CONCISE REPORT

Incidence of overall and site specific cancers in TNFα inhibitor treated patients with rheumatoid arthritis and other arthritides – a follow-up study from the DANBIO Registry

Lene Dreyer,1 Lene Mellemkjær,2 Anne Rødgaard Andersen,3 Philip Bennett,4 Uta Engling Poulsen,5 Torkell Juulsgaard Ellingsen,6 Torben Høiland Hansen,7 Dorte Vendelbo Jensen,8 Louise Linde,3 Hanne Merete Lindegaard,9 Anne Gitte Rasmussen Loft,10 Henrik Nordin,11 Emina Omerovic,12 Claus Rasmussen,13 Annette Schlemmer,14 Ulrik Tarp,15 Merete Lund Hetland316

INTRODUCTION

Treatment with TNFα inhibitors (TNF-I) is widely used in inflammatory rheumatic diseases such as rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA).

After more than 10 years of widespread use, it is still debated whether treatment with TNF-I agents is associated with an increase in cancer incidence.1–12 and additional observational studies with long-term follow-up, detailed drug history and independent registration of specific cancer cases are needed. The aim of the present study was to investigate the risk of cancer among TNF-I-treated patients by linking the national Danish DANBIO database of arthritis patients with the Danish Cancer Registry.

MATERIALS AND METHODS

DANBIO

Since 2000 Danish rheumatologists have voluntarily registered patients treated with TNF-I agents in the DANBIO database,13 and in 2006 reporting became compulsory. Coverage for TNF-I-treated patients is steadily greater than 90%. Since 2000, an increasing number of both prevalent and newly diagnosed non-TNF-I-treated arthritis patients from rheumatology departments have also been registered in DANBIO. At the beginning reporting occurred on a voluntary basis but since 2006 the departments have been committed to register all newly diagnosed or newly referred RA patients. In 2006–7 a DANBIO-initiated cross-sectional study involving 11 of 26 Danish outpatient departments of rheumatology contributed with the registration of 3704 RA patients in DANBIO, among these 2977 were TNF-I naive.14

For details of the Central Population Register, the Danish Cancer Registry and statistical analyses, see supplementary material (available online only).

Cohort identification and follow-up

A total of 10 495 patients registered in DANBIO between January 2000 and December 2008 was included. Among these patients, seven patients with systemic lupus erythematosus and 52 patients with a missing diagnosis were excluded. The remaining 10 436 patients were linked to the Central Population Register (information on dates of death or emigration) and to the Danish Cancer Registry (identification of all cancer cases to 2008), and 740 patients with a cancer diagnosis before first registration in DANBIO were subsequently excluded, leaving 9696 patients with arthritis for analysis. Among these, 5345 started TNF-I therapy between January 2000 and the end of 2008, while 4351 patients had never been treated with anti-TNFα (table 1).

The cohort was followed from first registration in DANBIO until the date of first cancer diagnosis, death, emigration or the end of 2008, whichever came first. For patients who did not start treatment with TNF-I at the date of the first registration in DANBIO, the exposure status changed from never exposed to ever exposed at the date of the start of first TNF-I treatment (n=1475).

ABSTRACT

Objectives To investigate the incidence of cancer in arthritis patients treated with or without TNFα inhibitors (TNF-I).

Methods Arthritis patients from the DANBIO database were followed-up for cancer in the Danish Cancer Registry during 2000–2008.

Results Hazard ratio for cancer overall was 1.02 (95% confidence interval (CI) 0.80–1.30) in 3347 TNF-I-treated RA patients compared to non-treated. Excess among TNF-I-treated was found for colon cancer (HR 3.52 (95% CI 1.11–11.15), whereas 6 and 0 ovarian cancer cases were observed in treated and non-treated patients, respectively. Compared to the general population, TNF-I-treated was found for colon cancer (HR 3.52 (95% CI 1.11–11.15), whereas 6 and 0 ovarian cancer cases were observed in treated and non-treated patients, respectively. Compared to the general population, TNF-I-treated was found for colon cancer (HR 3.52 (95% CI 1.11–11.15), whereas 6 and 0 ovarian cancer cases were observed in treated and non-treated patients, respectively.

Conclusions Our results suggest that TNF-I therapy in routine care is not associated with an overall excess of cancer in arthritis patients, but observed increased risks of colon and ovarian cancer need further investigation.

For numbered affiliations see end of article.
patients relative to non-treated patients, but an increase in risk was observed when comparing TNF-I-treated RA patients with patients, whereas a significant increase in risk was seen compared to the general population (SIR 1.61, 95% CI 0.95 to 2.77), based on 15 observed and 8.1 expected cases. Among non-treated patients the SIR of colon cancer was 0.53 (95% CI 0.20 to 1.40). Six cases of ovarian cancer were seen in TNF-I-treated RA patients, whereas no cases were observed in non-treated patients. The risk of ovarian cancer was non-significantly increased among those treated in comparison with the general female population (SIR 2.08, 95% CI 0.94 to 4.64).

No significant increase in the risk for all cancer sites combined was observed in any of the non-RA arthritis groups compared to the general population.

Various adjustments for disease activity and stratified analyses in TNF-I-treated RA patients compared to non-treated patients did not reveal increased risks for overall cancer (table 3).

### RESULTS

The DANBIO arthritis cohort experienced 24,811 person-years of observation, that is, 15,592 person-years accumulated after TNF-I treatment and 9,219 person-years accumulated in non-treated (never-treated patients and before TNF-I treatment). The mean follow-up time was 2.9 years in TNF-I-treated patients and 2.1 years in non-treated patients.

Overall, we observed 280 cancers in the total DANBIO RA cohort, with 222.7 expected from the general population, yielding a standardised incidence ratio (SIR) of 1.26 (95% CI 1.12 to 1.41). An increased SIR was observed for non-Hodgkin lymphoma 2.06 (95% CI 1.11 to 3.83), Hodgkin lymphoma 4.81 (95% CI 1.20 to 19.2), non-melanoma skin cancer 1.84 (95% CI 1.47 to 2.31) and lung cancer 1.47 (95% CI 1.07 to 2.05). No increased risk was observed for colon cancer 1.08 (95% CI 0.67 to 1.74).

No increase in the overall cancer risk was observed among RA patients treated with TNF-I compared to non-treated patients, whereas a significantly increased risk for all cancers was observed when comparing TNF-I-treated RA patients with the general population (table 2).

The same pattern with no increase in risk among TNF-I-treated patients relative to non-treated patients, but an increase in risk relative to the general population was seen for non-melanoma skin cancer and cancer in lymphatic and haematopoietic tissue (table 2). No increased risk of non-Hodgkin and Hodgkin lymphoma combined was observed among RA patients receiving TNF-I therapy when compared to patients not receiving therapy 0.92 (95% CI 0.29 to 2.92), while an increased SIR of 2.42 (95% CI 1.15 to 5.07) was observed when compared to the general population.

A significantly increased risk of colon cancer (HR 3.52, 95% CI 1.11 to 11.15) was observed in TNF-I-treated RA patients compared to non-treated patients, while a non-significantly increased risk was seen compared to the general population (SIR 1.61, 95% CI 0.95 to 2.77), based on 15 observed and 8.1 expected cases. Among non-treated patients the SIR of colon cancer was 0.53 (95% CI 0.20 to 1.40). Six cases of ovarian cancer were seen in TNF-I-treated RA patients, whereas no cases were observed in non-treated patients. The risk of ovarian cancer was non-significantly increased among those treated in comparison with the general female population (SIR 2.08, 95% CI 0.94 to 4.64).

As significant increase in the risk for all cancer sites combined was observed in any of the non-RA arthritis groups compared to the general population.

Various adjustments for disease activity and stratified analyses in TNF-I-treated RA patients compared to non-treated patients did not reveal increased risks for overall cancer (table 3).

### DISCUSSION

The strengths of our study include high coverage of biologically treated patients (>90%) as well as a high validity of the RA, AS and PSA diagnoses in the DANBIO Registry. The registration in DANBIO was independent of registration in the cancer registry. We had complete follow-up and had the possibility to compare the cancer risks in TNF-I-treated RA patients with non-treated patients recruited from the same rheumatology departments to minimise confounding, even though confounding from factors influencing treatment decisions such as comorbidity could not be avoided. Cancer incidence in both treated and non-treated patients was also compared to that of the general population of Denmark. In clinical practice in Denmark, previous or actual cancer disease is generally a contraindication for TNF-I treatment. Therefore, to avoid differences in the prevalence of cancer among treated and non-treated patients, we excluded all patients with a previous cancer diagnosis. The cancer incidence during the first year after initiating TNF-I treatment is most likely to be influenced by selection bias, but exclusion of the first year after initiating TNF-I treatment did not change the overall risk of cancer.

We found a moderately increased overall cancer risk in RA compared to the general population. However, there was no increase in overall cancer risk among RA patients treated with TNF-I agents compared to RA non-treated patients, which is in line with other observational studies. A meta-analysis of selected randomised trials of RA patients in TNF-I treatment with adalimumab or infliximab reported a three times increased risk of cancer during short-term follow-up, which was not confirmed in a recent meta-analysis. A meta-analysis of selected randomised trials of RA patients in TNF-I treatment with adalimumab or infliximab reported a three times increased risk of cancer during short-term follow-up, which was not confirmed in a recent meta-analysis. Also in support of no effect of TNF-I on overall cancer incidence, we found no evidence of an increase in overall risk by the cumulative duration of anti-TNF therapy, and risks did not vary by sex or age at the start of treatment.

In accordance with our findings, several studies have demonstrated a two to fourfold increased risk of malignant lymphomas in RA patients compared to the general population. The incidence of lymphomas was the same in our TNF-I-treated and non-treated RA patients, based on small numbers. Our results...
In conclusion, we found no excess of overall cancer associated with TNF-I therapy in RA patients in routine care. Evidence from previous studies concerning these cancers is sparse. Wolfe and Michaud reported risks significantly elevated. Surveillance bias does not seem an obvious explanation, because increased surveillance would have been expected to result in a general increase in cancer incidence at many sites. One may hypothesise that a higher use of non-steroidal anti-inflammatory drugs or aspirin in the disease-modifying antirheumatic drug-treated group and a more sedentary lifestyle may affect the incidence rate of colon cancer. Larger studies are needed to determine whether the increased risks of colon and ovarian cancer were chance findings in our study.

In conclusion, we found no excess of overall cancer associated with TNF-I therapy in RA patients in routine care. However, increased risks of colon and ovary cancer were found and need further investigation. We did not find an increase in the overall cancer risk in TNF-I-treated AS, PSA and other arthritides patients compared to the general population.

*p Values for homogeneity test based on Wald statistics.

†There were 128 cancer cases observed among non-tumour necrosis factor α inhibitor (TNF-α)-treated patients.

‡HR ratios estimated using Cox proportional hazard models with age as the underlying time scale and with further adjustment for sex and calendar time (2000–2005–2008).

§Adjustment for high disease activity at first visit (health assessment questionnaire (HAQ) ≥2; C-reactive protein (CRP) ≥30 mg/l; disease activity score in 28 joints (DAS28) ≥5.1). Similar results were found after adjustment for the same disease activity measures at the latest visit or at any time.

RA, rheumatoid arthritis.
