bill has omitted the words “*or for a company*” from the long title as well as the preamble of the act but the definition of “*public purpose*” itself has been changed to include an (ancillary) acquisition for “*a person (including a company, association of persons incorporated or not)*”.¹ Thus making the modification seem insincere as the rationale behind it was to make the law more public oriented.² If a private party purchases 70 per cent of the required land through negotiation, the balance 30 per cent can still be acquired by the government from unwilling owners, for that party. This implies a sovereign compulsion being enacted on those not inclined to sell their land, and consequently the show of state sponsorship for industrial houses can be maintained.³ This is definitely an improvement from the current legal provision, wherein 100 percent of the land required for a private project can be acquired by the State. Critics of the Bill like Mamata Bannerjee (“TMC”), an ally of the ruling party and Rashtriya Lok Dal leader Ajit Singh, have emphasized that allowing the government to acquire 10-15 percent of the required land after the rest had been brought through free market ought to serve the purpose.⁴ Nevertheless the definition has been widened to include projects for defense purposes and infrastructure.⁵ However, it does not provide any provision that ensures that rural communities are not taken advantage of by corporate bodies in unequal negotiations. It contains a provision for compensation if the land is acquired under urgency without defining the term ‘urgency’.⁶ The proposed Land Acquisition Compensation Dispute Settlement Authority dealing with compensation issues is a reasonable solution yet maybe not at the cost of a bar on the jurisdiction of the civil courts in these matters.

The objective of the Rehabilitation Bill is to prevent or minimize forced displacement of people by promoting non-displacing or least displacing alternatives. The provision for a Social Impact Assessment (“SIA”) seems acceptable, but the calculated impacts have been narrowed down to physical assets like buildings, temples, institutions, etc only. Whereas, social impacts like identity loss; the disappearance of a lifestyle; the breakdown of communities have been ignored. The SIA planned to be reviewed by an independent multi-disciplinary expert body, must also be prepared by a similar body.⁷

To avoid its misuse cases of displacement of people must get clearance from an independent statutory authority and not from the bureaucracy. The clearance must be conditional and revocable in the event of non-compliance or lapses. The perturbing issue remains that implementation of terms like ‘minimum displacement’ and ‘non-displacing alternative’ are entrusted to the bureaucracy and are to be used only as a last option.¹ On reviewing these bills, it can be safely said that opposition to the bills is warranted and that continues to be the rationale for it not emerging into a reality.

3.3 Arbitrary Compensation

Arbitrary compensation has been a cause of much grief and the motive behind local protests. The judiciary has more often than not, locked horns with the government over this issue. The first instance² of challenge was seen in 1951, when the Patna High Court upheld the objection that the differential rates of compensation provided under the land reform legislation, whereby the rates of compensation tapered down as the value of the land went up, were discriminatory. The judiciary extended the definition of amount of compensation to that equivalent to market value of such property, as provided in the Act.³ Even when the property was not vested in the state but was merely regulated or its use restricted, thereby depriving the owner of full enjoyment of his property, adequate compensation was to be paid.⁴ While in England, it was held that private property could not be acquired without compensation⁵, the same principle was reiterated in India.⁶ According to the much critiqued Act, Section 23 emphasizes that the market value of the property must be considered while determining compensation. Section 34 of the Act ensures an interest of 9% per annum if the compensation is not paid before or on possession of land. The interest is calculated from the date of possession till the compensation is paid. If the delay exceeds a year then an interest rate of 15% per annum will be calculated payable from the date of expiry of one year on the amount of compensation or part thereof which is due. It is unfortunate that even with the affirmation of the letter of law and the overt favor by the judiciary, the government and local authorities have managed to deny men their rights of adequate compensation, thus grossly violating basic rights of life, dignity and livelihood of people.

4 Conclusion

Rajiv Kumar, the current Secretary General of Federation of Indian Chambers of Commerce and Industry (“FICCI”) observed that, “*Politics on Land Acquisition*

¹ Supra Note 52

² Supra Note 13

³ State of West Bengal v Bella Bannerji AIR [1954] SCC 170

⁴ State of West Bengal v Subodh Gopal AIR [1954] SC 92

⁶ R.C .Cooper v. India, AIR [1970] SC 564

amendment may affect the development of the country.”¹ A more accurate statement cannot be made.

To escape the clutches of greed, corruption and blatant disobedience of rules, certain alternatives suggested can be experimented with. *Firstly*, the issue should be discussed with the different sections of society, especially those affected. An Ombudsman, as was provided in the Rehabilitation and Resettlement Bill, 2007² is a good option. However the term “grievance” that has been narrowly defined to encompass those that are not being offered the benefits, should be widened to include various other factors. For instance non-participatory project decisions taken, failures of consultation, non-compliance with the minimum displacement condition, non-inclusion of a person affected in the ‘affected’ category, etc. Hence, effective appointment of Ombudsman and its functionalities must be prescribed in both the bills.

Another sound proposal that had been made in the Land Acquisition (Amendment) Bill, 2007 was the provision for the state government to offer sellers a compensation package in two parts: a minimum lump sum amount related to the recent average market value of the agricultural land and an annuity or a monthly pension for the farmers retirement, from an all India trust fund where some shares of the new company are vested. *Additionally*, the authors believe that jobs for members of the displaced families or at least training or skill development that would enable them to earn a livelihood must be considered.

Further, complete rehabilitation should precede submergence, and the recommendation by the present Rehabilitation and Resettlement Bill, 2007 of “adequate progress in rehabilitation” prior to displacement of thousands, is not acceptable or satisfactory. The vagueness of the word “adequate” will prevent actual progress in rehabilitation thus empowering the bureaucracy with the scope of its misuse. In the event of deliberate or inadvertent lapses or non-compliance or deviations, certain sanctions must be enforced, to prevent future exploitation.

Another unique solution is ‘land titling’, also known as ‘*Torrens Title*’.³ Most dislocated farmers do not possess a title over their land, thus facilitating “land grabbing” by the greedy. Establishing a “titling system” is taxing as the title has to be traced back to its original roots, with absolutely no guarantee of final ownership. But the Rural Development Ministry’s ‘Department of Land Resources’ has drafted ‘*Land Titling Bill 2010*’⁴ to bring uniformity across the country and replace the existing deeds system fraught with excessive litigation due to inaccuracies in property records. There is no deficiency in agencies involved in such maintenance but the lack of interconnectivity leads to differing processes of updating of property records, resulting in inaccuracies in

the ultimate records. 'Bhoomi project' is an example of implementation of this bill, it is an attempt made by Karnataka State Government for computerization of land records. This project funded by the Ministry of Rural Development, Government of India and State Government of Karnataka, is accountable for 20 million land records of 6.7 million land owners in 176 taluks of Karnataka that have been computerized.¹ Some of the chief components include – the computer centre responsible for the mutation (change in land title) and updating, using tools like finger print authentication and scanning of important documents to ensure vigorous and secured system.² Lastly, one of the other major objectives of this program is to aid farmers to pursue land concerned litigation in courts. As the government has received much censure for the definition of the term 'public purpose', the Land Acquisition (Amendment) Bill 2011³ proposes to let the matter be decided by the States.⁴

Also often, projects are abandoned once the land is acquired. This has been illustrated in the case of Birla's when 750 acres of land had been acquired by the West Bengal Government in the 1950s for an automobile project. But since then only 300 acres have been used.⁵ Under the 2011 Bill, if the private project for which the land is acquired is unused for 5 years, then the land reverts to the State⁶. Moreover this will not stop private persons from starting the project to avoid the implementation of this provision and then abandoning it at a later stage. The Bill generously permits the original owners to buy back the land at compensation rates if no progress on the project has been made for five years.⁷ But one wonders if that is really possible. Thus to conclude, optimism prevails as, the government is contemplating the formation of a rehabilitation law and amending the Land Acquisition Act which is an achievement for the landless masses. It has taken more than two decades for the debate to reach this stage. Any opposition made towards the Bills should be cautiously moderated so that there is only progress ahead. Thus even with the demise of Fundamental Right to Property, the hope for the survival of Right to Property continues.

Property valuation

Formulating an equitable pro-development compensation model – lessons from the Pacific

Spike Boydell¹ and Ulai Baya¹

¹UTS: Asia-Pacific Centre for Complex Real Property Rights,
University of Technology, Sydney
Australia

Email: spike.boydell@uts.edu.au ; ulai.baya@uts.edu.au

Abstract:

Many Pacific Island countries are challenged by aspirations for development and western commercialism that conflict with the desire to maintain the best of custom and traditional land stewardship. In this paper, we explore the development of an equitable compensation approach that applies the principles of marriage value (or synergistic value) to recognise the reliance that island communities have on customary fishing grounds. Waterside tourism ventures are a marriage between a hotel development and associated infrastructure on the land, and the need to access and use the adjoining lagoon or ocean for recreation activities. Likewise, mineral exploration and development in the interior requires access to waters edge wharf facilities for export purposes, which impacts ecologically on customary fishing grounds.

We use an example where property rights over the customary fishing ground are sometimes held by traditional groupings from the interior rather than the waterfront landowning group on whose land, for example, a lease may have been granted for a resort development. Building on a detailed analysis of both the institutional arrangements and stakeholder interpretations, we combine these insights with lessons from other jurisdictions to explore and analyse five potential compensation models. We engage scenario analysis to allow the interests of the various stakeholders in a potential development to be reconciled, and this in turn allows for a discussion and elaboration on the appropriate valuation methods that can be applied, drawing on international best practice, through the integration of current International Valuation Standards.

Keywords:

compensation, synergistic value, custom, development, International Valuation Standards

1 Introduction

The growing influence of globalisation and modernity is impacting on the South Pacific, most notably in Melanesia through the potential economic benefits associated with resource exploration on (or below) customary land. The developing countries of the South Pacific region, spread over 11.5 million square miles of ocean, share a combination of geographical, biological, sociological and economic characteristics. Importantly, they all have enduring, traditional systems of customary land tenure (with 83-100% held in customary ownership), that conflict with Western notions of land ownership (Hann, 1998, Paterson, 2001) .

Our focus in this paper is on the resource rich countries of Melanesia, namely Papua New Guinea, Vanuatu, the Solomon Islands and Fiji. At the time of writing, significant reserves of bauxite, copper and gold have been identified in Fiji, whilst some \$60 billion seabed reserves of nickel are promised in the Solomons. Meanwhile, the more developed exploration of minerals in Papua New Guinea is an ongoing source of conflict between customary landowners, the government and offshore exploration companies.

Our purpose in this paper is to explore how an equitable compensation model can be formulated for resource rich developing countries, like those in Melanesia, where the principles of customary land ownership are protected by Constitutions and traditions alike. Currently, the approaches taken to compensate customary landowners for the loss of access to their traditional subsistence and spiritual recognition to the land is somewhat *ad hoc*. We have previously argued that the customary nature of land ownership and control in the region does not preclude the optimum use of land – in its many forms – for development (Boydell, 2010). Rather, there is a pronounced disconnect between indigenous values and capitalist interests, which we elaborate on in this introduction. In the next section, we provide a review of the literature and law relating to compensation on native land. This provides the requisite background for our inquiry into compensation approaches, using scenario analysis to present a hypothetical (but common) compensation issue. We interrogate international valuation standards for potential solutions to the compensation challenge, and conclude the paper with a discussion on why synergistic valuation may be part of the optimal approach.

The disconnect that exists between indigenous values and capitalist interests goes beyond legal pluralism (for example, on legal pluralism see Hooker, 1975, Griffiths, 1986), as we are not just concerned with the interaction of customary and western law. Rather, our plurality extends to notions of identity. As Hughes (2003, 346) argued, modern constitutionalism clouds the issue of identity as the state cannot be merely conceived of in abstract institutional terms, as assumptions of uniformity under a coherent body of law is at odds with the social and cultural reality of these countries. However, we do share the view of the von Benda-Beckmann's (von Benda-Beckmann and von Benda-Beckmann, 2006, 12) that 'along with many anthropologists, we think that the term *law* can be used as an analytical concept'. They go on to articulate law in both cognitive terms (how things are, and why they are) and normative terms (how things could or should be). We have developed the concepts of self and identity creation (the literal meaning of autopoiesis) further in our research on complexity epistemology (the study of emergent levels of knowing) and complexity axiology (the study of emergent levels of valuing) (McDermott and Boydell, 2011). We apply these interpretations to what we refer to as the *Plurality of Registers* when attempting to articulate the disconnect of worldviews between indigenous values and capitalist interests (see Figure 1).

What the *Plurality of Registers* highlights are discrete conceptions of knowing and valuing, with different social relationships, behaviour, permissibility, consequences – some of which are categorical (typified general rules) and some are ideological (more generalised). 'Law in this sense is a generic term that comprises a variety of social phenomena (concepts, rules, principles, procedures, regulations of different sorts, relationships, decisions) at different levels of social organisation' (von Benda-Beckmann and von Benda-Beckmann, 2006, 13). Simply stated, the customary value of land that is used for subsistence purposes and which retains strong spiritual ties to the ancestors whilst providing sustainable stewardship for future generations is intangible.

Yet in western economic terms, which ground notions of value as economic rent, or surplus of production, the value of such customary subsistence land is effectively zero dollars. There is no problem with these different worldviews... until they meet. And where they meet, the inalienable notions of land held by the customary stewards are very much at odds with the commodification of western understandings of ownership.

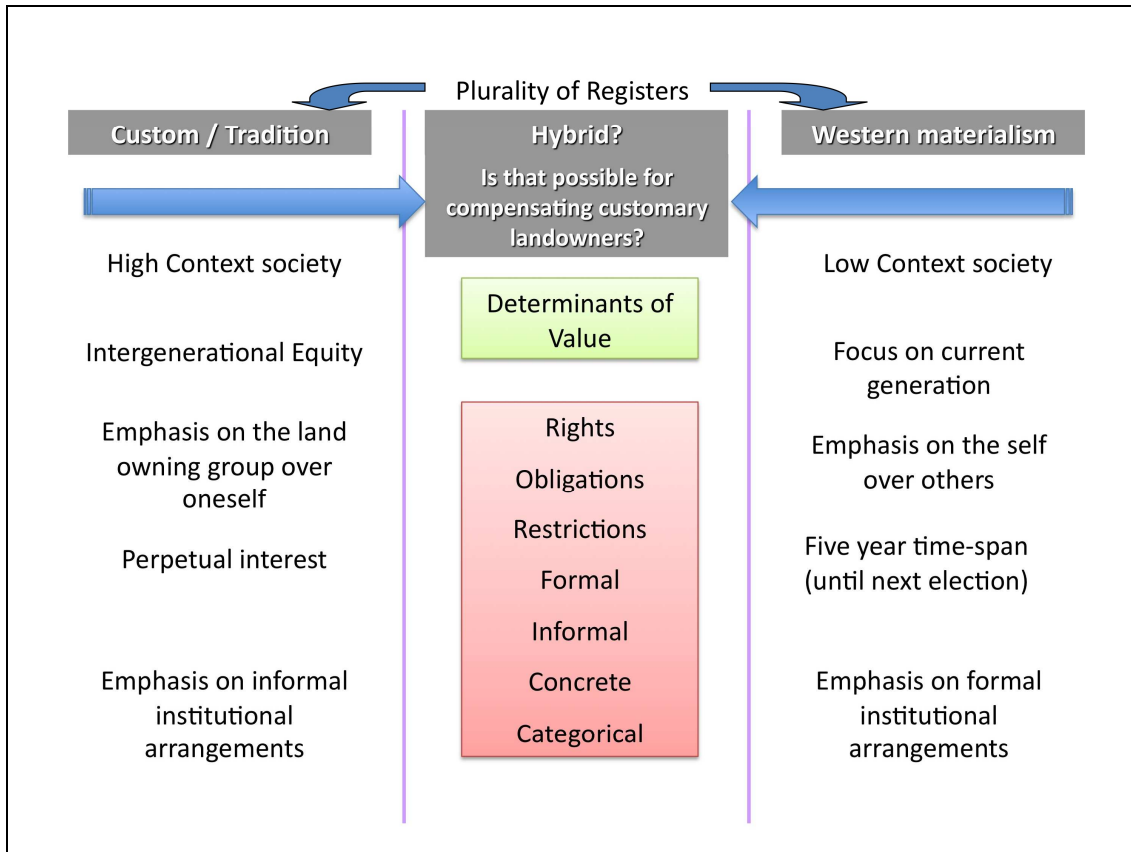

Figure 31: Plurality of Registers
(source: Boydell & Baya for this research)

These issues highlight our *Plurality of Registers* (or institutional arrangements) and Figure 1 provides a simplified graphic of these, which allows the relative extremes of custom / tradition and western materialism to be elaborated. A distinction has to be made between low-context and high-context cultures in land dealings and conflict management (Burgess and Burgess, 1997). There are major challenges to conflict management when a straightforward low-context (US, Canada, Western Europe, Anglo-Australian) approach is applied to a culturally sensitive high-context society (traditional, collectivist, honour based cultures e.g. Japan, China, Latin America, and Pacific Islands). The western approach identifies conflict as a struggle between competing interest and something to be addressed in a businesslike way. Language is explicit and the conflict is tackled head-on, adopting competitive (positional) bargaining or integrative (problem-solving) negotiation. This brash approach contrasts harshly with the high-context identification of conflict as a problem of relationships as well as interests. In such circumstances, a relationship-oriented process must encompass indirect and non-verbal communication to protect relationships and face. Accordingly, traditional societies often prefer locals to act as intermediaries, even though they may be party to the conflict and partial to one or other side, based on community trust and

respect. Such individuals are seen to have a longer-term interest in enduring solutions for the greater good of the society than impartial outsiders do.

Continuing the polarity of customary and western perspectives, such differences also exist in terms of timescale. The whole notion of time is different between the two worldviews. Land ownership from a customary perspective, and for indigenous people in general, is grounded on intergenerational equity. This can be explained as guardianship - to respect the spirits of the ancestors - and stewardship – to protect the land, applying what we know understand as sustainable principles, so that it will be able to be used and enjoyed for subsistence purposes by generations still to come (Boydell and Holzknicht, 2003). In contrast, western approaches under modernity have tended to focus more on the nuclear family and the current generation, as witnessed by unsustainable land practices, negative reaction to climate change policy proposals if it is to impact on an individuals lifestyle, and the urgency with which the earths natural resources are being extracted / exploited.

In making broad generalisations, high context societies, like those in Melanesia, place emphasis on intergenerational equity, in contrast to the western focus on the current generation. This is similarly demonstrated in the emphasis of the group over oneself, whereas the western model of possessive individualism prioritises the self over others. Our ongoing work with stakeholders in the region highlights (in this context) that, in some cases, chiefs utilise custom and tradition to maintain their cultural control and powerbase, and yet are cited as misusing that power for self-interest and personal benefit. It follows that a perpetual view is adopted when the emphasis is on custom and tradition. Conversely, in the western model, the time-span is often limited to a five-year outlook; in other words liberal democracies act in such a way as to allow the incumbent government to heighten their chances of re-election, assuming a three to five year election cycle. Custom and tradition emphasise informal institutional arrangements, and these are often devalued or challenged by the power / authority of formal legal institutions that are guaranteed by the State.

The conundrum is that frequently one or more stakeholders cannot comprehend the complexity inherent in the worldview of other stakeholders. In related work (McDermott and Boydell, 2011) we have attempted to identify the hierarchies of understanding between different parties (Beck and Cowan, 2003), and whilst such understanding can be abstracted theoretically the challenge can effectively mean that parties are operating at different vibrational (for want of a better word) levels such that they cannot comprehend the others perspective or worldview. The reality is that there is some overlap between the extremes we demonstrate in Figure 1. It is this overlap between worldviews that we have to address if we are to seek equitable compensation when, supported by governments relying on their constitutional right to mineral resources, mining interests seek to exploit the resources in, on or under land that has been held by custom owners.

Discussing property rights (be they customary, constitutional or mining) is made more complex because discourse on property rights has emerged within a broad range of disciplines. These include, but are not limited to, archaeology, anthropology, ethics, sociology, history, psychology, law, geography, biology, philosophy, economics, and planning. The most influential Western theorising about property is underpinned by what Hann (2007, 290) refers to as the ‘standard liberal model’, yet property is ‘much broader than the liberal tradition recognizes, and that the political, economic and social functions of property are in continuous flux’. Many of these disciplines draw heavily

on legal traditions, and in particular have been influenced by Henry Maine's (1861) metaphor of 'a bundle of rights'. The importance of the 'bundle' metaphor is that it highlighted the common circumstance that different individuals or groups may hold differing rights, obligations and restrictions over the same parcel (or piece) of land. The understanding and articulation of property rights, obligations and restrictions influence property relations in all human societies (Boydell and Searle, 2010). As Cole and Grossman (2002, 318) highlight, 'divergent conceptions of property rights can lead to differences in analysis and to confusions in cross-disciplinary scholarship'. Caution needs to be taken when research into property rights, like our own approach, strives to be transdisciplinary (Nicolescu, 2006, Max-Neef, 2005), and navigates the boundaries of diverse disciplines. As Bromley (1991) highlights, there are few concepts in economics that are more central, or more confused, than those of property, rights and in particular property rights. Yet as we demonstrate later in the paper, when we come to deal with valuing compensation, it is the valuers role to place economic value on these rights, even if such rights are indeed intangible.

Having provided an introduction and overview of the complex challenge, in the next section we provide context for the rights we propose to value by exploring compensation experience and practice from other jurisdictions.

2 Literature Review

There is no standard way in which the topic of equitable compensation of native / customary title is operationalised under comparative jurisdictions in the Pacific (Boydell and Baya, 2010). Existing compensation regimes in Melanesian States, with localised variation of application, share similar common law origins: one founded on the sanctity of property, forbidding deprivation of property rights without fair and just compensation. Common law influences include landmark developments in the area of native title jurisprudence amongst the indigenous peoples of neighbouring New Zealand and Australia, with similar progress from Canada. These developments are augmented by advances in a number of provisions of international instruments that obligates island States under International Law, such as *The Declaration on the Rights of Indigenous People of 2007*¹ relating to central matters such as customary title. Collectively, these obligations recognise the ownership of lands, territories and resources by their traditional owners that encompasses a wide gamut of legal relationship from property to use, including compensation (see Article 26(2) and Article 28(1)).

In the case of Australia, the *Native Title Act, Cth.* (1993) protects native title from extinguishment by adverse government action under s.48. Where it is sought to extinguish native title, this is usually facilitated by way of an *Indigenous Land Use Agreement* (ILUA). One of the few Australian decisions to discuss extinguishment simply is *Jango v Northern Territory* (2006) FCA 318 where, to demonstrate entitlement to compensation, the claimant group were required to establish as a threshold issue that they had native title rights and interests over the area at the time the compensation act occurred.

In Canada, aboriginal titles / rights are protected under the imprimatur of the Constitutional provision of s.35(1) of the *Constitution Act 1982*. In some

¹ Declaration on the Rights of Indigenous Peoples, UN GA 2007, see: <http://www.ohchr.org/english/law/ccpr.htm>

circumstances, however, aboriginal titles / rights can be regulated and compensation may be payable for allowable acts as in *R. v Van der Peet* (1996) 137 DLR (4th), 289.

Up until the *Attorney General v Ngati Apa* (2003) 3 NZLR 643, there were effectively no native / customary title claims in New Zealand (except for potential foreshore and sea bed claims), as all customary title to land had been effectively extinguished by the end of the nineteenth century through government purchases and the investigation and conversion to freehold effected post 1862 through the Native Land Court (now the Maori Land Court).

As we elaborate later in the paper, an analysis of contemporary practice indicates that negotiated settlements are the preferable compensation mechanism. Negotiated settlements are utilised in Canada, New Zealand, Australia, Papua New Guinea and Fiji. Whilst the process and outcomes may take different legal forms in each jurisdiction, they have in common diverse approach towards compensation packages in which lump sum payment is only one of several ways of delivering redress. This allows for a flexible approach of tailoring recipient needs to be met, through facilitating for intergenerational equity, environmental and resource decision-making powers, employment and cultural acknowledgement amongst others (see for example the \$2bn deal between Rio Tinto and five aboriginal groups where only \$3,500 p.a. will be paid to individual customary owners, the rest being in terms of scholarship, infrastructure, employment opportunities: <http://www.abc.net.au/news/stories/2011/06/03/3234490.htm?section=business>). Such compensation packages add time and complexity to the legal arrangements.

As our synergistic valuation approach elaborates later, it is important to also consider native title rights to the offshore and sea-bed, which have been litigated in a number of common law jurisdictions such as Australia, Canada and New Zealand. Similar rights has also been enunciated pertaining to the First Nations Peoples in the United States per *Native Village of Eyak v Trawler Diane Marie Inc.* (1998) 154F 3rd 1090(9th Cir). As the doctrine of native / customary title functions as a recognition system, each jurisdiction has a different legal test that claimants must satisfy in order to show that they have native title rights and interests. Once established the question of compensation for extinguishment or infringement of rights may arise.

The New Zealand Court of Appeal decision in *Attorney General v Ngati Apa* (2003) determined that the Maori Land Court has jurisdiction to investigate customary title to the foreshore and sea bed, a process that could result in a conversion of the title to freehold title. This confirmed that Maori customary/native title to the foreshore and sea bed has not been extinguished. Whilst the decision did not determine the nature and content of the customary / native title right, the legislative response by Government to the decision acted to define the content of these rights. In so doing, the Government is believed to have anticipated what the nature of the rights in the foreshore might be, if litigated, prescribing legal tests for territorial and non territorial rights based largely on the Canadian experience married with some Australian law (Boydell and Baya, 2010). As such, the threshold of proof was set higher than in any Commonwealth jurisdiction - thus failing to accord any status to the customary owners. The Act was replaced in September 2010 by the *Marine and Coastal Area (Takutai Moana) Bill*, specifically acknowledging the need to consider culturally appropriate test for the recognition of customary/native title rights. Clause 63 specifically acknowledges customary marine

tenure as an exclusive possession right to foreshore and sea bed and is an in alienable interest in land.

Canadian doctrines of aboriginal rights and titles have been largely influenced by the operation of s.35(1) of the *Constitution Act* of (1982), which recognises and affirms existing aboriginal rights as unextinguished at the time of its commencement. To the extent that extinguishment of rights and interests can occur prior to 1982, the test is one of clear and plain intention to extinguish as in *R. v Badger*. There is little substantive litigation on extinguishment as the overall purpose of s.35 saw the need to protect the distinct cultures and recognise their prior occupation of North America reconciling this with sovereignty of the Crown. This results in a distinctive body of jurisprudence with the overall purpose of reconciliation in mind. A recent decision by the BC Supreme Court in *Ahousaht Indian Band and Nation v (AG) Canada* [2009 BCSC 1494] asked the Court specifically define the content of their Aboriginal title only to the extent necessary to establish harvest rights and sell fisheries resources incident to that title. Whilst this action encompassed an area below low water mark and extended into the Pacific Ocean, it did not asked the Court questions of title that could potentially give rise to an exclusive right, but instead asked of a determination of a lesser right of the recognition to fish and the extent of its exercise in the area (see para 499.)

Australian native title in the offshore have been the subject of a number of major court decisions but this has largely influenced by the definition of native title in section 223 of the *Native Title Act 1993* (Cth.) [NTA]. Since the decision of *Wik Peoples v State of Queensland* (1996) 187CLR1, clarification on extinguishment and jurisprudential development has largely been dominated by the *inconsistency* model where its application was carried through in *Yarmirr v Northern Territory* [2001]HCA56 enunciating that where the continuing recognition of native title rights and interests to sea country was inconsistent with the common law itself, the common law prevails.

In the later case of the *Lardil People v State of Queensland* [2004]FCA298 the claimants asserted *inter alia*, ownership of seas, the sea bed, and the sub-soil below the sea bed and resources of the sea in their respective territories. The judge found that the concept of ownership held by the applicants was not one based on common law concepts of real property. Rather, it was a concept born out of the connection of peoples to each of the elements through their spirituality (see paras 115,147). As native title was earlier interpreted by the NTA in *Ward v Commonwealth* [2000]FCA191 requiring each individual native right and interests to be identified, this statement would mean that indigenous relationship to country including sea country must be translated into individual rights and interests. The NTA requires that the relationship between a community or claimant group and the land is to be expressed in terms of rights and interests in relation to that land. This means that a relationship that is essentially religious or spiritual must be translated into law. This would invariably require the fragmentation of an integrated view of reordering of affairs into rights and interests, which are considered apart from the duties and obligations which go with them (see para. 173).

The *Ward* judgment further observed that it is not useful to state native title rights in a broad way given the limitations pursuant to its definition at common law under s.223 of NTA and subject to common law rights of navigation, fishing and the international law right of free passage (para. 171). Nor was the non-inclusive right to occupy, use and enjoy the waters and land appropriate, because at common law the notion of possession and occupation involve notions of control and access. Applying earlier decisions in

Yarmirr, the *Ward* judgment found that control of access to the land and waters of the inter-tidal zone and the territorial seas as a right of exclusion even though as part of the traditional law, could not be recognised at common law. It is important to note that this decision is not a determination, that rights and control of the foreshore cannot be part of native title in the foreshore, rather the findings reinforces that they cannot be recognised by the common law in Australia because of the scope of native title definition under the NTA.

Further, the decision in *Akiba v Queensland* [2010]FCA643 saw some accommodation in that the claimants sea territory was viewed quite different in character than most of the mainland claimants and this difference impacted on the way the jurisprudence was to be applied. It was noted that the islander claimants in this instance were seamlessly attached and culturally associated to the claimed area that there is no sea-land dichotomy. Further it was emphasised that in determining the nature of customary title rights and interests of the claimants it is necessary to examine them from the perspective of the claimants 'because rights and interests of the islanders are those possessed under their traditional laws and customs, they must be at from the perspective of the claimants', see *Neowarra* at 364. The decision is important in that it makes it clear that offshore rights can include rights of a commercial nature.

As to the rights claimed *per se*, it was also emphasised that the description of what is theirs, what belongs to them, what they are entitled to, are for the above reasons fundamental to the ascertainment of those rights and interests. These, as it was observed, must be sourced in the society's laws and customs and such rights and interests do not for their vitality require recognition by someone other than the person who asserts them (*Sundberg.J.*, para. 500). Particular rights found were, (i) the rights of access to remaining and use their marine areas, and (ii) the right to access resources (including sea water) and to take for any purpose resources from those areas (which include the right to trade in resources) [at para 540].

Issues of offshore native title are not addressed in Papua New Guinea to the extent that the nature of rights and interest therein are not properly articulated for the interpretation of the Courts (*Tom'tavala*, 2010). Whilst there is assistance by way of s.8 of the *Native Customs Recognition Ordinance* (1963) providing Courts to take into account customary considerations in relation to (i) the ownership by custom of rights on, in, over or in connection with the sea or the reef or in, on, or on the bed of the sea or rights of fishing and, (ii) the ownership by custom of water, or of rights in, over or to water. Further, Courts are not strictly bound by rules of legal procedure and hearsay rules in this regard, per s.2 and with consideration that must also be given to the weight of public interest, under s.3.

As reported, the determination of Court in leading cases relating to offshore native title claims is difficult to sustain given that any pre-existing customary laws on which the claim is premised cannot be easily identified. Whilst the reported cases were premised on what is genuinely believed to be customary property, the end game of achieving compensation was not realised given the absence of a framework of rights and interests that the Court could rely on (see *Ene Land Group Inc v Fonsen Logging (PNG) Pty Ltd* [1998] PNGLR 1).

Given the absence of a comprehensive compensation policy that clearly specify the nature and extent of the compensable rights and interests, any mining development is bound to run into problems given that customary owners believe that they own

everything above and below the land, including the minerals. Often, friction arises between the customary owners on one hand and the developer on the other, with the former feeling that fair compensation has not been paid (McLeod, 2000). Fiji has had a mixed history in this regard, in that it recognised that it had no comprehensive system of compensation and commenced work towards a policy in 1999. This resulted in the development of a *Compensation Policy for Fiji's Mineral Sector* in 1999, that was to be submitted to Cabinet for final legislative approval - some twelve years later this approval has still not eventuated.

The definition of compensable damage and compensation was a key consideration in the derivation of Fiji's compensation policy, including the award of damages for any loss in value or damage to land, water, foreshore or other resources as well as rights arising from prospecting, exploration and mining activities, to landowners, occupiers and the surrounding communities, in monetary or non monetary forms (Republic of Fiji Islands, 1999). This draft policy is explicit in listing all possible damages, including the loss of cultural rights. However, it failed to translate the possibilities of compensable rights and interests that are intangible but inherent to the body of culture of the landowning unit that forms part of their traditional estate.

Given what has transpired, landowners are back at the mercy of compensation regime pre August 1999. The most notable development since then has been loss of royalty payments to the landowners, which is now paid to the State by the Department of Mines as a result of a *Mining Decree* issued in 2010. Currently Fiji has three major mining projects underway and several other significant initiatives ranging from prospecting to fully operational schemes. Due to the lack of a comprehensive mining compensation policy, compensation for the land based aspects of the mines has been largely inconsistent, due to the *ad hoc* nature of the negotiations. Like most of the Pacific Island States, compensation thus far has been largely limited to surface damage and leasing of surface land for mining or access purpose.

The *Mining Act* 1992 in Papua New Guinea (PNG) is where the principle elements of the national mineral policy can be found, in conjunction with other legislation relating to, for example, Income Tax, Water and Health. In brief, mineral operations in PNG are always caught between the 'public interest' of the State and the interest that customary law concedes to the landowners relating to surface lands (James, 1997). As State ownership rights over minerals comes into conflict with landowners surface rights governed by customary law, the compensation provisions are an attempt to conduct a good working relationship between the landowners and the State.

Where the State intervenes to compulsorily purchase land for mining tenements, landowners must be compensated as must those landowners indirectly affected by the exploration. Regarding the heads of consideration for compensation, the *Mining Act* mandates that landowners must be fully compensated for damages to land relating to deprivation of surface use, loss of earnings, disruption to agricultural land and the like. At first glance this appears reasonably comprehensive, given the history of mining and hard learnt lessons by both the PNG government and the people. However, the approach favours a disjoint of surface and underground tenure, thereby quashing any intangible flow that is provided through its fusion.

Mining in the Solomon Islands accounted for 30 percent of its GDP at its peak before closure of its major mine in 1999, and will probably make a similar contribution for the next several years if restored to its former operating level and augmented by nickel

exploration. Administered under the *Mines and Mineral Act* 1990, the issue of compensation is peppered through s.32-35, ranging from the use or compulsory acquisition of land relating to mining, surface rentals and the acquisition of surface rights. Royalties are considered in s.45. Although there have been three amendments to the Act, compensation provision wording is general in nature, vesting authority in the (hoped for) diligence of Government officials. Market value of surface lands is precisely described so as not to include the price of minerals underground, with heads of compensation limited to value of improvements, compensation for loss of trees and crops, and severance and disturbance. Compensation calculations for access rights are similarly routine, with the identification of the right landowning groups to be identified as a matter of priority, although compensation should not pay regard to the value of mineral underneath their land.

Whilst there is no intangible valuation consideration in the current compensation provisions, the Solomon Islands have the perfect opportunity to develop an exemplary mining policy given the current national rebuilding process may provide a chance for legislative reform of its main economic sectors.

Vanuatu has latent potential for mining according to the National Investment Policy (Government of Vanuatu, 2005). As there is currently no mineral extraction happening in Vanuatu, this provides an optimal opportunity for policy makers to formulate an equitable pro-development compensation model for its mining industry, to increase the contribution of private enterprise to economic development.

3 Research Methodology

This research reported in this paper forms part of an ongoing investigation into land resource compensation issues in Melanesia, which is a sub-project of our wider transdisciplinary collaborations on compensation, institutional arrangements and land trusts, and the financial management of inalienable customary land in Australia and the South Pacific.

Collectively, our research design is one of phenomenological transdisciplinarity, which implies our goal is to build models to connect theory to observed reality, allowing us to inform potential policy outcomes. ‘Transdisciplinarity concerns itself with what is between the disciplines, across the different disciplines, and beyond all disciplines’ (Nicolescu, 2006, 143). Methodologically, this research adopts what Creswell and Tashakkori (2007) refer to as a paradigm perspective. Our approach incorporates a breadth of sociological analysis, legal discourse, ecological and cultural sensitivity, and financial management activities. To achieve this we integrate an eclectic combination of research modes into history, law, social inquiry, theory, practice, and beliefs, with the attitudes of finance, finance providers, capital users, government organisations, NGOs, resource exploration companies, and indigenous property owners. These insights support our analysis of the existing institutional arrangements and provide important data that assists in the development of our integrated compensation model.

The paradigm perspective that we engage for our compensation research has its genesis in the classic definition of mixed methods research of Greene, Caracelli, and Graham (1989, 256), who defined mixed methods designs as ‘those that include at least one quantitative method (designed to collect numbers) and one qualitative method (designed to collect words)’. The application of this innovative approach has enabled us to

combine the legal discourse (words) surrounding indigenous property rights in the resource exploration context with the financial implications (numbers) pertaining to those rights in developing a compensation matrix.

As we highlighted in the previous section, there is a different scale between the extent of identified mineral resources in the four Melanesia countries that we have focused on, just as there are different physical land masses, land trust or incorporated land group development, genealogies and institutional arrangements. In some countries we have been able to undertake more fieldwork and community engagement, whereas in others our emphasis has either been with government agencies or NGOs. It is a work in progress, but having developed a compensation model we are testing its efficacy not just on mineral exploration, but also on resort development and other infrastructure schemes. In certain countries our involvement has extended to policy advice on the implementation of our suggested compensation modelling. This approach has enabled the researchers to assess the functionality of existing compensation policies, have broad access to government information and undertake extensive stakeholder analysis before offering recommendations on appropriate institutional processes that can be harnessed to assist in evolving change.

4 Findings and Discussion

Some of the agreement processes from other countries (e.g. Australia, New Zealand and Canada) outlined in our literature review are too complex for Melanesian needs. They point, however, to a trend towards framing agreements that are not designed to specifically compensate indigenous groups for extinguishment of customary title. Instead, they emphasise a structure of long-term relationships between indigenous groups and the Crown or State, including sharing of resource revenues and participation in decision-making affecting their lands. In part, this is the result of either the recognition of customary rights through court processes, or the anticipation by governments of such recognition. In this context, our subject countries have different levels of institutional arrangement. For example, Fiji has evidenced ownership for over a century and has had a Trust structure in place since the 1940s. In contrast, Papua New Guinea has some examples of Incorporated Land Groups but no centralised record system. Similarly, the Solomon Islands have only recently started evolving trust structures, and there are only two examples in Vanuatu (the Mele and Ifira Trusts, on the urban fringe of Port Vila). What is evident internationally, is that compensation has moved beyond a strict monetary sum, to a more complex tailored package of rights, almost always embedded in a contract, which is given statutory ratification.

We have analysed four compensation approaches, which we discuss in more detail in the following subsections, and then incorporate these into a hybrid model.

4.1 4.1 Model A – tailor compensation to the exact rights of custom landowners

Such an approach requires some kind of recognition system as a precursor to determining compensation, most likely a common law or statutory native title system.

Pros

- Tailors the compensation to the exact rights held – possibly providing a more nuanced quantum of compensation;

- It allows for western commodification of rights (which some Stakeholders seem to want); and
- It is likely to result in a lump sum compensation figure. Lump sum compensation avoids many of the complexities introduced by diverse (multi-criteria) compensation packages (e.g. how do you legally implement / enforce indirect payments?).

Cons:

- Sits very uncomfortably with those countries with a continued recognition of rights such as Fiji ;
- Complex;
- The establishment of rights on a case by case basis is costly, requires human resources and capacity that these Melanesian countries do not currently have;
- As a doctrine, native title (e.g. as applied in Australia) tends to exclude cultural, social and environmental factors, and can be a very blunt tool. Standard native title law will not encompass the rich nature of customary rights and hence will undervalue the non-physical facets of the relationship of holders to their land or marine rights;
- This model does not allow for a meaningful transfer of profit or wealth sharing; and is likely to result in a single lump sum monetary figure, rather than a diverse compensation package.

4.2 4.2 Model B – assume a common set of property rights prevail and tailor compensation to these

Native title claims, be they derived from the common law or statute are lengthy, expensive, and require specialists in the form of lawyers, anthropologists and historians. It is doubtful that Melanesian countries have the current capacity to enter into a recognition process. Where land is compulsorily acquired under Anglo-Australian legal frameworks, apart from the package of compensation (heads of claim) derived from the addition of the (unimproved) land value, value to the owner, special value, injurious affection, disturbance and severance, a number of states provide for an additional amount which is a judicial discretion known as *solatium*.

Solatium is a discretionary payment to acknowledge hardship, inconvenience, trauma or other unspecified loss caused by the resumption. In a number of negotiated agreements applied to extinguish native title (for mining activities and related infrastructure) in Australia, the concept of solatium has been applied to what can be called Special Indigenous Value (SIV). Sheehan (2010) suggests that there is a strong argument that SIV should be adopted by the compensation assessor as a relevant head of compensation, drawing on its concepts of special value to the owner and solatium. In considering an award of solatium, circumstances such as the length of time the claimant has occupied the land, the inconvenience likely to be suffered by reason of removal from the land, and the period of time the claimant would have been likely to continue to occupy the land may be considered, although hitherto awards have tended not to extend to factors like emotional stress arising from the compulsory acquisition.

The focus in the Australian examples is on ‘extinguishment’ of native title. This is a controversial concept in Melanesia, where customary land is seen as inalienable. Rather the situation is more aligned to damage, disturbance, and loss of access and loss of connection (notionally for a time constrained period rather than in perpetuity).

Sheehan (2010) suggests that in negotiated agreements it is necessary to ensure the compensatory framework for native title is correct, so working within existing case law and statutory constructs is compelling – but disregards the pre-eminence of custom in Melanesian constitutions. Moreover, Sheehan places reliance on Unimproved Capital Value (which can often be more easily assessed on the basis of market evidence in Australia than in Melanesia, where there is effectively no market for inalienable customary land). As the Pacific Islands Forum Secretariat recommends, ‘Administratively determined Unimproved Capital Value based returns to customary land must be avoided. Although these may seem uncomplicated, they do not facilitate a fair return to landowners’ (PIFS, 2008, 17). In the Australian situation, where Special Indigenous Value has been treated as analogous to solatium, the largest level of judicial discretion available at present is in Western Australia, where it can be awarded at up to 10% of the total compensation sum (although there are strong views that it should be a considerably high quantum).

Pros:

- Assumes a simple base-line that customary rights are similar in all areas;
- Can include a component for cultural, social and environmental aspects (i.e. solatium / Special Indigenous Value).

Cons :

- This model does not take into account the nature of the infringement;
- It necessitates commodifying the property rights;
- It does not provide for any particular equality or distribution of resources;
- Inappropriately in the Melanesian context, it relies on Unimproved Capital Value as a component of the compensation calculation;
- It can be difficult to quantify the cultural, social and environmental aspects of the development and the discretionary allocation of Special Indigenous Value at a sum that equates to 10% of the other compensation does not adequately recompense the sense of loss; and
- The model assumes a single monetary figure, rather than a raft of compensation measures.

4.3 4.3 Model C – development driven quantification

This approach circumvents the need to determine the nature and extent of customary rights. Instead, compensation is assessed by reference to the benefits accruing to the developer, rather than the infringement on the rights of the customary owner(s). The benefits accruing to the developer are based on the ‘marriage value’ that is created by recognising, and combining, the interests in the various land and marine components from mine site to wharf and to the edge of the EEZ. Simply stated, a mining development has limited commercial value if there is no wharf access to export the minerals.

This marriage value is known in contemporary literature as synergistic value. The International Valuation Standards (API & PINZ, 2008, s.4.3.6, IVSC, 2010, 131) defines *Synergistic Value* (Synergistic Value may also be known as Marriage Value) as: ‘An additional element of value created by the combination of two or more interests where the value of the combined interest is worth more than the sum of the original interests’.

In a development driven quantification, a standard compensation package could have a number of elements including, but not limited to:

- A financial component based on a share of the land at mine, land at wharf, and marine access marriage value, and associated synergistic value increase.
- Provisions need to clearly articulate the length of the arrangement (term), the process in the event of a change in user (such as premium for transfer based on a percentage of the increase in value between project inception and transfer), and the reversionary ownership provisions of the improvements (which should be returned in good and tenantable repair) at lease / licence expiration;
- A number of jobs for members of the various landowning and marine (or fishing ground) owning groups as well as the native landowners (number could be determined by reference to profit or some other changeable yardstick allowing for changes in business practice over time);
- The provision of housing or other community infrastructure;
- Schooling, health assistance, or whatever (to incorporate the minor cost of important trophy items that are often stated in leases over customary land, such as vehicles or boats).

Pros:

- Avoids the need to determine particular property rights;
- Provides for a diverse, flexible and index-linked compensation package;
- Encourages transfer of profits / adequate sharing of wealth;
- Can be set up to provide for intergenerational equity;
- Can distribute payments easily per year (or some other term) as occurs now; and
- Can be tailored to minimise / avoid some of the problems likely to ensue within the community when compensation is paid as a large, single, up-front lump sum (premium).

Cons:

- Much more difficult to legally implement.
- Raises questions of form (contract?) and enforcement.

4.4 4.4 Model D – negotiated agreement

Negotiated Agreements are emerging as international best practice, and are based around a negotiation that is determined on a case-by-case basis, with engagement of all stakeholders who have a legal / financial interest. This is a common Australian model. It is also a common way of doing business in New Zealand, although in that context it usually pairs recognition of rights with monetary compensation to redress past grievances. Negotiated agreements have been utilised in some resource schemes in Papua New Guinea, but are open to contestation as a result of uncertain genealogy. Negotiated agreements are confidential in nature, so there is little evidence available to reference.

Pros:

- Can lead to a quite diverse and sophisticated compensation package;
- Allows the customary rights owners to have a stake in what happens to their land – to ‘own’ the agreement; and
- Does not require precise identification of property rights.

Cons:

- Takes a long time – thereby holding up development significantly;
- Capacity is an issue, as the parties need to be fully advised and represented by independent legal and valuation practitioners, with the requisite skills to forecast future income growth and liabilities; and
- In the Australian and New Zealand application, the Crown (or State) needs to be a party, thereby complicating matters further.

4.5 Model E – the hybrid

As stated, international best practice is clearly moving towards negotiated frameworks. However, many of these are large-scale agreements, often taking years to negotiate, which embed compensation within an overall redress package. Both monetary and non-monetary forms of redress are given. The quantum of the monetary component does not always directly relate to market or non-market values of particular rights. In Australia, smaller scale arrangements are dealt with through Indigenous Land Use Agreements (ILUAs), allowing potential rights holders to contract (i.e. those who have claimed but not yet proven their native title rights), as the contracting does not depend on a precise identification of their rights. The compensation (composed of financial and non-financial components) does not therefore reflect a market value determination of their identified rights.

We have identified that any compensation mechanism should (i) be based on a rich understanding of the nature of the property rights, including the customary owners themselves as without such understanding any new mechanism may lack legitimacy; (ii) acknowledge the experience of other jurisdictions, whilst being appropriate to the given circumstances in a particular country; (iii) be sophisticated enough to ensure an appropriate transfer of wealth from developers to customary owners; (iv) not be limited to a singular monetary sum, but rather ensure ongoing social and economic improvement for custom owners; (v) respond to capacity problems; (vi) be embedded in a legal arrangement that provides certainty for all parties; (vii) determine how compensation will be held, managed, invested, accounted and distributed; (viii) ensure any development activity is undertaken sensitively and sustainably, prioritising cultural and ecological wellbeing; and (ix) provide for inter-generational equity.

The best way to contextualise a compensation mechanism is by exploring a hypothetical example (see Figure 2). In this example, we will assume that there may be several customary landowning groups impacted from mine to wharf. Indeed it is quite common in Melanesia for customary landowners living in the interior (or highlands) where mines are often found to have fishing rights over inner reef areas, such is the nature of traditional commerce and inter-clan arrangements. Our purpose in this example is to provide sufficient background to lead in to a discussion on synergistic value and a greater exploration of our hybrid compensation model.

The first stage of any disturbance of customary rights is to undertake a stakeholder analysis (see Boydell, 2008 for more discussion on this approach to stakeholder analysis).

Who are the potential beneficiaries:

- In terms of the marine and inner reef areas, these could be the custom owners of village A and village B, as well as those from other parts of the country with rights over marine and inner reef areas;

- Members of village B in terms of remuneration from the lease for the depot;

Figure 32: Wharf Scenario
(Source: Boydell & Baya for this research)

- Members of village B in terms of remuneration from indirect economic gain (employment at several levels). There is potential that members of village A will also benefit in the same way, but such provisions are unlikely to be written into the lease;
- This therefore creates a conflict between relating the land lease arrangement to the compensation for marine areas. So, village A should get both indirect and direct economic gain – and this is why there is a need for acknowledgement for the ‘marriage value’ (synergistic value) between the land component and water component. What this in essence means is that it is inappropriate to enter into a lease over the land without integrating access rights (and wharf construction rights, reef destruction compensation) to marine component, as fragmentation leads to social problems. Alternatively phrased, determining the calculation of compensation for the marine area has to acknowledge that remuneration from the land lease component has already benefited village B. Rather than changing the lease structures, you adjust the compensation to reflect that fact that there is a clear marriage value between the land interest held by village B and the marine interest jointly held by village A, village B and other rights holders;
- The Developer, and wharf / mine operator (who may also be the developer);
- Surrounding villages (other custom landowning groups)
- Public whose services may be called (food supplies through to banking ventures – i.e. local through to corporate)

- State, through tax (employee taxes, exploration licences and company taxes) and associated increase in GDP

Who might be adversely affected:

- Limitation of exercise of rights to village A & B (see next heading)
- Other members of the public who use the commons
- Fishing licence holders
- Marine environment from pollution

Who has existing rights:

- Village A
- Village B
- Any other customary interests in the waterway and marine areas
- Any existing fishing licensees

Below, we elaborate on these existing rights using a categorisation of rights model (Boydell, 2007, 117) that we have successfully engaged in a range of other projects.

Direct use: Rights to plant, harvest, build, access and similar, maybe shared rights

- Village A
- Village B
- Also, those to whom the custom owners grant subsidiary and overlapping rights for fishing / sand and gravel

Indirect economic gain: For example through employment in mine/depot/wharf, transport, equipment, services and food

- Village A
- Village B
- Plus members of other custom rights holding groups

Control: Conditions of direct/indirect use, held by persons other than the user

- Village A
- Village B
- Subject to any licence, overriding of State

Transfer: Effective powers to transmit rights-by will, sale, mortgage, gift, or other conveyance

- Jointly through village A and village B in a customary sense

Residual rights: Remaining rights at the end of a term (such as lease, death, eviction), includes reversionary rights

- Jointly custom owners of village A and village B

Rights of identification (symbolic rights): Associated with psychological or social aspects with no direct economic or material function

- Primarily village A and village B
- And the wider clan group to which village A and village B are aligned in ancestral connection

Duration: Length of time property right is held, indicating profits and/or savings

- As agreed in any lease arrangement

Flexibility: Right should cater for modifications and alterations

- Developer in negotiation with village A / village B
- Plus State (should it apply overarching legislation/decrees)

Exclusivity: Inverse of the number of people with shared or similar rights, more relevant to water property

- Village A and village B, as well as remote custom rights holders, for example, for a special traditional practice over that body of water

Quality of title: Level of security that is available as tenure shifts from the optimum

- How is the title guaranteed by the state? The state guarantees by virtue of administrative authority, per the *Yanner v Eaton* example.

Divisibility: Property right can be shared over territories, according to season, etc.

- Village A and village B
- And developer
- Or State if they require

Access: Entry/ admission into the marine area

- Village A and village B
- The State
- Any existing fishing licensees
-

Withdrawal (extraction): Extraction of resources by owner despite leasing property

- Village A and village B
- The State (if seabed)
- Those to whom the custom rights holders grant withdrawal rights

Management: Be able to make decisions on how and by whom a thing shall be used

- Village A and village B, but ideally through a particular individual who has authority to speak for the custom owners
- Environmental Management overseen by the State

Exclusion: Disallowing others from entry and use of resources

- Village A and village B
- The State

Alienation: Transfer of an interest (right) in property to another, in perpetuity

- Village A and village B jointly
- Or developer on application to transfer current interest or create a subsidiary interest

Who is likely to be voiceless:

- Individual members who are not in the majority – so there is a need to make sure that everyone who has a right to speak has spoken (including young/old, male/female), so absentees may have limited rights
- Role of absent members (who may send remittances)
- Neighbouring custom landowners

- Historical associates and those who have connection
- General public who use the area (other than through formal planning approval channels)

Who is likely to resent change and mobilize resistance against it:

- Absent members, who may romanticise how the village 'used to be' with the passage of time
- Other custom owners seeking to entice a particular exploration company to use their land for processing, depot or wharf facilities
- Other members of the public who use the commons
- Fishing licence holders

We now need to integrate this analysis into the valuation considerations. There is a large body of international literature on economic valuation and resource management (see for example the comprehensive set of links provided by the World Resources Institute: <http://www.wri.org/project/valuation-caribbean-reefs/references>), and ecosystem valuation (see <http://www.ecosystemvaluation.org/links.htm>). Much of the resource valuation literature takes a *Total Economic Value* approach, where values are allocated to use values (direct and indirect) and non-use values (option value, quasi-option value, bequest value and existence, or psychic, value). These approaches are used by several of the contributors in Ahmed et al. (2005), and applied in the Fiji context by Korovulavula et al. (2008). The valuation techniques engaged in these use and non-use approaches are (as with the VFT) those applied by economists (as opposed to valuers), and include: Effect on Production; Replacement Costs; Damage Costs; Travel Costs; and, the Contingent Valuation Method. These have been variously applied on a range of international situations, with varying success. We consider that, because of the inputs required and the outputs desired, they all fall short of addressing valuation for land resource compensation in a Melanesian context.

We argue that the synergistic value approach, a valuation method more familiar to the valuation profession than mainstream economists, has more to offer in the context of land resource compensation in Melanesia. This marriage value approach takes a more holistic approach, engaging with the economic benefits that are gained from providing a mining infrastructure in multiple locations with access inner reef and marine areas (or, for example, providing a mineral exploration company access to reclaim an area for a wharf facility with associated jetty). It has the ability to be adapted and expanded to also include items that relate to both the positives (e.g. partnership, employment, service sector and food supply, environmental conservation and cultural heritage), as well as the negatives (e.g. potential loss of access, environmental contamination, sedimentation, eutrophication, reef degeneration, loss of amenity / privacy, loss of cultural heritage).

Table 1: applying IVSC approaches to Land Resource Compensation scenario
(source: Boydell & Baya for this research)

	Cost Approach	Income Approach	Direct Market Comparison	Depreciated Replacement Cost	Synergistic (marriage) Value	Relief-from-Royalty Value	Premium Profits Method	Excess Earnings Method	Fair Value	Special (Indigenous) Value	Going-Concern Value	Discounted Cash Flow	Risk Replication Method	Marine Resource Inventory
Marriage of interests between the land and marine areas	X	X	X	X				x	X	X	X			
Loss of access, if any (taking)		X		X				X	X	X				
Removal of mangrove, if any (taking)	X	X		X	X	X		X	X	X				
Removal of reef, if any (taking)	X	X		X	X			X				X		
Removal of sand / shale (taking)	X	X		X	X			X				X		
Loss of mangrove habitat (damage)	X			X				X				X		
Increased vulnerability through lost nutrient filtering / flood control / storm buffer / shoreline stabilisation / microclimatic stabilisation / biodiversity maintenance / education and research / bio-prospecting / carbon sequestration	X		X	X					X			X		
Environmental contamination from resort waste, dumping and spillage (damage)	X		X	X					X			X		
Sedimentation (damage)	X		X	X					X			X		
Eutrophication (damage)	X		X	X					X			X		
Reef degeneration (damage)	X		X	X					X			X		
Construction contamination risk (damage that can be addressed through the EIA bond)	X		X	X					X			X	X	
Reduction of fish stock (damage)	X	X	X	X				X	X	X		X	X	
Potential loss of income from possible restriction on fishing access (damage)		X	X	X				X	X	X		X		
Loss of amenity / privacy (damage)				X					X			X		
Truncation of cultural association, and diminution / impact on cultural heritage (damage)				X					X			X		
Loss of direct cultural and spiritual connection (loss of Special Indigenous Value)				X					X			X		
Loss of ability to exercise cultural and spiritual connection (loss of Special Indigenous Value)				X					X			X		

The quantum of compensation will need to be determined on a case-by-case basis, with the synergistic value between the mine, mining infrastructure, depot/wharf and the marine area forming a main component on which to base the negotiated agreement.

In Table 1 we summarise, by way of example, the breadth valuation approaches that should be engaged in addressing the compensation issues to be negotiated in respect of our scenario. In this regard, we use as a basis for the terminology the 2010 Exposure Draft of the International Valuation Standards (IVSC, 2010) – and recommend that the forthcoming 2011 version be utilised once it is published. The tabulated compensation issues that are included (in Table 1) are not necessarily exhaustive, but are grounded on a synthesis of the literature on the sustainable management of land and reef areas as well as stakeholder evidence from our ongoing fieldwork in Melanesia. The table is for demonstration purposes only, and should be adapted as needed to fit the circumstances of the geographic location of the proposed scheme, the country context, and the proximity of associated physical and social factors.

The valuation components that are derived through this process will produce a much clearer indication of the overall compensation quantum. This figure, which the present value of the loss / infringement, should then be dealt with as a compensation package. This package should have regard for the benefits accruing from the scheme (if any), such as employment opportunities, food and service provision, training, and the current package of notionally goodwill items (such as village benefits, medical fees, schooling, donations and material items e.g. boats / vehicles).

This analysis highlights that the most comprehensive valuation is provided by the synergistic value approach. We discuss this finding and outline how we propose to field test our model in the concluding section.

5 Conclusion and Further Research

This research has identified the complexity of dealing with development on customary owned land in Melanesia. After demonstrating the lack of alignment between customary and western worldviews, we explored examples of compensation arrangements (particularly those impacting indigenous landholdings) from a number of countries. Having articulated our phenomenological transdisciplinarity approach, the international context allowed us to explore four approaches to compensation. We evolved these into a fifth approach, a hybrid, that we analysed through the stakeholder interests of a hypothetical wharf facility on customary land for mineral exportation. We discussed econometric approaches to valuation briefly, before engaging the diversity of approaches in the International Valuation Standards to our scenario. This analysis confirmed that the synergistic valuation approach has the potential to provide the most equitable compensation for land resource development schemes in a Melanesian context.

What remains to be done is to test this ‘equitable pro-development compensation model’ – our hybrid – on a number of live development situations in the region. We are currently in discussion with customary landowning groups, NGOs, a trust and government departments on how we might operationalise our model, in both a policy and practice context. We are also testing the concepts on land professionals in the Melanesian region through a series of workshops, as well as through an international symposium.

Public Private Partnerships and financing urban development

Stakeholder Management an Imperative to Successful Project Delivery: Evidence from Privately Financed Market Projects in Nigeria

Oluwaseyi A. Awodele¹, Stephen O. Ogunlana¹ and Ibrahim A. Motawa¹

Abstract:

Construction works procured using public private partnership arrangement (PPPs) are more risk prone than those procured using other forms, primarily due to the lengthy concession period and the multi-parties involved in the arrangement. There are differing types of stakeholders associated with PPP projects that in turn have multiple and often conflicting goals or needs. Successful project managers therefore need not only to realise that project success criteria relates to the client (i.e. iron triangle, cost, time and quality), but they also need to understand the needs and priorities of the different types of project stakeholders.

This paper focuses on stakeholder management in the context of PPP market projects in a developing economy. Projects, large or small, have knock on effects on local communities and economies. The study elaborates on how stakeholders on those projects have been managed. However, from two different case studies presented in the paper, it was revealed that whereas on one of the projects stakeholders were effectively managed, this was not the case on the second project. Poor management of stakeholders on the second case study explain the poor performance on the project and the failure to satisfy the end users.

The study establishes that failure to understand the needs of all other stakeholders to a project and their priorities leads to project failure. Thus, it is concluded that for successful implementation of PPP projects in a developing economy, especially in a market development that has both cultural and socio-economic impact on the people, adequate consideration should be given to the needs of all the stakeholders. The findings of the study should be useful to PPP promoters in market projects in devising possible ways of managing the different stakeholders involved in privately financed markets.

Keywords:

privately financed market, project success, stakeholder management, sustainable development

1 Introduction

The construction industry amalgamates a wide range of loosely integrated organizations that jointly construct, alter and repair a wide range of different building, civil and heavy

engineering infrastructures. These infrastructures (social or economic) constitute the backbone for economic growth and national development as they contribute directly to economic activities within a nation and improve the welfare of the people. This undeniably underscores the importance of the industry in any economy especially a developing economy.

However, in Nigeria, these much needed infrastructures are in short supply when compared with the demands of the growing population of the country. Global economic melt-down, debt crises and fiscal crises have accounted for the shortage of fund for infrastructure development in Nigeria. Hence, the need for the Nigerian government to rely on the private sector to invest in the development of infrastructure in form of Public Private Partnership (PPPs) arrangement. Unfortunately, despite huge resources being deployed by both public and private in the development of infrastructure in the country, projects still end up with cost and time overrun, and many are completed with compromised specification leaving stakeholders dissatisfied. Therefore, the challenge of how to handle a construction project successfully has attracted substantial research attention in the past decades especially PPP projects that have different types of stakeholders who in turn have differing and conflicting goals or needs.

The aims of this paper therefore, are to revisit the concept of project success from the context of PPP market projects - a kind of project with social connotations using private sector investment - and to elaborate on stakeholder management using lessons learned from PPP markets projects in the south-western part of Nigeria. The result is useful not only to participants in the PPP market projects in Nigeria but also to others would be participants in the developing countries in Africa and the rest of the world with rich cultural heritage.

2 Previous research

A project is a temporary endeavour undertaken to create a unique product, service, or result (PMBok, 2004). Kloppenborg (2009) remarked that a project requires an organised set of work efforts that are planned in a level of detail that is progressively elaborated upon as more information is discovered. According to the PMI (2000) each project typically has a unique combination of stakeholders (i.e. persons or organisation that are actively involved in the project, or whose interest may be positively or negatively affected by the project). All projects, either small or large, go through predictable stages constituting a project cycle. A project cycle according to Kloppenborg (2009) is a collection of general sequential project phases whose names and number are determined by the control needs of the organisation or organisation involved in the management of the project. Hence, an organisation's control needs are to be assured that the work of the project is proceeding in a satisfactory manner and that the results are likely to serve its customer's/stakeholder's intended purpose. A project exists within an environment, populated by stakeholders. The different expectations of stakeholders' can pose significant risks to a project. It is unlikely that the requirements of all stakeholders will coincide. Each will seek to influence the project in order to meet own ends. Pressures from stakeholders can generate change, increasing costs and delay. To manage stakeholders it is necessary to understand whether they are supportive or not and how much power and influence they wield. Chinyio and Akintoye (2008) argue that in terms of decision-making, stakeholders can be considered as being supportive, neutral, or opposed to the project. They further argued that those stakeholders that are opposed to projects are often in the minority but can be very vocal. This implies that no

matter how few or little they may be (i.e. stakeholders opposing the project) they need careful management and if possible to come to term with project ideas or decisions.

Numerous studies have addressed the issue of project success. For example Nguyen, Ogunlana and Lan, (2004) opine that a project is acknowledged as successful when it is completed on time, within budget, and in accordance with specifications and to stakeholders' satisfaction. Crawford and Bryce (2003) suggest that project success can be evaluated from two different dimensions viz: the efficiency dimension – doing the thing right and effectiveness dimension- doing the right thing. Takim and Akintoye (2002) used functionality, profitability to contractors, absence of claims and court proceedings and “fitness for purpose” for occupiers as measures of project success. Others such as Cooke-Davies (2002), Chua *et al.* (1999) clarified that project success is measured against the overall objectives of the project while project management success is measured against cost, time and quality/performance. Baccarini (1999) contends that project success should be measured both in terms of product success and project management success. What this implies is that for project management to be successful, a project manager (PM) needs to understand the objectives of the project as it relates to the client (mostly - time, cost and quality or what is termed “iron triangle” by Atkinson, 1999) and also take into cognisance others that may be affected by the project or those who may affect the project in one way or the other.

Previous researchers have identified the critical success factors (CSFs) that contribute to the successful delivery of large construction projects (Toor and Ogunlana, 2008 and 2009) and PPP projects in particular. For instance Li *et al.*, (2005) identified 19 CSFs for PPP projects in the United Kingdom, Zhang (2005) identified 47 CSFs. Jamali (2004) discusses the success and failure mechanisms of PPPs in developing countries using the experience from the Lebanese construction industry. Abdel Aziz (2007) reported that despite United State's initiatives, the implementation of PPPs has been facing some difficulties. One of the two main impediments identified in the USDOT, (2004) as cited in Abdel Aziz (2007) is local opposition i.e. lack of local community support. Opposition by transportation program administrators/staff was also reported as part of the impediments on another FHWA (2005b) report covering PPP implementation in seven states (see Abdel Aziz, 2007). Olander & Landin (2005) showed how failing to understand and manage external stakeholders can dramatically delay railway infrastructure projects, and surveys show that coping with external stakeholders is perceived as imperative to project success (Calvert, 1995). Moreover, Cleland (1986), had long affirmed that understanding and managing how internal stakeholders within the organisation impact a project is also important, and that managing them at times might constitute a major challenge. Chinyio and Olomolaiye, (2010) suggest that stakeholder management enhances greater competency in relational issues and minimises risks therein. In the opinion of Sutterfield et al (2006) project success comes from the adeptness of project manager in managing the interests of multiple stakeholders throughout the entire project management process. All the foregoing findings and many others affirm the need for more research work in the area of stakeholder management especially in PPP projects.

According to Aaltonen (2011) the managerial importance of stakeholder management has been accentuated in various studies all of which demonstrate that fair treatment of stakeholders is related to long-run survival of the organization (Clarkson, 1995; Freeman, 1984; Donaldson and Preston, 1995; Mitchell et al., 1997; Rowley and Moldoveanu, 2003; Savage et al., 1991). In Aaltonen's opinion, the majority of research on stakeholders has focused on theoretical discussions and debates about the concept of

stakeholders and the nature of stakeholder theory (Donaldson and Preston, 1995; Jones and Wicks, 1999; Mitchell et al., 1997; Rowley, 1997; Frooman, 1999). Various definitions of the term stakeholder exist in current literature. The Project Management Institute (PMI, 2008) defined stakeholders as individuals and organizations that are actively involved in the project or whose interest may be affected as a result of project execution or project completion". The definition is accepted in this paper because of the credibility of the PMI. Chinyio and Olomolaiye, (2010) explain that stakeholder management involves identifying and classifying stakeholders, which in turn facilitates both initial and subsequent engagement with them in a timely, planned and coordinated manner. Stakeholders can be classified as being primary or secondary, active or passive stakeholders depending on their involvement in projects. Winch, (2004) defined project stakeholders as being 'internal' or 'external' to the project. Internal stakeholders are the stakeholders that are formally members of the project coalition and, hence, usually support the project. They are often referred to as primary stakeholders (Cleland, 1998) or business actors (Cova and Salle, 2005). Such stakeholders have a formal, official, or contractual relationship with the project organization. External project stakeholders are not formal members of the project coalition, but may affect or may be affected by the project. Such groups are often referred to as non-business stakeholders (Cova and Salle, 2005) or secondary stakeholders (Clarkson, 1995).

Managing stakeholder therefore, involves managing relationships in order to motivate stakeholders to behave in ways that support the objectives of a firm (Chinyio and Olomolaiye, 2010). Harris (2010) suggested that practical stakeholder management requires the following five considerations: (i) Who are the stakeholders and their interests in the project? (ii) What opportunities do these interests offer the project or firm? (iii) What challenges or threat are thereby presented? (iv) What level of responsibility is appropriate in meeting stakeholder requirements? And (v) what are the necessary strategies demanded e.g. direct dealings, aggressive attitudes or accommodating or a combination of different courses of action? The PM can understand all aforementioned considerations through proper stakeholder analysis, effective communication with stakeholders and applying appropriate strategies and tactics. Manowong and Ogunlana (2010) sum up that having identified stakeholders through the stakeholder matrix created during the project's initiation, the PM should then utilize the attained stakeholder map to better understand the relationships among various stakeholders on specific problems. The next thing then, is for the PM to employ the right strategies in managing and dealing with the identified stakeholders. Weiss (2003) proposed the following tactics for coping with stakeholders (i) approach each stakeholder directly or indirectly, (ii) do nothing, monitor, take offensive or defensive actions with certain stakeholders; (iii) determine whether to accommodate, negotiate, manipulate, resist, avoid or wait and see with specific stakeholders; and (iv) combination of strategies.

Mathur, Price and Austin, (2008) argue for adequate stakeholder engagement. They assert that existing practices view stakeholder engagement: mostly from a management perspective; sometimes from an ethical perspective; less often as a combination of the two; and rarely have any element of the social learning perspective. However, they suggested an approach that will combine all the three perspectives for sustainability. From the foregoing, it is evident that efforts have been made in the area of project success and the impact of stakeholder management on successful implementation of construction projects. Little is known in these areas regarding PPP projects in Nigeria. Liu (1999) asserts that a set of success factors may not be transferable to another project due to the differences in the environmental variables, the nature of the project, the

nature of the stakeholders and their priorities. Furthermore, in a developing economy like Nigeria where the use of PPPs are still very recent, there is the need to review PPP project success in a systematic and comprehensive manner and document opportunities to improve the project management process.

3 Research Methodology

The study employs a qualitative research strategy in a multiple case setting. Data were collected on two PPP market projects within south-western region of Nigeria (i.e. the reconstruction of Erekesan Market in Akure and the Oluwole Urban Market complex, in Lagos Island). Markets, in this context, are infrastructures whereby people trade, and goods and services are exchanged, forming part of the economy. These facilities vary in size, range, geographic scale, location, types and variety of human communities, as well as the types of goods and services traded. Good examples include neighborhood markets, central markets which are held in the centre of town/cities, local markets in villages etc. Aside from having socio-economic importance, markets also serve as places where health information and religious information are disseminated. Political rallies are also held in markets because of the strategic location of most markets in the centre of cities, towns or villages (Awodele *et al.*, 2010). The central place theory of location of market, as observed by Hodder (1965), is true as it is common to see a market in the centre of the town, surrounded by major buildings such as the central church or mosque, town hall and the King's palace.

Case studies may employ either qualitative or quantitative evidence or both. For the purpose of this study, qualitative research strategy using various data collection methods was employed in data collection; involving semi-structured interviews with key project stakeholders from the public and private sectors, questionnaire survey, reviewing of project documents as well as direct observations on site. The case selection was not random but based on purposeful sampling. Market projects have been selected because of their socio-economic and non-economic importance to the community where they are located. The choice of these projects within the region was informed by the need for homogeneity in the data collected and the fact that PPP arrangement was used in developing both projects and they fall within the same geopolitical region of the country.

Furthermore, In case study researches the phenomenon is not isolated from its context but is of interest precisely because the aim is to understand how organizational behaviour and processes are influenced by the organizational and environmental context (Yin, 2009). In order to increase the reliability of the study as a case study research, case study protocol (CSP) was developed for the conduct of semi-structured interview this document act a good guide when conducting face-to-face interview with the interviewee. The number of formal interviews with internal stakeholders on these projects (i.e. from private and public partners on those projects, contractors as well as consultants) who are top management officers of the stratified groups was eightwith four interviewees each from each case study. In addition, the first author spent two weeks each to conduct informal interviews with external stakeholders (i.e. traders and shoppers) and made personal observations which serve as confirmatory evidence to the information gathered from the internal stakeholders.

3.1 Case Study 1

The Erekesan market in Akure, Ondo State was re-constructed following the destruction of the old King's market (Deji's Market) by fire in the year 2000. The market is situated in front of Deji's palace; right at the centre of Akure town. Agreement to redevelop the Old market to an ultra-modern market was reached between the Ondo State Government, Akure South Local Government (public) and Spring Bank plc - then Omega Bank Nigeria plc. (private). The trio formed a special purpose vehicle (SPV) called Sunshine International Venture Limited. The concession agreement was to jointly finance the project with the bank providing much of the finance. Akure South local government provided the land as its own equity share while Ondo State Government contributed 20% of the fund. Two years construction period was agreed and the market was to be operated for a period of 20 years before being transferred to the government. Six contractors were involved in the construction as the whole project was divided into six packages: blocks A, B, C, D, E and Traditional market side. Omega Bank Plc., through its subsidiary mortgage company Omega Saving and Loans, managed the project, while private consultants were employed to design and carry out the initial documentation on the project. With these multi-party nature of the project, five set of stakeholders are identified on the project viz: (i) government (i.e State and Local), (ii) bank, (Omega bank Plc.), (iii) contractors (Six of them), (iv) consultants, and (v) end users (Traders and Shoppers to the market).

3.2 Case study 2

The Oluwole Urban Market Complex (OUMC) in Lagos Island was developed as part of the efforts of the Lagos State government to reposition and redeem the image of the Oluwole area. Oluwole market has been known before, to be notorious for fraud and home to drug addicts. The market is situated on the corner of Martins Street and Nnamdi Azikwe Street in Lagos Island. OUMC is a four floor level concrete structure covering a floor area of about 3,889 square metres with 390 shops and 240 K-Klamps (traditional market stalls) on a site measuring 4,829sq.m. OUMC was equipped with onsite facilities manager, standby electricity supply, 24-hour security, merchandise loading bays and ramps, and other modern facilities. The project is a PPP initiative between Lagos State Development and Property Corporation (LSDPC), ARM Properties Plc. and AZDEC ASC Design Company who, acting together, formed a special purpose company 'The Oluwole Urban Mall Properties Limited' (OUMPL). OUMPL was given a concession to build and operate the market for 25 years. The market development is part of the entire redevelopment plan of Lagos State government to regenerate and rebuild the historic Lagos Island. The market was commissioned by Lagos State governor, Babatunde Raji Fashola in April, 2010 (see figure 1 for a picture of the market).

4 Findings and Discussion

Having described the two cases under study, the findings from the cases are hereafter analysed and presented under the following headings: (i) success of the project, and (ii) reasons for the performance recorded. Following those, cross-case analysis is done to highlight lessons learned.

4.1 Success or failure of case 1

Although, from the perspective of the internal stakeholders in case 1, the project is said to be successful in term of actualising the goal of the venture; i.e. to redevelop the old market into a modern day market that befits the centre of a capital city. However, going by the performance of the project in terms of cost, time and quality, the interviewee from the consultants and the government side felt the project was not successful. One respondent referred to the projects as “*Monumental loss to Ondo State in general and Akure land in particular*”. This is because the project was not delivered on time, to cost and to desired quality. Moreover, from an informal interviews with end users (i.e. traders and shoppers to the market) it was gathered that, overall, users are not satisfied with the facilities. They felt the project fell short of their expectations in terms of effectiveness and efficiency. Furthermore, personal observation of the facility confirmed the claim of the end users about lack of functional sanitary facilities and inadequate parking spaces. Moreover, other project documents like the initial contract sum and the final contract affirm that the project experienced both time and cost overrun (about 12 months completion delay and ₦150 million approximately £683,123.449 cost overrun). Further, visual information as evident in figure 2 shows that while some of the shops are still unoccupied; traders are still seen selling on the road outside the market.

4.2 Reasons for the performance recorded in case 1

Reasons advanced by the end users, especially concerning their dissatisfactions with the market, are as follows: (i) inadequate space for their trading; (ii) inadequate parking spaces which make it difficult for customers to visit the market; (iii) poor sanitary facilities due to lack of water; (iv) poor sales as a result of difficulties for shoppers in locating what to buy; and (v) the high amount being charged for a space/stall in the market compared to similar spaces elsewhere. From the internal stakeholders, it was gathered that poor cost and time performance of the project was due to some cultural issue as well as political problems which arose during the construction phase of the project. As a King's market (Oja Oba), Akure indigenes felt the market should be free, and should accommodate the market women selling traditional goods such as herbal leaves, hens, goats etc. who have been using the old market before. The idea of selling the market at completion also met with strong opposition from the indigenes who felt the cultural heritage of the city should be preserved. In addition, intermittent closure of the market for one festival or the other was cited as another reason for the poor patronage from traders.

4.3 Success or failure of case 2

All stakeholders interviewed adjudged the project to be very successful. Physical observation of the quality of the project also confirms the performance of the project in term of delivering to desired quality. Other facilities such as toilets, water supply/bore hole, and standby electricity supply and on site facilities management attest to the quality of the market as a truly 'modern market'. Documentary evidence on the lease/sales of the market reveals that the entire stall has been let/ purchased. Never the less, some of the stalls remain locked while some were empty when the project was visited in October 2010. Testimonies of some shop owners in the market are indicative of satisfaction with the project. For example, a shop owner remarked, "*the project provided us with an easy and convenient means to acquire a shop within the highly commercial Lagos Island*". Another shop owner said "*The quality of work on the project is commendable*". However, some of the end users interviewed stated that they could not conclude yet since the facility was still very new, but be able to talk competently on the performance of the market after two or three years. Some shop owners remarked that, though the cost of a stall in the market is high compared to what is obtainable elsewhere within Island. They are still satisfied because of other amenities

in the complex. One of them said, “*Obe to dun owo lopa*” meaning “every good thing comes with a price”.

4.4 Reasons for the performance recorded in case 2

The internal stakeholders to the project asserted that the success recorded on this project was as a result of the cooperation they enjoy from the state government and Oluwole royal family. Furthermore, they asserted that the interests of the previous owners of the Oluwole land were taken into account in the development of the project. It was gathered from them that the previous owners of the land were given 39 flats in Shasha housing estate, Alimosho local government area of Lagos State. Moreover, they were also given 39 K-klamps in the market. Informal discussions with some of these previous occupants of the land testify to these claims. One of them said in pidgin English that “*when dem do dis Oluwole...dey no forget us, nah we help dem*”. What this means is that they (the previous occupants) are all instrumental to the success and that when the project finished, the developer did not forget them. It was evident from the discussions that the previous occupants of the land were fully engaged in the process of the development. Their interests were considered during the design and construction process. The developers worked actively with them in deciding how and where to relocate them and the appropriate level of compensation. The former land occupiers were given flats and former shop owners were allocated shops within their ability to pay. These worked in favour of the project as a whole.

4.5 Cross case analysis

From the two case studies, it is evident that in case 1, poor performance of the project is due to poor stakeholder management; whereas the success recorded in case 2 can be attributed to effective or good stakeholder management. In case 2, the relocation of the previous owners of the land is a product of negotiating tactics in stakeholder management and also, allocating some part of the project to them can be seen as accommodating strategy. In case 1, the consultation and negotiation processes were absent or inadequate. This may have been as a result of the market being burnt down. In case 1, when there were serious opposition from market women especially the indigenes, promoters had to set aside the traditional market side for the people to use free of charge. This in turn affected the expected rate of return on the market and had a multiplier effect on the overall prices of stalls in the market.

5 Conclusion and Further Research

This paper has alluded to the importance of market as infrastructure with both economic and non-economic value; which calls for care when managing the different stakeholders involved. Key stakeholders in PPP market projects have been identified and the need to know their interests as input to the process of establishing stakeholder management strategies that best suit them highlighted. Aside from meeting client objectives, effective stakeholder management is an important component of project success for PPP projects.

The performances of two projects have been assessed from the perspective of the key stakeholders to the projects. It is evident that while one of the projects was adjudged successful (case 2) by all stakeholders, the reverse was the case on the other (case 1). The performance of project 1 is very poor and external stakeholders were not satisfied as the project failed to adequately consider every stakeholder to the project.

Emerging from these findings is the need for adequate consultation with all the key stakeholders to any privately financed market project so as to understand their real needs from the inception of the project and to endeavour to keep them satisfied. It is therefore recommended that stakeholder management process should occupy a central place throughout the life cycle of a PPP market project. This requires that people charged with management role in privately financed market projects should seek to improve their knowledge, skill and competencies in working with stakeholders. Government also, should endeavour to invest in the training and development of their staff in this area.

Abstract:

Construction is a high risk venture. In the bid to transfer the risks inherent in infrastructure development from the public sector to the private partner who can best handled them; Nigerian government have sought alternative procurement route in form of public private partnership (PPP) to procure infrastructures needed for the country's economic growth. The selection of private partner (i.e concessionaire) by the public or his professional advisers for construction projects is a critical function requiring careful thought and judgment. A wrong choice may not only lead to acrimonious client-contractor relationship, but also contribute to waste of resources. While many authors have argued for the use of an output-based specification rather than the traditional prescriptive model, many believe the choice should be based on the nature of the project whether it is social or profit oriented project. The paper therefore identified and assessed the criteria used in selecting appropriate concessionaire for PPP projects in Nigeria. Literatures were reviewed to identify evaluation criteria in use on PPP projects. Opinions of professionals who have experience of PPP procurement methods within Ondo State Nigeria were sought through questionnaires survey. The adequacy of these criteria was analysed using relative importance index (RII). The study revealed a disparity in the opinion of the respondents on the adequacy of these criteria. The paper concluded by recommending a transparent and objective competitive bidding process in the evaluation process which is an insurance against corruption allegations; adhering to a pre determined criteria to demonstrate commitment of the government and help in building the bidder confidence; reduction of risk in project execution and spur greater innovation on the part of the bidders.

Keywords:

competitive bidding, concessionaire, evaluation criteria, Ondo State, Public Private Partnership.

1 Introduction

The transition from the previous approach of government in provision of services to the new approach of private participation is evolving with new and challenging practices. This has been applied in telecommunications, energy, transport, water, wastewater, trash collection, ports, and so on. This scenario (Fitchranting ,2004) is bringing about a form of contractual relationship between a public agency (federal, state, local government) and private sector entity, with clearly defined public needs and rewards

like concession contracts. In Nigeria (like most other nations) governments have enacted laws and adopted own strategy in accordance with the local conditions and laws, like (Public Procurement Act, 2007) with the main objectives to: (a) regulate procurement process; (b) establish satisfactory regulatory frameworks; and (c) implement projects with private participation in order to engender transparency, value for money, and competition in the selection process.

However, this new stage requires a synergy of processes to select participant that will ensure efficiency and economy in the whole process. This is because wrong choice of bidder has resulted to failure of projects, criticism by the public, allegations of corruption and kickbacks (Aje, 2008). While many procurement laws/guidelines provide that lowest bidder ("technically and economically comprehensive; "substantially responsive") will be considered for award of contract (Public Procurement Act, 2007), arriving at this may be challenging and require determination.

Hence the evaluation of bidders before award is made critical. The procurement process must follow a logical and systematic procedure designed to cover all aspects - Tendering Procedure, prequalification of bid in appropriate routes like Single-Stage, One-Envelope, Single-Stage, Two-Envelope etc., Bid Evaluation and Procedure using quantitative weighting systems applicable to the procurement mode and concession project concerned (Public Procurement Act, 2007; Worldbank, 2006) - in order to determine the most realistic lowest evaluated bid amongst the bids submitted before the bid closing time on the date specified in the bid documents instruction.

Procurement in P3 does not fit into lowest or highest bid class (Ayuli, 2010) because the choice of best bid is often consider on many criteria by procuring authorities (world bank, 2002). In developing countries, large infrastructure projects procurement are often the target of allegations of corruption and kickbacks (Transparency International, 2006). This scenario is compounded by provisions of many procurement laws stating that lowest bidder (in any way qualified-"realistic"," technically and economically comprehensive', "substantially responsive") will be considered for award of contract (Public Procurement Act, 2007; Infrastructure Concession Regulatory Commission Act (ICRC), 2005). However, (Aje, 2008; Ayeni, 1987) contend that a bidder may not only fraudulently bid ridiculous price (just to win) but also be a bidder with no experience of the project especially where open competitive tendering/bidding process is adopted.

Beside, bid evaluation criteria are not only inadequate but not detailed enough based on assessment and analysis of economic data (ICRC, 2005). Sadly to note is the paucity of data bank making data e.g. interest rate, inflation rate etc unreliable to prepare a realistic price (Shamsudden, 2007). Thorough understanding of procurement modes and project financing options by parties (clients and bidders) is asymmetrical (Ojo and Awodele, 2010), hence evaluation of bid proposals on differing systems (procurement mode and financing option) for same project portends a critical issue for determination. Most invitation to bid adverts fall short of standard requirement contrary to law (Public Procurement Act, 2007). Therefore, this study aims to identify and assess the adequacy of criteria used in selecting concessionaire in PPP projects in Nigeria.

2 Overview of PPP Procurement

The provision of infrastructural facilities by government is becoming a complex process in terms of procurement and financing. Fitchrating (2004) the recognition of these gaps

has resulted in a nearly universal acceptance that the private sector should play a large role in the financing of infrastructure with the public sector being acting as project sponsor or passively as an institutional bond investor. This scenario is bringing about the marriage between the public and private sectors in form of contractual agreement and cooperative venture, building on the expertise of each other, which clearly defines public needs through the appropriate allocation of resources, risk and rewards (NCPP ,2005); Leiringer, 2001).This partnership arrangement can be in different forms as suggested by World Bank(1997):

1. **Service contract:** Under this option, the private sector performs a specific operational service for a fee, for example meter reading, billing and collection. Suitable for power, gas or water supply projects.
2. **Management contract:** In this option, the private sector is paid a fee for operating and maintaining a government-owned business and making management decisions. Useful for specific technical expertise projects.
3. **Lease:** Under the lease option, the private sector leases facilities and is responsible for operation and Maintenance e.g. in the running of energy equipment and petroleum refinery project.
4. **Concession:** Under concessions, the private sector finances the project and also has full responsibility for operations and maintenance. The government owns the asset and all full use rights must revert to the government after the specified period of time. This is currently adopted in the running of Nigeria Airport, seaport and highway (Lagos – Ibadan Expressway concessioned to BI-Courtney Ltd. for the sum of 89Billion naira for 30years.
5. **Build own transfer (BOT):** These are similar to concessions but they are normally used for new greenfield projects. Ibrahim (2007) contented that the private sector (Concession Company) under the arrangement is responsible for project design, finance, construction, operation and maintenance of the constructed public facility. However, ownership is retained by the concession company during the concession period before transfer to the government at the end of the concession period. Ibrahim further stated that BOT is a generic term taking forms like Build-Operate-Own (BOO), Build-Transfer-Own (BTO) and Build-Lease-Transfer (BLT) .The private sector receives a fee for the service from the users. **Build – Own – Operate (BOO)** Under this model, the private sector partner organization(s)design construct, finance and operates a facility for performing public services without transferring ownership of the facility to the public sector. **Buy – Build – Operate (BBO)** involve the transfer of a public asset (facility) e.g land, to a private organization entity under scales contract, who later rehabilitate the facility and operate it in a more cost – effectively manner. Public control is however, exercised through the terms of the control especial at the transfer. **Design – Build – Finance - Operate (DBFO).** DBFO project, a single point of responsibility for design, construction, financing and operating of a new public facility is award to a private entity, with the title to the facility remaining with the public sector. **Divestiture** option can take two forms – partial or complete divestiture. A complete divestiture, like a concession, gives the private sector full responsibility for operations,

maintenance and investment, but unlike a concession, a divestiture transfers ownership of the assets to the private sector.

3 Current Statutory Project Procurement Procedure

In most countries, governments and international multilateral banks and donor agency have enacted laws and bidding guidelines, which intend to serve as bases for legal framework and procurement procedure and proceedings for P3 and other public procurement processes (Public Procurement Act, 2007 and Infrastructure Concession Regulatory Commission Act, 2005 in Nigeria; India ; UNCITRAL, 2004: African Development Bank, 1997)). These laws engender transparency, value for money, competition in selection process. For the purpose of this research, salient parts of most of the procurement laws and procedures can be treated thus:

Invitation to tender

To commence procurement proceeding is by the way of invitation to tender/Bid (ITT/B)/ or Request for Proposal. This is usually through advertisement in national newspapers, official websites and, or tender journal of the procuring authority (Ministries, Departments, Agencies (MDA))(Public Procurement Act, 2007;world bank,2002). This makes the process competitive, ensures efficiency and economy, provokes integrity and fairness and, transparent in compliance with laws and regulations (UNCITRAL, 2004: African Development Bank, 1997; ICRC, 2005). The advert spell out general information like viz; intent to invite for bidding, procurement method, description of scope of work or service, conditions for eligibility, , procedure for collection and placing/submission of bid(venue, time and mode of packaging),opening of bid and other necessary information, duration of concession and a caveat on the bidding(usually stating that lowest bidder (in any way qualified-“realistic”,” technically and economically comprehensive’, “substantially responsive”) will be considered for award of contract. Aje (2008) summarises the major criteria required in bid documents as those dwelling on contractor/bidders technical capacity, financial capacity, commercial capacity, managerial capacity, general information and past experience performance.

Bid Submission

In competitive bidding under local and international bidding procedures, procuring authorities employ suitable routes in evaluating bids, considering the nature of the particular procurement concerned. These are: (i) Single-Stage, One-Envelope, (ii) Single-Stage, Two-Envelope, (iii) Two-Stage, Two-Envelope, and (iv) Two-Stage. The bid documents are usually categorized into technical and commercial proposals (or both combined) and financial proposal.

(a) Single-Stage, One-Envelope Bidding Procedure: In the Single-Stage, One-Envelope bidding procedure, the bidders submit the bid documents in one envelope containing both the financial proposal and the technical proposal, which are opened, evaluated and, following approval of procuring authority, the contract is awarded to the responsive lowest evaluated bidder. This is the mostly used procedure. It saves time and bidders expenses and, helps avoid public allegations.

(b) Single-Stage, Two-Envelope Bidding Procedure: In the Single-Stage, Two-Envelope bidding procedure, the bidders submit bid documents simultaneously in two sealed

envelopes, one containing the technical/commercial proposals and the other the financial proposal. Initially, only the technical/commercial proposals are opened and evaluated without amendments or changes permitted and without reference to price. The financial proposal remains sealed and are held in custody by the procuring authority. Bids that do not conform to the specified requirements may be rejected at this level by the procuring authority, as deficient bids. Following procuring authority approval of successful technical/commercial bids, the financial proposals are opened and evaluated based on price and, the award or contract is made to the responsive lowest bidder.

(c) Two-Stage, Two-Envelope Bidding Procedure. : While this is similar to “Single-Stage, Two-Envelope Bidding Procedure”, however, the procuring authority or bidders negotiates and is allowed/ required to amend or change the technical proposals after been evaluated. Following discussion of the amendments and changes to the technical proposals, the bidders are invited to submit supplementary financial proposals based on the revised technical proposals. Any deviation will result in rejection of the bids. This flexibility ensures that all technical proposals conform to the same acceptable technical standard and meet the requirements of the procuring authority. After the resubmission/replacing of bids, the process runs again, with bidders invited to the opening of the financial proposals. The original price proposals and the supplementary price proposals are opened and evaluated, and award of contract is made to the realistic lowest evaluated bidder. This procedure is good for complex project where expertise is essential.

(d) Two-Stage Bidding Procedure.: This procedure is similar to “Two-Stage, Two-Envelope Bidding Procedure”, but without submission of financial proposals. The objective of the exercise is to ensure that all technical proposals conform to the same acceptable technical standard and requirements. After the evaluation and approval of technical proposals, the second stage is to invite bidders to submit revised technical proposals and financial proposals based on the revised and agreed upon technical proposals. The financial proposals and revised technical proposals are opened and re-evaluated, and the award of contract is made to the responsive lowest evaluated bidder.

Prequalification and Evaluation of Bids

In a survey conducted by (Ogunsemi and Aje ,2006)the main reasons for prequalification and evaluation is to identify and determine those bidders who are interested and capable of undertaking the contract, to keep tendering time and cost to minimum, ensure value for money, to meet client objectives ,for public accountability. Though most procuring authorities usually maintain a list of prequalified contractors, who are often invited to bid, these practices deters others from competing and, perhaps negate the objectives of international donor agencies and particularly for P3 contract procurement (World bank,2001:UNITAR,2010). In Nigeria, Public Procurement Act (2007), section 23(3 a-e) and section 16 state the basic criteria for prequalification documents. Procuring authorities usually decide the methods and scoring processes and weightings before starting the selection process in order to maintain transparency and to increase bidder’s confidence. Criteria may be limited to;

a. Technical criteria.

1. Technical skills- Project Execution Plan (PEP) design, quality Assurance, Construction.
2. Project Organization/Management- Management team, other Key Personnel, Project control/schedule.

3. Past Relevant experience- Evidence of performance in related project.
4. Technology Base- Owned facilities and equipment for the project.
5. Supply chain management- List of Core/Technical Partners, subcontractors, and suppliers.
6. Environmental criteria-Health and Safety, Environmental Assessment (where applicable).

Moreover, section 16(6b-e) Public Procurement Act (2007), requires the legal and commercial capabilities of bidders to be established using criteria which may include:

b. Commercial Criteria.

1. Evidence of Registration with Corporate Affairs Commission.
2. Ownership structure of The Bidder's Company/Special Purpose Vehicle Company.
3. Evidence of Payment of Tax Clearance for at least 3 year.
4. Evident of Sources of Finance/Project Financing Structure/Company Audited Account.
5. Provision of Bid Security- Performance Bond.
6. Statement of Outstanding criminal legal proceeding against the bidder/any company director.
7. Statement /Schedule of Tender Risk.

These criteria can be quantitatively weighted and summed up, determine the minimum scoring level which qualifies a bidder for the evaluation of financial bid.

c. Financial Criteria.

Technical evaluation and or commercial criteria are then used to assess the bidders' financial proposals. Financial capacity can be established by analyzing the bidder's financial statements and whether other financial institutions are supporting its bid. These criteria may not be limited to;

1. Lowest Customer/ Bidder tariff required/Subsidies payable.
2. Highest upfront concession fee or periodic lease payments to the procuring authority.
3. Lowest Price for shares or assets to be sold.
4. Lowest Capital investment committed by the bidder.
5. Service Quality targets (output) coverage (value addition, geographical location etc.)
6. Shortest proposed concession period.
7. Most favorable project financing structure to procuring authority.
8. Least risk sharing/allocation

Financial information on the bidder's working capital and investment plans may also be included to ensure sufficient resources will be available. Consideration is often premised on combination of cost-benefit criteria analysis which fit the project need as couched by the procuring authority.

4 Research Methodology

The study was carried out in two main stages. The initial stage involved in-depth survey of existing laws, guidelines, literature to elicit information and identify commonly agreed criteria in use for infrastructure concession contract bid evaluation. The next stage involved questionnaire survey of active players in the construction concession contract particularly in Ondo State, Nigeria in order to assess adequacy of commonly identify and agreed criteria. The respondents were randomly selected but stratified sampled professionals -Quantity surveyor, architects, engineers, Lawyer and Accountant-(25 in population i.e 5 each) in the public and private sectors that represent project advisors in infrastructure Concession Procurement Contracts. The survey criteria were categorised into three parts; the first part consisted of Technical criteria, Commercial criteria and financial criteria. In stage one, A Yes(Y) or No (N) type scale indicating agree or disagree was provided against each criteria evaluated. The data from the survey exercise were analyzed using the percentage frequency analysis. In table 1, The frequency was calculated by using the following equation:

$$\begin{aligned}
 &\text{Percentage Frequency (F) = \%} \\
 &N_1 = \text{Number of (YES) agree} \\
 &N_2 = \text{Number of NO disagree} \\
 &N = \text{Total number of respondents} \\
 &F = \frac{N_{1,2}}{N} \% \dots\dots\dots\text{equation 1.}
 \end{aligned}$$

$$\text{The Mean Percentage(M) = } \frac{\text{sum of Percentage Frequency(M)}}{\text{no of criteria}} = \frac{\sum F}{Nc} \dots\dots\dots\text{equation 2}$$

In table 2, to analyze questionnaires’ data, two statistical methods were used. At first, frequencies of the various answers were calculated (in percentage). Then the Relative Importance Index (RII) was calculated. In this case, a rating scale of 1-5 was chosen when ‘1’ represents the lowest effect level and ‘5’ represents the highest effect level.

The RII equation is:

$$\text{RII} = \frac{\sum yx}{\sum x} \dots\dots\dots\text{equation 3}$$

Where y represents the given rating by the respondents to each factor on a range of 1–5 (with ‘1’ representing ‘not adequate ’ and ‘5’ representing ‘extremely adequate’) and x represents the percentage of respondents scoring.

Further numerical values calculated by the formula were classified differently varying from 6 to 10 (due to the indices obtained) in defined significance intervals of 0.8 as the ‘rank agreement factor’ thus:

- 6.00 ≤ ‘not adequate’ (NA) ≤ 6.80
- 6.80 ≤ ‘somewhat adequate’ (SA) ≤ 7.60
- 7.60 ≤ ‘adequate t’ (A) ≤ 8.40
- 8.40 ≤ ‘very adequate’ (VA) ≤ 9.20
- 9.20 ≤ ‘extremely adequate’ (EA) ≤ 10.00

5 Findings and Discussion

Review of various statutory regulations and laws on procurement of public goods and services and from extant literature as shown in table 1 below, revealed that, 85% of the laws/literature surveyed agreed to Technical criteria as adequate. Particularly, criterion like; Technical skills(meaning- Project Execution Plan (PEP) showing design, quality Assurance ,Construction),Project Organization/Management(meaning- Management team, other Key Personnel, Project control/schedule) and Past Relevant experience(meaning- Evidence of performance in related project etc are important. The Commercial Criteria attracted 92% of surveyed laws/literature .Criteria such as Evidence of Registration of company; Ownership structure of The Bidder's Company/Special Purpose Vehicle Company; Evidence of Payment of Tax for at least 3 year; Evident of Sources of Finance/Project Financing Structure/Company Audited Account etc are notable. This is in tandem with section 16(6b-e) Nigerian Public Procurement Act (2007), which requires the legal and commercial capacity on bidders. The financial criteria have overwhelming agreement of 100% adequacy. Notable criteria include Lowest Customer/ Bidder tariff required/Subsidies payable, Highest upfront concession fee or periodic lease payments to the procuring authority; Lowest Price for shares or assets to be sold; Lowest Capital investment committed by the bidder etc.

Source; Authors Survey; A= Public Procurement Act,2007;B= Infrastructure Concession Regulatory Commission Act,2005 , C= Ghana Public Procurement Act ,2003 ;D=United Nation Development Programme(UNDP); E=Worldbank(2002);F=The African Development Bank (AfDB) (1997) ;G=Asian Development Bank (2006); H= Aje O.(2008);J=Ayuli J. (2010);

From the analysis in Table 2 show below, given the limitation of the data available, it is evident that the majority of respondents agreed to large number of the criteria as significant and hence very adequate for evaluating bids. For technical proposal respondents agreed that somewhat adequate with an average RII of 7.39 while project organisation (RII, 9.50), technical skills (RII,7.33) and supply chain management RII,7.50) were adjudged very adequate criteria for bid evaluation. Again, Schedule of Tender Risk(RII,9.00), Ownership structure of The Bidder's Company/Special Purpose Vehicle Company(RII.7.67) and Statement of Outstanding criminal legal proceeding(RII,8.20) were very adequate for evaluating commercial bids. Capital investment cash flow analysis (RII,9.50) forming part of the financial bid was rated extremely adequate for bid evaluation by procuring bodies.

However, from the three major areas of criteria required for bidders' evaluation (Aje, 2008) argue that there seem not to be a universal/conventional check list. Besides Procurement in P3 does not therefore evaluate based on single criterion say lowest or highest bid (toll price) like most traditional bid evaluation process, due to variables associated with it.

Source; Authors' Survey.

Since the main objective of this paper is to identify and assess evaluating criteria implore in determine most responsive evaluated bid in P3 concession contracts, it can be deduce from the study that:

- I. The main purpose of bid evaluation is to determine the most responsive lowest evaluated bid, the process which is premised on evaluation criteria. These criteria are often stated in some procurement laws / procedure /guidelines amongst which are Public Procurement Act, 2007 and Infrastructure Concession Regulatory Commission Act, 2005 etc in Nigeria - in order to engender transparency, value for money, and competition in the selection process.
- II. There is consensus that major criteria required for bid evaluation are those dwelling on bidders' technical capability, commercial capability and financial

capability as requested in the examined laws and guidelines; and these criteria are found adequate especially for prequalification and evaluation processes.

- III. However, some criteria for prequalification are preferably be quantitative and others qualitative since quantitative criteria are more directly applicable and transparent, and qualitative criteria require a merit point system but be minimally used for aspects that cannot be quantitatively measured.

As an antidote to the seeming acrimonious Nigerian procurement process, adhering to a procurement plan and pre determined criteria for the bidding process would demonstrate commitment of the government and help in building the bidder confidence. In designing the bidding process therefore, it is essential to prequalify potential concessionaires(Armando ,1998; CRISIL (2006) to serve three purposes-first, it helps to ensure that only those firms with the requisite technical /commercial capacities to operate the project/concession participate in the bidding; Second, a defined number of bidders (resulting from the prequalification) may stimulate greater effort on the part of prequalified firms to prepare better financial proposals and will make it easier to obtain feedback on some aspects of the bidding documents (especially the draft concession contract) from those prequalified bidders and third, the number of applicants for prequalification will give a good indication of the risk measured by the market. The competitive process in the evaluation procedure can spur greater innovation on the part of the bidders and this can only benefit the procuring authority.

Depending on the type of P3 mode, so will the evaluation criteria fluctuate. Nigerian procuring authorities and investing concessionaire should be more concerned with the technical criteria included in the bids, while the bidder's financial proposal will need to assure the procuring authority on sufficiency of financial resource, financing plans in terms of project financing option etc (World Bank, 2006; ILI, 2007) as emphasized in the laws, guidelines of some international organizations and Ghanaian Procurement Law

6 Conclusion and Further Research.

A transparent and objective competitive bidding process is often seen as an insurance against corruption charges. This needed to be supported by adequate evaluation criteria, complete documentation of developments at each stage of the procurement process, objective decision making and transparent sharing with all affected parties. These are useful ingredients in ensuring a successful competitive bidding process, ensures selection of most realistic, substantially responsive bidder, who may not have nominally lowest bid price. Creating an evaluation mechanism through formation of high level tender board and evaluation committees would lend the bidding process credibility. Procuring authority need to establish a strong bid management structure able to handle the complexities of procuring the project and managing the bidding process. A competent and efficient procurement management team, linked to careful planning and coordination of the procurement process, ensures success of the selection proceedings.

It is important to examine the sufficiency of the information available to bidders and its compliance with standard requirements by law, guidelines etc . This is essential because, it could well noticed in Nigeria many concessionaires infrastructure contracts evolve unnoticed, and bid adverts fall short of standard requirement resulting into public outcry for foul.

Retail property - shopping centers, big box development, logistics and distribution

When the Going Gets Tough, the Tough Gets Going: etailers' Reactions during Recession

Dr Kevin Tang, Stuart McAuliffe

Institute of Sustainable Development & Architecture
Bond University,
Gold Coast, Australia

Email : ktang@bond.edu.au

Abstract:

Phases of economic downturn can harshly affect the performance of major economies in general, and the retail industry in particular. In spite of that, not all retailers are equally affected by recessionary phases, with some looking at it as an opportunity to further invest and create competitive advantage while some others resorting to cost cutting and waiting for the recession to pass. By using the recent economic downturn as a basis, the purpose of this paper is to investigate what are the retailers' actions towards the economic downturn and assess how their actions differ across different retailers in terms of size, location and sector of retailing. A total of 25 stakeholders associated with the retail sector (ranging from fund managers to store owners) were invited to participate in face-to-face interviews, resulting in 15 in-depth interviews across a wide range of retail categories. These exploratory data were combined with a review of the literature to explore retailer actions to the recent economic downturn. This paper suggests that there are growth opportunities for retailers during the trying times of economic downturn. Specifically, this paper suggests that large retailers see this as an opportunity to invest in Corporate Social Responsibility (CSR) practices as a means to aid in the recovery of the recession in terms of reducing costs and beyond in terms of developing competitive advantage. Other strategies include: Customer Relationship Management (CRM), differentiation via personalised service, realignment of marketing to changing consumer behaviour(s), and reduced costs and investment. The focus of this paper is specifically limited to the SEQ region and, as such, its generalisability to other region(s), states may be somewhat limited. Past research reveals that not all the retailers are equally affected by recessionary periods. Given this, the value of this paper lies in providing insight into strategic react to an economic downturn, and providing a foundation for examining these strategies and their link to retail performance via quantitative research.

Keywords:

Corporate Social Responsibility (CSR), Customer Relationship Management (CRM), economic downturn, retail

1 Introduction

As the recent economic downturn has drag over the 18 months mark, times have proven increasingly challenging especially for Australian retailers, as they have for retailers in other developed markets globally. The recent recession is most unique with regard to

the duration of its recovery, with the majority of economists expecting it to extend into 2011, a period of over 18 months. This compares to previous global recessions, which, on average, have been no longer than 11 months in duration (Gascon, 2009). While the global economy is experiencing the worst recession in over 70 years (Oliver, 2009), the Australian economy have remained relatively resilient. This is due to a combination of factors such as the extended tail of the resources boom, rapid policy action by the reserve banks in the country and government stimulus packages and infrastructure spending, and generally more robust financial systems (Oliver, 2009).

One of the most disturbing global indicators of the downturn is the decrease in real retail sales, particularly in the USA and Europe, with the severities of these declines experienced thus far consistent with past recessions (Davies, 2000; Gascon, 2009). The current downturn has, however, been marked by a huge performance disparity between retailers (Baker, 2009) and when looking to past recessions, research suggests that the retail sector is supported by previous academic research which suggests not all retailers are equally affected, and manage the effects of a recession in varied ways (Srinivasan et al., 2005). While Srinivasan et al. (2005) suggest that some organisations view recession as a time to invest and establish competitive advantage, in practice, many organisations immediately focus on cost saving measures and reducing staff numbers in times of an economic downturn.

In February 2011, major Australian book retailer, Angus and Robertson, announced retrenchments of over 321 jobs and closure of its 37 stores over a 3 weeks period. This move further sparked a series of “attacks” by consumers regarding the company’s loyalty to its workers, community and the Australian public in general, which negatively affected sales for months following and consumer brand perception to date (Sharp and Zappone, 2009). Other retailers, such as iconic Australian department store, Myer, and supermarket giant, Coles, have made substantial strategic investments despite the downturn. Myer invested most heavily in store refurbishments and the redevelopment of their customer loyalty program (Myer One), which resulted in a 15 percent growth in profit for the 2009 financial year (Myer, 2009). Coles similarly shrugged off the downturn to announce a 12.8 percent jump in net profit to almost AU\$2 billion, which was built on the back of investment in its supply chain operations, which generated significant returns and cut expenses (Gardner, 2009).

This paper seeks to attend to two central questions: first, what are the probable strategic reactions to the current economic downturn by retailers? Secondly, how do these reactions vary across retail organisations in terms of size, geographic location and sector of operation? The answers to these are significant for both managerial practice and theory, particularly given the impact of the recent downturn and the increased pace of change in business cycles (Srinivasan et al., 2005). We will now demonstrate the background of the research, follow by the outline of the qualitative methods used to collect our data, followed by the conceptual model that arises from our data and discussion of the findings.

The conclusion comprises of recommendations for retail practitioners, address limitations of the paper and propose directions for future research.

2 Literature Review

There are limited academic evidence in the area of strategic react to economic, with only a few articles in the leading journals addressing the issue (Coulson, 1979; Cundiff,

1975; Srinivasan et al., 2005; Yang, 1964). Outside of these list there is some discussion retailer react to recessionary periods (Bradley and Taylor, 1992; Dawson and Larke, 2004; Davies, 2000; Piercy, 1983; Simmons, 1981; Simmons, 1983). In particular, a few key strategies and opportunities that took place during recessionary phases are discussed, which include (but not limited to): opportunities for merger and acquisition, managing supplier relationships through rationalising product lines, information exchange with suppliers, emergent market segment opportunities, capitalising on the online channel, establishing discount chains, introducing private-label products, and reducing prices to mainstream stores (Bradley and Taylor, 1992; Davies, 2000; Dawson and Larke, 2004). Yet, these strategies can have mixed effects towards different retailers, and indeed, not all retailers are impacted equally by recessionary periods, with some retailers experiencing growth through aggressive investment and capturing the market share of competitors (Srinivasan et al., 2005).

Usually, most retailers respond to recessionary periods by altering their corporate behaviour as consumers adapt their consumption behaviour. The way an organisation handles change in the environment (i.e. a recession) drastically affects both the level and type of react (Dutton and Duncan, 1987; Dutton and Jackson, 1987). For example, retailers that view a recession as an opportunity perceive that they have control over both the situation and the resultant outcome, and therefore focus on investment (e.g. building extension, brand extension). Retailers that took the recession as a threat, recognize a lack of control over the situation and the resultant outcome, and respond by conserving resources. Srinivasan et al. (2005) propose that backward-looking or defensive strategies are way of the past and suggest firms need to proactively engaging with consumers during recessionary periods.

Similar research suggested that there are a number of variables that impact a firm's strategic react to a recession (Shama, 1993). One variable is geographical location, or region, as different regions constitute different economic entities, which might be experiencing different economic climates with different consumer needs. For example, several authors have reported differences across US states in recessionary conditions (Sebastian, 1989; Rex, 1990). A second variable is the retail-operating sector, with the underlying theory behind sector-level differences being that different sectors may experience different, even opposite, economic climates at the same time (Milward, 1988). For example, in Australia, the food and beverages sector has been particularly strong during the recent economic downturn (Australian Food News, 2009). Finally, organisational size has been shown to impact firm performance during recession (Shama, 1993). Larger retailers possess more market power and resources, which can assist in cushioning the impact of a weak economy. On the other hand, smaller retailers might operate in a protected market niche to ride through the recession, while others may be unable to borrow needed cash and potentially be forced to exit the market.

Practically, many retailers also react by taking far-reaching strategic realignment in an attempt to maintain or improve current financial performance. Some of the more common strategies include cutting costs, production and investment, entering foreign markets, working more with equity capital, improving efficiency, and re-structuring debt (Beaver and Ross, 1999; Pearce and Michael, 1997). Often, cost reduction is automatically associated with a smaller workforce, or reduced working hours. However, there are counter-arguments against the redundancy strategy, with research showing that downsizing results in mixed effects on organisational performance (Cascio et al., 1997; Pfeffer, 1998). For instance, Cascio et al.' (1997) study of the impact of downsizing on

performance over a 15 year period and found that reductions in employment was not translated into improvement in performance in any way across all firms they studied. In fact, reactionary strategies such as workforce downsizing during a recession may have negative impacts by eroding customer loyalty in the longer term (Pfeffer, 1998).

From our literature review recollection, it is clear that further research is imminent to provide further understanding of the strategic choices that retailers make during recessionary periods, evaluating how these actions differ across retail organisations and linking these decisions to key performance outcomes such as revenue growth and profit. This paper addresses the first two of these three areas so as to assist retailers in their recessionary decision making. With this in mind we explore retailers' strategic reactions to the current economic downturn, to identify and compare differences across the retail industry based on organisational size, geographic location, and the specific sector of operation.

3 Research Methodology

Given the exploratory and qualitative nature of this enquiry, in-depth interviews were deemed most appropriate to deeply explore and capture retailer perspectives on strategic actions to the economic downturn. Consistent with theory building research and the discovery-driven purpose of the study, our sampling technique sought to generalise theory rather than be statistically representative. Data were collected from a range of individuals working in or associated with the retail industry, and included fund managers, senior managers, retailers, retail consultants and suppliers. A total of 50 invitations were sent to potential interviewees, resulting in 15 in-depth interviews.

The interviews followed a semi-structured format (Mick and Buhl, 1992) to allow for questions and discussion to flow naturally. Questions started broad, probing on the effect of the economic downturn on the retail industry in general, and appropriate strategies to navigate through and recover from the recession. Floating prompts were used for deeper meaning and understanding of the actions and issues of interest as they arose throughout each interview. Paraphrasing was also used to clarify interviewees' actions, and to ensure the interviewers understood the respondent's react and allow for any follow up questions (Strauss and Corbin, 1998). Interviews lasted between 30 and 45 minutes and actions were recorded with an audio-tape and transcriptions written for analysis.

Two interviewers were used in the data collection process to reduce the role of bias (Lincoln and Guba, 1985). Analysis occurred after each interview to identify themes, commonalities, and patterns, and to allow the actions to inform subsequent interviews. After an initial careful review of the transcripts, open coding was conducted, whereby text from each interviewee was classified into emerging categories (Strauss and Corbin, 1998). As part of this process, triangulation took place to check the credibility and validity of the information gathered, and whereby multiple perspectives were used to interpret a particular theme or pattern.

Throughout the study, a number of methods for improving the quality of the research were adopted. First, data were triangulated from multiple primary and secondary sources, collected from a range of individuals associated with the retail industry and across a variety of retail sectors, as well as company literature and trade and academic sources focused on the economic downturn and retail trends. Second, all three

researchers provided independent interpretations of the findings to ensure consensus. Third, three respondents were given the opportunity to provide feedback on initial findings. These three sets of activities all reinforced the reliability and construct validity of conclusions.

4 Findings and Discussion

We now reports on and discuss the findings from the in-depth interviews. It is important to note here that five key strategic actions for managing the recession were identified. However, given that some of these actions could naturally apply to any recessionary period (i.e. differentiation, repositioning of offer to changing consumer behaviour, and cost cutting measures), only those that are unique to the recent economic downturn and are mediated by organisational characteristics, are discussed. Excerpts from the interviews are used to illuminate and contextualise the key themes, which are presented in the conceptual model (Figure 1).

The conceptual model implies that there were five key themes emerging from our qualitative inquiry. The model also suggests that the macro environment (in this case, the economic downturn) impacts retailers' strategic operating decisions and these decisions are mediated by certain variables. From the literature review and in-depth interviews, we focused on three potential mediating variables between the macro environment and retailers' strategic decision making. Based on our discussions, two of the moderating variables play an equally important role. First, we found that corporate social responsibility (CSR) was mediated by the size of the organisation. Second, we found that customer relationship management was typically related to retailers in the fast moving consumer goods (FMCG), supermarket, and convenience sectors – arguably with large product assortments and large amounts of data available to mine. We did not find major differences between the strategic actions of our interviewees based on geographic location (regional or suburban SEQ). However, it is possible that these strategic actions may in fact be mediated by geographic location if this study was conducted in a bigger scale. While most of the strategies uncovered here are arguably intuitive, it was surprising to note that CSR practices were underpinned by economic, environmental, and competitive reasons as a result of the economic downturn. This supports Srinivasan et al.'s (2005) view that some organisations engage in proactive marketing during recessionary periods, and that these firms tend to view the recession as an opportunity. The two themes which appear to be unique to the recent economic downturn or to retailers in SEQ, which are presented with solid borders in Figure 1, are now discussed.

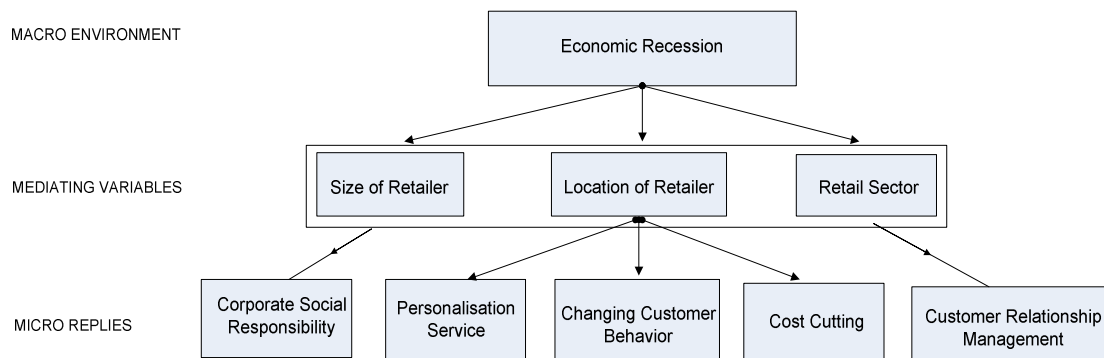

FIGURE 1. Conceptual Model

4.1 Corporate Social Responsibility (CSR) practices

Several of our informants viewed the issue of CSR as a retail strategy that will lead to cost savings, customer awareness and satisfaction and increasing staff morale during the recession, as well as aiding in the recovery process ahead. However, this view was largely expressed by retailers that were relatively large in size (i.e. with corporate staff levels in excess of 100). While additional investment during an economic downturn is not new (Srinivasan et al., 2005), the notion of investing in CSR practices during such times is new. Looking back 10, 20, or 30 years, other CSR movements lost momentum in the face of recessions, but the recent recession is different, as the CSR mindset is now much more solidified (Neff, 2009).

Our research suggests that retailers, particularly those large in size, are already, or are in the planning phase of, investing heavily in this area as a means to recover from the recession, increase business performance and gain competitive advantage. As part of this discussion, corporate social responsibility was broadly highlighted as an important metric and one which requires close monitoring and control. The following passages reflect this perspective:

The way we approach [CSR] is that it reduces costs. For example, we are about to charge for carry bags, and we have done testing to show that we will be able to reduce usage by 80 percent and that will take a huge cost out of our operations. We will take the profits from the money and reinvest it in the community. So once customers are on board, we get the tick for reinvesting it in the community, but we also get a tick from our cost saving. We have reduced the carbon footprint of our supply chain in the last 12 months by 40 percent. The fact is that as a consequence, the associated operating cost reductions are significant. The way we approach sustainability is that it either reduces cost or saves us money. We have had a major focus this year on "grow your own veggies"; we just thought it was a nice little promotion. But when it started, before we knew what we were doing, we were into several hundred thousand dollars of sales a week. It just took off beyond our wildest dreams. We are not tree huggers and do not do it for the sheer hell of it [. . .] Another thing we have just done in terms of green behaviour is review our waste management, and through careful management systems we have reduced our costs and reduced the amount of land fill that we put out. It [green and sustainable retailing] makes good business sense (P4).

CSR is a big thing that underpins everything else and is not going to go away [. . .] An important aspect of this in our industry is about eliminating waste [. . .] a recession is the ideal time to cut unnecessary costs and save money through adopting more efficient ways

of doing business. We have looked at our distribution chain in terms of its carbon footprint and we ensure that no trucks are driving around the country at less than full capacity. The bottom line is that our per box distribution costs are down, we attain fuel savings and we are reducing the carbon emissions of our network. Another aspect we have just invested heavily in is environment-friendly buildings. To us a green office space is about more than getting recognised by the green building council, we expect that it will have a direct effect on our employees' morale, the number of day's sick leave they take and position us as an employer of choice for graduates. We take a holistic approach to green and sustainable practices, it is much more than lip service, and during the economic downturn we are seeing cost savings which will continue into the future (P9).

These perspectives are particularly forward-thinking given that research by Nidumolu et al. (2009) with CEOs from 30 large corporations in the USA and Europe identified that many are of the view that the more environment-friendly the organisation is, the less competitive they become in that such investment will increase costs and not deliver immediate financial returns. Nonetheless, one of the key findings of their research was that CSR is a combination of both organisational and technological innovation that yields both bottom-line and top-line returns; environmental-friendliness lowers costs as companies essentially reduce their inputs and generate additional revenues from sales to new consumer segments, improved products or new businesses streams.

This argument is further supported by trade research undertaken by global management consulting firm A.T. Kearney (Mahler et al., 2009), who examined 99 companies across 18 industries, including retail, with a strong commitment to sustainability. The study compared their performance with industry averages and found that in 16 of the industries studied, companies committed to sustainability outperformed industry averages by 15 percent over the six months from May through to November 2008. Together these findings suggest that investing in sustainability for the long-term may be the best way to protect an organisation's value through good times and bad.

4.2 Customer Relationship Management (CRM) for personalised offerings

The second theme that emerged from the interviews which is distinctive to the recent recessionary period related to tailoring personalised offerings through customer relationship management (CRM). Discussions around effective strategies to combat the recent recession also focused around the importance of consumer intelligence, particularly through better utilisation of existing data sources. It is important to note, however, that this discussion tended to exist in FMCG retailers from the supermarket and convenience sectors. These are sectors that have substantially large product assortments and as such, are able to access large amounts of information from purchase scan data and customer loyalty programs. Many of our informants believed that, as a result of the economic downturn, it has become increasingly important to understand consumers – not only in terms of who they are (i.e. demographics and psychographics) but also in terms of their behaviour (i.e. basket analysis), which can then act as the basis for innovative ideas, products, and more precise marketing tactics. Through CRM and analysis, it was broadly recognised that more strategic and personalised product and communication offers can be developed and used to increase individual basket sizes:

Retailers marketers typically begin with a shotgun [. . .] they put an advertisement in the paper promoting a product [. . .] but 99 percent of people may not see it, and it's a potential waste of funds [. . .] meanwhile Carrefour have shown that you can use data to understand your shoppers better and target your marketing efforts. They have been able to identify not only what people purchase, but have also been able to identify ways in which they can

target particular segments of their customers – the special offer they send one customer may be very different to the special offer they send another client. You can reward different types of customers based on their behaviour in your store (P3).

This thinking is an extension to the shift in retailing from being product-centric to customer-centric and having a “one-to-one” dialogue with customers (Beatty et al., 1996). It is within this context that retailers are also shifting from mass marketing and advertising activities to more targeted and personalised relationship-building activities (Spellings, 2009). This approach is also important given the current focus on reducing operating costs as it reduces wasted time and money on unfocused campaigns to a broad audience, and thus lowering marketing costs. Leading retailers have reported impressive marketing results from campaign personalisation. For example, conversion rates have grown from 2 to 11 percent in certain categories, repeat purchase rates have risen by more than 100 percent, and average transaction sizes have increased by 10 percent (Cataldo, 2000).

Respondents also discussed the value in sharing customer data with suppliers in order to work more collaboratively and in identifying mutually beneficial opportunities in effectively meeting the changing needs and expectations of consumers. These thoughts are consistent with the findings of Davies (2000), which suggests that retailers effectively use data to aid in the retailer-supplier relationship during tough economic times:

It is important to understand consumers and their shopping behaviour by obtaining data on consumer purchases at the point of sale. Not only to track how well products sell, but to see what products go well with each other. This information is very valuable [. . .] We are also able to get data from loyalty cards and are able to match customer demographics with this purchase data. With this information we are not only able to tailor our offer, but we are able to control our inventory levels in stores. The other benefit that there is with this kind of information is that it is very valuable for suppliers, and it can be sold back up the supply chain too (P2).

For many retailers, supplier collaboration is something of a new concept; many are cautious about sharing sensitive sales data. More and more retailers are, however, reaping the benefits of working more in partnership with suppliers. In recognition of this, a number of savvy retailers around the world are developing and implementing supplier collaboration processes and the tools to support them. For example, manufacturers whose products are sold in Sainsbury's, the second largest food grocer in the UK, are able to purchase a combination of loyalty and transaction data to find out what type of customer is buying their products and how new product launches are faring (Whitehead, 2003).

5 Conclusion and Further Research

With this paper we set out to identify the strategic actions that retailers are employing to combat the current economic downturn and qualitatively evaluate how the size of an organisation, its geographic location (i.e. South East Queensland) and the retail sector the organisation operates within may mediate the relationship between the external environment and the implementation of strategic actions. While our research reveals several strategies that have been identified in previous research (i.e. differentiation, realignment of offer to changing consumer values, and reduced costs and investment), the contribution of our research lies in two areas.

Our first contribution is in terms of the two key themes uncovered which are unique to this recession, or to the region. The first of these is that large retail organisations in South East Queensland see investing in corporate social responsibility practices as crucial in aiding in the recovery of the recession and beyond. This is important as adopting such practices brings financial benefits through reducing waste and additional sales to scrupulous consumers, but also because environmental sustainability offers the chance to establish a position as a market leader and gain competitive advantage (Srinivasan et al., 2005). In addition, when genuine environmental leadership is rewarded in the marketplace (with market share, price premiums, public respect, and increased visibility), it motivates all industry players to innovate and shift their current thinking behind products, technologies, processes, and business models. This can have flow on effects to companies approach to innovation (Nidumolu et al., 2009).

The second theme unique to the recent recession is customer relationship management (CRM) for personalised offerings. This theme uncovers the importance for organisations to achieve a new level of customer intimacy. Managing customer data effectively can also assist retailers in understanding a customer's lifetime value, which can be used to plan customer acquisition, retention and growth strategies. A related retail priority lies in the utilisation of customer data for segmentation purposes as a means to grow specific niches and incremental revenues. Once a customer base is segmented into groupings of customers who think and behave in a similar way, retailers can begin to see patterns emerge that inform each group's preferences and needs (Chau, 2007) in order to deliver personalised, customer-triggered messages that result in improved loyalty to an individual retailer or retail chain (Cataldo, 2007).

Our second contribution is in the development of a conceptual model of retailer strategic react to recessionary periods. This model forms the bases for future research where quantitative analysis can be applied to examine the relationship between the retail strategies uncovered and key retail performance measures. Such research will provide valuable insights as to the effectiveness of strategic actions to recessionary periods and provide retailers with the tools to manage future recessions. It would be a logical next step to test this conceptual model and assess the relationship between these strategies and retail performance metrics. Furthermore, global comparisons of these strategic actions would be worthy of investigation to establish if they are indeed specific to the region.

It is important to note that the results presented here should be interpreted relative to certain limitations. Whilst the data is enhanced due to the fact that we were able to interview a range of strategic and practitioner thought leaders in the field of retailing, we recognise that the scope of the research is limited to Australia's South East Queensland region. This has some potential implications for the generalisability of the results. How the recent economic downturn might impact retailers nationally and internationally, and the long-term impact of the changes in consumer behaviour on retailers, are areas worthy of further investigation. It is also worth noting that our respondents were drawn from medium to large size retail organisations and therefore the findings may not apply to smaller retailers. Finally, as previously noted, given the studies focus on retailers in Australia's South East Queensland it is possible that the strategic actions discussed in this paper may in fact be mediated by geographic location if this study was conducted nationally. Despite these limitations, our findings provide retailers with insights as to how investment in corporate social responsible (CSR) practices and using customer relationship management (CRM) to deliver personalised

offerings can be a means of developing competitive advantage in times of economic downturn. Our data suggest that some retailers are already pursuing these strategies, and time will tell if these retailers will exceed competitors in terms of market growth during the recession and beyond.

Risk management

Insights into Capital Program Audit Effectiveness

Alexia Nalewaik¹

¹SKEMA Business School,
Lille, France

Email: alexian@qsrequin.com

Abstract:

Complex projects and mega-programs tend to experience great volatility, resulting in overspending and significant delays in completion. The need is greater than ever for careful oversight of these endeavors, especially those using public funds. Although audit is the most commonly used oversight method, traditional performance audit techniques and standards are insufficient, providing a mere illusion of adequate administration. The question becomes one of how audit can be improved, and stakeholders satisfied regarding program management, expenditure visibility, and risk.

This paper builds upon previous analyses of project complexity, stakeholder expectations, and obstacles to audit, and advocates an assurance-based approach that focuses on governance, accountability, and risk mitigation as project oversight tools. The approach is grounded in experience, supplemented by empirical research of audit findings from over 600 projects, and is being realized in practical application. This paper will also review more deeply the study population of audit data, providing more insight into audit results and effectiveness.

Elements of the assurance methodology are currently being applied on:

Los Angeles Community College District, Bond program, \$5.725 billion

MGM Resorts International-Dubai World, CityCenter Las Vegas, \$9.1 billion

Autoridad del Canal de Panama, Third Set of Locks, \$5.25 billion

Keywords:

accountability, audit, construction, governance, risk management

1 Introduction

Where owners have more to construct than funds available, or are experiencing cost & schedule overruns, there is often a heightened atmosphere of expenditure awareness. On construction mega-programs, this is the norm rather than the exception. Consequently, stakeholders for both public and private sector construction programs are demanding greater accountability for and transparency of expenditures, and stricter governance.

Audit represents one independent oversight method utilized in construction. However, variability in audit sampling and review techniques, team composition, quality and availability of data, and other factors significantly affect the results produced by the audit. Thus, the effectiveness of audit may be limited as a construction oversight mechanism. Available literature on the topic of construction audit is sparse, and often

designed to teach accountants about the industry of construction instead of providing audit methodology guidance. There is very little published information available for practitioners and / or academics, and next to none for the entities audited. Yet, in order to best define the scope of the audit, phrase a solicitation for services, and select the audit team, auditees need to understand the factors that impact audit results.

The research agenda grew from a suspicion that construction program performance audits were not meeting stakeholder expectations and/or the audit scope did not include the depth and breadth of review promised. This stemmed from the author's significant experience in construction audit and cost/risk management, and discussions with clients and peers. Specifically, the author observed that some audits appeared to be more effective (generate more qualitative findings and/or questioned expenditures) than others, and realized that certain audits conducted did not match the defined scope.

An increase in the number of grand jury investigations of construction projects (per California Penal Code Section 933.5), conducted in response to citizen complaints, corroborated stakeholder concerns about the construction programs, especially when the grand jury surfaced more serious findings than the routine controls errors reported in the performance audits. Similarly, State and City Controller audits of construction projects validated stakeholder complaints, and caused consternation over the quality of audit reports when the supplementary audits resulted in jail time for construction program leaders, findings not discovered by the performance audits. During the course of this dissertation, 'investigations' of publicly-funded construction programs by local newspapers significantly increased, changes in legislation mandated stricter audit administration through the application of audit standards, and pending legislation (if enacted) would mandate transparency of expenditures – these, too, indicated a perceived failure of the existing performance audit mechanism.

However, because the concepts of 'quality' and 'expectations' were subjective and difficult to evaluate, the concerns about audit effectiveness were next elucidated as several specific questions, which could be answered quantitatively:

How does audit scope impact the quantity of audit findings?

If a construction expert is on the audit team, are audit findings affected?

Does the application of audit standards affect audit findings?

Does a higher percentage of tested expenditures yield more findings?

With answers to these questions, a new construction audit methodology could potentially be developed, providing a mechanism for appropriately deep capital program review, which could thus effect better control of capital expenditures and performance. Where stakeholders wish to receive the maximum benefit for monies spent, it is possible that better control of expenditures and performance would satisfactorily address stakeholder expectations and concerns.

2 Literature Review

Published construction audit theory, academic papers, and applied research were difficult to find. Thus, literature review on the topic of construction audit began with the history of audit, including financial audit, and the evolution of performance audit from

financial audit to government evaluation (Waring & Morgan, 2007; Penno, 1990; Newcomer, 1994) and oversight mechanism (Shand & Anand, 1996; Wheat, 1991). This included legislative requirements (Walsh, 1996), sampling theory, compliance (Trodden, 1996), iterative performance cycles (Steel & Van Scotter, 2003), and operational audits (Lane, 1983). The literature provided insight into the typical auditor's skill-set (accounting and financial analysis), systems focus of audits (Glynn, 1996), and the statutory dominance of accounting- and controls- focused auditing (Sloan, 1996).

A review of audit standards (Brown & Craft, 1980) led to questions about their insufficiency (Davis, 1980), and the near absence of performance audit standards (Holmquist & Barklund-Larsson, 1996). The literature review demonstrated that current audit standards created a framework for audit engagement oversight, adding a level of administration in order to improve report and work-paper quality. Yet, none of the standards addressed in depth such issues as auditor skills, sampling, risk, or testing. This gap begged the question of how requiring standards use could result in a 'better' audit.

Building upon the concept of audit as a project management tool, literature review included the application of audit techniques in project management. This included Total Cost Management, PMI's PMBOK, ISO certification, stage gate reviews & PRINCE2 (Huemann, 2004), risk management (Barzelay, 1996; Rikhardsson *et al.*, 2006), program evaluation (Goldenberg, 1983), quality assurance (Bowman, 1994), scenario planning (John *et al.*, 2008), cost reporting (Rasche & Esser, 2006), and value engineering / peer review (Merrow, 1988). The literature confirmed that audit skills were utilized in construction projects (Huemann, 2004), and they translate well when applied as part of other mechanisms. However, although 'risk' was important to stakeholders (Chapman, 2003), there was little formal research available in the intersection between risk, governance, and internal controls (Rikhardsson *et al.*, 2006).

Subsequent literature review covered project governance (Stretton, 2010) and stakeholders (Beach, 2009), in order to put accountability expectations in context. This included stakeholder attitudes toward risk (Chapman, 2003), consequences (Behn, 2002; Roberts, 2002), success (Klakegg, 2009), continuous improvement (Goldenberg, 1983), and resource use (Roth, 1996). The differences between accounting and accountability (Barzelay, 1996; Newcomer, 1994) were studied. Most often associated with performance audit and accountability, the three graces of economy, efficiency, and effectiveness (U.S. Government Accountability Office, 2007) were considered, including procurement performance measures (Kestenbaum & Straight, 1995). The literature surfaced a subtle difference between public accountability and financial accountability (Glynn, 1996), a distinction between systemic and substantive auditing (Trodden, 1996), and a new definition of satisfactory accounting (Barzelay, 1996). Together, these explained the need for both financial audit and performance audit, and supported the notion that the performance audit could reasonably be expected to go 'above and beyond' a mere accounting of expenditures. The process of governance was seen to include accountability and stewardship (Stretton, 2010), where accountability equalled providing justification to stakeholders for actions and omissions and auditing was defined as a process of validating accountability (Rasche & Esser, 2006).

On capital mega-programs, where multiple powerful stakeholders mean overlapping accountability relationships, stakeholder expectations were seen to conflict (Beach, 2009), creating a situation in which a project could simultaneously be both a success and a failure. To understand this, a literature review of construction megaproject theory was necessary. This included understanding project failure (Mian, 2005), cost overruns

(Flyvbjerg, December 2005), schedule slippage (Merrow, 1988), the catch-22 of project planning (Flyvbjerg, *Design by Deception: The Politics of Megaproject Approval*, 2005; Butts & Linton, 2009), project complexity (Wood & Gidado, 2008), trust in project culture (Zuo & Ma, 2005), and the volatile nature of construction (DeCarlo, 2004; Guo, 2004). The literature showed that cost overruns were common in megaprojects, and that audit was a necessary tool for accountability to stakeholders regarding the expenditure of funds, especially where those entrusted with the funds were expected to do so “legally, effectively, efficiently, economically, ethically, and equitably”. (U.S. Government Accountability Office, 2007)

3 Data Population

Because documentation from taxpayer- funded projects were a matter of public record, audit results were obtained easily. With the objective of identifying a homogeneous yet broad data population, the author selected school (K-12) and community college bond-funded construction programs in the State of California (United States of America), in which the Owner-entities were statutorily bound to conduct an annual performance audit. The construction programs represented by the population were unilaterally subject to the same public procurement laws, inspection requirements, State and Federal oversight requirements, and similar taxes and economic conditions.

All agencies audited were also required to publish their audit reports. The publication requirement was not met by all agencies in the State, thus audit reports for some Districts were unavailable at the time of data gathering, even though the audits had been conducted. Not all public agencies abided by the annual audit requirement, and thus audit reports were completely unavailable for other Districts. By gathering the audit reports available at the time, 240 performance audit reports were obtained for meta-analysis along with, for comparison purposes, 378 expenditure audit reports. The data population represented 73 discrete Districts, with audit reports published between the years of 2002 and 2010, and construction programs that varied in size from \$4 million to \$14 billion in capital improvements. The data population represented \$37 billion, nearly half (by U.S. dollar value) of all bond-funded programs in the State of California, which totalled \$76 billion at the time the data was gathered.

Some of the audit reports were from the same construction programs, where the audit work represented different years, a different population of expenditures, and audit work performed by different audit firms or audit team members. There was no consistency in the timing of the expenditure audits, as the audits in the population were not statutorily-required. There was consistency in the timing of the performance audits, as all the audits in the population were required to be conducted at fiscal year-end, which for all Districts was during the month of June. The expenditure and performance audits were conducted by many different audit teams and companies. There was little documentation about the composition and calibre of audit teams, in terms of construction industry skill-set and education. It was likely there was also no consistency in the quality of documentation audited. However, it was assumed for this study that the audit firms, project management teams, and construction companies would be consistent in their inconsistency, thus maintaining data homogeneity.

The data to be extracted from the population of audit reports included: audit type, contract type, total expenditures, expenditures tested, expenditures questioned, number of qualitative findings, type of qualitative findings, audit standards applied, total

invoices, number of invoices tested, and construction expert as team member. In the population of 378 expenditure audits, only 114 reported the number of invoices tested, and only 100 reported the number of invoices available. Similarly, in the population of 240 performance audits, only 63 reported the number of invoices tested, and only 10 reported the number of invoices available. This lack of data did not significantly impact the analysis, as the number of invoices tested and available were not key to the primary research questions. However, the auditors failed to provide an accounting of the capital program 'spending to date' in 48 instances, and failed to report the total amount of expenditures tested in 128 instances. Because the audit firms were reluctant and/or unable to provide additional information, these data gaps rendered a portion of the data population useless for the purposes of analysis, and the sheer quantity of missing data called into question the very competence of the audit firms.

4 Previously Published Results

Preliminary review of the available data (618 audit reports) yielded basic univariate statistics, from which preliminary conclusions were formed. The expenditures questioned in the 378 expenditure audits were on average (mean) 2.65% of total expenditures, compared to a mean of 0.02% questioned in the 240 performance audits. These percentages raised questions about the methodology used by audit firms for selection of expenditures to be tested and for expenditure review. It was posited from the questioned cost percentages that, by reviewing both a high percentage of expenditures and high number of invoices in context and in sequence, the auditor could better understand the history of and relationship between expenditures from period to period than could be obtained by reviewing only individual expenditure records, thus leading to an increase in the questioned costs and overall audit effectiveness. (Nalewaik, Systemic Audit and Substantive Evaluation in the Built Environment, 2010)

It was observed that a higher percentage of expenditures was tested in the population of expenditure audits (a mean of 59% tested, compared to 24% tested in performance audits). It was concluded this was likely because the size and scope of the expenditure audits were, by their very nature, limited to disbursements against a single contract (Nalewaik, The Inadequacy of Publicly-Funded Construction Audits, 2011), against which there may have been only dozens of invoices. In contrast, the performance audits were of large construction programs involving multiple projects and thus many contracts and hundreds (if not thousands) of expenditures, where a high percentage of those expenditures could not be tested within the constraints of audit cost and time.

The low percentage of expenditures questioned raised concerns about the calibre of the auditors conducting the work, and their understanding of the construction industry. It was wondered whether questioned costs were especially low where audits were conducted by accounting firms with only certified public accountant (CPA) staff, supporting the notion that advanced skills in accounting and application of financial auditing techniques might not be entirely appropriate for construction audits. Similar observations were made when the California League of Bond Oversight Committees (CALBOC) alleged fraud, deceit and misrepresentation in the profession by certain audit firms licensed by the California Board of Accountancy. CALBOC correspondence stated that "most, if not all, licensees of the board, engaged in the practice of public accountancy, lack the staff and expertise to measure the efficiency, effectiveness and economy of a facilities program. A typical CPA firm does not have experience and expertise in managing a school facilities program. We contend that one cannot judge

and evaluate the performance of processes and systems in which one is not experienced.” (California League of Bond Oversight Committees, 2009)

The low percentage of expenditures questioned, for all audits, also raised concerns about the methods used by audit firms to win audit work. “Audit firms routinely promise a certain high percentage of expenditure recovery or a return on investment in multiples of the [audit] fees charged. ... The data in this study...proves auditors’ salesmanship belies their ability to generate questioned cost results.” (Nalewaik, The Inadequacy of Publicly-Funded Construction Audits, 2011) If stakeholders expected a higher return on their audit investment, they were likely disappointed.

Table 1. Effect of Audit Type on Audit Findings
(Nalewaik, The Need for Assurance in Project Management, 2011)

Audit Findings	Expenditure Audit	Performance Audit
Contract compliance violation	32.01%	1.67%
Excessive or unallowable charges	27.25%	3.75%
Lack of expenditure support	23.28%	0.42%
Incorrect rates charged	16.67%	2.08%
Inadequate controls or accounting	7.41%	10.42%
Incorrect math	1.32%	0.42%
Duplicated scope of work or payment	0.26%	0.83%
Recommendations for program management improvements	0.00%	30.00%

The differences between the categories of findings by audit type, shown in the table above, indicated that audit scope could have an effect on the audit findings, in that certain types of audit might be more suited to questioning expenditures and other types of audit might be better suited to yielding qualitative findings. Further, it was posited that stakeholders were likely unaware of this, and might not have appropriately scoped their construction audits, thus failing to receive expected benefit from the audits.

It was questioned whether the traditional technique of statistical sampling was effective for the performance audits, where the capital program scope necessitated many design, engineering, consultant, procurement, services, and construction contracts. A preliminary conclusion was drawn from the data that “statistical sampling surfaced only routine contract compliance and accounting controls issues” (Nalewaik, Systemic Audit and Substantive Evaluation in the Built Environment, 2010). It was observed that “certain types of high-dollar-value errors were not identified in the population of expenditures, which ... could be very relevant in the management and oversight of capital projects” (Nalewaik, The Inadequacy of Publicly-Funded Construction Audits, 2011). The high incidence of “no issues” reported (128 in the performance audit population, and 164 of the expenditure audits) led to the question of whether a broader audit scope, different audit methodology, or more multifaceted audit team would have yielded more findings or better satisfied stakeholder expectations.

It was noted that the expenditure audits contained no findings related to project / program management improvements. This was likely due to the scope of the expenditure audit; because expenditure audit scope did not include evaluation of performance, the qualitative findings concentrated on contract compliance and controls. Similarly, the heavy concentration of expenditure audit compliance- and controls-related qualitative findings may have occurred “because certain contracts [may] have been judgmentally (not randomly) selected by the Districts for expenditure audit due to

concerns about the propriety of expenditures or contract performance” (Nalewaik, *The Inadequacy of Publicly-Funded Construction Audits*, 2011).

The data population was comprised entirely of audit reports from school districts and community colleges in California, which issued General Obligation Bonds for construction. All the agencies were required by California State Proposition 39 and Assembly Bill 1908 (AB1908, State of California Education Code, Sections 15278 et seq.) “to ensure voters will be given a list of specific projects their bond money will be used for ... and to ensure that the proceeds from the sale of school facilities bonds are used for specified school facilities projects only, and not for teacher and administrator salaries and other school operating expenses, by requiring an annual, independent performance audit to ensure that the funds have been expended on specific projects only.” (The Office of the Secretary of State of California, 2000) A high percentage of the performance audits (195, or 81% of the population) self-identified in their audit reports as ‘agreed-upon procedures’ (AUP) audits. The scopes of these audits were designed solely to meet the statutory requirements. “The procedures for the audit involved validating funds were expended for approved projects, with no detailed review of expenditures. Thus, 164 (68%) of the audits reported no exceptions were found with Proposition 39 compliance.” (Nalewaik, *The Inadequacy of Publicly-Funded Construction Audits*, 2011) However, Proposition 39 also explicitly stated its primary objective is to “ensure accountability so that funds are spent prudently” (The Office of the Secretary of State of California, 2000). Referencing the literature review, by specifically requiring a ‘performance’ audit, Proposition 39 evoked the traditional definition of performance audit and implied an assessment of accountability. The CALBOC documentation likewise stated the “AICPA [American Institute of Certified Public Accountants] expects a performance audit to offer much more than a review of the agreed upon procedures [and] the California State Controller’s Office has concluded that an ‘agreed upon procedures review’ does not constitute a performance audit.” (California League of Bond Oversight Committees, 2009) From the data, a preliminary conclusion was drawn that the prevalence of extremely-limited-scope AUP audits indicated a desire on the part of the Districts to adhere to the letter but not the intent of the law, thus satisfying regulatory audit requirements at the lowest possible cost.

5 New Findings and Discussion

By culling the audit reports to include only those containing all necessary data, the population was reduced to 467 audit reports (357 expenditure and 110 performance audits). Five audit reports were added to the population, from public and private sector construction projects on which a different audit methodology was applied.

The ‘new’ risk-based methodology used for the five new audit reports involved testing a high percentage of expenditures (greater than 50%, in context and in sequence), including construction experts on the audit team, and auditing contracts and / or projects by judgmentally selecting those representing an element of organizational risk. This method redefined audit by substantially broadening its definition to include any activity that consumed project resources. The mechanism was designed to improve the audit process for expenditure and performance audits, while also enabling ‘audits’ (deep analysis, using rigorous audit methods) of non-traditional audit areas such as: scheduling, design, policies and procedures, and program management.

On whole, the results from the redacted population yielded slightly different statistics but were very similar to those from the originally published findings. The data population yielded the following descriptive statistics:

The expenditures questioned in the expenditure audits were on average (mean) 7.21% of the total expenditures, compared to a mean of 0.08% questioned in the performance audits, and a mean of 44.65% in the risk-based audits.

The highest percentage of expenditures were tested in the population of risk-based audits: 100% of expenditures were tested for the risk-based audits, compared to 77.79% tested in expenditure audits and 66.03% tested in performance audits.

Of the performance audits, 76.36% were conducted as agreed-upon-procedure audits, of which 86.71% (72 of 84) reported no findings and no questioned costs.

From a correlation matrix and other data, the following was concluded:

Expenditure audits did not test a mixed group of expenditures. They tested either construction payment applications, or non-construction invoices. This was likely because such audits often tested a contract instead of a project, on which the sample type would be mutually exclusive.

Many of the performance audits followed an agreed-upon-procedures method, in which questioned costs and qualitative findings were rare. Most of the performance audits tested a mixed population of both construction and non-construction expenditures. This was likely because the performance audits typically reviewed a sampling of all expenditures on a construction program, not just a contract.

The newly-added population of risk-based audits included construction experts on the audit team, tested a consistently higher percentage of expenditures yielded significantly more questioned costs than other audit methods evaluated, and were not conducted according to specific audit standards.

Where performance or expenditure audit scope was expanded to include qualitative review, there were often construction experts on the audit team, more qualitative findings (than other audit types) were generated, and the engagement was often conducted according to consulting standards.

When construction experts were on the audit team, a higher dollar amount was tested (than other audit team configurations). This was likely related to correlation between dollar amount tested and audit type, and is not a significant correlation. Where a construction expert was on the audit team, more qualitative findings were generated.

In the full data population, the dollar amount of expenditures tested was higher when there was a mix of construction and non-construction expenditures. Corollary 1: Performance audits tested a higher dollar amount (not percentage) than expenditure audits. Corollary 2: Where the total expenditure population was high, the total amount tested was likewise high. This was likely because the performance audits typically reviewed an entire construction program, and the total expended on a program would be much higher than that on a single contract or project.

Where a higher number of invoices were tested, more qualitative findings were generated. This may have occurred if the auditors gained greater understanding and identified trends by reviewing more invoices.

6 Conclusion and Further Research

Although audit is one of the independent third-party construction oversight mechanisms most often requested by governing boards and Chief Financial Officers (CFO), various factors significantly affect audit results and traditional audit techniques might not be effective in certain industries where expenditure interrelationships, context, and sequence are meaningful and provide necessary information. Available literature on the topic of construction audit is scarce. In order to best satisfy stakeholders, auditees need to understand the factors that impact audit results and use that understanding to appropriate scope and guide their construction program audits.

This research reviewed over 600 audit reports, and answered the research questions:

Does audit type affect the number of qualitative and quantitative findings? Yes.

Does the risk-based audit yield significantly more quantitative findings? Yes.

Do performance audits classified as agreed-upon procedures yield fewer qualitative and quantitative findings? Yes.

Do performance audits with a broader scope yield more findings? Yes, they yield more qualitative findings.

Is the type of findings (qualitative, quantitative) affected by the type of contract audited? No.

If construction professionals are on the team, does the audit yield more findings? Yes, they yield significantly more qualitative findings, and slightly more quantitative findings.

- If GAGAS standards are applied, are there more qualitative or quantitative findings? No.

Does a higher percentage (of expenditures or invoices) tested yield more qualitative or quantitative findings? More qualitative findings, yes, with a higher number of invoices tested.

The next stages of the review will include further statistical analysis and contextual insights drawn from the correlations, cross-tabulations, histograms, and more. The author has concerns about developing a predictive model, as the model could be used to generate false confidence of certain audit scopes yielding more findings.

This research does have implications for industry, both audit and construction, and as such the author recommends further study in the following specific areas:

In order to better understand stakeholder expectations, a survey should be conducted to identify stakeholders, and qualify both their expectations (audit ‘success’) and their level of audit awareness. For the purposes of this dissertation, consideration of stakeholders was limited to the tax-paying public, District governing boards, and

government agencies. This selection was based on the perceived level of stakeholders' influence and urgency, as evidenced by vehement insistent outcry and subsequent impact. Further study will yield more information about these and other stakeholder groups.

An assumption was made that audit firms, project management firms, and construction companies would be consistent in their inconsistency, thus maintaining a homogeneity in the data population. Further qualitative study of the composition and calibre of audit teams (in terms of leadership, experience, education, and construction industry expertise) could have an impact on the discipline of construction audit. Specifically, much deeper review is needed of the correlation between experts and audit effectiveness.

The risk-based audit method is not likely to supercede traditional statutorily-required audits, but could supplement them. Although the risk-based audit data for this study included both audits of contracts and specific expenditure categories, the audits yielded both qualitative and quantitative findings. This methodology considerably redefines audit by substantially broadening its definition to include any activity that consumes project resources. More study of the method is needed to understand its potential profound impact.

Opportunities need to be explored for including audit as part of standard quantity surveyor, project management, and cost engineering academic curricula.

Abstract:

The successful completion of a construction project within the budgeted cost, on schedule and to desirable quality standard depends on adequate management of the risks associated with the cash flow during the project life cycle. This paper identifies the key risks influencing the contractor's cash flow in Nigeria and appraises their impact on the delivery of construction projects in Nigeria. The identified risks were prioritised according to their significance of influence on contractor's cash flow. The data for this research were collected by means of questionnaire surveys, based on which 33 key risks were collated. The strategies for managing the risks were sought from the perspectives of project stakeholders and external forces. It is concluded that majority of the identified risks were mainly related to the design team, contractors and government policy/agency, while the 2 top ranked risks namely poor funding and delay payments were related to the clients. The study recommends that project stakeholders should work cooperatively from inception to commissioning in order minimize construction risks and ensure value for money invested.

Keywords:

contractor's cash flow, project delivery, risks, risk management, stakeholders

1 Introduction

Risks occur in the construction projects because they are one-off activities with, many unique features, such as financial intensity, complicated processes, abnormal environment and changing organisation structures. (Wikipedia, 2010) asserts that risks are simply future issues that can be avoided or mitigated rather than present problems that must be immediately addressed. They concluded that there are different types of risks, but the risks associated construction projects are financial risks which are unexpected variability or volatility of returns.

(Kwakwe, 1997) described risks as an unwanted negative consequence of an event of which the possible outcome can be identified, predicted and quantified. (Smith, 1999) opined that while risks cannot be eliminated, successful projects are those where risks are effectively identified, analysed and managed. (Odeyinka and Lowe, 2002) asserts that financial management has long been recognised as an important management tool and that proper cash flow management is crucial to the survival of a construction company, because cash is the most important corporate resources for its daily activities. They concluded that an accurate forecast of construction cash flow has been a difficult issue due to risks and uncertainties inherent in construction projects.

This paper first presents a critical literature review of risks associated with construction projects cash flow and then identifies the key risks influencing the contractor's cash flow and assessed their impacts on project delivery in the Nigerian construction industry with the aid of a questionnaire surveys and develop strategies for managing them.

2 Literature Review

2.1 An Overview of Contractor's Cash Flow

The successful completion of a construction project within the budgeted cost and time depends on adequate management of the risks associated the cash flow during the project life cycle. (Akindoyemi, 1988) opined that lack of adequate financial planning by the two parties to a contract has in the past led to poor cash flow. He concluded that this in effect has adverse effects on the Nigerian construction industry and thus contributed to the abandonment of projects across the country.

(Navon, 1995) asserted that proper cash flow management is important as a means to obtain loans, as banks and other money lending institutions are normally much more inclined to lend money to companies that can present periodic cash flow forecasts. The contractor's cash flow in the construction industry is basically the revenue and costs. Lowe and (Whitworth, 1996) opined that most revenue of the contractor's is variable and hence is determined by progress on site. They explained further that risk will occur if the valuations do not match the outgoing or if the certificates are not honoured within the stipulated time. They concluded that risk will also occur if there was a lot of cash tied up in a long time to settle by the client.

2.2 The Importance of Risk Management Research in the Nigerian Construction Industry

Although many researchers have worked on cash flow in construction industry; take for instance, on the international scene, (Lowe, 1987) used simulation approached to predict cash flow of building client. (Lowe and Lowe, 1987) also examine the cash flow of construction clients in general. (Odeyinka, 2003) developed and validates models for assessing risk impacts on construction cash flow forecast. With all these efforts, there is still a need to commit more efforts in both research and practice to systematically identify and management risks associated with contractor's cash flow in Nigeria. This suggestion does not refute many researchers' contribution in a particular aspect of cash flow management in Nigerian Construction Industry such as (Ogunsemi, 1991) cash flow forecast as a tool for reducing project abandonment in Nigeria, (Onukwube, 2005) cash flow and financial management in some selected Nigerian Construction firms and others.

The overseas research and experience can contribute to the management of risks associated with contractor's cash flow in Nigeria. However, the unique cultural, environmental economic and political background in Nigeria and lack of advanced technology and management technique in the Nigerian construction industry, there is a need for research in this area, which is the main focus of this paper.

2.3 Risks versus Cash Flow

According to (Akintoye and Macleod, 1997) financial risk to contractor includes whether the building owner has enough money to complete the project (cash flow). They concluded that the contractor is concerned about availability of money in a

suitable manner and time to enable him progress with the work and complete it at scheduled time. (Flanagan and Norman, 1993) asserted that the environment within which decision making takes place can be divided into three parts: certainty, risk and uncertainty. They concluded that certainty does not happen very often in the construction industry.

(Kaka, 1996) identified risk factors affecting cash flow profiles to include estimating error, tendering strategies, cost variances and duration overrun. (Khosrowshahi, 2000) also identified other risk factors that impact on cash flow to include delay payment and difficulty in obtaining the right amount of fund at reasonable interest rates. (Patrick *et al.*, 2007) identified risks associated with project cost overrun as an important aspect of cash flow to include inaccurate cost budgeting, price escalation of material and labour, non-availability of material, supplier/ subcontractors' default; unpredictable weather, fluctuation in currency, excessive interface on project management, political instability and corruption.

3 Research Methodology

This paper aims to study risks associated with contractor's cash flow in Nigerian construction industry. The research methodology used comprised of comprehensive literature review, distribution of questionnaire to construction industry practitioners. The survey data were analysed using relative importance index. The risks were sourced from a wide range of literature including journal paper as well as those books that are specifically related to Nigerian construction industry. The questionnaire consisted of two sections. The first section solicited general information about the respondents; The second section contained a total of 70 risks associated with construction projects and asked the respondents to review and indicate the likelihood of occurrence of these risks as highly likely, likely or less likely and the magnitude of consequence on project performance in term of time, cost, quality, safety, environmental sustainability and contractor's cash flow. Some of the projects detailed that were used in the analysis are shown in table 1 below.

Table 1: Respondents Profiles
(Source: Authors survey, 2011)

Experience	%	Position	%	Educational Qualification	%
0-5 years	1.5	Foreman	12.0	Trade Test	2.0
5-10 years	2.5	General Foreman	15.0	H. N. D.	5.0
10-15 years	30.0	Site Supervisor	4.0	B Sc.	35.0
More than 15 years	64.0	Management Cadre	69.0	Higher Degree	58.0
Total	100		100		100

A pilot survey was carried out to test and verify the risk list with a few industry experts. The survey questionnaire was redesigned based on the pilot survey feedbacks. It is believed that the 70 risks listed in the survey are comprehensive to represent all risks that might affect contractor's cash flow in Nigeria. The 33 risks identified were categorised into six groups as presented by (Patrick *et al.*, 2007), with three related to clients, nine related to consultants, nine related to contractors, two related to subcontractor/suppliers, five related to government agencies and five related to external factors (that is economic circumstance, physical working and social environments).

The questionnaires were distributed to 120 practitioners in Nigeria and 98 responses were received. This represents about 82% response rate. The respondents had an

average of 14 years working experience and about 69% of them are in senior management position, 98% have higher education and are professionally qualified. Therefore, this background information regarding the respondents indicated that responses provide by them could be relied upon for this research.

4 Data Analysis and Results

The purpose of this investigation is not only to generate a list of risks, but to identify the key risks that can significantly influence the contractor's cash flow and affect the delivery of construction projects. The risks explored in the survey included a large number of factors, choosing the top 10 ranked ones (out of 33 identified risks factors) are assumed as an appropriate way to represent the key risks as used in similar research by (Patrick *et al.*,2007). The result of ranking is shown in table 2 below:

Table 2: Significance of risks on contractor's cash flow
(Source: Authors survey, 2011)

Key risks	RII	Ranking
Poor funding client	0.8197	1
Delays in payment from client	0.8086	2
Delay in agreeing valuation/day work	0.8004	3
Delay in receiving interim certificates	0.7991	4
Agreeing interim valuation on site	0.7902	5
Contractor's poor management ability	0.7806	6
Inability to employ qualified professionals	0.7800	7
Poor competency of labourer	0.6902	8
Delay payment by commercial Banks	0.6888	9
Delay in settling claims	0.6708	10
Variation by client	0.6678	11
Price inflation of construction materials	0.6602	12
Contractor's difficulty in reimbursement of Subcontractors/Supplier	0.6500	13
Inadequate safety measures during operations on site	0.6400	14
Lack of readily available utilities on site	0.6378	15
Unsuitable construction programme planning	0.6200	16
Inadequate site information (soil test and survey report)	0.6180	17
Design variations	0.6000	18

Table 2: Significance of risks on contractor's cash flow – cont'd.

Key risks	RII	Ranking
Bureaucracy of Government	0.5800	19
Change of Government	0.5200	20
Delay in release of retention	0.4802	21
Poor interpersonal relationship among the Professionals	0.4202	22
Suppliers in competency to delivery of materials on time	0.4106	23
Unavailability of sufficient amount of skilled labour	0.4100	24
Imposition of subcontractors/suppliers on construction site	0.3806	25
Change in currency exchange rates	0.3776	26
Change in interest rates	0.3668	27
Inclement weather, strikes, war e.t.c.	0.3507	28
Kidnapping of construction workers	0.3486	29
Problem of foundation	0.3342	30

Imposition off labourers on construction site	0.3232	31
Inaccurate cost estimate	0.3000	32
Low management competency of subcontractor	0.2826	33

From the table 2 above, the main risk variables with high extent of occurrence are poor funding by client, delay in payments from client, delay in agreeing variation/day work, delay in receiving interim certificates, agreeing interim valuation on site, contractor poor management ability, inability to employed qualified professionals, poor competency of labourer, delay payment by commercial banks and delay in settling claims. The statistical results shown in table 3 disclose the relationship between the category of risks and the 33 key risks identified. This was based on a categorization by (Patrick *et al.*, 2007) in a similar research in China.

Table 3: The categorisation of the 33 identified key risks.
(Source: Authors survey, 2011)

Category of risks	The 33 identified keys risks	with significant impact on				
		Cost	Time	Qty.	Safety	Environment
Risks related to Clients	Tight project schedule,	✓	✓	✓	✓	✓
	Delay in payment from client,	✓	✓	✓	✓	✓

	construction site.	✓	✓	✓

From statistical table 3 above majority of the 33 risks are related to the design team and the contractors, compared with less risk related to government agencies and external forces, while much less risks are related to the clients and subcontractor/ suppliers. This means that a large portion of the risks investigated originated from the design team and contractors. This is so because majority of the contractors in Nigerian construction industry are indigenous contractor who does not take risk mitigation into consideration and lack advanced managerial competency. The design team on the other hand consider most of their contractual obligations as responsibility to the client and not to the contractor. They believe that they are the boss to the contractor and that they can treat the contractor like their subordinate.

In addition, table 3 presents the relationship between category of risks and the project performance objectives. The distribution of the risk in table 3 shows that risk related to clients, contractors can influence all the five project delivery parameters while the risk related to design team, subcontractors, suppliers, government policy/ agency and external forces can influence part of the project performance objectives.

5 Discussion of Findings

To further reinforced the importance of different project stakeholders on the successful delivery of construction projects, an in-depth discussion on the risks factors relating to each stakeholders are presented as follows:

5.1 Risks related to Clients

Two risk factors related to the clients were identified with significant influence on all the project performance objectives while the third ‘variation by clients’ was found to have significant impact on cost and time. A thorough examination of the three risks factors in table 2 shows that they were ranked first, second and eleventh. This indicates that the client can influence the contractor’s cash flow and project delivery objectives maximally.

5.2 Risk related to Design Team

In all nine risk factors were related to the design team, four of it were ascertained to have significant influence on cost, time and quality of the project while the remaining five risk factors significantly influences the project cost and time. A careful look at table 2 shows that four of the risk factors were ranked among the top 10 while the second four risks factors were ranked among the first 20 and the last one ranked 32nd. Therefore, the design team play an important role in determining the contractor’s cash flow and also influence the project delivery objectives greatly.

5.3 Risk related to Contractor

Nine risk factors were related to the contractors, four of the risk factors were acknowledged to have extensive influences on all the project performance objectives while two were found to have significant impact on cost, time and quality. Another two risk factors were found to have substantial influences on cost, time and safety while the last risk factor was identified to have influence on cost and time. A detailed examination of table 2 indicates that the first two risks were ranked among the top 10, while the next four were ranked between 11 and 20 factors. The remaining three factors were between 21 and 30. This shows that the contractor have major influence on the cash flow and the project delivery objectives.

5.4 Risk related to Subcontractors/Suppliers

The two risk factors related to the subcontractors/suppliers were ascertained to have significant influence on the time and quality of the project. A close examination of the two risk factors shows that they were ranked between 21 and 30 respectively in the table 2, this imply that they may have influence on the contractor's cash flow and project delivery objectives.

5.5 Risk related to Government Policies/Agencies

Five risk factors were related to government policies and agencies. Three of these factors have extensive influences on cost and time while the remaining two risk factors were found to have significant influence on cost. A thorough examination of table 2 indicates that the first risk was ranked 9th, while the next two were ranked 19th and 20th in table 2. The remaining two risk factors were ranked 26th and 27th. This implies that the Government being the major initiator of capital projects in Nigeria have great influence on contractor's cash flow and project delivery objectives.

5.6 Risk related to External Forces

Five risk factors were related to external forces. Two of the risk factors were acknowledged to have significant influence on cost, time and quality while another two risk factors were found to have extensive influences on cost and time. The last risk factor was found to have influence on cost of the project. A detailed examination of the risk factors in table 2 indicates that the first was ranked 12th, while the remaining four were ranked between 25th and 31st. Two of the risk factors in this group 'Price inflation of construction materials and inclement weather, strikes, war e.t.c are not directly related to a particular project stakeholder, but global and environmental risks respectively.

Table 4: Comparison of key risks identified in two parallel surveys in Nigeria and China.

Category of risks	Key risks associated with construction projects	
	Key risk identified in China Survey	Key risk identified in Nigeria Survey
Risks related to Clients	Tight project schedule, Project funding problems, Variations by the client,	Tight project schedule, Delay in payment from client, Variation by clients,
Risks related to Design Team	Design variations, Inadequate program scheduling, Inadequate site Information (soil test and survey report), Incomplete or inaccurate cost estimate,	Delay in agreeing Variation /Day work, Delay in receiving interim certificates, Agreeing interim Valuation on site, Delay in settling claims, Inadequate site Information (soil test and report), Design variations, Delay in release of retention, Poor interpersonal relationship among Consultants, Inaccurate cost estimate.
Risks related to Contractors	Contractors' poor management ability Contractor's difficulty in reimbursement, Poor competency of labourer, Unavailability of sufficient professionals and managers, Without buying safety insurance for employees, Inadequate safety measures or unsafe operations, Lack of readily available utilities on site, Unavailability of sufficient amount of skilled labourers, Prosecution due to unlawful disposal of construction waste, Serious air pollution due to construction activities, Serious noise pollution caused by construction, Water pollution caused by construction,	Poor competency of labourer, Contractor's poor management ability, Inability to employ qualified professionals, Unstable construction programme planning, Unavailability of sufficient number of skilled labourer, Problem of foundation Contractor's difficulty in reimbursement of subcontractors/suppliers, Inadequate safety measures during operations on site, Lack of readily available utilities on site,
Risks related to Subcontractors/Suppliers	Low management competency of subcontractors, Suppliers incompetence to delivery of material on time,	Suppliers incompetence to delivery of material on time, Low management competency of subcontractors,
Risks related to Government Policy/ Agency	Excessive procedures of government approvals, Bureaucracy of government,	Delay payments by commercial Banks, Bureaucracy of government, Change of Government,

Risks related to External Forces	Price inflation of construction materials,	Change in currency exchange rates, Change in interest rates. Price inflation of construction materials, Imposition of suppliers/Subcontractors on construction site, Inclement weather, strikes, war e.t.c, Kidnapping of construction workers, Imposition of labourers on construction site.
----------------------------------	--	---

(Patrick *et al.*, 2007) conducted a parallel survey using a similar question to explore Chinese construction industry practitioners' perception with regard to risks associated with construction projects in China. Table 4 above was used to compare the summary of the result of the two surveys conducted.

From table 4, a large portion of the identified risks associated with construction projects in Nigeria and China are equivalent. For example, all the risks related to the clients and subcontractors/suppliers are the same, while parts of the risks related to design team, contractors, government policy/agencies and external forces are the same.

A careful look at table 4 shows that more risks related to design team, government policy/agencies and external forces were identified in Nigeria. This indicates that construction activities in Nigeria are exposed to more problems than in China.

6 Conclusion

Risks management has been recognised as an important process in order to achieve adequate cash flow in construction projects. In this research a total of 33 key risks were identified and ascertained to have significant influence on the Contractor's cash flow in Nigeria and the project performance objectives. These risks were compared with the findings of a parallel survey in China to ascertain the generic risks in both countries and highlight the unique risks associated with Nigerian construction projects. The unique risks include delay in agreeing variation, day works and valuation, delay in receiving interim certificates, delay in settling claims and release of retention, poor interpersonal relationship among the design team, problem of foundation, delay payment by commercial Banks, change of government, currency exchange rates and interest rates, imposition of suppliers, subcontractors and labourers on construction sites, inclement weather and kidnapping of construction workers. It is these unique risks that result in contractor's cost and time overrun and in some cases projects abandonment in Nigeria.

An initial analysis using relative important index showed that the main risks variables influencing the Contractor's cash flow in Nigeria are poor funding by client, delay in payments from client, delay in agreeing variation/day work, delay in receiving interim certificates, agreeing interim valuation on site, contractor's poor management ability, inability to employ qualified Professionals, poor competency of labourer, delay payment by commercial Banks and delay in settling claims. A further analysis of identified risks found that they are mainly related to design team and the contractors, followed by government policy/agency, external forces, clients and subcontractors/suppliers.

Although only 3 risk factors were related to the clients, they are crucial to the regular cash flow of the contractors.

7 Recommendation

The recommendations were based on the research findings and the author field experience. The recommendations were also based on appropriate strategies to be taken by stakeholders in managing their relevant risks as indicated below:

7.1 Managing risks related to Clients

The clients should minimize the risks related to it by preparing fund disbursement plan that will ensure prompt release of fund as at when due and secure a standby source of finance that would accommodate any unforeseen expenditure during operation on site.

7.2 Managing risks related to the Design Team

The design team should arrange comprehensive site investigation to obtain reliable design data and keep design within the client's capability. They should establish an efficient communication scheme that would improve their inter-personal relationship.

7.3 Managing risks related to the Contractors

The contractors should stop subletting their labour works and employ labour on permanent basis, so as to have control over their competency.

The contractor should map out sufficient construction strategies and ensure that utilities and safety equipment are always ready for use on site.

7.4 Managing risks related to the Subcontractors/Suppliers

The subcontractors should improve their management skills and competency through constant professional training while the appointment of supplier should be based on sound investigation of their credit witness and ability to fulfil the contract of supplying the required materials on time.

7.5 Managing risks related to Government Policy/ Agency

All government agencies should make more effort to create a friendly working environment that would reduce approval procedures, minimize corruptions and bureaucracy. The commercial Banks should ensure prompt release of cash advance payment to the contractors to enable them procure materials in advance and guide against fluctuation claim. Whenever there is change in the leadership of government at all the three tiers of Government the new head should continue all ongoing viable projects rather than commencing new projects.

7.6 Managing risks related to the External forces

The youth in the coastal line area should be oriented and integrated into Nigerian society, so as to reduce the incidence of kidnapping of construction workers, imposition of subcontractors/suppliers and labourers on construction sites.

All contracting organisations, such as owners, design team, contractors, sub-contractors, suppliers, government agencies, e.t.c. should have formal risk management process to mitigate all types of risks allocated to them. Finally, the Contractors who are the main

source of risks should employ professionals within their organisations who will assist them in managing risks throughout projects life cycle.

The adaptive capacity of hospital facilities to cope with the risk of disasters caused by extreme weather events: a case study approach

Abstract:

A three-year study is currently being conducted to determine the adaptive capacity of hospitals in Australia and New Zealand to cope with climate change-related extreme weather events. The primary objective of this research is to develop strategies that can be employed to improve the resilience of hospital facilities to these events. A case study approach was adopted to collect data through focus groups comprising participants who had experienced extreme weather events. Using risk and opportunity management methods, focus group workshop sessions were used as a structured approach to identify, assess and control the risks and opportunities associated with an extreme weather event scenario. The research findings indicate that there is considerable scope for clinical and non-clinical staff to work cooperatively in developing preventative as well as response and recovery strategies. The findings reinforce the view that the relationship between building users and building facilities needs to operate in an integrated fashion if any adaptive strategy is to be effective. This raises interesting governance issues which will be explored in future research.

Keywords:

adaptive capacity, case study, hospitals, opportunity, risk

1 Introduction

In recent years there has been an accumulation of evidence pointing to links between climate change and extreme weather events (Hennessy et al., 2007; Steffen, Love, & Whetton, 2006; Stern, 2009). For Australia and New Zealand, this is likely to manifest itself as more frequent and severe heatwaves, floods and storms (Australian Greenhouse Office, 2006; Hennessy et al., 2007; Preston & Jones, 2005). Extreme weather events are caused when an individual climate variable such as temperature or rainfall “exceeds a particular threshold and deviates significantly from mean climate conditions or when there is a critical combination of different variables” (Linnenluecke & Griffiths, 2010, p. 2). This can occur either when climatic conditions fluctuate much more than normal, thus resulting in a severe weather event, or when the event falls outside the normal climatic season, such as a flood occurring during a normally dry season. Due to the unpredictability and impact of these events, they pose significant risk to society at large, and place strain on critical infrastructure. The health sector is especially vulnerable to natural disasters (PAHO/WHO, 2004) and the capability of hospitals to carry out their

vital roles during and immediately after an extreme weather event is paramount to the success of the wider recovery process. While new hospitals are relatively resilient to external forces, existing building stock would benefit from the application of adaptation strategies to improve their resilience (Australian Greenhouse Office, 2007). The aim of this research is to identify what actions can be employed by hospital management, both clinical and facilities, to enable the continuity of health care during an extreme weather event.

Whilst the impact of climate change on healthcare delivery is currently the focus of considerable research (Bonnett et al., 2007; Lalonde, 2007; McCaughrin & Mattammal, 2003), physical healthcare infrastructure has been relatively neglected. The importance of addressing this deficiency was acknowledged by the Australian Science Engineering and Innovation Council (PMSEIC Independent Working Group, 2007) and by the Council of Australian Governments (2007) when they recommended that Australian governments should give priority to developing climate change adaptation strategies for Australia's health infrastructure. Given the age of Australian and New Zealand healthcare infrastructure, they recognised that extreme weather events are likely to create increasingly challenging physical and patient-related demands which were not envisaged in original hospital designs. Hence it is important to undertake research which focuses on the interplay between health service providers and designers, constructors and managers of hospital facilities.

The research method adopted was a multiple case study approach employing in-depth focus group workshops. The case study approach yielded successful outcomes with the focus group sessions identifying a detailed range of controls that could be employed to mitigate risks and also opportunities for the development of adaptive strategies. There was general agreement amongst workshop participants that the exploration of risk and opportunity profiles which marked the culmination of this stage of the project was of both conceptual and practical use in the management of hospitals particularly during and after an extreme weather event.

2 Research agenda

The research project commenced in June 2009 and comprises three stages viz.

- Stage 1 - vulnerability analysis
- Stage 2 - adaptive capacity analysis
- Stage 3 - development of adaptive strategies

A case study approach was used for Stages 1 and 2 with the same case study hospitals being used for both stages. Stages 1 and 2 of the project have now been completed and Stage 3 has recently commenced. The results from Stage 1 are discussed in previous publications (Carthey, Loosemore, Chandra, & Chand, 2010; Loosemore, Carthey, Chandra, & Chand, 2011); the topic of this paper is the Stage 2 results.

3 Research Methodology

The case study approach deployed for Stages 1 and 2 is widely accepted as a useful tool for studying organisational responses to crisis and for developing theory inductively by recognizing patterns of relationships across cases (Loosemore & Hughes, 2001). This is important because understanding the operation of hospitals requires more than a simple appreciation of building related issues given that a hospital is a complex organisation

with many diverse stakeholders and functions. Responses to extreme weather events are similarly complex and involve an interplay of many economic, social, organisational, political and cultural considerations which can only be explored fully using a case study approach (Yin, 2009). A broader approach, such as a survey or questionnaire may have failed to provide the depth of insight needed to understand the social and organisational complexity of the adaptive system in responding to an extreme weather event.

3.1 Description of Case Studies

Three major referral hospitals were chosen in close consultation with partner health services in Australia and New Zealand. The case studies were selected based on their size and age, population dependency, historical climatic records and future climatic predictions. The three case studies comprised Coffs Harbour Base Hospital; Whangarei Hospital; and Ceduna District Health Services. Each of these facilities had previously been subjected flash floods, floods caused by storm surges and heatwaves respectively.

3.2 Description of Case Studies

3.3 Coffs Harbour Base Hospital

Situated on the mid North Coast of NSW, Coffs Harbour Base Hospital is the largest hospital in the North Coast Area. It serves a population of 100,000, an estimated 68,000 of which resides in Coffs Harbour city. Coffs Harbour is a humid, sub-tropical area with an average annual rainfall of 1,700mm (Coffs Harbour City Council, 2009). Flooding and storms are relatively common, although its intensity has increased dramatically in recent years, with the region experiencing six major flooding events in 2009 alone. Whilst Coffs Harbour Base Hospital is relatively new, being operational only since 2001, the hospital suffers from its location adjacent to a creek and on a flood plain, and the area around the hospital is one of the first in town to be inundated in a flooding event.

3.4 Whangarei Hospital

Whangarei Hospital serves a district of 78,000 and is located in the North Island of New Zealand in the Northland area which has a population of approximately 155,000 people. The hospital building is situated on a hill, and accessed by only one road which can be cut off during floods and storms. A major renovation was undertaken in 2001, but many of the buildings date from the 1950s-1960s or even earlier. The NZ Ministry for the Environment (2009) warns that due to climate change, Northland's temperature is expected to rise by 3°C over the next century and the frequency of floods could increase fourfold by 2090. Specifically, summer and autumn tropical storms may bring an increase in the intensity of extreme rainfall causing severe flooding to the hospital and surrounding areas (Ministry for the Environment, 2008).

3.5 Ceduna District Health Services

Ceduna is located in the remote northwest corner of the Eyre Peninsula, South Australia and is approximately 10 hours by road from Adelaide. Out of its small population of 3,731, 25.5% of the population in 2006 identified themselves as indigenous i.e. of Aboriginal or Torres Strait Islander origin (Australian Bureau of Statistics, 2010). Located within an arid zone, the town is exposed to hot, dry summers with limited rainfall, during which time the daytime temperatures can reach up to 47°C for a week or longer. In early 2009, when Adelaide reported up to 6 days over 40°C - some of the

hottest days recorded in the region for more than 70 years - Ceduna recorded a temperature of 46.2°C (ABC News, 2009).

Ceduna District Health Services offers a mix of 25 acute care beds and 10 beds for high level aged care, with a further 29 beds for low level aged care located on another site (Country Health SA, 2009). A major upgrade of the health service facilities are currently being undertaken (South Australia Parliament House of Assembly Public Works Committee, 2009).

4 Data collection

Data collection was by means of a series of focus group sessions using a risk management tool called 'Risk and Opportunities Management System' (ROMS, 2011) to capture stakeholder experience. Focus groups are designed to promote interaction and self-disclosure among a carefully structured group of respondents who can share their perspectives about a specific topic in a non-judgemental environment (Morgan, 1997). ROMS is a process which uses multimedia technology to provide a structured approach to identifying, assessing and controlling the risks and opportunities associated with an nominated problem – in this case “How to respond effectively to an extreme weather event scenario”. By acknowledging employees' expertise and insights as an organisation's key asset in managing risks, it provides a multimedia platform for the organisation's key stakeholders to come together to engage in an interactive and constructive process (Loosemore, 2010). The scenarios for these ROMS workshops were different in each case study and reflected the local extreme weather event possibilities. Scenarios are an accepted method in risk management in helping stakeholders think about risks and opportunities (Henstra & McBean, 2005). In our case studies the scenarios were generated from scientific advice and statistical evidence from UNSW Climate Change Research Centre (a partner in this research). In both Stages 1 and 2 the ROMS workshops were conducted in each case study hospital with key stakeholders including clinicians, emergency department staff, facility managers, nurses, technical staff, health care specialists and health service representatives. Stage 1 involved a one-day workshop to identify and assess the risks and opportunities for each case study hospital and Stage 2 (the subject of this paper) involved another one-day workshop to consider the controls which could reduce the risks to an acceptable level and maximise the opportunities associated with the climate change scenario. The results of Stage 1 (Carthey et al., 2010) showed that the overriding organisational objective was continuity of service delivery with the primary supporting objectives of (a) preserving the building structure's integrity along with its building services; (b) having effective communication both externally and internally; (c) maintaining access to and from the site; and (d) ensuring availability and safety of relevant staff on hand to respond to the crises. From the profile of the risks and opportunities identified from the first round of focus-groups, it was also clear that many of the risks and opportunities were in a dynamic relationship where the occurrence of a single event could trigger a number of associated events. For example in one of the case studies the lack of an early warning flood monitoring system resulted in the inundation of a car parking area with the consequential loss of 90 cars belonging to staff, and key clinical and maintenance staff not having enough time to arrive on site before the roads became inaccessible.

5 Findings and discussion

In Stage 1 a total of 90 risks and 36 opportunities had been identified across the three case studies. In the Stage 2 ROMS workshops a total of 158 'additional controls' were identified. Additional controls are items that the stakeholder group felt could be accomplished 'in-house' to supplement or complement their existing controls in order to mitigate the risks or maximise opportunities. An end 'residual level' is computed, showing the resulting severity(/benefit) of the risk(/opportunity) if those additional controls identified were to be implemented. This is calculated based on the stakeholders' judgement of the probability of the risks(/opportunities) happening and the impact to their ability of achieving the objectives if it were to happen (i.e. residual probability x residual consequence = residual level). Table 1 shows an extract from the second workshop at Coffs Harbour Base Hospital by way of illustrating the nature of some of the additional controls identified.

Table 1. . Some of the additional controls identified for the objective “to ensure staff and patient safety” at Coffs Harbour Base Hospital

	Risks and Opportunities	Additional Controls	Residual Probability	Residual Consequence	Residual Level
Objective	To ensure staff and patient safety (including vulnerable patients within the community) (Weighting 40%)		Rare Unlikely Possible Likely Almost certain	Insignificant Minor Moderate Major Extraordinary	Low Medium High Very High Exceptional
Risks	(13) Roads being cut (Almost Certain, Major, Very High)	Lobby Road and Traffic Authority/Council to upgrade roads from hospital to bypass – as part of Pacific Highway upgrade and Coffs Harbour bypass to ensure all weather access	Likely	Major	Very High
		Further develop support provided to local hospitals	Almost Certain	Moderate	High
		Developing a process of when we receive early warning that those on call physically come into the facility so we have them on site (intensivist, anaesthetist, general surgeon etc)	Almost Certain	Minor	Medium
	(21) Adequacy of community age care facilities BCM plans and capacity to implement those plans (Possible, Major, High)	Help age care providers to secure funding to develop risk management/emergency/business continuity management plans	Possible	Major	High
		Lobby commonwealth to make risk management plans/business continuity management part of age care facility accreditation process	Rare	Major	Medium
		Lobby local Government planners to make location of age care facilities in development application approval consider risk of where they are building	Rare	Major	Medium
	(25) Inability to respond to speed of event (Possible, Major, High)	Improve internal communications relating to early warning – give staff time to move cars etc	Possible	Major	High
		Provision of real time data about levels of creeks (currently a critical lag of 15 minutes) - linked to triggers which commence activation of plans	Unlikely	Major	Medium
		Automated early warning system is needed to ensure that alarms ring if rate of creek flooding rises above a certain rate – currently manual	Unlikely	Major	Medium
Opportunities	(21) Develop and implement flood mitigation strategy for the site (e.g. Coffs Harbour bypass may present opportunity, engage with urban planning controls) (Possible, Major, High)	Work together with council and SES to develop a mitigation strategy – document procedures	Unlikely	Major	Medium
	(38) Build a multi-storey car park (Unlikely, Moderate, Low)	Private medical centre developer wants to build one – negotiate with them as a JV to build one	Likely	Moderate	High

Table 1 provides a sample of the large range of possible controls identified to reduce the risk exposure of hospitals to climate change related extreme weather events. In each case study, the foreseen residual risks and opportunities profile were compared to the

original risk profile from the Stage 1 workshops (for combined results from all three case studies, see Figure 1). When compared to the original risk profile, the residual risk profile shows how the risks and opportunities would shift as a result of implementing the additional controls, assuming the organisation chooses to and is able to act on the additional controls and that the controls have their intended effect. Figure 1 show how across the three case studies, the existing climate change risks can be significantly lowered, and the opportunities improved with the *caveat* that the lowering of risks and the improvement of opportunities represents the most optimistic projection of outcomes.

Figure 1. Graphs of the combined results from the three case studies profiling the distribution of (a) original risk versus residual risk and (b) original opportunity versus residual opportunity.

Three main observations can be made regarding the additional controls:

1. The controls relate to a wide range of health service delivery issues. Some are building related; others are organisational in nature and some relate to situations where the organisation and the building are closely inter-connected.
2. Some controls have a particularly strong impact and have a ‘knock-on’ effect on other controls. For example an automated early flood warning device.

3. Although by definition additional controls should be able to be accomplished 'in-house' the implementation of a control may not always be within the sphere of influence of the health service organisation in question – for example lobbying the Roads and Traffic Authority and the local Council to upgrade access roads is a case in point.

Observation 3 raises some interesting issues with respect to the ability to implement a control which is not directly within the sphere of influence of the stakeholders. In order to explore this issue further, a coding exercise was undertaken to categorise the nature of the controls identified. The objective of the coding exercise was to systematise possible strategies in order to compare like-with-like and to identify any patterns that could be used towards formulating an adaptive strategy. Patterns were identified by examining co-occurrences such as correlation between “themes, respondents or events” (Guest & McLellan, 2003, p. 188). Each item coded was checked against the others to establish analytical categories, in a process referred to as ‘constant comparison’ (Pope, Ziebland & Mays, 2000).

This analysis was, in essence, a fine grained exploration of spheres of influence. Controls were coded into endogenous and exogenous categories and then further broken categorised into ‘within sphere of influence’, ‘partially within sphere of influence’ and ‘outside sphere of influence’. These categories reflect the nature of healthcare systems which are characterised by a complex hierarchical structure of decision takers with varying spheres of influence (Becker, 2007). The term ‘endogenous’ refers to the sphere of influence of decision takers in the case study hospitals. The term ‘exogenous’ refers to the sphere of influence of external agencies, such as other government departments or private organisations. The approach which was adopted is similar to that advocated by Wu et al (2006, pp. 352-353) who grouped risk factors, in their case inbound supply risk factors, into similar categories. It is interesting to note that natural disasters are classified by Wu et al as “external uncontrollable” (i.e. ‘exogenous and outside sphere of influence’), whereas the ROMS process has helped our case study organisations to gain an element of control to deal with these external risks. Examples of endogenous and exogenous controls are provided in Table 2. Although these are presented as two distinct categories, in practice the boundary between the two is often a fuzzy continuum. It was clear from our second workshop that the likelihood of a control being proposed and, in turn, implemented is directly correlated to the degree of influence or authority which a stakeholder is able to exert. For example, in the case of Ceduna hospital, the stakeholders were assertive in taking control over seemingly exogenous issues. When faced with the challenge of needing to provide accommodation on site for an extended period of stay for staff during a heatwave event, ideas of appealing to a higher authority for funding quickly turned inwards, with participants noting “I think we can do some of that ourselves... we could publically raise funds [from the local community] for beds and the like”.

Table 2 gives examples of each endogenous control and exogenous control with 3 levels of spheres of influence with the proviso that the boundary between these spheres of influence has been presented as clear cut for illustrative purposes.

Table 2. Endogenous and exogenous controls

	Categories	Definition	Example (extracted from workshop transcript)
Endogenous (En)	Within sphere of influence (a)	Actions that can easily be implemented using existing resources and associations within the hospital organisation	Set up a pseudo pharmacy service for visitors
	Partially within sphere of influence (b)	Actions that will require collaboration or assistance from other health departments	Develop support system amongst local hospitals
	Outside sphere of influence (c)	Strategic decisions relating to the hospital that its organisation does not have the authority to make	Build a new hospital
Exogenous (Ex)	Within sphere of influence(a)	Actions involving or dealing with outside bodies but which the hospital organisation can easily manage and control	Educate public about extreme weather event risks
	Partially within sphere of influence (b)	Actions involving or dealing with outside bodies but which the hospital organisation can manage and control somewhat	Negotiate with nearby mining company to share their resources
	Outside sphere of influence (c)	Actions involving or dealing with outside bodies and which the hospital organisation has little scope or likelihood of management and control	Lobby commonwealth government to change the building requirements for aged care facilities

As part of the process of identifying suitable adaptive strategies, Stage 2 of this research project is primarily concerned with the interplay between organisational activity (the users) and the built environment (the physical infrastructure). In order to ascertain the ratio of controls relating to ‘organisational activity’ and ‘physical infrastructure’ the data was further analysed by sieving the results of the sphere of influence exercise illustrated in Table 2 through these two identifiers. The results of this exercise are illustrated in Table 3. In all 158 additional controls were analysed as part of this exercise.

Table 3. Coding of additional controls into categories of endogenous and exogenous, with sub categories of ‘within sphere of influence’, ‘partially within sphere of influence’ and ‘outside sphere of influence’

	Total	Organisational [#]	Built Environment ^{##}
Endogenous (En)	109	57	52
En – within sphere of influence	88	50	38
En – partially within sphere of influence	15	7	8
En – outside sphere of influence	6	0	6
Exogenous (Ex)	49	30	19
Ex – within sphere of influence	21	17	4
Ex – partially sphere of influence	15	7	8
Ex – outside sphere of influence	13	6	7
TOTAL	158	87	71

Protocols; internal procedures; disaster plans

Building envelope; building services; equipment; layout and provision of space

Given that the data is derived from three case studies no statistical inferences can be drawn from the results of the analyses. They do however provide an interesting insight into the stakeholders’ perceptions of risk and opportunity management. The scenario presented to stakeholders at the commencement of the ROMS workshops for Stage 2 was “What controls in addition to existing controls can the organisation implement internally to minimise risks and maximise opportunities?”. This approach is very much in line with systems thinking where the main causes of change in an organization (i.e. a system) are considered to be the interactions within the organization itself, not influences from outside the organization. Problems of the organization are not attributed

to outside circumstances – the competitors, the press, the markets, the economy or the government. “Systems thinking implies that there is no outside; that you and the cause of your problems are part of a single system” (Senge, 1990, p. 67). This view does not mean ignoring effects of external factors; it does however mean that the way the system responds to external factors depends on the dynamic structure of the system itself (Mbiti, 2008). Previously we have made the point that natural disasters are classified by Wu et al (Wu et al., 2006) as “external uncontrollable”, whereas the ROMS process provides organisations with an element of control to deal with these external risks. The ability of our case study participants to think inside the system boundaries is confirmed in the results obtained from the coding of the additional controls. Table 3 illustrates that the dominant area for suggested improvement, both in terms of organisational activity and the built environment is ‘endogenous – within sphere of influence’ with very few suggestions being deemed to be outside the sphere of influence. In the exogenous zone it is worth noting that ‘exogenous-within sphere of influence’ (for example a public education program) has the largest number of controls and typifies an organisation taking a pro-active role in influencing external circumstances. This analysis is still at an exploratory stage of the ongoing research project and may lead to the development of an assessment tool to measure the adaptive capacity of hospital facilities both in terms of the management of the physical infrastructure and the management of the organisational activities.

The ratio between endogenous organisational controls and endogenous physical infrastructure controls is evenly balanced indicating that the stakeholders do perceive the physical environment as being important to the stakeholders. This was to some extent an unexpected result given that most of the workshop participants were clinicians or administrators whose primary responsibility has more to do with organisational issues than issues relating to the built environment.

6 Conclusion and Further Research

Extreme weather events are, by definition, an extraordinary event which falls outside of the norm. The ability to mitigate the risks posed by such an event and to identify opportunities for improvement is a reflection of the adaptive capacity of hospital facilities (facilities being defined in the broad sense of the physical infrastructure and the users of the facility). Whilst it could be argued that extreme weather events are uncontrollable occurrences, this does not necessarily mean that the impact of the event cannot be lessened or indeed absorbed by a combination of a robust physical infrastructure and a properly prepared organisation. Although the study is limited to three case studies the application of the ROMS system produced a large and rich data set which allowed insight into user perceptions of controls which could be implemented to improve the adaptive capacity of hospital facilities.

To date research into physical healthcare infrastructure has been relatively neglected. Our research has added to knowledge in this field. Amongst other things our analysis of the data from the case studies demonstrates that it is possible to categorise controls into user activities i.e. organisational and physical infrastructure with the proviso that the built environment includes not just the building envelope and building services but also the provision of space. The findings demonstrate that hospital organisations are capable of identifying risks associated with extreme weather events and of conceptualising a wide ranging set of controls which can be implemented to improve the adaptive capacity of hospitals. The findings also demonstrate that stakeholders perceive most of

the proposed additional controls as being endogenous and within their sphere of influence which is indicative of a positive and proactive mind set.

The use of a case study approach in Stages 1 and 2 of the project has provided a clear insight into user perceptions. Stage 3 of the project, which is about to commence, will seek to validate the findings of Stages 1 and 2 by undertaking extensive consultation with key decision takers.

An assessment of housing finance availability to property developers in Nigeria

Iniobong John and Opeyemi Oyeyipo

Department of Building,
University of Lagos, Akoka, Yaba, Lagos,
Nigeria

Email: domass12@yahoo.com; soldout5812@yahoo.com

Abstract:

Access to housing finance is a critical bottleneck for the majority of property developers in developing countries like Nigeria. Lack of available and accessible fund has been identified as one of the challenges confronting the housing conditions for middle and lower income households in Nigeria. The problem of housing finance is more acute in developing countries than in a developed country mainly because of the lower per capita income and the paucity of external sources of finance. The aim of the paper was to assess the availability of housing finance to property developers in Nigeria. The objectives of this study was to assess the ease of access to housing finance by property developers, to evaluate the challenges in sourcing funds from financial institutions in Nigeria and to evaluate the current level of government intervention in housing provision in Lagos state. The survey research method was adopted for this study. A structured questionnaire was used as the principal instrument for collecting data from respondents. The results indicate that government's effort in housing provision in Lagos is below average. The findings show that interest rate, the amount of money requested for and security (collateral) are the critical challenges faced by private developers when sourcing for funds from financial institutions. The study highlights government and financial institutions as being responsible for the inadequacy of housing finance. The paper recommends that private developers should collaborate and explore alternative sources of finance for their activities.

Keywords:

housing finance, property developers, housing provision, financial institution, Nigeria.

1 Introduction

Nigeria is a land of contrasts. Great oil and gas wealth, reasonable agricultural exports, and a fast growing manufacturing and services sectors as well as a fast growing telecommunications sector with poor growth in infrastructure. Nigeria; though prominent, is one of Africa's promising economies. Conversely, its major strength lies in the enormous human capital resources. Based on United Nations standards, Nigeria is an underdeveloped country and majority of its people are poor and live in the rural hinterland which are underdeveloped and lack basic amenities such as clean water, sanitation, electricity and good housing for all. Most of its cities are overpopulated with poor living condition for a majority of its occupants.

Shelter occupies a unique place in the life of human beings; a person requires security, privacy and certain elements of personal identification, which a house can offer (Windapo and Iyagba; 2007). In sharing this view, Olayiwola, Adeleye and Ogunshakin

(2005), opine that housing is also one of the best indicators of a person's standard of living and of his place in the society. Housing represents one of the most basic human needs and has a profound impact on the health, welfare, social attitudes and economic productivity of the individual.

Onibokun (1985) explains that housing problems have resulted in overcrowding, poor and inadequate social amenities, unsatisfactorily and unwholesome environmental conditions and urban squalor, the absence of open space, the over development of land area leading to the crowding of buildings, in-accessibility within residential areas as well as scarcity and high cost of building materials. In general, it seems evident that the urban housing problems is mostly a phenomenon originating from the large and uncontrolled influx of people from the rural regions marked by gross underdevelopment into land locked urban areas in search for a 'better life'.

The Nigerian government, have enacted several policies aimed at providing affordable housing to its teeming population with little success. The private sector is presently co-opted into the lucrative business of housing provision. The demand for housing is especially higher than supply so this informs the interest of the private sector whose major driving interest in investment of funds is profit making. Despite the ongoing effort of the private sector in investing in housing, the demand level remains high. Also, majority of the houses built by private sector investors are majorly for commercial interest, hence are not affordable by the low income class who constitute a majority of the population. The difficulty in accessing fund and the high interest rates on funds accessed for building projects also contribute to high overall cost of housing provision.

Ojo (1983) reckons that the field of housing finance is in a state of continuous change, change in practices, methods, clientele and sources. This can be attributed to the dynamics of the socio-political climate of the country alongside other external forces. The financing of building construction projects is expected to be one of the major responsibilities of our financial system. Oloyede (2007) is of the view that real estate and its finance are essential elements of economic development, economic growth and capital formation. However, housing finance in many developing countries has been limited to state owned specialised housing banks, which is a sector that is primitive and under-developed.

Access to housing finance is a critical bottleneck for the majority of the private sector, including the private developers in developing countries like Nigeria. Hoek-Smith (1998) argues that lack of available and accessible housing finance has been identified as one of the important hurdles in improving the housing conditions for middle and lower income households. According to Ojo (1983), the problem of housing finance is more acute in developing countries like Nigeria than in a developed country like the U.K. mainly because of the lower per capita income and the paucity of external sources of finance. Lack of effective demand for housing finance on an economic basis reflected primarily the low per capital income, resulting largely in lack of developed commercial sources of housing finance in the country. In financial sector in Nigeria has been undergoing a lot of restructuring in nearly a decade. The ability of financial institutions to provide funds for housing development has been slow coupled with the ever stringent conditions which form the basis of collateral requested by most financial institutions. The objectives of this paper are to assess the availability of housing finance to property developers in Nigeria, to evaluate the constraints faced by private developers in sourcing funds from financial institutions in Nigeria and to evaluate the level of government effort to housing provision.

2 Literature review: scope of the research

Over a decade, the real estate development sector has made significant contribution to many sectors in the economy (Jamil and Ahmad, 2007). Private sector property developers are actively involved in the provision of shelter in Nigeria. There exist in the real estate business, the problem of availability of housing finance to property developers which the study will try to unravel.

Housing finance by its nature is a capital intensive ventures which if financed through personal financial resources will require slow and tedious accumulation of saving. Ajanlekoko (2001) opines that since housing (real estate) provides benefits over many years, long term credit financing is a more logical option as it will spread the repayment burden. This will require the availability of long term facilities having institutional capacity, structure and mechanism that will allow a convenient and effective linkage between the saver/investors and the consumers of the fund. In Nigeria, housing is financed through a number of institutional sources: commercial/merchant banks, insurance companies, federal mortgage bank of Nigeria (FMBN) and other mortgage institutions. There are various challenges affecting housing provisions in Nigeria; amongst which include the availability of funds.

3 Research Methodology

A survey research design was adopted in the study. Specifically, a cross-sectional strategy was used where samples were drawn from the population of study at one point in time. The study was conducted in Lagos state which is viewed by some as the commercial capital of Nigeria despite the movement of the capital to Abuja. The city houses a good number of private developers who have been in business over a period of time. The population for the study comprises private owned property development firms of all categories (small, medium and large) based in Lagos. Specifically, senior management staffs, site engineers, project managers and other key personnel involved in construction activities of these property development firms were the targeted respondents. Structured questionnaire was used as the principal instrument for obtaining responses for housing finance availability to property developers in Nigeria. A total sample of sixty nine (69) was drawn from these collections of private developers of various categories (small, medium and large) registered with the Nigerian Institute of Estate Surveyors and Developers. Purposive sampling, which is a non-probabilistic sampling technique was adopted for the study due to our inability to obtain a current and comprehensive list of private developers operating or based in Lagos as at the time of carrying the study.

4 Findings and Discussion

4.1 Characteristics of respondents' organisation

An insight into the nature of the respondents' organisation will deepen our understanding of the nature and quality of their responses. Project managers constitute the highest proportion of the respondents indicating their high involvement in the procurement process of most property developing companies.

Table 4.1 Demographic data of Respondent

Designation of Respondent	Frequency	Cumulative	
		Percent (%)	Percent
Managing director	3	6	6
Commercial manager	13	26	32
Principal partners	8	16	48
Project manager	14	28	76
Others	12	24	100

Commercial managers account for 26% of the total population. Managing directors who participated in the survey account for 6% of the population.

Table 4.2 Inadequacy of housing finance and its causes

	Frequency	Cumulative	
		Percent (%)	Percent
Inadequacy in housing finance			
Yes	39	97.5	97.5
No	-	-	97.5
Indifferent	1	2.5	100
Who is responsible for the inadequacy			
Government	2	5.1	5.1
Financial institution	1	2.6	7.7
Government & financial institution	22	56.4	64.1
Government, financial institution & public	14	35.9	100

Majority of the respondent agree that there is an inadequacy of finance for housing and property development relative to the demand for such fund. This could lead to cases of abandoned project in the worst case. Respondents opine that government and financial institutions are responsible for the inadequate supply of funds for construction projects. Although government regulate the activities of financial institutions through the Central Bank of Nigeria, the financial institutions can also make access to funds for property development more difficult with its endless list of requirement.

The respondents' perception of the effort of the Lagos state government on housing provision is shown in the pie chart below. 57% of the total population share the view that government involvement can be regarded as fair, while 40% of the total respondents argue that their level of involvement in housing provision is poor, only 3% of respondents reckon that government's effort in housing provision can be considered better than that of the private sector property developers.

Fig 1: Pie chart of the level of government effort in housing provision in Lagos.

The mean item score of constraints encountered in sourcing for funds for housing projects from commercial banks in Lagos state is indicated on Table 4.3. High interest rate is the major constraint to property developers in sourcing for loans to be used for housing projects. The application procedure presents little constraints in sourcing for loans for housing projects. This agrees with a general fact that interest rate and collateral are the most critical constraints in accessing fund in the housing sector in Nigeria.

Table 4.3: Constraints in sourcing for loans from commercial banks

Constraints	N	MIS	Rank
Interest rate	39	0.94	1
Amount requested for	38	0.89	2
Security collateral	39	0.89	2
Application time	36	0.73	4
Information level	38	0.69	5
Application procedure	39	0.67	6

The effectiveness of the source of finance in housing provision was evaluated on a scale of 1 to 4 where any formal source of housing finance equal and above 4.00 is considered as highly effective as an important source of finance in housing provision while factors below the mean limit is regarded as having a low effect on housing provision.

Table 4.4 Effectiveness of the following sources of housing finance

Formal source of housing finance	N	Mean	Rank
Commercial banks	38	3.66	1
Cooperative societies	38	2.93	2
Federal mortgage bank	37	2.69	3
Mortgage institution	38	2.48	4
National housing fund	38	2.31	5
Development institution	38	2.11	6
Insurance companies	38	1.83	7
Microfinance institution	38	1.59	8

As shown on table 4.4, commercial banks with a mean score of 3.66 are the most effective formal source of housing finance, while microfinance institution is viewed as the least contributor to housing provision in Lagos.

5 CONCLUSION

Government and financial institutions are largely responsible for inadequate finance of construction project which will directly impact on the level of housing availability. Government policies on housing provision should be more proactive in meeting the ever increasing demand for housing in Nigeria. Government policies should also encourage private investors to build affordable houses by making available mortgage funds at a low interest rate. Presently, interest rate placed on loans high and the limits to the amount that can be made available to property developers is little in comparison with huge capital outlay required for construction projects. This study recommends that property developers in Nigeria should invest in innovative housing solutions that are cost effective and yet sustainable; such as prefabricated housing units that can be assembled on site and are affordable and durable.

Abstract:

This is an exploratory research aimed at identifying and evaluating social-cultural values and the impact such values could have on the technical risk management in oil refinery business of Kuwait. Generally, the management of risks in the oil refinery tends to be centred on the collection and simulation of technical data which can then be used to make decisions on the wellbeing of the workforce as well as the refinery installations. While the number crunching in the process is immensely vital, there tends to be a problem of ignoring if not sidelining the social cultural values of the people dealing with risk management processes. It could be presumed that trivialising people's values when setting the technical performance of oil and gas installations could be the starting point for poor integration and implementation of risk management strategies because the psychology of risk, as perceived by the locals. This research was conducted using an interview based survey to explore how the Kuwait Petroleum Corporation (KPC) incorporates the social cultural dimension of risk management processes. Based on a stratified sample of 19 respondents the result indicates that there is an unusually low level of recognition of social-cultural values in the risk management process in the KPC. The research recommends a further research so as to gain a clear understanding of the drivers for such a scenario.

Keywords:

risk management strategy, social-cultural values, technical data, oil refinery business, Kuwait

1 Introduction

Generally, the management of risks in the oil refinery tends to be centred on the collection and simulation of technical data which can then be used to make decisions on the wellbeing of the workforce as well as the refinery installations. Villai et al (2006) argued that in some corporations the simulation of fire related risk incidences takes a much larger share of resources than that evaluation of related factors to risk of the operations in general. While the number crunching in the process is immensely vital, there tends to be a problem of ignoring if not sidelining the social cultural values of the people dealing with risk management processes. It could be presumed that trivialising people's values when setting the technical performance of oil and gas installations could be the starting point for poor integration and implementation of risk management strategies because the psychology of risk, as perceived by the locals. This research was conducted using an interview based survey to explore how the Kuwait Petroleum

Corporation (KPC) incorporates the social cultural dimension of risk management processes. This paper was designed to test a hypothesis that “presently the social – cultural values of the workforce of the KPC hydrocarbon facilities have no impact on the technical risk management processes and techniques”. Based on two stratified samples (n) comprising of 19 respondents in each sample the result indicates that there is an unusually low level of recognition of social-cultural values in the risk management process in the KPC. The wider implication of neglecting the social-cultural values in the risk management processes is that there could be an inherent error in the technical risk assessment used in the refinery processes because of the failure to recognise the influence that can be exerted by the psychological factors of those partaking of the risk management processes. The challenge however is how to quantify such human induced errors in the risk management processes that can be attributable to social-cultural values of the organisation.

2 Culture at the Work Environment

Kopelman (2009) says “culture is conceptualised as a subjective construct; it is reflected by an individual’s mental representations and consists of interrelated patterns or dimensions, which come together to form a unique social identity shared by a minimum of two or more people”. Cross-cultural research often relies on geography as a proxy for culture; but culture amounts to more than external attributes (Kopelman, 2009). For example, observed differences in bargaining behaviour between decision makers from the United States, Japan, Israel, and Yugoslavia suggested they were not due to differences in languages, currencies, or experimenters, but were attributed to group-level psychological differences, i.e., national culture (Kopelman, 2009). While some people perceived their negotiation capabilities to be strong as the negotiation developed, others felt the opposite. “Often, hypotheses theoretically grounded in differences in cultural values focus on individualism versus collectivism and predict that collectivists, who are more group focused, will be more cooperative” (Kopelman, 2009). However, if the collectivists have their own cultural beliefs, it could be difficult to convince them otherwise with or without tangible evidence pointing to the need to take a different view from that which they may have known over the years as the “norm”.

When decision makers assume a collectivist approach, their workforce could cooperate more than those whose leaders’ take an individualist approach (Kopelman, 2009). This means that “a main effect of culture such that decision makers from collectivist cultures will find it easier to forgo individual gains for the greater good of the group than decision makers from individualist cultures who will be more self-interested” (Kopelman, 2009). Such perceptions of how to behave in certain situations can be dictated by the way someone has been trained but also by the way they are expected to behave due to their social cultural wellbeing within the organisation. However if the decision that has to be made is centred on their technical capability, it might be presumed that they would be expected to decide objectively. Such would be expected even in a risk management process.

2.1 Social-Cultural Values and Risk management

Chijoriga (2011) explained that most business that deal with risk of some sort tend to consider both quantitative (statistical or mathematical) and qualitative risk assessment methods as part of the overall risk management process. The major difference is that the quantitative methods facilitate the classification of risks while qualitative methods focus more on the “judgmental and subjective factors” that could influence the decision

making. In the engineering sector, Perez-Floriano and Gonzalez (2007) opined that international risk management and safety systems “*leave some room for failure if local cultural factors are not accounted for*”. They reckon the problem is of “*great importance for the global corporate social responsibility for organizations that operate in industries where workplace risks are common*” because “*even a slight oversight in the implementation of a home-developed risk management system may translate into a catastrophe elsewhere*” (Perez-Floriano and Gonzalez, 2007).

The main reason for such a scenario, it could be argued, is that while the technical aspects of risk management have been fully developed, the commonly held standards of acceptable or unacceptable, important or unimportant, right or wrong, workable or unworkable in any society – herein called social values – can be dynamic and severely under developed. The ideas, beliefs, attitudes, opinions, principles long cherished by members of a society can have an influence on the perception of risk (Karlsen, 2011); yet they cannot easily be linked to success and or failure of the risk management processes. Figure 1 illustrates the key factors that make up the uncertainty management maturity model, developed by Karlsen (2011). However, the model only covered the processes, the application, experience and culture; yet the social-psychological values could be added to the model, as show by light green process on figure 1.

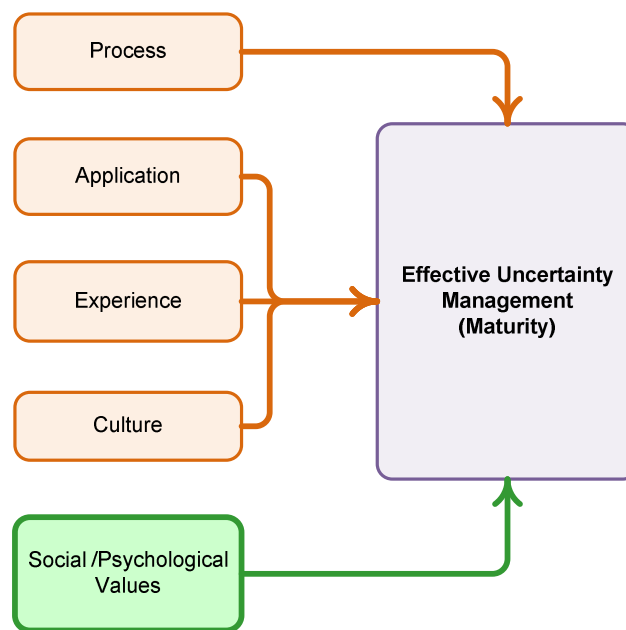

Figure 33: Uncertainty Management Maturity Model (Adapted: Karlsen, 2011)

The uncertainty management maturity model (Figure 1) can influence the organisational climate, Karlsen (2011) argued in that it aggregates the attributes of the organisation such as “*attitudes, feelings, and modes of behaviour which characterises life in the organization*”. Karlsen (2011) also noticed that within the organisation, culture has a bearing on “*organization’s values, beliefs, practices, rituals, and customs*”. This implies that for any organisation, “*safety in the workplace should be a cause of concern for organizations and employees given that the social, physical and psychological well-being of workers depends on a safe work environment*” and “*thus organisations must find ways to best communicate hazard information to their workers and promote of safety in the workplace*” (Perez-Floriano and Gonzalez, 2007).

Davies (2002) reviewed the risk standards of the UK nuclear industry and found out that at some point risk management processes were centred on certification processes by licensed risk assessors accredited by the health and safety executive (HSE); and that there has been a movement to use probabilistic approaches to the evaluation of risks, including reviews of every 10 years. While the procedures and systems have been strongly enough, sometimes events occur that could not have been envisaged. A case in point is what Grimston (2011) reported about the Japanese earth quake and Tsunami. “At 14:46 local time on 11 March, a magnitude 9 earthquake struck off Japan's north-east coast. The 11 operating nuclear power reactors in the region all "tripped" as designed (the nuclear fission process was stopped), with consequences as shown in Figure 2.

Figure 34. Picture of the Fukushima Nuclear Plant after the March 11 Japanese Earthquake and Tsunami Damage (Source: Grimston, 2011)

Davies (2002) dwells so much on the procedures, regulations and safety; yet these tasks are performed by the people. The only reference to the people is about the “licensing”; which is an all encompassing statement assuring the reader that the social-cultural aspects of the assessors could have been taken care of by the licensing of the assessor. This is the major weakness of the current technical risk management strategies because decision makers’ social-cultural values are not considered as vital to the process in a much formal way.

2.1.1 Evidence of social-cultural Factors in risk management process

From the literature, it can be argued that there is little evidence of how the social-cultural factors are being incorporated in risk management process. All the technical processes for risk management articulate, to a large extent, the scientific steps that are necessary for the process to be implemented successfully. This factor is critical in that it highlights the gap in the way decision makers adopt social-cultural factors during the risk management processes. Since the industry is able to model the technical procedures necessary for the implementation of risk management, it could be argued that there is a need for a similar approach relating to social-cultural procedures necessary for an effective implementation of the technical risk management processes.

2.2 Cycle of Decision Making and Risk Management in the Oil and Gas Industry

“A key factor in achieving successful management policies in the oil and gas industry is the availability of adequate and reliable records of generation rates, characteristics, and distribution of different wastes produced by the industry. This is irrespective of the fact that such rates and distributions are highly site-specific and significantly vary from one location to another” (Elshorbag and Alkamali, 2005). This means that there is a correlation between the management of risk and the risk management policies of an organisation. For instance, the HM Treasury (2004) developed a model which an organisation could base their policy on the management of risks in their business. The model explains that the capability of leadership (BS 31100: 2008); policy and strategy; people; partnerships and resources; and processes can lead to a more robust system that can integrate qualitative and quantitative mechanisms in risk management. While the risks in the hydrocarbon industry are plentiful, so are the business chances. If however operational risks are not properly contained, they would impact the environment, especially the communities around the refineries. Aven and Vinnem, 2005) developed a model that abstracted the decision making process (Figure 3) from the organisational and strategic level – denoted by (1); to the decision problem and alternatives (2); the analysis and evaluation of risks (3); and the management review and judgement (4); before the main decision can be made.

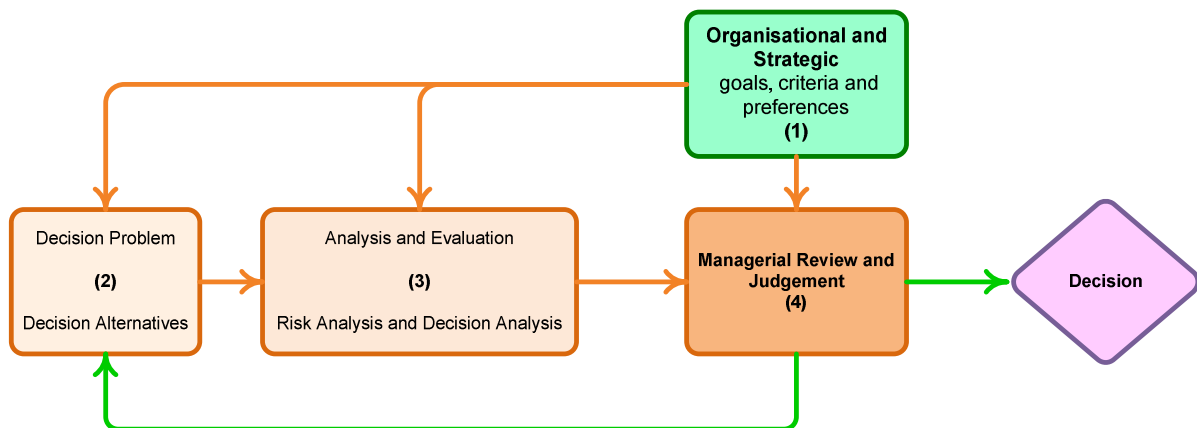

Figure 35. Model of the decision making process (Source: Aven and Vinnem, 2005).

Regardless of the method used, a decision can only be made if there is management review and judgement – whose characteristics are qualitative at best. One could argue that “management review and judgement” section of the model in Figure 3 carries, among other things, the key elements of social cultural values that can drive a manager to perceive risk in their own way; over and above the technical elements that they may have known in their day to day operations. Take for instance the general risk assessment and risk management based on the hazard and operability (HAZOP) and hazard identification (HAZID) (DoE, 1996) studies; no matter how technical the processes would be, there would still be a requirement for the “judgement” of the final outcome before the decisions are made. This type reasoning led to Villani et al (2006) stating that there are certain sources of uncertainty safety systems relating to:

People’s behaviour: a number of reasons can make people behave in a way different than expected. One of the most important is fear. Different people react to panic in

different ways. Some of them may face a dangerous path in a desperate attempt to leave the building. Others may simply run away from the fire as far as possible, even if it means not trying to leave at all. There are also people that do not know the escape route and may take a wrong direction, or take another route in order to find a family member.

Out-break behaviour: the uncertainty in this case is related to the conditions under which a risk event occurs. It comprises the kind of material that is burned, humidity, temperature and other air related variables, among many others;

Equipment failures: most of the time failures are due to inadequate maintenance or inappropriate use.

The foregone factors are compounded by the fact that the hydrocarbon industry is a multi cultural and multi-disciplined industry with workers from around the world with varied industrial experience. From the foregoing, one could critically argue that while the literature points to key indicators of the requirement for social-cultural specifications that may promote a robust risk management process, there is no evidence as such in the way the industry operates. This means that the gaps within the risk management processes may not necessarily be triggered by the technical competencies of the processes; rather by the way social-cultural values that influence decision makers are incorporated in an organisation. Therefore the perception of risk could be said to be critically weaker. This research, therefore, was set to test if the Kuwait Petroleum Corporation (KPC) workforce can realise the impact of social-cultural values on the risk management processes on the hydrocarbon installations.

3 Research Methodology

Theoretically, the choice of the research strategy depends on many factors, but the key ones according to Naoum (2007) are but not limited to: (i) the type of the research; (ii) the availability of the information required to carry-out a successful research. Flick (1998) further reasoned that an ideal research methodology at a point in time should be viewed from its appropriateness. Because the research forms part of the on-going doctoral research project aimed at unifying risk management systems for an organisation it was crucial that the choice of the research methodology as well as the data collection tool be a “gradual” development. For this reason, a qualitative research methodology was adopted. Naoum (2007) stated that “*qualitative research is subjective in nature and that it emphasises meanings; experiences and descriptions*”. This research method takes two categories:

Exploratory: used when you have a limited amount of knowledge about a topic. A research can explore the topic with a combination of various methods such as interviews, observations, and the like to make sure the information makes sense (Naoum, 2007; Dawson, 2002).

Attitudinal: a subjective way to evaluate the opinion or view of a person about a topic (Dawson, 2002).

Qualitative approach can be said to rely so much on the attitude of the researcher and that the measurement is based on opinions, views and perceptions (Naoum, 2007). There is a need for a researcher to get ‘rich and deep’ data to make such a research method to be effective; and for such to happen it was important to generate a set of

questions that were used in an interview based survey with the employees of the KPC that were naturally stratified by their role in the corporation.

4 Findings and Discussion

Figure 4 summarises the category of questions that were necessary to generate enough primary information from the interviews. This paper was designed to test a hypothesis that “*presently the social –cultural values of the workforce of the KPC hydrocarbon facilities have no impact on the technical risk management processes and techniques*”.

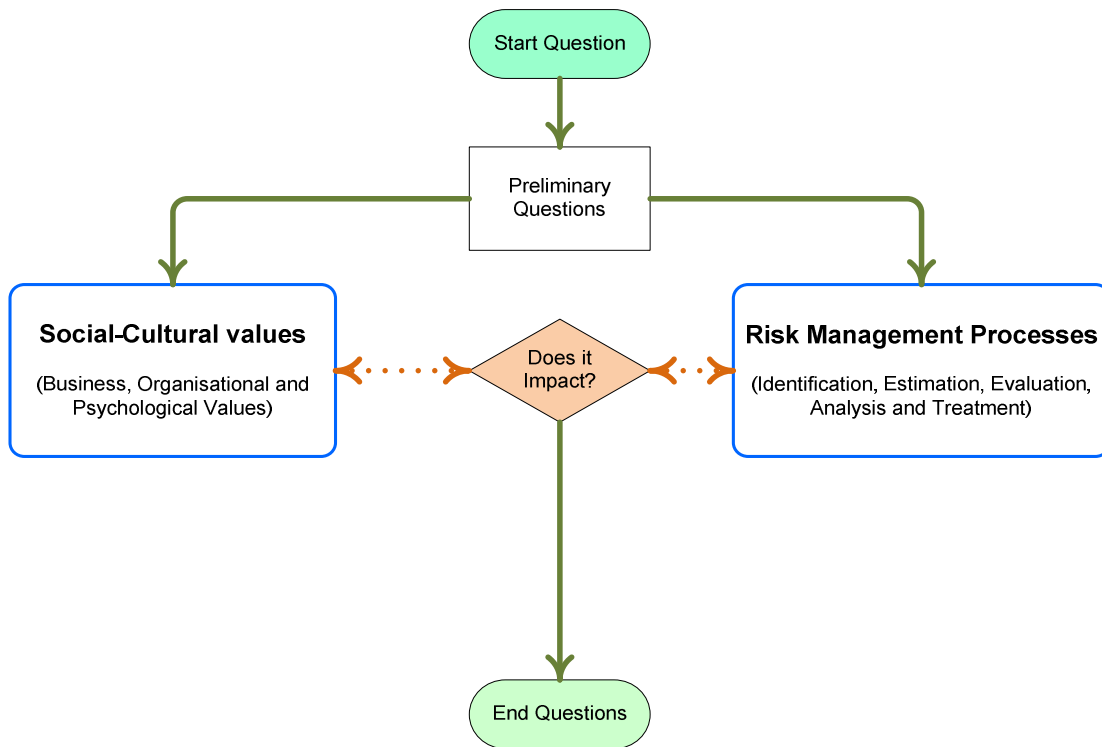

Figure 36: Summary of the set of questions used in the interview based on the Questionnaire

The Null Hypothesis (H_0) states that “the social-cultural values of the workplace of the Kuwait Petroleum Corporation hydrocarbon facilities have no impact on the technical risk management processes and techniques”.

Alternative Hypothesis (H_a) states that “the social-cultural values of the workplace of the Kuwait Petroleum Corporation hydrocarbon facilities have a positive impact on the technical risk management processes and techniques”

The social cultural values were aggregated in one section with the processes of risk assessment aggregated on the other. Using a likert scale of 1 to 5; where 1 meant “very insignificant impact”; 2 meant “insignificant impact”; 3 meant “neutral”; 4 meant “significant impact” and 5 meant “very significant” impact; the risk management processes of (i) risk identification; (ii) risk estimation; (iii) risk evaluation and (iv) risk treatment; where assessed and the results are presented in Table 1.

Table 19. Aggregate of the results from the Chi Square test of independence

RISK PROCESSES				
SOCIAL-CULTURAL CHARACTERISTICS (Beliefs, practices, rituals, customs, ideas, believes,)	risk identification	risk evaluation	risk estimation	risk treatment
Sample A (Plant A)	67	57	53	57
Sample B (Plant B)	48	68	73	62

The level of significance, $[\alpha]$ at 0.05 and the degrees of freedom $[\nu]$ was determined using the formula $[r-1][c-1]$, where ‘r’ and ‘c’ stand for number of rows and columns respectively (Table 1). Hence, the degree of freedom $[\nu] = [2-1][4-1] = 3$. Using the X^2 distribution table the critical value works out to be 12.838 (Stephens, 1999). However the Chi square test results in the value of 6.9044 which is way below the statistic of 12.828. The implication is that the Null hypothesis cannot be rejected; which means that as far as the workforce is concerned, they do not see the significance of the social-cultural values in the risk management processes of the firm.

4.1 Assessing the Implications of the Research Findings

For the Null hypothesis to be rejected there needs to be overwhelming evidence that respondents were for the idea that indeed social-cultural values could have an impact on the risk management processes and techniques at work. The implications of the result is that if there is a fault in the risk management process that could be triggered by non technical sources such as the way people relate to each other or by their work culture it would be difficult to isolate and confidently apportion the “cause and effect”. This is because the workforce felt that they could not easily pinpoint themselves as the possible weakest link in the risk assessment process. This could be said to relate to “human factors and human nature” where the workforce may not easily understand their role in the overall risk management process and how their being human can have an influence in their decision making process. Therefore the implications of the findings is that if the source of weaknesses in the risk assessment process emanated from the workforce, it would be difficult to deal with because the perception of the workforce leans towards technical risk management processes as the main area of concern if one was to effectively manage risks. This means that the workforce does not feel that people’s behaviour is as important as technical risk management processes that are deployed by the organisation. The poor link between human behaviour could, in turn, be linked to a poor perception of how social-cultural factors have an impact on how people behave.

5 Conclusion and Further Research

The amalgamation of social-cultural dimensions to the risk management processes of the Kuwait Petroleum Corporation hydrocarbon facilities has been envisaged to be critical to the promotion of a risk culture in the operations. This has been as a result of presumptions that relate to the way technical risk management processes have been developed based on international standards applicable to general industries. Because the literature review indicates the importance of organisational culture, social and psychological dimensions of the any organisations have equally been observed to have a significant impact on the decision making processes relating to the safety and reliability of installations. However a preliminary survey carried out using 2 samples each from a

separate facility has concluded that as far as the workers are concerned they do not see a significant level of impact that their social-cultural dimension to the business would affect the overall risk management approach. However, the level of significance based on the chi square test may not have been the ideal way to assess the level of rejection to the proposition. Therefore further research is necessary in the area of assessing the impact of social cultural factors on the overall risk management processes in the oil and gas industry of Kuwait. Further research could yield reasons for such a perception from the workforce.

5.1 Further Research

The research has been part of the ongoing PhD research on the social –cultural dimension for risk management in the oil and gas industry of Kuwait; therefore further research is required in the area of the factors leading to the perception that there is insignificant impact of the social cultural values to overall risk management process. Since the workforce have not been able to link behaviour to their social cultural values at work and that that could affect their technical performance, it could be argued that more work needs to be done to establish the drivers for such a perception in the organisation.

Rural practice

A preliminary study on the legal and policy background for provision of affordable housing on or by the rural estate in England.

Adam Corbin¹

Abstract:

This paper focuses upon legal and policy aspects of affordable housing provision likely to be of interest to owners and managers of rural estates in England. At this stage, a macro approach is taken, where the paper seeks to promote understanding of relevant key areas with a view to stimulating further discussion based upon this understanding. These key areas include the policy setting and mechanics of affordable housing provision, funding arrangements, and legal structures used for affordable housing provision. In conclusion five themes are drawn out for further discussion during the collection of qualitative data. In effect this paper is intended to ask more questions than it answers in order to set the scene for structured interviews, which will be the next step in this research.

Keywords:

rural, housing, affordable, housing association

1 Introduction

The provision of affordable housing is a complex area of law, having been subject to a multiplicity of changes over the last 100 years. Every successive government seems to want to either ‘tweak’ or ‘revolutionise’ legal provisions for housing, with the intent of doing a better job than the last. This paper does not seek to rehearse the history of changes to the law on housing, unless relevant; but seeks to explain the legal and policy position as of June 2011. First, the policy setting for the provision of rural housing is discussed and the rationale for the research defined. Second, an overview is provided of the regulatory setting for provision of affordable housing generally, and where poignant, in rural areas. Finally, some key themes are drawn out for further discussion as this research progresses into qualitative data collection. This paper is concerned with the situation in England only as since devolution, Scotland, Wales, and Northern Ireland have all taken slightly different directions.

2 Recent policy background to affordable housing in rural areas

The great British need for more housing has been a recurring theme of politics over the last 100 years or so (BBC Radio 4, 2011; Hughes and Lowe 2000), and ‘affordable housing’ have become buzz words of election manifestos (Labour Party 2010; Liberal Democrats 2010), and political speeches see e.g. Demianyk (2009). The meaning of

‘affordable’ in terms of housing can be a relative term, depending, amongst other things, upon the geographical location or means of an individual; this has been a recurring theme in housing policy (Malpass 2000). The term is defined in The Communities and Local Government (DCLG) Good Practice Guide ‘Delivering Affordable Housing’ as:

*“...social rented and intermediate housing, provided to specified eligible households whose needs are not met by the market [...] **Social rented housing** is rented housing owned and managed by local authorities and RSLs [Registered Social Landlords], for which guideline target rents are determined through the national rent regime [...] **Intermediate affordable housing** is housing at prices and rents above those of social rent but below market price or rents...”* (original emphasis) (Great Britain. DCLG. 2006).

The specific inclusion of the word ‘prices’ in the definition of intermediate housing indicates that the definition applies equally to housing for purchase and housing for rent, as confirmed later in the guidance.

The particular problem of affordable housing (or lack of it), in rural areas has regularly been flagged up in government reports and papers in recent years (Goodman, 2006; Burgess, 2006; Burgess 2010; Taylor, 2008). Outwardly, at least, there is a political will to grapple with the issue, which is often raised by the current Housing Minister (Lawson, 2010; DCLG, 2010a). In fact Berlin (2010), argues that the shortage can be taken as a “*given*” and his report proceeds upon the basis of a “*solutions approach*”, this paper is intended to continue in that spirit.

For the purposes of this work, the definition of a rural estate coined by Forum for the Future (2006) is adopted: “...an area of land, incorporating agriculture alongside other land-based businesses, managed as a whole organisation with overlying aims”. Unfortunately there is no data available on the amount of estates in England. However, if this definition is considered alongside the Agriculture in the United Kingdom 2010 (DEFRA 2010a) statistics for holdings in England of over 20 hectares; we at least have an indicator, though it is acknowledged that many estates comprise of more than one holding. In 2010 there were 67,500 holdings of over 20 hectares farming a total of 8,552,600 hectares (DEFRA 2010a). In any event the general trend is towards consolidation (Munton, 2009), with evidence of farm sizes increasing (DEFRA, 2010b), indicating that the power of estates is growing.

Given this overall and increasing predominance of large landholdings in rural areas, it is argued here that rural estates should be considered as key players in the delivery of affordable housing in rural areas. However, it is also argued that there is a failure to engage with estate owners and their managers. For instance Varley (2008), in discussing management of the Clinton Devon Estate housing stock said:

“Commercial and residential let property to over 100 rural businesses and 400 families was managed as a separate business and whilst over 75% of residential rents could be considered “affordable” little attempt was made to “join up” or align objectives with other elements of the wider Estate strategy. The provision of “low cost housing” for local people was just “what the Estate did”.”

A recent study by the East Midlands Development Agency (emda) on the contribution of rural estates to the local economy found that estates had a “significant role in housing

provision in their localities” and recognised that estates “can play a key role in the sustainable development of settlements” (emda, 2009). This key role has added value; it is a fact that rural estates have the right characteristics to provide other services needed for sustainable communities, such as shops, pubs, village halls, and recreation areas.

It is clear then that rural estates hold much of the land which might be used for affordable housing in rural areas, and are ideally poised to assist in the provision of affordable housing. Further, in many cases these estates are already providing affordable housing whether or not by design. Whilst there is no evidence that rural estates in particular are not pulling their weight, there is evidence that not enough affordable housing has been provided in rural areas (DEFRA, 2004), or indeed at all (Hills, 2007). Berlin (2010), recommended that The Homes and Communities Agency (HCA) commit to “Build on relationships with large public landowners and estates, with a view to identify ways of bringing forward land for rural affordable housing”. Whilst Goodman (2006), identified rural land owners as gatekeepers, and suggested that the decision on whether to release land is based upon factors such as price, business, and social interests; she then recommended various ‘carrots’ such as changes in taxation, planning policy and regulation, to improve the amount of land released. This all seems very plausible but assumes that either landowners want to fully divest themselves of their interest in a proposed site, or the legal structures for being involved in the provision of affordable housing are acceptable to them. It is argued here that there is scope for estates to become involved on many different levels, a plurality which does not seem to be recognised in current policy. No one has suggested, for instance, that the estate might like to form its own housing association. In 2009, in response to the Taylor Review, the DCLG commenced a consultation on proposals to incentivise landowners to bring forward additional land for rural affordable housing (DCLG, 2009), the consultation has not yet been formed into something more concrete, to the chagrin of some (Rural Coalition, 2011). The proposals centre on referrals by landowners (to the ultimate affordable housing scheme), and landowners retaining an interest (such as the freehold of the development) these correspond to recommendations 17 and 18 of the Taylor Review. It is suggested here that there may be additional ways for landowners to remain involved, or to entice landowners into releasing land for development of affordable housing. Indeed, it is the wider object of this research to establish whether there is sufficient regulatory scope for rural estates to become more widely and actively involved in the provision of affordable housing in rural areas; and if so, to understand why rural estates do not always engage with the idea of affordable housing provision.

3 Provision of affordable housing: an overview

The definition of when housing becomes ‘affordable’ has been outlined above, with a distinction drawn between rental housing and housing for sale, in this section, the mechanics of housing provision in these two areas are explained briefly.

3.1 Provision of homes

Under section 8 of the Housing Act 1985 (HA85) ‘Local Authorities’ are required to “*consider the housing conditions and needs in their district with respect to the provision of further housing accommodation*”. These ‘Local Authorities’ are defined depending upon where they are in England or Wales, and may be District Councils, Unitary Authorities, Metropolitan District Councils, Common Council, or Borough of London. “*Housing conditions*” relate to the condition of standing stock; whilst “*needs*” relate to the needs of residents in the Local Authority area and also those of persons

who might conveniently be housed in it (*Watson v Minister of Local Government and Planning* [1951]). This housing is paid for by a combination of subsidy from central government, local authority funds, and rental income from tenants, which may or may not originate from housing benefit provided by central government.

3.1.1 Providers

The housing stock itself may, or may not be provided by the Local Authority itself (HA85 section 9), in fact under section 161 of the Local Government and Housing Act 1989 Local Authorities are not bound to have housing stock at all. Since Medieval times when Almshouses provided shelter for the poor and sick, there has been a voluntary or ‘third sector’, intent on housing those in need (Malpass, 2000). However, this sector was not really recognised as a partner in the provision of affordable homes until the passing of the Housing Act in 1961 (Malpass, 2000). Since then, there has been a steady increase in the predominance of this ‘third sector’ (Malpass and Murie, 1999; Handy, 2007a). The bodies in this sector consist of what can be known as ‘Housing Associations’, these are defined by section 1 of the Housing Associations Act 1985 (HAA85) as:

“a society, body of trustees or company—

(a) which is established for the purpose of, or amongst whose objects or powers are included those of, providing, constructing, improving or managing, or facilitating or encouraging the construction or improvement of, housing accommodation, and

(b) which does not trade for profit or whose constitution or rules prohibit the issue of capital with interest or dividend exceeding such rate as may be prescribed by the Treasury, whether with or without differentiation as between share and loan capital.”

Despite this statutory definition, the treatment of a housing association for purposes such as taxation, regulatory oversight, and even judicial review varies according to the characteristics of the individual association (Alder and Handy, 2003; *R(Weaver) v London & Quadrant Housing Trust* [2009]). The most recent legislation, the Housing and Regeneration Act 2008 (HRA08), provides for significant changes in the regulation of this sector (Handy, 2008). Section 59 of the HRA08 has now opened up the definition of a Housing Association which might be subject to regulatory oversight, and receive funding. However constitutions will still vary, both as a result of history, and according to the purpose of the association. The possibilities range from charitable trusts, to co-operatives, to Industrial and Provident Societies, to fully mutual associations. Suffice to say for now that there are many options, which need to be evaluated according to the objectives to be achieved.

Housing associations may have received a volume of housing stock from a Local Authority under a Large Scale Voluntary Transfer (LSVT) agreement as provided by section 106A of the HA85 (subject to certain checks and balances therein), or they may have built or accumulated housing stock under their own steam. Also in existence is a hybrid body called an ‘Arms Length Management Organisation’ (ALMO), this is a body which is usually partly tenant controlled and has delegated responsibility for the management of a Local Authority’s housing stock, or part thereof, under section 27 of the HA85 (Terry *et al.*, 2005).

3.1.2 Regulation

Since the passing of the HRA08, regulation of the sector is by the Tenant Services Agency (TSA) under section 81, regulation having previously been conducted by The Housing Corporation. However, in October 2010 the DCLG announced that the TSA was to be abolished, with its regulatory functions absorbed by the HCA, though this is dependent upon parliamentary time, and as such has not yet happened (HCA, 2010a). Sections 59, 68, 69, and 70 of the HRA08 ensure that virtually any provider of social housing, to rent or on a shared ownership basis, is subject to regulation and oversight by the TSA, this has the effect that Local Authorities and Housing Associations alike are covered. The TSA has ten regulatory objectives set out under section 86 of the HRA08, and performance is evaluated yearly based upon these objectives, see e.g. TSA (2009a). The TSA has brought in a new regulatory framework for housing providers, entailing a much more purposive and broad brush approach, than under the previous regulator (TSA, 2009b), in fact there are only six broad standards which each encompass some more specific guidance (TSA, 2009c). When the Housing and Regeneration Bill was passing through Parliament there was a concern that the TSA would be given too much power, and this would detract from the independence of housing associations (Handy, 2007b; Handy, 2008). In fact, the HRA08 does bestow wide powers of regulation upon the TSA, but fettered by provisos that require the regulator to have regard to the desirability of housing associations maintaining their independence, and a requirement for consultation on any changes to regulation (sections 194-196). Given the, all be it fettered, powers of the TSA a decision to become subject to this sort of oversight is not to be taken lightly, and this sort of commitment can only be long term.

3.2 Tenure

The duty to provide housing is focussed upon the provision of rental housing, however there are also certain provisions allowing Local Authorities to sell properties, though it may be difficult to argue that this is part of their duty under section 9 of the HA85.

3.2.1 Rental properties

The allocation of homes by the Local Authority is subject to the provisions of the 1996 Housing Act (HA96), and in particular, the guidance issued under section 169, which acts as a gateway to an individual being allocated with accommodation. Under section 159 of the HA96 the Local Authority can then either give the individual a tenancy or nominate them for a tenancy provided by someone else; it should be noted that this provision does not apply to certain existing tenants. The relationship between a Housing Association and a Local Authority is primarily one of contract, and can vary individually, but generally, it is that of client and service provider, with some statutory oversight. Most housing associations will their own allocation policy that is in accordance with their objectives, which must be published in summary form (HA85 section 106(1)). The regulatory compliance of allocation policies can be a problem where a landowner is seeking to have control of, or a say in who moves into the affordable homes. Housing Associations will also have a duty to co-operate with Local Authorities, to such an extent as is reasonable in the circumstances, in offering accommodation to those who qualify under that local authority's allocation policy (HA96 section 213).

3.2.2 Tenancies offered

Which one of the four types of tenancy available is offered by a public, private or third sector housing provider will depend, amongst other things, upon when it was granted, to

whom, by whom, and under what circumstances. Just one of these tenancies could be the subject of a book, therefore only the points on each that are relevant to this work are outlined here.

Protected tenancies' are regulated by the Rent Act 1977 (RA77), and though now superseded are still relatively commonplace, particularly in rural areas. They only apply to private landlords where the property was let before January 15th 1989 (HA88 part 1), and subject to several exclusions which may depend upon when the tenancy commenced. The tenant is entitled to generational succession where there is no spouse or partner to succeed (even if the spouse or partner has already succeeded), and there are limited grounds for landlord possession. A 'fair rent' is set by a 'rent officer' subject to section 70 of the RA77, based upon the characteristics of the property and subject to a maximum increase formula based upon RPI and set under the Rent Acts (Maximum Fair Rent) Order 1999.

'Secure tenancies' are regulated under the HA85 Part 3, and provided by 'social landlords' who are either Local Authorities, or certain Housing Associations who were registered as 'social landlords' (RSLs) under what is now the HA96, and granted the tenancy on or before January 14th, 1989. There are certain landlord and tenant conditions which must be satisfied for a secure tenancy to arise, and numerous exceptions to the rules. Secure tenants have the right to one generation succession, restricted grounds for landlord possession (which is only possible with a court order), and various other beneficial rights. Tenants of Local Authorities pay 'reasonable rents' under section 24 of the HA85, which are largely a matter of discretion for the local authority (Arden and Dymond, 2007). Rents paid by housing association tenants are covered by the Rent Act regime as described above (RA77 part 6).

'Assured tenancies' were introduced by the 1988 Housing Act (HA88), and apply to tenancies granted by what were at that time RSLs after January 14th, 1989, and to 'protected tenancies' in the private sector which in reality means they replaced RA77 tenancies. The headline features are spousal or partner succession, and limited grounds for possession by the landlord (which may be possible without a court order). There is a limited right to refer the rent to a rent assessment committee, on notice (HA88 sections 5-6), which is assessed according to the value of other such tenancies with vacant possession. Rents are further controlled by the TSA whom since 1999 (then as the Housing Corporation) have issued guidance (now under section 197 of the HRA08) to limit yearly increases in the total rental income of a housing association (Alder and Handy, 2002). The guidance also contains rent caps depending upon the size of a given property (TSA, 2009d). Most tenancies currently granted by Housing Associations are of this type.

'Assured shorthold tenancies' are also provided for by the HA88, they are the virtually unregulated form of tenancy practitioners and members of the public are most familiar with. The important point to note is that following the HA96 all tenancies granted after February 28th 1997 are considered to be of this type, they will only be 'assured tenancies' where an 'opt in' notice is served.

3.3 Sales

3.3.1 *Right to buy (RTB)*

Those with 'secure tenancies' are endowed with a right to purchase the property they live in under part 5 of the HA85, particularly section 118. The secure tenant must have enjoyed the status of a 'public sector tenancy' for two years or more, but the landlord and dwelling can vary during that period. The 'public sector tenancy' can be with a Housing Authority. Section 20 and Schedule 5 of the HA85 contain exceptions to the 'public sector tenancy', which include charities, co-operatives, and some non-public funded Housing Associations, amongst others.

3.3.2 *Right to acquire (RTA)*

Section 16 and 17 of the HA96 gives 'assured' tenants a similar right to purchase their dwelling if it was provided with public funding, or the proceeds of other RTA sales, or because of a LSVT; and the tenant satisfies the RTB conditions as above. The excepted situations are similar to those under schedule 5 above, but contained in a separate schedule 5 to the Housing (Right to Acquire) Regulations 1997. Of particular importance is 1A, which prevents RTA "*where the dwelling-house is situated in a rural area designated by order of the Secretary of State*".

3.3.3 *Other provisions*

Section 32 of the HA85 allows a Local Authority to make general disposals of land or housing stock, subject to general or individual consent by the Secretary of State under section 34 of the HA85. Housing Associations can also make voluntary disposals of property at their discretion and provided within their objects.

3.3.4 *Shared ownership*

Shared ownership is typically provided using one of two models. Either the tenant purchases a long lease over a proportion of the property for a premium, then pays rent on the residual value of the property; or the tenant purchases the legal title of the property outright, but only a proportion of the equitable interest, the remainder of which he 'rents'. It is usually possible to 'staircase' up or down, meaning to increase or decrease the share of the property value the tenant holds. Whilst it is general policy that tenants should be able to staircase all the way to 100% ownership, in certain protected areas, which include many rural settlements of <3,000 inhabitants, there is an 80% limit on tenant equity, to ensure that affordable properties remain available (HCA, 2010b). There has been a steady increase in the popularity of shared ownership schemes (Bramley and Dunmore, 1996), and despite some the problems with evictions for rent arrears (Cowan, 2010), this is a policy which the current government seem all for (Arden, 2010). A particular problem arises in relation to the objects of charitable Housing Associations and shared ownership. As outlined by Holden (1999), there must come a point where a person who owns a certain amount of equity in their home is no longer in need, a point agreed by Alder and Handy (2003). Fortunately the Charities Commission has now provided guidance on such schemes, and the short answer is: yes it is possible (Charities Commission, 2009). The longer answer is that it very much depends upon the persons to whom the accommodation is provided, the part shared ownership has in the overall scheme, and whether or how non-charitable parts of the enterprise benefit the charitable parts (Charities Commission, 2009).

4 Funding

4.1 HCA grant funding

Grants from Central Government (the DCLG) for provision of affordable housing in England are now subject to the provisions of the HRA08, which has significantly altered past provisions. The 2011-15 Affordable Homes Programme – Framework (‘the framework’) introduces some new ideas and possibilities, which the Housing Minister, in his forward to the framework document, says will make a significant difference (DCLG and HCA, 2011). The following information is based upon the HCA literature, and TSA consultation documents, as such it is not yet clear what the exact position on these provisions will be.

4.1.2 Eligibility

For the purposes of this grant funding there may be two different bodies, one being the developer (‘Investment Partner’), and the other, the Housing Association (‘Registered Provider’ or RP), alternatively, the two roles may be combined in one body. Those Housing Associations who are not registered with the TSA are required to begin the process of registering at the time of application, where they are to manage HCA funded properties. Likewise, Investment Partners will need to be registered with the HCA, if they are not already, before they can receive funding.

4.1.3 Affordable rent product

The key to the effectiveness of this new funding scheme is the ‘Affordable Rent Product’ (DCLG and HCA, 2011), which is intended to allow increased borrowing against proposed and existing housing stock, by increasing the value of the tenancies provided (Shapps, 2010). No new type of statutory tenancy is to be created (yet), rather the TSA, under its HRA08 section 197 powers, will authorise a new rental scheme for non Local Authority RPs with rents based upon up to 80% of market rental value. The TSA in partnership with the RICS has issued guidance on how this value would be assessed (TSA, 2011). In addition to the relaxation on the rental basis, the RPs will also be able to offer tenancies at a minimum term of two years, instead of the current assured tenancy (TSA, 2010). It would appear then, that it will be possible for RPs to grant assured shorthold tenancies, provided they contain sufficient safeguards for the tenant to pass the TSA standards (TSA, 2010). It will also be possible to convert existing empty lets into affordable rent properties (*Journal of Housing Law*, 2011); however there seems to be no question of converting existing tenancies into the new product, unless by consent.

4.1.4 Planning policy

The combined effect of PPS3 (DCLG, 2010b), and the policy document ‘Delivering Affordable Housing’ (DCLG, 2006), is that ‘affordable housing’ is considered as such for the purposes of rural exception sites. Rural exception sites are those where planning permission would not normally be granted, but there is an identified local need for affordable housing. However, the new affordable rent product is not specifically included in this definition, so a consultation (now closed) was started on whether such tenancies should be included (DCLG, 2011). If they are, this would make a difference to the funding of developments on rural exception sites, making more business sense.

4.1.5 *Funding for shared ownership and social housing*

Whilst affordable rent is expected to be the mainstay of the latest funding drive, the Framework also invites applications for shared ownership schemes and social rent schemes (DCLG and HCA, 2011). To clarify, social rent will be any housing let on the pre ‘affordable rent’ scheme basis; funding for such schemes will require “*exceptional*” circumstances and “*a strong case*” to be put forward (DCLG and HCA, 2011). The provision of affordable home ownership schemes will not attract funding unless they are a part of a wider ‘affordable rent’ scheme.

4.2 Section 106 agreements

Most practitioners will be familiar with the idea of agreements under section 106 of the Town and Country Planning Act 1990. The framework envisages that affordable housing schemes funded under section 106 should be financed without the need for HCA grants, the intention being that the increased value of the ‘Affordable rent product’ will improve viability. However, the HCA will consider such schemes on a necessity basis (DCLG and HCA, 2011).

4.3 Local Authority ‘gifts’ and loans, and other miscellaneous funding

There is evidence of Local Authorities disposing of land under sections 32 and 34 of the HA85 to enable provision of affordable homes (Improvement and Development Agency, 2008). Local Authorities are also able to give loans or grants to RSLs (HA96 section 22) and RSLs are able to borrow from the Public Works Loans Commissioners (HA96 section 23). All of these provisions are likely to be subject to approval from the Secretary of State. There are also mechanisms whereby certain receipts from disposals, grant surpluses and rent surpluses can be recycled into funding certain projects (see Alder and Handy, 2003).

4.4 New homes bonus

The new homes bonus is intended to encourage Local Authorities to promote housing schemes in their areas, to mitigate any disadvantages caused by having more homes to service with the council tax revenues, and encourage local people to be more supportive of new schemes (DCLG and HCA, 2011). The bonus will come from Central Government, will match Council Tax income for each dwelling and will be paid to the Local Authority for a period of six years (BBC News, 2010).

5 Key themes for delivery of affordable housing on or by the rural estate

The options for the rural estate will depend upon what objectives are desirable or need to be fulfilled in the management of the estate. The following thoughts are intended to provoke discussion leading to a better understanding of the possibilities for delivery of affordable housing on or by the rural estate.

5.1 Control

It is clear from the above that the general rule in affordable housing, as in many other areas, is the more funding given, the more regulatory oversight taken. So to some extent there is a trade off between funding and control. This control affects allocation decisions, management policies, finances, reporting and transfer of interests. An example might be that a landowner may not wish to fully divest control of a site to a co-

operative housing association; for fear that a monster is created on his doorstep. Another is that a landowner may need some housing for staff, but may not have an appropriate interface with the association to get his allocations.

5.2 Business sense

Whilst it is not contended that estates only operate on profit making principles, they are clearly important. The management of existing housing and land for housing has to be cost effective in terms of revenue, capital, and taxation. Are there problems with the taxation treatment of rural housing assets which affordable housing provision can assist or would hinder? Would divesting the management of a proportion of estate housing stock to a housing association improve management efficiency?

5.3 Ongoing commitment

The flip side of control is that a landowner may wish to rid himself of costly and time consuming property management, or may wish to keep a housing association at arm's length. By convention estates usually wish to retain their land, at least whilst it meets their wider objectives, so is there a fear that becoming involved in the provision of affordable housing will mean a heavy ongoing commitment, if the land is retained?

5.4 Complexity

Having attempted to explain provision of affordable housing for the last ten pages, it would be wrong to claim it is not complicated! Is it the case that estate managers are satisfied with the management structures they have for their housing, and do not wish to become tangled in this web of regulation and oversight?

5.5 Philanthropy

There are some estates that are either already run as charities, or where certain areas of housing provision are tantamount to charities. Might the use of a charitable housing association structures improve the management and objects of these estates? There is also a matter of degree here; philanthropic aspirations may not extend fully to the running of a charity, how possible is this?

6 Conclusions

Many of these problems may be solved by employing the correct choice of housing association structure, and putting in place appropriate management procedures. The next step in this research will be to establish whether the themes outlined above are 'real world' accurate and establish the degree to which they are, or are not, through qualitative data collection. Following this, an in depth analysis will be conducted into appropriate structures, or changes in law or policy which may assist.

Adaptive Reuse of Heritage Buildings: Sustaining an Icon or Eyesore

Peter A Bullen¹ and Peter ED Love¹

¹School of the Built Environment,
Curtin University, GPO Box U9187, WA 6845,
Australia

Email: p.bullen@curtin.edu.au

Abstract:

There is growing acceptance that heritage buildings are an important element of Australia's social capital and that heritage conservation provides economic, cultural and social benefits to urban communities. The decision whether to reuse a building entails a complex set of considerations including location, heritage, architectural assets, and market trends. The role of building conservation has changed from preservation to being part of a broader strategy for urban regeneration and sustainability. A growing body of opinion supports the view that adaptive reuse is a powerful strategy for handling this change. Urban development and subsequent redevelopment has a significant impact on the environment and this research investigates how the conservation of heritage buildings may contribute to a more sustainable urban environment. This paper examines practitioners' views and experiences associated with adaptive reuse of heritage buildings within the context of urban regeneration, conservation and sustainability.

Keywords:

adaptive reuse, heritage, conservation, urban regeneration, sustainability

8 Introduction

Heritage buildings form an integral part of Australia's social capital. There is growing acceptance within Australia that conserving heritage buildings provides significant economic, cultural and social benefits (Bullen and Love, 2010). According to the Department of Environment and Heritage (DEH, 2004) heritage buildings provide a valuable glimpse of the past and lend character to communities and therefore should be conserved for future generations. The integration of historic conservation with environmental concerns has become an innate feature of an agenda to support sustainability (Stubbs, 2004; Bullen and Love, 2010). As part of a wider revitalisation strategy to promote sustainability within the built environment, many buildings of cultural and historical significance are being adapted and reused rather than being subjected to demolition (Ball, 1999; DEH, 2004; Wilkinson and Reed, 2008; Wilkinson *et al.*, 2009; Bullen and Love, 2009).

To date there has been limited research that has examined the economic benefits of heritage buildings (Bullen and Love, 2010). As a result, the retention of heritage buildings are often viewed as being 'investment sinkholes' with issues associated with

social and environment sustainability being ignored. In Western Australia (WA), for example, the City of Perth (2011) has been advocating that significant financial savings and returns that can be made from the adaptive reuse of historic buildings in an attempt to preserve the past for the future.

Adaptive reuse may help communities, governments and developers in the quest to reduce the environmental, social and economic costs of continued urban development and expansion (Ball, 1999; Wilkinson and Reed, 2008; Bullen and Love, 2009). Adaptive reuse can transform heritage buildings into accessible and useable places as well as provide the added benefit of regenerating an area in a sustainable manner. Many cities have begun to realise that reusing heritage buildings is an important part of any regeneration program (Ball, 1999). Yet, many building owners and developers still regard the reuse of heritage buildings as being an unviable option as planning and building regulations may restrict their functioning (Bullen and Love, 2010). In addressing this issue, the Property Council of Australia (2005) has advocated that heritage regulations should require the retention of only the best and most useful features of an historic building. This paper examines practitioners' views and experiences associated with adaptive reuse of heritage buildings within the context of urban regeneration, conservation and sustainability.

9 Adaptive reuse and the Conservation of Heritage Buildings

Adaptive reuse involves converting a building to undertake a change of use required by new or existing owners (Latham, 2000; Wilkinson *et al.*, 2009). The change of use may require refurbishment and/or complete renovation of existing buildings or structures. In most States of Australia, adaptive reuse is a process that invariably involves physically changing the function of a disused or ineffective building (DEH, 2004). Changes to buildings can involve major internal space reorganisation and service upgrades or replacement. Alternatively, adaptive reuse may simply require minor restoration works where nothing changes except the building's functional use.

When adaptive reuse is applied to heritage buildings, it not only retains the building but conserves the effort, skill and dedication of the original builders (Love and Bullen, 2009). Adaptive reuse also conserves the architectural, social, cultural and historical values (Latham, 2000). Accordingly Bromley *et al.* (2005) have advocated that adaptive reuse is essentially a form of heritage conservation (Bromley *et al.*, 2005). There has been a shift away from confining heritage value to prestigious, monumental or historically significant buildings. Buildings of more vernacular origins such as redundant offices or obsolete community halls are seen to have heritage value (Hamer, 2000). The practical outcomes of adaptive reuse and the conceptual values of conservation support the reuse of heritage buildings as a sustainable strategy. Cooper (2001) suggests that the outcomes of adaptive reuse include improvements in material and resource efficiency (environmental sustainability), cost reductions (economic sustainability) and retention (social sustainability).

9.1 Maintaining Heritage Buildings

The act of conserving parts of cities as history, and then reusing those spaces for a variety of uses, is being driven by growing calls for urban regeneration (Ball, 1999; Ball, 2002; Bullen and Love, 2010). The conservation of heritage buildings has become a key driver of regeneration (Pendlebury 2002; Strange and Whitney 2003,). Pickard (2001) contends that sustainable historic environments should:

- reflect local life;
- improve quality of life;
- maintain local identity, diversity and vitality;
- minimise the depletion of non-renewal heritage assets;
- develop collective responsibility for heritage assets;
- empower community action and involvement;
- provide a robust policy framework for integrating conservation objectives with the aims of sustainable development more generally; and
- define the capacity by which historic centres can permit change.

In terms of environmental performance, heritage buildings even after adaptive reuse may not reach the desired standards of new buildings. They may also have reached a state where adaptive reuse is uneconomical or their layout may be inappropriate for any change of function, particularly commercial buildings (Wilkinson *et al.*, 2009; Bullen and Love, 2011a,b). Re-using rather than replacing buildings is generally the most resource effective strategy to provide accommodation, especially if a conservation strategy is incorporated into the design (Ball 1999; Douglas 2002). The most successful adaptive reuse projects are those that respect and retain a building's heritage significance as well as add a contemporary layer that provides value for the future. When a building can no longer function with its original use, adaption is the only way that a building's fabric heritage significance can be preserved and maintained. Some State agencies in Australia, such as WA, are enacting policies for the adaptive reuse of heritage buildings. Such policies contain standard criteria to ensure that an adaptive reuse project has minimal impact on a building's heritage values, such as:

- discouraging "façadism"—that is, gutting the building and retaining its façade;
- requiring new work to be recognisable as contemporary, rather than a poor imitation of the original historic style of the building; and
- seeking a new use for the building that is compatible with the immediate area.

10 Research Methodology

The decision-making processes that owners and practitioners are confronted with when considering adaptive reuse and issues pertaining to sustainability are diverse. An interpretative research approach was therefore adopted as it can capture information about the beliefs, actions, and experiences of stakeholders involved in the decision-making process surrounding adaptive reuse. Moreover, in considering the viability of adaptive reuse, it is necessary to consider the 'context' of the building in terms of its impact on social and natural environments as well as those of an economic nature.

10.1 Data Collection

Interviews were chosen as the primary data collection mechanism as they are an effective tool for learning about matters that cannot be directly observed (Taylor and Bogdan, 1984). Interviews were used to understand the views and experiences associated with adaptive reuse, which allowed a channel for 'context' to be captured (Kvale, 1996). The interview guide is the most widely used format for qualitative interviewing and was adopted for this research (Patton, 1991). In this approach, the interviewer has an outline of topics or issues to be covered, but is free to vary the wording and order of the questions to some extent. The general themes that the interviewer focused on were:

- effectiveness of adaptive reuse of heritage buildings as a strategy to achieve sustainability;
- attributes that make a heritage building suitable or unsuitable for adaptive reuse;
- impact of various factors on the decision to reuse heritage buildings; and
- the barriers and opportunities surrounding adaptive reuse of heritage buildings.

Sixty semi-structured interviews were conducted over a four month period with a stakeholder group comprising such as architects, developers and building managers. Interviewees were chosen for their ability to contribute towards this study through both tacit and explicit knowledge of adaptive reuse. Individual representatives from firms from the metropolitan area of Perth were selected using the technique of stratified random sampling and invited to participate in the research.

Content analysis was used as the primary analysis technique on the collected data. In its simplest form this technique is the extraction and categorization of information from documents. Inferences from the data can only be drawn from the relationship with what the data with their institutional, societal and cultural contexts (Krippendorff, 1980). The text derived from the interviews was analysed using QSR NVivo 9.0, which enabled the development of themes and additional data sources and journal notes to be incorporated into the analysis. Using NVivo enabled the researchers to develop an organic approach to coding as it enabled triggers or categories of interest in the text to be coded and used to keep track of emerging and developing ideas (Kvale, 1996). These codings can be modified, integrated or migrated as the analysis progresses and the generation of reports, using Boolean search, facilitates the recognition of conflicts and contradictions. This process enabled the key themes needed to be considered during the adaptive reuse or demolition decision-making process to be identified.

11 Findings and Discussion

The use of the coding mechanism within NVivo enabled a number of criteria to be identified and quantified. Criteria that were identified as being important reasons for implementing an adaptive reuse strategy for heritage buildings by interviews were: ‘encouraging further conservation’ (92%), ‘enhancing the quality of the built environment’ (78%), ‘reducing the use of private transport’ (76%), ‘maintaining cultural identity of a community’ (72%). Issues that were considered to be the most important when deciding whether or not to carry out conservation of a particular building were the: ‘need to respond to changes in the urban environment’ (98%), ‘Incorporation of sustainability principles’ (95%) and ‘need to treat old buildings as renewable resources’ (95%).

The interview process required respondents to determine their level of agreement to a range of statements. All respondents agreed that ‘enabling a building to accommodate changes over time increases value’, and ‘the age of a building does not necessarily impact on usefulness’. Opinion was equally divided amongst interviewees pertaining to whether obsolescence of a building was a valid reason for disposal. Similarly, respondents perceived the obsolescence of a building provided the potential for refurbishment or redevelopment as well as disposal.

Interviews identified the most significant outcome considerations of a building that was subjected to adaptive reuse were: ‘ease of access for disabled or elderly’, ‘ability to provide a safe and healthy environment’, ‘convenience of the building location’, ‘ability

of the building to assimilate future changes’ and ‘how the building fits in with the streetscape’. Incentives were identified as one of the measures that could be used to encourage building owners and developers to conserve buildings rather than demolition and redevelop. The incentives that were deemed to be the most persuasive included ‘relaxation of building requirements for heritage listed buildings’ and ‘monetary contributions to construction works’. Development bonuses such as density and plot ratio bonuses’ and ‘flexibility in meeting current construction regulations’ were also identified. Noteworthy, ‘speeding up the planning processes was considered the least influential incentive. Interviewees were highly supportive of adaptive (building) reuse and refurbishment as opposed to demolition and re-building. There appeared to be a great understanding of the concepts relating to the need to initially plan and design buildings well so that they could be preserved and refitted later in their lifecycle.

11.1 Adaptive reuse Decision-making

Respondents identified various factors that should be considered during the feasibility stage of the decision process (Figure 1). Respondents identified that ‘cultural significance’ (68%) and ‘heritage significance’ (83%) should be assessed collaboratively with stakeholders. In addition, the practical aspects of various use options should be fully explored while keeping community values and heritage values in mind.

Feasibility studies should determine whether projected outcomes can meet sustainability benchmarks and whether demolition and subsequent rebuilding would increase density and plot ratio. 74% of respondents perceived it to be necessary to explicitly determine the technical and economical challenges of adaptive reuse during the feasibility study. In particular, the determination of how existing components and the intended construction method would maintain the structural integrity of the building was deemed pivotal. In conjunction, a cost benefit analysis that was extended to triple bottom line objectives (including economic, social and environmental sustainability) was also identified as being required.

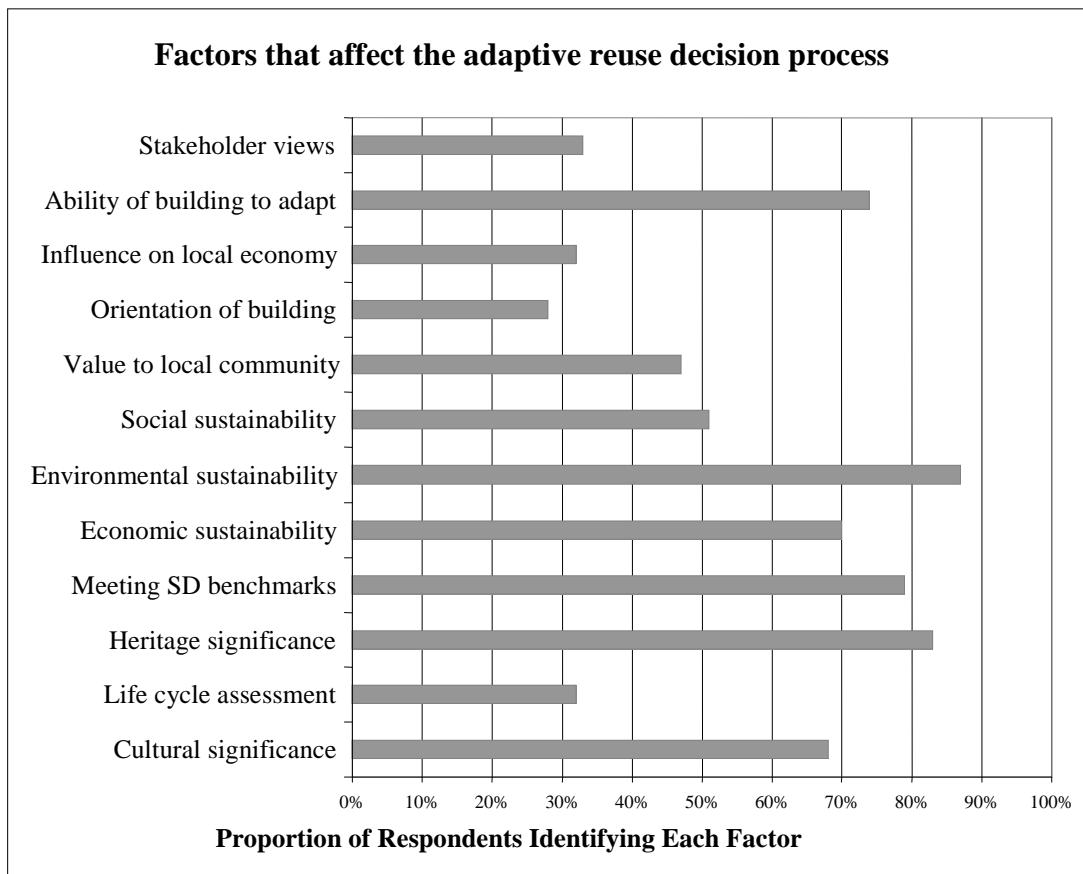

Figure 1. Factors affecting adaptive reuse decision-making

11.2 Opportunities and Barriers of Adaptive reuse

A wide range of barriers and opportunities to adaptive reuse were identified in the interviews (Figures 2 and 3). Although economic considerations were prevalent and of concern to interviewees, there was evidence of a shift, albeit a subtle one, towards the other tenets of sustainability. However, an inability to estimate economic viability of adaptive reuse was considered to be a barrier (53%). This indicates a fairly close division of opinion regarding the difficulty to estimate the costs of adapting a building compared with the costs of constructing a new one. However, the difference in opinion widens when considering environmental and social viability. Here 61% and 77% identified barriers to adaptive reuse to be an inability to estimate environmental and social viability respectively.

Many barriers to adaptive reuse pertain to cost, as a perception existed that it was more economical to demolish and construct a new building than to reuse. Compliance with building codes (59%) was deemed to be problematic as they were too rigid and did not encourage technical innovative to be developed. Adaptive reuse was perceived to be cost effective by 47% of interviews in most cases but the availability and price of materials to match existing elements/fixtures/fittings was an issue of concern. It was

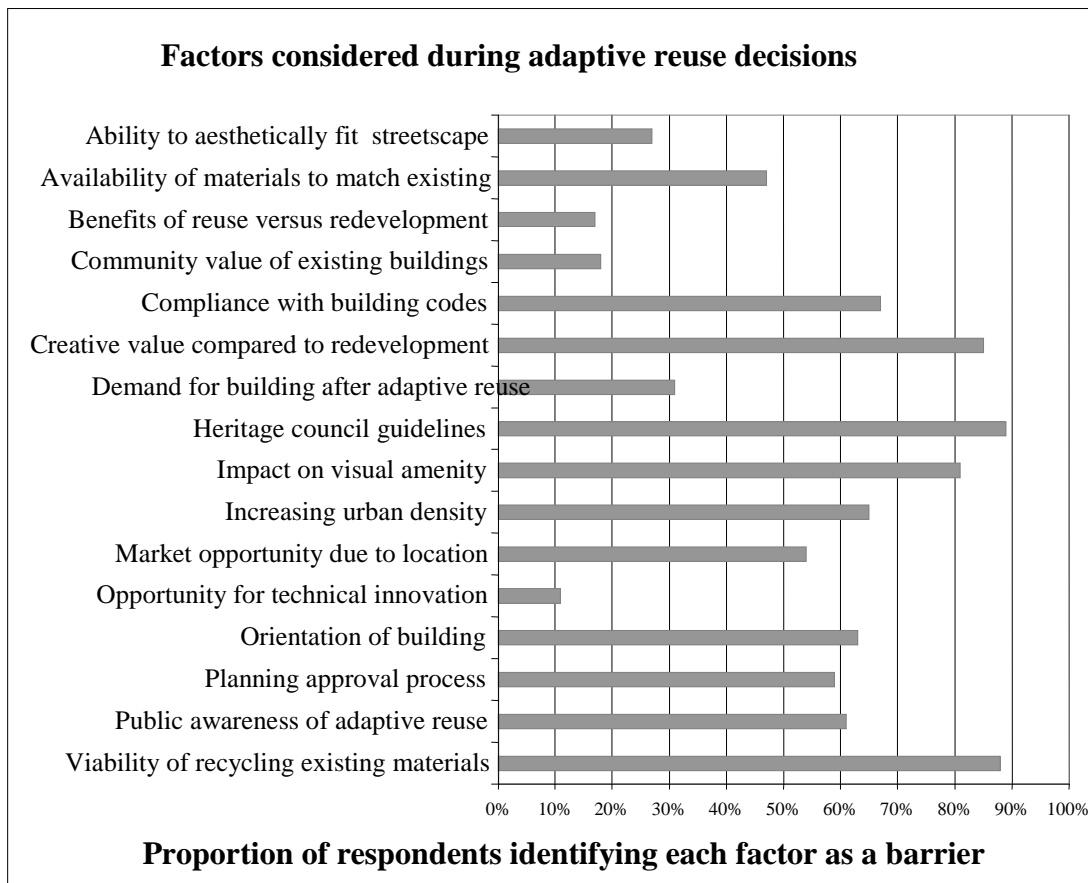

Figure 2. Barriers to implementing adaptive reuse

perceived that retaining older buildings rather than building more new ones would create a more aesthetical environment for the community (58%).

While older commercial buildings often do not support passive environmental techniques, it was perceived that existing buildings do provide opportunity to test many new innovative technologies and develop diverse solutions to enhance sustainability (65%). The location of existing buildings was seen to be a critical component of market opportunity, but opinion was fairly evenly divided with 54% seeing it as a barrier and 46% seeing it as an opportunity for adaptive reuse.

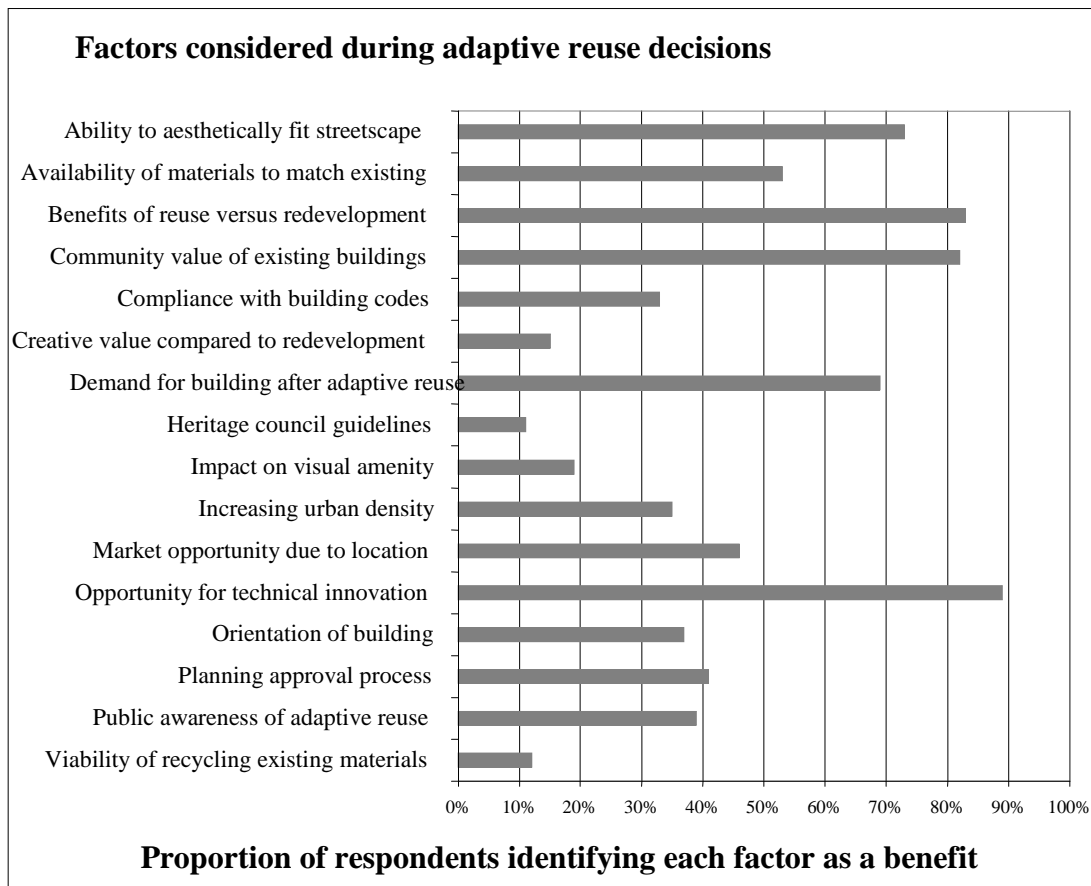

Figure 3. Benefits of implementing adaptive reuse

11.3 Impact of Adaptive reuse on Sustainability

According to 73% of respondents adaptive reuse would impact sustainability by reducing the amount of demolition. However only 61% felt the impact would be beneficial as shown in Figure 5, while 12% felt it would have a negative impact as shown in Figure 4. 77% of respondents felt the economic viability of a building after adaptive reuse would improve and in turn have a positive impact in terms of sustainability objectives. But it would only be viable if costs and benefits were factored in over the life of the building. Although adaptive reuse was seen as a more sustainable option than redevelopment, the decision would be case sensitive, with 41% of respondents, identifying that decisions needed to be based on options that lead to the most effective use of land such as increased density. Only 46% of respondents identifying this factor felt it would have a positive impact on sustainability. Energy efficiency was identified by 76% of respondents as a key factor that would affect sustainability. Although 43% of them felt that in some cases adaptive reuse could inhibit energy efficiency and the opportunity to increase urban density, it had other benefits in this context such as visual amenity and cultural heritage values. Provided the structure of existing buildings is still functional, 53% of respondents felt that adaptive reuse should be a prime consideration in terms of sustainability. The majority of

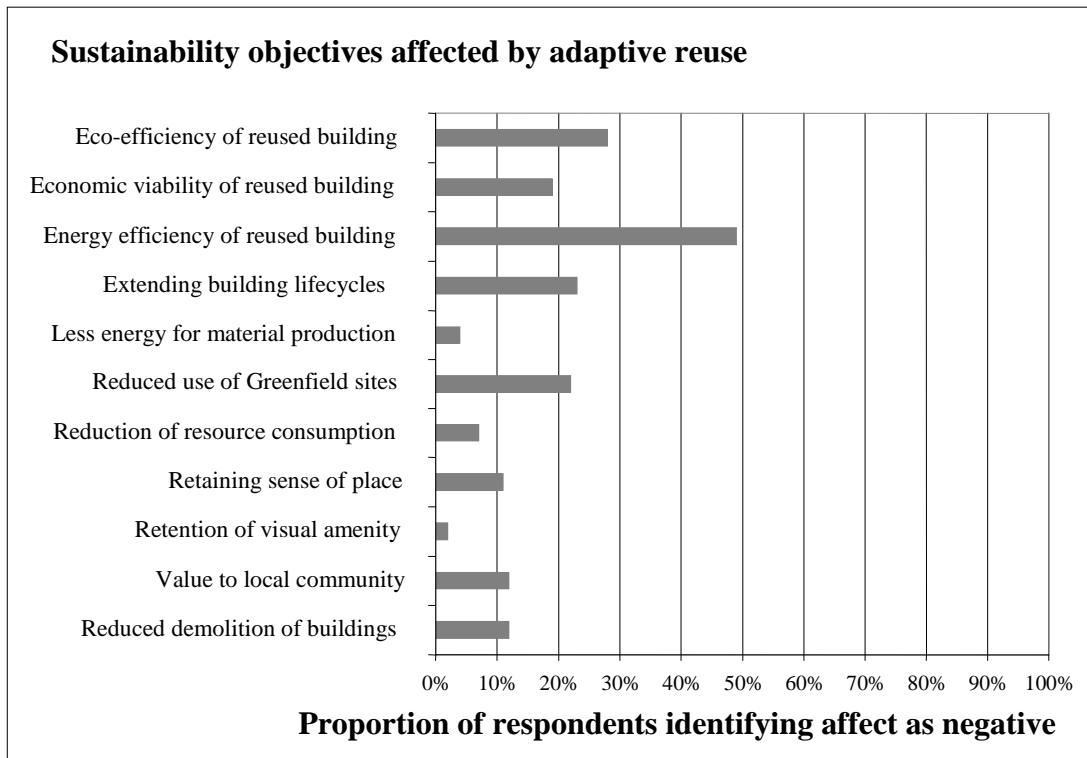

Figure 4. Negative effects of adaptive reuse on sustainability objectives

responses emphasised that it must be assessed on a case by case basis, but with an innovative approach the longer term sustainability of a building should be enhanced by adaptive reuse.

Adaptive reuse was seen to be effective because 75% of the respondents that referred to economic viability, felt the costs to demolish outweighed the costs to improve the building. Out of the 62% of respondents identifying eco-efficiency as a factor, 55% referred to case studies that show eco-efficiency of buildings is increased during adaptive reuse by using efficient heating, insulation and low impact materials. It would appear from the respondents generally that utilising existing buildings through adaptive reuse provides the opportunity to make the total built environment more aesthetically pleasing and productive, while retaining streetscapes and our sense of place.

Figure 5. Positive effects of adaptive reuse on sustainability objectives

12 Conclusion

The concept of adaptive reuse of heritage buildings as a component of sustainability was strongly supported by respondents, but doubts remain about viability particularly economic issues. To a large extent, as sustainability of local communities depends on the sense of place and value they place in their local community. Heritage invests local communities with a powerful reason to look after their local environment and lead more sustainable lifestyles as they have a powerful connection to their physical environment through visual amenity and the intrigue and uniqueness offered by heritage buildings and streetscapes. People feel a stronger sense of connection with their local surroundings through heritage, which is quite different to the mentality associated with new building stock, in that it can be, replicated anywhere and therefore lends no specific connection to the local environment. Heritage buildings are cultural icons their preservation impacts on community well-being, sense of place and therefore social sustainability. Due to the importance of these factors, it is preferable to reuse heritage buildings rather than replace them regardless of bad plot ratios and lack of efficiency. Heritage invests local communities with a powerful reason to look after their local environment and lead more sustainable lifestyles. Old buildings can be a visual amenity that provides a sense of connection with local surroundings through heritage.

Heritage buildings are cultural icons that impact on community well-being, sense of place and therefore social sustainability. Due to the importance of these factors, it is preferable to retrofit heritage buildings rather than replacing them regardless of bad plot ratios and lack of efficiency or the perception that they have become eyesores for disposal. Heritage invests local communities with a powerful reason to look after their

local environment and lead more sustainable lifestyles. Old buildings can be a visual amenity that provides a sense of connection with local surroundings through heritage.

The contribution of heritage buildings to the three tenets of sustainability has not been explored comprehensively and as a result there is a conflict of interest between the preservation of heritage values and progression of the sustainable urban design agenda. In some cases it appears that the heritage requirements attached to buildings may obstruct the use of new materials or techniques needed for adaptive reuse.

Any assessment that considers the reuse of heritage buildings should also incorporate criteria that ensure the adaptive reuse will not affect heritage values of the building. Despite presenting many positive outcomes in terms of sustainability, the adaptive reuse of heritage buildings creates many problems. These tend to concentrate around the technical difficulties that working on heritage buildings will generate. Many of the materials and components used in heritage buildings are no longer readily available and may have to be manufactured to special order. Even if the materials are obtained there is no guarantee that suitably qualified craftsmen will be available locally or even nationally. These problems will impact on the economic viability of carrying out an adaptive reuse project and may prove totally impractical for developers as an investment. In many cases, the only way that a heritage building will present a viable opportunity as an adaptive reuse project will be if incentives are available for developers. The ability to make heritage buildings attractive to developers as viable reuse projects relies heavily on the introduction of legislation that reduces building code and planning requirements and offers substantial financial incentives in the form of tax concessions. The research has highlighted several broad questions concerning the decision process for the adaptive reuse of heritage buildings not the least of which is whether heritage buildings are icons that should be conserved or whether they in fact eventually become eyesores that are liabilities.

Abstract:

There is a need for partnering as the policies implemented have to be profitable to all. This could raise a dilemma for the government who on the one hand want to be strict and regimental and on the other need to create an enabling environment for construction to flourish. Flexibility and efficiency is needed as is a collaborative approach to policy implementation.

With government asset stripping the public sector at the moment, it means government building at a scale required to tackle the housing problem is not possible. The government however has a big part to play in ensuring that the housing providers deliver sustainable affordable houses. They are either commercial developers looking to maximize profit or individual home owners. The policies, legal requirements and building regulations need to be enforced and also incentives given to guarantee the occupiers and buyers a home of the future, which can be referred to as sustainable.

Should we expect such high sustainable standards from a developing government trying to empower the people and gratify its population with basic amenities of shelter? The impact of construction is felt by all and Nigeria is a country with a huge housing shortfall, where everyone gets involved in self build.

This research aims to answer questions raised and analyze the challenges and opportunities facing the government in its policy implementation as well as individuals and developers providing sustainable affordable housing in Nigeria. It would aim to create a decision support toolkit that could assist the government.

Keywords:

affordable housing, building regulations, government policy, sustainability

1 Introduction

Policy development 'basic shelter is what we all need initially' (Maslow, 1943) shortfall is huge, speed is essential. The government has a huge problem to resolve and not enough resources to deal with it. However housing is at the top of the scale as it creates

other issues and if not catered for adequately could make the government very unpopular.

This paper will appraise impact of government policy in the provision of sustainable affordable housing units for a fast growing Nigerian population. It is hoped this will identify some areas for change. Key questions arise such as: *With climate change and new policies can we equally provide affordable housing? Is it fair to expect the same standards for affordable housing in a developing country like Nigeria as one would ask for in UK a developed country with tried and tested policies in place?*

The aim of the research would be to try to answer the above proposed questions including 'Is affordable housing in a developing country like Nigeria sustainable or is there a need in total shift from old policies and a price to pay?'

In the pursuit of the aim of this research the study would seek to achieve the following objectives: (1)Conduct a literature review; (2)Collect data that are relevant to the research questions; (3)Analyze same and finally (4)develop a framework model or toolkit that can aid policy development and implementation of sustainable affordable housing in Nigeria.

African leaders have learned from their own experiences that, peace, security, democracy, good governance, human rights and sound economic management are conditions for sustainable development. They are making a pledge to work, both individually and collectively, to promote these principles in their countries and sub regions and on the continent. (Nepad 2001)

1.1 Partnering and profiting

The government has over the years tried many forms of housing provision for example in the UK partnering with major house builders in a joint venture that would create a profit sharing structure. The contractors and house builders would always be utilized as government cannot build this number of houses without external assistance. In the past they employed the labour directly themselves through the Nigerian ministry of works and housing. The huge overheads created by such a large workforce normally defeats the purpose going past a number of housing units desired to be built. There is however now a need to have an arrangement that would work for everyone involved.

1.2 Housing Issues and affordability

The low income of the average Nigerian makes home ownership challenging. A third of the nation in the lower income bracket can't get on the housing ladder. A fifth earns less than £30.00 per month (Oluwaluyi, 2008) with Lagos being one of the worst in the country. Land prices are highest in Lagos and unaffordable to a good proportion. There are no jobs and the population is rising. Waiting lists are long for rental apartments, and landlords charge a premium with tenants paying almost half their salaries on rent. (Daramola S and Aina, 2004)

Affordability is generally accepted as a household paying no more than 30% income for their housing, and the populace are considered cost burdened otherwise, as difficulties can arise in paying for other things like food, clothing, transport and medical care. (US dept of housing and urban devt. 2011)

The Minister of State Works and Housing and Urban Development in 2009, Mrs. Grace Ekpiwhere, was quoted as saying that Nigeria had an estimated 16 million housing shortfall. (This day, 2009) Also a claim that housing production would catch up by government and the private sector partnering to build at a rate of 400,000 new units per year seems untenable and unjustifiable. Building pace has been nowhere near that and present indications don't show any improvement on how the policy would bring that about. Acquiring mortgage debt is an insidious problem in Nigeria because of the imbalance of cost of building to an individuals earning power. Since the majority of the methods required in constructing a house are monopolised. As it were, these companies can fix the prices for the bricks, blocks and cement needed for construction (Nnanna, 2010)

The Nigerian building and construction industry last year contributed 2.00% to the GDP the highest contributor at 18.7% was the wholesale and retail arm closely followed by the oil and gas industry at 15.85% contributions (The National bureau of statistics, 2011). There is therefore the need for higher contribution from the housing sector and a need to make it a more sustainable process.

Present governments in developing countries like Nigeria do not take on this responsibility adequately to provide social housing. For example the Lagos state property development corporation (LSDPC) is an organisation in Lagos which has become a government enterprise that's solely profit driven. They have adopted a policy to only build in areas that would generate the highest returns. The organisation commenced as a government parastatal and is now an autonomous organisation.

Nigeria has a long unenviable history of civil-military political cycles, the state seems to be perpetually in crisis. The country's several democratization attempts and the interchange with military rule, most of which often come with great promises, have failed with the result that both forms of government are now largely doubted by majority of the ordinary citizens. (Yagboyaju, 2010)

1.3 Self builders – the majority

In Nigeria it's popular for the individual to want to build his own home. There is a feeling of pride and achievement that this gives him or her and a new status in their immediate family and society.

Almost every Nigerian has grown up surrounded by cement block manufacturers parading their products in their vicinity and understanding the concept of purchasing a plot of land. This land is usually bought at great cost and left to wallow for a while until the individual is able to either clear and fence it or continue to commence construction works on it.

It's not unusual for a construction project to commence and take up to ten years to complete. It's usually as the self builder has funds that he progresses the works and building materials are often left idle on the site for months on end awaiting the next phase of development. 30-40% of the population lives in urban areas, with an average household of 5 persons. The occupancy ratios of houses in Nigeria is 6 persons for a room of 20 sq m. 60% of Nigerians are without adequate shelter (under-housed and no housing). Residential home ownership is less than 25% compared with 75% internationally. (ERSO UN Habitat 2008)

1.4 House developers

In Nigeria house developers are a growing industry fed by services, society, safety and land security seekers. As issues surrounding landed property being sold to multiple buyers continue to be common in the high courts, it makes buyers wary of family land owners who purport to be the scion of the families and attempt to sell plots of to unknowing buyers keen to jump on the self build bandwagon.

House developers are trying to tap into this market of the populace suffering from a fear of falling into the hands of fraudsters. Also they are providing infrastructure which the government is meant to provide but are usually not able to. The provision of services infrastructure is a key requirement in any housing development as adequate roads, drainage network, water, electricity (if possible) and sanitation is key to creating a good sustainable development that would add value to the property.

1.5 Enabling environment

The government's policies need to create an atmosphere that draws in external and internal investors, developers, self builders, material manufacturers/suppliers and all parties. Land use decree is been discussed over the years as a cog in the wheel of speedy, safe land acquisition. The deficiency of this part of the system is notorious. Also increasing cost of building materials with cement being the main culprit is another problem. The industry feels the government can and should ensure that the price of cement is lowered by allowing greater competition and also investing in research that would allow other materials to compete effectively on the same playing field. Government is also asset stripping and a good example is cement factories being sold off to private companies. The cost of cement is still not reducing rather a monopoly seems to be created.

1.6 Government policy history

The Nigerian National Housing policy was formulated in 1991 with the aim of providing affordable housing to the populace and an example of government initiatives to improve the system. However the policies are not being properly implemented and where they are, they are not being well monitored. This policy was revised in 2004 to resolve problems in usage. A presidential technical committee on housing and urban development was set up by government to address these new housing reforms. It recommended the restructuring of the federal mortgage bank of Nigeria (FMBN) and the creation of real estate developers association of Nigeria (REDAN), and building materials producers association of Nigeria (BUMPAN). The new housing reforms created financial mechanisms and institutions that will make available to the private sector (developers) funds for the production of mass houses, and allow purchasers (mortgagors) to have easy access to borrowed money through the primary mortgage institutions (Ebie 2004)

Principal organizations on whose shoulders rest the mass housing delivery mechanism under the national housing fund (NHF) scheme include:-

- The real estate developers association of Nigeria (REDAN) formed on 9th May, 2002.
- The federal mortgage bank of Nigeria (FMBN) – Act No 7 of 1977 and updated Act No 82 of 1993.

- The primary mortgage Institutions under the umbrella body of the mortgage banking association of Nigeria (MBAN).
- The building materials producers association of Nigeria (BUMPAN) formed on 4th March, 2004. (Ozili, 2009)

1.7 Policy Implementation

One area to improve government policy would be in the building regulations or building code as it's referred to in Nigeria. It's aimed at curbing the anomalies such as the use of fake and untested building materials, lack of adequate building regulations. This would invariably arrest the incessant waves of building collapse. (Mosaku, 2006) There are still a number of cases of collapsed buildings and poorly built structures due to a poor implementation and monitoring. The building officers don't do their jobs adequately and there is corruption in the various sectors in charge of overseeing building works.

The sustainability code in the UK has also been newly created to enable a sustainable development that would minimize high carbon production. In its creation in Nigeria it would be required to be flexible and collaborative in its delivery approach.

In order to strengthen political governance and build capacity to meet these commitments, the leader of the new partnership for Africa's development will undertake a process of targeted capacity building initiatives. These institutional reforms will focus on: Administrative and civil service, strengthening parliamentary oversight, promoting participatory decision making, adopting effective measures to combat corruption and embezzlement, undertaking judicial reforms (NEPAD 2001)

1.8 Monitoring sustainable delivery

Globally building construction is responsible for the current atmospheric pollution and wastes generation. Globally, building construction is responsible for the current consumption of 25% of wood and 40% of aggregates, 16% of water and 40% of the energy annually spent (Braganca et al., 2002) It is however observed also that the rising cost of building construction in Nigeria can be attributed to some other factors, which include high transportation cost, devaluation of national currency (Naira), uncontrollable prices of building materials and the over dependency on the importation of building materials (Fasakin and Ogunsemi, 2003) Starting with Lagos state in Nigeria the federal government have created a carbon awareness campaign,(Tribune 2010) however there is the need to take it to the next level by ensuring that the populace have a thorough understanding of what not doing things appropriately could involve and the dangers for the future generations. Sustainable delivery is defined also as cutting back now to ensure that the future would have enough. There needs to be a committee or appointments made by the president and his cabinet to give the public the understanding that this is being driven right from the leadership and authorities.

One accepted definition of sustainability is that proposed by the World commission on environment and development in their 1987 study commonly known as the Bruntland commission report (WCED 1987). Most advocates of sustainable development recognize that, for it to be realized, would require changes in human values, attitudes and behaviors. Raskin et al (2002) suggest that such critical value changes are needed to promote new quality of life, human solidarity and ecological sensibility to counter the

present value system that places much emphasis on consumerism, individualism and the domination of nature (Mabogunje 2004)

1.9 Government challenges

The government has major challenges as the millennium development goals set and accepted by the present government has highlighted some other key issues which are yet to be tackled by them. Millennium goal 7 focuses on integrating the principles of sustainable development into country policies and programs; reverse loss of environmental resources. Nigeria has become increasingly urbanised in the past five decades. The proportion of the population living in urban areas rose from 15% in 1950 to 23.4% in 1975 and to 43.3 % in 2000 and projections indicated that more than 60% will live in the urban area by 2025. A sizeable proportion is likely to live in slums if care is not taken. (Millennium development report 2010) The issue of primary education which if properly implemented would go a long way in helping to educate the masses about the dangers of indiscriminate energy consumption and the advantages of recycling. Although the economic situation has created a country of forced recyclers, there are still other issues of primary healthcare, gender equality, water, sanitation and Aids. The government can be made to realize that by creating a good housing infrastructure it would alleviate some of these issues especially water provision, sanitation and better healthcare. It would also reduce the transference of disease as less people crammed into a room or house and reduction in urban slums always minimizes transference of illnesses. In line with the MDG targets, financing focuses on developing city wide infrastructure and upgrading slums to improve living conditions and enhance economically productive activities. (Millennium development report 2010)

Another challenge is that Africa has become increasingly uncompetitive, as a result of its weaknesses in governance and infrastructure, low capacity in science and technology and lack of innovation and diversification from primary products. (Commission for Africa 2005)

1.10 Government opportunities

Just as the country did and played catch up to the telecommunications age it's hoped that Nigeria can play catch up to the housing delivery in a sustainable manner. Developed countries seem to be going back to basics in terms of using local materials and reducing drastically energy each house is consuming. The need to create warmth for example in a cold region demands a higher amount of energy. Hence it's hoped that Nigeria a developing country in the tropics which needs to cool its interiors mainly can design buildings and use materials that would be sympathetic to this area and climate.

If the rural areas utilized the local materials available to them and it was developed effectively by the NBRRI to a sufficient standard, it would be more attractive in terms of looks and cost for the local populace. The uptake would be massive and there would then be a fall in demand for cement like materials. These local materials like mud, clay and laterite would become growing industries for manufacturers and suppliers. This would create an income for this group and would encourage further research into uses and development of the material.

Government need to give incentives to the developers and self builders to use local materials as opposed to what they have been used to for years. Incentives would include, tax incentives, government subsidies on rates.

As capital is highly mobile investors will favour the sectors/locations that provide the best risk/reward profile. Short term and overly complex public policies with limited effects on the profitability of investment projects are unlikely to attract private financial flows. On the other hand overly generous tax credits and regulatory incentives in the form of exceptions from environmental or labour laws could create economic distortions and harmful distribution effects. (Glemarec & UNDP, 2011)

Effective states – those that can promote and protect human rights and can deliver services to their people and a climate for entrepreneurship and growth – are the foundation of development. Without progress in governance, all other reforms will have limited impact. While there have been improvements in many African countries, weakness in governance and capacity is the central cause of Africa's difficult experience over the last decades. Improvements in governance, including democracy, are first and foremost the responsibility of African countries and people, and they take time and commitment. (Commission for Africa, 2005)

2 Research method

Structured interviews with key government officials, developers and self builders. Also interviews with tenants looking to get on the housing ladder, questionnaire will be sent to all this groups, statistical surveys, case studies of housing estates built by developers etc. Also using the qualitative and quantitative methods and using spss packages.

The quantitative research approach offers results in precise measurements and tends to be good for confirmation and deduction. Determining the relationship between one and the other is usually achievable. It's found to be good for knowing how many or how much, as some data is in the form of numbers and statistics. Quantitative research is objective and seeks precise measurements & analysis of target concepts. It's been employed for the user's surveys and questionnaires as it's more efficient and able to test hypothesis.

Qualitative – As this is usually recommended during the earlier phases of the research project, (Neill, J 2007) the design would emerge as the study unfolds. The data is in the form of words, pictures or objects. Qualitative research is subjective and individual's interpretation of events is important, e.g. uses participant observations and in depth interviews. This has commenced and is proceeding well. The qualitative method is also richer though time consuming, but less able to be generalized. The case study type of qualitative was also selected. Creswell (1998) defines the case study as an exporation of a bounded system or a case (multiple cases) over time through detailed in depth data collection involving multiple sources of information rich in context. Some consider "the case" as an object of study (e.g. Stake, 1995) while others consider it a methodology (e.g. Merriam 1998) According to Creswell, the bounded system is bounded by time and place and it is the case being studied.

2.1 The Code for Sustainable Home

Launched by the Government in 2007 the Code for Sustainable Homes replaces EcoHomes as the National standard to be used in the design and construction of new-build residential properties in England. The code is a set of sustainable design principles covering performance in 9 key areas: 1.) Energy & CO2 emissions, 2.) Water, 3.) Materials, 4.) Surface water run-off, 5.) Waste, 6.) Pollution, 7.) Health & well-being, 8.) Management, 9.) Ecology. The code uses a rating system of 1-6 stars and involves a

Design Stage Report and a Post Construction Report which is submitted to the Building Research Establishment to provide a final code certificate. Formal code assessment of new-build dwellings can only be carried out by a suitably qualified licensed and registered, Code Assessor. Developers wishing to lead the field in sustainable development will want to have their developments assessed under the code as soon as possible in the project life cycle to achieve as high a code as possible. (Department for communities and local government, 2007)

These codes need to be adopted by the developing countries like Nigeria and even though they are beginning to realize the importance of sustainable development it's been difficult to get out of the starting blocks due to other more pressing issues like rapid development of slums, transportation and ensuring reduction of building collapses prevalent in the country as an outcome of poor adherence to existing policies and codes. There is therefore a need to police the builders further and also to weed out corrupt practices amongst the officials, as a result of slack supervision and unprofessional conduct at different levels.

The code focuses on how these problems highlighted can be tackled right from the onset in the design aspect before the building gets to the construction phase. Analysis of existing regulations indicates that developing countries need to ensure that these requirements are adhered to as long time development can only be sustained if the design and materials are coordinated adequately with the right supervision for an efficient delivery. Inefficiency is the bedrock of failure in trying to create a guideline.

Adequate design will improve production taking cognizance of locality and culture. There is waste generated in energy, in developing countries inadequate power supply, an influx of individually generated power from home owners. The desire to create a thermal environment that would satisfy the human body condition has created the need for air conditioners in every room in the house, This is obviously not viable for affordable housing. Good design and usage of materials would eliminate this and make the house more affordable to run and maintain. Shared water supply source would negate the need for each home to have a borehole and a shared filtered ground source would supply a maximum number of householders creating a good economy of scale in delivery. A mix of climate appropriate design will make the delivery better and reduce running costs of buildings. Solar orientation of buildings to allow good cross ventilation, reduction in water usage, rainwater harvesting techniques and good sanitation are some of the all-important infrastructure and service requirements.

2.2 Toolkit

A toolkit is being proposed and its likely to be developed in three parts namely (a) the principles will be highlighted, (b) the process will be shown and finally (c) case studies will be used to highlight the practical resource aspects. It's meant to help interpret the findings based on the information gathered using the 9 key areas of the sustainable code. This would be used as the key resource to draw conclusions on the way forward. It will serve to aid the users namely government planners and decision makers, house builders and home owners to make decisions. The toolkit can be defined as something focused around conscious, repeatable methods for gathering raw research from multiple sources in specific contexts and transforming it into real insight & information. (Beecher, 2008) It's proposed that the toolkit will have a sustainability and affordability checklist as well as a menu of potential performance indicators.

This would be a systematic analysis of the prevailing surrounding situation to come to the most appropriate technological sustainable design policy for any proposed project. The toolkit as said will aim to look at the 9 key areas of the sustainable code focusing on design and technology of the materials as well as other factors surrounding creating affordable housing in a sustainable way. Energy & CO2 emissions is one of the bigger issues for sustainability and good designs can be created for the varied Nigerian climate by combining energy efficient construction with passive heating and cooling to achieve a sustainable society. Future buildings must be energy efficient, and energy conservation measures must be adopted in existing buildings.

The adaptation to natural surroundings and the people in the area is also significant to forming a seamless relationship with all parties involved in the development.

In the UK the code for sustainable homes and the ever tightening building regulations have had a big impact on house builders and ensured changed building practices. Likewise legislation needs to drive the move towards sustainability in the built environment in Nigeria.

The government needs to give incentives to consumers reducing their cost and to producers making it more viable to produce. As research meliorates the range of innovative materials and solutions for house builders to choose from also improves and helps to satisfy discerning consumers.

By 2020 45% of global construction is projected will be in emerging markets like Nigeria. Over the next decade infrastructure construction is expected to grow by 128% in emerging markets compared with 18% projected growth in developed markets.(RICS 2010) While 70% of the global population will live in urban areas by 2050, (World fact book 2010) affordable housing is therefore a key issue to target to avoid urban slums.

3 Conclusion

Policy formulation must be centered on national interest. While designing policies that will promote investments and trade, indigenous businesses must not be exposed to harsh and unfair competition from better advantaged foreign peers. Thus policies must be designed that will give indigenous entrepreneurs a fair chance to build capacity and expertise. A strong illustration of this is the petroleum sector local content policy and this could be replicated across selected sectors where there is high job creation potential and Nigeria has a strong competitive advantage. (National committee on Job creation, 2011) The house building industry definitely falls into this category and would benefit tremendously especially in the construction of affordable housing which requires various levels of skill sets.

A frame work toolkit will be created to assist the government and the officials assess the benefits and performance indicators for the policies to enable a proper delivery of a plan of action in line with the nation's sustainability agenda.

Emphasis is being given to providing nationwide infrastructure and basic services in poor communities across Nigeria under the community based urban development program. This is in addition to the implementation of a national urban renewal and slum upgrading programme (MDG report 2010)

With the country in a new dispensation with the just concluded national and local elections, it's hoped that the policies that are in place and new ones to be passed will be geared towards the national interest and effective speedy delivery of much needed services and infrastructure to the populace.

Its hoped as this research progresses for structured interviews, questionnaires to be sent out and further information gathered and analyzed to assist in coming to some reasonable outcomes that would be useful in creating policies of national interest, that would ensure that the financial, social, environmental and knowledge transfer requirements are met. There needs to be cooperation across the board amongst the building professionals and the policy makers allowing a proper synergy of both parties to work for the common good.

Winning in the Long Run? The measurable impact of sustainability characteristics on the financial performance of office and retail properties in Europe (Working Paper 6)

Bernet J, Sayce S, Ledl R, Vermeulen M

Abstract:

This paper reports on the first empirical findings of a RISC ET supported project aimed at establishing data which links the financial performance of standing commercial property investments within a range of European property portfolios, with their sustainability characteristics. The conceptual model for the work was established last year in a series of working papers including a presentation at COBRA 2010 (Bernet et al, 2010). It is important that this model is not reliant on any building being analysed having a 'green' certification as few buildings in continental Europe are so rated and rating systems where used vary in their composition.

The project is in response to the requirement for investors, many of whom have now adopted a policy of moving towards responsible investment, to better understand the financial implications of their adopted strategies. Since the authors, a team from Danube Krems University and Kingston University, set up the project last year, investors from across Europe have supplied data from real assets of institutional investment portfolios across Europe, from Portugal to Denmark and from Scotland to Hungary.

This data is being supplemented by location and economic data and the sustainability indicators chosen are building on previous research and using the Sustainability Reporting Guidelines of the Global Reporting Initiative GRI (Version 3) and the Construction and Real Estate Sector Supplement CRESS (Final Draft). The environmental aspects are measured in accordance with the Best Practice Recommendations on Sustainability BPR of the European Public Real Estate Association EPRA (Draft Version), referring to the common metrics identified by the Green Property Alliance GPA (Ground Rules for Property).

The sustainability and financial data is being analysed using customised investment software and standard data mining tools such as SPSS Statistics in order to present first findings in a quest to establish whether or not, currently, there is indeed a 'Green Alpha'.

Abstract:

This paper is grounded in a project supported by RICS Education Trust related to UNDP's Territorial Approach to Climate Change (TACC). Following pilot interviews with members of the Bagisu tribe in Eastern Uganda we posited a hypothesis that secure tenure does not necessarily require land registration [cf. de Soto] and that good governance of land does not require a [formal or indeed any] market.

This paper reports subsequent encounters with members of the Acholi, Langi and Iteso tribes that begin to test the hypothesis; it reports discussions with LEMU (the Land and Equity Movement in Uganda) on complimentary research funded by USAid and, finally, it reports the early experiences of the TACC project in developing an Integrated Territorial Climate Plan in a context where customary forms of land tenure dominate.

These various reports form the context for a theoretical discussion of the nature and trajectory of the customary property relations that are so extensive in sub-Saharan Africa. The paper seeks to explore whether replacing the customary forms observed here with 'free markets' may be a loss of socio-diversity as damaging for human futures as a loss of bio-diversity. Markets are primarily concerned with allocative efficiency, but here we ask whether the enormity of the land crisis demands forms of adaptive efficiency that transcend the market mechanism.

We make no firm conclusion other than affirming Montagu's dictum (1976) that, "In humans... the rules governing property are culturally determined and are learned; there is no pattern of signals common to the whole species."

institutions, customary tenure, Uganda

1 Introduction

In an earlier paper (Jenkins et al, 2009) we reported on a three day workshop that aimed to define sustainable development as a set of principles, a strategy and an action plan with the people of Mbale, Uganda under the auspices of the Coalition Against Poverty (CAP). In a subsequent paper (Jenkins et al, 2010) we reported how the emerging sustainable development strategy began to dovetail with the UNDP Territorial Approach to Climate Change (TACC) pilot project in Uganda. And we undertook primary research among the largest people group in the region, the Bagisu, in order to discover

whether the customary tenures would be a help or hindrance to sustainable development aspirations. In this paper we discuss the nature and trajectory of the customary property relations that are so extensive in sub-Saharan Africa consequent on the institutional analysis of the forms of customary tenure that we have identified among other people groups in this region.

The preliminary conclusions of our earlier publications provide working hypotheses for the research reported here. Contrary to expectations, we discovered a well developed tendency to privatised rather than communal property institutions among Bagisu. This tendency co-existed with a deep trust in customary, informal property relations. The experiences of the Bagisu suggested that secure tenure does not require land registration and that good governance of land does not require a market, at least not a well developed market. It seems that some forms of investment, like the early action portfolio within TACC, are no more at risk in areas of customary tenure than areas where land is registered. Indeed, paradoxically, large tracts of customary land are held and transferred peaceably in the Bagisu region, whereas more acute and frequent disputes predominate in Kampala and the Baganda heartlands where social capital is focussed and most registered land is to be found. Nevertheless we discovered in our discussions with Bagisu a worrying trend to land fragmentation and an expectation of increasing disputes over land.

We were also concerned about the assumption in earlier versions of the UN FAO discussion document, *Towards Voluntary Guidelines on Responsible Governance of Tenure of Land and Other Natural Resources* (2009) that

Essentially, the existence of communal and customary tenures must be respected but somehow this must occur within “properly functioning land markets.” (Pratt, 2010)

As we previously suggested, it is only in western economies that institutional analysis invariably encounters ‘the market’ (Ball, 2006, Dale et al., 2002, Viruly, 2009). While the view from the 20th century seemed to confirm a movement towards markets, we doubted that this is inevitable. Partly ours was a theoretical understanding inherited from social anthropology

In humans... the rules governing property are culturally determined and are learned; there is no pattern of signals common to the whole species. (Montagu, 1976)

But partly because empirically we know that the root of all property systems is not markets but power relations (FAO, 2009, p5).

In fact the UN FAO has removed this tension between ‘respect for communal and customary tenures’ and ‘properly functioning land markets’ from more recent versions of the emerging Voluntary Guidelines. As will become apparent, our subsequent journey through eastern Uganda and our encounters with Land and Equity Movement of Uganda (LEMU) identified institutional frameworks that were more communal and less marketised yet than those of the Bagisu. Out of ‘respect for communal and customary tenures’ it would be wholly inappropriate to demand ‘properly functioning land markets’ in these contexts. Nevertheless, we envisage that the customary tenures are at significant risk. We identify this dynamic and in turn raise some new questions.

2 Research Methodology

The whole data collection process was intended to elucidate the mechanisms that are in use for the management and transfer of lands; to better understand the positive dimensions of customary tenure elucidated by those practitioners; to identify forms of risk that may compromise proposed investments, especially with TACC in mind, and establish community intentions in relation to perceived environmental and social threats.

There are three principal methods of research used here: documentary analysis, interviews and reflexive practice.

We previously reported significant documentation within the United Nations¹ (UNDP, UNEP & FAO specifically), within the Ugandan Government² and among Ugandan academics related to environmental degradation and climate change and their impacts on land. This is augmented appreciably by international sources, primarily the development departments of governments (DfID, SIDA and DANIDA are particularly active in Uganda) and international NGO's like IUCN, IISD etc. (A full bibliography will be published with an RICS Education Trust report). Additionally, the regional governments of Mbale have developed a Sustainable Development Action Plan and other documentation that integrates scientific and technical information about the region's economy, infrastructure, governance, climate and environment.

Since the publication of the earlier paper (Jenkins et al, 2010) we discovered the works of LEMU (Adoko and Levine, 2004, 2005a and b, 2007). This was particularly significant for the research program we identified in that paper, because it transpired that LEMU had undertaken a noteworthy research program of adjacent regions on related topics over a period of several years, funded by USAID and a private UK foundation. This allowed us to modify the original scope of the proposed research, specifically to trim some of the intended program (leaving sufficient to test LEMU's evidence in relation to the Langi, Acholi and Iteso people groups) and creating opportunity to encounter groups over a wider geographic area.

The scale of LEMU's research is significant. Over a period of several years between 2002 and 2007 Adoko and Levine undertook extensive investigations into land rights issues among the Acholi, Langi and Iteso peoples. They were able to survey all land owners in a series of randomly selected counties using qualitative research tools. They have also been engaged in a critique of the government's land policy and legislation and have made several submissions to the government's consultative process on land reform. They campaign for land justice in Uganda and provide enabling services to communities.

They point to the monetising of the economy and the way in which "commoditisation undermines social ties in subtle ways." They point to the weakening of the clan structure and the gradual usurpation of its social and administrative roles by the Local Councillor (LC) framework. Their chief claim relating to land policy and legislative framework in Uganda is:

¹ Charting a New Low-Carbon Route to Development: A Primer on Integrated Climate Change Planning for Regional Governments (2009) UNDP provides a useful bibliography.

² The UNDP TACC Project Document (January, 2010) compiles Ugandan government publications and programme plans.

Despite a legal context, which is very favourable to customary tenure, Government policy has been seen most clearly in its practice, and it has clearly shown no interest at all in customary tenure. Whatever the intentions of Parliament in passing the 1998 Land Act, the Government's interest in recognising customary tenure was in order to facilitate the privatisation (their emphasis) of land, to enable the growth of a land market, and the acquisition of land by "investors". Various provisions made in the 1998 act to support and protect customary tenure have never been implemented (see below). The Government has taken away the authority of 'customary' institutions of land administration for administering land held under customary tenure, despite the clear statement of the 1998 Land Act. Given that one of the rules of customary ownership is that land sales are prima facie not allowed (though a sale can be accepted if good reason is shown for allowing it), it is clear that giving authority on land disputes to state institutions will tend to accelerate the privatisation of land and undermine the protections built into customary tenure. (Adoko and Levine, 2005, p3)

While we have no quarrel with this analysis in general terms, we are impressed by the resilience of customary tenures. Our analysis of LEMU's data, verified by our own relatively modest efforts, is that it discloses a multiplicity of land institutions that varies between and within people groups. We see evidence of emerging markets; we observe strong traditional clan structures in some places; we see examples where the LC system has come to dominate: we see examples where, in all this variety, hybrid systems of institutions exist that have little to do with tradition and even less to do with the actual law. We find that there are often competing authorities: for examples disputes may be referred to clan elders, or LC's or the courts.

The chief source of primary data was interviews, including several group interviews with tribal and community leaders collectively, based on the model of the pilot conducted in 2010. Such group interviews have the distinct advantage that consensus can likely be taken as factual for the participants, even if this falls short of objective proof. Sometimes this involved the bringing together of participants who knew each other (as when the interview took place with village elders ~ and twice in the company of the whole village) and sometimes we brought strangers together so that their corroboration of facts or events suggested a high degree of reliability. In the event, we interviewed along the eastern/ northern axis of Uganda between Mbale and Gulu, as well as within greater Mbale.

For the study as a whole, land owners from the Bagisu, Langi, Iteso and Acholi people groups were approached to ascertain land institutions¹ and something of their cultural context. We attempted to create a form of group interview that approached a natural conversation, but structured in the sense that thematic areas were systematically pursued: on ownership and control over lands; on land financing; on land sales etc.

It was important for the group to select the setting. The interviewer acted as facilitator, prompting the discussion as necessary. The purpose of the interview would be explained in general terms. Consent and anonymity were discussed prior to the

¹ To include modes of land transfer, land use allocation and management

‘conversation.’ Consent was always granted to publish (sometimes anonymity was requested) and consent was usually granted to tape conversations. Culturally it was important to thank the participants in some way: this included the provision of soft drinks as well as small monetary payments. The 2010 pilot interviews were conducted in English and transcribed and analysed using Nvivo. Subsequent rounds of interviews with landowners were conducted in February, March, April and May 2011. These interviews were conducted through interpreters in five languages and the findings depend on translations that were provided at the time of interview and recorded on tape together with written field notes.

Eight group interviews were conducted. Interviews also took place with

- Individual landowners
- The Secretary of the District Land Board in Mbale regarding formally registered lands, informal tenures and points of conflict and their nature.
- A selection of natural resources officers and planning officers of Mbale, Manafwa and Bududa district councils.
- Representatives of two international firms of Chartered Surveyors based in Kampala.
- Judy Adoko of LEMU.
- The following were also important in contributing to the picture provided here
- Lectures were presented on the subject matter to Students and Faculty of Makerere, Kyambogo and Uganda Christian Universities. Formal and informal feedback was illuminating.
- A CPD lecture on the TACC process was presented to the Institution of Surveyors of Uganda (5th May, 2010) together with a feedback session regarding tenure related risk.
- Site visits and meetings with 3 of the 4 NGOs that are implementing the series of A/R¹ projects identified within the TACC process and a subsequent seminar with all 4 NGOs.
- Meetings that formed part of the TACC process. This includes discussions with the Programmes Director and staff of the UNDP in Kampala, a TACC donors meeting, meetings with DfID Uganda, and two TACC Project Board meetings.

A further twist to the original research intention occurred when one of the authors acquired roles in the TACC process beyond that envisaged when the research was engaged : the transition from observer to participant bringing with it a personal and epistemological reflexive element.

3 Findings

3.1 Findings on tenure

Ugandan land law is embedded in the 1998 Land Act that

... recognises customary tenure as a legal form of tenure and customary rights holders can be individuals, families or communities. Palmer et al (2009)

¹ Afforestation/ Reforestation

The amount of land under customary tenure is said to exceed 80% for Uganda as a whole (Batungi, 2008). As regards the study region, almost the whole is subject to customary tenure. The legislation establishes a method of registration for freehold and leasehold tenure but the rate of conversion is very slow. According to the Secretary to the Land Board in Mbale only a few hundred small parcels of land are registered each year. The governance of this is quite complex, expensive and open to abuse (Jenkins et al, 2010). Even a fast track approach known as systematic land demarcation that was introduced to Mbale in 2009 appears very slow.

There are variations in the model of tenure between people groups: variations include the extent to which the forms of property are privatised versus communal; who can own land; the ways in which land use is managed; rules of inheritance; dispute resolution processes; the extent to which the local state has been permitted to engage with the regulation of land ownership.

As we travelled north from Mbale to Gulu and examined the different tribal land institutions, there was a sense of sedimentary analysis: different layers exposed as if an auger had taken a sample core. And as we examined the deeper levels of the core we found a tendency for greater communal traditions of land holding and inheritance. In the pilot study we heard Bagisu perceptions of Iteso and Acholi ways with the land. As we encountered these peoples directly we were able to confirm some of these perceptions. However, care needs to be taken here to avoid a romantic and generalising trap. The reality is that different clans within tribes have developed different institutions and the outcome is a complex patchwork.

As an example of this, we reported how for Bagisu inheritance operates after death through the “heir” (pronounced “hair”). Literacy and competence feature in the selection of the heir, which involves *consultations* within the clan. However, it is the heir’s task to distribute the land between those entitled: all sons. Bagisu own and hold their land individually. Where wealth is held in landed assets their distribution on inheritance leads to fragmentation. This has become a significant problem for Bagisu. Among the neighbouring Iteso, whose practice is much more varied, we engaged with one village near the town of Kumi, where inheritance was *decided with* the clan. Indeed, we discovered from two elders that their land had been redistributed though they were still alive. No heir was appointed, perhaps unusually among the Iteso (Adoko and Levine, 2007) and this gave them greater say in how the land would be allocated. Nevertheless this was a collective decision. And this was traditional: they too had inherited the land from fathers who had still been alive. It was apparent that they were polygamous and they saw this as a way of avoiding disputes later. Further north, one farmer of the Langi people explained to us that the matter of inheritance was *decided by* the elders. His father’s land had been inherited by four sons but it had not been distributed between them but was owned jointly and managed co-operatively. Among the Acholi in the north, we heard that while farmers managed land as individuals or families, the tenure was depicted as being communally owned and land holdings are kept together on inheritance. Nor are decisions matter for elders, but the clans come together and *collectively decide*.

In regard to these communal tenures, we need to make further enquiries about the substance of decision making. It was not suggested for instance that land is allocated by elders on the basis that services might be provided as in a feudal system. Nor does it seem that land is allocated according to some arbitrary (ab)use of power: among the Langi clan elders are elected at sub-county level and held accountable.

In relation to security of tenure there was no mention made among the Langi and Acholi of the kinds of disputes that disrupt quiet enjoyment among the Bagisu. Among the Langi disputes over land are resolved via a judicial process. Such disputes are resolved peaceably by and large, though sometimes there is frustration at the length of the dispute process. Among the Acholi, the idea that someone would grab land was greeted with mirth. Disputes do occur within the clan gathering but they are also settled there. No appeal is made to district officials as is common in the immediate area around Mbale. ACODE¹ also confirm that the corridor North West from Mbale through Kumi and Siroti toward Gulu is not one that is associated with land conflicts.

To all intent and purposes these tenures are securely held and very little land is registered.

There was far less population pressure among the Langi and Acholi than Bagisu and everyone had plenty of land to farm that wanted it. One developing issue for the Langi concerned ‘no man’s land.’ These communal lands had once been plentiful and hunting and grazing occurred over large areas. In recent times encroachment on these lands was the source of increasing disputes. Among the Iteso we discovered exactly the same phenomenon but here we heard from a council official that was attempting to reclaim 40 square miles of such land. The Acholi also enjoyed ‘free land’ without the difficulties described in Lango and Iteso.

3.2 Findings on land markets

As regards land markets our research establishes that institutions about disposition of land assets exhibit similar variety. Already we identified very thin markets among the Bagisu. One well known western aphorism may help here: two people may trade, but it takes three persons to have a market.

The rural Bagisu are reluctant to sell land and essentially it requires that people fall on hard times. When this happens, the seller seeks to trade. The pecking order appears to relate not to price but to trust: the preference is for a family member, a clan neighbour and finally someone drawn more widely from the clan. There also seems to be tacit recognition that if someone recovers their personal situation, there may be a buy-back.

In Mbale town, while there are no professional estate agency services² (apart from survey), it is not unknown for outsiders to acquire property, though this is a more precarious business, and for true foreigners (muzungus) any interest acquired in land is subject to the restrictions imposed by the Uganda Investment Authority.³ However, we are aware that wealthy investors are engaged in acquiring portfolios of urban land and that as a consequence there is a growing awareness of land value and much discussion about rising real estate prices. The value of land was particularly high in trading centres, where the returns to land from small ‘lock-up’ premises are high. The competitive exchange of small scale land assets between strangers is still a rarity and given the customary nature of the tenure, such incipient markets remain informal.

¹ <http://www.acode-u.org/>

² We noted earlier (Jenkins et al 2010) via interviews with chartered surveyors in Kampala and feedback from ISU suggest that there is insufficient commodification of property rights to support estate agency businesses.

³ There are many cautionary tales about foreign investors subsequently losing property to native claimants.

Among the Iteso the acquisition of land by outsiders is far less likely. Among the Langi, landowners have no right to sell without due process and permission from the clan elders. One respondent told us that he would not be able to sell land to meet school fees, though he might be granted permission to trade land if one of his children showed sufficient promise to go to University. This might bring clan benefits. While the price of a hectare of arable land varied between £150 and £250 in this gentleman's village, dependent mostly on location ie distance to the land from the village, most people would not have cash to acquire the land, borrowing money was very unlikely and bartering was common, a cow being worth £130 or so.

Among the Acholi, the clan is dominant. The clan or koch is comprised of extended family units, and within the family unit 'everyone' of age has a 'garden' to tend. The proceeds of the gardens are pooled and surpluses are sold by the family. We talked to a successful lady farmer who has 30 acres under cultivation with 16 family members. She explained that she did not truly own the land; that no individuals own land. Ownership remains with the koch who would theoretically make any decision to sell. It does not countenance sales of land. Where the kind of problem arises that among the Bagisu prompt land sales, the Acholi would have a clan meeting and make a collection to assist the one in need. She described a case in which a brother had killed someone from a neighbouring clan. In this case her koch raised the money and paid compensation to the dead man's clan. She acknowledged that in rare cases some clans, if weakened, for example family size had shrunk because of illness and death, may trade land.

Such tenurial forms are complex: no single owner enjoys all the rights in land. We disagree with LEMU's analysis on this point. They suggest (Adoko and Levine, 2005, p5) that because the farmer controls the use of the land, that the land should be regarded as privately owned.¹ But in circumstances where the farmer cannot buy or sell, their position is analogous to a tenant farmer. Of course, in the exceptional case where land is sold, the proceeds belong to the farmer and their position is analogous to private ownership. In the future, if clan structures weaken as LEMU predict, more land might be privatised, though it needs to be remembered that the outcome of a decision to sell is usually a trade within the clan and not an open market sale.

The lady farmer had also acquired a 'lock-up' shop in town where the surplus was sold and where she traded in other goods acquired from past surplus. The clan's jurisdiction did not run over the urban land. A lawyer had verified papers relating to it, though from the description of the process it is unlikely that this was registered. In relation to this business she would consider a commercial loan from a bank to acquire more land: this would not happen to clan owned land.

Our preliminary hypothesis was that good governance of land does not require a formal [or indeed any] market. We have not encountered evidence that contradicts this. Nor have we encountered evidence to suggest in relation to the farming of land, that the practices of these tribes people are sub-optimal. Once upon a time the World Bank and others would have argued that there was insufficient investment in the land and that underinvestment was due in part to communal ownership that was problematic as collateral. However, there was little real evidence of this historically and most lenders have moved on. What we can say is that most of these peoples exhibit a preference for forms of polyculture over monoculture.

¹ This assists them to build a case for investment in customarily held land.

3.3 Findings on investment risk in relation to ITCP

The TACC project identifies the need for an Integrated Territorial Climate Plan (ITCP) that in turn identifies strategic projects that lead to sustainable forms of economic development. These projects will be medium to large scale, aimed at infrastructure provision and suitable for funding by carbon markets. In order to give confidence to the communities a number of lesser scale, quick win projects have already been established. Chief among these¹ were four reforestation projects that would require extensive planting on customary lands.

Jenkins et al (2010) established that a presumption of increased investment risk due to the customary nature of tenure is not warranted. We noted how fears about land disputes have receded as have worries that customary tenures might be too transient for stable management. In relation to reforestation projects the real problem for sustainability comes from population pressures that may jeopardise growth-to-maturity, but they are thought to be tenure neutral.

One tenure related challenge remains: the rules regarding certification of reforestation schemes within the Clean Development Mechanism are complex and although “projects with different land tenure situations can effectively participate in the CDM” (BioCarbon Fund, 2011) in practice there are many obstacles. This is a shame in that the operation of the CDM can lead to enhanced security of tenure for land owners and the BioCarbon Fund has suggested a series of recommendations to ease restrictive rules (ibid.).

Furthermore Kerr et al (2006) have demonstrated that the Land Use, Land-Use Change and Forestry (LULUCF) sector does not favour poor communities. Nevertheless there are alternative possibilities on voluntary carbon markets and as the TACC Project Board has heard “Under Ugandan legislation, customary tenure (either inherited or granted by customary authorities) will generally suffice in terms of the tenure requirements for the carbon methodology” of some schemes.²

4 Discussion

At the micro level we identified a rich variety of institutions and meanings and were able to get some understanding of the interactions that we encountered by reference to some familiar labels and one or two not so familiar labels (muzungu, koch). An explanation for these differences is more difficult to establish. Culture is clearly important. We noted how the Bagisu described themselves as being business-like and entrepreneurial and it might therefore come as no surprise to see them in the vanguard of privatising tendencies as regards land. Many of them do not necessarily like what they now experience in the land as a consequence of this disposition and it is equally unsurprising to see some envy their northern neighbours.

The situation of their northern neighbours is also culturally conditioned. For example, the Acholi are seen as war-like, the Iteso as pragmatic. The long exposure to and experience of the Acholi in the northern conflict helps explain this. We can speculate that the stronger bonds of the clan are an outcome of social organisation required to survive conflict.

¹ Other projects concerning fuel efficient stoves and soil stabilised brick manufacture are less impacted by considerations of tenure.

² Technical feasibility assessment of the TACC project for the Mbale Region of Uganda.

Clearly also environment will have a significant impact on cultural development. We were able to note differences between urban and rural institutions. There is prima facie evidence of the town as the catalyst of social and cultural change. The experience of Bagisu in the crowded foothills of Mount Elgon is quite other than the experience of the peoples of the northern plains.

We hope to extend our understanding of this micro-scale variety and we are developing a greater multi-disciplinarity in the pursuit. But our purpose in this discussion is to approach the issue from a macro level. We do not approach this from classical perspectives within social theory: the analysis is not functionalist, or bedded in conflict theory. We aim more modestly to provide a narrative account that contextualises our findings.

In this narrative, advanced capitalism brings its land systems to Africa ~ its own norms and institutions, the norms of privatised and commodified property relations. Of course these are not static and the innovative forms that they bring may well find fertile soil or new syntheses in Africa (derivates in customary tenures for example). However, these property forms meet with resistance ~ the norms and institutions of tribal and customary tenure. Competition between jurisdictions is mostly carried on using peaceful means, though in the postcolonial as well as in the colonial period, this erupts periodically in violence. Ultimately the new property relations are and are seen to be the more powerful: they are supported by the institutional apparatus of global finance. These property relations are identified with progress and they spread, but unevenly, in part dependent on the culture and power of indigenous groups. Metropolitan elites, representing the dominant global system, vie with or negotiate with powerful tribes and nations. Ultimately the global system is likely to predominate: the condition for this is its internal credibility.

Placing Uganda in this scenario is relatively straightforward. We begun the process with a discussion of the historical development of land institutions in Uganda (Jenkins et al, 2009) noting the British influences. Indeed Uganda's current property systems were much influenced by officials from the UK (see McAuslan 2003). This system dominates in the metropolitan heartlands, where there is resistance from the traditional Buganda kingdom, though this resistance is now perhaps more to do with who manages the new system than the competition between jurisdictions. Nevertheless we have made mention that the writ of customary tenures still runs over 80% of the Ugandan nation. This is a significant testimony to the enduring strength of tradition, but arguably today that strength is more apparent than real. To different degrees among different people groups the 'progressive' system is leading to pressures that privatise and commodify land *within* traditional strongholds. If LEMU is right, even a strong self confident culture like the Acholi, with its taboo on sex before marriage and consequently low population growth and stable land availability, has been undermined by war and the culture of the IDP camps.

Our estimate is that this lengthy period of stalemate between the jurisdictions is coming to an end. The dynamic is not driven primarily by internal pressures, but by the global land crisis [Jenkins, 2009] and the particular expressions of that crisis that pertain in Sub Saharan Africa and that we have described in Uganda. The world's land crisis is driving higher prices and ever bigger transactions on continental Africa (Smaller and Mann, 2009). Moreover, it seems that global jurisdictions will take precedence over local, regional and national jurisdictions (ibid.).

In our futures, a generalised problem of land supply will be the source of intensifying conflicts unless imaginative solutions are heard and demonstrated. Part of our concern is peacekeeping and peacemaking. It is clear that disputes over land in Uganda will intensify as and when the clan structures weaken further and that an apparatus for conflict resolution is wanting.

But another issue of primary concern is the path dependency of the global system. The lack of socio-diversity is something that humanity might come to regret. And this is something that may have gone unnoticed but for the disaster and disruption to global economy that was caused by its own recent internal crises. These observations suggest the need for further reflection at this particular threshold. Is there something of value that will be lost if the customary systems disappear? Are those systems capable of withstanding the land crisis on their own merit? Do they potentially offer anything back to the dominant system? Are they capable of innovative syntheses?

Note that at this point we are saying nothing about the relative efficiency of global versus customary relations: elsewhere Jenkins identifies North's apologism for the US as a superpower (Jenkins, 2009b). Nor at this stage in the argument are we saying anything about the ethical merits of one system over against the other.

What Hayek (1960), Huxley (1964), amongst others, pointed to, was the necessity of creating an environment in which alternative approaches to problem solving are encouraged: maximising *adaptive* efficiency, in contrast to the *allocative* efficiency that consumes business and government interests. More recently, Sim (2009) suggests that such a 'one size fits all system' is a strategic error. Globalisation is not a tide to be turned, but the form and institutional framework of globalisation is very much at stake. Will it be one dimensional or will it enable diversity in relation to the land among other things?

We can visualise the possibilities of experimentation within nation states within known property forms in the Figure 1.

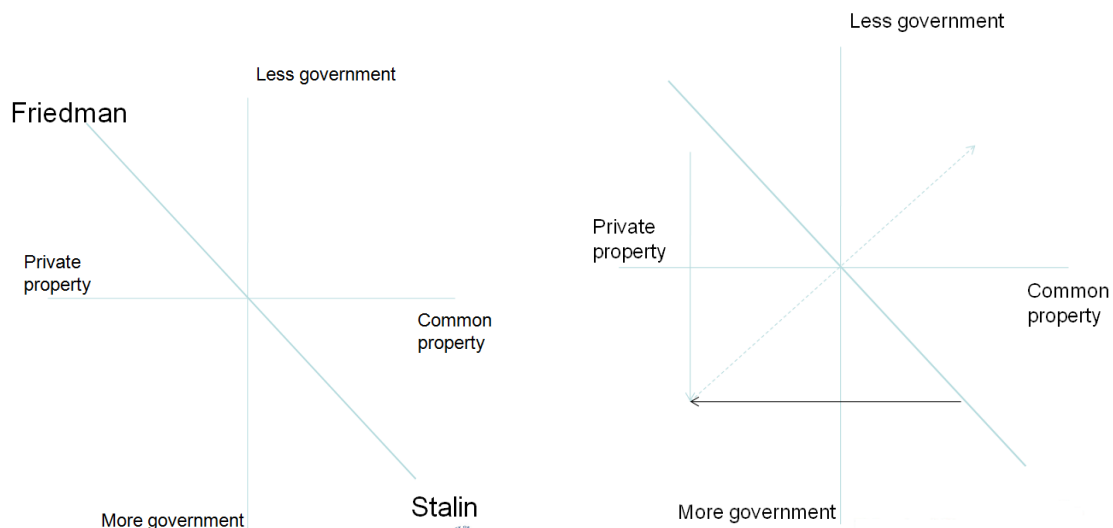

Figure 1 Here we see (left window) the main axis of 'experimentation' in the last half of the twentieth century, and (right window) current trends as a post credit crunch America thinks of big government again, while China thinks about private property.

The customary tenures occupy the top right quadrant. We might identify them as Big Society forms of property tenure. The questions we pose concern their future: will they have one, should they have one?

5 Conclusion

This paper reports encounters with members of several tribes in Uganda as well as with a series of representatives of Ugandan national and local government and non government organisations, as well as international governments and the UNDP engaged in the TACC project.

It describes the rich variety of tenurial forms and relationships that pertain on the land in northern and eastern Uganda. We conclude that these relationships are under threat and primarily because of pressures on global land supply. We invite discussion of our findings.

Urban regeneration policy and practice

Reconceptualising the management of urban regeneration in the Asian region through resilience.

Dr. Jamie MacKee

University of Newcastle, Newcastle, NSW, 2308,
Australia

Email: Jamie.Mackee@newcastle.edu.au

Abstract:

Recent thinking amongst conservationists, urban planners, and those in the cultural field, has focused on differences in the views and beliefs about cultural heritage and urban regeneration. Examples include the approaches to and understanding of conservation in the Asian region that tend to rely on total reconstruction or restoration to preserve monuments in the urban environment. This is underpinned by the belief in the importance of intangible values as opposed to tangible, the spiritual aspects of a site or place and the relationship between landscape and monument within the cultural landscape. There have been attempts to address these differences. Conservation guidelines such as the Nara Document on Authenticity and charters such as the Burra Charter provide flexibility in interpretations of cultural significance. However, the debate remains fractured and the solutions provided remain firmly within the Western/Euro-centric mechanistic reductionist worldview. This paper proposes an alternative theoretical framework to understanding and interpreting the process of urban regeneration in the Asian region by adopting the principles of resilience thinking. Resilience thinking engages in a transdisciplinary way the dynamic interconnections and interdependencies amongst the key systems of the urban environment. In summary, the work in the field of resilience thinking has made great gains in providing an understanding of the complex nature of social-ecological systems and how these could be better prepared to deal with disturbances and in the long term be sustainable. From the studies on urban resilience there is potential for an exciting opportunity to rethink our understanding of cultural built heritage and urban regeneration as a social-ecological system developing a more universal approach to its regeneration and ultimately its sustainability.

Keywords:

Urban regeneration, resilience thinking, cultural built heritage, adaptive cycles.

1 Introduction

Recent thinking amongst conservationists, Architects, urban planners/designers and those in the cultural field, has focused on differences in the views and beliefs about urban regeneration and cultural heritage (Taylor and Altenburg 2006, Seung Jin, 2005, Taylor 2004, Wijesuriya 2004, 2003b, Chen and Aass 1989). Examples include the approaches to and understanding of conservation in the Asian region that tend to rely on total reconstruction or restoration to preserve monuments in urban contexts. This is underpinned by the belief in the importance of intangible values as opposed to tangible.

The spiritual aspects of a site or place or monument rather than any material or tangible evidence are significant. (Taylor and Altenburg 2006, Seung-Jin 2005, 1998, Taylor 2004, Munjeri 2004, Wijesuriya 2003b, 2003c, Mackee and Briffett 2000a).

These approaches often conflict with current conservation practices as stated by bodies such as the United Nations Educational, Scientific and Cultural Organisation (UNESCO) and the World Heritage Centre (WHC). This particular attitude, often attributed to the Asian region, is not supported by the theories of conservation or urban reconstruction founded on the large body of Western/Euro-centric cultural and philosophical traditions adopting the Venice Charter (ICOMOS 1965) and other international and national charters (Chen and Aass 1989, Agrawal 1975). There have been attempts to address these differences. Conservation guidelines such as the Nara Document on Authenticity (Larsen and Marstein 1995, ICOMOS 1994, Stovel 1994), Hoi An Protocols (UNESCO 2005) and charters such as the Burra Charter (Australia ICOMOS 1999) provide flexibility in interpretations of cultural significance. However, the solutions provided remain firmly within the Western/Euro-centric mechanistic reductionist worldview.

Many people researching in this field have written on how these values manifest themselves in the context of interpreting and incorporating cultural heritage into urban regeneration in the Asian region (Taylor and Altenburg 2006, Seung Jin, 2005, Taylor 2004, Wijesuriya 2004, 2003b, Chen and Aass 1989, Agrawal 1975). Fewer people have attempted to explore these differences and how they might translate to an alternative appropriate approach to including cultural heritage in urban regeneration in the East. These attempts have only been within the scope of proposing country specific charters (Seung Jin, 2005, 1998, Taylor 2004, Menon 2003, 1994). MacKee's (2009a, 2009b, 2009c, 2008, 2007, 2006) work attempted to bridge this divide by postulating an approach that used as its starting point the philosophical and cultural traditions of the region linked to established synergies with systems theory. A recommendation for future research from this paper was the potential of resilience thinking to provide the foundation for an alternative approach to urban regeneration and the greater inclusion of cultural built heritage.

This paper seeks to develop the potential for a theoretical framework for the merging of urban regeneration and the field of resilience thinking presenting a literature review and the basis of a theoretical framework and agenda for future research.

2 The notion of Resilience Thinking

Research has shown, in general, systems are holistic, strongly connected, operate cyclically and to support the cyclical processes rely on feedback loops (Macy 1991, Laszlo 1972, Bertalanffy 1968). In studying the changes that occur in natural eco-systems research has led to the notion that these systems are invariably very complex (Walker and Salt 2006). The highest level of complexity is evident in social-ecological systems, that is the relationship between human systems and ecological systems (Berkes and Turner 2006, Walker and Salt 2006, Berkes, Colding and Folke 2003, Holling 2003, Berkes and Folke 1998). Understanding the complexity of these co-evolving systems their interrelationships, change dynamics and transformation has provided the rich foundation for looking at the 'resilience' of these systems (Berkes and Turner 2006, Walker and Salt 2006, Berkes, Colding and Folke 2003, Berkes and Folke 1998). At the heart of resilience thinking is the very simple notion of coherence despite change

and the idea that to ignore change is to increase our vulnerability and forego emerging opportunities (Walker and Salt 2006, pp 9-10). In resilience thinking humans and nature are considered as elements of the one system, as they are interdependent. To think of one in isolation of the other is to come up with only a partial solution (Walker and Salt 2006). In essence, Resilience, defined by Walker and Salt (2006) is a systems capacity to absorb disturbances without a regime shift and they see it as the key to sustainability (Walker and Salt 2006, p38).

2.1 Resilience thinking in the context of urban regeneration and cultural heritage

A component of resilience thinking that has direct links to the notion of urban regeneration is the model of the adaptive cycle (refer figure 1). This has been derived from comparative studies of the dynamics of ecosystems and how they recover and reorganise after catastrophic events. This adaptive cycle has four distinct phases that are representative of ecosystems and more significantly for this study social-ecological systems. These four phases are (Resilience Alliance 2009):

Growth or exploitation (r)

Conservation (K)

Collapse or release (Ω)

Reorganisation (α)

Represented in this cycle are two major phases often referred to as ‘transitions’. The first phase or *foreloop* that runs from r to K is characterised by slow incremental phase of growth and accumulation. The second of these phases is the *backloop* from Ω to α and is the rapid phase leading to reorganization and growth (Resilience Alliance 2009). This adaptive cycle model is used in resilience thinking to explain how ecosystems adapt after catastrophic events.

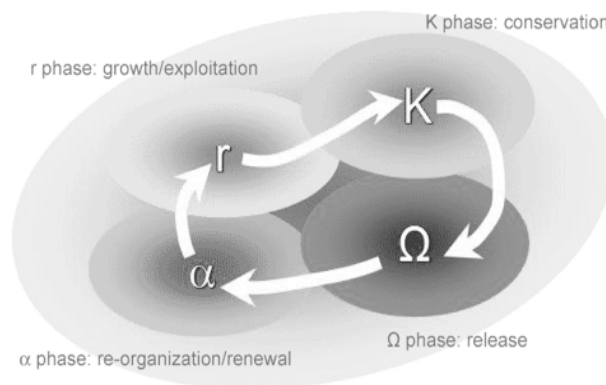

Figure 1: The model of the adaptive cycle developed by the proponents of resilience thinking. (Source: Resilience Alliance <http://www.resalliance.org/570.php>)

Another link between resilience theory and its potential application for urban regeneration is Redman’s (2005) discussion of the notion of resilience thinking in archaeology. He postulates that “...*resilience thinking looks at change transformation and adaptive cycles and archaeology provides the opportunity to study not only one completed cycle but multiple completed cycles* “ (Redman 2005, p70). Redman’s

contention is that the study of persistence and change in systems is at the heart of resilience thinking and can be verified by archaeology in the study of many systems historically over time. In so doing archaeology confirms the notions of adaptive cycles of change and transformation and the dynamic changes that occur over time in social-ecological systems (Redman 2005). Redman's study has implications for the current research in that, as with archaeology, the conservation of buildings and specifically large areas of aging urban centres is about dealing with persistence despite change and transformation. This changes the temporal, utilisation and management contexts. For cultural built heritage archaeology establishes and confirms the changes and transformations that have occurred to the monument over time. This allows us to understand previous life cycles and to plan for the future.

Redmen and Kinzig (2003) continue the notion of adaptive cycles as evidenced over time in archaeology. This article investigates resilience theory because of its explanation of 'the role of change in adaptive systems'. This is in order to see the transforming stages making it highly relevant to use to understand archaeology, in particular studying the 'resilience of past and present societies' as they are adaptive and changing. They state that this approach is not common in other disciplines. The authors go on to explain resilience theory and then continue to show how when it is used it can have 'complementary or contradictory conclusions' and finally they discuss the idea of a 'long-term integrative perspective for understanding linked social and ecological systems' (2003 p.14). They offer a detail description of the theoretical framework then show that collaboration has occurred with conceptualisation of these cycles in "ecology, archaeology and economics, among other fields" and they concentrate on Holling's (2003) use of the concept in ecology for their study. They show that there are paradoxes of resilience and adaptive capacity and critique the panarchy approach. They also state that resilience can solve problems in 'short run but not in the long term'. In their conclusions they bring in two case studies of archaeological societies to show the similarities in the use of resilience theory to understand ecological changes and show what parts work and what do not in the theory. They show that this theory is being more and more incorporated by archaeologists to "examine their historical processes within a resilience theory framework" (2007 p.14). The work of Redman (2005) and Redman and Kinzig (2003) provides the strongest argument for linking the concepts of resilience thinking to a notion of urban regeneration. The ideas of change, transformations and adaptive cycles are notions that are related to how the urban fabric can be perceived through time and explored in terms of conserving, incorporating and rebuilding.

The work of Childs (2001) looking at settlements and cities as complex systems similar to ecology, while not being explicit has implicit links to resilience. He makes direct reference to buildings and how they develop and evolve similar to a system. Childs (2001) uses 'biological evolutionary theory' to explain this process of change and interactions of buildings between each other 'giving rise to collectively made forms' (2001, p.55). He then considers the city as a civic ecosystem, as a "complex set of interactions among multiple buildings" which may 'give rise to aggregate forms and that these can change over time depending on flow of resources in communities. Here Childs considered 'coherence' and 'resilience', he gives the example of how ruins are a result of disaster and examples of resilience or lack of for cities. He states that not all change is 'cataclysmic' and that "different systems have different degrees and types of resilience" (2001, p.69). Childs concludes to show that buildings are not isolated entities as they "alter each others fitness" (2001, p.70). This work is informative and

useful in looking at how resilience might be considered as a basis for looking at the conservation of cities if they are thought of as complex systems.

This work points toward a method of looking at urban regeneration through the lens of resilience. More specifically for the aims of this research they provide a very useful argument that culture; heritage and built heritage can be considered as systems that are interconnected and interdependent. The application of resilience thinking to the conservation of built heritage provides the opportunity to understand and deal with the persistence and survival of heritage against the persistent forces of physical, social and natural change. That is, resilience thinking engages in a transdisciplinary way the dynamic interconnections and interdependencies amongst the key systems in the built environment.

3 Discussion

Resilience is the capacity of a system to absorb shocks while maintaining function. It provides the capacity for renewal and reorganization. In a resilient system change has the potential to create opportunity for development and innovation. However there are four critical factors that must exist for the success of a resilient system these are presented in table 1.

Table 1: Four Critical Factors for a Resilient system (Source: Folke *etal*, 2002)

	Critical Factor	Description
1	Learning to live with change and uncertainty	Creating a knowledge base for how to relate to and respond to environmental feedback
2	Nurturing diversity for resilience	Functional diversity and redundancy as per nature
3	Combining different types of knowledge for learning	Integration of knowledge and their sources for a holistic approach
4	Creating opportunity for self organisation towards socio-ecological sustainability	Adaptive co-management by which institutional arrangements and ecological knowledge are tested and revised in a dynamic, ongoing, self-organised process of trial and error

These four critical factors (Folke *etal*, 2002) provide guidance for developing a framework for applying the concept of resilience to the conservation of the cultural built heritage. The first factor would relate to the fact that built environment exists through time which impacts in uncertain unpredictable ways. The idea of a knowledge base provides for trying to deal with the uncertainty, again through the life of the piece of heritage, this implies research.

The second factor requires understanding of the nature of the piece of heritage and the diversity of the built environment within which it has come to exist. A requirement for

this factor in heritage is an understanding of the conditions of redundancy and obsolescence.

Important for the third factor is the in the context of cultural built heritage is the multidisciplinary approach and the knowledge provided by the many stakeholders. This is imperative for a holistic approach that has been suggested as currently lacking in heritage conservation (MacKee 2009a).

Finally the key to attaining the fourth factor is the understanding that urban regeneration can be a sustainable process with the implementation of the appropriate institutional processes. These must acknowledge the dynamic nature of cultural heritage and importance of a suitable management organisation.

Figure 2 shows an initial proposal for a comparative cycle that could be used to describe the life cycle of cultural built heritage. This is developed as a sub-set of the adaptive cycles of resilience to be used as a basis for exploring urban regeneration. In this cycle there are transitions. The first can be shown from the first stage of the cycle 'commission and operation' to 'obsolescence'. This is a long slow transition that is subject to the economic and societal demands of the environment in which the cultural built heritage exists. Similarly this is a phase of growth.

The next transition from 'obsolescence' to 'adaption/renewal' is one of decision-making and significant change. In this phase significant decisions are made about how to adapt the piece of heritage. This decision can be supported by scenario planning as suggested by Peterson (2003). In his paper he proposes scenario planning as a tool for decision-making because it "...offers a framework for developing more resilient conservation policies when faced with uncontrollable, irreducible uncertainty" (Peterson, p358, 2003). The notion of uncertainty describes the future of cultural built heritage in the Asian region in the context of rapid urban development occurring.

The third transition is to the planning and development phase. Once a decision has been made regarding how to deal with the urban fabric then work can proceed on development. Once planning and development is completed then the cycle recommences.

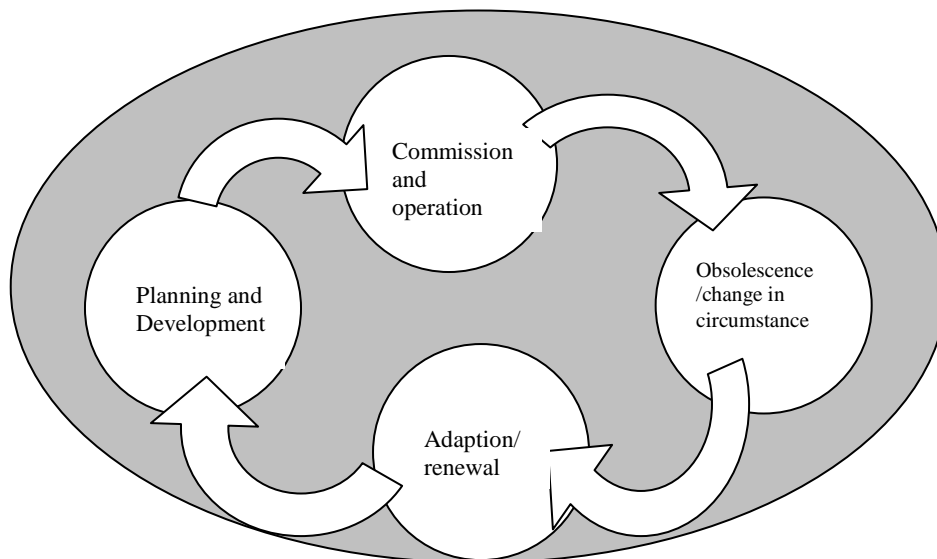

Figure 2: The life cycle of the urban environment. (Source: MacKee 2010)

The description of the life cycle in figure 2 offers the initial proposal for the integration of the adaptive cycles of resilience to urban regeneration. From these very first steps work needs to focus on the further integration of the four critical factors described in table 1. These are important to the success of the integration of resilience and urban regeneration.

4 Conclusion and Further Research

This paper has provided a literature of review of resilience thinking to support the merging of this field and urban regeneration in the Asian region. A number of writers in the field have highlighted discussed the differences that occur in the approaches of western and eastern based indigenous conservation practices (Taylor and Altenburg 2006, Seung Jin, 2005, Taylor 2004, Wijesuriya 2004, 2003b, Chen and Aass 1989, Agrawal 1975). This is evident in the rise of locally based conservation charters and guidelines (Seung Jin, 2005, 1998, Taylor 2004, Menon 2003, 1994). MacKee's (2009a, 2009b, 2009c, 2008, 2007, 2006). Documents such as the Nara Document on Authenticity (Larsen and Marstein 1995, ICOMOS 1994, Stovel 1994), the Hoi An Protocols (UNESCO 2005) and the Burra Charter (Australia ICOMOS 1999) are also evidence of this trend.

MacKee (2009a 2009b, 2009c) proposing an alternative approach to conservation in the Asian region has written on the synergies between traditional Asian philosophies and systems thinking. From this came the notion of resilience as an appropriate approach for developing a framework for an approach to urban regeneration.

The review presented here has outlined the beginnings of a potential theoretical framework for adopting resilience thinking as a way of managing urban regeneration. A component of resilience, adaptive capacity, provides the means for realizing this objective. Further work needs to be done however it would appear from this foundation study that great potential lies in the merging of resilience thinking and the management of urban regeneration. There are lessons in this study for the wider built environment outside the Asian region.
