## **Glasses across chemistries and length scales**

*Morten M. Smedskjær, Department of Chemistry and Bioscience, Aalborg University*

Glasses are non-equilibrium materials that exhibit a glass transition and have a non-crystalline structure. Glass materials can therefore be found across a variety of chemical compositions, from oxides to metal-organic frameworks. They feature heterogeneity and exhibit varying degree of structural disorder on different length scales, which has profound consequences for their properties. In this talk, I will discuss how we attempt to decipher their structure-property relations using topological data analysis, constraint theory and machine learning methods. I will then highlight how this knowledge can be used to design more fracture-resistant glasses.
