## Introduction

The small subunit (SSU) ribosomal RNA (rRNA) genes have been used to study of microbial diversity and evolution for the last 30 years. Today, databases containing full-length SSU rRNA reference sequences remains fundamental for many core analyses in microbial ecology, such as community profiling using 16S/18S rRNA amplicon sequencing and in-situ studies based on fluorescence in situ hybridization (FISH) microscopy. The quality of the data produced relies heavily on the reference databases used, and it is widely recognized that the current databases are underpopulated, ecosystem skewed, and subject to primer bias. Here we present a method that combines reverse transcription of polyadenylated full-length SSU rRNA molecules with Illumina based synthetic long-read sequencing to obtain high quality, full-length SSU rRNA sequences in a high throughput manner. We applied the approach to complex samples from seven different ecosystems and obtained more than 1,000,000 SSU rRNA gene sequences from all domains of life with an estimated raw error rate of 0.17%. We observed a high fraction of novel diversity including several deeply branching phylum level lineages. Here we describe how the method works and demonstrate how the access to comprehensive ecosystem specific SSU databases affect our ability to study microbial ecology.

### Method overview and evaluation RNA processing Library & Sequencing Data processing Pre-amplification and size selection Before size selection After size selection based on linked-tags Size (nucleotides) Clonal amplification of 100,000 - 1,000,000 cDM molecules SSU size selection De novo assembly of individual bins Unique tag site Poly(A) tailing and first strand synthesis End repair and circularization Adaptor trimming, SSU filtering and HMM domain sorting Read-tag library PCR Single stranded ligation and second strand synthesis Linked-tag library PCR Full-length SSU rRNA sequences Double stranded cDNA with unique tags and Sequencing of internal Sequencing of linked-tags SSU reads linked to tags defined primer binding sites in both ends Primer based method 2000 (Can be used for any marker gene <1800 bp) Primer binding Unique tag site site Unique tag Anealing of adaptors by two cycles of PCR B. subtilis 300 Amplicon with unique tags and defined primer binding sites in both ends Proceed to Library & Sequencing Figure 1. Overview and validation of the full-length SSU rRNA sequencing protocol. a, Schematic overview of the preparation of full-length SSU rRNA gene sequences from total community RNA.

Figure 1. Overview and validation of the full-length SSU rRNA sequencing protocol. a, Schematic overview of the preparation of full-length SSU rRNA gene sequences from total community RNA. First, SSU rRNA is enriched from extracted total community RNA using size selection. The enriched SSU rRNA is polyadenylated and the polyA-tail used as a generic priming site for first strand synthesis (reverse transcription). Another generic priming site is added to the other end of the cDNA molecule by single stranded ligation and used for second strand synthesis. PCR adaptors used for first and second strand synthesis contain unique tags (green and blue), which, in combination, become the unique "linked-tags" of the molecules. The adaptors also contain generic priming sites that are used for PCR amplification of the tagged molecules. The amplicons are size selected to remove incomplete or truncated products. A defined number of full-length SSU rRNA amplicons are size selected to remove incomplete or truncated products. A defined number of full-length SSU rRNA amplicons are size selected to remove incomplete or truncated products. A defined number of full-length SSU rRNA amplicons are size selected to remove incomplete or truncated products. A defined number of full-length SSU rRNA amplicons are size selected to remove incomplete or truncated products. A defined number of full-length SSU rRNA amplicons are acad-tag library and a linked-tag library. The read-tag library is prepared by fragmenting the full-length SSU rRNA amplicons using lllumina Nextera tagmentation and library preparation. The resulting sequencing outcome is an internal SSU rRNA fragment read connected to a single unique tag read. The linked-tag library is prepared by circularizing full-length SSU rRNA amplicons to physically link the tags in close proximity. PCR is used to amplify the linked-tags, which are then identified with sequencing. The linked-tags are used to bin all SSU rRNA fragment tag-reads originating from the same parent molecule. De novo ass

## **Application to environmental samples**

## Novel phylum-level archaeal lineages (DAS1-8)

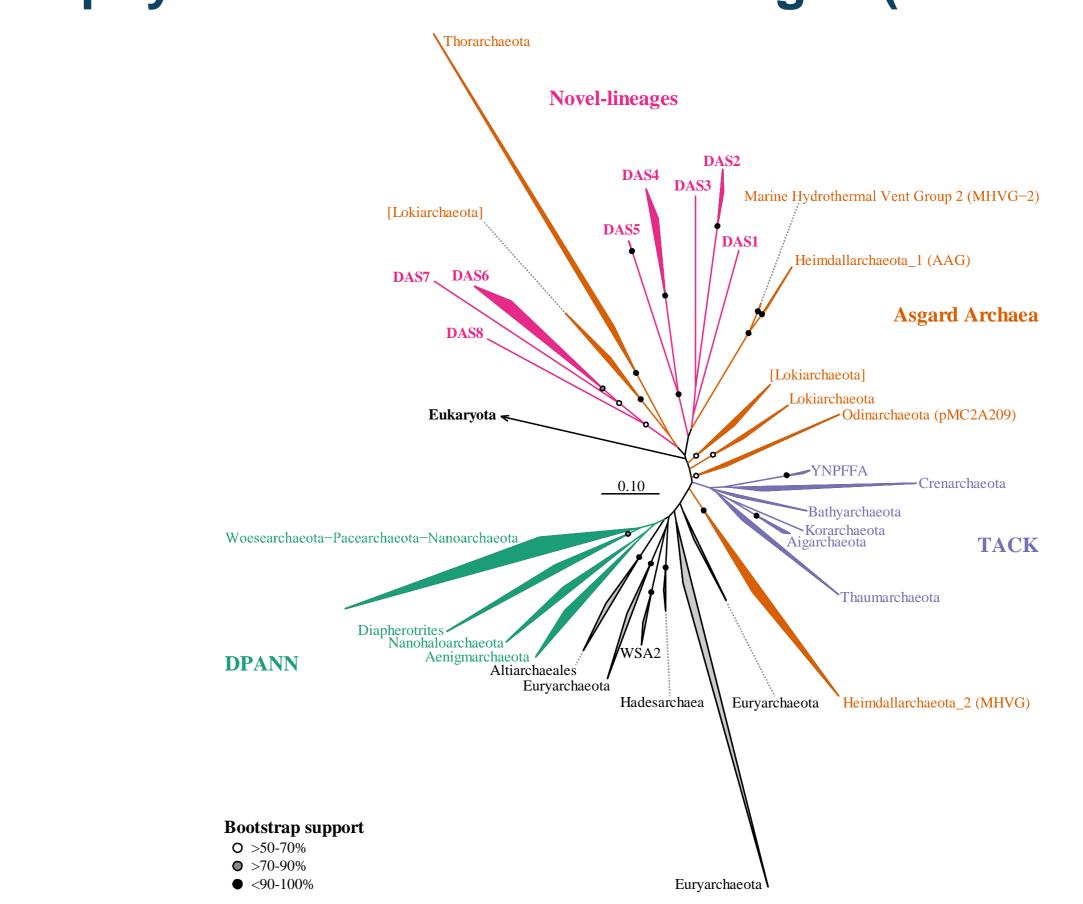

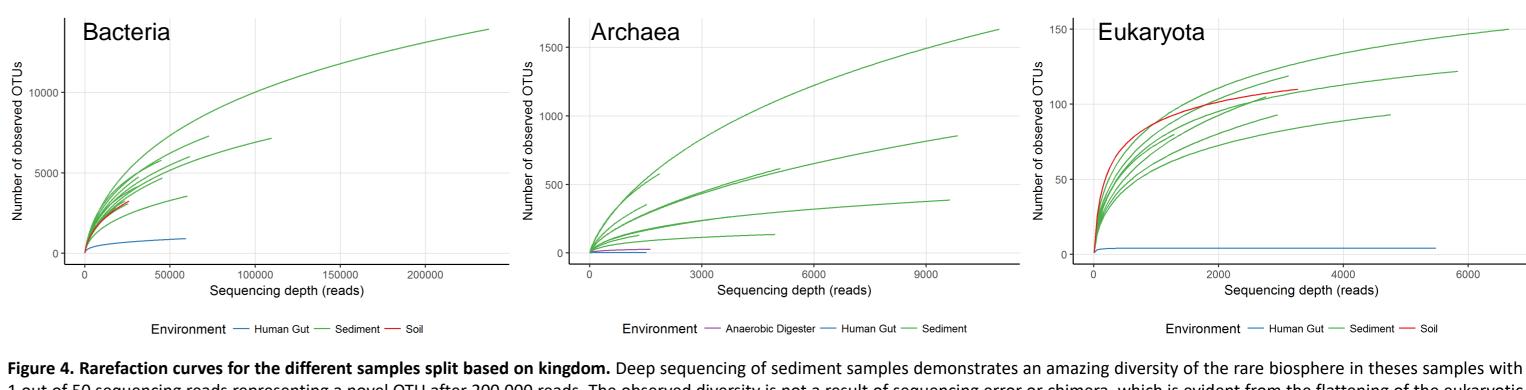

Figure 3. Discovery of novel archaeal diversity. a, Maximum-likelihood phylogenetic tree showing coverage of the domain Archaea. The tree contains archaeal OTUs clustered at 97% generated in this study that have ≤82% similarity to any database sequence, their closest match in the Silva SSU NR99 v. 128 database, the archaeal reference set from the recent 'Tree of Life' article (Hug et al., 2016) and representatives of the newly described Asgard Archaea super phylum (incl. Thorarchaeote SMTZ1-83, Odinarchaeote LCB\_4 and, Heimdallarchaeote LC\_3 and AB\_125)(Zaremba-Niedzwiedzka et al., 2017). Hypervariable regions were masked with a 50% positional conservation filter, giving 1078 alignment positions, and the tree calculated using RAXML v. 8.2.10 (Stamatakis, 2014). Bootstrap support is shown where greater than 50% based on 'rapid bootstrap' analysis with 1000 iterations. Clade names and clustering are based on the position of reference sequences. Clades names enclosed in square brackets do not include a genome or pure culture reference sequence – being based on classification of reference sequences in the Silva v. 1.28 taxonomy. Clades are coloured by their affiliation to archaeal superphyla. Novel lineages detected in this study appear magenta.

### The hidden diversity of the rare biosphere

1 out of 50 sequencing reads representing a novel OTU after 200,000 reads. The observed diversity is not a result of sequencing error or chimera, which is evident from the flattening of the eukaryotic data for the human gut samples.

## Conclusions and perspectives

- Millions of primer-free, high-quality full-length SSU rRNA sequences from all domains of life
- A fully populated tree of life is [maybe] within reach
- Novel undescribed phylum-level archaeal linages discovered
- Primer-version compatible with any marker gene [<1800 bp]</li>
- Partial 23S/28S LSU genes also obtained, doubling the potential for design of new primers and probes
- More robust evaluation and design of primers and probes
- Eco-system specific databases will enable highly specific primers and probes
- Enhance all in situ studies that rely on primers and probes e.g. FISH
- Guide efforts to obtain genomes from undescribed branches of the tree of life
