ABSTRACTS

ISPOR 16TH ANNUAL EUROPEAN CONGRESS RESEARCH ABSTRACTS

RESEARCH PODIUM PRESENTATIONS – SESSION I
HEALTH CARE EXPENDITURE OR REIMBURSEMENT STUDIES – BIOLOGICS

BI1
ADHERENCE AND RESOURCE USE AMONG PATIENTS TREATED WITH BIOLOGICS. FINDINGS FROM THE BEETLE STUDY (BIOLOGICAL DRUGS: EVALUATION OF ECONOMICS, TREATMENTS, AND LABELING IN REAL-WORLD SETTING)

Degli Esposti L, Sangiorgi D, Buda S
CliCon Srl, Ravenna, Italy

OBJECTIVES: Systemic administration of anti-TNF alpha leads to an anti-inflammatory and joint protective effect in pathologies such as rheumatoid arthritis, psoriasis, Crohn's disease. The aim of this study was to assess adherence to therapy and stay on treatment (no switches or interruptions) of patients treated with biologics according to therapeutic indication and to calculate health care resources consumption (drugs, outpatient services, hospitalizations). **METHODS:** An observational retrospective cohort analysis based on 5 Local Health Units administrative databases was conducted. Patients who filled at least one prescription for anti-TNF alpha between January 1, 2009-December 31, 2011 were included. Patients were followed-up for one year. Patients were defined as adherent if they had >80% of follow up period covered by drugs dispensation. **RESULTS:** A total of 1219 patients were analyzed, 47% male, age 49.6±14.6. Patients affected by rheumatoid arthritis were 36%, psoriasis 31%, Crohn's disease 10%, psoriatic arthritis 7%, ulcerative colitis 3%, ankylosing spondylitis 3%, diagnosis not available 11%; 420 (34%) were treated with Adalimumab, 615 (50%) Etanercept, 184 (15%) Infliximab. Among the 94% of patients who did not switch, patients treated with Infliximab seemed to have the highest rate of adherent patients across all indications: 51%, vs. 27% Etanercept and 23% Adalimumab; at the multivariable logistic regression model, Infliximab resulted a protective predictor of non adherence for all indications (OR ranged from 0.08 to 0.43). For patients who started a first-line biological drug, stay on treatment was 73% for Infliximab, 67% Etanercept, 64% Adalimumab. The mean annual expenditure for each patient in analysis was €11,120; in particular, non-pharmacological expenditure was €988 for adherent and €1,255 for non-adherent patients; at the multivariable generalized linear model, Infliximab was associated with the lowest cost for all indications. **CONCLUSIONS:** Patients treated with Infliximab were associated to higher adherence and stay on treatment and lower costs, as compared to Adalimumab and Etanercept.

BI2
WHAT ARE THE KEY DRIVERS OF REIMBURSEMENT FOR BIOSIMILARS? AN EXAMINATION OF REIMBURSEMENT PROCESSES AND RECOMMENDATIONS ACROSS NINE COUNTRIES

de Silva SU, Smith TA, Bending MW
Mapi, London, UK

OBJECTIVES: Biosimilars are biotherapeutic products that are similar in terms of quality, safety and efficacy to an already licensed reference biotherapeutic product. The first biosimilar (Omnitrope) received EU regulatory approval in 2006; since then, 14 biosimilars have received marketing authorisation. This study examined the differences in the approaches to reimbursement of biosimilars in countries using HTA to inform decision-making. **METHODS:** Four biosimilar medicines were selected to provide sufficient documentation in seven European countries, South Korea and Australia. Regulatory approval and HTA reimbursement decision documents were identified and a qualitative analysis of the processes, recommendations by indication, evidence and key decision drivers was undertaken to explain differences in recommendations across countries. **RESULTS:** Twenty-one different indications were appraised; 90% of appraisals were 'recommended', 9% 'recommended with restrictions', and 1% were 'not recommended'. The Netherlands and Germany accepted 'clinical comparability' to the originator as sufficient evidence for automatic reimbursement. Sweden and France were the only countries to appraise and to recommend for all indications. Scotland and Wales recommended all biosimilars but restricted indications in some cases. Agencies accepted the notion of clinical comparability and extrapolation across indications when appraising the evidence. A cost-minimisation analysis and budget impact analysis were key economic decision drivers. A full cost-effectiveness analysis was only requested by NICE. Other factors influential in recommending reimbursement were: lobbying, dual reimbursement processes, and other reimbursement mechanisms. **CONCLUSIONS:** As the market for biosimilars continues to grow, it is imperative that specific HTA reimbursement processes are developed for assessing biosimilars. This includes further research on how different drug classes should be considered; especially pertinent due to the increase in biosimilars for monoclonal antibody-based drugs, which differ from the product classes (erythropoietin, white blood cell stimulators, growth hormone and insulins) currently dominating the market.

BI3
DIFFERENCES IN APPROACH TO BIOSIMILARS: NICE VERSUS SMC RECOMMENDATIONS

Izmirlieva M, Ando G
IHS, London, UK

OBJECTIVES: Several biosimilar products have been approved for marketing in the European Union, but their market penetration remains slow. Lack of clear reimbursement guidance could be one of the reasons for this slow penetration. This study examines how many, if any, biosimilar products have been assessed in the UK by NICE and by the SMC and to what extent recommendations by the two HTA organisations are consistent. **METHODS:** Secondary research was conducted, including a review of all NICE and SMC final guidance and of guidance in progress by NICE to compare the HTA process outcome and issues raised by the two HTA agencies. **RESULTS:** NICE has issued only one final guidance for a biosimilar product (Omnitrope) and has another guidance in progress (for epoetin including biosimilars). The SMC has issued guidance for 4 biosimilar versions of filgrastim (Ratiograstim, TevaGrastim, Zarzio and Nivestim), 2 biosimilar versions of epoetin (Binocrit and Retacrit) and 1 version of somatropin (Omnitrope). All SMC guidance for biosimilars issued to date has been positive. The NICE guidance for Omnitrope is positive despite some reservations about the economic model. **CONCLUSIONS:** Considering the limited overlap between NICE and SMC decisions (only one drug - Omnitrope - was considered by both agencies), it is difficult to assess consistency in the SMC approach compared to NICE's approach at this stage. Based on the biosimilars HTA guidance by NICE and the SMC to date, a cost-minimisation analysis may be acceptable for biosimilars even if such an approach - in the absence of a full cost-effectiveness model - might be rejected for an originator product. Both HTA agencies recommend that prescribing for biosimilars should be by brand name to avoid automatic substitution in the pharmacy.

BI4
IMPACT OF EXCLUSIVE HOSPITAL DISTRIBUTION OF BIOSIMILAR ON DRUG HEALTH CARE BUDGET

Rémuzat C[1], Vataire AL[2], Cetinsoy L[2], Aballea S[1], Toumi M[3]
[1]*Creativ-Ceutical, Paris, France,* [2]*Creativ-Ceutical, PARIS, France,* [3]*University Claude Bernard Lyon 1, Lyon, France*

OBJECTIVES: There is an increased trend in shifting biologics distribution to exclusive hospital pharmacy channel. Although it looks obvious that such process will generate savings through tenders at regional or national level such policy consequences were not clearly quantified. We used a model developed for EU commission to assess the consequences of such policies on biosimilars for selected EU countries (model developed for the European Commission for the project"EU Pharmaceutical expenditure forecast" http://ec.europa.eu/health/healthcare/key_documents/index.en.htm). **METHODS:** We built a model to assess policy scenarios impact on pharmaceuticals reference forecast for seven EU Member States (France, the UK, Germany, Poland, Portugal, Greece and Hungary). We tested the impact of shifting biosimilar distribution to hospital channel on pharmaceutical industry revenue, Health insurers budget and society cost. **RESULTS:** For the period 2012-2016 the savings of biosimilars (based in million Euros) for Health insurance will be for: UK 2,023; GE 1,127; FR 1,634; PL 200; GR 19; PO 272; HU 29. The extra savings by shifting of the biosimilars distribution to exclusive hospital pharmacy will be: for UK 353; GE 3,392; FR 1,684; PL 37; GR 206; PO 65; HU 176. The difference is relatively small for UK, although significant. However, it is considerable for Germany and France (around 3 and 2 time original saving). Similar figures (revenue loss) are seen for pharmaceutical companies. **CONCLUSIONS:** Although the impact of such policy varies from one country to one another based on initial proportion of biosimilar distributed through hospital and level of discount over branded products, this policy appears to have a substantial impact on drug expenditures and might contribute to sustainability of health insurance in EU countries. Germany and France might benefit dramatically from such policy.

CANCER OUTCOMES RESEARCH STUDIES

CA1
RESPONSIVENESS OF THE EQ-5D IN ONCOLOGY: A META-ANALYSIS

Smith AB[1], Cocks K[1], Taylor M[2], Parry D[3]
[1]*University of York, York, UK,* [2]*York Health Economics Consortium, York, UK,* [3]*AstraZeneca UK, Macclesfield, UK*

OBJECTIVES: The EQ-5D is often employed in clinical trials to derive quality-adjusted life years for cost-utility analyses, and in comparisons of health-related quality of life across conditions. However, there are concerns that the EQ-5D is less

responsive to change particularly in oncology. Therefore the objective of this study was to determine the level of responsiveness of the EQ-5D in oncology. **METHODS:** A systematic review identified relevant articles reviewing responsiveness of the EQ-5D in adults (EMBASE, Medline). Effects sizes (ES) were calculated for the studies identified where not already reported. A meta-analysis was undertaken of the effect sizes: homogeneity of variance was assessed (fixed effects) and random effects models applied where there was significant heterogeneity. Responsiveness was also compared for improvement/deterioration in health status. Analyses were conducted in SPSS v18. **RESULTS:** Data were available from 12 studies (3 breast, 2 prostate, as well as ovarian, lung and renal cancers) each with EQ-5D data at a minimum of 2 time points leading to a total of 45 entries. The overall unweighted ES was -0.26 (95%CI: -0.31 to -0.21), however there was significant heterogeneity in terms of effect sizes ($Q(44) = 427.00$, $p<0.001$) which was accounted for using the random effects model ($Q(44) = 39.58$, $p>0.05$). The overall weighted effect size (ES) was -0.17 (95%CI: -0.33 to -0.01). The weighted ES for improvement was 0.08 (95%CI: -0.02 to 0.18), and -0.52 (95%CI: -0.64 to -0.41) for deterioration. **CONCLUSIONS:** There is considerable heterogeneity in the reported effect size of the EQ-5D. Responsiveness of the EQ-5D in oncology trials as measured by effect sizes is modest at best. The instrument appears to be more sensitive to deterioration in health status than to improvements. Further work will explore the ES of the EQ-5d in comparison with responsiveness of disease-specific measures and changes in health status.

CA2

THE BURDEN OF CAREGIVING IN CANCER: THE STATUS OF CLINICAL RESEARCH

Foster RE, Bardos JI, Wilson TJ, Hamerslag L, Kusel J
Costello Medical Consulting Ltd., Cambridge, UK

OBJECTIVES: The responsibility of caring for cancer patients, often suffering from a magnitude of health problems, can result in a considerable burden for their caregivers, both physically and psychologically. The objective of this study was to assess the status and extent of clinical research into the burden of caregiving for cancer patients. **METHODS:** ClinicalTrials.gov was searched for all cancer trials that considered caregiver burden, using a matrix of search terms such as 'carer', 'burden of care' or 'caregiver'. The impact of geographical location or cancer type on the proportion of trials assessing caregiver burden, the outcome measures used and the proportion of trials including caregiver burden as an outcome over time were investigated. **RESULTS:** From a total of 36,184 cancer-focused trials documented worldwide, 1,596 (4%) assessed caregiver burden. Outcome measures included caregiver quality of life (QoL), satisfaction with care and mood states. The impact of caregiver burden in cancer trials within different world regions varied, with the highest proportion of trials that considered caregiver burden located in Mexico (23%) and Asia (14-22%). Trials for five major cancer types (breast, lung, prostate, colorectal, liver) assessed caregiver burden at similar frequency (4-5%). Evaluation of completed trials demonstrated that the proportion of cancer trials considering caregiver burden increased from <1% between 1997-2001 to 7% after 2012. **CONCLUSIONS:** Fewer than 5% of all cancer trials documented worldwide have evaluated the impact of caregiver burden, although geographical variation does exist. The equal assessment of caregiver burden across cancer types may suggest that no single cancer type is considered to have a higher degree of caregiver burden. Interestingly, while the number of total cancer trials evaluating caregiver burden documented to date is relatively low, the incidence has increased over the last 15 years, suggesting that the growing importance of caregiver burden is being recognised.

CA3

EMA APPROVAL OF DRUGS ON THE BASIS OF PIVOTAL NON-COMPARATIVE PHASE II TRIAL DATA

Macaulay R
HERON Health, London, UK

OBJECTIVES: The recent European Medicines Agency (EMA) approval of crizotinib has highlighted the potential for regulatory approval to be gained on the basis of pivotal non-comparative Phase II data. This research aims to determine the circumstances under which the EMA will approve submissions on this basis. **METHODS:** All publicly available European Public Assessment Reports (EPARs) were screened up to June 2013. Submissions that were based on pivotal Phase II data were identified and the acceptance decision, disease, and level of benefit were extracted. **RESULTS:** Eight drugs (bevacizumab, bortezomib, crizotinib, dasatinib, everolimus, gefitinib, imatinib, ofatumumab) across ten indications been submitted to the EMA on the basis of pivotal non-comparative Phase II data. All submissions were for entry indications except imatinib, which was also submitted for two further indications on this basis. All, except crizotinib, were for indications with no alternative therapies and all were for onology indications except everolimus which was for subependymal giant cell astrocytoma (SEGA). All, except crizotinib, were EMA designated orphan medical products for these indications. One submission was rejected (bevacizumab), one was restricted (ofatumumab), and eight were approved. Top-line supportive Phase III data was only available in two submissions (crizotinib and everolimus). Overall response rates (ORRs) were the primary endpoints in all submissions except imantinib and dasatinib in leukaemia indications and everolimus in SEGA. Rejected drugs had ORRs of 47% (ofatumumab, rejected subpopulation) and 38% (bevacizumab). Approved drugs had ORRs of 60% (crizotinib), 58% (ofatumumab, approved subpopulation), 40% (imatinib), and 35% (bortezomib). Despite low ORRs, imatinib was used to treat a disease with no licensed therapies (gastrointestinal stromal tumours), and bortezomib offered a 10% complete remission rate. **CONCLUSIONS:** Pivotal Phase II data can support EMA approval if it demonstrates substantial clinical benefits for small patient populations with severe diseases that lack therapeutic alternatives.

CA4

MEASURING THE COST OF LOST PRODUCTIVITY DUE TO PREMATURE CANCER-RELATED MORTALITY: A EUROPEAN OVERVIEW

Hanly P[1], Soerjomataram I[2], Sharp L[3]
[1]*National College of Ireland, Dublin, Ireland,* [2]*International Agency for Research on Cancer, Lyon, Ireland,* [3]*National Cancer Registry Ireland, Cork, Ireland*

OBJECTIVES: To assess the economic burden of cancer by estimating years of potential productive life lost (YPPLL) and costs of lost productivity due to premature cancer-related mortality across Europe. **METHODS:** We derived the number of cancer deaths by sex for 23 of the most common cancer sites in 30 European countries from GLOBOCAN. YPPLL were calculated by multiplying the number of cancer-specific deaths for each productive age group (15-64) by standard life expectancy at the mid-point for each age group. Using the human capital approach, we multiplied standardised YPPLL for each individual by country- age- and gender-specific annual wages from age of death until retirement following adjustments for labour force participation and unemployment. Costs were expressed in 2008€. **RESULTS:** All cancer sites combined generated a total of €150.9 billion in premature mortality costs in Europe in 2008. Western Europe accounted for almost half of the total, followed by Northern (21%), Southern (21%) and Central & Eastern Europe (9%). Findings contrasted with YPPLL where Central & Eastern Europe had the highest burden. Male costs exceeded female costs by 88% in Europe as a whole (male: €98.4 billion; female: €52.5 billion) and across all European regions. Lung was the most expensive site (€34.7 billion; 23% of total costs), followed by breast cancer (€13.6 billion, 9%), colorectal cancer (€12.1 billion, 8%), brain & CNS (€9.1 billion, 6%) and pancreatic cancer (€7.5 billion, 5%). According to premature mortality cost per death, testicular cancer was the most expensive site (€2.5 million per death), followed by brain & CNS cancer (€481,512) and Hodgkin lymphoma (€474,559). **CONCLUSIONS:** Lost productivity costs due to cancer-related premature mortality are significant in Europe. Productivity costs provide an alternative perspective on the cancer burden on society and may inform cancer control policy decisions.

CONCEPTUAL PAPERS

CP1

INCREMENTAL COST PER QUALITY-ADJUSTED LIFE YEAR GAINED? THE NEED FOR ALTERNATIVE METHODS TO EVALUATE MEDICAL INTERVENTIONS FOR ULTRA-RARE DISORDERS

Schlander M[1], Garattini S[2], Kolominsky-Rabas P[3], Nord E[4], Persson U[5], Postma M[6], Richardson J[7], Simoens S[8], Sola Morales O[9], Tolley K[10], Toumi M[11]
[1]*University of Heidelberg, Wiesbaden, Germany,* [2]*Mario Negri Institute for Pharmacological Research, Milano, Italy,* [3]*University of Erlangen-Nuremberg, Erlangen, Germany,* [4]*Norwegian Institute of Public Health, Oslo, Norway,* [5]*The Swedish Institute for Health Economics, Lund, Sweden,* [6]*Unit of PharmacoEpidemiology & PharmacoEconomics (PE2), Department of Pharmacy, University of Groningen, Groningen, The Netherlands,* [7]*Monash University, Melbourne, Australia,* [8]*KU Leuven, Leuven, Belgium,* [9]*HITT, Barcelona, Spain,* [10]*Tolley Health Economics, Buxton, UK,* [11]*University Claude Bernard Lyon 1, Lyon, France*

OBJECTIVES: To critically appraise the problems posed by the systematic valuation of interventions for ultra-rare disorders using conventional health economic analysis methods. **METHODS:** An international group of clinical and health economic experts met in conjunction with the Annual European ISPOR Congress in Berlin/Germany, November 2012, to identify and deliberate underlying issues openly, adhering to the Chatham House rule. **RESULTS:** The group reached a broad consensus, including: The complexities of research and development new treatments for ultra-rare disorders (URDs) may require conditional approval and reimbursement policies, such as coverage with evidence development agreements, but should not be used as a justification for showing surrogate endpoint improvement only. As a prerequisite for value assessment, demonstration of a minimum significant clinical benefit should be expected within a reasonable timeframe. Regarding the economic evaluation of interventions for URDs, the currently prevailing logic of cost effectiveness (using benchmarks for the maximum allowable incremental cost per quality-adjusted year, QALY, gained) was considered inappropriate since it does not capture well-established social preferences regarding health care resource allocation. Such social preferences include, but are not limited to, a priority for care for the worse of (related to initial health state), for those with more urgent conditions (the so called "rule of rescue"), a relatively lower priority based upon capacity to benefit, and a dislike against "all or nothing" resource allocation decisions that might deprive certain groups of patients from any chance to access effective care. **CONCLUSIONS:** Alternative paradigms to establish the "value for money" conferred by interventions for URDs should be developed with high priority. Such methods should capture and reflect prominent societal value judgments, beyond efficiency as conventionally defined by QALY maximization under a budget constraint.

CP2

THE MULTIMODEL ENSEMBLE APPROACH TO REDUCING STRUCTURAL UNCERTAINTY IN DECISION ANALYTICAL MODELLING

Parham PE[1], Hughes DA[2]
[1]*Bangor University, Gwynedd, UK,* [2]*Bangor University, Bangor, UK*

Decision analytical modelling represents an essential tool for undertaking health economic evaluation. Markov models provide a mathematical framework for such analyses, particularly in the context of assessing the cost-effectiveness of treatments for chronic diseases where economic outcomes are typically extrapolated beyond the duration of clinical trials. However, structural uncertainty is a key challenge, to methodologists and decision makers alike, that has hitherto attracted insufficient attention. Best practice guidelines advocate the testing of structural assumptions through alternative modelling approaches or conducting scenario analyses. It should be recognised, however, that structural differences in model design represent a strength, rather than limitation, of the modelling process and in fields such as climate modelling, multi-model comparisons and ensemble predictions have been used extensively as the basis for more robust policy decisions. Methods for combining models represents an emerging field in climate modelling, but the simplest approach is to treat all models equally and the mean of all model predictions has been shown to improve on the 'best' model predictions in numerous studies. A weighted multi-model approach may also be developed, but this remains an area of ongoing debate. To date, health economists have not fully embraced the potential of the multi-model paradigm to reduce structural uncertainty. In this work,

we illustrate how this approach may be developed to a) simultaneously and systematically compare health economic outcomes predicted by multiple Markov models; b) address the question of whether (and how) to weight different models within an ensemble based on different performance metrics and model skill scores; c) identify, quantify, and partition total uncertainty across a multi-model ensemble into different sources (for example, to highlight where future research priorities may optimally lie to further improve the robustness of policy recommendations through model improvement and data collection); and d) apply this approach to some real-world examples.

CP3

THE GROWING ROLE OF QUALITATIVE INTERVIEWS IN HEALTH OUTCOMES RESEARCH

Guillemot J[1], Gauthier A[1], Hass B[2], Basso F[3], Cognet M[1]
[1]*Amaris, London, UK,* [2]*Boehringer Ingelheim GmbH, Ingelheim, Germany,* [3]*Boehringer Ingelheim GmbH, Vienna, Austria*

OBJECTIVES: Qualitative interviews, as tools for scientific evidence generation, are often excluded from consideration in health outcomes research. Lack of methodological rigour and the non-reproducibility and non-generalizability of results are often used to justify quantitative methodologies. Here we present an illustrative example of qualitative interviewing's value within health outcomes research. In a study aiming to measure patient and physician preferences for hepatitis C treatments, a discrete choice experiment was designed and a systematic literature review was conducted. **METHODS:** To assess the comprehensibility and relevance of the questionnaire as well as to estimate the value and preciseness of assumptions, pre-tests consisting of a questionnaire pilot followed by a semi-direct interview were conducted. The semi-direct interviewing followed rigorous methods, including defined themes assembled in a discussion guide and behavioural rules for the interviewer to promote axiological neutrality. Analytical methods using predefined codes for the interpretation enabled a systematic understanding of datasets. **RESULTS:** The qualitative component mostly validated but sometimes challenged the theoretical assumptions of the discrete-choice experiment, which had been previously developed on the basis of the systematic literature review. Interviews shed light on occasional complexity and lack of comprehensibility of some questions. The qualitative analysis provided insights to patients' and physicians' experience of their treatment selection process. It included socio-psychological dispositions, like the aversion for work absenteeism or the importance of social representation encouraging patients to prefer treatments which side effects would not affect their social capacities. **CONCLUSIONS:** This method provided in-depth and structured feedback from a small group of patients and physicians. As health outcomes studies increasingly require to expand their level of detail and sensitivity by entering subjective fields of personal preferences, patients' experiences and decision-making processes, there is a pressing need for conducting qualitative micro-level studies prior to supporting broader, field-based studies.

CP4

CONCEPTUAL AND PRACTICAL CONSIDERATIONS WHEN DEALING WITH MISSING UTILITY DATA IN LONGITUDINAL TRIALS, AND SUBSEQUENT USE IN COST-EFFECTIVENESS ANALYSES

Weston AR[1], Brnabic A[1], Standfield LB[2]
[1]*Optum, Sydney, Australia,* [2]*Griffith University, Queensland, Australia*

Patient preference-based health-related quality of life measures (utilities) are a critical input in cost-effectiveness analyses of pharmaceuticals and other health care technologies. Over recent years it has become more common for utility data to be collected alongside key clinical data within the pivotal Phase III trials. However, utility data are often not available for all patients throughout the entire course of the trial. The authors discuss the concept that there are unique characteristics of utility data that need to be considered when dealing with missing values, including the large inter-patient variability typically present at baseline. Missing data arise because i) patients become more ill and are less able to complete patient-reported instruments, ii) patients die during the course of the trial, or iii) patients are censored at later stages of the trial due to rolling recruitment. Whilst this is often a problem in oncology trials, it is also a consideration in other interventional and observational research designed to inform pharmacoeconomic evaluations. Situations where individual patient data are accessible and where only summary statistics are available are discussed. The practical considerations of how such re-analysed data should then be included within an economic model are discussed, given the manner in which utilities are incorporated will vary depending on the nature of the health states used.

A GUIDE TO ADJUSTING SURVIVAL TIME ESTIMATES TO ACCOUNT FOR TREATMENT SWITCHING IN RANDOMISED CONTROLLED TRIALS

Latimer NR[1], Abrams KR[2], Lambert PC[2], Crowther MJ[2], Wailoo AJ[1], Morden JP[3], Akehurst RL[1], Campbell MJ[1]
[1]*University of Sheffield, Sheffield, UK,* [2]*University of Leicester, Leicester, UK,* [3]*The Institute of Cancer Research, Sutton, UK*

OBJECTIVES: Treatment switching is a common issue in clinical trials of cancer treatments – often patients randomised to the control group are permitted to switch onto the experimental treatment at some point during follow-up. In such circumstances an intention to treat (ITT) analysis will result in biased estimates of the overall survival advantage – and therefore the cost-effectiveness – associated with the experimental treatment. Methods to adjust for switching have been used inconsistently and potentially inappropriately in health technology assessments (HTA). We present an analytical framework to guide analysts on the use of methods to adjust for treatment switching in the context of economic evaluations. **METHODS:** We conducted a review of methods used to adjust for treatment switching in HTA, and two rigorous simulation studies to assess the performance of adjustment methods in a range of realistic scenarios. We tested different simulated trial sample sizes, crossover proportions, treatment effect sizes, levels of administrative censoring, and data generating models. Combining the findings from our review and our simulation study, we made practical recommendations on the use of adjustment methods in HTA. **RESULTS:** Our review demonstrates that adjustment methods make important limiting assumptions. Our simulation studies show that the bias associated with alternative methods is highly associated with deviations from their assumptions. Our recommended analysis framework aims to help researchers find suitable adjustment methods on a case-by-case basis. The characteristics of clinical trials and the treatment switching mechanism observed within them, should be considered alongside the key assumptions of the adjustment methods. **CONCLUSIONS:** The limitations associated with switching adjustment methods mean that different methods are appropriate in different scenarios. In some scenarios all methods may be prone to important bias. The data requirements of adjustment methods have important implications for people who design and analyse trials which allow treatment switching.

MO2

USE OF REAL-WORLD EVIDENCE (RWE) TO VALIDATE A TRIAL-BASED HEALTH ECONOMIC MODEL

Munakata J[1], Li H[2], Luo R[3], Guo Y[3], O'Sullivan A[4], Duran A[5], Nelson M[6]
[1]*IMS Health, San Francisco, CA, USA,* [2]*IMS Health, Alexandria, CA, USA,* [3]*IMS Health, Plymouth Meeting, PA, USA,* [4]*IMS Health, Waltham, MA, USA,* [5]*IMS Health, London, UK,* [6]*IMS Health, Alexandria, VA, USA*

OBJECTIVES: Decision makers often rely on health economic models populated with clinical trial data to inform initial assessments about treatment selection, coverage, and reimbursement. To date, there have been few (if any) published model re-analyses using real-world evidence (RWE). The purpose of this study is to 1) assess real-world health and economic outcomes associated with oral anticoagulant vs. low molecular weight heparin (LMWH) as prophylaxis for venous thromboembolism (VTE) in patients undergoing total hip (THR) or knee (TKR) replacement, and 2) compare results of a health economic model populated with clinical trial data vs. RWE. **METHODS:** Patients who underwent THR or TKR between July 2011 and June 2012 were identified in a US commercial insurance claims database. Patients were required to be continuously enrolled 3 months pre-/post-index and were excluded if treated with multiple anti-coagulants within 10 days post-index. A propensity score matching technique was employed to reduce selection bias. Patient characteristics, inpatient-related VTE events and health care costs were determined. A health economic model previously parameterized with clinical trial data was repopulated and reanalyzed using inputs derived from the claims study. **RESULTS:** A total of 14,880 patients were identified (7,440 oral anticoagulant, 7,440 LMWH). In both groups, mean age was 59 and 53% were female. Compared with LMWH, oral anticoagulant use was associated with fewer symptomatic VTE events over 1-year. When repopulated with clinical inputs from claims data, the model projected similar VTE event differences as trial-based model (-0.023 vs. -0.015). Costs (per patient/year) in oral anticoagulant and LMWH groups were consistent across the trial-based model ($385 vs. $1,011), claims-based model ($437 vs. $1,290), and direct reported results from claims analysis ($506 vs. $1,125). **CONCLUSIONS:** Use of RWE is a practical and objective way to validate a trial-based health economic model. Future work should consider study design issues and practical use of results.

MO3

MULTI-STATE STATISTICAL MODELLING TO QUANTIFY AN INDIVIDUAL-BASED MICRO SIMULATION MODEL FOR RADIOTHERAPY TREATMENT IN LUNG CANCER PATIENTS

Bongers ML[1], De Ruysscher D[2], Oberije C[3], Lambin P[3], Uyl-de Groot CA[4], Coupe VMH[1]
[1]*VU University Medical Center, Amsterdam, The Netherlands,* [2]*University Hospitals Leuven/KU Leuven, Leuven, Belgium,* [3]*MAASTRO Clinic, Maastricht, The Netherlands,* [4]*Erasmus University Rotterdam, Rotterdam, The Netherlands*

OBJECTIVES: We developed an individual-based micro-simulation model for radiotherapy treatment in non small-cell lung cancer (NSCLC). The aim was to explore the suitability of multi-state statistical modelling in heath economics, as a tool to parameterize a simulation model that tracks clinical events over time, taking patient and tumour features into account. **METHODS:** The model contains the four clinical states 'A: alive without local recurrence (LR) or metastasis (M)', 'LR', 'M', and 'Death'. Transition rates were estimated using multi-state statistical modelling, a technique that allows the simultaneous estimation of hazards for multiple transitions, taking covariates as well as the occurrence and timing of previous events into account. Each of the hazards from A to either LR, M and Death were adjusted for the presence of the other competing risks. Individual patients were simulated by repeatedly sampling a patient profile, consisting of patient and tumour characteristics. Subsequently, for each patient a pathway through the model was simulated. The internal validity of the model was verified by comparing intermediate simulation outcomes and overall survival under two different radiotherapy strategies to the original data used for estimation. Finally, the model was externally validated by comparing model outcomes to Dutch cancer registry data. **RESULTS:** Model simulations for the two radiotherapy strategies demonstrated internal validity, with predicted probabilities for the occurrence of LRs, Ms, deaths, and the occurrence of toxicities within 3 years that fell within the 95% confidence intervals of the data. The same was observed for the prediction of overall survival. Comparison of the model predictions to the Dutch cancer registry data showed a moderate fit. **CONCLUSIONS:** Multi-state statistical modelling is a useful technique for obtaining the transition rates that are required for the quantification of a micro-simulation model. In future, our model will be used to evaluate the cost-effectiveness of individualized treatment strategies.

MO4

BAYESIAN CALIBRATION METHOD TO ESTIMATE TRANSITION PROBABILITIES FOR A MARKOV MODEL BASED ON A CONTINUOUS OUTCOME MEASURE: APPLICATION IN PARKINSON'S DISEASE

Neine M[1], Briquet B[1], Mokdad CE[1], Vataire AL[2], Aballea S[1]
[1]*Creativ-Ceutical, Paris, France,* [2]*Creativ-Ceutical, PARIS, France*

OBJECTIVES: Estimating transition probabilities for Markov models is challenging when the effectiveness of the studied intervention is measured using a continuous score, and only aggregate data by treatment are available. We developed a Bayesian calibration method to estimate transition probabilities and applied it in Parkinson's disease (PD). **METHODS:** A previously published Markov model with health states corresponding to Hoehn and Yahr (H&Y) stages was adapted. Patient-level datasets were simulated to replicate results of clinical trials for different drugs, using the UPDRS scale to assess severity, and transition probabilities were estimated from simulated data to provide a reference case. Two calibrations methods were tested for obtaining transition probabilities without patient-level data. Firstly, the Solver tool of Excel was used, with the mean change in UPDRS score and associated variance as targets. Secondly, a Bayesian calibration was implemented in OpenBUGS to estimate the posterior distribution of transition probabilities, assuming the change in UPDRS score has a normal distribution, with observed mean and variance. All other model input parameters were taken from the original model. **RESULTS:** With simulated patient-level data, the incremental cost (IC) was estimated at €-7,015 (95% credibility interval: €-23,953; €5,977) and incremental QALYs (IQ) at 0.455 (0.112; 0.950). With calibration using the Solver tool, there was an infinity of solutions resulting in IC ranging from €-10,141 to €-8,206 and IQ ranging from 0.422 to 0.473. With calibration using OpenBugs, the IC was estimated at €-6,852 (€-24,244; €6,448) and the IQ at -0.448 (0.108; 0.959). **CONCLUSIONS:** Incremental costs and QALYs obtained using the Bayesian calibration and analysis of patient-level data were similarly distributed. Mean results obtained using the Solver tool were comparable, but no statistical distribution around results could be provided. This example suggests that the Bayesian calibration is a valid method to derive transition probabilities from continuous outcome measures.

PATIENT PREFERENCE STUDIES

PP1
A METHODOLOGY FOR PREDICTING THE IMPACT OF COPAYMENTS ON THE UTILIZATION OF HEALTH TECHNOLOGIES

Sabatelli L
GLOB MOD, Barcelona, Spain

OBJECTIVES: Copays (or copayments) for health-technologies, such as pharmaceutical products, are used by governments and insurers to prevent moral hazard, reduce unnecessary utilization of resources, and contribute to the cost of health care. Nevertheless they may also reduce access to necessary care, and the financial protection associated with health insurance. In addition, from the perspective of the manufacturer, the introduction of copays may determine unexpected and abrupt falls in demand. The methodology here presented uses data extracted from surveys on product utilization and patient income, prior and after the introduction of copays in various countries and regions, to predict the potential impact of copays on the demand for a pharmaceutical product in a given country or region. **METHODS:** This approach uses multi-level multivariate regressions and a micro-economic model of demand (which assumes maximization of utility and preference independence) to anticipate changes in utilization (and therefore in demand) as a function of the amount of copay charges. Data from a computer simulation were used to test the method. **RESULTS:** A non-linear relationship between copay and drug-consumption, determined by the combined effect of the amount charged and of the average population income was identified, predicting changes in aggregate demand and in income-specific demand. For instance: if we consider two countries both adopting a 1 Euro co-pay charge on a (not easily substitutable) product and whose average income differs by 20%, we expect the demand to be almost 3% lower in the country with the lower income than in the country with the higher income. **CONCLUSIONS:** Under general market assumptions, it is possible to build models that estimate the potential impact of copay charges. These models can be used to help design health policies and market strategies.

PP2
MULTINATIONAL CONSISTENCY OF A DISCRETE CHOICE MODEL IN QUANTIFYING HEALTH STATES FOR THE EXTENDED 5-LEVEL EQ-5D

Krabbe PFM[1], Devlin NJ[2], Stolk EA[3], Shah KK[4], Oppe M[3], van Hout B[4], Quik EH[1], Pickard AS[5], Xie F[6]
[1]*University of Groningen, University Medical Center Groningen, Groningen, The Netherlands,* [2]*Office of Health Economics, London, UK,* [3]*Erasmus University Rotterdam, Rotterdam, The Netherlands,* [4]*University of Sheffield, Sheffield, UK,* [5]*University of Illinois at Chicago, Chicago, IL, USA,* [6]*McMaster University, Hamilton, ON, Canada*

OBJECTIVES: To investigate the feasibility of choice experiments for EQ-5D-5L states using computer-based data collection, and to examine the consistency of the estimated parameters values derived after modeling the stated preference data across countries in a multinational study. **METHODS:** Similar choice experiments were executed in Canada, England, The Netherlands, and United States (US). Interactive software was developed to standardize the format of the choice tasks across countries, except for England where face-to-face interviewers were used. The choice task required respondents to choose between two sub-optimal health states. A Bayesian design was used to generate 200 pairs of states that were randomly grouped into 20 blocks. Each respondent completed one block consisting of 10 pairs. A main-effect alternative-specific multinomial probit regression model was used to estimate regression coefficients and to derive values for each health state that capture the relative differences in levels between states. **RESULTS:** In total there were 1775 respondents, at least 400 respondents from each country, who completed 17750 paired comparisons, resulting into 35500 assessed health states. The mean time to perform one choice task was between 29.2 (US) and 45.2 (England) seconds. All regression coefficients were statistically significant, except level 2 for Usual Activities in The Netherlands (p=0.51). Three regression coefficients with illogical ordering were observed (The Netherlands: level 3 Pain/Discomfort, England: Level 3 Usual Activities & Pain/Discomfort). Predictions for the complete set of 3125 EQ-5D-5L states were similar for the four countries. Intra class correlation coefficients between the countries were high: from 0.89 (England vs. US) through 0.99 (Canada vs. US). **CONCLUSIONS:** This proof of concept study indicates that computer-based choice tasks for the EQ-5D-5L in the general population are feasible and parameter of the choice tasks estimates are generally consistent and logical, and the estimated values are largely consistent between the 4 countries.

PP3
CAN THE USE OF SOCIAL MEDIA AND MOBILE APPS IMPROVE PATIENT KNOWLEDGE OF DISEASE AND HEALTH OUTCOMES? A SYSTEMATIC REVIEW

Abogunrin S, Martin A
Evidera, London, UK

OBJECTIVES: The use of interactive social media (SM) based on Web 2.0 technology, e.g. Twitter, Facebook, MySpace; and mobile apps, is increasing but its role in improving patient knowledge of their disease and its management is unclear. We conducted a systematic review to assess the evidence for health benefits from SM. **METHODS:** We searched MEDLINE and EMBASE for relevant articles published in the last five years that used words synonymous with SM; patient, carer, or parents' preferences, opinions or views; pharmacological interventions; and disease. We included comparative studies or systematic reviews on the use of any SM by patients, that measured differences in knowledge about disease, uptake of pharmacological interventions, or clinical outcomes from better management of disease. Articles were excluded if they reported only the use of SM by health care professionals, or if they were case studies, narrative reviews or expressed expert opinions. **RESULTS:** We identified 3,232 unique abstracts, 24 of which reported the use of interactive, internet-delivered programs (n=13), Facebook (n=4), and mobile apps (n=3) , for improving health outcomes of patients with cancer, or inflammatory, mental health, musculoskeletal, neurologic, ophthalmologic, or sexual health-related disorders. Patients receiving SM-based interventions showed improved knowledge of their disease, and better clinical outcomes compared with controls. Two additional studies reported on the use of SM aimed at increasing knowledge, and self-efficacy in parents of children with cystic fibrosis. Overall, the studies showed that SM-based interventions improved knowledge of disease and clinical outcomes compared with control groups. **CONCLUSIONS:** Surprisingly little research has been conducted on the value of SM to aid and support patients. What evidence exists suggests that SM tools offer health benefits. fFrther work is needed to confirm these effects and to assess how best the tools might increase patients' knowledge about disease, treatment adherence and clinical outcomes.

PP4
THE IMPORTANCE OF PATIENT REPORTED OUTCOMES IN REIMBURSEMENT OF ORPHAN PRODUCTS IN EUROPE

Lyons EJ[1], McGeagh J[1], Es-Skali IJ[2], Parmenter L[3], Nijhuis T[4], Boucher G[1]
[1]*Quintiles, Reading, UK,* [2]*Quintiles Consulting, Hoofddorp, The Netherlands,* [3]*Quintiles Outcome, Reading, UK,* [4]*Quintiles, Hoofddorp, The Netherlands*

OBJECTIVES: To determine the importance of patient reported outcomes (PROs) in the reimbursement of orphan drugs in Europe and identify any HTA authority preferences for particular PRO measures. **METHODS:** All 31 products assigned an orphan designation by the European Medicines Agency (EMA), between January 2009 and May 2013, were evaluated against the following criteria: approval for marketing, submission for reimbursement/price negotiation to NICE, SMC, G-BA, and HAS, presence or absence of PROs, approval or rejection of reimbursement application. Where available, HTA guidance documents resulting from the applications were reviewed in detail to determine the impact of PRO measures on the reimbursement decision. **RESULTS:** Of the 31 products assigned an orphan designation, 26 were granted marketing authorisation by the EMA. Eleven products were submitted to NICE for reimbursement in England of which 7 submissions contained PROs and 6 were approved. In Scotland, 11 products were submitted for reimbursement to the SMC and of the 7 submissions containing PRO data, 3 were recommended for reimbursement. One submission is still pending. In Germany, 7 products were submitted to the G-BA of which 5 contained PROs and were allowed to enter into price negotiations. The French HTA authority, HAS, evaluated 20 submissions of which 9 contained PROs and 19 were approved. **CONCLUSIONS:** The results of our assessment of EMA approved orphan drugs indicates that a great deal of variation exists across Europe with respect to the evaluation of orphan drugs for reimbursement or price negotiation. In some countries, reimbursement is largely independent of evidence of reported patient benefit while in others, where evidence of economic value is critical for success, robust PRO data are essential.

RESEARCH PODIUM PRESENTATIONS – SESSION II
RESEARCH ON METHODS – CLINICAL STUDIES

CL1
A COMPARISON OF METHODOLOGIES FOR ESTIMATING SURVIVAL IN PATIENTS TREATED WITH SECOND-GENERATION TYROSINE-KINASE INHIBITORS (TKIS) FOR CHRONIC MYELOID LEUKAEMIA (CML)

Pennington B[1], Batty AJ[1], Clifton-Brown E[2]
[1]*BresMed, Sheffield, UK,* [2]*Pfizer Ltd., Tadworth, UK*

OBJECTIVES: NICE have previously recommended nilotinib, but not dasatinib, as a first-line (TA251) and second-line (TA241) treatment in chronic phase (CP) CML. Within these appraisals, different methods were used to estimate overall survival (OS). Bosutinib, a potent dual Src/Abl TKI, is undergoing a NICE appraisal in second-line or later CML (ID495). The objective is to review the OS methods used and assess their impact on cost-effectiveness and recommendations in CML appraisals. **METHODS:** We identify the methodologies used for estimating OS in TA241 and TA251 and investigate the impact of using these to estimate OS for the TKIs, including bosutinib, in relapsed/refractory CML. Finally, we consider the implications of the various methodologies on the cost-effectiveness results and recommendations in previous and future NICE assessments of TKIs for CML. **RESULTS:** The base-case in TA241 used a surrogate relationship between response (MCyR) and OS

to derive OS estimates for nilotinib and dasatinib of 13.0 and 13.4 years respectively (second-line CP). Using the same approach for bosutinib gives an OS of 12.8 years (third-line CP). The base-case in TA251 used a cumulative approach, where OS is equal to the duration of treatments in the pathway. If this method is applied to the TKIs in second-line CML (TA241), OS is reduced to approximately 9.4 and 10.1 years for nilotinib and dasatinib respectively (second-line CP). Similarly, bosutinib OS (third-line CP) is also reduced using this method and a substantial increase in the ICER is seen. **CONCLUSIONS:** There are methodological inconsistencies in NICE's assessments of TKIs for CML. Applying the OS methodology from TA251 to TA241 may have led to nilotinib not being recommended for routine use in the NHS. The impact of new methodologies on previous appraisal results and recommendations should be considered when assessing the validity of a new approach.

CL2
ADDRESSING HETEROGENEITY IN BASELINE RISK OF COPD EXACERBATIONS USING META-REGRESSION

Cope S[1], Buckley F[2], Baldwin M[3], Kraemer M[4], Jansen J[2]
[1]*Mapi, Toronto, ON, Canada,* [2]*Mapi, Boston, MA, USA,* [3]*Novartis Pharmaceuticals UK Limited, Horsham, West Sussex, UK,* [4]*Novartis Pharma AG, Basel, Switzerland*

OBJECTIVES: To evaluate differences across randomized controlled trials (RCTs) concerning interventions for moderate to severe chronic obstructive pulmonary disease (COPD) in terms of baseline exacerbation rates and the association with treatment effects by means of a network meta-analysis (NMA). This NMA is performed based on RCTs evaluating the long-acting bronchodilators indacaterol 75/150/300µg OD, salmeterol 50µg BID, formoterol 12µg BID, tiotropium bromide 18µg/5µg OD, and glycopyrronium bromide 50µg OD. **METHODS:** The rate of moderate or severe exacerbations was extracted from RCTs identified with a systematic literature review. A Bayesian NMA was used to synthesize the treatment effects of the different trials. The association between treatment effects and baseline exacerbation rate with placebo was assessed with a meta-regression model assuming a constant treatment-by-baseline risk interaction term. **RESULTS:** Twenty-four RCTs were included that differed mainly in terms of smoking status, COPD severity, use of inhaled corticosteroids, exacerbation definition, and exacerbation history. Across the RCTs the rate of exacerbations per patient year for patients in the placebo arm ranged from 0.40 to 1.91. Baseline risk was negatively associated with the rate ratios reflecting treatment effects across the RCTs. The coefficient for baseline risk was -0.35 (95% credible intervals: -0.49, -0.18). **CONCLUSIONS:** Based on a NMA of RCTs regarding the efficacy of long-acting bronchodilators in terms of the rate of exacerbations per patient year, baseline risk of exacerbations acts as a significant treatment effect modifier and should be accounted for in the model.

CL3
VALIDATION OF SURROGATE ENDPOINTS IN ADVANCED SOLID TUMOURS: SYSTEMATIC REVIEW OF STATISTICAL METHODS, RESULTS, AND IMPLICATIONS FOR POLICY MAKERS

Ciani O[1], Davis S[2], Tappenden P[2], Garside R[3], Stein K[1], Cantrell A[2], Saad E[4], Buyse M[5], Taylor R[1]
[1]*University of Exeter, Exeter, UK,* [2]*University of Sheffield, Sheffield, UK,* [3]*University of Exeter, Truro, UK,* [4]*Dendrix, Sao Paulo, Brazil,* [5]*IDDI, Louvain-la-Neuve, Belgium*

OBJECTIVES: Licensing and reimbursement of anticancer drugs should rely on evidence from patient-relevant endpoints such as overall survival (OS). Nevertheless, evidence from surrogate endpoints may also be useful, as it may expedite the regulatory approval and coverage decisions of new therapies. It is therefore essential that candidate surrogate endpoints be properly validated. However, there is no consensus on statistical methods for such validation and on how the evidence thus derived should be applied by policy makers. **METHODS:** We review meta-analyses of therapeutic interventions against advanced solid tumours published until December 2012 that quantified the statistical association between progression-free survival (PFS) or time-to-progression (TTP) and OS. We assessed the suitability of the two surrogates using three current surrogate validation frameworks: Bucher's framework, the German Institute of Quality and Efficiency in Health Care's (IQWiG) framework and the Biomarker-Surrogacy Evaluation Schema (BSES3). **RESULTS:** Thirty-one meta-analyses were included which employed a variety of statistical methods to assess surrogate validity. The strength of the association between PFS or TTP and OS was generally low. The level of evidence (observation-level vs. treatment-level) available supporting an association between PFS or TTP and OS varied considerably by cancer type, by evaluation tools and was not always consistent even within one specific cancer type. **CONCLUSIONS:** Not in all solid tumours the treatment-level association between PFS or TTP and OS has been investigated. According to the IQWiG's framework, only PFS achieved acceptable evidence of surrogacy in metastatic colorectal and ovarian cancer treated with cytotoxic agents, whereas in no indication did the two candidate endpoints achieve good evidence of surrogacy according to BSES3. Our study emphasises the challenges of surrogate-endpoint validation and the importance of building consensus on appropriate statistical techniques to examine surrogacy and on the development of evaluation frameworks for policy makers.

CL4
FRAMEWORK FOR EVIDENCE ASSESSMENT BASED ON GRADE AND APPLICATION TO HPV VACCINATION IN MALES IN THE EUROPEAN HEALTH CARE CONTEXT

Siebert U[1], Sroczynski G[2], Baker P[3], Borget I[4], Castellsagué X[5], Chapman R[6], von Knebel-Doeberitz M[7], Mortensen GL[8], La Torre G[9]
[1]*UMIT – University for Health Sciences, Medical Informatics and Technology / ONCOTYROL / Harvard University, Hall i. T./ Innsbruck / Boston, Austria,* [2]*UMIT – University for Health Sciences, Medical Informatics and Technology, Hall i.T., Austria,* [3]*Men's Health Consultant, Brighton, UK,* [4]*Institut Gustave Roussy, Villejuif, France,* [5]*L'Hospitalet de Llobregat, Barcelona, Spain,* [6]*Evidera, London, UK,* [7]*University of Heidelberg, German Cancer Research Center, Heidelberg, Germany,* [8]*AnthroConsult, Aarhus C, Denmark,* [9]*Sapienza University of Rome, Rome, Italy*

OBJECTIVES: To develop and apply an extended framework for evidence assessment based on the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach using the example of male human papilloma virus (HPV) vaccination Europe. **METHODS:** A pan-European multidisciplinary expert group was established to develop an extended GRADE framework that includes explicit assessment of cost-effectiveness, medical needs, and patient aspects, ethical and social issues. Using an expert panel process, we assessed the feasibility of using this framework by applying it to male HPV vaccination in Europe. Studies were assessed using the specific framework tools; results and feasibility were discussed; and consensus was achieved through a modified Delphi method. **RESULTS:** We identified three advisory committees (ACIP/USA; NACI/Canada; STIKO/Germany) using GRADE for vaccines assessment. Institutions handled data beyond vaccine efficacy and safety differently and did not formally grade economic evidence. We adopted the grading methodology of ACIP for the key factor 'Benefits and Harms' and developed modules for grading evidence type and quality of economic evaluations ('Economic Evaluation') and for systematically assessing epidemiology, disease burden and unmet medical needs, as well as ethical, social and patient aspects ('Values and Preferences'). The feasibility test demonstrated that all framework components were feasible in the case of HPV vaccination. Overall evidence type for cost-effectiveness was low with uncertainty in results. Cost-effectiveness was best, when all HPV-related diseases and outcomes were included and when assuming low coverage in females and lower vaccine prices. **CONCLUSIONS:** The GRADE approach is applicable in assessing vaccinations and was successfully applied to HPV vaccination in males. The assessment of benefits and harms can be extended by explicit assessment of the evidence on cost-effectiveness and other key factors including unmet medical needs, and ethical, social and patient aspects. This extended framework can better inform policy- and decison makers.

CHALLENGES IN MODELLING THE COST EFFECTIVENESS OF INTERVENTIONS IN CARDIOVASCULAR DISEASE

Burgers LT, Redekop WK, Severens JL
Erasmus University Rotterdam, Rotterdam, The Netherlands

OBJECTIVES: Modelling is essential in performing economic evaluations for various reasons. For example, modelling is necessary if extrapolation of short-term or intermediate results to long-term outcomes is required and numerous strategies need to be evaluated without direct evidence. However, modelling inherently poses challenges that need to be dealt with since models always represent a simplification of reality. The aim of this study is to identify and analyse the challenges in modelling the cost-effectiveness of cardiovascular disease (CVD) interventions. **METHODS:** A questionnaire was sent to 40 corresponding authors (systematically selected) of recent model-based economic evaluations of CVD interventions published in high-impact cardiovascular, health economics and general medical journals. Respondents were asked to provide their own challenges and also rank the importance of challenges identified using a pilot version of the questionnaire distributed to 7 experienced researchers. Furthermore, we analysed the discussion sections of the papers to identify unmentioned challenges. Solutions, if available, were based on input from the respondents and the recommendations of the ISPOR-SMDM task force. **RESULTS:** The systematic literature search identified 1720 potentially relevant articles. The limit of 40 authors was reached after screening 294 titles and abstracts. Beside the challenge of lack of data, preliminary results show that it was difficult to obtain a sufficiently valid, precise and accurate cost-effectiveness estimate due, for example, to interrelating clinical outcomes or extrapolating from surrogate outcomes. Both challenges often exist in CEAs evaluating CVD prevention strategies. **CONCLUSIONS:** The preliminary results of this study showed examples of CVD modelling challenges encountered during studies published in high-impact journals. Modelling guidelines do not provide sufficient assistance in resolving all challenges but it is probably unrealistic to expect this. Some of the reported challenges are specific to the type of intervention and disease, but most challenges are present in all types of interventions and diseases.

CV2
APPLICATION OF BEHAVIOURAL ECONOMICS TO THE UNDERSTANDING OF ADHERENCE: DOES AN INDIVIDUAL'S TIME PREFERENCE INFLUENCE ADHERENCE TO MEDICATIONS?

Fargher EA, Morrison V, Plumpton CO, Hughes DA
Bangor University, Bangor, UK

OBJECTIVES: There is general support that individual time preference affects health-related behaviours. People with a high, positive time preference value their immediate health higher than future health, even if presented with extreme scenarios of intertemporal choice. We hypothesised that adherence to medication requires trade-offs between immediate and delayed health benefits. Patients with lower time preference rates may be more adherent to medication as they place a higher value on the future benefits of adherence. **METHODS:** Hypertensive adult patients across Europe were invited to complete a web-based survey that had been translated and piloted. Patients' time preference was assessed (4-items) to calculate individual discount rates (%) in both short term (3-years) and medium term (6-years). Medication adherence was measured using the Morisky questionnaire (primary analysis) and the Medication Adherence Report Scale (MARS, secondary analysis). Sample size calculation, based on 5% one-sided confidence, assuming 30% non-adherence with Morisky measure indicated n=323 per country. Missing data were imputed using multiple imputation in STATA. The significance of the association with adherence was assessed using the Wald test statistic. **RESULTS:** 969 patients completed the questionnaire across England, Wales and Hungary, 79% of possible responses were observed. Short and medium term time preference rates in England, Wales and Hungary were in the expected directions, but the relationship was not statistically significant. Based on Morisky adherence - Wales (short): adherent 8.7%, non-adherent 9.4% (p=0.541); (medium): adherent 4.7%, non-adherent 5.0% (p=0.611). England (short): adherent 7.8%, non-adherent 9.5% (p=0.163); (medium): adherent 3.7%, non-adherent 4.5% (p=0.095). Hungary (short): adherent 19.0%, non-adherent 18.2% (p=0.504); (medium): adherent 8.9%, non-adherent 8.6%

(p=0.596). **CONCLUSIONS:** Time preference rates were aligned with those in the published literature but the association between time preference and adherence was non-significant in both primary and secondary analyses at an individual country level.

CV3
PATTERNS OF GENERIC AND PROPRIETARY PRESCRIBING OF STATINS OVER TIME IN ENGLAND
Leonard SA, Wilson TJ, Hamerslag L
Costello Medical Consulting Ltd., Cambridge, UK
OBJECTIVES: Given economic pressure on UK National Health Service resources, it has been recommended that general practitioners prescribe more low-cost, generic drugs as opposed to high-cost, proprietary drugs when a substitution can be made without compromising patient care. One of the Better Care Better Value (BCBV) indicators of good prescribing practice proposed by the NHS Institute for Innovation and Improvement is an increase in the prescription of low-cost drugs for lipid modification. The objective of this analysis was to evaluate patterns of generic and proprietary prescribing of statins from 2007–2012 inclusive. **METHODS:** Prescription Cost Analysis databases from data.gov.uk were reviewed between 2007–2012. Data on the number of prescription items dispensed each year in the community in England for simvastatin and atorvastatin (as commonly-prescribed examples) were extracted, along with each drug's preparation class: drugs prescribed and available generically, or drugs prescribed and dispensed by proprietary brand name. For both simvastatin and atorvastatin, the proportions of prescription items in the different preparation classes were compared each year. **RESULTS:** Proprietary simvastatin prescription items as a proportion of all simvastatin prescription items decreased each year, from 2.87% in 2007 (843,000 proprietary items) to 1.76% in 2012 (752,000 items), representing a proportional decrease of 39% in the 6-year period assessed. Proprietary atorvastatin prescription items as a proportion of all atorvastatin prescription items were close to 100% between 2007–2011 (approximately 11 million proprietary items each year), but fell to 30.55% in 2012 (3.9 million items), coinciding with the expiry of atorvastatin's patent in May 2012. **CONCLUSIONS:** In England, prescribing of high-cost proprietary items for these two examples of lipid-modifying drugs has decreased since 2007, suggesting that the BCBV prescribing indicator for statins is being met. Such reductions, particularly as seen with atorvastatin in 2012, are likely to have a significant budget impact.

CV4
IMPACT OF SHORT PERIODS WITH IMPROVED OR WORSENED INR CONTROL ON LIFE EXPECTANCY AND QALYS IN PATIENTS WITH ATRIAL FIBRILLATION
Lesén E[1], Björholt I[1], Björstad Å[1], Fahlén M[2], Odén A[3]
[1]*Nordic Health Economics, Gothenburg, Sweden,* [2]*Department of Medicine, Kungälv Hospital, Kungälv, Sweden,* [3]*Department of Mathematical Sciences, Chalmers University of Technology, Gothenburg, Sweden*
OBJECTIVES: Warfarin-treated patients with poor international normalized ratio (INR) control, measured with time in therapeutic range (TTR) or the standard deviation of transformed INR (SDT_{INR}), have an increased risk for clinical events. To what extent only a short period with an altered INR control may influence outcomes remains unknown. This study assessed the impact of transient periods of improved or worsened INR control on life expectancy and quality-adjusted life years (QALYs) among warfarin-treated patients with atrial fibrillation (AF) using both metrics. **METHODS:** Warfarin-treated patients with AF, registered in the patient record system Journalia during years 1985-2000, were included. Information on all-cause mortality was collected from the Cause of Death Register. Scenarios where patients were assumed to have a transiently altered INR control during 30 days were modeled statistically using hazard functions, and the impact on remaining life expectancy and QALYs was assessed. **RESULTS:** When using SDT_{INR}, a 70-year old man within the 2.5th worst INR control percentile was estimated to gain 10.8 days of life or 0.0168 QALYs from a 30-day improvement in INR control to that of an average 70-year old man. Correspondingly, 15.5 days of life or 0.0196 QALYs would be lost if a 70-year old man within the 2.5th best INR control percentile would have an average INR control during 30 days. The magnitudes were smaller when TTR was used to determine INR control. **CONCLUSIONS:** Even short periods of altered INR control is expected to have impact on life expectancy and QALYs among patients with AF.

MEDICAL DEVICE & DIAGNOSTIC RESEARCH

COMPARING VIRTUAL COLONOGRAPHY WITH CONVENTIONAL COLONOSCOPY FOR COLORECTAL CANCER SCREENING: WHAT ARE THE DRIVERS OF COST-EFFECTIVENESS?
Kriza C[1], Emmert M[2], Wahlster P[1], Niederländer C[1], Schaller SU[1], Kolominsky-Rabas PL[1]
[1]*Centre for Health Technology Assessment (HTA) and Public Health (IZPH), University of Erlangen-Nuremberg, Erlangen, Germany,* [2]*School of Business and Economics, Institute of Management, University of Erlangen-Nuremberg, Nuremberg, Germany*
OBJECTIVES: The majority of recent cost-effectiveness reviews concluded that computerized tomographic colonography (CTC) is not a cost-effective Colorectal Cancer (CRC) screening strategy yet. The objective of this review is to examine cost-effectiveness of CTC versus optical colonoscopy (COL) for CRC screening and identify the main drivers influencing cost-effectiveness due to the emergence of new research. **METHODS:** A systematic review was conducted for cost-effectiveness studies comparing CTC and COL as a screening tool and providing outcomes in life-years saved, published between January 2006 and November 2012. The following databases were searched: PubMed, Science Direct, Cochrane Library and the York Centre for Reviews and Dissemination databases. The search methodology was in line with PRISMA guidelines, including the use of the PICOS review system. **RESULTS:** Nine studies were included in the review. There was considerable heterogeneity in modelling complexity and methodology. Different model assumptions and inputs had large effects on resulting cost-effectiveness. The most important assumptions that influenced the cost-effectiveness of CTC and COL were related to CTC threshold-based reporting of polyps, CTC cost, CTC sensitivity for large polyps, natural history of adenoma transition to cancer and importantly, adherence. CTC was found to be cost-effective in three studies, assuming the most favourable scenario. **CONCLUSIONS:** CTC has the potential to be a cost-effective CRC screening strategy when compared to COL. There is a strong need for a differential consideration of patient adherence and compliance to CTC and COL. Recent research shows that laxative-free CTC screening has the potential to become a viable alternative screening method for CRC as it can improve patient uptake of screening. This project is supported by the German Federal Ministry of Education and Research (BMBF) as part of the National Cluster of Excellence, Medical Technologies – Medical Valley EMN' (Project grant No. 13EX1013B).

MD2
MARKET ACCESS OF IMPLANTABLE MEDICAL DEVICES: EVIDENTIARY REQUIREMENTS ACROSS GLOBAL MARKETS
Chawla AS[1], Spinner DS[1], Ransom JF[2], Doyle J[2], Faulkner EC[1]
[1]*Quintiles Consulting, Durham, NC, USA,* [2]*Quintiles Global Consulting, Hawthorne, NY, USA*
OBJECTIVES: With tightening health system budgets, medical devices (MDs) are being increasingly scrutinized for their impact on overall health care cost. The evidence bar for implantable MDs is particular high since most implantable devices are not reimbursed separately by payers, but via direct bundled payments to the provider. To characterize that trend, the objectives of this study were to: 1) Identify specific evidence criteria that maximally impact the payer decision, 2) Note differences in HTAs across global markets, and finally 3) Outline differences in evidence requirements between drugs and devices. **METHODS:** A multimarket review of implantable MD HTAs and reimbursement decisions published from 2008-2013 was conducted. Identified by HTA Watch, HTAs included those from Australia, Belgium, Canada, France, Germany, Italy, the UK and the US. They spanned a variety of indications, including cardiovascular, orthopedic, neurological, trauma, among others. HTAs and reimbursement decisions were characterized for clinical and economic evidence requirements and apparent correlations and/or impacts on ultimate agency recommendation. **RESULTS:** Evidence criteria evaluated by HTA agencies and payers primarily included: 1) Availability of supportive randomized controlled trials (RCTs), 2) Safety, 3) Efficacy/long-term outcomes, 4) Cost/cost-offsets/budget impact, and 5) Quality of-life improvement. In contrast to drug HTAs, clinician training and learning curve effects were often evaluated. Importantly, agencies recognized the challenge in demonstrating statistically- and clinically-significant evidence of improvement in outcomes. As such, many MDs were recommended on a restricted basis to specific patient subpopulations or on a coverage based on continued evidence development. While requirements considered most critical were largely uniform across global markets, regional nuances impacted the ability to obtain favorable reimbursement of implantable devices. **CONCLUSIONS:** Similar to drugs, MDs face rising hurdles in terms of demonstrating value, both clinical and economic. Optimal global market access for implantable MDs hinges on monitoring evolving evidentiary requirements and on carefully planning to collect evidence early in the developmental cycle.

MD3
DECISON MAKING UNDER UNCERTAINTY: COVERAGE WITH EVIDENCE DEVELOPMENT IN THE CONTEXT OF MEDICAL DEVICES
Sorenson C[1], Drummond M[2]
[1]*London School of Economics and European Health Technology Institute for Socio-Economic Research, London, UK,* [2]*University of York, Heslington, UK*
OBJECTIVES: Coverage with evidence development (CED) is increasingly being used to provide provisional coverage for promising, but unproven, interventions, while additional data are generated. This study aimed to explore the application of CED in the context of devices. **METHODS:** First, a literature review was conducted on international CED schemes and the CED approach more generally. In total, 50 articles were gathered and reviewed. Second, semi-structured telephone interviews were conducted with different expert groups (payers/HTA bodies, industry, and academics/policy analysts) to better understand the use of CED in different jurisdictions; identify and explore device CED case studies; and, gather expert opinion on the challenges associated with the CED approach and potential strategies to improve current policy and practice. A total of 25 experts were invited to participate, of which 20 (80%) agreed and were interviewed. **RESULTS:** Canada, the UK, and US have the most experience with CED applied to devices; Germany and The Netherlands have both recently introduced new CED policies for devices and procedures. Devices that have undergone CED in these jurisdictions include ICDs, stents, TAVI, laparoscopic surgery, and spinal cord stimulators. While there are distinct differences in the national approaches to CED, common challenges were identified: 1) establishing a clear framework for initiating, overseeing, and stopping CED studies, 2) identifying and applying appropriate study methods, 3) funding CED studies, 4) incentivizing studies, and 5) applying new evidence to inform coverage decisions. **CONCLUSIONS:** Devices are viable candidates for CED, given some of their unique characteristics and often uncertain evidence base at the time of coverage determination. However, improvements are needed, including enhanced clarity and predictability of CED selection criteria and processes, greater stakeholder collaboration, new models to fund studies and collect data, better incentives for physicians to engage in studies, and strengthened requirements for use of new evidence in coverage policies.

MD4
QUALITY CRITERIA FOR THE DEVELOPMENT OF IMPLANT REGISTRIES
Niederländer CS, Wahlster P, Kriza C, Schaller SU, Kolominsky-Rabas PL
Centre for Health Technology Assessment (HTA) and Public Health (IZPH), University of Erlangen-Nuremberg, Erlangen, Germany
OBJECTIVES: During the last few years, there has been a steady increase in the number of implant registries, mainly in the field of arthroplasty. The benefit of a registry depends on its content and quality. However, there are no further data requirements, legal and financial issues or requirements for the organizational

procedure specified for implant registries in general. Therefore, the aim of this work is to identify quality criteria for the design and development of implant registries and to develop a minimal data set. **METHODS:** The systematic literature search was performed in different databases (Pubmed, Medline, the Cochrane Library, Scopus, Embase as well as the CRD York database) and different journals. **RESULTS:** Ten articles were identified that describe a general implant registry design and structure as well as 45 articles about the creation of specific registries. Most recommendations for the organization of implant registries could be found in the field of arthroplasty. To generalize the results, it can be said, that all registries have to deliver a minimal data set including prostheses, patient and surgical procedure details. The geographical area, length and periodicity of data collection, number of patients enrolled, the composition of the team as well as information about security and confidentiality of data should be reported. **CONCLUSIONS:** Well-structured registries are a cornerstone of the regulatory process of medical devices and a major tool for decison makers and managers. However, only a small number of papers that describe specific requirements for the construction of an implant registry could be identified. With the establishment of clear guidelines, the outcomes of the implant registries can be fundamentally improved. This project is supported by the German Federal Ministry of Education and Research (BMBF) as part of the National Cluster of Excellence, Medical Technologies – Medical Valley EMN' (Project grant No. 13EX1013B).

PRICING STUDIES

PRICE DIFFERENCES TRIGGERED BY THE AVAILABILITY OF BIOSIMILARS IN DEVELOPED COUNTRIES

Reinaud F[1], Ando G[2]
[1]*IHS, Paris, France,* [2]*IHS, London, UK*

OBJECTIVES: The goal of this study is to analyse price differences triggered by the availability of biosimilars in developed pharmaceutical markets. **METHODS:** 1) Market availability of biosimilars in the following markets was studied: Australia, Canada, France, Germany, Italy, Spain, UK, Japan and the United States. Biosimilars were selected based on their availability in these markets, and 2) Ex-factory price differences at launch between biosimilars and their originator counterparts were analysed. **RESULTS:** Price differences between biosimilars and their originator counterpart were on average 25%. One exception aside, biosimilars always trigger double digit price differences. Given the limited availability of biosimilars, it is too soon to say if results will be consistent over time. Nevertheless, the general trend shows that large price differences are observed in Canada and the US (at least 35%) and lower trends in Australia (around 16%). In the top 5 European pharmaceutical markets, price differences range between 17% and 30%. In Japan, price differences are also high, 29% on average. It should also be highlighted that the market entry of biosimilars does not always trigger the price of their originator to drop; in rare occasions only are their prices brought into line. **CONCLUSIONS:** Owing to the fact that biologic drugs are commonly expensive and with double digit price differences between biosimilars and their originator counterpart, the market entry of biosimilars should enable governments to generate significant savings. Nevertheless, a limited number of biosimilars are at the moment approved and in addition to the fact that no legislation is in place in the US, there is no sign of improvement in the other countries studied. As a consequence, savings will only be achieved if governments incentivise the development of biosimilars as well as their use.

PHARMACEUTICAL POLICIES, REGULATION AND EFFICIENCY

Maniadakis N[1], Kourlaba G[2], Shen J[3], Holtorf AP[4], Kalo Z[5]
[1]*National School of Public Health, Athens, Greece,* [2]*National and Kapodistrian University of Athens School of Medicine, Athens, Greece,* [3]*Abbott, Basel, Switzerland,* [4]*Health Outcomes Strategies LLC, Basel, Switzerland,* [5]*Syreon Research Institute, Budapest, Hungary*

OBJECTIVES: In the context of ever increasing demand and expenditure for health services it is important to identify policies which may maximise efficiency. Often, pharmaceuticals (approximately 20% of total health care expenditure) are a primary target for achieving efficiencies. This study aims to study the efficiency of pharmaceutical control policies. **METHODS:** Data on pharmaceutical policies and markets across 65 countries were collected from the published literature, with emphasis on the following domains: pricing, reimbursement, dispensing, expenditure and demand control. In each domain, policies were classified and through a multiple-country expert survey were graded for the degree of regulation. Countries were clustered according to their policy mix. Principal component analysis (PCA) served to group policies into three components: pricing policies, reimbursement policies and demand and cost control policies. Regression analysis with pharmaceutical expenditure as % of GDP as dependent variable was used to analyse the efficiency of policies. Independent variables were life expectancy, dependency ratios, mortality rates, GDP per capita and health system type. **RESULTS:** Spearman correlation coefficients indicated that there was no statistically significant association between total pharmaceutical expenditure as % of GDP and regulation in the coverage, pricing, reimbursement, dispensing policy and system type. A statistically significant positive correlation between regulation and indirect price and cost controls (0.334, p=0.028) and demand controls (0.333, p=0.019) implies that more regulation in these domains is associated with higher expenditure. Following the PCA, regulation in demand control policies was associated with higher expenditure (0.342, p=0.025) and the same applies for the aggregate of the components (0.314, p=0.040). In regression analysis the coefficients (p-value) were pricing:-0.003(0.950), demand control:0.062(p=0.067), reimbursement: -0.057(0.439), mortality: 0.001(0.414), Life Expectancy: 0.062(0.474), elderly ratio: 0.689(0.774), GDP-per-capita: -1.788(0.017). **CONCLUSIONS:** A variety of policies were developed recently to control pharmaceuticals. More regulation does not appear to increase efficiency or decrease expenditure.

PR3

VARIABILITY IN HYBRID DRUG AVAILABILITY AND PRICING IN EUROPE

Flostrand SJA[1], Lor S[1], Hughes ALH[2]
[1]*IMS Consulting Group, La Défense Cedex, France,* [2]*IMS Consulting Group, London, UK*

OBJECTIVES: Medicinal products where active substance, strength, form, or administration route have been modified differ from generic drugs as bioequivalence cannot be demonstrated. In Europe, these 'hybrid' products have a clear registration pathway (Directive 2001/83/EC) requiring investment in pre-clinical and clinical trials. However; beyond the regulatory pathway, pricing and market access remains a national matter and few countries have specific methods to evaluate hybrids; both innovative- and generic-like prices may result. This study evaluated hybrid price differences and consequences for availability of hybrids across Europe. **METHODS:** Using IMS MIDAS data and the HMA database of registered drugs, we screened 5,000 products to identify 40 hybrid products which were significantly differentiated from the reference product, launched between 2008-2012 and analysed their prices and availability based on sales achieved, versus the reference product within and across 10 European markets. **RESULTS:** Hybrid prices vary widely, but most frequently, generic rules are applied, limiting the interest of companies to make hybrids available across European markets. There is wide variation in availability of hybrids across markets, suggesting a decision not to launch in markets where prices are particularly unfavourable. Countries applying fixed generic pricing rules appear to have fewer hybrids. Yet where they are launched, hybrids are not classified as generics, so uptake is inhibited by non-substitution rules and prescribing quotas. **CONCLUSIONS:** The lack of clear evaluation criteria and pricing variability within and across countries are barriers to the availability of hybrid products to patients in Europe. To the degree that such products better meet patient needs versus generic medicines, these barriers reduce patient welfare and prescriber choice. In a context where patient-oriented outcomes are increasingly seen as important, hybrid drugs have a role to play given their ability to improve administration, compliance, convenience and in some cases improve safety and efficacy. Consequently, clear rules for hybrid evaluation, pricing and access are desirable as they would improve patient care and reduce uncertainty for hybrid manufacturers.

PR4

OVERVIEW OF COVERAGE WITH EVIDENCE DEVELOPMENT IN SWEDEN

Schroeder M[1], Kornfeld A[2], Ben Abdallah I[2], Rémuzat C[2], Toumi M[3]
[1]*Creativ-Ceutical, Copenhagen, Denmark,* [2]*Creativ-Ceutical, Paris, France,* [3]*University Claude Bernard Lyon 1, Lyon, France*

OBJECTIVES: Coverage with evidence development (CED) in Sweden has become common over the last decade. It is considered as a tool to address uncertainty. The objective of this research is to assess from 2005 to 2012 CED in Sweden. **METHODS:** We downloaded available CED from pricing authority (TLV) database, and extracted detailed information in an ad hoc grid developed for that purpose. The following information was extracted: date of product approval, name, indication, date of CED installation, end of CED, type of evidence to be generated, limitation of initial file supporting the need of additional evidences. **RESULTS:** A total of 28 cases were retrieved covering 9 main disease areas. Eleven were for orphan drugs and 10 for Central nervous system (CNS) disorders including depression anxiety, epilepsy, pain, ADHD, schizophrenia, restless syndrome and Parkinson disease. Other were classified as follow, 5 for cardiovascular disorders, 3 oncology, 2 diabetes, 2 respiratory disorders and 5 others. The main drivers to request CED were weak cost-effectiveness model (14 cases) driven by uncertainty about utility, patients benefit, transition probabilities, model structure etc. The second reason was low relevance of clinical evidence for clinical practice (8 cases), followed by long term efficacy extrapolation (5 cases) and others mainly related to comparative effectiveness, daily dosage, safety, target population, etc. (11 cases). For each CED more than one driver could be identified. Requirements were mostly real world evidence generation. **CONCLUSIONS:** CED in Sweden is likely to be driven more by uncertainty than drug prices due to low involvement of oncology, inflammation and other disease area where biologics are prescribed. Orphan drugs represent a leading target for CED as often little information is available at time of launch. Most CED are not finalised to assess the actual CED impact on long term coverage.

RESEARCH ON METHODS – PRO/QOL STUDIES

MAPPING THE CCQ ONTO EQ-5D SCORES (IM)POSSIBLE?

Boland MRS[1], van Boven JF[2], Rutten-van Mölken MPMH[1]
[1]*Erasmus University Rotterdam, Rotterdam, The Netherlands,* [2]*University of Groningen, Groningen, The Netherlands*

OBJECTIVES: Studies assessing the effectiveness of new Chronic Obstructive Pulmonary Disease (COPD) treatments commonly use disease-specific health-related quality-of-life (HR-QoL) instruments such as the Clinical COPD Questionnaire (CCQ). However, for the economic evaluations, utility data is necessary. This study aims to develop a model to predict mean utility values for a group of COPD patients using CCQ data. **METHODS:** We combined the data from two trials (RECODE and GO-AHEAD) including over 5000 observations with a broad range of disease severity. Data was randomly split into an estimation and validation sample. The overlap between the CCQ and EQ-5D was assessed using principal component and correlation matrix analysis. Different types of models were created with increasing complexity. We analysed the effect of using different observations of the same patients as unique observations and performed a sensitivity analysis using different EQ-5D value sets to estimate EQ-5D utilities. The external validity was tested with the dataset of the MARCH trial. **RESULTS:** The principal component analyses showed a poor correlation of the dimension pain/discomfort with any of the CCQ items and the CCQ items cough and produce phlegm did not load onto any EQ-5D dimension. The model using ordinary least square with the individual CCQ items as dummy variables, controlled for sex, resulted in the best predicted performance. The mean

absolute error was on average 0.15 but was considerably high (>0.34) if the observed EQ-5D value was below 0.5. Sensitivity analysis revealed that different EQ-5D value sets resulted in different algorithms but similar predicting ability. **CONCLUSIONS:** Our study showed that there are conceptual differences between the CCQ and EQ-5D and mapping should be considered as second-best option compared to directly collected EQ-5D data. Furthermore, the mapping performance seems to depend on the severity of the study population.

QL2

MEASURING PATIENT-RELEVANT TREATMENT BENEFIT IN DERMATOLOGY – DEVELOPMENT AND VALIDATION OF THE SHORT QUESTIONNAIRE "PATIENT BENEFIT INDEX 2.0"

Blome C[1], von Usslar K[1], Augustin M[2]
[1]*University Medical Center Hamburg, Hamburg, Germany,* [2]*University Medical Center Hamburg-Eppendorf, Hamburg, Germany*

OBJECTIVES: Evidence on patient-relevant treatment benefit is the main criterion for reimbursement decisions in many European countries. Usually, an increase of quality of life (QoL) during treatment is used as benefit indicator. The Patient Benefit Index (PBI) method, in contrast, evaluates benefit retrospectively: Before treatment, patients rate importance of treatment goals; after treatment, they rate goal achievement. This prevents any bias due to response shift which has repeatedly been found in pre-post QoL assessment. Here, we developed a short PBI version ("PBI 2.0") applicable to different skin diseases. **METHODS:** Treatment goal items for the PBI 2.0 were developed based on nine validated disease-specific PBI versions. Items were tested for content, completeness, and comprehensiveness in qualitative interviews with n=16 patients with atopic dermatitis, leg ulcers, psoriasis, and vitiligo. Items were revised on basis of patient feedback. The PBI 2.0 was tested for convergent validity, completeness, and congruence with disease-specific PBI versions in a cross-sectional study on n=379 patients with the above-mentioned diagnoses. **RESULTS:** The 74 disease-specific items could be condensed to 15 pilot items. Based on the qualitative interviews, we could reduce to 12 items. The majority of patients rated the PBI 2.0 to be comprehensible (93-98%, depending on diagnosis group), readable (94-100%), easy to answer throughout (78-90%), and complete (65-88%). Treatment goals mentioned as missing mostly concerned goals unrelated to benefit of medical treatment (e.g. information on the disease). The percentage of missing values ranged from 0.0% to 2.9%. PBI 2.0 preference-weighted global scores correlated significantly with QoL as measured with Dermatology Life Quality Index and EQ-5D (r=0.19 to 0.58). Convergent validity of the PBI 2.0 and the respective – about twice as long – disease-specific versions were equal, except for the vitiligo version. **CONCLUSIONS:** The PBI 2.0 is a qualitatively and quantitatively validated short questionnaire on patient-relevant treatment benefit in dermatology.

QL3

THE MEASUREMENT OF HEALTH-RELATED QUALITY OF LIFE: GERMAN FINDINGS FROM THE MULTI-INSTRUMENT COMPARISON (MIC) STUDY

Schlander M[1], Khan MA[2], Iezzi A[2], Maxwell A[2], Richardson J[2]
[1]*University of Heidelberg, Wiesbaden, Germany,* [2]*Monash University, Melbourne, Australia*

OBJECTIVES: Different multi-attribute utility (MAU) instruments are known to produce different values for "utility" and measure different constructs, despite the common label "utility". To date, the Multi-Instrument Comparison (MIC) project has been the largest comparative study of health and well-being instruments undertaken worldwide. Here we report the first results from the German branch of the study. **METHODS:** A total of 1269 German respondents (either healthy or suffering from defined chronic disorders, i.e., asthma, arthritis, cancer, depression, diabetes, hearing loss, heart disease) were recruited and participated in the study, completing various MAU instruments, including the EQ-5D, SF-6D, HUI3, 15D, QWB, AQoL(-4D and-8D). Cross-validation tests drew heavily on correlation. Preliminary findings, based upon Pearson correlation coefficients (indicating the extent to which changes in one variable correspond with changes in another), showed low correlations between measures of utility and measures of subjective well-being. While preferences might differ from subjective well-being, their correlation might be higher. Hence, a better measure should be intraclass correlation (ICC). **RESULTS:** Intraclass correlations between MAU instruments ranged from to 0.8 (HUI3 vs. AQoL-8D) to 0.4 (AQoL-4D vs. 15D). Linear regression results, reflecting the comparative performance of the various MAU instruments with regard to changes in measured utilities (as applied in standard cost utility analysis), and detailed results including pairwise comparisons of instruments, especially as to sensitivity to changes in a given dimension, will be presented. **CONCLUSIONS:** A major conclusion of the present study is that, despite some similarity in the mean scores, the instruments tested are dissimilar with regard to virtually all other criteria used to compare them. In effect, each instrument appears to measure a different construct of "health". Implications for the presumably "generic" measurement of "utility" may be far reaching and will be discussed.

PSYCHOMETRIC VALIDATION OF PERCEIVED DEFICITS QUESTIONNAIRE – DEPRESSION (PDQ-D) IN PATIENTS WITH MAJOR DEPRESSIVE DISORDER (MDD)

Lam RW[1], Saragoussi D[2], Danchenko N[3], Rive B[4], Lamy FX[5], Brevig T[6]
[1]*University of British Columbia, Vancouver, BC, Canada,* [2]*Lundbeck SAS, ISSY LES MOULINEAUX CEDEX, France,* [3]*Lundbeck SAS, Issy-les-Moulineaux, France,* [4]*Lundbeck S.A.S., Issy-Les Moulineaux, France,* [5]*Lundbeck S.A.S., Issy-les-Moulineaux, France,* [6]*H. Lundbeck A/S, Valby, Denmark*

OBJECTIVES: The Perceived Deficits Questionnaire (PDQ) provides a self-report measure of cognitive dysfunction. The current work aims at assessing the psychometric properties of the PDQ adapted for MDD (PDQ-D). **METHODS:** A non-interventional, online panel survey with baseline assessment and 6-week follow-up of US and UK residents (aged ≥18 years) with and without MDD [diagnosed with depression by a physician and current Patient Health Questionnaire-9 (PHQ-9) score ≥10]. In addition to PDQ-D, the following instruments were included: Medical Outcomes Study Cognitive Functioning-Revised [MOS COG-R]; PHQ-9, Patient Global Impression of Severity [PGIS] and Change [PGIC]; SF-36 Health Survey [SF-36], Lam Employment Absence and Productivity Scale [LEAPS], Sheehan Disability Scale [SDS] and Work Productivity and Activity Impairment: Specific Health Problem [WPAI:SHP]. **RESULTS:** The study population consisted of 855 subjects at baseline (418 US and 437 UK), with MDD patients representing 49% of the sample in each country; 169 and 153 MDD patients were invited for the follow-up in the US and UK, respectively. Internal consistency was high for the total scale and for the four proposed subscales (Attention, Retrospective memory, Prospective memory, and Planning), with Cronbach's alpha ranging from 0.81 to 0.96. Convergent validity was supported by strong correlations with other measures of cognitive functioning (0.8 Pearson's coefficient) and moderate correlations with several construct measures known to be associated with cognitive functioning, including health-related quality of life, productivity at work, and other functional impairment (Pearson's coefficients ranging from 0.3 to 0.6), and by substantial differences in scores in subgroups known to differ in cognitive functioning impairment. The PDQ-D was also responsive to changes in depression symptom severity. Confirmatory factor analyses supported the scoring of a global scale for perceived cognitive functioning. **CONCLUSIONS:** The PDQ-D is a reliable, valid and responsive instrument for assessing MDD patients' perception of deficits related to cognitive functioning.

MOTHERS' OWN MILK FOR THE FEEDING OF PRETERM INFANTS: A SYSTEMATIC LITERATURE REVIEW

Garcia-Stewart S, Mitchell SA
Abacus International, Bicester, UK

OBJECTIVES: To conduct a systematic review to examine the incremental benefits of mothers' own milk (MM), with or without fortification, compared with donor milk (DM) and/or preterm formula (PF) for the nutritional support of preterm infants both in the neonatal intensive care unit (NICU) and following hospital discharge. **METHODS:** English-language studies published post-1990 were identified from electronic databases (Medline, EMBASE and Cochrane Library) and conference proceedings. Eligible studies enrolled infants with mean gestational age less than 35 weeks with no restriction on geographical location. **RESULTS:** Thirty-three unique studies met eligibility criteria: United States (n=12), Canada (n=2), Australia (n=2), Mexico (n=1), Israel (n=2), Europe (n=13) or multinational (n=1). There was a paucity of both RCT data (n=7) and studies which reported exclusive use of MM feeding (n=3). In addition, there was considerable heterogeneity between studies with regard to study design, duration of follow up and amounts of MM ingested, and a robust meta-analysis was therefore not feasible. However, a significant beneficial effect for MM over DM and/or PF for the incidence of sepsis, necrotizing enterocolitis (NEC) and longer-term neurodevelopment was reported in a number of individual studies. With regard to anthropomorphic outcomes of body weight, length and head circumference, there was no clear consensus on the effect of feeding regimen. Sixteen studies reported the relationship between the dose of MM received and outcomes; increased MM dosages in the feeding regimen were associated with significantly lower rates of sepsis, NEC, and hospital readmissions, reduced NICU costs, and improved neurodevelopment. **CONCLUSIONS:** Exclusive or high-dose MM with or without fortification is associated with short- and long-term beneficial effects in preterm infants. These results confirm MM to be the optimal nutrition for preterm infants and stress the importance of developing comprehensive strategies to overcome the challenges of providing MM and improving breastfeeding rates in preterm infants in the NICU.

UTERINE-SPARING SURGICAL TREATMENT MODALITIES IN WOMEN WITH UTERINE FIBROIDS: A SYSTEMATIC REVIEW AND INDIRECT TREATMENT COMPARISON

Panagiotopoulou N[1], Nethra S[1], Karabis A[2], Ahmad G[1], Burls A[3]
[1]*Pennine Acute Hospitals NHS Trust, Manchester, UK,* [2]*Mapi – HEOR & Strategic Market Access, Houten, The Netherlands,* [3]*City University London, London, UK*

OBJECTIVES: To evaluate the safety and effectiveness of conservative surgical treatments for uterine fibroids in women who wish to preserve their uterus. **METHODS:** A systematic literature search of electronic databases (MEDLINE, EMBASE, CENTRAL) and grey literature up to October 2012 identified 5 RCTs (436 patients): 2 comparing uterine artery embolization (UAE) with myomectomy (MYO) and 3 comparing UAE with laparoscopic uterine artery occlusion (LUAO). Primary outcome measures included patients' satisfaction, re-intervention and ovarian failure rate. Secondary outcomes were clinical failure, hysterectomy and complication rates, hospitalization and recovery times, pregnancy rate, pregnancy complications and live-birth rate. Standard and network meta-analysis were performed on relevant outcomes. **RESULTS:** Of the three most popular uterine-sparing surgical treatments for fibroids, network meta-analysis showed that MYO and UAE resulted in higher rates of patient satisfaction and lower rates of clinical failure than LUAO in the first year after treatment [OR 2.56, 95%CrI 0.56-11.75, P(better)=11% and 2.7, 95%CrI 1.1- 7.14, P(better)=1%; 0.29, 95%CrI 0.06- 1.46, P(better)=7% and 0.37, 95%CrI 0.13- 0.93, P(better)=2% respectively]. Moreover, MYO resulted in lower re-intervention and hysterectomy rates than UAE and LUAO [0.08, 95%CrI 0.02- 0.27, P(better)<1%, 0.08, 95%CrI 0.01- 0.37 P(better)<1%); 0.16, 95%CrI 0.01-0.85 P(better)=2%, 0.15 95%CrI 0- 8.74 P(better)=16% respectively] even though the later techniques had an advantage over MYO due to shorter hospitalization and quicker recovery. There was no evidence of convincing difference between the three techniques in the number of women experiencing ovarian failure, minor or major complications. However, MYO may lead to better conception outcomes in

comparison to UAE (pregnancies: 3.44, 95%CI 1.18- 10.03; live-births: 3.02, 95%CI 1.00- 9.09). **CONCLUSIONS:** LUAO is less effective than UAE and MYO in the treatment of symptomatic fibroids for women who want to preserve their uterus. The choice between UAE and MYO should be based on individuals' short and long-term expectations.

META-ANALYSIS OF BCG VACCINE EFFICACY FOR INFANTS IN IRELAND

Schmitz S[1], Usher C[2], Adams R[2], Kieran J[1], Barry M[2], Walsh C[1]

[1]*Trinity College Dublin, Dublin, Ireland,* [2]*National Centre for Pharmacoeconomics, Dublin, Ireland*

OBJECTIVES: BCG vaccination policy is greatly debated. An important issue for countries using the vaccine is to try and estimate any influence it has on the tuberculosis (TB) incidence in their population. The aim of this study is to estimate the effectiveness of the BCG vaccine in infants in Ireland. **METHODS:** We searched PubMed and Embase for studies assessing a relative reduction in TB events after vaccination in infants. Studies meeting relevant inclusion and exclusion criteria were sought. Observational data from Ireland was combined with raw data from studies identified in the literature in a random-effects meta-analysis model to estimate the relative risk (RR) of vaccine efficacy against pulmonary TB, extra-pulmonary TB (EPTB), TB meningitis and TB deaths. **RESULTS:** Two meta-analyses were found. The first meta-analysis reviewed identified 5 randomised control trials and 11 case control studies against pulmonary TB (Trials 0.26 95% CI 0.17, 0.38; Cases 0.48 95% CI 0.37, 0.62) and TB deaths (Trials 0.35 95% CI 0.14, 0.88). The second meta-analysis identified a further 7 case-control studies and evaluated BCG efficacy against EPTB (0.23 95%CI 0.13, 0.42] and TB meningitis (0.27 95%CI 0.21, 0.33). Estimates from observational data from Ireland for pulmonary TB were (0.14, 95%CI 0.09, 0.20), EPTB (0.11, 95%CI 0.05, 0.21), TB meningitis (0.17, 95%CI 0.04, 0.75) and TB deaths (0.13, 95%CI 0.00, 6.37). Pooled RR estimates from Irish data and international estimates show a significant reduction in TB cases: Pulmonary TB: 0.26 (95% CI: 0.13, 0.54), EPTB: 0.16 (95%CI: 0.08, 0.34), TB meningitis: 0.27 (95%CI: 0.21, 0.34) and TB deaths: 0.33 (95%CI: 0.14, 0.81). **CONCLUSIONS:** This meta-analysis of local observational data with international trial data indicates that vaccination of infants with the BCG vaccine reduces the risk of pulmonary TB, EPTB, TB meningitis and TB deaths.

CO-ADMINISTRATION OF ANTIPSYCHOTICS AND ANTI-DEMENTIA DRUGS IN AUSTRIA

Hinteregger M[1], Füzi J[2], Reichardt B[3]

[1]*Main Association of Austrian Social Security Institutions, Vienna, Austria,* [2]*Sickness Fund Burgenland, Eisenstadt, Austria,* [3]*Sickness Fund Burgenland, Eisenstadt, Burgenland, Austria*

OBJECTIVES: The use of antipsychotics for people with dementia is regarded as problematic, causing cerebrovascular side effects and increasing mortality. In some countries, health-policy makers have already addressed a need for action to reduce the prescription of antipsychotics in dementia. The main goal of the analysis is to determine the extent of co-medication of antipsychotics for patients with medically-treated dementia in Austria, stratified by age and sex. **METHODS:** Provided in a pseudonymised manner, the data comprise all filled prescriptions of cholinesterase inhibitors and memantine in the years 2011 and 2012 at the expense of the 13 major Austrian health insurance funds, covering more than 97% of the Austrian population. Additionally, antipsychotic medication of the involved patient pseudonyms is included, as well as age, sex and – where occurred – date of death. For the analysis, the overlapping time frame is relevant, i.e. when both substance groups were consumed. Descriptive statistics are used to capture the extent and variability of a co-medication of these two substance groups. **RESULTS:** Starting with 72,549 patients included in the data (66% female), 31,605 (43.6%) were concurrently being prescribed antipsychotics to their anti-dementia drugs. The median for the overlapping time frame is 294 days, for anti-dementia prescriptions it is eleven and for antipsychotics it is seven. Age is a factor for increasing antipsychotic medication. Considering demography, there are no remarkable differences between men and women. **CONCLUSIONS:** Our data demonstrate that the use of antipsychotics in dementia is notably common in Austria, with a high prevalence as well as a tendency to long-term use. The results reflect the prescription reality and can be used as a solid basis for discussions, possible actions and evaluations about antipsychotics in dementia in the Austrian health system.

ASSESSING PRODUCT SAFETY VIA PATIENT BASED ACTIVE SURVEILLANCE (AS): A STUDY IN 30.000 WOMEN USING HORMONE REPLACEMENT THERAPY (HRT)

Heinemann K[1], Bardenheuer K[1], Potthoff P[2]

[1]*ZEG-Berlin, Berlin, Germany,* [2]*Kantar Health GmbH, München, Germany*

OBJECTIVES: The novel progestin drospirenone (DRSP) has antimineralocorticoid properties with potentially beneficial as well as unfavorable effects on cardiovascular outcomes compared to other progestins. A patient based AS study was set up to compare incidence rates of serious adverse events – in particular cardiovascular outcomes - in users of oral continuous combined preparations. **METHODS:** Prospective, controlled cohort study (2002-2011) with three arms: women using 1) DRSP/estradiol; 2) other oral continuous-combined HRT (occHRT); and 3) all other oral HRTs. The study population included women aged 40 or older in seven European countries starting or switching to an oral HRT at time of inclusion in the study. Outcomes were collected from the patients and validated by the treating physicians. A multifaceted 4-level follow-up procedure was to ensure low loss to follow-up rates. The analysis is based on Cox regression models comparing the cohorts. **RESULTS:** A total of 30,597 users of oral HRT preparations – reflecting more than 101,000 WY of observation – were recruited by 1,052 centers. Incidence rates of DRSP/estradiol and low-dose occHRT for venous thromboembolic events were 17.5 (95% CI: 11.2-26.0) and 18.2 (95% CI: 11.9-26.6) per 10,000 WY, respectively. The respective incidence rates for arterial thromboembolism were 10.9 (95% CI: 6.1-18.0) and 29.8 (95% CI: 24.1-36.4) per 10,000 WY with a hazard ratio adjusted for age, BMI, hypertension, region, family history of fatal ATE, diabetes, user status of 0.5 (95%CI: 0.3-0.8) for DRSP/estradiol vs. other occHRT. **CONCLUSIONS:** Results indicate a good safety profile with respect to cardiovascular risk for DRSP/estradiol. Serious cardiovascular events occur less frequently in DRSP/estradiol users compared to users of other continuous-combined HRT. This specificAS approach proved to be a successful approach with high long term follow-up success and high validity of safety results.

BUDGET IMPACT OF HPV16/18 GENOTYPING TESTS FOR THE MANAGEMENT OF NON-CONCORDANT COTESTING CERVICAL CANCER SCREENING RESULTS: A UNITED STATES PAYER PERSPECTIVE

Huang J[1], Hertz D[2], Conner A[2], Garfield S[2]

[1]*Roche Molecular Diagnostics, Pleasanton, CA, USA,* [2]*GfK Bridgehead, Wayland, MA, USA*

OBJECTIVES: To assess the impact of managing women with high-risk HPV positive and Pap negative results (hrHPV+/Pap-) attending cervical cancer (CxCa) screening with a Pap and HPV test (co-testing). The strategies tested reflect different options available if a hrHPV test versus a hrHPV including 16/18 genotyping (3-in-1 test) is used upon initial screen. **METHODS:** A budget-impact model was developed, from a US payer perspective. Data from the ATHENA (Addressing THE Need for Advanced HPV Diagnostics) trial and published literature were used to populate the model. The scenarios tested include repeat co-testing in 12 months, reflex genotyping HPV16/18, or routine co-testing with genotyping results already available from a 3-in-1 test for triage to colposcopy. The model examined the annual cost of testing and treatment for cervical intraepithelial neoplasia grade 2 or worse (≥CIN2) and the cost of patients loss-to-follow-up. For a hypothetical population of women between ages 30 to 69, it assumes 48.5% were co-tested within the CxCa screening program every 3 years. Of those, 6.7% of women receive hrHPV+/Pap-results. Test performance was modeled as equivalent for both genotyping scenarios. **RESULTS:** In the hrHPV+/Pap- population, the cost of ≥CIN2 cases detected and treated for each testing strategy and the rate of progression to invasive CxCa per 10,000 hrHPV+/Pap- results was $10,530/9.2 (repeat co-testing at 12 months), $8,500/2.6 (reflex HPV16/18) and $7,278/2.6 (routine co-testing with 3-in-1 test). Using HPV16/18 genotyping to manage discordant co-testing results increased ≥CIN2 cases detected and prevented disease progression. Compared to other HPV tests that require reflex genotyping, screening with a 3-in-1 test reduced the cost of follow-up by 17% annually. **CONCLUSIONS:** Genotyping for HPV 16/18 improved the detection of ≥CIN2 cases over repeat co-testing in 12 months; moreover, compared to other HPV testing strategies, the 3-in-1 test reduced costs and may be a prudent screening alternative.

ECONOMIC IMPACT OF THE USE OF AN ABSORBABLE ADHESION BARRIER IN PREVENTING ADHESIONS FOLLOWING OPEN GYNECOLOGIC SURGERIES

Roy S[1], Carlton R[2], Clark RS[2], Migliaccio-Walle K[2]

[1]*Johnson & Johnson Global Surgery Group, Somerville, NJ, USA,* [2]*Xcenda, LLC, Palm Harbor, FL, USA*

OBJECTIVES: Abdominal adhesions are common after gynecologic surgeries, often resulting in complications such as bowel obstruction and chronic pain, which may lead to increased length of stay and more frequent readmissions. GYNECARE INTERCEED® Absorbable Adhesion Barrier is associated with fewer adhesion-related outcomes compared to surgeries without an adhesion-barrier. This analysis assesses the budget impact of GYNECARE INTERCEED® for reducing the incidence of postoperative adhesions in open surgical gynecologic procedures. **METHODS:** A model was constructed to evaluate the budget impact to hospitals of adopting GYNECARE INTERCEED® for women undergoing open surgical gynecologic procedures. C-section surgery, hysterectomy, myomectomy, ovarian surgery, tubal surgery, and endometriosis surgery were modeled with and without the use of GYNECARE INTERCEED®. Incremental GYNECARE INTERCEED® material costs, medical costs arising from complications, and adhesion-related readmissions were considered. GYNECARE INTERCEED® use was assumed in 50% of all procedures. Budget impact was reported over a 3-year period from a US hospital perspective (US$2013). **RESULTS:** Assuming 100 gynecologic surgeries of each type and an average of one GYNECARE INTERCEED® sheet per surgery, a net savings of $439,975 with GYNECARE INTERCEED® over 3 years is estimated. GYNECARE INTERCEED® use resulted in 80 fewer patient cases developing adhesions. Although the use of GYNECARE INTERCEED® added $91,500 in material costs, this was completely offset by the reduction in complication costs ($230,766 savings) and fewer adhesion-related readmissions ($300,709 savings). By preventing adhesion-related complications, GYNECARE INTERCEED® prevented over 206 additional hospital days for patients. **CONCLUSIONS:** This analysis represents the first economic assessment of GYNECARE INTERCEED® use in open gynecologic surgeries that incorporates the cost of the adhesion barrier, complications, and readmissions. Adoption of GYNECARE INTERCEED® absorbable adhesion barrier for appropriate gynecologic surgeries would likely result in significant savings for hospitals which would largely be driven by clinical patient benefits in terms of fewer complications and adhesion-related readmissions.

BUDGET IMPACT OF DIENOGEST IN TREATING ENDOMETRIOSIS ASSOCIATED PELVIC PAIN IN BRAZIL: A PUBLIC PERSPECTIVE ANALYSIS

Ferracini M, Nakada CP

Bayer Healthcare Brazil, São Paulo, Brazil

OBJECTIVES: Evaluate the budget impact to the public health care system in Brazil after introducing dienogest (2 mg) as a treatment option in detriment of GnRH analogues (GnRHa) for patients with endometriosis-associated pelvic pain (EAPP). **METHODS:** The analysis was conducted from the public perspective over a five-year time horizon. The budget impact model (BIM) specifically considered

women with EAPP. A recently cost-minimization (CM) model developed for EAPP provided the estimates of average treatment cost in Brazil based on local guidelines. This CM model compared different treatment pathways for women with EAPP and used a 50% improvement in pelvic pain as a definition of a treatment response. A patient flow was developed based on epidemiological and demographical data. Based on market uptake assumptions, results from the CM model and the patient flow, the BIM estimated the incremental budget impact after adopting dienogest. The model assumed that during the first year, 6.76% of EAPP patients receive dienogest in detriment of GnRHa. After five years, it was assumed that dienogest would capture 30% of the GnRHa market in EAPP. **RESULTS:** Based on the patient flow developed, approximately 0.52% of the population were estimated to be diagnosed with EAPP and receiving treatment with GnRHa. In the year after introduction of dienogest, the overall budget used to treat EAPP was estimated to decrease by up to 2.98% with the budget saving estimated to increase to around 12.98% by Year 5. **CONCLUSIONS:** This analysis portends that the budgetary impact of adding dienogest to the public health care system in Brazil, in detriment of the GnRHa, result in a budgetary cost saving alternative.

PIH10

HOW MUCH DOES BENIGN PROSTATIC HYPERPLASIA COST? A BUDGET IMPACT ANALYSIS ON ITALIAN PATIENTS TREATED WITH 5A-REDUCTASE INHIBITORS

Povero M[1], Pitrelli A[2], Pradelli L[1]
[1]*AdRes HE&OR, Turin, Italy,* [2]*GlaxoSmithKline, Verona, Italy*

OBJECTIVES: Second-line pharmacological therapy for benign prostatic hyperplasia (BPH) includes 5α-reductase inhibitors (5ARIs, dutasteride and finasteride). Aim of this study was the evaluation of the budget impact related to the variation in dutasteride and finasteride prescribing trends. **METHODS:** Target population is the number of Italian BPH-patients, age ≥ 40 years, treated with dutasteride or finasteride. The BPH-patients management was modeled on a dynamic cohort for 4-years. Epidemiological input data were elaborated from a observational study on pharmaceutical prescription data of Italian BPH-patients; hospitalization rates were taken from a cohort study investigating BPH-related surgical and not surgical hospitalizations. Costs were calculated as average of Italian DRGs weighted for BPH-related procedure frequency. Current Italian prescription shares of dutasteride and finasteride were compared with a 20% shift of prescriptions from dutasteride to finasteride (Scenario A) and a 20% shift of prescription from finasteride to dutasteride (Scenario B). **RESULTS:** According to current prescribing trends, 372,078 hospitalizations for BPH are expected in 4 years. Mean annual cost for BPH-patients management results in 355 million €. Hospitalization cost is the main driver (228 milion €/year) while pharmacological therapy accounts for 35% of the total cost (126 million Euro/year). Scenario A: additional 11.485 hospitalizations related with BPH occur in 4 years; these lead to an increase in NHS cost only slightly offset by the savings in drugs acquisition cost: -0,08% savings on NHS budget (-0,28 milion €/year) Scenario B: the cost of drugs increases of 5% (+6 million €/year) and prevents 9,920 hospitalizations in 4 years; the net budget impact of scenario B is +0,08% increase in cost (+0,27 milion €/year). **CONCLUSIONS:** The shift of prescription from dutasteride to finasteride leads to modest savings on NHS Budget while the shift from finasteride to dutasteride offsets the majority of increase in drug budget improving the outcome in patients.

PIH12

COSTS OF ALTERNATIVE METHODS OF CHILD DELIVERY IN SERBIA

Odalovic M[1], Lakic D[1], Tadic I[2], Tasic L[2], Petrova G[3]
[1]*University of Belgrade Faculty of Pharmacy, Belgrade, Serbia and Montenegro,* [2]*University of Belgrade – Faculty of Pharmacy, Belgrade, Serbia and Montenegro,* [3]*Medical University of Sofia, Sofia, Bulgaria*

OBJECTIVES: Different types of labour need different resources. Therefore, different costs could be expected. Objectives of this study were to determine if significant differences in costs of different type of labour and methods of delivery exist and to determine factors related to estimated costs. The costs of spontaneous labour with vaginal delivery (SVD), induced labour with vaginal delivery (IVD), and planned C-section (CS) without labour were estimated. **METHODS:** Retrospective, population-based study was conducted for the period January – December, 2010. Health Insurance Fund of Republic of Serbia (HIFRS) database was used as a data source. Direct medical costs of mother/newborn pair were estimated. Costs were observed from the perspective of HIFRS and expressed in European Monetary Unit (EUR). **RESULTS:** A total of 99 women were selected for the study sample; average age was 30.55±5.42 years. The majority of women (46.5%) had SVD, 28.3% had IVD and 25.2% had CS. Women with CS were longer hospitalized compared to women with SVD and IVD (8.52±4.74 vs. 4.59±2.89 and 5.04±3.01 days, respectively, p<0.05). Newborns after CS were longer hospitalized compared to newborns after SVD and IVD (5.76±2.20 vs. 4.0±2.07 (p<0.05) and 5.14±3.39 (p>0.05)). Majority of women (88.0%) and children (80.0%) after CS were hospitalized at semi-intensive and/or intensive care unites. The average costs of delivery, regardless of the method, were 417.02±284.14 EUR. The costs of C-section were higher compare to SVD (640.18±240.04 vs. 243.27±131.70 EUR, p<0.05) and IVD (640.18±240.04 vs. 497.10±327.91 EUR, p>0.05). **CONCLUSIONS:** The highest costs of labour in Serbia were costs of planned CS. Longer maternal/newborns hospital stay and more frequent hospitalization at semi-intensive and/or intensive care unites after CS were leading factors of estimated high costs. Considering high costs of CS, it is necessary to review such clinical practice for the purpose of optimizing the use of resources.

PIH13

COST BURDEN OF ROTAVIRUS GASTRO-ENTERITIS REQUIRING HOSPITALIZATIONS IN THE CZECH REPUBLIC AND IN SLOVAKIA

Vitova V[1], Mullerova J[2], Tichopad A[1], Dolezel J[3], Hlavinkova L[4], Pazdiora P[5], Stefkovicova M[6]
[1]*CEEOR s.r.o., Prague, Czech Republic,* [2]*CEEOR Slovakia, Bratislava, Slovak Republic,* [3]*GlaxoSmithKline, Prague, Czech Republic,* [4]*GlaxoSmithKline Slovakia, Bratislava, Slovak Republic,* [5]*Charles University Hospital Pilsen, Plzen, Czech Republic,* [6]*Regional Authority of Public Health, Trencin, Slovak Republic*

OBJECTIVES: Rotavirus (RV) is the most frequent cause of severe gastroenteritis frequently requiring hospitalization. RV is responsible for > 1/2 of all hospital stays for acute gastroenteritis. The objective was to estimate the burden of community acquired rotavirus gastro-enteritis requiring hospitalization (CRVGE) in children ≤ 5 years old in Czech Republic (CR) and Slovakia (SK). **METHODS:** Multi-center, retrospective patient chart review was conducted in both pediatric and infection disease settings in CR (n=109) and SK (n=115). Resource use analysis including length of hospital stay and tests performed were evaluated. Patients requiring rehydration, complications and comorbidities were considered. Direct cost from payer's perspective were retrieved from official DRG lists (CR) and fixed hospitalization cost rates per case (SK). Micro-costing was done in parallel based on the resource use data. **RESULTS:** Mean length of hospital stay in CR and SK was 3.9 (SD 1.9) and 4.1 days (SD 1.7) respectively. Prevalent diagnostic tests used were latex agglutination 44.0% (CR) and immunochromatography 92% (SK). Rehydration was required in 84.4% (CR) and 97% (SK) of cases. Comorbidities were reported in 24.8% (CR) and 27% (SK); complications in 10.1% (CR) and 7.8% (SK). The national list-based reimbursement per hospitalized CRVGE is € 370-645 (CR) and € 561 (SK). The calculated average total costs, including treatment prior to, and after admission, were € 462 (CR) and € 583 (SK). The major cost item was the hospital stay with €391 (CR) and €540 (SK). Costs for tests and drugs during hospitalization were €30 (CR) and €25 (SK). The costs of pre and post-hospitalization care were €20 (CR) and €13 (SK). **CONCLUSIONS:** Although the length of hospitalization in both countries is similar costs seem to be substantially lower in CR, possibly as a result of recently launched DRG system. Common complications and comorbidities account for 30% of average hospital costs.

PIH14

USE OF ANTENATAL CORTICOSTEROIDS LOWERS HOSPITALIZATION COSTS RELATED TO PREMATURITY

Meneguel J[1], Fonseca M[2], Fonseca F[3], Almeida F[1], Grinsburg R[1]
[1]*UNIFESP, São Paulo, Brazil,* [2]*Federal University of São Paulo / Axia.Bio Consulting, São Paulo, Brazil,* [3]*Federal University of São Paulo, São Paulo, Brazil*

OBJECTIVES: According to WHO the use of antenatal corticosteroids (CEA) in pregnant women at risk of preterm birth <34 weeks can prevent thousands of preterm neonates (PN) deaths. The impact of the use of CEA in hospital costs in developing countries is not known. Our objective was to compare morbidity and hospital costs of PN whose mothers received or not CEA. **METHODS:** Analysis of PN medical records with gestational age 26-32 weeks born from Jan/2006-Dez/2009 in a tertiary, public and university hospital. We excluded infants with malformations. Maternal characteristics, hospital neonatal morbidity, use and doses of CEA and all used resources (tests, medications and procedures) were collected. Costs were estimated in Brazilian Reais, from the hospital perspective. **RESULTS:** Of 211 PN, 170 received at least one dose of CEA to 6 hours before delivery (G1) and 41 did not (G2). The groups had similar characteristics but G1 had more male infants (p <0.05) and cesarean sections (p <0,00). Morbidity: G2 needed more advanced resuscitation (16.5% vs 34%, p = 0.01), experienced more intraventricular hemorrhage III / IV (7.6% vs. 22%, p <0.00) and retinopathy of prematurity (12.4% vs. 24.4%, p = 0.05). Resource use: G1 consumed less mechanical ventilation days (5.3 vs 10.6, p = 0.04) and oxygen days (10.7 vs 17, p = 0.02); the number of NICU and Intermediate Care Nursery days were respectively (19.6 vs 27.5, p = 0.07) and (24 vs 29.5 days, p = 0.14); there was no difference concerning use of CPAP (p = 0.07) and surfactant (p = 0.06). The average cost of hospitalization per patient was BRL 18,409 in G1 and BRL 24,090 in G2 (p = 0.03). **CONCLUSIONS:** The CEA is a simple measure, which helps to reduce PN morbidity and utilization of health care resources, reducing hospital costs.

PIH15

EXAMINING THE BURDEN OF ILLNESS OF THE UNITED STATES VETERAN PATIENTS DIAGNOSED WITH ALZHEIMER'S DISEASE

Wang L[1], Xie L[2], Du J[2], Li L[1], Baser O[3]
[1]*STATinMED Research, Dallas, TX, USA,* [2]*STATinMED Research, Ann Arbor, MI, USA,* [3]*STATinMED Research/The University of Michigan, Ann Arbor, MI, USA*

OBJECTIVES: To examine the burden of illness of patients diagnosed with Alzheimer's disease (AD) in the U.S. veteran population. **METHODS:** A retrospective database analysis was performed using the Veterans Health Administration (VHA) Medical SAS datasets from October 1, 2008 through September 30, 2012. Patients diagnosed with AD were identified using International Classification of Disease 9th Revision Clinical Modification (ICD-9-CM) diagnosis code 331.0. The first diagnosis date was designated as the index date. A comparator group was created as well by identifying patients without an AD diagnosis but with the same age, region, gender, index year, and matching Charlson Comorbidity Index (CCI). The index date for the comparator group was randomly chosen to reduce the selection bias. A 1-year continuous health plan enrollment was required before and after the index date for both groups. One-to-one propensity score matching was used to compare the health care costs and utilizations during the follow-up period between the disease and comparator groups. **RESULTS:** A total of 68,856 patients were included in the AD and comparison cohorts. After 1:1 matching, a total of 24,542 of patients were matched from each group, and the baseline characteristics were proportionate. The AD cohort had higher percentages of inpatient (18.46% vs. 2.06%, p<0.01), emergency room (15.80% vs. 4.31%, p<0.01), physician office (98.17% vs. 58.18%, p<0.01), outpatient (98.30% vs. 58.92, p<0.01), and pharmacy visits (84.89% vs. 61.78%, p<0.01). AD patients also incurred higher inpatient ($7,416 vs. $636, p<0.01), emergency room ($150 vs. $41, p<0.01), physician office ($2,752 vs. $1,155, p<0.01), outpatient visits ($3,086 vs. $1,300) and pharmacy costs ($774 vs. $350, p<0.01) compared to patients without AD. **CONCLUSIONS:** In this study, AD was associated with higher health care resource utilization and a significantly higher economic burden.

A COST OF A CHILDBIRTH WITH IN VITRO FERTILIZATION IN POLAND

Góra K, Hermanowski T, Wrona W
Department of Pharmacoeconomics, Medical University of Warsaw, Warsaw, Poland

OBJECTIVES: To predict the cost of a delivery following assisted reproductive technologies (ART) in Poland. Moreover, the cumulated *in vitro* fertilization (IVF) effectiveness ratio was calculated and the costs of drugs for each of the three stimulation protocols used in IVF (long with GnRH agonist, short with GnRH antagonist and short with GnRH agonist) were estimated. **METHODS:** In order to calculate the IVF effectiveness, a pooled analysis of the results from European IVF monitoring reports concerning Poland from 2008 to 2010 was performed. Costs of the clinical and biotechnological parts of IVF were based on the Ministry of Health calculation. Drugs' costs were estimated considering both dosages based on the Summaries of Products Characteristics and the retail prices. Costs were calculated based on identified costs in both the patient and payer perspectives. **RESULTS:** The overall birth rate per cycle was 21,70%. The probability of a delivery was 1,5 higher during fresh cycle than in frozen embryo transfer. A total of 24,09% of embryo transfers resulted in delivery. The cost of drugs used during ovarian stimulation protocol was estimated on 6 055 PLN. The average cost per cycle was 13 565 PLN. Drugs account for 45% of this value. The average cost per birth was 42 848 PLN. **CONCLUSIONS:** *In vitro* fertilization is an expensive procedure for a patient in Poland. It is due to a limited effectiveness, usually requiring several repeats of the whole cycle of IVF with no drugs reimbursement. The ovarian stimulation is the most expensive part of the procedure. Thus, reimbursement of medication should also be established.

PIH18

COST-EFFECTIVENESS OF MATERNAL TOXOPLASMA SCREENING IN AUSTRIA: A DECISION-ANALYTIC MODEL

Prusa AR[1], Walter E[2], Pollak A[1], Hayde M[1], Kasper DC[1]
[1]*Medical University of Vienna, Vienna, Austria,* [2]*Institute for Pharmaeconomic Research, Vienna, Austria*

OBJECTIVES: Toxoplasma infection during pregnancy presents a serious hazard to the fetus including lifelong disabilities of connatal infected children. This foodborne illness is a common burden worldwide. Prevention strategies of the health care providers are diverse. In Austria, the maternal toxoplasma screening has been implemented four decades ago. The aim of this study was to determine cost-effectiveness of the maternal toxoplasma screening. **METHODS:** We developed a two arm decision-analytic model. One arm of the model assessed the costs and consequences of no prevention, while the other one evaluated the screening. The study population included pregnant women and offspring screened and treated for toxoplasma infection. The average number of births was 76,547 and 50,000 pregnant women were susceptible to infection. The analysis focused on lifetime consequences of the connatal infection. This encompassed direct costs (screening, cost of illness, maternal and pediatric treatment), indirect costs (changed job situation of parents, human-capital of dead individuals, blindness and special schools), quality-adjusted-life-years (QALYs) and reduced expectation of life. Costs were presented per child and for the Austrian birth cohort. Costs from published sources were used (2012 Euro) from the societal perspective. QALYs, life-years (LYs) and costs were projected over a life-time horizon and discounted at 3% p.a. **RESULTS:** Maternal toxoplasma screening reduced transmission risk by 40% and one quarter of affected children showed symptoms. We found five-times higher lifetime costs per child without prevention compared to screening. Also direct costs were lower in the latter group; screening costs did not offset costs of sequelae. A split in direct and indirect costs components demonstrated that proportion of direct costs without prevention amounted to 20% and 95% with screening. Screening resulted in QALYs gained and LYs saved. **CONCLUSIONS:** Funding the maternal toxoplasma screening saves money and is cost-effective for the society and the Austrian health care system.

PIH19

COST-EFFECTIVENESS OF UNIVERSAL PAEDIATRIC ROTAVIRUS VACCINATION WITH RIX4414 IN GREECE

Karabela P[1], Efklidou E[1], Lyberopoulou E[1], Panagopoulou C[1], Standaert B[2]
[1]*GlaxoSmithKline, Halandri, Greece,* [2]*GlaxoSmithKline Vaccines, Wavre, Belgium*

OBJECTIVES: Rotavirus gastroenteritis is a major health burden in young children worldwide. This study investigates the cost-effectiveness of universal paediatric rotavirus vaccination with RIX4414, a two-dose human rotavirus vaccine, in Greece. **METHODS:** A Markov cohort model with a cycle time of one month was constructed in Microsoft Excel. The birth cohort of 114,766 infants, based on 2010 official registry was entered into the model and followed over average life expectancy with acute rotavirus events measured up to five years of age. Probabilities, utility scores and costs for hospitalisations, hospital-acquired rotavirus infection, medical consultations, emergency visits and deaths due to rotavirus were taken from published sources and national databases. Costs and benefits were reported at 2012 euros, discounted at 3% and 1.5% respectively per year and compared between a vaccinated and unvaccinated cohort from a Social Sick-Fund perspective. **RESULTS:** Vaccination with RIX4414 incurred an incremental cost of €16,569 per QALY at a price of €48/dose. The estimated number of rotavirus-related diarrhoea events per year up to the age of five is 45,906. Total direct medical cost of rotavirus disease without vaccination is around €8,980,000 per year in Greece. Vaccination (40% coverage) reduces the number of gastro-enteritis events by 27% to 33,492 and the number of rotavirus-related medical visits from 17,214 per year to less than 11,000. Total cost of rotavirus disease, including the costs of vaccination, in the vaccinated cohort is estimated at €10,087,614 per year, with a cost reduction on direct medical costs of €3,343,781. This cost reduction reflects the high financial disease burden related to the medical visits including paediatricians, emergency and hospital visits. **CONCLUSIONS:** Paediatric vaccination against rotavirus with RIX4414 versus no vaccination in Greece improves health outcomes, reduces direct medical costs and is cost-effective from a social sick fund perspective.

PIH20

CLINICAL AND COST-EFFECTIVENESS OF A PROCALCITONIN TEST AS A PROMPT INDICATOR OF PRODOMOL MENINGOCOCCAL DISEASE IN FEBRILE CHILDREN: COST-EFFECTIVENESS ANALYSIS

Bell JM[1], Shields M[1], Angus A[2], Dunlop K[3], Bourke T[1], Kee F[1], Lynn FA[1]
[1]*Queen's University Belfast, Belfast, UK,* [2]*Belfast Health & Social Care Trust, Belfast, UK,* [3]*South Eastern Health and Social Care Trust, Belfast, UK*

OBJECTIVES: To establish if the procalcitonin (PCT) test's diagnostic performance is more clinically and cost-effective than C reactive protein (CRP) and White Cell Count (WCC) tests for suspicion of prodomal stage Meningococcal disease (MD) in children presenting at emergency department (ED) with a fever without source. **METHODS:** A decision analytic model was designed to reflect realistic clinical pathways for a child presenting with non-specific fever to ED. Test accuracy was evaluated using data from independent studies carried out in developed countries identified through a systematic literature search. Studies were combined to determine the optimal cut-off value for the PCT, CRP and WCC tests, each as an indicator of MD. Summary Receiver Operator Curve (SROC) analysis was used to determine the inter-study and overall diagnostic performance of each test from the areas under the curve (AUC), with 95% confidence intervals (CIs). Components of each clinical pathway were costed in UK sterling using the National Schedule of Reference Costs 2010-2011. Hospital stays were costed using the appropriate Health Resource Group code. **RESULTS:** Seven studies involving 881 children with non-specific fever provided data for inclusion. The PCT test was more accurate (sensitivity=89%, 95%CI=75-96; specificity=71%, 95%CI=37-91) for early MD compared to CRP (sensitivity=84%, 95%CI=74-90; specificity=60%, 95%CI=44-74) and WCC (sensitivity=50%, 95%CI=39-60; specificity=68%, 95%CI=54-79). PCT had the best PLR (3.0, 95%CI=1.8-7.8) to be viable as a rule-in test for MD and a borderline NLR as a rule-out test, making it a better option to either CRP (2.1, 95%CI=1.4-3.1) or WCC (1.5, 95%CI=1.0-2.3). Outcomes from the decision analytic model indicated that the PCT test was the most cost-effective (£2547 per patient treated), followed by the combined CRP and WCC test (£3069 per patient treated). **CONCLUSIONS:** The improved sensitivity and specificity of the PCT test provides a more cost-effective test than the currently recommended CRP and WCC tests.

COST-EFFECTIVENESS ANALYSIS IN THE TREATMENT OF HEAVY MENSTRUAL BLEEDING IN SPAIN

Lete I[1], Calaf J[2], Crespo C[3], Canals I[4], Espinós B[4], Cristóbal I[5]
[1]*Hospital Santiago Apóstol of Vitoria, Vitoria-Gasteiz, Spain,* [2]*Hospital de la Santa Creu i Sant Pau, Barcelona, Spain,* [3]*Oblikue Consulting, Barcelona, Spain,* [4]*Bayer Health Care, Barcelona, Spain,* [5]*Hospital Sanitas La Zarzuela, Madrid, Spain*

OBJECTIVES: To evaluate the cost-effectiveness of first-line treatment of heavy menstrual Bleeding (HMB) from the perspective of the Spanish National Healthcare System. **METHODS:** A cost-effectiveness analysis was performed using a Markov model to simulate the evolution of a cohort of women in reproductive age, with HMB and who wish to preserve their fertility status, in a time horizon of 5 years. The treatment strategies were levonorgestrel intrauterine system (LNG-IUS), estradiol valerate/dienogest (E2V/DNG), combined oral contraceptives (COC) and oral progestins (PROG). Clinical data was modelled indirectly combining literature and expert opinion. Outcomes were symptom-free months (SFM), quality-adjusted life months (QALM) and costs expressed in € in 2012. A probabilistic sensitivity analysis was conducted to examine the robustness of the results. **RESULTS:** The mean treatment cost of HMB at 6 month was 205€ for LNG-IUS, 318€ for E2V/DNG, 412€ COC and 766€ PROG. In the analysis over 5 years, LNG-IUS produced savings of 578€ compared to E2V/DNG, 991€ compared to COC and 1,821€ compared to PROG. Regarding the effectiveness, LNG-IUS provided 51.30 SFM, while E2V/DNG, COC and PROG provided 50.64, 49.09 and 47.77 SFM, respectively. Moreover, 77%, 65%, 56% and 46% of the patients treated with LNG-IUS, E2V/DNG, COC and PROG, respectively, continued treatment without surgery during the 5 year period. Considering QALM as outcome, LNG-IUS and E2V/DNG were the options that yielded more gains in QALM (49.71 for LNG-IUS, 48.09 for E2V/DNG, 46.59 for COC and 44.66 for PROG). LNG-IUS was the most effective and less costly, therefore dominant option. In the oral treatments comparison, E2V/DNG was dominant, providing savings and gains in terms of SFM and QALM. The probabilistic sensitivity analysis on the key parameters confirmed the robustness of the base case. **CONCLUSIONS:** LNG-IUS is a cost-saving option for the treatment of HMB in Spain. Among oral treatments, E2V/DNG is also a dominant strategy.

SYSTEMATIC LITERATURE REVIEW AND COST-EFFECTIVENESS ANALYSIS OF FETAL FIBRONECTIN TEST FOR PREDICTING PRETERM IN BRAZIL

Decimoni TC[1], Sansone D[1], Etto H[1], Santos AM[1], Araújo G[2], Fonseca ES[2], Fonseca M[2]
[1]*Axia.Bio Consulting, São Paulo, Brazil,* [2]*Federal University of São Paulo / Axia.Bio Consulting, São Paulo, Brazil*

OBJECTIVES: Brazil is among the countries with the highest incidence of preterm births. Incorporation of diagnostic tests to predict a preterm birth could improve the efficiency of the clinical practice reducing hospital expenses related to maternal hospitalization. The aim of this study was to compare the cost-effectiveness of fibronectin testing (FN) vs cervical length (CL) measurement in women with symptomatic preterm labor. **METHODS:** Systematic review of the literature of the diagnostic tests and development of a decision analytic model using the accuracy of the diagnostic tests to predict preterm birth and project the results in terms of effectiveness and cost. The analysis was performed for a hypothetical cohort of 10,000 patients, for each test, with symptomatic preterm labor between 24 and 34 weeks of gestation. The primary perspective of the study was of the Brazilian Health system (SUS). Data sources were the medical literature, SUS official published prices for medicines and DATASUS (SUS database). Costs are in 2012 Brazilian Reais. **RESULTS:** A total of 14 studies were included. There was a wide variation concerning the accuracy of the tests among the studies, particularly with respect to gestational age at

testing/delivering and definition of the CL test threshold. The values obtained were LR+ 3,98/LR- 0,33 (FN) and LR+ 2,22/LR- 0,54 (CL). For the whole hypothetical cohort the total costs of the FN and CL were 2,3 billion and 890 million, respectively. The difference of avoided hospitalizations between the tests was 244 for FN. ICER was BRL 5,834,35. **CONCLUSIONS:** Both diagnostic tests are important alternatives for the detection of premature birth in Brazil. Studies of prediction of preterm delivery using CL have important limitations beyond the fact that CL measure is an operator/machine dependent procedure. In women with symptomatic preterm labor FN is a cost-effective test strategy for prediction of preterm births.

COST-EFFECTIVENESS OF VACCINATION AGAINST HERPES ZOSTER AND POSTHERPETIC NEURALGIA: A CRITICAL REVIEW

Kawai K[1], Préaud E[2], Baron-Papillon F[2], Acosta CJ[1]
[1]*Merck & Co., Inc, West Point, PA, USA,* [2]*Sanofi Pasteur MSD, Lyon, France*

OBJECTIVES: To systematically review cost-effectiveness studies of vaccination against herpes zoster (HZ) and post-herpetic neuralgia (PHN). **METHODS:** We searched MEDLINE and EMBASE databases for eligible studies until June 2013. We extracted information regarding model structure, model input parameters, and study results. We compared the results across studies by projecting the health and economic impacts of vaccinating 1 million adults over their lifetimes. **RESULTS:** We identified 14 cost-effectiveness studies performed in North America and Europe. Results ranged from approximately US$10,000 to US$100,000 per quality-adjusted life years gained, though most studies in Europe concluded that zoster vaccination is likely to be cost-effective. All studies used similar model structure. Differences in results among studies are largely due to differing assumptions regarding duration of vaccine protection and a loss in quality of life associated with HZ and to a larger extent, PHN. In addition, studies found that vaccine efficacy against PHN, age at vaccination, and vaccine cost strongly influenced the results in sensitivity analysis. **CONCLUSIONS:** Our review generally supports the economic value of this preventive intervention, particularly in Europe, which will become increasingly important as population ages. Future research addressing key model parameters and cost-effectiveness studies in other parts of the world are needed.

PIH24

AN ECONOMIC EVALUATION ALONGSIDE A CLINICAL TRIAL (EEACT) IN PELVIC FLOOR MEDICINE

Brennan VK[1], Dixon S[2], Jones G[2], Radley S[3], Jacques R[2], Wood H[2], Ledger W[4]
[1]*RTI Health Solutions, Sheffield, UK,* [2]*University of Sheffield, Sheffield, UK,* [3]*Sheffield Teaching Hospitals Charitable Trust, Sheffield, UK,* [4]*University of New South Wales, Sydney, Australia*

OBJECTIVES: To determine the cost-effectiveness of using an online questionnaire (ePAQ-PF) in combination with a telephone consultation compared to standard care. **METHODS:** All women, aged ≥ 18 years and referred to urogynaecology services in Sheffield were eligible. Women completed ePAQ-PF online and then received a telephone consultation (intervention), or face-to-face consultation (standard care). Costs for ePAQ-PF completion and consultation were derived in a microcosting study. Resource use data were collected at 6-months follow-up. The SF-12 was administered at baseline and follow-up. SF-6D estimates were used to calculate quality-adjusted life-years (QALYs). Patient experience was measured by the Patient Experience Questionnaire and Client Satisfaction Questionnaire. **RESULTS:** A total of 195 women were randomised. Consultation costs for the intervention group (£31.75) were lower than for the control (£72.17). The intervention group incurred greater direct costs and personal expenditure during follow-up. However lower costs associated with productivity loss for the intervention group resulted in lower indirect costs per-patient. Mean total costs per-patient were £38.04 greater in the intervention group (£1,139.86) than the control (£1101.82). SF-6D scores reduced slightly during follow-up for the intervention group, and increased slightly for the control, resulting in QALY loss for the intervention group, and QALY gains for the control. Statistically significant gains in patient experience were identified for the intervention group, although in strict cost-utility terms the intervention was dominated by the control. Incremental costs and QALYs resulted in a negative incremental cost-effectiveness ratio (ICER). **CONCLUSIONS:** Although the intervention was not cost-effective compared to the controls, there was a significant difference in an important aspect of the care process, which was not captured by the ICER. This highlights the importance of decision makers accounting for intervention effects that fall outside the conventional conceptualization of the QALY. Methods could be developed that allow non-health effects, such as process utility, to be incorporated into the QALY.

PHARMACOECONOMIC ANALYSIS OF PROGESTOGEN PREPARATIONS FOR THREATENED ABORTION TREATMENT IN UKRAINE

Tkachova O[1], Iakovlieva L[1], Mishchenko O[1], Matyashova N[2]
[1]*National University of Pharmacy, Kharkiv, Ukraine,* [2]*National University of Pharmacy, Kharkiv, Ukraine*

OBJECTIVES: Comparative evaluation the cost effectiveness of threatened abortion treatment by two regimens: oxyprogesteronicaproas and dydrogesterone in Ukraine. **METHODS:** Pharmacoeconomic analysis was based on the results of comparative randomized trial (Belousov Yu. B., Karpov O.I., Ailamazian E.K., 2008). Two regimens for threatened abortion treatment: oxyprogesteronicaproas and dydrogesterone were evaluated. Treatment with dydrogesterone (20 mg per day or 2 tablets per day) was carried out during 8 weeks before closure forming placenta (56 days). Oxyprogesteronicaproas (250 mg per day) was used from 14 to 20 weeks of gestation (42 days). For determining the cost of therapy only the cost of drugs and auxiliary materials (syringes, alcohol) for both schemes were taken into account. The prices of drugs were taken from the information system "Drugs" of Company "Morion" (February, 2013, Ukraine). The currency ratio of UAH to dollar (USA) on 01.02.13 was 8,12:1. As an indicator of efficacy the number of saved pregnancy after treatment was used. **RESULTS:** The effectiveness of oxyprogesteronicaproas therapy was 88.6%, and dydrogesterone - 96.3%, the cost of treatment was $ 78.63 and $ 77.96 respectively. Cost-effectiveness ratio was $ 88.7 for oxyprogesteronicaproas and $ 80.9 for dydrogesterone. **CONCLUSIONS:** Cost-effectiveness analysis shown, that the use of dydrogesterone is more effective and less costly for threatened abortion treatment in Ukraine. The results of pharmacoeconomic analysis will optimize the government, insurance companies and patients cost.

PIH26

COST-EFFECTIVENESS OF INFANT PNEUMOCOCCAL VACCINATION IN THE NETHERLANDS

Vemer P[1], Postma MJ[2]
[1]*UMC Groningen, Groningen, The Netherlands,* [2]*University of Groningen, Groningen, The Netherlands*

OBJECTIVES: The Dutch National Immunization Program offers the 10-valent pneumococcal conjugate vaccine (PCV10). Also licensed for use in the infant population is the 13-valent PCV (PCV13). To update cost-effectiveness (CE) estimates of PCV13 over PCV10, using current epidemiological and economic data. **METHODS:** We modeled vaccinating a birth cohort with either PCV10 or PCV13 (3+1 dose schedule), and calculated costs and effects linked to resulting disease. We modeled invasive pneumococcal disease (IPD), non-invasive pneumonia and acute otitis media, and considered death and lifetime impairments after IPD. We calculated direct effects in the vaccinated cohort and indirect effects –herd immunity for the vaccine-type (VT) serotypes and replacement for the non-VT serotypes– in the rest of the population. Since no price is available, we use a price difference of €11 per dose and vary this price difference in sensitivity analyses. Epidemiological and economic data are taken as current as possible. A set of scenarios explore different assumptions, including different sets of epidemiological data, assumptions on vaccine efficacy and indirect effects. **RESULTS:** Taking only direct effects into account PCV13 cannot be considered cost-effective, unless the price difference is much lower than €11 per dose. In three scenarios, PCV10 dominates PCV13; in the other scenarios the ICER is between €89000 and €153000 per QALY gained. If indirect effects are also taken into account, the ICER of PCV13 compared to PCV10 is below € 20,000 per QALY for all scenarios. Scenarios do not have a large impact on the policy decision, unless we assume extra efficacy of PCV10 against non-typeable Haemophilus influenzae. **CONCLUSIONS:** Replacing PCV10 with PCV13 is not likely to be cost-effective in preventing invasive pneumococcal disease in young children. Taking potential benefits in elderly into account, PCV13 is likely cost-effective. The CE of PCV13 was highly sensitive for indirect effects our analysis.

PIH27

COST-MINIMIZATION ANALYSIS OF DIENOGEST VERSUS GONADOTROPHIN-RELEASING HORMONE ANALOGUES OR DYDROGESTERONE FOR ENDOMETRIOSIS TREATMENT IN RUSSIA

Avxentyeva M
The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia

OBJECTIVES: To perform pharmacoeconomic evaluation of dienogest vs gonadotrophin-releasing hormone analogues (GnRHa) or dydrogesterone for endometriosis in Russia. **METHODS:** Literature search did not reveale clinically significant differences in efficacy between dienogest 2 mg and GnRHa in terms of pain reduction associated with endometriosis. There was no difference in efficacy with dydrogesterone 60 mg once daily and placebo. Cost-minimization analysis was used to assess and compare drug costs of dienogest 2 mg daily, GnRHa - most often used in Russia including triptorelin, leuprorelin, buserelin (with obligatory application of add-back therapy for all three GnRHa) and dydrogesterone. Costs were calculated for a period of 6 months. **RESULTS:** Costs of endometriosis treatment per patient per 6 months were 1102€ for triptorelin, 1118€ for leuprorelin, 340€ for buserelin, 369€ for dydrogesterone and 295€ for dienogest. Dydrogesterone is less effective and more costly alternative in comparison with buserelin and dienogest. Among alternatives with the same efficacy dienogest is the most efficient option leading to savings from 74€ to 823€ per patient in 6 months. **CONCLUSIONS:** Using dienogest for treatment of endometriosis in Russia is as effective as using GnRHa but can lead to considerable cost savings because add-back therapy is not required.

PIH28

COST MINIMIZATION ANALYSIS OF THE DIENOGEST USE IN PATIENTS WITH ENDOMETRIS UNDER BRAZILIAN PUBLIC AND PRIVATE PERSPECTIVE

Ferracini M, Nakada CP
Bayer healthcare Brazil, São Paulo, Brazil

OBJECTIVES: To provide the results from a cost-minimization (CM) model that compares the use of dienogest with the use of GnRH antagonist (GnRHa) leuprorelin acetate, both for 6 months, in women with endometriosis-associated pelvic pain (EAPP) in Brazil. **METHODS:** A(CM) model was developed in the form of a decision tree to mimic treatment sequence in Brazil. The analysis was conducted under the private and public payer perspectives, only direct costs were included, procedures and drug costs were obtain from Brazilian official databases of public and private health care system fees. This CM model compared different treatment pathways for women with EAPP and used a 50% improvement in pelvic pain as a definition of a treatment responder to elicit treatment duration. Treatment response assessment was at 12 week period. Two basic treatment pathways were defined: a two treatment sequence (2TS) and tree treatment sequence (3TS). The 2TS consists of: GnRHa/dienogest followed by surgery. The 3TS consists of: GnRHa/dienogest, dienogest/GnRH as second treatment and surgery as final option. Subsequent treatments were only for patients that did not respond to previous treatment. Discount was not applied as costs occurred within 1 year period. **RESULTS:** The CM model shows that for both treatment pathways and perspectives dienogest is a cost-saving alternative. Under private payer perspective for 2TS and 3TS: BRL 1020.42 VS BRL 2328.94 and BRL 1461.22 VS BRL 2377.52 for dienogest and GnRHa respectively. Under public payer perspective for 2TS and 3TS: BRL 882.74 VS BRL 768.13 and BRL 942.18 VS BRL 856.77 for dienogest and GnRHa respectively. Efficacy for 2TS and 3TS are: 91.58%

and 97.87% respectively. **CONCLUSIONS:** This analysis portends dienogest as a cost-saving alternative for the treatment of EAPP compared to GnRHa in Brazil from the public and private payer perspective.

PIH29

INVESTIGATING THE IMPACT OF MENTAL HEALTH STATUS ON HEALTH AND SOCIAL CARE COSTS OF OLDER PEOPLE AFTER ACUTE HOSPITAL ADMISSION

Berdunov V, Franklin M, Tanajewski L, Harwood R, Goldberg S, Gladman J, Elliott RA
University of Nottingham, Nottingham, UK

OBJECTIVES: In England, nearly two-thirds of older people in acute hospital care suffer from co-morbid physical and mental health conditions. This study investigated the health and social care costs for a group of older (70+) people identified with a mental health condition after hospital admission. **METHODS:** The Better Mental Health (BMH) study recruited 247 patients at hospital admission in Nottingham, England. Electronic administrative records were sought for six months post-admission from health (services: general practices, hospitals, ambulance transport, intermediate and mental health care) and social care. The cohort was characterised by one or more aspects of mental health: cognitive impairment, depression, delirium, and neuropsychiatric health. Differences in mean cost between groups were assessed using t-tests; association between mental health and service-level cost was investigated using GLM regression. **RESULTS:** Health and social care costs were derived for all 247 participants, except primary care, derived for 122 (subset) participants due to GP recruitment. In the subset, mean (95% CI, median, range) total cost was £9842 (8573-11256, 7717, 715-48795). Mean cost (95% CI) for mental health care was significantly ($p<0.05$) higher for patients: with depression than without (£194 (106-322) Vs. £55 (17-111)); bottom-50% on the neuropsychiatric health scale (£202 (124-298) Vs. £55 (16-118)). Patients with delirium, compared to without, had significantly lower costs for GP consultations (£316 (196-492) Vs. £552 (429-701)) and hospital outpatient visits (£333 (253-444) Vs. £497 (400-621)). The GLM did not identify a significant association between aspects of mental health and service-level costs. **CONCLUSIONS:** This study suggests a person's mental health affects consumption of some, but not all, services evaluated. In general, these patients are costly, high resource-users, of health and social care services; however, this consumption pattern cannot be attributed to one particular aspect of mental health. Future work should investigate the impact of physical *and* mental health comorbidities on resource-use.

MEDICATION ADHERENCE AND ADVERSE HEALTH OUTCOMES IN COMMUNITY DWELLING OLDER PATIENTS

Cahir C[1], Fahey T[2], Teljeur C[3], Bennett K[4]
[1]*Trinity College Dublin, Dublin 8, Ireland,* [2]*Royal College of Surgeons in Ireland, Dublin, Ireland,* [3]*Health Information and Quality Authority, Dublin, Ireland,* [4]*Trinity Centre for Health Sciences, Dublin, Ireland*

OBJECTIVES: To determine the association between medication adherence and adverse drug events (ADEs), health related quality of life (HRQOL) and hospitalisation in older community dwelling patients. **METHODS:** A retrospective cohort study of 855 patients aged ≥70 years from 15 general practices in Ireland in 2010. Medication adherence was measured by: (i) the Medication Possession Ratio (MPR) using national pharmacy claims dispensing data; and (ii) self-report using the Morisky Medication Adherence Scale. ADEs and hospitalisation were measured by patient medical record and self-report for the previous 6 months. ADEs were reviewed by two independent clinicians. HRQOL was measured using EQ-5D. Multilevel Poisson and linear regression were used to examine how the number of ADEs, utility and hospitalisation varied by adherence after adjusting for patient and practice level covariates; socioeconomic status, deprivation, co-morbidity, number of drugs, functional disabilities, social support and health insurance. **RESULTS:** A total of 592 (69%) patients were adherent based on dispensed pharmacy claims data (MPR ≥80%) and 553 (63%) self-reported adherence to their medication. The median MPR for self-reported adherent patients was 0.88 (IQR: 0.78, 0.95) compared to 0.86 (IQR: 0.71, 0.93) for non-adherent patients ($p<0.01$). Non-adherence (MPR<80%) was not significantly associated with any ADEs but self-reported non-adherent patients had an increased risk of any ADEs (IRR 1.18; 95% CI 1.05, 0, 1.33 $p<0.01$). Non-adherent patients had a significantly lower mean HRQOL utility (MPR coefficient, -0.11, SE 0.03, $p<0.001$; self-report coefficient, -0.06, SE 0.01, $p<0.001$) and an almost two-fold increased risk in the expected rate of any hospitalisation (MPR IRR, 1.75; 95% CI, 1.42, 2.15, $p<0.001$; self-report IRR, 1.53; 95% CI, 1.16, 2.01, $p<0.01$) compared to adherent patients. **CONCLUSIONS:** Non-adherence was significantly associated with adverse health outcomes. Developing methods to assist older adults in accurate and safe management of their medications may increase their quality of life.

VALIDATION OF ACCEPT, A NEW GENERIC MEASURE TO ASSESS HOW PATIENTS WITH CHRONIC DISEASES BALANCE BETWEEN THE ADVANTAGES AND DISADVANTAGES OF FOLLOWING THE RECOMMENDED TREATMENT REGIMEN IN REAL-LIFE

Arnould B[1], Gauchoux R[2], Meunier J[1], Gilet H[1], Regnault A[1]
[1]*Mapi, Lyon, France,* [2]*Mapi, Real World Evidence, Lyon, France*

OBJECTIVES: To reduce, score, and validate the Accept questionnaire. **METHODS:** Accept is a 32-items PRO questionnaire measuring the concept of Acceptance. It was developed based on grounded theory and qualitative research. Each treatment characteristic was assessed on a response scale opposing "easy to accept" to "not easy to accept". We conducted an observational prospective study on 182 subjects engaged in long-term treatment regimen. Adult patients where consecutively recruited by a network of pharmacists when prescribed with a drug indicated in various chronic diseases (including asthma, diabetes, various cardio-vascular diseases, retroviral infections, osteoporosis). Patients were asked to complete Accept and MMAS-4 questionnaires at Month 1, 3 and 6 after having given their informed consent. The structure was explored through PCA, and confirmed with multi-trait analysis. Internal consistency reliability of dimensions was assessed through Cronbach's alpha. Scale-scale correlations were calculated. **RESULTS:** After reduction, Accept was made of 25 items organised in 1 overall Acceptance score and 6 domain-specific scores (efficacy, tolerance, convenience, constraints, treatment duration, multiple medication). Cronbach's alpha was 0,85 for overall Acceptance score, which met convergent and divergent validity criteria (both 100%). The domain-specific scores showed satisfactory to good results (Cronbach's alpha ranging from 0,67 - 0,87, convegrent validity ranging from 63% to 100%, and divergent validity ranging from 33% - 100%). Scale-scale correlations ranged from 0.02 to 0.58, confirming the multi-dimensional nature of the questionnaire. The good properties of Accept were stable over time. **CONCLUSIONS:** Accept is a brief, comprehensive, generic questionnaire focused on Acceptance. Initial validation in a population of patients with a wide range of long-term treatment showed promising results and confirmed the position of Acceptance. Further, disease-specific, large prospective study are needed to assess the ability of Accept to predict persistence to treatment.

DETERMINANTS OF NON-ADHERENCE TO MEDICATIONS AMONG CHRONIC PATIENTS IN MACCABI HEALTH CARE SERVICES

Simon Tuval T[1], Triki N[2], Chodick G[2], Greenberg D[1]
[1]*Ben-Gurion University of the Negev, Beer-Sheva, Israel,* [2]*Maccabi Healthcare Services, Tel Aviv, Israel*

OBJECTIVES: Implementation of co-payments may reduce the use of essential medications, worsen patients' outcomes, and increase overall health care costs. The aim of this study was to examine to what extent non-adherence of chronic patients to medication stems from financial reasons and what determinants are associated with non-adherence. **METHODS:** A telephone survey was conducted among a representative sample of Maccabi Healthcare Services chronic patients aged ≥55 yrs (n=522). Respondents were defined as non-adherent if they reported they had stopped taking prescribed medications in the previous year and/or not purchasing prescribed medications due to its cost. Additional information collected included: age, gender, income, receiving explanation from a physician regarding the therapy, and out-of-pocket expenditure for prescribed medications. **RESULTS:** Mean age of the study population was 69.9±9.0 yrs (53% were male). Sixteen percent of respondents were defined as non-adherent, in 60% of them it was due to medication's cost. No significant differences were found between adherent and non-adherent respondents with regard to: age, gender, family status, country of birth, supplementary insurance coverage, or education. In a multivariable logistic regression model, non-adherence was associated with: lack of physician explanation about prescribed medications (OR=2.88, 95%CI: 1.46-5.68, P=0.002); higher out-of-pocket expenditure on medications (OR=1.93, 95%CI: 1.04-3.61, P=0.04), and lower household income (OR=0.81, 95%CI: 0.69-0.96, P=0.01). **CONCLUSIONS:** Information provided by physicians is associated with adherence of chronic patients to prescribed medications. Low income and high out-of-pocket expenditure for prescribed medication are associated with non-adherence. Since adherence is strongly affected even by a relatively low and flat co-payment as applied in Maccabi Healthcare Services, health policy makers may consider adoption of value-based co-payments that are differentiated by treatment value rather than by its cost, and targeted mainly at chronic patients. This approach may lead to improved adherence and outcomes with the potential of reducing long-term costs.

COST-EFFECTIVENESS OF MEDICATION ADHERENCE ENHANCING INTERVENTIONS: A SYSTEMATIC REVIEW

Oberjé E[1], de Kinderen R[2], Evers SM[2], de Bruin M[1], van Woerkum C[3]
[1]*University of Amsterdam, Amsterdam, The Netherlands,* [2]*Maastricht University, Maastricht, The Netherlands,* [3]*Wageningen University, Wageningen, The Netherlands*

OBJECTIVES: In light of the presumed costs of non-adherence to medication and the pressure to reduce unnecessary health care expenditures in the current economic climate, a review that assesses evidence of cost-effectiveness of adherence enhancing interventions would be timely. The objective of this paper is to examine the cost-effectiveness of adherence enhancing interventions and the quality of the studies reviewed. **METHODS:** MEDLINE, PsycInfo, EconLit and the Centre for Reviews and Dissemination databases were searched for randomised controlled trials that performed full economic evaluations of adherence enhancing interventions. Information was collected on study characteristics, cost-effectiveness of treatment alternatives, quality of economic evaluations, and risk of bias. **RESULTS:** Fourteen studies were included, of which the overall quality was found to be moderate. Five used a societal perspective, eight a provider perspective, and a single study used a patient perspective. Ten studies examined interventions that were both more costly and more effective than usual care, and four were less costly and more effective. Comprehensive evidence from the societal perspective yielded disappointing results for potential cost-effectiveness of adherence interventions. Studies from other perspectives provided weak to moderately promising evidence that adherence interventions can be cost-effective. **CONCLUSIONS:** Few randomised controlled trials examined the cost-effectiveness of adherence interventions. There was limited evidence of potential cost-effectiveness of adherence programmes. Most interventions did not report whether their intervention was effective in the first place, and many suffered from methodological limitations. To demonstrate that adherence interventions offer societal benefits, we recommend that the most promising interventions are subjected to a rigorous cost-effectiveness evaluation.

PIH34

A SYSTEMATIC REVIEW OF PATIENT PREFERENCES FOR SUBCUTANEOUS MEDICATIONS

Ridyard C, Dawoud D, Hughes DA
Bangor University, Bangor, UK

OBJECTIVES: Of the many routes of drug administration, some are more acceptable to patients than others; for example when a choice is presented, patients will usually prefer an oral over an injectable medication, all else being equal. Patient preference may be expressed in terms of health and non-health-related measures, which include: health technology-related attributes (including ergonomics, ease of use, convenience), behaviour (e.g. needle phobia and patients' perceptions of treatment), and adverse reactions attributable to the route of administration. Preferences may result in process-related (dis)utility, and be revealed as (non)adherence. This review aims to examine ambulatory patients' preferences for subcutaneously administered, self-injectable medications, compared with other routes of administration for the same medicines. **METHODS:** Ten electronic databases were searched for publications published between 2002 and 2012 using terms pertaining to methods of administration, preferences and adherence. Eligibility for inclusion was determined through reference to specific criteria by two independent reviewers. **RESULTS:** Of the 1,146 papers screened, 70 met the inclusion criteria. Studies focused mainly on methods of administration for insulin and treatments of paediatric growth disorders and multiple sclerosis. Pen devices were significantly preferred to needle & syringes administration in 11 out of 12 studies – particularly with respect to ergonomics, convenience and portability; however, preferences between autoinjectors and pen devices were less pronounced. Oral administration was preferred to subcutaneous administration in 6 studies (but did not reach statistical significance), as was inhaler therapy (favoured significantly in 3 out of 4 studies). **CONCLUSIONS:** The review identified a number of studies which revealed important differences in patient preference between methods and routes of drug delivery. Further evidence is required to support the notion that preference translates to better adherence.

PIH35

THE EFFECT OF MEDICAL DEVICES WITH DOSE-MEMORY AND REMINDER FUNCTIONS ON PATIENTS' TREATMENT ADHERENCE, CONFIDENCE AND DISEASE SELF-MANAGEMENT

Hall R[1], Harald-Kongsø J[2], Humphrey L[1], Willgoss T[1]
[1]*Adelphi Values, Bollington, UK,* [2]*Novo Nordisk, Søborg, UK*

OBJECTIVES: Adherence to treatment is an important issue in the management of chronic diseases and an indicator of patients' ability to self-manage their condition. Some medical devices have been designed to help support patients' self-management and adherence by including dose-memory and reminder functions. This literature review explored the role and impact of these devices on patients' adherence to treatment, confidence and disease self-management. **METHODS:** A search of Medline, Embase and PsycInfo was performed to identify articles published in English from 2003-2013, which studied the effect of devices with memory and/or reminder functions on treatment adherence, confidence and self-management. The main attributes of the abstracts selected for inclusion and full-text review, were summarized. **RESULTS:** The database searches yielded 940 abstracts. Of the 47 meeting the inclusion criteria, 32 were retained. The articles explored the impact of memory and/or reminder devices on treatment adherence, device usability and users' (patients, health care professionals (HCPs) and caregivers) relationship and attitudes towards the devices. Devices with memory and/or reminder functions were found to improve self-reported and electronically-monitored treatment adherence in prophylactic medication use (e.g. contraceptives) and a range of chronic diseases including HIV, diabetes and asthma. Memory functions were considered valuable in disease management by patients and HCPs. Of particular value was that memory and/or reminder functions provided dose-history information, enhanced patients' confidence with, and ability to manage their medication and condition, and helped reduce forgotten or incorrect medication dosing. **CONCLUSIONS:** The incorporation of memory functions alone and in combination with reminder features in medical devices can improve patient's adherence, confidence and self-management. This can lead to improvements in disease control and clinical outcomes, thereby offering clinical and economic value. This review highlights the importance of conducting further qualitative and quantitative research in this area to fully understand the value of these types of devices to patients and HCPs.

PIH36

COMPARISON OF ELDERLY ADULTS BY NUMBER OF RX MEDICATIONS USED: RESULTS FROM THE NATIONAL HEALTH AND WELLNESS SURVEY ACROSS 5EU COUNTRIES

Annunziata K[1], Isherwood G[2], Sternbach N[1]
[1]*Kantar Health, New York, NY, USA,* [2]*Kantar Health, Epsom, Surrey, UK*

OBJECTIVES: Compliance with medications among elderly patients is particularly important, as the consequences may be quite serious. Results suggest that use of three or more medications may put a considerable burden on elderly patients and may affect their compliance. This analysis profiles elderly patients across 5EU by the number of medications currently used and their compliance related behaviors. Combination products were considered as one prescription medication. **METHODS:** Results were taken from the 2011 5EU National Health and Wellness Survey, a nationally representative, self-administered survey. Respondents were adults age 18 and over from France, Germany, Italy, Spain and UK. This analysis focuses on adults age >= 65. Physical and mental quality of life was measured using the SF12v2 scale. Activity impairment was measured using the Work Productivity and Activity Impairment scale. **RESULTS:** Out of the total sample of age >=65 (n=10,612), ~37% of elderly adults across 5EU currently use four or more prescription (Rx) medications to treat their conditions, 44% use 1-3 Rx medications, and 18% use no Rx medications. Activity impairment is greater among those using 4+ medications (38.6 vs. 22.7 vs. 16.0). Emergency room visits and hospitalizations are also higher. This group appears to be more proactive in engaging in cost-saving behaviors to alleviate some of the treatment costs in the past 6 months (30% vs 24% vs 15%) (e.g., asking for generic alternatives (19% vs 16% vs 8%), ever changing prescription to another drug (61% vs 51% vs 45%) and switching to a generic version of a prescribed drug (35% vs 27% vs 18%). **CONCLUSIONS:** Considerably higher health care costs and greater activity impairment can be seen among elderly patients using more prescription medications. Given the financial burden of using multiple medications, and the lower incomes of these patients, cost-saving methods are more frequently utilized by these patients.

PRELIMINARY ITALIAN ARCHIVE OF EQ-5D DATA ON INDIVIDUALS FROM THE GENERAL POPULATION AND WITH DIFFERENT DISEASE CONDITIONS

Cortesi PA[1], Ciampichini R[1], Mantovani LG[2], Scalone L[3]
[1]*Charta Foundation, Milan, Italy,* [2]*Federico II University of Naples, Naples, Italy,* [3]*University of Milano - Bicocca, Monza, Italy*

OBJECTIVES: In the last 15 years our research activity collected several HRQoL data, through the EQ-5D-3L and other generic (SF-36) or condition-specific questionnaires. The objective was to assess and compare HRQoL among different population subgroups. **METHODS:** We reviewed all the HRQoL studies conducted by our research group between 1998 and 2012. We identified several conditions to be compared in terms of VAS score and utility index: these were assessed using the Italian social tariffs and then adjusted for age and sex. **RESULTS:** The archive included QoL data from 7,754 subjects (51.5% male), grouped in 29 different subgroups: type 1 and 2 diabetes mellitus, moderate to severe haemophilia, major depression, atopic dermatitis, severe and chronic hand eczema, psoriatic arthritis, schizophrenia/schizophrenic disorder, β-thalassemia major, gastroesophageal reflux, abdominal aortic aneurysm, systemic sclerosis, chronic hepatitis B, chronic hepatitis C, hepatitis from other causes, cirrhosis, hepatocellular carcinoma, liver transplant, general Italian population aged from 18 to 75 years. Overall, the subjects were aged from 14 to 96 years (mean(+SD)=55.7(+17.1), median=57.7). The adjusted EQ-5D-VAS mean+SD ranged from a minimum of 33.9+14.1 in patients with a major depression episode, to a maximum of 82.5+12.9 in patients with atopic dermatitis 8 weeks after flare. The mean+SD VAS was 73.2+11.4 in the general population. The adjusted mean+SD utility index ranged from 0.60+0.17 in psoriatic arthritis before starting treatment with biological agents, to 0.931+0.09 among chronic hepatitis B patients. **CONCLUSIONS:** The many EQ-5D data collected in the last 15 years are merged now in a unique archive that can be used to assess and compare the burden of disease in terms of HRQoL in different subpopulations. This archive is to be considered preliminary and deemed to be integrated with additional data from ongoing or future projects, and perhaps with other analogous archives created in other contexts and Countires.

PIH38

LEVEL AND FACTORS IMPACTING THE PATIENT DISSATISFACTION IN THE PRIMARY CARE VISITS BASED ON THE CROSS-SECTION MEASUREMENT – A PROSPECTIVE FINNISH STUDY

Soini EJ[1], Koskela T[2], Kangaspunta V[3], Ryynänen OP[4]
[1]*ESiOR Oy, Kuopio, Finland,* [2]*Department of General Practice, University of Tampere, Tampere, Finland,* [3]*School of Medicine, University of Tampere, Tampere, Finland,* [4]*Department of Public Health and Clinical Nutrition, University of Eastern Finland, and General Practice Unit, Kuopio University Hospital, Kuopio, Finland*

OBJECTIVES: A key dimension impacting clinical outcomes in health care evaluation is satisfaction (i.e. the level of meeting user's expectations for the service), which impact adherence and persistence. Yet, evidence regarding patient dissatisfaction is scarce. Thus, we asked what the level of dissatisfaction is after a health centre (HC) visit, and which factors impact the dissatisfaction? **METHODS:** A prospective survey to primary care patients visiting 3 Finnish HCs (Linnainmaa, Omapihlaja, Pirkkala) in Pirkanmaa district during 31.1–11.2.2011 was done. No inclusion/exclusion criteria were used. Comprehensive patient-, clinician- and HC-related data was collected. The patient's satisfaction was measured immediately after the visit in the form of handling problem during a visit (Likert range 0–10). This was inversed to assess the drawback related to the visit (0=full benefit; problem was solved; 10=no benefit; full drawback). An explorative statistical analysis was done including multivariate data mining in order to find the model with the best Akaike information criteria. The model aimed to demonstrate the independent factors impacting the drawback and control heterogeneity. **RESULTS:** A total of 90.1% of the full sample (n=647) answered to the drawback question. 40.3% of the patients had problem solved during the visit (i.e. reported 0) and just 6.9% of the patients experienced drawback exceeding 5. The factors increasing the drawback in the stepwise OLS regression model with the +1 ln-transformation for the drawback were longer waiting time, asthma/copd and male sex. The factors decreasing the drawback were patient's higher subjective health status, patient's higher subjective health status in comparison to others of same age/sex, some long-term conditions (rheumatoid disease, allergy, hip/knee joint erosion), clinician's longer experience, clinician in specialising education and certain HC. **CONCLUSIONS:** Some 60% of the patients experienced that their problem was not fully handled. Multiple factors impact the drawback which could be notified in the planning of HC services.

PIH40

MEASUREMENT OF SOCIETAL MEDICAL CARE PREFERENCES WITH THE SAME COST PER QALY: A DISCRETE CHOICE STUDY

Shiroiwa T[1], Saito S[2], Shimozuma K[3], Kodama S[4], Noto S[5], Fukuda T[1]
[1]*National Institute of Public Health, Saitama, Japan,* [2]*Okayama University, Okayama, Japan,* [3]*Ritsumeikan University, Kusatsu, Japan,* [4]*Kyoto University, Kyoto, Japan,* [5]*Niigata University of Health and Welfare, Niigata, Japan*

OBJECTIVES: The principal of QALY is sometimes referred to as "A QALY is a QALY is a QALY", which means all QALYs have the same value, while QALYs may not fully reflect public preferences. If the use of QALYs in decision making proves beneficial but insufficient, what other factors should be taken into consideration simultaneously? **METHODS:** We conducted a face-to-face survey using a discrete choice method to measure societal medical care preferences. The profiles of assumed patients consisted of the following four factors: (a) age (young or elderly patient); (b) objective of care (treatment or prevention); (c) severity of health state (severe or mild); and (d) past experience of receiving care (yes or no). These

factors were orthogonally combined to construct 16 patient profiles. All assumed medical care had the same ICER (cost per QALY). Respondents were randomly assigned to two of the 16 profiles and asked which one of the patients should preferentially receive treatment from a societal point of view, given a limited medical resource. Respondents were stratified by age and sex. **RESULTS:** A total of 1091 responses were collected from 50 sites across Japan. The most preferred factor was "younger patient (a)", followed by "treatment (b)" and "severe health state (c)", which had the same degree of preference. No statistical significance was found for "no past experience of care (d)". Public preference for medical care for elderly patients increased with increasing age. University-graduated people tended to prioritize care for patients who are younger and in severer conditions. **CONCLUSIONS:** Our survey revealed that public medical care preferences are influenced by factors such as age, even with the same cost per QALY. Based on an economic evaluation, age is an important factor for decision-making that reflects societal preferences.

PIH41

POTENTIALLY INAPPROPRIATE PRESCRIBING (PIP) AND ITS ASSOCIATION WITH INSTRUMENTAL ACTIVITIES OF DAILY LIVING (IADL) IMPAIRMENT IN OLDER PEOPLE

Moriarty F[1], Cahir C[2], Fahey T[1], Bennett K[3]
[1]*Royal College of Surgeons in Ireland, Dublin, Ireland,* [2]*Trinity College Dublin, Dublin 8, Ireland,* [3]*Trinity Centre for Health Sciences, Dublin, Ireland*

OBJECTIVES: Older people are particularly vulnerable to adverse effects of prescribed drugs. PIP can be defined as the use of medicines with an unfavourable risk benefit ratio. There has been little research on the relationship between PIP and humanistic outcomes, such as functional impairment. This study aims to measure the prevalence of PIP in an older Irish population and to investigate its association with IADL impairment. **METHODS:** A retrospective cohort study of 2,051 community-dwelling participants in The Irish Longitudinal Study on Ageing (TILDA) aged ≥65 years with linked medication dispensing history from a national pharmacy claims database was carried out. Exposure to PIP in the 12 months prior to assessing functional impairment was determined using the Screening Tool for Older Persons' Prescriptions (STOPP), the Beers' criteria (2012) and Assessing Care of Vulnerable Elders (ACOVE) indicators relating to inappropriate medications. Logistic regression was used to determine the association between exposure to PIP and presence of any IADL impairment, adjusting for age, gender, socioeconomic status, number of repeat drug classes co-morbidity and medication adherence. **RESULTS:** The overall prevalence of PIP was 66.89% (n=1,372). Of these 514 (25.06%) had one instance of PIP, while 858 (41.83%) had two or more. Prevalence was highest using the STOPP criteria (57.29%), compared to prevalences of 37.64% (Beers' criteria) and 23.5% (ACOVE indicators. Participants with ≥2 PIP indicators were significantly more likely to have an IADL impairment (adjusted OR=1.91; 95%CI=1.15-3.18) compared to no PIP. Similar associations were found for the individual measures of PIP. Age, number of repeat drug classes and co-morbidity were also significantly associated with IADL impairment. **CONCLUSIONS:** PIP in the elderly is highly prevalent and exposure to PIP is independently associated with increased risk of having IADL impairment. This suggests the importance of considering appropriateness when prescribing medicines in order to minimise adverse outcomes.

PIH42

ADDING A REMINDER SHORT MESSAGE SERVICE (SMS) BEFORE AND TABLET COMPUTER DURING CLINIC IMPROVES ELECTRONIC PATIENT REPORTED OUTCOME MEASURES (EPROMS) COLLECTION

Roberts N, Williams D
Royal Cornwall Hospital, Truro, UK

OBJECTIVES: Patient Reported Outcome Measures (PROMs) monitor both symptom progression and treatment effectiveness, and play an increasing role in everyday clinical practice. Electronic PROMs (ePROMs) enable real-time reporting back to the patient and medical team, comparison with similar patient cohorts and long-term cost-effective outcome measurement. Concerns have, however, been expressed about electronic PROMs collection in the elderly. The primary objective of this three-phase pilot study was to measure uptake using a web-based ePROMs platform following the introduction of reminder short messaging service (SMS) before and Tablet Computer during clinic. **METHODS:** Eighty-seven consecutive new elective orthopaedic patients in a single surgeon's practice were recruited. Group 1 (n=27) received only a reminder letter, Group 2 (n=34) also received a reminder SMS message via mobile or home telephone and Group 3 (n=26) also had access to a Tablet Computer in clinic. **RESULTS:** Mean age in Group 1 was 55.1 (24-77) years, Group 2 was 60.5 (23-85) years and Group 3 was 54.2 (17-77) years (p>0.05). Overall 75% patients had Internet access and 33% of Group 1, 50% of Group 2 and 73% of Group 3 recorded an ePROMs score (p=0.03). In Group 2 and 3 26% of patients did not remember receiving a SMS message that was delivered. **CONCLUSIONS:** Collecting and using PROMs data in everyday clinical practice is challenging. This small pilot study shows that adding a reminder SMS before and access to a Tablet Computer during clinic improves ePROMs collection onto a clinical outcomes web-based system. Further process improvements, such as additional staff training and telephone call reminders, might further improve uptake and a more comprehensive study is planned.

PIH43

EIGHTY-NINE LOCAL ROCHE SPONSORED FRENCH STUDIES PERFORMED IN THE PAST 10 YEARS WERE EVALUATED TO DETERMINE HOW PATIENT REPORTED OUTCOMES WERE USED

Pau D, Triglia A, Gavini F
Roche, Boulogne-Billancourt, France

OBJECTIVES: Patient Reported Outcomes (PROs) are increasingly used in clinical studies as well as requested by health authorities (EMA, FDA). This descriptive analysis aims to explore how PRO were used in the French affiliate of Roche. **METHODS:** A total of 89 local studies performed between 2003 and 2013 were evaluated to determine how PROs were collected and evaluated. **RESULTS:** Forty (45%) out of 89 studies were clinical trials, 44 (49%) were non-interventional studies (NIS) and 5 were expanded access program studies. A total of 33 (37%) studies used at least one PRO; 13 (39%) were clinical trials and 20 (61%) were NIS. There were no PRO in the field of transplantation, 21% of the studies in oncology used PRO, 47% in virology, 60% in anemia and 72% in rheumatology. More than 3600 sites participated in the 33 studies using PRO: 17424 patients were included, 14237 patients (82%) answered at least one PRO and 12314 (86%) of the questionnaires received were considered to be analyzable for statistical analysis (non analyzable PROs were usually due to missing data). The median number of questionnaires per study was 2, (range 1-6). While most studies in virology and anemia used 1 or 2 questionnaires per study, rheumatology studies used at least 3 questionnaires per study. The median study duration was 12 months, (range 1-60). While 84% of PRO were collected at inclusion in the study, 73% of PROs were received after the 6 month visit, 65% at the 12 month visit and less than 50% after 12 months. Seven studies (21%) used PRO as a primary endpoint, and the percentage of patients who answered the questionnaire answered was higher (mean 91%) than when PRO was a secondary endpoint (mean 79%). **CONCLUSIONS:** Careful consideration should be given to number of questionnaires used per study as quality decreases as number of evaluations increases.

PIH44

CONFIRMATORY FACTOR ANALYSIS AND EVALUATION OF CLINICALLY IMPORTANT DIFFERENCES IN MENOPAUSE-SPECIFIC QUALITY OF LIFE ASSOCIATED WITH BAZEDOXIFENE/CONJUGATED ESTROGENS IN A VULVAR/VAGINAL ATROPHY POPULATION

Abraham L[1], Bushmakin AG[2], Pinkerton JV[3], Cappelleri JC[2], Mirkin S[4]
[1]*Pfizer Ltd., Tadworth, Surrey, UK,* [2]*Pfizer Inc, Groton, CT, USA,* [3]*Department of Obstetrics and Gynecology, Division of Midlife Health, University of Virginia Health System, Charlottesville, VA, USA,* [4]*Pfizer Inc, Collegeville, PA, USA*

OBJECTIVES: To confirm the factor structure of the Menopause-Specific Quality of Life (MENQOL) questionnaire for a vulvar/vaginal atrophy (VVA) population by applying confirmatory factor analysis (CFA), and to determine whether improvements in health-related quality of life (HRQL) observed in a VVA population with bazedoxifene/conjugated estrogens (BZA/CE) relative to placebo can be deemed clinically relevant. **METHODS:** In a randomized control trial, postmenopausal women with ≥ 1 bothersome moderate-to-severe VVA symptom received BZA 20 mg/CE 0.45 or 0.625 mg, BZA 20mg or placebo for 12 weeks. HRQL and treatment satisfaction were evaluated using the MENQOL questionnaire and the Menopause Symptoms-Treatment Satisfaction Questionnaire (MS-TSQ), respectively. The structure of the MENQOL questionnaire was evaluated using a CFA. Clinically important differences (CID) for the MENQOL were determined using a regression model to estimate differences in domain and total scores corresponding to one category difference in MS-TSQ items, which were used as anchors. **RESULTS:** The postulated CFA model fit the MENQOL data (Bentler's Comparative Fit Index >0.9). Treatment with BZA 20 mg/CE 0.45 and 0.625 mg compared with placebo was associated with statistically significant improvements in MENQOL vasomotor and sexual functioning domains, and total score (p <0.001). BZA 20 mg/CE 0.625 mg was also associated with significant improvements in physical functioning (p=0.019). Change from baseline in MENQOL vasomotor functioning for BZA 20 mg/CE 0.625 mg over placebo was greater than the estimated CID, with BZA 20 mg/CE 0.45 mg approaching CID. Changes in total score for BZA 20 mg/CE 0.625 mg compared with placebo also approacöhed CID. Changes in MENQOL sexual functioning from baseline over placebo, while statistically significant and quite large, were less than the CID estimate. **CONCLUSIONS:** CFA modeling provides strong support for the existing factor structure of the MENQOL questionnaire. Improvements in HRQL seen with BZA/CE approached or exceeded CIDs for VMS functioning and total score.

PIH45

EXAMINATION OF PELVIC FLOOR MUSCLE FUNCTION AFTER PELVIC FLOOR MUSCLE TRAINING AND USING CUBE PESSARY

Hock M[1], Németh Z[2], Varga P[3], Ambrus E[3], Krómer A[3], Csengeri K[3], Kovács V[3], Kránicz J[1], Boncz I[1], Bódis J[1]
[1]*University of Pécs, Pécs, Hungary,* [2]*Petz Aladár Hospital, Győr, Hungary,* [3]*Zsigmondy Vilmos Harkány Spa Hospital, Harkány, Hungary*

OBJECTIVES: Follow up of pelvic floor muscle function after pelvic floor muscle training and using cube pessary, paying special attention to the changes in the strength of pelvic floor muscle and in the ability to relax. **METHODS:** To determine the degree of the changes in the strength of pelvic floor muscle and in the ability to relax, 35 patients had been contacted before provided with cube pessaries and pelvic floor muscle training. Thirty out of 35 subjects supported our study. Five subjects were excluded due to vaginitis, so finally 30 survey data were processed. Pelvic floor muscle function measurements were performed at the beginning when cube pessaries were given to the subjects and later after a 3-week period of usage. Patients were selected with the help of the non random sample method. Demographic data and gynecological history selection were based on our own general survey questionnaire, while FemiScan surface EMG was used to measure pelvic floor muscle strength and the ability to relax. Statistical analysis involved t-test or Mann-Whitney U-test, significance level was defined at p< 0.05. **RESULTS:** Although pelvic floor muscle strength showed positive changes, statistically significant changes were not detected in the surveyed group. In the analysis of survey data of the ability to relax pelvic floor muscle statistically significant difference (p=0,001) could be detected in the average results either at the beginning when cube pessaries were given to the subjects or after a 3-week period of usage. **CONCLUSIONS:** Cube pessary usage and pelvic floor muscle training may have a positive effect on pelvic floor muscle function.

PIH46
A PARENT-ADMINISTERED BUT CHILD-COMPLETED PATIENT-REPORTED OUTCOME (PRO) PROVIDES A MEASURE WITH CONTENT VALIDITY THAT IS VALID AND RELIABLE FOR USE IN CHILDREN AGED 6 TO 11 YEARS
Arbuckle R, Marshall C
Adelphi Values, Bollington, UK
OBJECTIVES: Collecting data about symptoms and health-related quality of life impacts in children aged 6-11 is particularly challenging. Children themselves do not necessarily have the reading skills or the cognitive and recall capacity to self-report on their own, but equally parents are not always with their child or may not observe them closely enough and some symptoms are not observable. To overcome these challenges we developed a parent-administered child-report symptom measure in which the parents helped the child read and understand the PRO items. **METHODS:** Iterative rounds of qualitative concept elicitation and cognitive debriefing interviews with children (aged 6-11) and parents supported the development and refinement of daily diary instructions, items and response scales. The resulting items were included in an observational study of 185 children (aged 6-11) who completed the diary at home for seven days in order to support the development of scoring and psychometric validation. Feedback on the draft scales was obtained from both children and parents following the at-home completion phase, with the parent survey and debriefing focusing on how much help they had provided to the children in regards to reading, understanding, recalling and responding during the seven days. **RESULTS:** The diary questions were developed to be completed by the child, but instructions indicated that the parent could help the child read and understand them. Observation of parents helping the child and subsequent debriefing provided evidence that parental help aided the child in recalling accurately. However, the children did push back if they disagreed with their parent's suggested response, suggesting they were not unduly influenced. Subsequent psychometric validation confirmed that this approach and the refined items provided valid, reliable and responsive scores. **CONCLUSIONS:** This PRO development provides evidence that a parent-assisted child self-report symptom measure had strong content validity and was valid, reliable and responsive to changes over time.

PIH47
PATIENT SURVEY DATA RESULTS: PREFERENCES FOR REMINDERS IN PRO STUDIES
Ross E, Ross J, Holzbaur E
Almac Clinical Technologies, Souderton, PA, USA
OBJECTIVES: To identify effective reminder strategies, survey data focused on patient preferences for reminders in Patient Reported Outcomes (PRO) studies was investigated. This presentation will share these results to provide recommendations for patient reminder strategies to optimize patient compliance and data quality. **METHODS:** A survey was completed in 2013, involving patients who participated in at least one clinical study in the past two years that required patient diaries. The survey sought to establish patient preferences (modality/timing) for receiving diary reminders based on their experiences, including an evaluation on their personal technology behaviors. **RESULTS:** Responses were provided by 405 patients. The patients stated their reasons for non-compliance of their patient diaries: 51.4% reported "non-compliance due to forgetting"; 41.1% reported "being too busy"; 27.6% reported "a lack of diary access"; and 2.7% reported "other reasons". Patients also stated their modality preferences for reminders. The preferred choice was text messages (67.2%); followed by hand-held alerts (34.3%); phone calls (34.1%); calendar alerts (32.6%); and email (6.2%). Although the majority of patients indicated checking text messages and emails daily, significantly more patients checked text messages immediately when compared to email (52.9% vs. 15.1%) suggesting that text messages would be a more effective way to remind patients. The majority of patients wanted to be reminded of their diary assessments (97.3%), appointments (95.8%), and medication dosing (95.0%). **CONCLUSIONS:** As the top reason for non-compliance was "forgetting", this suggests that reminders can be helpful in improving compliance. Results show that patients prefer to be reminded, also suggesting that reminders can improve compliance. Technology behaviors suggest that text messages could be an effective way to remind patients. Patient preferences for reminders should be given careful consideration – since incorporating optimal reminder strategies can likely improve the patient experience, compliance and data quality.

PIH48
STRUCTURAL VALIDITY OF A 14-ITEM ABRIDGED VERSION OF THE MENOPAUSE CERVANTES HEALTH-RELATED-QUALITY-OF-LIFE SCALE
Coronado P[1], Sánchez-Borrego R[2], Palacios S[3], Ruiz MA[4], Rejas J[5]
[1]*Hospital Universitario San Carlos, Madrid, Spain,* [2]*Diatros, Barcelona, Spain,* [3]*Instituto Palacios de Salud y Medicina de la Mujer, Madrid, Spain,* [4]*Autonoma University, Madrid, Spain,* [5]*Pfizer S.L.U., Alcobendas/Madrid, Spain*
OBJECTIVES: The Cervantes scale is a specific health-related-quality-of-life (HRQoL) questionnaire developed in Spanish women through and beyond menopause. The original scale contains 31-items and it is time-consuming in the routine medical practice. The aim of this work was to reduce the 31-item scale and to produce an abridged version with the same dimensional structure and similar psychometric properties. **METHODS:** A representative sample of 563 women [mean age 60 years old (SD=6.7, Min=46, Max=82)] extracted from the Ginerisk study was used. The Ginerisk was an epidemiological, cross-sectional study carried out in 4,157 Spanish post-menopausal women attending out-patient clinics of Gynecology throughout Spain in year 2011. Item analysis, internal consistency reliability, item-total and item-domain correlations and item correlation with the generic Spanish version of the MOS-SF12v2 questionnaire dimensions were initially studied. Dimensional Confirmatory Factor Analysis (CFA) and Full-model CFA were used to check structure stability. A 3-fold cross-validation method was used to obtain stable estimates, by means of multi-group analysis. **RESULTS:** The scale was reduced to a 14-items version: The Cervantes-SF, containing four main dimensions: Menopause and health, Mental health, Sexuality, and Couple Relationship, being the first dimension composed by 3 sub-dimensions: vasomotor symptoms, health, and Aging. Goodness-of-fit statistics were better than those of the extended version (chi-square/df=2.130, AGFI=0.859, PCFI=0.919, RMSEA=0.044). Internal consistency was good (Cronbach's alpha=0.830) but slightly lower than that of the original scale. Correlations between extended and reduced subscales was high and significant in all cases ($p<0.001$), ranging from r=0.857 for Aging to r=0.971 for Vasomotor symptoms. **CONCLUSIONS:** The Cervantes scale may be reduced to an abridged version of 14-item (Cervantes-SF) which maintains the original dimensional structure and psychometric properties. This version extends 45% of the original length, being faster to apply and making it specially suitable for routine medical practice.

PIH49
VALUE ATTRIBUTES OF GENERIC VERSUS BRANDED DRUGS IN SÃO PAULO, BRAZIL
Ferraz MB, Nardi EP
Universidade Federal de São Paulo, Sao Paulo, Brazil
OBJECTIVES: To assess the patients' and their accompanying family members or carers' value attributes and perceptions about GD when compared to the corresponding brand name drugs (BD). **METHODS:** A total of 25 patients and 25 accompanying persons were consecutively selected and interviewed while visiting 6 commercial pharmacies located in different regions of São Paulo city. Also 25 patients and 25 accompanying persons were consecutively selected and interviewed while waiting for their regular outpatient visits at the university outpatient clinic. The questionnaire consisted of questions regarding socio-economic, demographic and educational items, quality of life (QoL), and the interviewee perception regarding the value attributes of GD when compared to BD. The study was approved by the local ethic committee. **RESULTS:** Respondents were predominantly women (57%) and the mean age was 54 years. Additionally, 55% relied exclusively in public health care system and 55% were regularly employed. Mean QoL as assessed by SF-6D was 0,74. Respondents overwhelmingly (99%) believed GD to be cheaper than BD. Some 36% and 63% also reported GD to be less and equally effective, respectively, as compared to BD. GD were perceived as either safe or less safe than BD in 46% and 46%, respectively. Some 74% of the sample agreed with the statement that they would prefer to take a BD if there was no price difference to the GD, and 85% admitted they regularly compare the prices of BD and GD before deciding which drug to buy. **CONCLUSIONS:** Multiple factors may contribute to the decision to buy a GD. Among these perceived effectiveness, safety and price appear to be the most important factors. Further studies are needed to better understand the decision-making process regarding GD use and its consequences for the health care system and families.

PIH50
ARE ISRAELI ADULTS WILLING TO PAY HIGHER HEALTH TAXES FOR A WIDER COVERAGE OF LIFE-EXTENDING MEDICATIONS?
Greenberg D[1], Hammerman A[2], Shani A[3], Neumann PJ[4]
[1]*Ben-Gurion University of the Negev, Beer-Sheva, Israel,* [2]*Clalit Health Services Headquarters, Tel-Aviv, Israel,* [3]*Sheba Medical Center, Tel-Hashomer, Israel,* [4]*Tufts Medical Center, Boston, MA, USA*
OBJECTIVES: The Israeli National List of Health Services (NLHS) offers a generous coverage for drugs and other technologies. However, not all approved drugs are covered under the basic health insurance and are frequently subject to out-of-pocket payments. We assessed the ex-ante willingness to pay (WTP) for a more generous public coverage for life-extending medications. **METHODS:** We conducted a telephone survey among a representative sample of the adult population in Israel (n=502). We asked participants to indicate whether they will be willing to pay an increased health tax assuring that all life-extending interventions will be covered and provided by their health insurance plans with no cost-sharing. We also collected information on respondent age, gender, income, education, self-rated health and coverage of supplementary/private health insurance. **RESULTS:** Mean age of the study population was 51.7±15.9 years. 63.5% indicated that they would be willing-to-pay an increased health tax for a generous public coverage of medications. Respondents willing-to-pay were younger (49.3±15.0 vs. 55.9±16.4 years; $p<0.001$), reported a higher self-rated health ($p=0.001$), and WTP increased with respondent's income ($p=0.005$), and were also covered by a commercial health insurance ($p=0.002$). Among all respondents (WTP set at zero for those unwilling to pay) the median extra monthly WTP was in the range of 0-$7. The independent predictors for WTP identified in the logistic regression analysis were: respondent age (OR=0.974; 95% CI 0.960-0.989); and being Jewish (OR=2.997; 95% CI 1.745-5.147). **CONCLUSIONS:** Additional sources of funding should be identified and allocated to allow a more generous coverage of life-extending medications. Respondents are willing-to-pay extra health taxes (up to 7.5% of the current average health tax) to assure that all life-extending interventions are included in the NLHS at no co-payment. While these potential extra funds are sufficient to cover a wide range of technologies it is unlikely that the health tax will be raised in Israel in the near future.

PIH51
WILLINGNESS TO PAY (WTP) FOR A BRAND NAME DRUG IN SÂO PAULO, BRAZIL
Ferraz MB, Nardi EP
Universidade Federal de São Paulo, Sao Paulo, Brazil
OBJECTIVES: To assess WTP of patients and accompanying family members or carers for a brand name drug (BD) as compared to a GD for treating an acute and a chronic condition. **METHODS:** A total of 25 patients and 25 accompanying family members or carers were consecutively selected and interviewed while visiting 6 commercial pharmacies located in different regions of São Paulo city. Also another 25 patients and 25 accompanying family members or carers were consecutively selected and interviewed while waiting for their regular outpatient visits at the university outpatient clinic. A questionnaire with 2 hypothetical scenarios describing

an acute condition (acute tonsillitis in an 8 year old child) and a chronic condition (an adult with diabetes mellitus type 2) was developed. WTP for a BD as compared with a GD was assessed in both scenarios using the payment scale and the open-ended formats. The study was approved by the local ethical committee. **RESULTS:** Respondents were predominantly women (57%) and the mean age was 54 y.o. A family income of less than R$ 1.356,00 was reported by 16%. For the total study sample, the maximum WTP for a BD (over and above the mean retail price of a GD) for the acute and chronic case scenarios were on average R$ 27,54 and R$ 21,04 when measured by the payment scale and R$ 36,54 and R$ 24,77 when measured by the open-ended question, respectively. These values are 36% to 65% above the mean retail prices of the corresponding GD. **CONCLUSIONS:** Patients and accompanying persons were willing to pay considerably more for the BD when compared to GD. This may be driven by the perception of higher perceived effectiveness and safety of BD.

PROTECTIVE FACTORS FOR UNIVERSITY STUDENTS' HEALTH

ViÂšnjiÄ‡ A[1], VeliÃ„Âkovi Ã„Â V[1], SokoloviÄ‡ D[2], Ranđelović S S[3], MilovanoviÃ„Â Â M[4]
[1]*University in NiÂš, Medical Faculty, NiÂš, Serbia and Montenegro,* [2]*University in Niš, Medical Faculty, NiÂš, Serbia and Montenegro,* [3]*Viborg County Hospital, Viborg, Denmark,* [4]*Clinical Centre in NiÂš, Serbia and Montenegro*

OBJECTIVES: To assess which of the studied factors were positively associated with the students' health and to investigate which of these factors stood out as the most important protective factors for their health. **METHODS:** Data were obtained from a cross-sectional study conducted during the academic 2011/2012th at the universities in Niš, Belgrade and Novi Sad, which surveyed a total of 2285 students of both sexes. This study examines variables such as physical, psychological and social health, protective factors and risk factors. Students were assessing their own health answering the questionnaire. **RESULTS:** Only 11.8% of the surveyed students have assessed their health as excellent, 72.5% as very good or good, and 15.7% as poor or very poor. Better health status was positively correlated with the quality of sleep, the existence of free time, physical and social activities, religiosity and built health values in all three universities. Kruskal-Wallis H test showed that better students are more satisfied with their life ($p < 0.001$), that better assess their health ($p < 0.01$) and less drink alcoholic beverages. Female students had more physical pain, were more frequently depressed than men, they were more easily tired, they were much more nervous and had more problems than men with sleep. Men assessed their health as better than female students. However, the satisfaction scale ($\chi 2$ homogeneity test; $p < 0.001$) were found females to be more satisfied with their lives than male students. **CONCLUSIONS:** General health is affected by various physical, psychological and social aspects of health. The results show that there are significant protective factors for better social, psychological and general health in students that may be affected. Therefore, health promotion decision makers should adopt contemporary strategies that will in the future put emphasis on the social and psychological components of students' health.

PIH53
SOCIETAL BURDEN OF HYSTERECTOMY IN REPRODUCTIVE-AGED WOMEN WITH UTERINE FIBROIDS

Vámossy I[1], Ágh T[2], Blasszauer C[3], Bagó M[3], Mészáros Á[4], Kalo Z[5]
[1]*Gedeon Richter Plc., Budapest, Hungary,* [2]*Syreon Research Institute, Budapest, Hungary,* [3]*MedicalScan, Budapest, Hungary,* [4]*Semmelweis Univesity, Budapest, Hungary,* [5]*Eötvös Loránd University, Budapest, Hungary*

OBJECTIVES: Uterine fibroids (UF) affect approximately 20% to 40% of reproductive-aged women. The mainstay of treatment of symptomatic UF is surgical. Myomectomy surgically removes UF while preserving the uterus. However, hysterectomy that is considered to be the definitive treatment of UF, causes infertility.The aim of our study was to analyze the prevalence of hysterectomy in Hungary among reproductive-aged women with UF to assess the societal burden due to lost fertility. **METHODS:** Database were analyzed. Surgical procedures for the treatment of UF (ICD-10: D25), in 20-45 years old women between 2007 and 2012 were analyzed based on the Hungarian National Health Insurance Fund database. Economic burden of lost fertility was assessed by the human capital approach. Present value of life for a newborn child was calculated by applying 2011 GDP per capita and 3.7% discount rate. **RESULTS:** Among 11,095 women with surgical procedure related to UF the prevalence of hysterectomy was 61.5% (n=6827). Most hysterectomised women (n=4781) were 40-45 years old; unexpectedly a significant number of 20-40 years old women with UF had hysterectomy (n=2046). Present value of a newborn child was 262,314 EUR in 2011. **CONCLUSIONS:** Our results indicate that immediate hysterectomy, even in women under 40 years, is still a frequently performed surgical procedure for the treatment of UF. The macroeconomic consequences of lost fertility due to hysterectomy in reproductive-aged women with UF are significant. Even only one additional child-birth due to avoided hysterectomy would result in significant societal and economic benefits. Further scientific evaluations are needed to define more accurately the long term macroeconomic impact of preserved fertility in women with UF.

MANAGEMENT OF OBESE WOMEN DURING PREGNANCY ACROSS EUROPE ACCORDING TO CLINICAL PRACTICE GUIDELINES

Callejo D[1], Díaz-Cuervo H[1], Fernández-Ortiz L[1], Rebollo P[1], Simmons D[2], van Poppel M[3]
[1]*LASER Analytica, Oviedo, Spain,* [2]*Addenbrooke's Hospital, Cambridge, UK,* [3]*VUmc, Amsterdam, The Netherlands*

OBJECTIVES: To review, within the framework of the FP7 DALI (Vitamin D And Lifestyle Intervention for Gestational Diabetes Mellitus (GDM) Prevention) study, guidelines for the management of obese women during pregnancy across Europe to assess the specificity of the recommendations in this group at risk of adverse pregnancy outcomes. **METHODS:** To determine whether additional clinical tests, advice, planning, management or pregnancy follow-up were recommended for obese women during pregnancy,Clinical Practice Guidelines (CPGs) were collated from across the Endocrinology and Obstetrics National Societies websites of the 9 European countries participating in the FP7 DALI study (Austria, Belgium, Denmark, Ireland, Italy, The Netherlands, Poland, Spain, UK). This was complemented by a Medline search and a survey among the investigators of the DALI study. **RESULTS:** Fifteen CPG for 9 countries were retrieved. All but Spanish guidelines, which recommend O'Sullivan test, recommend OGTT 75g to detect GDM in obese women. Most of them include 24-28 weeks as the time for OGTT, but other schedules are also used, especially when risk factors other than obesity are present. Other common recommendations for obese women in European CPGs were diet advice (included in the guidelines of 6 different countries), special birth planning (5 countries), exercise and other lifestyle recommendations (4 countries) and vitamin D supplementation, multidisciplinary follow-up (including endocrinologist or diabetologist) and additional ultrasound scan (3 countries). **CONCLUSIONS:** Recommendations for obese women in the studied countries are heterogeneous and in many cases do not include actions beyond screening for GDM. Existing guidelines will be reviewed in the light of the findings from the interventions studied in the framework of the DALI study.

LONG-TERM FISCAL IMPLICATIONS OF FUNDING ASSISTED REPRODUCTIVE THERAPIES: A GENERATIONAL ACCOUNTING MODEL FOR SPAIN

Villoro R[1], González-Domínguez A[1], Pérez-Camarero S[1], Hidalgo A[2], Polanco C[3]
[1]*Instituto Max Weber, Madrid, Spain,* [2]*University of Castilla La Mancha, Toledo, Spain,* [3]*Merck, S.L, Madrid, Spain*

OBJECTIVES: Infertility affects 14% of couples in reproductive age in Spain. Progressive population ageing leads the assessment of policies that favor birth-rates. The objective is estimating the lifetime economic benefits of publicly financing assisted reproductive therapies (ART) in Spain, by calculating the return on this investment. **METHODS:** Generational accounting model that simulates the flow of taxes paid by the individual minus those direct government transfers received (e.g. health care, education, pensions) over the lifecycle of a child. The cost of ART was calculated as the average cost of conceiving a child through currently available ART in Spain. The difference between discounted transfers and taxes minus the cost of ART equals the net present value (NPV) of a child conceived by ART. Year 2006 was set as the base case because of its macroeconomic stability. A 3.5% discount rate was applied. Sensitivity analysis tested robustness of results under different scenarios. **RESULTS:** An ART-conceived child would contribute €534,624 in net taxes to the government and would receive €479,952 in governmental transfers over her lifecycle. After discounting the cost of ART (9,000€) the NPV is estimated at €45,672. Each Euro invested in subsidizing ART reverts into fiscal benefits of €5. Sensitivity analysis shows that even in extreme macroeconomic scenarios, the long-run NPV of an ART-conceived child ranges between €11,233 and €62,470. The return on investment varies between €1.25 y €6.94 € for each Euro invested in ART. The break-even age at which the financial position begins to be favorable to the Spanish Treasury was set at 34-42 years. **CONCLUSIONS:** Generational accounting models allow estimating long-term fiscal implications of public funding of ART. Each Euro invested in subsidizing ART reverts into fiscal benefits of €5. Thus, investment in ART leads to substantial discounted future fiscal revenue for the Spanish Treasury, notwithstanding its beneficial psychological effect for infertile couples.

PIH56
WOULD A NEW THERAPY FOR CHILDREN BE REFUSED IN THE CONTEXT OF THE GERMAN AMNOG?

Walzer S, Droeschel D
MArS Market Access & Pricing Strategy UG (h.b.), Weil am Rhein, Germany

OBJECTIVES: The new German law AMNOG was introduced in 2011. According to it all newly launched therapy options would need to be evaluated by the Institute for Quality and Efficiency in health care (IQWIG) and the joint federal committee (Gemeinsamer Bundesausschuss, GBA) before a final price negotiation will happen. Given the specific characteristics of pediatric patients it is uncertain if a new drug for those patients would successfully pass the AMNOG process. **METHODS:** The AMNOG evaluation criteria were applied to the specifics of pediatric drugs. A special focus was given to the benefit assessment method, clinical trial designs and the AMNOG process. **RESULTS:** Current HTA evaluation methods being applied to medical therapies, in general, need to be modified when applied to pediatric therapies. For example, traditional benefit evaluations that require randomized clinical trials are standard but cannot always be fulfilled in this patient population. In pediatric development programs one-arm studies are standard with surrogate endpoints in order to minimize the exposure of children to an experimental therapy. Additionally the naturally low sample size within pediatric indications linked to the different natural subgroups of children (babys, toddlers, etc.) make a formal additional benefit proof even harder. Hence from a benefit assessment perspective the clinical study design, sample size and choice of endpoint are most crucial but could hardly be executed in pediatric trials. With respect to the AMNOG process only pediatric trials in orphan disease could pass successfully given the exception rules for the additional benefit. **CONCLUSIONS:** If the German health care system is to secure the full benefits of potential new pediatric therapies, it will need to provide a similar process as it is granted for orphan drugs.

PIH57
HEALTH OUTCOMES OF FEMALE ANABOLIC-ANDROGENIC STEROID USERS

Noone J[1], Blanchette CM[2]
[1]*University of North Carolina at Charlotte, Charlotte, NC, USA,* [2]*University of North Carolina, Charlotte, NC, USA*

OBJECTIVES: Anabolic-Androgenic Steroids (AAS) have been used for muscle mass development for over fifty years. The health outcomes of supraphysiologic doses of AAS have been debated, but most existing information pertains to men. This purpose of the study is to use the National Longitudinal Study of Adolescent Health (AddHealth) to elucidate health outcomes of AAS usage in women. **METHODS:** A cohort study of female AAS users were assessed in two time periods six years apart. Baseline descriptive statistics were used to describe age, income, race, drug use, education, and work performed for the sample. Follow up health outcomes include diabetes, heart disease, hyperlipidemia, anger, physician visit, use of medical care in the last year, Body Mass Index (BMI), blood pressure (BP), C-reactive protein, and HbA1C. Each dependent variable was tested in independent logistic regressions and in sensitivity tests using a MANOVA. **RESULTS:** The sample included 49 female respondents. Education was associated with a two-fold greater odds of AAS use comparing those who attended vocational school to those who attended college (OR=2.22, p=.03). Anger was associated with 88% greater risk of AAS use (OR=1.88, p=.04). HbA1c in the pre-diabetic range, while not statistically significant may be associated with AAS use (OR=1.85, p=.05). No other health outcomes were identified. **CONCLUSIONS:** This study contributes to the literature of female AAS use showing little in health care usage and long term health consequences. Anger is associated with male users but little research exists pertaining to this phenomenon in women. Elevated HbA1c is not commonly associated with AAS use, but due to the small sample size more research should assess AAS use among females.

USER AND TREATMENT CHARACTERISTICS OF ORAL CONTRACEPTIVES IN THE EUROPEAN UNION

Bezemer ID[1], Verhamme KM[2], Gini R[3], Mosseveld M[2], Rijnbeek PR[2], Sturkenboom MC[2], Penning-van Beest FJA[1], Herings RMC[1]

[1]*PHARMO Institute for Drug Outcomes Research, Utrecht, The Netherlands,* [2]*EMC Rotterdam, Rotterdam, The Netherlands,* [3]*Agenzia regionale di sanità della Toscana, Firenze, Italy*

OBJECTIVES: As a basis for future safety evaluations of oral contraceptive (OC) use in Europe, current user and treatment characteristics were assessed in four European health care databases. **METHODS:** A descriptive retrospective database study was performed over 2009-2010 in GP databases from The Netherlands (IPCI), UK (THIN) and Italy (HSD) and linked pharmacy dispensing and hospital admission data from The Netherlands (PHARMO). Study follow-up started at the first OC prescription in 2009-2010 (users), one year after database entry or at Jan 1, 2009. Health indicators at start of follow-up included BMI and previous diagnosis of, or use of drugs for selected chronic conditions. Also, previous diagnoses of deep vein thrombosis, pulmonary embolism, cerebrovascular disease, myocardial infarction, breast cancer and cervical cancer were assessed. Treatment characteristics of OC included history of use, type of OC (chemical substance) used during 2009-2010 and switches or discontinuations. **RESULTS:** Among 4.9 million women, 14% had OC prescribed in 2009-2010. In The Netherlands and UK, 12-16% and in Italy 6% had a record of OC use. The prevalence of OC recorded prescription at January 1, 2010 was 81 per 1000 women of all ages and 271 per 1000 women aged 15-24, a much lower figure than what is recorded by surveys, probably due to switches between use and non-use and to reimbursement and/or prescription policies that reduce recording in GP databases. Among the non-users in 2009-2010, up to 22% had a history of OC recorded use. Little differences in health indicators were found between users and non-users in the databases where the information was available. **CONCLUSIONS:** Trends in health among European women in general also apply to OC users. However, OC use is not registered very well in health care databases which limits the possibilities of pharmacovigilance. Distribution channels and reimbursement policies vary, as well as recording in the databases.

PIH59

MEDICATION TREATMENT AND HEALTH CARE UTILIZATION FOR ATTENTION-DEFICIT/HYPERACTIVITY DISORDER (ADHD) IN GERMANY

Schlander M[1], Banaschewski T[2], Trott GE[3], Schwarz O[4]

[1]*University of Heidelberg, Wiesbaden, Germany,* [2]*University of Heidelberg, Mannheim, Germany,* [3]*University of Wuerzburg, Aschaffenburg, Germany,* [4]*Institute for Innovation & Valuation in Health Care, Wiesbaden, Germany*

OBJECTIVES: To explore health care utilization and treatment patterns for attention-deficit/hyperactivity disorder (ADHD) in Germany, with particular emphasis on psychostimulant prescriptions. **METHODS:** The complete claims database of the organization of physicians registered with statutory health insurance (SHI) in Nordbaden/Germany was available for analysis, covering the total regional population enrolled in SHI (2.24 million lives). The dataset for years 2003 to 2009 was reorganized as to allow patient-centered evaluation. For calendar year 2009, 21,287 patients with ADHD (male, 15,108; female, 6,179; including 5,931 patients or 27.9% [male, 4,582; female, 1,349] with coexisting conduct disorder [F90.1 or a combination of F90 and F91 codes according to ICD-10]) were available for analysis. **RESULTS:** Preschool children (age 0-5 years) with ADHD were prescribed medication in very rare cases (1.6% in 2009) and after an average lead time of more than one year only. Most received some form of nonpharmacological therapy or were left untreated (42%). In contrast, 41% of children (age group 6-12 years, since 2003, continuously increasing from 32%) and 54% of adolescents (age group 13-17 years, rate remaining stable since 2006) were prescribed either stimulant (methylphenidate, MPH, or amphetamine) or nonstimulant (atomoxetine) drugs. Males and patients with concomitant conduct disorder were more likely to receive medication treatment. Modified-release MPH formulations were more widely used than immediate-release MPH. Overall use of medication increased steadily, from 32.2% of ADHD patients in 2003 to 39.9% in 2009, whereas its rate decreased over time in adult patients (declining from 38% in 2003 to 26% in 2009). – Upon individual review of all prescriptions of ADHD medication for members of the control group, no evidence was found supporting potentially inappropriate use of stimulant medication. **CONCLUSIONS:** Treatment patterns were highly age and gender specific. Except for preschoolers, therapeutic management of patients with ADHD relied heavily on drug treatment.

PIH60

TRENDS IN HOSPITAL ADMISSIONS AMONG MEN AND WOMEN ABOVE THE AGE OF 60 LIVING IN STOCKHOLM AND UPPSALA COUNTIES IN SWEDEN

Karampampa K[1], Andersson T[1], Drefahl S[2], Ahlbom A[1], Modig K[1]

[1]*Karolinska Institutet, Stockholm, Sweden,* [2]*Stockholm University, Stockholm, Sweden*

OBJECTIVES: To measure the change in the risk of first, second, and third hospitalization and the change in the proportion of hospitalization-free men and women above the age of 60 living in Stockholm and Uppsala counties in Sweden between 1972 and 2010. **METHODS:** Individuals were followed in national registers for hospitalizations and deaths from all causes between 1972 and 2010. Censoring occured at whichever of the following events appeared first; hospitalization (first, second, thrid), death, or December 31, 2010. Survival analysis was used to determine the proportion of hospitalization-free individuals. Discrete time logistic regression was used to obtain the the relative risk (RR) of first, second and third hospitalization. **RESULTS:** An increase in the proportion of hospitalization-free individuals over time was observed for both men and women; for example 87% more 82 year-old men, born in 1928, were free of hospitalizations since the age of 60 compared to those born in 1912. Between the years 1972 and 2010, the average annual decrease in the risk of first hospitalization after the age of 60 was 1% for both men (RR: 0.991, 95%CI: 0.991-0.992) and women. The average annual risk for hospitalization decreased for the second and thrid event as well; however the reduction was not significant. **CONCLUSIONS:** With the increase in the proportion of elderly in the population, the number of individuals with chronic diseases may increase, leading to higher demand for medical and social care. We have observed downward trends of the risk of first, second, and third hospitalization after the age of 60, which could be explained by a postponement of severe morbidity to higher ages. Focus on primary care and changes in inpatient care in Sweden may also partly exaplain the annual reduction in the risk of hospitalization.

PIH62

DO EMA AND FDA HAVE DIFFERENT OPINIONS/REQUIREMENTS IN TERMS OF PEDIATRIC STUDIES FOR SITAGLIPTIN (ALONE OR IN COMBINATION)?

Caron M[1], Emery MP[1], Maier W[2]

[1]*Mapi Research Trust, Lyon, France,* [2]*Mapi, London, UK*

OBJECTIVES: Since the implementation of Pediatric Regulations/Legislations in the USA (Pediatric Research Equity Act - PREA) and in Europe (Pediatric Investigation Plans - PIPs), product development programs should include pediatric studies. The objective of this study is to review opinions (EMA) and requirements (FDA) given by both agencies in the case of sitagliptin (alone and combined) for the treatment of diabetes mellitus in children. **METHODS:** The EMA and FDA websites were explored to: 1) Identify the products marketed under the INN of sitagliptin (alone or in combination), and 2) Identify the associated PIPs or PREA requirements. The search was performed on January 18, 2013. **RESULTS:** Eight products were marketed in Europe [i.e., sitagliptin (Januvia, Ristaben, Tesavel, Xelvia) and sitagliptin + metformin (Janumet, Efficib, Ristfor, Velmetia)]. Four products were authorized in the USA [i.e., sitagliptin (Januvia); sitagliptin + metformin (Janumet, Janumet XR); sitagliptin + simvastatin (Juvisync)]. The FDA and the EMA provided the same opinion for sitagliptin alone, i.e., deferred pediatric study for patients aged 11 to 16. The FDA and the EMA disagreed on sitagliptin + metformin. The EMA granted a waiver for all subsets of the pediatric population on the grounds that the specific medicinal product does not represent a significant therapeutic benefit over existing treatments, while the FDA required a pediatric study under PREA for the treatment of type 2 diabetes in pediatric patients aged 11 to 16. As for sitagliptin + simvastatin, the FDA grants a waiver on the grounds that the product does not represent a meaningful therapeutic benefit over existing therapies for pediatric patients. **CONCLUSIONS:** The FDA and the EMA have similar opinions except for the combination sitagliptin + metformin. One reason could be the higher prevalence of type 2 diabetes mellitus in children in the USA as compared to Europe.

INFECTION – Clinical Outcomes Studies

THE GEOGRAPHIC CORRELATION BETWEEN LYME DISEASE INCIDENCE AND DEGENERATIVE NEUROLOGICAL DISEASE MORTALITY: AN ECOLOGICAL STUDY

Veley KM, Malka ES

PPD, Morrisville, NC, USA

OBJECTIVES: The objective of the present study was to assess the geographic correlation between the incidence of Lyme disease (LD) and mortality due to certain degenerative neurologic diseases (DND) in the US. **METHODS:** For this ecological study, public data sources at the CDC were queried to quantify LD cases and DND deaths for the 5-year period 2002-2006. Alzheimer's disease, Parkinson's disease, and motor neuron disease were preselected as DND of interest. The separate datasets, for LD and DND, were combined by matching county and state names. Counties with at least 1 case of LD and at least 10 deaths due to DND were included in analyses. All analyses were performed in SAS. **RESULTS:** Of the 3141 counties of the US, 1372 reported at least 1 case of LD, 2742 reported at least 10 deaths due to DND, and 1339 met both conditions and were therefore included in analyses. The observed number of LD cases and DND deaths for a single county ranged from 1-6407 (mean: 78; median: 3) and 10-9207 (mean: 165; median: 55), respectively. The Spearman rank test indicated that there is a fair degree of correlation between LD incidence and DND mortality ($r=0.44$, $p<0.0001$). In sensitivity analyses, (1) excluding outliers, defined as observations $\geq 99^{th}$ percentile (LD>53; DND>1255), and (2) evaluating each disease separately, the correlation remained similar in magnitude and statistically significant (coefficient: 0.32-0.41; $p<0.0001$). **CONCLUSIONS:** There is a fair degree of correlation between LD incidence and DND mortality: US counties with a higher number of LD cases tend to have a higher number of

deaths due to DND. This study is limited by its ecological nature and more rigorous epidemiologic research is needed to elucidate the association between LD and DND.

PIN2

IMPACT OF HIGHLY ACTIVE ANTIRETROVIRAL THERAPY (HAART) REGIMEN ON ADHERENCE AND RISK OF HOSPITALIZATION IN VETERANS WITH HIV/AIDS

Rao GA[1], Sutton SS[1], Hardin J[2], Bennett C[2], Bramley T[3], D'Souza AO[3]
[1]*WJB Dorn VA Medical Center, Columbia, SC, USA,* [2]*University of South Carolina, Columbia, SC, USA,* [3]*Xcenda, Palm Harbor, FL, USA*

OBJECTIVES: High pill burden has been associated with poor adherence to HAART and adverse clinical outcomes. This study evaluated the impact of HAART as a single-tablet regimen (STR) and multiple-tablet regimen (MTR) on outcomes in HIV patients within the Veteran's Affairs (VA) system. **METHODS:** A retrospective, cohort study assessed patient VA dispensation data for HIV medications during the study enrollment period (7/1/2006 to 9/30/2011). Patients were assigned to the following cohorts: STR if they received a HAART regimen of a single tablet/day or MTR if they received a regimen of ≥2 tablets/day and no single tablet/day regimen during the enrollment period. Patients were followed from the index date (start of HAART regimen) until the earliest of treatment discontinuation, end of study period, or last date of health care-related activity (eg, VA benefits file or death). Hospitalization and adherence (medication possession ratio [MPR] ≥95%) were evaluated. Multivariate cohort differences in outcomes were controlled for using Cox-proportional hazard and logistic models; covariates were measured during a 6-month baseline period. **RESULTS:** In all, 15,602 patients (STR, n=6,191; MTR, n=9,411) met study criteria; average age of the study sample was 52 years. Both cohorts had similar CD4 counts (mean [SD]: 432.2 [282.8] vs 419.3 [280.9]; P=0.287) but significantly fewer patients receiving STR vs MTR had an undetectable viral load at baseline (42% vs 46%, P<0.001). During follow-up, significantly more STR patients were adherent compared to MTR patients (75% vs 55.7%, P<0.001). STR patients were also significantly less likely to experience hospitalization compared to MTR patients (26.8% vs 31.3%, P<0.001). After controlling for baseline covariates, STR patients had twice the odds of being adherent (OR: 1.98, P<0.001) and 31% lower hazard of experiencing hospitalization during follow-up (HR: 0.69, P<0.001). **CONCLUSIONS:** Treatment with STR compared to MTR improves adherence rates and decreases hospitalizations in patients with HIV/AIDS.

PIN3

A DECISION ANALYTIC MARKOV MODEL TO EVALUATE THE HEALTH OUTCOMES OF SOFOSBUVIR FOR PREVIOUSLY UNTREATED PATIENTS AND THOSE WITHOUT TREATMENT OPTIONS WITH CHRONIC HEPATITIS C VIRUS GENOTYPE 2 INFECTION

Younossi ZM[1], Gordon S[2], Saab S[3], Ahmed A[4], Cure S[5], Guerra I[5]
[1]*Inova Fairfax Hospital, Falls Church, VA, USA,* [2]*Henry Ford Hospital, Detroit, MI, USA,* [3]*David Geffen School of Medicine at UCLA, Los Angeles, CA, USA,* [4]*Stanford University, Stanford, CA, USA,* [5]*OptumInsight, Uxbridge, UK*

OBJECTIVES: Sofosbuvir (SOF) is a nucleotide polymerase inhibitor with excellent clinical efficacy in combination with ribavirin (RBV) for 12 weeks for patients who are chronically infected with hepatitis C virus (HCV) genotype 2. A decision-analytic Markov model evaluated the health outcomes of SOF+RBV compared with current treatment options for patients who are previously untreated, had no response to prior interferon treatment, or are unable to take interferon. **METHODS:** The analysis modeled 3 cohorts of chronic HCV genotype 2 patients with an average age of 50 and 25% with cirrhosis at the start of treatment followed-up to 100 years of age from a US third-party payer perspective. SOF+RBV for 12 weeks was compared with 1) pegylated interferon (PegIFN)+RBV for 24 weeks in the treatment-naïve patients; 2) PegIFN+RBV for 48 weeks in the treatment-experienced; and 3) no treatment in those unable to take interferon. Sustained virologic response (SVR) and adverse event rates were based on phase III clinical trials. Transition probability, utility, and cost estimates (in 2013 US dollars) were based on a literature review, public sources, and consensus by a panel of 4 hepatologists. **RESULTS:** In the treatment-naïve cohort, the SOF+RBV regimen resulted in an 83% decrease in the cases of liver disease complications including hepatocellular carcinoma, decompensated cirrhosis, liver transplant, and HCV-related death compared with PegIFN+RBV. The reduction of the listed liver disease sequelae was 59% in the treatment-experienced vs. PegIFN+RBV and 93% in the interferon-unable cohort vs. no treatment. The number needed to treat (NNT) with SOF+RBV rather than PegIFN+RBV to achieve one additional SVR was 6 in the treatment-naïve and 4 in the treatment-experienced cohorts. **CONCLUSIONS:** SOF+RBV was projected to yield better health outcomes in genotype 2 patients compared to PegIFN+RBV, largely driven by superior efficacy, and the potential to cure those who are unable to take interferon-based therapies.

PIN4

THE RELATIVE EFFICACY AND SAFETY OF SIMEPREVIR AND TELAPREVIR IN TREATMENT-NAÏVE HEPATITIS C INFECTED PATIENTS IN A JAPANESE POPULATION – A BAYESIAN NETWORK META-ANALYSIS

Bryden PA[1], Quigley J[1], Scott DA[1], Kuwabara H[2], Cerri K[3]
[1]*Oxford Outcomes Ltd., Oxford, UK,* [2]*Janssen Pharmaceutical KK, Tokyo, Japan,* [3]*Janssen Pharmaceutical NV, Beerse, Belgium*

OBJECTIVES: Simeprevir (SMV) is an oral, once-daily potent protease inhibitor for the treatment of chronic Hepatitis C genotype-1 infection (cHCV). In phase IIb/III RCTs conducted in Japan, SMV, in combination with peginterferon-α and ribavirin (PegIFN/RBV), demonstrated potent efficacy in cHCV genotype 1-infected patients relative to PegIFN/RBV and was generally safe and well-tolerated. Telaprevir (TVR) in combination with PegIFN/RBV is licensed for the treatment of cHCV in Japan. In the absence of head-to-head comparisons of TVR and SMV, we undertook a network meta-analysis (NMA) to examine the relative efficacy and safety of SMV and TVR in combination with PegIFN/RBV in a Japanese population. **METHODS:** A systematic review identified RCTs in Japanese treatment-naive patients with the above treatments and with the following endpoints: Sustained Virological Response (SVR), discontinuation of all medications (overall/due to Adverse Events (AE)), and incidence of anemia, rash (all grades) and pruritus-common adverse events of cHCV treatment. A Bayesian NMA was performed for all endpoints, assuming fixed study effects. Unpublished SMV studies meeting the inclusion criteria were obtained. **RESULTS:** Three studies met the inclusion criteria: 2 phase III RCTs (SMV n=183; TVR n=189), and 1 SMV phase IIb RCT (n=92). Baseline characteristics were generally comparable for all studies. SMV shows a higher odds ratio (OR) of achieving SVR versus TVR (OR 1.68 (0.66-4.26)). SMV shows a lower OR of discontinuation: overall 0.35 (0.12-1.00) and due to AEs 0.87 (0.23-3.34) versus TVR. SMV shows a lower OR of experiencing anemia 0.20 (0.07-0.56) and rash 0.42 (0.17-0.99) but a higher OR of experiencing pruritus 1.26 (0.46-3.47) versus TVR. The main limitation of this study is the small number of trials included in the analysis. **CONCLUSIONS:** In this indirect comparison, SMV, in combination with PegIFN/RBV, showed a favourable risk-benefit profile compared to TVR with PegIFN/RBV in Japanese treatment-naïve Hepatitis C infected patients.

PIN5

PUBLIC HEALTH IMPACTS OF PROBIOTICS IN CONTROLLING UPPER RESPIRATORY TRACT INFECTIONS IN FRANCE

Gerlier L[1], Lenoir-Wijnkoop I[2], Berdeaux G[1]
[1]*IMS Health HEOR, Vilvoorde, Belgium,* [2]*Utrecht University, Utrecht, The Netherlands*

OBJECTIVES: Two meta-analyses (York Health Economics Consortium [YHEC]; Cochrane) reported the beneficial effects of probiotics (live microorganisms which when administered in adequate amount confer a health benefit on the host). They demonstrated efficacy at reducing the duration and number of upper respiratory tract infections (URTI) and antibiotics use. The purchase of probiotics by consumers is likely to have positive externalities to the national health system and society. The aim of this analysis was to estimate the public health consequences of probiotics consumption, in France. **METHODS:** A 1/1,000 virtual age and gender standardized population was generated using a Markov model (TreeAge 2009). URTI risk factors were age, active/passive smoking, living in the community. Influenza like illness (ILI) and flu daily incidence rates came from Sentinelles, a practitioner network aimed at identifying flu outbreak. Epidemiologic data were used to differentiate cold, ILI and flu. One-day cycles were used over the 2011-2012 flu season. Probiotics effects came from two meta-analyses. Outcomes included numbers of URTIs days and episodes, antibiotics courses and sick leave days avoided with probiotics. **RESULTS:** According to YHEC data, probiotics reduced URTI episodes (average 7 days) by -0.77 days [-1.5;-0.04]. Extrapolating these results to the French population, probiotics would save 2.85 million URTI-days, the number of antibiotic courses would drop from 1,004,000 to 674,000 (difference about -330,000) and the number of sick leave days avoided in adults would be 653,000. According to Cochrane data, probiotics would reduce the probability to have an URTI episode by 0.58 [0.36;0.92] and antibiotic prescription by 0.67 [0.45;0.98]. The probiotic impact would become larger in terms of URTI-days avoided (-7.1 million), antibiotic courses (-509,000) and workdays lost (-1.2 million). **CONCLUSIONS:** The probiotics public health impact on URTI is significant at a national level even though this analysis was restricted to the 1% of patients visiting a practitioner.

PIN6

LONG-TERM OUTCOMES OF CHRONIC HEPATITIS C IN THE POPULATION OF NEWLY DIAGNOSED RUSSIAN PATIENTS

Ryazhenov VV, Sboyeva SG, Emchenko IV
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To predict the future incidence of chronic hepatitis C in Russia and assess potential impact of the available antiviral therapies (pegylated interferon a-2a/a-2b or standard interferon a-2b combined with ribavirin) on long-term morbidity and mortality rates in the population of newly diagnosed Russian patients with chronic hepatitis C. **METHODS:** Based on the national epidemiologic data and published natural history studies, the prognostic Markov model was developed. Depending on the results of antiviral therapy, patients' flows over 25-year time frame were simulated. End points of interests included: the incidence of compensated and decompensated cirrhosis, hepatocellular carcinoma and cumulative time that patients will spend in each state, the number of patients, who will require liver transplantation, and HCV-related mortality rates. **RESULTS:** During years 2013-2017 about 276,000 new cases of chronic hepatitis C will be diagnosed in Russia. After 25 years since being diagnosed 130, 189 and 227 of 1,000 patients received pegylated interferon a-2a, pegylated interferon a-2b and standard interferon a-2b, respectively, will develop compensated cirrhosis. The cumulative time that patients will spend in compensated cirrhosis state will be 848, 1,218 and 1,482 patient-years, respectively. During the established time frame, there will be expected 25, 36 and 43 cases of hepatocellular carcinoma and 35, 51 and 62 HCV-related deaths. 28, 40 and 49 patients, respectively, will require liver transplantation. **CONCLUSIONS:** The findings from the present study provide the opportunity to plan volumes of medical care that will be required to Russian patients with chronic hepatitis C during 25 years since disease was first diagnosed. The treatment with pegylated interferon alfa-2a is considered the most preferable strategy due to considerably lower long-term morbidity and mortality rates as compared to pegylated interferon a-2b and standard interferon a-2b treatment.

[8]IFS, Interdisziplinaeres Facharztzentrum Sachsenhausen, Frankfurt/M, Germany, [9]Center of Gastroenterology, Bonn, Germany, [10]Center of Gastroenterology, Dortmund, Germany, [11]Center of Gastroenterology, Herne, Germany, [12]Factum – company for statistics, scientific information and communication mbH, Offenbach/Main, Germany, [13]Roche Pharma AG, Grenzach-Wyhlen, Germany

OBJECTIVES: Estimates assume that 400,000 to 500,000 people are chronically infected with Hepatitis C in Germany. About 27% of end-stage liver cirrhosis and 25% of hepatocellular carcinoma are associated with HCV. The economic relevance of hepatitis C results from high costs for antiviral treatment as well as accompanying and secondary diseases. The aim of the study was to gain information on epidemiological characteristics, treatment outcomes and costs. **METHODS:** Underlying data were collected in a non-interventional trial between 2008 and 2011. Inclusion criteria were a confirmed HCV diagnosis and need for antiviral treatment. Besides sociodemographic and clinical parameters, HCV related resource utilization was gathered for a subgroup of patients. Data presented are mean values. **RESULTS:** Data on 7,637 patients receiving antiviral treatment with peginterferon-α-2a and ribavirin were collected. This analysis relates on 3,708 patients without HIV coinfection and/or drug substitution treatment. Mean age was 43.7 years, 60.3% were male. Most patients had a genotype-1 (61.3%) or genotype-3 infection (28.5%). The majority of patients was treatment-naïve (86.5%), 7.3% were relapser and 5.6% non-responder. Main sources of infection were injection drug use (34.8%) and blood products (14.2%). Mean duration of infection was 13.6 years. In average 48.9% of treatment-naïve GT-1(4-6) and 63.0% of GT-2/3 patients achieved SVR. For prior relapse patients and non-responder SVR-rates were: GT-1(4-6): 35.4%; GT-2/3: 58.5 and GT-1(4-6): 23.3% GT-2/3: 37.9%, respectively. Costs for antiviral treatment amount for €20,889 in GT-1(4-6) patients and €13,610 in GT-2/3 patients. Costs for the management of adverse events or HCV-related diseases sum up for €11.70. Ambulatory care, diagnostics procedures and hospital care amount for a small proportion of total costs. **CONCLUSIONS:** This study provides an overview on epidemiologic characteristics, treatment outcomes and treating costs in routine care. Treatment of HCV is costly and mainly affected by length of antiviral therapy.

PIN8

ESTIMATION OF THE NUMBER OF CASES OF NOSOCOMIAL SKIN AND SOFT TISSUE INFECTION IN ADULTS CAUSED BY GRAM-POSITIVE BACTERIA IN PUBLIC HOSPITALS IN MEXICO

Gryzbowski E[1], Peniche-Otero G[1], Herrera-Rojas J[1], Huicochea-Bartelt JL[2], Muciño-Ortega E[2], Bolaños-Cornejo D[1]

[1]Customized Premium Products S.A. de C.V., Mexico City, Mexico, [2]Pfizer S.A. de C.V., Ciudad de México, Mexico

OBJECTIVES: To estimate the number of cases of nosocomial skin and soft tissue infection (SSTIs) in adults caused by Gram-positive bacteria (GPB) in public hospitals in Mexico. **METHODS:** The total number of hospital discharges in patients ≥18 years were extracted from databases of the National Health Information System. A rate of 5.97 cases of nosocomial infection (NI) per 100 discharges (issued by Instituto Mexicano del Seguro Social between 2011 and 2012) was applied. Through a systematic literature review and critical reading of studies developed under the Mexican setting (using the Critical Appraisal Skills Programme guidelines), we assessed the type of infection and determined the proportions of: microbiological culture obtained and microbiological culture giving positive isolates. In the last stage, microorganisms were classified according to their Gram staining characteristics. **RESULTS:** In the year 2011 there were 5,517,139 discharges from public hospital, inferring 329,373 cases of NI rate (16.9% under 18 years and 83.1% in adults). We estimated that SSTIs represents 33.2% of NI (42,430 cases), of these, a microbiological culture was obtained only in 63.0% of the cases (26,731) and pathogen were isolated in 87.0% of microbiological cultures (23,256), among these, GPB was identified in 44.2%. According to our estimates a conservative number of cases of nosocomial SSTIs in adults caused by GPB in 2011 was 10,279 and the pathogens reported were *Staphylococcus aureus* (71.1%), *Enterococcus spp* (14.2%), and others (14.6%). **CONCLUSIONS:** Although we found high heterogeneity in NI reports which may decrease the quality of the estimates presented in this research, in our opinion these results could help clinicians in the choice of initial antibiotics in order to reduce the probability of failure due emergence of resistant organisms.

PIN9

EFFECT OF ANTIVIRAL TREATMENT RATES ON THE PREDICTED FUTURE BURDEN OF GENOTYPE-1 CHRONIC HEPATITIS C IN THE UNITED KINGDOM

Westerhout KY[1], Treur M[1], Cerri K[2]

[1]Pharmerit International, Rotterdam, The Netherlands, [2]Janssen Pharmaceutical NV, Beerse, Belgium

OBJECTIVES: Chronic hepatitis C (CHC) treatment aims to prevent end-stage liver disease (ESLD) through sustained viral response (SVR). Treatment rates differ significantly across Europe (<1-16%). New protease-inhibitor based therapy offers an opportunity for increased SVR rates versus pegylated-interferon/ribavirin (>70% vs. 50%). The analysis estimates the impact of various treatment rates on future ESLD sequelae associated with genotype-1 CHC in the UK. **METHODS:** A Markov model was applied to estimate disease progression of a cohort of genotype-1 CHC patients over a 20-year time horizon. Endpoints included the following ESLD states: decompensated cirrhosis (DCC), hepatocellular carcinoma (HCC), liver transplantation (LT) and liver-related death (LrD). Model structure, progression rates, CHC prevalence and disease severity at baseline were based on published economic evaluations. The number of ESLD cases averted by a 1-year increase in the current UK treatment rate (3%) to 12% and 16% was estimated for a 71.5% and 50.0% SVR rate. **RESULTS:** Applying a 3% treatment rate and 71.5%/50.0% SVR rate predicted 8590/8647 cumulative DCC and 3577/3595 HCC cases, 814/820 LTs and 7613/7659 LrDs. The number of ESLD cases averted by applying a 12% treatment rate was estimated to be 565/395 DCC and 180/126 HCC cases, 51/36 LTs and 453/317 LrDs. Increasing treatment rate to 16% showed a decrease of 816/571 DCC and 260/182 HCC cases, 74/52 LTs and 655/458 LrDs. The overall reduction in ESLD cases was estimated to be -6.1%/-4.2% and -8.8%/-6.1% in both scenarios respectively. **CONCLUSIONS:** A 1-year increase in treatment rate was predicted to reduce the burden of genotype-1 CHC in 20 years in the UK. Different treatment rates across Europe imply unequal opportunities for patients to prevent CHC sequelae. Identifying CHC patients and offering antiviral therapy to maximise SVR could prevent substantial further severe liver disease and mortality.

PIN10

RECENT TRENDS IN INCIDENCE AND DEMOGRAPHICS OF PEDIATRIC MENINGOCOCCAL DISEASE IN THE UNITED STATES

Davis KL, Candrilli SD

RTI Health Solutions, Research Triangle Park, NC, USA

OBJECTIVES: Approximately 1,000-1,200 people in the United States (US) develop meningococcal disease (MD) each year. MD is a life-threatening bacterial infection most common in infants (age <1 year), adolescents, and persons living in close quarters. We estimated annual incidence and demographic characteristics of MD in the US pediatric population from 2000 to 2009. **METHODS:** Data for pediatric (age ≤20 years) MD-related hospitalizations (discharges with ICD-9-CM 036.xx) from the 2000, 2003, 2006, and 2009 HCUP Kids' Inpatient Databases (KID) were retrospectively analyzed. Annual MD incidence per 100,000 pediatrics (adjusted to 2010 US population) was estimated using KID sampling weights and year-specific population denominators from US census data. **RESULTS:** Pediatric MD incidence steadily decreased from 1.9/100,000 in 2000 to 0.7/100,000 in 2009, a 63% decline. Incidence was highest, by far, in infants, which also decreased during 2000-2009 (7.6/100,000 to 3.8/100,000, a 50% decline). Among children aged 1-4 years, incidence fell from 2.7/100,000 to 0.8/100,000 during this period, a 70% decline. In children aged 5-10 years, we observed a 75% decline (1.2/100,000 to 0.3/100,000); similar incidence and trends were seen for age groups 11-18 and 19-20 years. Pediatric MD cases were predominantly male, with male representation increasing from 55% to 61% of cases during 2000-2009. The racial composition of pediatric MD shifted somewhat during this period, with representation declining among whites (from 56% to 45% of cases) and increasing among blacks (from 8% to 11% of cases). Geographic distribution remained fairly constant, with highest representation from the South (~30% of cases) and West (~30% of cases). **CONCLUSIONS:** Pediatric MD incidence declined during the 2000's, possibly due to the introduction of the meningococcal conjugate vaccine in 2005. However, MD incidence remained substantially higher in infants compared with other age groups and there appeared to be a demographic shift in cases away from females and whites.

PIN11

THE GLOBAL BURDEN, INCIDENCE, AND PREVALENCE OF CHRONIC HEPATITIS C

Ainsworth CM[1], Kiri S[2], Ling CS[1], Heyes AE[1], Hass B[3]

[1]RTI Health Solutions, Manchester, UK, [2]Boehringer Ingelheim Ltd., Bracknell, UK, [3]Boehringer Ingelheim GmbH, Ingelheim, Germany

OBJECTIVES: To identify and understand hepatitis C virus (HCV) prevalence and mortality rates, disease course, and the availability of data on patient and viral characteristics that may affect treatment and outcomes. **METHODS:** A targeted review was undertaken in MEDLINE, using a predefined search strategy, to identify studies describing HCV burden. Additional searches were performed on the ISPOR conference and key epidemiological websites. **RESULTS:** A total of 1,773 references were identified. Results indicated that global HCV prevalence increased from 2.3% to 2.8% between 1990 and 2005, with highest prevalence in East Asia (> 3.5%). HCV screening programmes and mandatory reporting are present in only a few countries, so prevalence is likely to be even greater. In 2010, there were estimated to be 499,000 deaths globally related to HCV, making HCV-related complications the 25th most common cause of death and a significant global health problem. The prevalence of HCV genotypes varies geographically. Genotype 1 is most prevalent in North and South America, Europe, and the Asia-Pacific region (~45%-80%). Genotype 3 is most prevalent in South Asia (Pakistan, India, and Thailand) (~52%-80%); genotype 4 is most prevalent in the Middle East (~60%-92%). There is a lack of data for the majority of African and some Middle Eastern countries. Genotype 1 is associated with increased insulin resistance, worse response to therapy, and higher risk of developing cirrhosis and hepatocellular carcinoma. Genotype 3 is associated with increased steatosis (up to 73% of patients vs. 51% in patients with other genotypes) and fibrosis. **CONCLUSIONS:** In light of upcoming treatment alternatives, detailed epidemiological studies will help ascertain more accurately the prevalence of each HCV genotype, so that the true burden of HCV can be understood and treatments targeted appropriately.

PIN12

BURDEN OF VARICELLA IN EASTERN EUROPE: A SYSTEMATIC REVIEW AND CRITICAL ANALYSIS

Yang HK[1], Song KM[1], Manoff S[2], Liaw KL[2], Kuter B[1]

[1]Merck & Co, Inc., West Point, PA, USA, [2]Merck & Co, Inc., Upper Gwynedd, PA, USA

OBJECTIVES: Varicella is a common and vaccine-preventable disease, but its impact on public health in Eastern Europe (EE) has received little attention. This study aimed to review the epidemiology and economic burden of varicella in EE. **METHODS:** A systematic literature review was conducted in PubMed and government websites to identify published data on epidemiology and economic burden of varicella in EE. Extracted study data included varicella incidence, complications, mortality, vaccination program availability and coverage rates, as well as health care resource utilization and medical costs associated with varicella. Critical analyses of study quality and data gaps were analyzed at the country level. **RESULTS:** Published varicella data were identified from fourteen countries including Bosnia Herzegovina, Bulgaria, Croatia, Czech Republic, Estonia, Hungary, Latvia, Lithuania, Poland, Romania, Russia, Serbia, Slovakia, and Slovenia. Only Latvia has a universal varicella vaccination program, while the remaining countries either only recommend

varicella vaccination for high-risk individuals or have no recommendations. The annual incidence of varicella in EE ranged from 164 per 100,000 in Latvia to 481 per 100,000 in Poland. Hospitalization rates associated with varicella ranged from 1 per 1,000 cases in Estonia to 30 per 1,000 cases in Latvia. Frequent complications among hospitalized patients included respiratory, skin, hematologic, and neurologic complications. Mortality rates ranged from 0-20 per 100,000 cases in Poland, Serbia, and Slovenia. Varicella incidence peaked in winter in Poland and Slovenia. No data on direct and indirect costs of varicella in EE was available. Overall, Poland and Slovenia had the most data on burden of varicella while limited data existed for the remaining countries. **CONCLUSIONS:** Epidemiologic and economic burden of varicella in EE have not been extensively studied. Given limited varicella vaccination policy in this region, gaps in evidence need to be addressed to inform policy makers about the public health impact on varicella.

PIN13

PREVELANCE OF HYDETED DISEASE IN SUGICALY OPERATED PATIENT IN SOME LIBYAN GENERAL HOSPITAL

Hadida E

NCDC, Tripoli Libya, Tripoli, Libya

OBJECTIVES: Determine the prevalence of HD in cases referred to surgical wards in four hospitals in east part of Libya during period from 2004 to 2009. **METHODS:** Data was collected from four hospitals; Tripoli medical centre, central Hospital, Alzawia hospital and Gharian general hospital. Hospital data of, patients diagnosed as HD were collected from surgical departments. **RESULTS:** Out of 94,142 files were reviewed from four Hospitals there were 401(0.42%) confirmed cases of Hydatid disease. Among these medical records there were 233(58.1%) from Tripoli Medical Centre, 144(35.9%) from Centre Tripoli Hospital, 16(4%) from Al Zawiyah Hospital and 8(2%) from Gharyan Hospital. The gender distributions were 41.4% males and 58.6% females. Young adult ages between 15-30 were most commonly infected (35%). Liver and lungs was most common site of infection (81.1% and 13.5% of cases, respectively) Spleen was (2.0%). Cysts were found in sites like Pancreas, Ovary and kidney were (3.4 %) **CONCLUSIONS:** Hydatid disease is a Health problem affecting young Libyan population. The mean age of the patients was (2-40) years and more common in women) housewives) and students, the most common site of HD found in liver followed by lungs. Further studies are required to find the etiologic factors of HD in different areas in Libya.

PIN14

PREDICTOR FACTORS FOR THE PRESENCE OF POST HERPETIC NEURALGIA AT 3 MONTHS IN HERPES ZOSTER PATIENTS AGED 50 AND OVER IN ITALY: RESULTS FROM A GP-BASED OBSERVATIONAL PROSPECTIVE MULTICENTER STUDY

Bricout H[1], Perinetti E[2], Marchettini P[3], Ragni P[4], Zotti C[5], Gabutti G[6], Volpi A[7], Franco E[8]

[1]*Sanofi Pasteur MSD, Lyon, France,* [2]*Sanofi Pasteur MSD, Roma, Italy,* [3]*ISTITUTO SAN RAFFAELE DI MILANO E SCUOLA UNIVERSITARIA DELLA SVIZZERA ITALIANA, Milan, Italy,* [4]*DIR. SANITARIA ASL REGGIO EMILIA, Reggio Emilia, Italy,* [5]*UNIVERSITA' DEGLI STUDI DI TORINO, Turin, Italy,* [6]*Hygiene and Public Health, Chiavari (Genova), Italy,* [7]*Università di Roma Tor Vergata, Roma, Italy,* [8]*UNIVERSITA' DEGLI STUDI DI ROMA TOR VERGATA, Roma, Italy*

OBJECTIVES: To identify predictors for the presence of Post Herpetic Neuralgia (PHN) at 3 months in Herpes Zoster (HZ) patients aged 50 and over in Italy. **METHODS:** General Practitioners (GPs) from regions throughout Italy included immunocompetent patients over 50 years old with a new HZ diagnosis and followed them during 6 months with visits (V) at 0, 1, 3 and 6 months. Occurrence and level of pain using a 0 to 10 visual analogic scale (VAS), clinical symptoms, patients' quality of life (QoL) and their health care resources utilization were recorded. A multivariate regression model was run to assess the predictor factors for the presence of PHN at 3 months. Univariate analysis was first undertaken on each variable to identify possible associations with PHN (level of significance, 25%) to be considered in the multivariate regression model. **RESULTS:** From March 2009 to July 2010, 108 GPs included 413 patients (148 Males and 265 Females) with HZ aged 67.9 y± 10.7 years. Most of them (89.6%) had pain at V0 (VAS score:5.8/10) and 91.5% received systemic antivirals, 70% within 72 hours after rash onset. During the follow-up, 52 patients consulted at least one specialist (dermatologist, neurologist, ophthalmologist…) and no cases were hospitalized. At 3 month, 20.6% presented PHN (VAS score: 3.7/10), and still 9.2% at 6 months (VAS score: 3.7/10). By logistic regression analysis a VAS score over 3, the presence of more than 50 vesicles and the gender male were the main predictive factors at the initial visit that were significantly associated with the presence of PHN at 3 months. **CONCLUSIONS:** Even if most of patients with HZ received the standard of care, many experienced intense and long-lasting pain. This study identified specific factors at presentation that could help identify patients who will develop PHN.

OBJECTIVES: The current study has been designed to investigate risk factors influencing the viral transmission and development of HPV infections within the Italian population. **METHODS:** A standardized and computer-guided questionnaire was administered to male and female patients with a HPV-induced pathology (e.g. atypical squamous cells of undetermined significance, cervical intraepithelial neoplasia, cervical cancer, anal-colorectal cancer, head-neck cancer and anogenital warts). Six clinical centres across Italy participated in this multicentre study. The patients' risk profile was assessed and compared to that of a control group of healthy subjects attending the same clinics. The effects of risk factors were evaluated using a backwards stepwise multivariate logistic regression model with covariate adjustment. The following predictors were included: level of education, occupation, age at first intercourse, number of sexual partners, smoking, previous sexually transmitted diseases, age at first pap smear, pap smear frequency, use of oral contraceptives and the number of pregnancies. **RESULTS:** Overall, 600 respondents were eligible for the analysis, consisting of 465 patients (44.0±16.3 years) and 135 controls (44.0±13.2 years). More than 5 sexual partners increased the risk of acquiring HPV infections up to 2.52-fold (95%CI: 1.34-4.74), while smoking or an early sexual debut (≤ 18 years) raised it by about a factor of 1.62. Higher levels of education were associated with a protective effect. The overall rate of individuals at high risk with more than 5 sexual partners and at least another additional factor corresponded to 26.3% (158 out of 600). The proportion of subjects with an average risk (respondents with less than 5 partners and at least another additional factor) amounted to 53.2% (319 out of 600). **CONCLUSIONS:** Analysis of risk factors can be used as part of the economic assessment of other effective HPV vaccination strategies, including an immunization programme for pre-adolescents of both sexes in Italy.

A STUDY OF A. BAUMANNII IN A TERTIARY CARE HOSPITAL WITH CONSIDERATION TO RISK FACTORS OF INFECTION AND RESISTANCE PATTERN

Sudhapalli V[1], Kanad D[1], Vilakkathala R[2], Mallayasamy SR[2], Mukhopadhyay C[3], Varma M[4]

[1]*Manipal College of Pharmaceutical Sciences, Manipal University, Manipal, Karnataka, India,* [2]*Manipal College of Pharmaceutical Sciences, Manipal, Karnataka, India,* [3]*Kasturba Medical College, Manipal University, Manipal, India,* [4]*Kasturba Medical College, Manipal University, Manipal, India*

OBJECTIVES: To ascertain the epidemiological factors associated with Acinetobacter infections and the resistance pattern of this organism. **METHODS:** A cross sectional, observational, retrospective study was carried out, over a period of 6 months in a tertiary care hospital (Oct 2012 to Mar 2013). The data collected was analysed to understand the pattern with respect to patient demographics, prescription patterns, comorbidities as risk factors to infection, and resistance patterns. **RESULTS:** Based on this study it was observed that surgery was not a risk factor for Acinetobacter infections. Male patients had a greater risk of A. *baumannii* infections. Age distribution of infections was mainly in 41-60 years and 61-80 years. The bacteria were found to be resistant to almost all categories of drugs except colistin, and tigecycline. The mean length of stay of a patient of A.*baumanni* infection was found to be 23.51±27.97 days. Tigecycline and cefixime were the most prescribed antibiotics (97.9%) in the present study. Cefoperazone-sulbactam was found to have an antibiotic action against the bacterium. **CONCLUSIONS:** This study concluded that male patients were at a greater risk of A.*baumannii* infections. However surgery could not be considered as a risk factor for the same. Length of stay of patients was on average 23.51±27.97 days. This study showed tigecycline and cefixime were the most prominently used antibiotic. The strain in this study was resistant to almost all cephalosporins except Cefoperazone-Sulbactam which had activity in 57.14% of the samples tested.

INFECTION – Cost Studies

BUDGET IMPACT ANALISIS OF SWITCHING FROM DPT AND MONOVALENT VACCINES TO DTAP–IPV-HIB COMBINED VACCINE INTO RUSSIAN IMMUNIZATION SCHEDULE

Kulikov A[1], Akimova YI[2]

[1]*First Moscow State Medical University named after I.M. Sechenov, Moscow, Russia,* [2]*First Moscow medical academy named after I.M. Sechenov, Moscow, Russia*

OBJECTIVES: The current Russian immunization program for children from 0 to 20 months is carried mainly by DPT and monovalent vaccines. In addition, vaccination against Hib infection so far is only available for children at risk (approx. 20%). Introduction of DTaP-IPV-Hib combined vaccine could reduce the number of injections received by the child and increase coverage against Hib infection from 20% to 97%. The objective of this evaluation is to calculate the incremental of switching from current monovaccines and DTP-based routine immunization schedule using a pentavalent combined vaccine DTaP-IPV-Hib through a different schemes. **METHODS:** A budget impact analysis of the switching to the different schemes DTaP-IPV/Hib vaccine is performed on the suggested Markov model. The three alternatives (against current immunization program) are compared: a 3+1DTaP-IPV-Hib immunization (Scheme P), a mixed DTwP / DTaP-IPV-Hib immunization (Scheme mix) and a potential scenario - the current scheme, but with expanded (97%) Hib coverage- Scheme 1.The cohort of infants born in 2011 year is followed over their lifetime. Direct and indirect medical costs are measured from the perspective of the public payer. For reference, accepted exchange rate is 1€ = 41 rub. **RESULTS:** The budget impact analysis has shown that the switching from the current vaccination schedule for one of the alternative require additional funds in the amount of 705 101 317 rub. (17197593 €) for Scheme mix, 708 100 310 rub.(17270739€) for Scheme 1 and 1818409 406 rub.(44351449 €) for Scheme P. **CONCLUSIONS:** According to the budget impact analysis, the lowest additional cost of introduction one of alternative scheme would require Scheme mix. Thus, this scheme will be preferred for the Russian health care system.

PIN18

BUDGET IMPACT OF THE INTRODUCTION OF ELVITEGRAVIR/COBICISTAT/EMTRICITABINE/TENOFOVIR, THE FIRST INTEGRASE INHIBITOR-BASED SINGLE TABLET ANTIRETROVIRAL REGIMEN FOR HIV TREATMENT, TO THIRD PARTY PAYERS IN THE UNITED STATES

Brogan A[1], Talbird SE[1], Thompson JR[1], Kim YA[2], Olson J[2], Peterson J[2], Piontkowsky D[2], Pietrandoni G[3]

[1]*RTI Health Solutions, Research Triangle Park, NC, USA,* [2]*Gilead Sciences, Inc., Foster city, CA, USA,* [3]*Walgreens Pharmacy, Deerfield, IL, USA*

OBJECTIVES: Single tablet regimens like elvitegravir/cobicistat/emtricitabine/tenofovir (EVG/COBI/FTC/TDF) for the treatment of HIV infection are associated with

improved medication adherence, better virologic suppression, lower hospitalization rates, and lower health care costs. The objective of this study was to estimate the budget impact to a US health care plan of the use of EVG/COBI/FTC/TDF in adults with HIV who are treatment-naïve or currently on treatment with no resistance to the components of EVG/COBI/FTC/TDF. **METHODS:** The model estimates total direct health care costs associated with HIV management before and after the introduction of EVG/COBI/FTC/TDF. HIV epidemiology, hospitalization rates, and adverse event incidence and their associated costs were calculated using results of published studies or publically available sources. Regimen utilization was obtained from recent chart audit analysis and EVG/COBI/FTC/TDF market share was projected to come from protease inhibitor (PI)-based regimens in relative proportion to each regimen's market share. The budget impact was calculated annually and cumulatively over a 3-year period without discounting, following standard methodology for budget impact analyses. **RESULTS:** For a hypothetical health care plan with 1 million members, the model estimated 450 HIV-positive members currently on treatment and 72 HIV-positive members initiating HIV therapy each year. Over a 3-year period, the introduction of EVG/COBI/FTC/TDF was expected to result in greater use of single tablet regimens and lower use of more expensive PI-based regimens, yielding lower pharmacy costs ($226,194, 0.5% lower), fewer hospitalizations (1.1% fewer), and lower hospitalization costs ($31,288, 1.1% lower) versus scenario without EVG/COBI/FTC/TDF. Total cost savings over 3 years were estimated at $240,375 (0.4% lower), equivalent to a reduction in per-member-per-month (PMPM) costs from $1.61 to $1.60. PMPM results were insensitive to changes in parameters. **CONCLUSIONS:** The introduction of EVG/COBI/FTC/TDF is expected to result in fewer hospitalizations with a negligible impact on pharmacy and total costs over a 3-year period for a US health care plan.

PIN19

BUDGET IMPACTS OF PROBIOTICS IN CONTROLLING UPPER RESPIRATORY TRACT INFECTIONS IN FRANCE

Berdeaux G[1], Lenoir-Wijnkoop I[2], Gerlier L[1]
[1]*IMS Health HEOR, Vilvoorde, Belgium,* [2]*Utrecht University, Utrecht, The Netherlands*

OBJECTIVES: Two meta-analyses associated with a public health model demonstrated that probiotics (live microorganisms which when administered in adequate amount confer a health benefit on the host) have an important public health impact: they reduce upper respiratory tract infection (URTI) episodes with less antibiotics and sick leave prescriptions, in France. This analysis reports the budget impact for the National Health System (NHS) and the Nation. **METHODS:** The public health impact model (1/1,000 virtual age-gender standardized population generated with a Markov model: 1-day cycles, 2011-2012 winter period, URTI incidence from a General Practitioner [GP] network) was used. Economic perspectives were society, NHS and family. The analysis was limited to patients having visited a GP. Resource utilization came from the GP network. Unit costs were applied: Ameli.fr for drugs, Classification Commune des Actes Médicaux for GP visits, gross domestic product (GDP)/capita or allowances for sick leaves. Outcomes included direct medical and indirect costs. Results were reported according to each meta-analysis, Cochrane and York Health Economics Consortium (YHEC). **RESULTS:** The economic impact of probiotics was about €95 million saved from the Society perspective according to YHEC (Family: -€21.7 million; NHS: -€15.4 million) and €229.1 million according to Cochrane (Family: -€130.4 million; NHS: -€34.6 million). Absenteeism was the main driver for the society perspective representing 98% (YHEC) or 78% (Cochrane) of the savings. For the NHS, the main driver was sick leave (94%, YHEC-based) or GP visit (67%, Cochrane-based): avoiding URTI episodes (Cochrane) generates more visit savings than reducing disease duration (YHEC). More savings were observed in children, active smokers and people with more human contacts compared to the general population. **CONCLUSIONS:** Probiotics savings are substantial, whether they reduce URTI episodes frequency or duration. Noteworthy, 2011-12 winter URTI incidence rate was low and this analysis focused on the 1% URTI accessing the NHS.

PIN20

ANTIBACTERIAL TREATMENT OF METICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS COMPLICATED SKIN AND SOFT TISSUE INFECTIONS: A BUDGET IMPACT ANALYSIS IN THE GREEK HOSPITAL SETTING

Karampli E[1], Ollandezos M[1], Petrakis I[2], Tsoulas C[2], Patel DA[3], Kyriopoulos J[1]
[1]*National School of Public Health, Athens, Greece,* [2]*Pfizer Hellas, Athens, Greece,* [3]*Pharmerit International, Bethesda, MD, USA*

OBJECTIVES: Meticillin-resistant staphylococcus aureus (MRSA) is an important cause of antimicrobial-resistant health care-associated infections worldwide. Its prevalence remains high in the Greek hospital setting. Complicated skin and soft tissue infections (cSSTIs) due to MRSA are associated with prolonged hospitalization, additional costs of care and significant morbidity. The purpose of this study was to conduct a budget impact analysis relative to different management scenarios for MRSA-cSSTIs from a hospital perspective. **METHODS:** Equal efficacy for the pharmacotherapies under evaluation was assumed and resource use was elicited via an expert panel. The model was based on a decision tree for the management of hospitalized patients with MRSA-cSSTIs, simulating costs and outcomes for the duration of hospitalization according to the therapeutic scenario, including empiric and first-line therapies. Inpatient costs consisted of hospitalization, diagnostic, medical and antibiotic costs. Economic results (Euros 2013) reflect the hospital setting. **RESULTS:** Total per patient cost according to first-line agent was €2,458, €2,730, €2,850, €3,495 and €3,098 and mean length of stay (LOS) was 9.2, 12.5, 10.3, 13.0 and 14.0 days for linezolid, vancomycin, daptomycin, tigecyline, teicoplanin respectively. An estimated 10,287 MRSA-cSSTI patients are treated annually in Greek hospitals. Thus, by increasing the use of linezolid by 11% over a three-year period, for the management of MRSA-cSSTIs, this could result in savings of €331,602 for the hospital budget (current:€29,081,597, projected:€28,749,994). By reducing the LOS for linezolid patients from 9.2 days (current LOS in Greece as per expert panel) to 7.6 days to match data from a large phase IV study in MRSA-cSSTIs (Itani 2010), potential savings amount to €808,673. **CONCLUSIONS:** The analysis corroborates literature findings with regards to the early switch/early discharge potential and outcomes due to oral antibacterial switching in cSSTIs. Increased use of linezolid in the treatment of MRSA-cSSTIs could result in substantial savings for the Greek hospital budget.

PIN21

COST REDUCTION ASSOCIATED WITH USE OF SUBGLOTTIC ASPIRATION TO REDUCE VENTILATOR-ASSOCIATED PNEUMONIA IN TURKEY

Kockaya G[1], Erslon MG[2], Can H[3], Akin O[1], Ozcan S[1]
[1]*Covidien, Istanbul, Turkey,* [2]*Covidien, Boulder, CO, USA,* [3]*Covidien, Ankara, Turkey*

OBJECTIVES: Ventilator-associated pneumonia(VAP) is a serious complication risk for patients who require invasive mechanical ventilation(IMV). VAP is associated with longer intensive care unit and hospital stays, which may increase health care expenditures. VAP may occur in 8% of IMV patients. Subglottic aspiration (SA) may decrease VAP by up to 45% in IMV patients. The goal of this analysis is to calculate the potential cost reduction associated with SA use for VAP reduction in IMV patients in Turkey. **METHODS:** A literature analysis was conducted in PubMed(2000-present) to determine the published cost of VAP in Turkey. Published costs were used for the conversion to Turkish Lira(TL). An annual inflation rate of 3% was applied to the cost data to project the estimated cost in 2013. The exchange rate for USD to TL was estimated at 1.8. A weighted average of the number of patients in each study was used to calculate the cost of treatment. The cost of SA to the Social Security Institution (SGK) was calculated as 33.94 TL, which includes the cost of the SA tube(TaperGuard EVAC; 25 TL) and the SA service reimbursement amount from the SGK of 8.94 TL. 8% and 45% were taken as the VAP rate and reduction with SA rate in IMV patients, respectively. The number of patients requiring IMV in a hospital was estimated at 1000 per year. **RESULTS:** The average inpatient costs of IMV patients with and without VAP were calculated to be 13.556 TL and 3.971 TL, respectively. The total VAP cost, based on 80 VAP cases in 1,000 IMV cases without SA, was calculated as 1.085.297 TL. A hospital using SA for all IMV cases is estimated to have VAP costs equal to 488.384 TL and SA costs of 33.940 TL for a total cost of 522.324 TL. Cost reduction from SA use was calculated as 562.973 TL. **CONCLUSIONS:** VAP increases health expenditures by 9.595 TL per patient. A hospital with 1,000 IMV patients per year that uses SA in all IMV patients may realize an estimated cost reduction of 562.973 TL associated with use of SA in IMV patients.

PIN22

BUDGET IMPACT OF AN INDIVIDUALIZED APPROACH IN THE TREATMENT OF HBEAG-NEGATIVE CHB PATIENTS EXPLOITING THE WEEK-12 PEGINTERFERON ALFA-2A STOPPING RULE IN ITALY

Iannazzo S[1], De Francesco M[1], Coco B[2], Brunetto M[2], Tomic R[3], Paolini D[3], Palmieri G[3], Bonino F[2]
[1]*IMS Health, Milan, Italy,* [2]*University Hospital (AOUP), Pisa, Italy,* [3]*Roche S.p.A., Monza, Italy*

OBJECTIVES: Treatment options for chronic hepatitis B (CHB) are the direct inhibition of viral replication by continuous administration of nucleosides analogues (NUCs) or a finite 48-weeks course of peg-interferon (PEG). PEG can induce the off-therapy immune control of CHB leading to HBsAg loss/anti-HBs seroconversion but at a low success rate. On the other hand life-long treatment with NUCs is expensive. Exploiting the early identification of PEG-non-responders by combined HBV-DNA and HBsAg quantification at week-12 (stopping-rule), a new sequential therapeutic strategy may benefit both patients and payers. We measured the impact on the Italian National Health Service budget using the PEG-week-12-stopping-rule in the treatment of HBeAg-negative CHB. **METHODS:** A Markov model was developed over a 5 year horizon in the states: CHB, virologic response, relapse, HBsAg clearance, compensated and decompensated cirrhosis, hepatocarcinoma, liver transplant, post-liver transplant and death. The target population (treatment naïve CHB patients) was determined based on Italian national population forecasts and epidemiological data. The current mix of treatment with NUCs (entecavir, tenofovir, adefovir, lamivudine and telbivudine) and PEG (with no stopping rule) was compared with a mix based on a hypothetical uptake of PEG (with the stopping rule). The percentage of uptake from NUCs started at 25%, increasing over time. **RESULTS:** The estimated impact on the Italian NHS budget, over 5 years of treatment, resulted in a saving of approximately €74 million, 95% of which accounted for drug cost. The beneficial impact of the stopping-rule became clear from the second year, when a break-even point was reached. **CONCLUSIONS:** The large estimated savings in drug costs following the uptake of PEG + stopping-rule in the treatment of CHB HBeAg negative patients, together with previously published cost-effectiveness results, demonstrate a potentially advantageous profile of such a strategy, that could allow for more efficient use of health care resources.

PIN23

EXAMINING THE RELATIONSHIP BETWEEN COUNTRY-LEVEL FACTORS AND VACCINE WASTAGE: A DATA DRIVEN MODEL OF SESSION SIZES IN BANGLADESH, MOZAMBIQUE, INDIA (UTTAR PRADESH), AND UGANDA

Yang W[1], Parisi M[2], Lahue BJ[2], Bishai DM[1]
[1]*Johns Hopkins University, Bloomberg School of Public Health, Baltimore, MD, USA,* [2]*BD, Franklin Lakes, NJ, USA*

OBJECTIVES: Vaccination is a cost-effective intervention; however limited infrastructure in developing countries can pose significant challenges in efficient vaccine delivery. Countries prefer multidose presentations due to lower acquisition and cold chain costs, but open vial vaccine wastage is a major part of program cost. The aim of this study was to examine country-level factors that impact open vial wastage. **METHODS:** A demographics-based budget impact model with a 10 year time horizon was developed in Excel v14 using Palisade's @Risk v6.0 software. The model estimated daily vaccine utilization and wastage rates for Pentavalent, Pneumococcal, HPV and IPV using Lee's (2010) model, calibrated to arrival distributions based on field data session sizes from Bangladesh, Mozambique, India (Uttar Pradesh), and Uganda. The statistical distribution was determined using maximum likelihood, stratified by urban/rural for each clinic type. The model ran 1000 iterations, with each drawing independently from the statistical distributions of session sizes by clinic type. **RESULTS:** The negative binomial family offered the best fit to session size by Akaike Information Criterion. The leading

determinant of wasted doses was the number of children arriving. Depending on whether the clinic setting was urban/ rural, or outreach/fixed center, median session sizes varied between 5-13 children. Vaccine wastage added significant cost due to variations in session size even when modeled using a low multidose vial strategy. For instance, open vial waste from pneumococcal delivered in 5-dose presentation contributed $20MM in waste to Ugandan 10-year program costs. Results for each country and the impact session size distributions will be presented. **CONCLUSIONS:** Our analysis of field data confirmed significant session size variation within/across country immunization settings. Given challenges in mandating session sizes, pressures on vaccine budgets and high value of vaccine delivery, policy makers must consider new solutions to reduce the impact of waste on total program costs.

PIN24

BUDGET IMPACT ANALYSIS OF CEFTAROLINE VERSUS LINEZOLID OR VANCOMYCIN ON THE TOP OF STANDARD THERAPY IN THE TREATMENT OF COMPLICATED SKIN AND SOFT TISSUES INFECTIONS IN RUSSIAN FEDERATION

Kulikov A, Komarov I

I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To estimate the budget impact of the inclusion of ceftaroline compared to linezolid or vancomycin on the top of complicated skin and soft tissues infections treatment scheme with antimicrobials according to Russian health care system. **METHODS:** The budget impact analysis was conducted. Direct expenses associated with complicated skin and soft tissues infections and resulting follow-up costs were calculated using general tariff agreement of Russian obligatory insurance system and official national statistics. For reference, accepted exchange rate was 1 EUR = 40 RUB. **RESULTS:** Ceftaroline inclusion into the standard complicated skin and soft tissues infections therapy provided cost saving benefits compared with inclusion of linezolid or vancomycin in the complicated skin and soft tissues infections standard therapy scheme. Total health care costs of complicated skin and soft tissues infections therapy were approximately 77 997 RUB (1 950 EUR) per patient in ceftaroline group (therapy duration – 9 days), 78 816 RUB (1 970 EUR) per patient in vancomycin group (therapy duration – 10 days) and 117 893 RUB (2 947 EUR) per patient in linezolid group (therapy duration – 12 days). Treatment of complicated skin and soft tissues infections using standard therapy with ceftaroline inclusion compared to one with vancomycin or linezolid leads to cost savings of 819 RUB (20 EUR) or 39 896 RUB (997 EUR) per patient, respectively. **CONCLUSIONS:** The results of budget impact analysis illustrate that including ceftaroline into the standard therapy of complicated skin and soft tissues infections in comparison with vancomycin or linezolid has potential to reduce Russian health care system total costs for complicated skin and soft tissues infections treatment.

PIN25

ESTIMATING THE COST IMPACT OF SWITCHING FROM A VIAL TO A PRE-FILLED SYRINGE MODE OF ADMINISTRATION FOR THE DTAA-IPV-HIB '5-IN-1' VACCINE IN INFANTS

Kumar G[1], Padhiar A[1], Carroll S[2], Woods B[1], Shread K[2]

[1]*Oxford Outcomes Ltd., Oxford, UK,* [2]*Sanofi Pasteur MSD, Maidenhead, UK*

OBJECTIVES: To estimate the cost impact to the NHS of switching from vial and syringe (V&S) to pre-filled syringe (PFS) administration of the '5-in-1' vaccine for diphtheria, tetanus, pertussis, polio and *Haemophilus influenzae* type b. **METHODS:** A model was developed to estimate the cost impact of the switch in children less than 2 years old. Vaccines supplied were assumed to reach three destinations: administered (an estimate of 785,320 primary courses); opened and not administered (assumed to account for 7% of V&S and 0% of PFS supplied); or not opened by the expiry date (assumed to account for 0% of supply). All vaccines accrued acquisition and storage costs. PFS has bulkier packaging, leading to higher storage costs. Administered vaccines incurred costs for staff time, consumables (only required for V&S) and potential needlestick injuries (assumed not to occur with PFS). As prices paid for vaccines by the NHS are not disclosed, the cost of a single dose was assumed equal for PFS and V&S. Appointment times were obtained from a survey of 200 nurses, which estimated that PFS saved on average 4 minutes 47 seconds relative to V&S across three doses. All unit costs were sourced from the literature. **RESULTS:** The introduction of PFS was estimated to save £7.91 per 3-dose primary course and £6,214,562 per year for the NHS. Reductions in wastage and staff time contributed the greatest savings. Varying the wastage rate from 1-10% resulted in total cost savings of £3-8million; investigation into better estimates of vial wastage would strengthen the results. All other sensitivity analyses had a minimal impact on results. **CONCLUSIONS:** The switch to PFS administration is estimated to have generated substantial cost-savings to the NHS. PFS has the potential to improve the efficiency of immunisation programmes by simplifying vaccine delivery and reducing the risk of handling errors.

PIN26

PHARMACOECONOMIC ANALYSIS OF DIFFERENT ANTIVIRAL THERAPIES IN THE TREATMENT OF RUSSIAN PATIENTS WITH CHRONIC HEPATITIS C

Ryazhenov VV, Sboyeva SG, Emchenko IV

I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To assess the cost-effectiveness of pegylated interferons alfa-2a and alfa-2b combined with ribavirin in the treatment of Russian patients with chronic hepatitis C and identify potential budget impact considering the indicator of rational drug use (IRDU). **METHODS:** The pharmacoeconomic model was developed based on the data from randomized controlled trial MIST (M. Rumi et al., 2010). The cost-effectiveness ratios (CERs) for different patient subgroups were expressed as costs of medicines per one patient with sustained virologic response. 24- and 48-week time frames were used for patients with genotypes 2/3 and 1/4, respectively. To assess quantitatively the impact of pharmaceutical form and recommended dose regimens, the IRDU was used. One-way sensitivity analyses (SAs) were performed to investigate the robustness of the cost-effectiveness estimates. **RESULTS:** Treatment with pegylated interferon alfa-2a was associated with lower total costs. The estimated budget savings varied from 20,907.97 RUB to 104,366.07 RUB per one patient. CERs for pegylated interferon alfa-2a were less than that for pegylated interferon alfa-2b in all patient subgroups. The lowest CER was observed for patients with genotype 2 received pegylated interferon alfa-2a (240,789.70 RUB per one patient with SVR) and the highest CER – for cirrhotic patients with genotype 1 received pegylated interferon alfa-2b (1,879,694.72 RUB per one patient with SVR). The analysis of the IRDU showed, that inefficient budget expenses associated with pegylated interferon alfa-2b treatment may reach 58,770.84 RUB per one patient infected with HCV-genotypes 1/4. SAs demonstrated that results were robust to changes in the drug costs. **CONCLUSIONS:** The present study has demonstrated that administration of pegylated interferon alfa-2a has the better pharmacoeconomic profile in the treatment of Russian patients with chronic hepatitis C.

PIN27

THE COST OF STOPPING (FUTILITY) RULES TELAPREVIR AND BOCEPREVIR IN THE TREATMENT OF GENOTYPE 1 HEPATITIS C PATIENTS IN BRAZIL

Morais AD, Pereira ML

Janssen Cilag Farmaceutica, São Paulo, Brazil

OBJECTIVES: To estimate the cost of treatment discontinuation due to label stopping (futility) rules of telaprevir (TVR) and boceprevir (BOC) triple therapy in Brazilian public (SUS) and private health care system (SS). **METHODS:** Treatment costs considered drug acquisition costs from a public and private payer perspective in Brazil. Stopping rules (SR) were defined according to the label of each drug. For TVR the SR were defined at week4 (SR WK4) and at week 12 (SR WK12) as viral load (VL) > 1.000 IU/ML. For BOC, SR were defined at week 12 (SR WK12) as VL >100 UI/mL and at week 24 (SR WK24) as detectable VL. Patients eligible for the SR were gathered for naïve and experienced patients from the respective phase 3 trials. As data for SR WK24 was not published for BOC in naïve patients it was assumed to be the same as SR WK12 and a deterministic sensitivity analysis was carried out. **RESULTS:** Under the SUS perspective, the average cost of naïve patients interrupting treatment with TVR was R$ 670 compared to an average cost of R$ 3.396 per interrupted treatment with BOC, and for treatment experienced patients, TVR had an average cost of R$ 352 compared to an average cost of R$ 3.041 for BOC per patient meeting the SR. Under the SS perspective, TVR had an average cost of R$ 1.433 per interrupted naïve treatment and R$ 753 per interrupted treatment in experienced patients and BOC had an average treatment cost of R$ 8.305 per naïve patient interrupting treatment and R$ 4.753 per interrupted treatment in experienced patients. **CONCLUSIONS:** BOC had higher costs associated with treatment futility when compared to TVR, especially in treatment experienced patients, in both the public and private health care systems in Brazil.

PIN28

COMPARATIVE EFFECTIVENESS OF TRIPLE THERAPY VERSUS DUAL THERAPY FOR CHRONIC HEPATITIS C VIRUS INFECTION IN KAZAKHSTAN

Almadiyeva A[1], Kostyuk A[1], Nurgozhin T[2]

[1]*National Center for Health Development, Astana, Kazakhstan,* [2]*Nazarbayev University, The Center for Life Sciences, Astana, Kazakhstan*

OBJECTIVES: Currently, 23 thousand people (registered) are suffering from Hepatitis C in Germany (more 60% genotype 1). TThe licensing of direct-acting antivirals heralds a new era in the treatment of hepatitis C virus (HCV) genotype 1. Clinical studies showed a significant increase in sustained virological response rates from 38-46% to 63-79%. This study was to evaluate the cost-effectiveness of newly introduced triple therapy with Telaprevir (TVR+PR) compared to dual therapy (PR) for the treatment of genotype 1 hepatitis C virus (HCV) infection in previously untreated patients. **METHODS:** A systematic literature review identified relevant studies. A Bayesian mixed treatment comparison model was fitted for each patient population. Previously published economic Markov model comparing triple therapy (TVR + PR) and dual therapy (PR) has been adjusted for the Kazakhstan context of health care (payer perspective). Clinical outcomes and dose were taken from the phase ADVANCE-3 trial. Other parameters of the model - including utilities - were adapted from Kazakhstan or if not available from the international literature after an extensive search of the literature. Drug costs were taken from the list of drugs Kazakhstan. All costs were inflated to 2012 goda.Skidka of 3% and the horizon of life were considered. **RESULTS:** Base-case analysis shows that the triple treatment (TVR + PR) than dual therapy (PR) leads to increased costs, and the best results. The results were robust when analyzing multiple sensitivity. The discount rate seemed to have a great impact. **CONCLUSIONS:** Telaprevir triple therapy for previously treated patients with HCV-genotype 1, more efficient than the dual therapy, but it leads to increased costs (in particular, the cost of medications).

PIN29

PHARMACOECONOMIC EVALUATION OF THE FIXED-DOSE COMBINATION OF ABACAVIR/LAMIVUDINE IN THE ANTIRETROVIRAL THERAPY OF NAÏVE HIV INFECTED PATIENTS IN RUSSIA

Pyadushkina E[1], Omelyanovsky V[2], Avxentyeva M[2], Rebrova O[3], Andreeva N[1]

[1]*Autonomous Non-profit Organization "National Centre for Health Technology Assessment", Moscow, Russia,* [2]*The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia,* [3]*Pirogov Russian National Research Medical University, Moscow, Russia*

OBJECTIVES: To estimate the costs of once-daily fixed dose combination (FDC) abacavir/lamivudine (ABC/3TC) compared with twice-daily combination of its individual components (ABC+3TC) and twice-daily FDC zidovudine/lamivudine (ZDV/3TC) in efavirenz (EFV)-based regimens for treatment-naïve adults with HIV infection in Russia. **METHODS:** An Excel based model was developed to estimate the costs over 48- and 96-week time horizon for three compared regimens. Probabilities of switching to alternative and 2[d] line therapy due to low adherence and side effects were estimated for each regimen based on literature search. Costs of antiretroviral

drugs in the 1st and 2d line of therapy and routine follow-up costs were calculated based on prices of state procurements in the framework of national project of HIV prevention and the tariffs of the Russian health care system in 2012. One-way sensitivity analysis was performed. **RESULTS:** ABC/3TC+EFV is not associated with more costs vs ABC + 3TC + EFV regimen and even saves approximately 3390.60 rub (€80.30) per patient over 96 weeks of treatment. The sensitivity analysis showed that ABC/3TC FDC remains to be cost saving compared with ABC+3TC as long as the its package price is less than 6564.17 rub (€155.46) while keeping other model parameters unchanged. Still ABC/3TC+EFV is 28% more expensive than ZDV/3TC+EFV, though more effective and safe treatment option: the difference in costs vs ABC/3TC+EFV is 45267.05 rub. (€1,072.05) per patient over 96 weeks. **CONCLUSIONS:** FDC ABC/3TC may be considered as a more efficient and convenient treatment option than its monocomponents combination for first-line antiretroviral therapy of HIV patients in Russia. FDC ABC/3TC is more expensive versus ZDV/3TC, but the difference in costs seems appropriate for more safe and convenient alternative.

PIN30

THE IMPACT OF CHLAMYDIA AND GONORRHOEA POINT OF CARE NUCLEIC ACID AMPLIFICATION TESTS ON CLINICAL PATHWAYS AND COSTS IN GENITO-URINARY MEDICINE CLINICS IN THE UNITED KINGDOM

Adams EJ[1], Ehrlich A[1], Turner KM[2], Shah K[1], Macleod J[2], Goldenberg S[3], Pearce V[4], Horner P[2]

[1]*Aquarius Population Health, London, UK,* [2]*University of Bristol, Bristol, UK,* [3]*Guy's and St Thomas' NHS Foundation Trust, London, UK,* [4]*V. Pearce Consulting Ltd., Hove, UK*

OBJECTIVES: To explore new patient pathways using a chlamydia/gonorrhoea point of care nucleic acid amplification test (POC NAAT), and estimate and compare the costs of the new pathways with the current pathways using standard laboratory-based NAAT testing in the UK. **METHODS:** Consensus building activities were conducted with four sexual health clinics in the UK. They were selected through purposeful sampling to reflect a wide range of service delivery. Current pathways in which a chlamydia/gonorrhoea test was used were mapped out, and then new pathways using a POC NAAT were constructed. The consensus pathways were then costed using a patient pathway model built in Excel, and the cost of the current and POC NAAT pathways compared. **RESULTS:** Pathways using a POC NAAT for asymptomatic and symptomatic patients and chlamydia/gonorrhoea only tests were shorter and less expensive than most of the current pathways (average savings of £4-8 for symptomatic and asymptomatic screening pathways if the POC NAAT costs £18/test). Patients that are tested using the POC NAAT can be treated on the same day, thus saving costs compared to patients who are treated at a subsequent appointment. **CONCLUSIONS:** A POC NAAT could be introduced to services and reduce current costs, and may mean more appropriate and quicker care for positive patients.

PIN31

COST ANALYSIS OF VACCINATION FOR CHILDREN IN UKRAINE

Antonchak Z, Zalis'ka O, Horbachevska O-H

Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

OBJECTIVES: In Ukraine immunization by age conducts against 10 infectious diseases: tuberculosis, hepatitis B (HBV), diphtheria, pertussis, tetanus, polio, Haemophilus influenzae, measles, rubella, mumps .The Law of Ukraine from 21.10.2009 N 1658-VI approved the Program of immunization and protection against infectious diseases during 2009-2015.During the years 2011-2012 the media incorrectly submitted data on the results of vaccination and many parents refused vaccination and as a result there were about 12,000 cases of measles and rubella, it's 80 times more than in previous years. On State program of vaccination in 2010 was allocated 237 mln UAH (1 USD=7.99 UAH), in 2011 - 237 mln, in 2012 - 302 mln UAH. **METHODS:** We conducted a cost per 1,000 children aged 0 to 1 years. Direct costs were calculated for vaccine Pentaxim (Sanofi Pasteur) which combined vaccine against hepatitis B (ukrainian producer "Biolik") and was compared the costs for vaccine Infanrix hexa (GSK). We included the vaccine costs, the loss during storage, and the costs of medical personnel for vaccination. We used the prices from the ukrainian electronic pricing database "MORION" on 01.06.2012. Analysis of evidence-based data has shown that Pentaxim is equal clinical efficacy of Infanrix hexa, but increases the rate of vaccination coverage against hepatitis B. **RESULTS:** The costs for Pentaxim and HiB vaccine were 633 240 UAH and costs of medical personnel (pediatrics, nurses) were 36763 UAH. The costs using vaccine Infanrix hexa were 803880 UAH, the costs of medical personnel – 18 381 UAH, respectively. **CONCLUSIONS:** In 2012, 385 116 children vaccinated by Infanrix hexa and general costs were 118 307 590 UAH vs 363 000 children by Pentaxim were 95 830 447 UAH. The results shown the need additional 22477143 UAH, which is justified to increase vaccination coverage against hepatitis B by 6%.

PIN32

ASSESSING THE ECONOMIC BURDEN AND HEALTH CARE UTILIZATIONS OF VETERAN PATIENTS DIAGNOSED WITH THE HEPATITIS C VIRUS IN THE UNITED STATES

Wang L[1], Xie L[2], Li L[1], Kariburyo MF[2], Baser O[3]

[1]*STATinMED Research, Dallas, TX, USA,* [2]*STATinMED Research, Ann Arbor, MI, USA,* [3]*STATinMED Research/The University of Michigan, Ann Arbor, Michigan, MI, USA*

OBJECTIVES: To examine the economic burden and health care utilizations of the hepatitis C virus (HCV) in the U.S. veteran population. **METHODS:** A retrospective database analysis was performed using the Veterans Health Administration Medical SAS datasets 01OCT2008-30SEP2012). Patients diagnosed with HCV (International Classification of Disease 9th Revision Clinical Modification [ICD-9-CM] codes 070.41, 070.44, 070.51, 070.54, v02.62) were identified, and the first diagnosis date served as the index date. A comparator group was created by identifying patients without HCV but with the same age, region, gender and index year, and matching them by baseline Charlson Comorbidity Index. The index date for the comparator group was randomly chosen to reduce selection bias. A 1-year continuous health plan enrollment period pre- and post-index date was required for both groups. One-to-one propensity score matching (PSM) was used to compare health care costs and utilizations during the follow-up period between the HCV and comparison groups, adjusting for baseline demographic and clinical characteristics. **RESULTS:** Eligible patients (N=270,752) were identified for the HCV and comparison cohorts. After applying 1:1 PSM matching, a total of 107,953 patients were matched from each group and baseline characteristics were well-balanced. HCV patients were more likely to be hospitalized (15.90% vs. 3.19%, p<0.01) and report more emergency room (20.36% vs. 8.17%, p<0.01), physician office (99.18% vs. 61.06%, p<0.01), outpatient (99.25% vs. 61.84%, p<0.01) and pharmacy visits (91.11% vs. 63.13%, p<0.01) which resulted in higher health care costs for inpatient ($5,284 vs. $911, p<0.01), emergency room ($237 vs.$76, p<0.01), outpatient ($4,673 vs. $1,760, p<0.01), physician office ($4,247 vs. $1,560, p<0.01), pharmacy ($889 vs. $460, p<0.01) and total costs ($10,846 vs. $3,131, p<0.01) for HCV patients relative to the comparison group. **CONCLUSIONS:** Patients diagnosed with HCV were more likely to report higher health care utilization and were associated with a higher economic burden compared to the matched controls.

PIN33

VACCINE TIMELINESS: A COST ANALYSIS OF THE IMPLICATIONS OF DELAYED VACCINATION

Curran D[1], Terlinden A[2], Poirrier JE[1], Masseria C[3], Krishnarajah G[3]

[1]*GlaxoSmithKline Vaccines, Wavre, Belgium,* [2]*Navigha, Tervuren, Belgium,* [3]*GlaxoSmithKline, Philadelphia, PA, USA*

OBJECTIVES: : Pertussis (whooping cough) is a highly contagious bacterial disease. Infants in the first few months of life are particularly vulnerable with the highest reported rate of pertussis, risk of severe disease and deaths. Although, vaccination coverage rates have reached record-high levels in the United States (US), vaccine timeliness remains an issue. **METHODS:** Using data from the 2010 National Immunization Survey (NIS), we estimated the vaccination timeliness for DTaP vaccines in US infants. A previously published static model accounted for the reduction of incidence of pertussis by vaccination according to a strict adherence to the ACIP vaccination schedule. The annual numbers of pertussis cases prevented in infants and the associated costs avoided from a health care system perspective were estimated. **RESULTS:** From the NIS dataset, the mean age at DTaP vaccination was 76.3, 147.4 and 223.9 days, which means that on average each vaccination was in average delayed by 16.3, 27.4 and 43.9 days (with delays accumulating over time), respectively. The model predicted 3052 pertussis cases annually in infants <1 year of age in the US. Applying a strict adherence to the vaccination schedule, approximately 313 cases of pertussis, 112 hospitalisations and 1 death could be avoided each year. This translates into savings of 57 QALYs and $1.3 million of costs to the health care system. **CONCLUSIONS:** Although previous publications have presented the number of cases avoided by timely vaccination, to our knowledge this is the first one to present the associated costs. Administering vaccines on time not only avoids cases but may also have a significant impact on quality of life and costs. These costs avoided may be redirected to developing tools and/or infrastructure to improve the vaccine timeliness of infants in future. Further research is needed to better understand the role of vaccination timeliness and completion.

PIN34

STUDY OF ANTIBIOTIC CONSUMPTION PATTERN IN HOSPITAL ACQUIRED PNEUMONIA

Kunhikatta V[1], Rau NR[2], Naik AN[1], Yamsani B[1], Thunga G[1], Nair S[1]

[1]*Manipal College of Pharmaceutical Sciences, Manipal University, Manipal, India,* [2]*Kasturba Medical College, Manipal University, Manipal, India*

OBJECTIVES: To analyse the antibiotic consumption pattern in hospital acquired pneumonia (HAP) patients in a tertiary care teaching hospital **METHODS:** A prospective observational study, carried out in a tertiary care teaching hospital from January 2011 to December 2012. HAP patients who fulfill the inclusion criteria were identified and enrolled into the study after taking informed consent. Patients were followed from the day of diagnosis of HAP, till the day of discharge or death. Patient data like demography (age, sex), antimicrobial agents used (dose, duration of treatment), length of hospital stay and clinical outcome were recorded in a predesigned data collection form. The cost of antimicrobial therapy was recorded from the day of admission till the day of discharge. Antibiotic consumption was calculated using defined daily dose (DDD) methodology. **RESULTS:** Total 310 patients were included in the study. Among study population 229 (73.9%) patients were male and mean age was 55.9±18.4 (mean±SD). Out of 310 patients 218 were improved, 37 were worsened or discharged against medical advice and 55 were expired. Mean length of hospitalization was 9.45±6.75 (mean±SD) days. Total 27 antimicrobial agents were used for the treatment pneumonia among these patients. Among these antimicrobial agents, consumption (DDD/100 bed days) was highest for piperacillin-tazobactum (parenteral, 0.12) followed by ceftriaxone (parenteral, 0.10), azithromycin (oral, 0.10) and trimethoprim-sulphamethoxazole (oral, 0.08). The percentage of treatment success was highest among patients treated with piperacillin-tazobactum+macrolide combination (10%) followed by cephalosopin+macrolide combination (8%). However the cost of treatment was high for piperacillin-tazobactum+macrolide regimen **CONCLUSIONS:** This study provides estimate of quantities of different antimicrobial agents used in the treatment of hospital acquired pneumonia. Piperacillin-tazobactum (parenteral) is highest consumed among 27 antimicrobial agents. Since percentage of treatment success is almost similar for piperacillin-tazobactum+macrolide combination (10%) and cephalosopin+macrolide combination (8%), use of cephalosopin+macrolide combination should be encouraged in susceptible patients considering the lesser cost.

PIN35

COUNTING THE COST OF MENINGOCOCCAL DISEASE IN FRANCE

Faivre P[1], Bénard S[1], Wright C[2], Voisine J[3], Gaudelus J[4]

[1]*st[è]ve consultants, Oullins, France,* [2]*Meningitis Research Foundation, Bristol, UK,* [3]*Méningite France-Association Audrey, Ecouflant, France,* [4]*Hôpital Jean Verdier, Bondy, France*

OBJECTIVES: Invasive meningococcal disease (IMD) is life-threatening and can result in severe sequelae. In France, no data has been published on the costs of severe IMD cases. This study aimed to estimate lifelong management costs associated with severe cases of IMD in France. **METHODS:** Two scenarios were developed: a 6-year old child with *purpura fulminans* resulting in amputation of both legs below the knee and a 3-year old with meningitis and severe neurological sequelae. Additional scenarios included other typical sequelae of IMD: chronic renal insufficiency (CRI), profound deafness, epilepsy. Scenarios were validated by national experts of IMD. Health, disability, educational and other resources were obtained from experts and families of patients with similar sequelae. Unit costs (2013) were obtained from the literature, the National Health Insurance (NHI) and companies' websites. Time horizon was based on life expectancies of patients (77 and 55-years respectively). A 4% discount rate decreasing to 2% after 30-years was applied. Costs are presented from NHI, public funded organisations and patient or his/her private health insurance perspectives. **RESULTS:** *Purpura fulminans*with amputations is associated with a lifelong discounted cost of €768,874. Adding CRI doubles the amount (€1,480,545). Meningitis with severe neurological sequelae results in a lifelong discounted cost of €1,924,475. Adding profound deafness and epilepsy slightly increases the total cost (€2,267,251). The first year is the most expensive in both scenarios (€166,890 and €160,647 respectively). The main cost drivers are respectively for each scenario prostheses and child/adult stay in institutions. Overall, NHI covers 1/2 of total cost, public funded organisations 1/3 and patient/private health insurance for the remainder. **CONCLUSIONS:** This study fills a gap in the body of knowledge on IMD sequalae care and costs in France. The potentially high economic burden of IMD, in addition to its physical, psychological and social burden, reinforces the need for prevention.

PIN36

HOW MUCH DENGUE COSTS TO BRAZIL? A RETROSPECTIVE ADMINISTRATIVE CLAIMS ANALYSIS FROM THE PUBLIC PAYER PERSPECTIVE

Silva MA, Fernandes RA, Takemoto M, Haas LC, Amaral LM, Vasconcellos JF, Menezes LP
ANOVA, Rio de Janeiro, Brazil

OBJECTIVES: In the 21st century, Brazil became the country with the most reported cases of dengue fever. This study aims to describe hospital costs for managing dengue in the Brazilian Public Healthcare System (BPHS). **METHODS:** BPHS Hospital Information Database (SIH/SUS) was used to collect data for the period of 2008-2011. Individual claims coded as "Classic Dengue (CD) Treatment" or "Dengue Hemorrhagic Fever (DHF) Treatment" in the SIH/SUS (regardless ICD-10 codes) were identified in this system and compiled by geographic region, disease type and year. **RESULTS:** A total of 304,548 individual dengue claims were obtained for the 2008-2011 period. They represented an overall cost of 97,642,495BRL for all 4 years (ranging from 17,843,318BRL in 2009 to 31,235,501BRL in 2010). The 4-year national average cost per inpatient admission was 321BRL (295BRL [2008] - 333 BRL [2010]), with mean length of stay (LOS) of 3.3 days and in-hospital mortality rate of 0.46%. The northeast region represented 43.1% of overall expenditures, while the south accounted for only 1.6%. The hemorrhagic syndrome was responsible for 10%, 7% and 10% of overall cost, individual dengue claims and total hospitalization days, respectively. Mean cost per inpatient admission for DHF was 50.6% higher than CD's (468BRL vs. 316 BRL), mean LOS was 55.2% higher (5.0 vs. 3.2 days) and in- hospital mortality rate was 997.8% higher than the one from CD (3.0% vs. 0.27%). Stratifying by region, 9.6%, 36.6%, 34.7%, 1.7% and 17.4% of DHF costs were respectively localized on the North, Northeast, Southeast, South and Midwest. **CONCLUSIONS:** The analysis of SIH/SUS administrative information provided insightful information about dengue costs. Although DHF represented only 7% of individual claims, its mean cost per inpatient admission and in-hospital mortality rate was considerably higher than CD's, persisting as an object of concern for health authorities.

PIN37

BURDEN OF HERPES ZOSTER AND POST-HERPETIC NEURALGIA IN SWEDEN

Nilsson J[1], Cassel T[2], Lindquist L[3]
[1]*OptumInsight, Stockholm, Sweden,* [2]*Sanofi Pasteur MSD Sweden, Solna, Sweden,* [3]*Karolinska Institute, Solna, Sweden*

OBJECTIVES: Herpes zoster (HZ) and post-herpetic neuralgia (PHN), one of its more severe and frequent complication, are very painful and debilitating conditions. The societal economic burden of HZ in Sweden is not well described today. The objective of this study is to describe the burden of HZ and PHN in Sweden in the year 2011. **METHODS:** Data for inpatient care, outpatient primary care, the prescriptions of drugs, sick leave and the number or diagnostic tests were collected from national databases. The incidence of the HZ was estimated based on the number of prescriptions of antiviral drugs, on which a correcting factor has been applied. **RESULTS:** Almost 30,000 patients were diagnosed with HZ, with two third occurring in patients older than 50 years. The societal cost to treat these patients, including the cost to treat those patients who later developed PHN, added up to nearly 227 MSEK (21M€) which corresponds to 7,600 SEK per patient (876€). The main contributors to the total cost for the treatment of HZ patients were primary care (43%); sick leave (28%); hospitalization (10%) and specialist care (7%). Medication was a relatively small contributor with 8.5 MSEK (4%) to the overall costs for patients at all ages. **CONCLUSIONS:** The current study demonstrates that the burden of HZ is significant in Sweden, especially in people aged 50 years and older. This economic burden is expected to increase in the coming years since the population older than 50 years represents a growing proportion of the population. Thus, the society and the health care payers potentially have a lot to gain by introducing a vaccination program to patients aged 50 years and older, to reduce the burden and increase their quality-of-life.

PIN38

HOSPITAL ADMISSIONS RELATED TO TUBERCULOSIS IN BRAZIL: EPIDEMIOLOGICAL AND ECONOMIC PROFILE, FROM THE PUBLIC HEALTH CARE PERSPECTIVE

Amaral LM, Fernandes RA, Takemoto M, Vasconcellos JF, Haas LC, Silva MA, Menezes LP
ANOVA, Rio de Janeiro, Brazil

OBJECTIVES: Among infectious diseases, tuberculosis is the second leading cause of mortality worldwide. Since 2000, Brazil is one of twenty two countries classified as "high burden countries" by World Health Organization. This study aims to report epidemiological and economic profile of tuberculosis related hospitalizations in Brazil. **METHODS:** Retrospective analysis of Brazilian public hospital admissions for tuberculosis was developed according to ICD-10 classification (A15-A19) as reported in Brazilian Hospital Information System (SIH/SUS) database, from January 2008 to December 2011. Epidemiological data were extracted from public reporting system. Costs represent federal reimbursement values for hospitalizations (medical procedures, exams, drugs and fees) estimated in 2013 Brazilian Real (BRL). **RESULTS:** Reported tuberculosis cases and prevalence rates per 100,000 inhabitants for 2008, 2009, 2010, and 2011 were: 85,329 (45.0); 88,800 (46.4); 86,654 (44.8); and 89,759 (46.0), respectively. Hospitalizations in the same period were 18,216, 15,338, 16,153, and 19,048, leading to a hospitalization rates of 21.35%, 17.27%, 18.64%, and 21.22% with mean length of stay varying from 15 to 17 days. Mortality rates showed stability, varying from 2.95% to 3.49% for overall tuberculosis related deaths, and 6.19% to 8.14% for in-hospital mortality. About 40% of all deaths were related to hospitalized patients. From 2008 to 2011, hospitalizations costs were 19,546,160BRL, 21,791,027BRL, 23,889,130BRL and 29,410,353BRL, respectively, with an increase in cost per patient over the years (1,073BRL in 2008 to 1,544BRL in 2011). Total cost for the period represents 3.5% of all hospitalizations costs related to infectious diseases (ICD-10 chapter I). Geographic distribution indicated southeast region accounting for 45% of cases, 38% of hospital admissions, and 47% of costs. **CONCLUSIONS:** Tuberculosis is a major public health issue, with great impact on patients' health and growing hospitalization related costs for the Brazilian health care system. Southern region concentrates most cases and costs, probably due to the presence of important treatment and diagnoses centers.

PIN39

USE OF ANTIBIOTICS AND PRESCRIPTION MEDICATION IN INFLUENZA DISEASE IN THE UNITED KINGDOM

Meier G[1], Pockett RD[2], McEwan P[3], Watkins J[4], Humphreys I[2]
[1]*GlaxoSmithKline Vaccines, Wavre, Belgium,* [2]*Swansea University, Cardiff, UK,* [3]*HEOR Ltd., Monmouth, UK,* [4]*Public Health Wales and Cardiff University, Pontypool, UK*

OBJECTIVES: Determine the use of antibiotics and prescription medication in primary care in the management of influenza, stratified by age, risk and complications. **METHODS:** A cross-sectional observational study was carried out using data derived from GPRD, (January 2001 - March 2009). Subjects included were: all those with general practitioner (GP) coded episodes of care for acute respiratory events related to infection (influenza and Influenza-like-illness). Analysis was stratified by age and 'at-risk' status recommended for influenza vaccination in the UK. Primary prescription information was collected for the following categories: antipyretics/analgesics, antibiotics, amantadine, aminoglycosides, nasal decongestants, antisecretory drugs and mucosal protectants, and antihistamines. UK 2011 NHS reference costs were used. **RESULTS:** A total of 53% of all patients had at least one medical prescription with 30% of patients receiving antibiotics. Proportionally more patients with complicated influenza had prescriptions (83%) compared to patients with uncomplicated influenza (50%), and most cases were unvaccinated. Across all age groups complicated influenza had a greater number of prescriptions compared to those with uncomplicated cases (3.0 vs. 2.5). 67% and 27% of complicated and uncomplicated influenza cases received antibiotics. Antipyretics and analgesics were prescribed to 7% of patients, with antisecretory drugs and mucosal protectants prescribed to 6% of patients. Antibiotics, analgesics and antisecretory drugs (including mucosal protectants), were the three most commonly prescribed classes of drugs, and represent 41%, 31% and 12% of all prescriptions respectively. The annual cost is expected to be around £13,956,177 per annum with 40% of this cost attributable to antibiotics. **CONCLUSIONS:** In-hospital and over-the-counter medication use is not collected in this database, therefore this is not a comprehensive assessment of the full extent of pharmaceutical management of influenza. The extensive use of antibiotics prescribed by GPs is of concern, especially in uncomplicated influenza episodes at a time of increasing resistance. Current clinical practice therefore needs urgent review.

PIN40

EVALUATING ECONOMIC BURDEN OF TICK-BORNE ENCEPHALITIS. EVIDENCE FROM RUSSIA

Avxentev N[1], Avxentyeva M[2], Platonov A[3], Kolyasnikova N[3], Gridneva K[3], Dolgin V[3], Titkov A[3], Derkach EV[4]
[1]*New Economic School, Moscow, Russia,* [2]*The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia,* [3]*Central Research Institute of Epidemiology, Moscow, Russia,* [4]*Autonomous Non-profit Organization "National Centre for Health Technology Assessment", Moscow, Russia*

About 3500 people have suffered tick-borne encephalitis (TBE) in 2011 in Russia, and approximately 16% of them had focal form with a high case-fatality and disability rate. However, no research has investigated its social costs. **OBJECTIVES:** to evaluate the socio-economic burden of TBE in Russia. **METHODS:** We proposed a probability-tree model accounting for 4 clinical outcomes of the disease: full recovery, progression to chronic disease, disability, and death; probabilities were taken from Russian clinical and epidemiological studies. Each outcome was associated with particular costs that included direct current and deferred medical and social costs. Tariffs of the Russian health care system were used to calculate all medical costs; indirect costs were estimated using the average monetary daily productivity and mean disability allowance. All future costs were discounted to the basis year (2011). The model estimated the one-year average socio-economic burden of the disease which could be aggregated into the gross burden by incorporating data on annual TBE incidence in previous years. Additionally we evaluated disability adjusted life years (DALYs) attributable to TBE using standard WHO methodology. **RESULTS:** We found that economic TBE burden in Russia in 2011 was about $49.5 million, 78% of which was deferred costs, caused by death and disability. We

estimate total 4177 DALYs caused by TBE in 2011. **CONCLUSIONS:** TBE burden is quite large in Russia, thus economic evaluation of preventive measures is essential in order to choose the most cost-effective options.

PIN41

HEALTH CARE COSTS ASSOCIATED WITH CHRONIC HEPATITIS C INFECTION IN EUROPE

Lingohr-Smith M, Lin G
Novosys Health, Flemington, NJ, USA

OBJECTIVES: Chronic hepatitis C virus (HCV) infection is estimated to effect approximately 15 million persons in Europe. It is a prevalent cause of progressive liver disease including cirrhosis and hepatocellular carcinoma (HCC) and nearly 90,000 deaths that occur annually in the European region are related to HCV infection. The objective of this study was to evaluate the direct health care costs of HCV infection in countries of the European Union. **METHODS:** ENTREZ PUBMED was searched systematically for studies published between 2008 and 2013 that evaluated the health care costs of persons with HCV infection in countries of the European Union. Of the 110 studies identified only 3 contained overall health care costs. Cost data was extracted, inflation adjusted to 2013 costs and averaged. **RESULTS:** Based on the included studies, the average annual health care cost for a person with chronic HCV infection is €2,756 with mild disease, €6,258 with cirrhosis, and €11,437 with HCC. An HCV-related liver transplantation is estimated to have an average cost of €68,497. The reported annual health care costs of patients with chronic HCV infection vary widely, with annual costs ranging between €340 and €6,773 among those categorized as having chronic infection and/or mild disease and between €34,834 and €124,594 among those who have had a liver transplantation. **CONCLUSIONS:** The majority of recent studies have investigated antiviral drug treatment costs; few have examined the overall health care costs associated with chronic HCV infection in Europe. Based upon the data available, chronic HCV infection is associated with a substantial health care burden even among those categorized as having mild disease. Further research is needed to better understand the costs of HCV infection to enable more relevant screening and treatment strategies, especially among those at high risk for developing severe liver disease.

PIN42

PERTUSSIS IN BRAZILIAN CHILDREN: MORTALITY, LENGTH OF STAY, AND COSTS IN HOSPITALIZED PATIENTS

Fernandes RA, Haas LC, Takemoto M, Silva MA, Vasconcellos JF, Amaral LM, Menezes LP
ANOVA, Rio de Janeiro, Brazil

OBJECTIVES: Bordetella pertussisinfection is highly contagious and can progress to severe conditions, especially among young children and elderly. This study aims to describe hospitalization patterns and costs for pertussis in children in public hospitals in Brazil, from 2008 to 2011. **METHODS:** A retrospective analysis of Brazil public hospital admissions for pertussis was developed according to ICD-10 classification (A37: Pertussis) in children (aged ≤9 years), as reported in Brazilian Hospital Information System (SIH/DATASUS) database from January 2008 to December 2011. Costs represents federal reimbursement values for hospitalizations (includes medical procedures, exams, medications and taxes), presented in 2013 Brazilian Real (BRL). **RESULTS:** A total of 3055 hospital admissions for pertussis during the four-year period were identified. There was a downward trend in the first three years of the analysis, while the opposite occurred in the fourth year, with 2011 having the highest number of cases (907, 655, 394 and 1,099 for 2008, 2009, 2010, and 2011, respectively). Infants were the most affected, with those less than one year of age accounting for 91% (n = 2,779) of all pertussis admissions in the age group analyzed. In-hospital mortality rate was 13.9% for all cause in the period. Mean length of stay was 7.56 days. Total cost for the period was 3,754,877 BRL, which represents 94.9% of pertussis hospitalization costs for all ages (3,958,133 BRL). Mean cost per patient was 1,229 BRL. **CONCLUSIONS:** The costs with pertussis hospitalizations in children can be substantial in Brazil, from the public health care perspective. Despite the existence of a National Immunization Program, the number of cases in children remains high. It is therefore important that decision makers reassess the prevention and treatment patterns of this disease.

PIN43

COST OF INFLUENZA IN GERMANY

Anastassopoulou A[1], Wahle K[2], Hain J[1], Schroeder C[3], Ehlken B[3]
[1]*GlaxoSmithKline GmbH & Co, Munich, Germany,* [2]*University of Muenster, Muenster, Germany,* [3]*IMS Health, Munich, Germany*

OBJECTIVES: To evaluate cost of children and adults diagnosed with seasonal influenza in Germany, filling a data gap of more than a decade. **METHODS:** This cost-of-illness study was conducted from payer and societal perspective based on a retrospective database analysis by using a longitudinal electronic medical records database (IMS® Disease Analyzer). Patients with influenza episodes (ICD-10 diagnosis J09-11) being observable 12 months before index date and 1 month afterwards were included. The selection window was May 2010 to April 2012 to cover two influenza seasons. Published unit costs and tariffs for Germany in 2012 were used. **RESULTS:** A total of 23,068 influenza episodes (19,446 patients) managed by primary care practitioners (PCP) and 7,295 episodes (5,988 patients) managed by pediatricians were eligible for analysis. Mean age of patients with at least one episode was 43 years (SD 20) in the PCP panel and 7 years (SD 4) in the pediatrician panel. Total average mean cost (SD) from societal perspective in adult patients was €471 (576) and in children €99 (140)/episode. In about 11% of the adult patients the total cost exceeds €1,000/episode. This is primarily due to the higher percentage of patients with complications (63%) compared to the entire PCP study cohort (38%). Workdays lost were the main cost driver (82%) in adult patients; more than 40% of patients missed between 2 and 6 days of work/episode. In children, the main cost driver was physician visits (66%). Complications increase the cost by three fold in children and two fold in adults (average mean cost (SD) for children: €137 (144) vs. €49 (33) and adults: €622 (670) vs. €377 (485)). **CONCLUSIONS:** Results based on a large and representative patient sample demonstrate that the cost of seasonal influenza episodes is substantial, especially when complications occur. Costs in children may be higher of what is actually reported.

PIN44

THE COST OF CLOSTRIDIUM DIFFICILE INFECTION IN HUNGARY

Strbak B[1], Gulacsi L[1], Kertesz A[2], Kopcsone Nemeth I[3], Baji P[1], Pentek M[1], Brodszky V[1]
[1]*Corvinus University of Budapest, Budapest, Hungary,* [2]*United Szent Istvan and Szent Laszlo Hospital, Budapest, Hungary,* [3]*Hungarian Defence Forces Military Hospital, Budapest, Hungary*

OBJECTIVES: Clostridium difficile is the leading cause of antibiotic associated infectious nosocomial diarrhoea. *C. difficile* infection is a high-priority problem of public health in each country. The available literature of *C. difficile* infection's disease burden is limited. The authors aimed to identify the most important cost elements and quantify the cost of *C. difficile* infection in Hungary. **METHODS:** A retrospective chart review and experts interviews were done in a sample of 151 patients with *C. difficile* infection in 2011 in two Hungarian hospitals. In the chart review data on demographic, disease severity, therapy, the standard precautions and the infection related contact precautions were collected. Cost analysis was done from the service provider's perspective. **RESULTS:** In department of medicine the annual average cost of *C. difficile* infection was €800 per patient, the annual total cost of a recurrent patient was €1810, the annual additional cost of contact precautions was €330 per patient, the annual average cost of an episode was €570, the additional cost of contact precautions was €235 per episode. In intensive care unit the annual average cost of *C. difficile* infection was €1810 per patient, the annual total cost of a recurrent patient was €3680, the annual additional cost of contact precautions was €470 per patient, the annual average cost of an episode was €1070, the additional cost of contact precautions was €330 per episode. The most notable cost elements in intensive care unit were the hygienic costs and nurse wages, in department of medicine were the hygenic costs. **CONCLUSIONS:** The importance of C. difficile infection in public health and the associated disease burden are significant. The costs differed based on the length of isolation, and the type of the provider department. The available data in Hungary are limited, further studies in epidemiology and health economics are required.

PIN45

DYNAMIC MODELING TO ESTIMATE THE ECONOMIC IMPACT OF INCREASING INFLUENZA VACCINATION IN THE UNITED STATES

Inocencio TJ, Hughes KE
Avalere Health LLC, Washington, DC, USA

OBJECTIVES: This analysis was conducted to demonstrate potential downstream health care cost savings as a result of increasing vaccination rates for influenza in the United States. **METHODS:** An age-structured susceptible-exposed-infectious-recovered (SEIR) compartmental model was constructed to model the course of influenza infection over the course of 1 year in the United States. A realistic age structure was incorporated using mixing rates between age groups from the European POLYMOD survey. The SEIR model was adapted to include another compartment for vaccination. A series of difference equations was used to model transitions to and from each compartment. Time-dependent vaccination rates were obtained using monthly estimates of vaccination rates obtained from the Centers for Disease Control and Prevention (CDC). Cost and health care utilization data were obtained from the existing literature, and included outpatient visits, hospitalization, and antiviral drug treatment. Costs were reported in 2013 U.S. dollars. Microsoft Excel 2011 was used to conduct the analysis. **RESULTS:** Under a base case vaccination rate of 40 percent, an estimated 11 percent of individuals in the United States were projected to have symptoms of influenza infection. Health care costs attributable to influenza infection were estimated to be $13.6 billion. Increasing vaccination rates to 50 percent decreased the percentage of symptomatic individuals to approximately 7 percent, resulting in downstream health care costs of $9.5 billion. Further increasing vaccination rates to 60 percent is projected to further reduce downstream health care costs to approximately $5.0 billion. **CONCLUSIONS:** This exploratory analysis demonstrates that significant health care cost savings can be realized by increasing vaccination rates for influenza in the population.

PIN46

THE ASSOCIATION BETWEEN ADHERENCE TO ANTIRETROVIRAL THERAPY AND ECONOMIC OUTCOMES AMONG COMMERCIALLY INSURED AND MEDICAID HIV PATIENTS IN THE UNITED STATES

Korsnes JS[1], Goodwin B[2], Candrilli SD[1]
[1]*RTI Health Solutions, Research Triangle Park, NC, USA,* [2]*GlaxoSmith Kline, Research Triangle Park, NC, USA*

OBJECTIVES: Achieving optimal outcomes in the treatment of HIV requires high, sustained levels of medication adherence to antiretroviral therapy (ART). Across many conditions, suboptimal adherence has been shown to lead to poorer outcomes among patients. This study assessed the extent to which patients diagnosed with HIV are adherent with ART treatment guidelines and to illustrate associations between ART adherence and economic outcomes. **METHODS:** Commercially insured and Medicaid patients in the US from MarketScan claims databases with ≥2 claims containing an HIV/AIDS diagnosis code between June 1, 2006 and December 31, 2011 who received an ART prescription between June 1, 2007 and December 31, 2010 were selected for initial inclusion. For each patient, the first ART prescription received during that time defined the index date. Patients were ≥18 years old on their index date and had ≥12 months of continuous health plan enrollment with drug benefits before and after their index date. Adherence was measured by patients' proportion of days covered (PDC) with a complete ART regimen during the 12-month post-index date period; patients with PDC ≥80% were considered adherent. Multivariable models (i.e., generalized linear; Poisson) assessed the relationship between ART adherence and economic outcomes (i.e., costs; number of health care encounters), controlling for demographic and clinical characteristics. **RESULTS:** A total of14,590 commercially insured patients met all inclusion criteria, and 59% were adherent; 5,744 Medicaid patients met all

inclusion criteria, and 42% were adherent. After adjusting for confounders, ART adherence was associated with 29% and 31% reductions in non-pharmacy costs (p<0.0001)), 67% and 80% increases in total pharmacy costs (p<0.0001), 43% and 49% reductions in hospitalizations (p<0.0001), and 41% and 26% reductions in emergency department visits (p<0.0001), among commercially insured and Medicaid patients, respectively. **CONCLUSIONS:** This study suggests that ART adherence among commercially insured and Medicaid HIV patients in the US may be suboptimal, and that adherence is associated with improved economic outcomes among these patients.

PIN47

A SYSTEMATIC REVIEW OF ECONOMIC EVIDENCE IN HEPATITIS C: AN OVERVIEW OF COST, UTILITY AND COST-EFFECTIVENESS DATA

Woods MS[1], Kiri S[2], Ling C[1], McCrink L[1], Zimovetz E[1], Hass B[3]
[1]*RTI Health Solutions, Manchester, UK,* [2]*Boehringer Ingelheim Ltd., Bracknell, UK,* [3]*Boehringer Ingelheim GmbH, Ingelheim, Germany*

OBJECTIVES: To perform a systematic literature review of economic evidence for genotype 1 hepatitis C virus (HCV) treatments. **METHODS:** Searches were performed in MEDLINE, MEDLINE In-Process, EconLit, Embase, BIOSIS, and the Cochrane Library, to identify economic evaluations, cost/resource studies, and utility studies in patients with genotype 1 HCV. Searches were limited to articles published since 2000. Additional searches were performed on the ISPOR conference and key Health Technology Assessment (HTA) websites. **RESULTS:** The review identified 53 economic evaluations, 17 HTA documents, 57 cost/resource use studies, and 19 utility studies. The majority of economic evaluations were in interferon-containing regimens and were performed using lifetime horizon Markov models. Incremental cost-effectiveness ratios ranged from $4,570.31 to $157,404.13, depending on patient severity, the treatment used and the duration of treatment. Boceprevir and telaprevir triple therapies were shown to be cost-effective compared with peginterferon and ribavirin alone. In the cost studies, total all-cause, annual costs for patients with HCV ranged from $3,236 to $85,081, depending on the patients' disease status and whether they were currently receiving treatment. Indirect costs for HCV patients were reported less frequently, but they ranged from $1,424 to $10,316 per patient per year. Utilities for patients with HCV ranged from 0.24 for patients experiencing severe adverse events to 0.89 for patients in sustained virological response. Recent economic models tended to use utility data taken from previous models or HTA submissions. **CONCLUSIONS:** Numerous recent cost-effectiveness studies are available for HCV; however, many of the economic evaluations are based on previous models. There is a particular scarcity of updated country-specific utility data. As more treatment options become available, and more robust models are developed, enhanced utility and cost studies may be needed.

PIN48

RECENT TRENDS IN HOSPITAL COSTS, LENGTH OF STAY, AND MORTALITY ASSOCIATED WITH PEDIATRIC MENINGOCOCCAL DISEASE IN THE UNITED STATES

Davis KL, Candrilli SD
RTI Health Solutions, Research Triangle Park, NC, USA

OBJECTIVES: Meningococcal disease (MD) is a rare, life-threatening infection most common in infants (age <1 year), adolescents, and persons living in close quarters. In this study, we documented trends in hospital costs, length of stay (LOS), and mortality associated with pediatric MD cases in the United States (US) from 2000 to 2009. **METHODS:** Data for pediatric (age ≤20 years) MD-related hospitalizations (discharges with ICD-9-CM 036.xx) from the 2000, 2003, 2006, and 2009 HCUP Kids' Inpatient Databases (KID) were retrospectively analyzed. Charges were converted to costs using a 0.5 cost-to-charge ratio. Weighted, nationally representative estimates of costs per admission (in 2012 US dollars), LOS, and case fatality rates were descriptively analyzed for each year. **RESULTS:** By year, total (weighted) numbers of pediatric MD-related hospitalizations in the US were: 2000 (N=1,680), 2003 (N=1,089), 2006 (N=745), 2009 (N=581). Mean [SD] LOS for these hospitalizations was 8.4 [12.9] days in 2000, which decreased modestly to 7.7 [9.6] and 7.9 [8.3] days in 2003 and 2006, respectively, before a substantial increase to 9.3 [13.9] days in 2009. Mean [SD] cost per admission fluctuated accordingly, increasing from $25,739 [$60,929] in 2000 to $33,530 [$62,499] in 2009. Case fatality rates, however, remained relatively unchanged during the period, declining slightly from 4.7% in 2000 to 4.3% in 2009, although a noticeable spike occurred in 2003 when 5.8% of cases died. **CONCLUSIONS:** MD in the US pediatric population is associated with high costs resulting from hospital stays that typical exceed 1 week. Our estimated case fatality rate (~5%), while high, is lower than the 10-15% fatality rate estimated by the US Centers for Disease Control, which includes estimates from all age groups combined (pediatrics and adults). In light of these findings, recent efforts to raise awareness of MD as a serious public health concern should be continued.

PIN49

HEALTH CARE COSTS OF HIV IN THE CZECH REPUBLIC. A SINGLE CENTER ANALYSIS

Skoupa J[1], Snopkova S[2], Dvorak P[3], Pospisil J[4]
[1]*1st Medical Faculty, Charles University, Prague, Czech Republic,* [2]*Faculty Hospital and Masaryk University, Brno, Czech Republic,* [3]*EconHealth s.r.o., Prague, Czech Republic,* [4]*Faculty Hospital, Brno, Czech Republic*

OBJECTIVES: To assess direct medical costs of HIV patients, based on CD4+ lymphocyte count and duration since diagnosis in the Czech setting. **METHODS:** We analyzed retrospectively costs of HIV patients in a single center. The analyzed sample included patients with a disease history of 12 month and longer, who regularly visited the center. Resource use, derived from the hospital information system, included services delivered at the HIV center and other hospital wards. The retrospective period covered up to 36 months; average annual costs were calculated. Resource use was analyzed separately for (a) groups of CD4+ count (<200; 200-499; ≥500); (b) time since diagnosis (<5 years; 5-10 years; >10 years). For comparison, two-sided Student's t-test was used; to achieve normal distribution, values were transformed to common logarithms. Costs are stated in € (1€=25.5CZK). **RESULTS:** A total 100 patients (about 10-15% of all HIV treated in the Czech Republic) were included. The mean age was 41.9 years (range 23-71), time since diagnosis 5.8 years (range 1-26), and period of assessment 30.5 months. Average total annual costs were highest for CD4+ <200 (22,905€; p<0.05) vs. CD4+ 200-499 (17,801€) and CD4+ >500 (17,043€). HIV medication accounted for the majority of costs in all three subgroups (range 62% in CD4+ <200 to 88% in CD4+ >500). Patients with a disease duration of >10 years had highest annual costs of 22,841€ (p<0.05) compared to 15,783€ (duration 5-10 years) and 16,777€ (<5 years). HIV-medication accounted for the majority of costs here as well (from 70% to 88%; NS). In this analysis 17 % of costs in patients with disease duration of >10 years were due to hospitalization vs. 5 % in both other groups (NS). **CONCLUSIONS:** Similarly to published literature, we found highest costs in patients with low CD4+ lymphocytes and longer disease duration.

PIN50

THE BURDEN OF CLOSTRIDIUM DIFFICILE IN SPAIN: A RETROSPECTIVE MATCHED-COHORT STUDY

Hart WM[1], Asensio A[2], Isidoro B[2], Watt M[3], Nazir J[3]
[1]*EcoStat Consulting UK Ltd., London, UK,* [2]*Hospital Universitario Puerta de Hierro, Madrid, Spain,* [3]*Astellas Pharma Europe Ltd., Chertsey, UK*

OBJECTIVES: Clostridium difficileinfection (CDI) is the leading cause of infectious diarrhoea in hospitalised patients. The majority of published burden of CDI studies refer to US or northern European populations. Knowledge of the burden of CDI on health care resource utilisation in Spain is limited. The aim of the study was to provide recent data on the burden of CDI in terms of hospital resources and costs and in particular attributable length of stay. **METHODS:** A retrospective study was carried at a leading teaching hospital in Madrid. Data refer to sequential cases of CDI during the year 2011. Data were extracted from patient records using a predefined structured protocol. Hospital onset CDI cases were matched at a ratio of two non-infected patients for each case to adjust for confounding variables. **RESULTS:** A total of 44 CDI cases were identified of whom 25 were health care-associated and hospital-onset. The mean duration of diarrhoea (days) was 10.12+7.98. Using median regression, the attributable length of stay (LOS) due to CDI was 9.98+2.21 days. The average number of isolation days was 9.21+8.27. The majority of patients were treated with oral metronidazole. The first episode cure rate was 83.7%, 30-day and overall mortality were 18.6 and 25.6% respectively, attributable mortality was 4.65%. A total of 9.3% of patients experienced a recurrence occurring within 2-8 weeks within hospital stay. The cost attributable to an individual case of CDI would be 4,331 euros, of which over 90% is associated with hospital LOS. **CONCLUSIONS:** Our results highlight the significant burden of CDI in a large Spanish hospital. These costs will only continue to rise as the incidence of CDI continues to increase. A major breakthrough in cost reduction of CDI would be an intervention or procedure that shortens hospital length of stay and/or reduces episode recurrence.

PIN51

COST AND LENGTH OF STAY ASSOCIATED WITH VANCOMYCIN-INDUCED NEPHROTOXICITY

Stevens V[1], Yoo M[1], Brown J[2]
[1]*University of Utah, Salt lake City, UT, USA,* [2]*SUNY Buffalo School of Pharmacy, Buffalo, NY, USA*

OBJECTIVES: Decreased susceptibility to vancomycin has led to recommendations for increased serum concentration targets for some infections, which has been shown to increase the risk of nephrotoxicity (NT). The objective of this study was to determine if vancomycin-induced nephrotoxicity has a significant impact on cost from the hospital perspective or on length of stay. **METHODS:** A cost of illness study from the hospital perspective. We conducted a secondary analysis of a cohort of 398 randomly selected inpatients receiving vancomycin in a tertiary care hospital in Rochester, New York, USA. Total and variable costs were generated by hospital accountants using micro-costing methods. NT was defined as 0.5 or 50% or greater increase in serum creatinine from baseline. Generalized linear models with log link and gamma distribution and semi-log regression were used to model total and variable costs and length of stay, respectively. Cost estimates are reported in 2009 USD. **RESULTS:** Forty-nine (12%) of patients had NT. The unadjusted median variable costs for patients with NT were higher than for patients without NT ($47,511 vs. $22,355, p<.0001). On multivariable analysis, variable costs were 18% greater for patients with NT compared to patients without, but this difference was not statistically significant. The median length of stay for patients with NT was two-fold greater than for patients without NT (22 vs. 11 days, unadjusted, p<.0001). After accounting for severity of illness and other factors, NT patients stayed on average 46% longer than non-nephrotoxic patients. **CONCLUSIONS:** Patients with NT have significantly increased length of stay relative to patients without NT. Further research is needed to confirm whether increased length of stay has a meaningful impact on costs. As vancomycin susceptibility continues to decrease, higher doses of vancomycin may lead to an increased incidence of NT and an increase in resource utilization among these patients.

PIN52

COST ASSOCIATED WITH ADVERSE EVENTS AND HEALTH CARE RESOURCES UTILIZATION IN HEPATITIS C VIRUS INFECTION IN QUEBEC, CANADA

Lachaine J[1], Vachon ML[2], Lambert-Obry V[1], Beauchemin C[1]
[1]*University of Montreal, Montreal, QC, Canada,* [2]*CHUQ, Laval University, Quebec, QC, Canada*

OBJECTIVES: The purpose of this study was to estimate the health care resource utilization, more specifically resource utilization for management of the most common adverse events (AE) associated with current treatment of hepatitis C virus (HCV) infection, in a real life setting. **METHODS:** A retrospective study of the Quebec provincial drug reimbursement program (RAMQ) was conducted using a random sample of patients who filed at least one script for an HCV medication (pegylated-interferon and ribavirin (Peg-Riba) +/-boceprevir or telaprevir) between January 2007 and December 2012. Data on medical (excluding nurse visits) and pharmaceutical services were extracted from the RAMQ database. We report health care resources used during HCV treatment including outpatient physician's visits and procedures, emergency

visits, hospitalization days and costs associated with adverse events, which included medical services and medications. **RESULTS:** The study included 1,081 patients who used at least one HCV medication (mean age of 46.4 years [SD=10.7], 64.8% men). Peg-Riba only, Peg-Riba+boceprevir and Peg-Riba+telaprevir was used by 1,029 (95.2%), 50 (4.6%) and 18 (1.7%) patients respectively. Fifty-seven patients (5.3%) required a subsequent HCV treatment during the study period. The mean duration of treatments was 30.4 weeks (SD=16.1). During HCV treatment, the average number of health care resources per patient was 13.2 physician's visits and procedures, 1.0 hospitalization day and 0.9 emergency visit. While receiving HCV treatment, 191 (17.7%) of patients required erythropoietin, 353 (32.7%) received rash treatments and 541 (50.0%) were treated for depression. Estimated costs associated with management of these three AE were CDN$10,834, CDN$78 and CDN$268 per patient respectively. **CONCLUSIONS:** HCV treatment is associated with significant health care resource utilization. A high proportion of patients experienced AE for which management was associated with substantial additional costs, especially the anemia treatment. Thus, the cost of AE should be considered in future treatment options.

PIN53

THE COSTS OF MANAGING GENITAL WARTS IN THE UK BY DEVOLVED NATION: ENGLAND, SCOTLAND, WALES AND NORTHERN IRELAND

Chapman R[1], Coles VAH[2], Lanitis T[1], Carroll SM[2]
[1]*Evidera, London, UK,* [2]*Sanofi Pasteur MSD, Maidenhead, UK*

OBJECTIVES: Genital warts (GW), 90% of which are caused by human papillomavirus (HPV) types 6 and 11, are a significant problem in the UK. The cost of managing GW in 2010 was previously estimated at £52.4 million. The objective of this study was to estimate the cost of GW management up to 2012, and to determine the cost by UK jurisdiction. **METHODS:** Population statistics were obtained from the Office of National Statistics for the UK, England and Wales; the General Register Office and 2011 census data for Scotland; and the Northern Ireland (NI) Statistics and Research Agency. Numbers of GW cases in genito-urinary medicine (GUM) clinics were obtained from the Health Protection Agency for the UK and England; the Information Services Division for Scotland; the Communicable Disease Surveillance Centre for Wales; and the Public Health Agency for NI. The number of cases treated in primary care was estimated from The Health Improvement Network database. Population statistics and GW cases were extrapolated by jurisdiction to 2012. The number of visits and therapy required for GW management were estimated by GUM experts for standard and hard-to-treat patients. Costs were obtained from the most recent National Health Service (NHS) Payment by Results tariffs, Personal Social Services Research Unit and British National Formulary. **RESULTS:** The model estimated 220,779 GW cases in the UK, costing £58.42 million annually (£265 per patient). For England, 157,693 cases were estimated costing £41.72 million; for Scotland 7,461 cases costing £1.90 million; for Wales 7,091 cases costing £1.87 million; and for NI 3,619 cases costing £0.95 million. **CONCLUSIONS:** The full NHS costs for the management of GW have never before been estimated separately for each jurisdiction. The results of the model reveal a significant economic burden which is important to quantify when understanding the value of quadrivalent HPV vaccination.

PIN54

IMPACT OF TREATMENT FAILURE ON THE TOTAL COST OF TRIPLE THERAPY INCLUDING BOCEPREVIR OR TELAPREVIR BASED ON THE FRENCH EARLY ACCESS PROGRAM (ANRS CO20-CUPIC) STUDY

Valladares A[1], Calleja JL[2], Serra MÁ[3], Chacón F[1], Nocea G[1]
[1]*Merck Sharp & Dohme, Madrid, Spain,* [2]*University Hospital Puerta de Hierro, Madrid, Spain,* [3]*University Clinic Hospital, University of Valencia, Valencia, Spain*

OBJECTIVES: The ANRS CO20-CUPIC study was designed to evaluate triple therapy (TT) efficacy and safety in HCV-cirrhosis treatment-experienced patients in the French Early Access Programme. A 60-week interim analysis has been reported confirming better clinical outcomes than double therapy in a real clinical setting. However, independently of the protease inhibitor (PI) used, boceprevir (BOC) or telaprevir (TLV), treatment failure (TF) was reported in up to 60% of the patients. Little is known about these patients' treatment cost: that of successfully treated patients can be generally calculated from the full course of PI treatment, but the cost of those who failed highly depends on TF timing. Our objective is to estimate the average PI cost/patient who failed treatment based on CUPIC study reported data. **METHODS:** Using reported data on ITT virological response and TF, BOC and TLV on-treatment rates over time were estimated. Based on this curve, the average PI treatment duration and average PI cost/patient who failed treatment were calculated. When not enough information about time to treatment discontinuation was available, the same conservative approach was applied for both drugs, considering the midpoint of the treatment interval. Sensitivity analyses on the time to TF were performed to confirm the robustness of the results. **RESULTS:** A total of 472 patients (72%) were included in the 60-week interim analysis. Independently of the IP used, about 60% the patients who start treatment did not achieve viral cure and their estimated average PI treatment duration was 26 wks in BOC patients and 11 wks in TLV patients. The average PI cost/patient who failed treatment with TLV (23.012€) was 26% higher than that of treatment with BOC (18.253€). The sensitivity analysis confirmed the robustness of the base case estimation. **CONCLUSIONS:** In a scenario of comparable efficacy between both PIs, the resources wasted on TF acquire a great importance in selecting the least costly of the two alternatives. Based on CUPIC study reported data, the average PI cost/patient who failed treatment was significantly higher in TLV patients than in BOC patients.

PIN55

PREDICTORS OF COSTS OF ANTIRETROVIRALS FOR HIV INFECTION IN ITALY: A MULTICENTRIC RETROSPECTION IN 2012

Tontodonati M[1], Cenderello G[2], Celesia BM[3], Trezzi M[4], Ursini T[1], Costantini A[5], Gaggero D[2], Gussio M[3], Manzoli L[6], Polilli E[7], Sozio F[7], Catalani C[4], Butini L[5], Parruti G[7]
[1]*Pescara University, Pescara, Italy,* [2]*Galliera Hospital, Genoa, Italy,* [3]*ARNAS Garibaldi, Catania, Italy,* [4]*Ospedal Il Ceppo, Pistoia, Italy,* [5]*Ancona Hospital, Ancona, Italy,* [6]*Pescara Chieti University, Chieti, Italy,* [7]*Pescara General Hospital, Pescara, Italy*

OBJECTIVES: Most industrialized countries strive to guarantee long term sustainability for HIV antiretroviral treatment . By assessing the most relevant current predictors of costs of antiretrovirals(HAART) might represent the first step to understand spending drivers and to plan cost reduction strategies. **METHODS:** A retrospective sample of HIV outpatients followed at 5 Italian Hospitals in 2012 was collected. Demographic features, current HIV viral load, current and Nadir CD4 T-celI counts, time from HIV diagnosis, AIDS-defining events, HAART line and HCV coinfection were taken into consideration. Individual ARV regimen-costs were based on local pharmacy datasets from December, 2011, and log-transformed in the final multivariate models. Univariate analyses were performed to identify potential predictors and stepwise multivariate regressions were used to identify independent predictors of higher individual costs, using Stata 10.1 package. **RESULTS:** We included 2044 patients, 69.0% males, mean age 47.2±10.0 years; 33.4% HCV-coinfected, mean time from HIV diagnosis 13.3±7.9 years, mean nadir CD4 T cell counts 239±169.3 cell/mm3; mean current CD4T-cell counts 590±302.6 cell/mm3, 30.8% AIDS classified. Patients on HAART were 1,902 (93.0%),among treated patients, 19.0% presented an HIV-viremia>50 c/mL. Mean annual individual HAART-costs were € 9,376±3,501 (782-29,852). At univariate analysis, a significant association was found between costs and age time from HIV diagnosis, previous AIDS diagnosis, HCV-coinfection current and Nadir CD4T-cell counts, HAART-line, HIV-viremia and site of care. In the final regression model, HAART costs showed independent and direct correlation with HAART lines (p<0.001), detectable viremia (p<0.001) and time from HIV diagnosis (p=0.009); inverse correlation with Nadir CD4 T-cell counts (p=0.01). Being treated at 2 of 5 centre was another predictor of higher costs.(P<0.001). **CONCLUSIONS:** Higher HAART-costs were strongly associated with previous treatment failures and detectable HIV-viremia; a more compromised immune status at clinical presentation and a longer duration of HIV infection showed independent contribution, focusing on timely diagnosis of HIV infection.

PIN56

ECONOMIC IMPLICATIONS OF ALTERNATIVE TREATMENTS AND CARE LOCATIONS FOR ACUTE BACTERIAL SKIN AND SKIN STRUCTURE INFECTIONS WITH SUSPECTED MRSA

LaPensee K[1], Fan W[1], Revankar N[2], Ward A[3], Kongnakorn T[3], Pelligra C[3]
[1]*The Medicines Company, Parsippany, NJ, USA,* [2]*Evidera, London, UK,* [3]*Evidera, Lexington, MA, USA*

OBJECTIVES: Develop model simulating economic implications of alternative treatment strategies for acute bacterial skin and skin structure infections (ABSSSIs) with suspected Methicillin-Resistant *Staphylococcus aureus* (MRSA) that considers antibiotic switches, course duration, route of administration and location of care (LOC). **METHODS:** Discrete event simulation (DES) tracks patient pathways through various LOC (ED, inpatient, outpatient) during ABSSSI treatment for suspected MRSA. Model assumes 60% of patients hospitalized. Multiple pathways are allowed: patients responding can move to outpatient to finish treatment, switch treatment at discharge or receive 2nd line treatment if not responding. Patients accrue resource use, time in LOC and costs. Hospital days obtained from analysis of Premier Hospital Database. Three cohorts created; all assigned to receive vancomycin (VAN) 1st line therapy. Upon discharge, one cohort continued on VAN, one switched to oral linezolid (LIN), one to daptomycin (DAP) to complete treatment. Costs are from the Medicare perspective in 2012 USD. **RESULTS:** Hospital plus outpatient days range from 11.1 (VAN) to 14.5 (LIN); costs ranged from $6,983 (LIN) to $8,122 (VAN) with suspected MRSA. By comparison, reatment duration ranged from 9.97 (VAN) to 13.02 (LIN) and total costs ranged from $6,889 (LIN) to $9,354 (VAN) when MRSA is not always suspected. Despite longer LIN treatment, costs are lower because of avoided infusion costs. Outpatient costs account for 22% (LIN) to 33% (VAN) of total costs. Sensitivity analysis examined impact on cost when treatment duration varied per drug labeling. Total costs varied from $6,756 to $7,158 when duration of LIN ranges from 8 days to 12 days. **CONCLUSIONS:** Treatment choice and LOC have major impact on ABSSSI resource use and costs. Suspected MRSA increases treatment duration and cost. Economic implications for payers and providers should be evaluated using models that capture these elements in view of long-acting lipoglycopeptide IV antibiotics in development that avoid repeated infusions and may allow for less inpatient treatment.

PIN57

WHEN TREATMENT IS MITIGATED BY ADVERSE EVENTS: THE ECONOMIC IMPACT OF TREATMENT-ASSOCIATED ADVERSE EVENTS IN CIRRHOTIC NON-RESPONDERS TREATED WITH BOCEPREVIR OR TELAPREVIR AND PEGINTERFERON ALPHA/RIBAVIRIN

Sullivan S[1], McDermott C[1], Dieterich D[2], Martel-Laferriere V[2], Saab S[3], Gordon S[4]
[1]*University of Washington, Seattle, WA, USA,* [2]*Mount Sinai School of Medicine, New York, NY, USA,* [3]*David Geffen School of Medicine at UCLA, Los Angeles, CA, USA,* [4]*Henry Ford Hospital, Detroit, MI, USA*

OBJECTIVES: Adverse events (AEs) and premature treatment discontinuation of protease inhibitor (PI) therapy in the treatment of chronic hepatitis C (CHC) may mitigate the benefits of improved sustained virologic response. We use data from a recent study to estimate the economic impact of PI therapy in the cirrhotic non-responder population. **METHODS:** In the Compassionate Use of Protease Inhibitors in viral C cirrhosis (CUPIC) study, patients with compensated cirrhosis and genotype 1 CHC were treated with boceprevir (n=205) or telaprevir (n=292) in combination with peginterferon alpha and ribavirin. The investigators reported safety and tolerability in an interim 16-week analysis. Using CUPIC data and micro-costing technique, we estimate the costs of treatment-related hematologic and rash AEs by severity (Grades 2-4) and the cost of drug wastage using PI discontinuation rates due to serious AEs (SAEs) (7.3% boceprevir; 14.7% telaprevir). We surveyed 3 hepatologists to ascertain treatment patterns related to AEs and combined these estimates with cost data to compute mean costs per treatment group from the US payer perspective during the first 16 weeks of therapy. **RESULTS:** The AE-related costs were $1,980 and $2,161 for telaprevir and boceprevir treated patients, respectively, for the first 28 days of treatment. Medication-related costs of premature discontinuation due to SAEs were estimated at $8,463 for telaprevir and $1,575 for

boceprevir. Total costs of AE and discontinuation were $10,443 and $3,736 for telaprevir and boceprevir treated groups, respectively. The results were not sensitive to variation in treatment practices and costs. **CONCLUSIONS:** The costs of treatment of cirrhotic non-responders during the first 16 weeks were estimated to increase by 18% over triple therapy costs due to AEs. These data indicate that the total cost per cure may be substantially higher than the drug costs and underscore the importance of evaluating total cost of HCV treatment when selecting new agents.

PIN58

DIRECT MEDICAL COSTS AND HEALTH CARE RESOURCE UTILIZATION ASSOCIATED WITH SELECTED ANTIBIOTIC TREATMENT PATHWAYS IN ACUTE BACTERIAL SKIN AND SKIN STRUCTURE INFECTIONS IN THE UNITED STATES

Fan W[1], LaPensee K[1], Mao J[2], Iorga S[2], Lodise TP[3]
[1]*The Medicines Company, Parsippany, NJ, USA,* [2]*OptumInsight, Eden Prairie, MN, USA,* [3]*Albany College of Pharmacy and Health Sciences, Albany, NY, USA*

OBJECTIVES: Current guidelines for the treatment of acute bacterial skin and skin structure infections (ABSSSI) recommend several treatment pathways based on the infection types and severity. The objective of this study is to establish the health care resource utilization (HRU) and costs associated with the most common patient treatment pathways in US. **METHODS:** The medical and pharmacy administrative claims of adult ABSSSI patients with continuous commercial or Medicare Advantage enrollment with Part D prescription drug coverage between 01 January 2009 and 31 December 2011 were extracted from a large national health plan affiliated with OptumInsight. The four most common treatment pathways were identified based on the evidences of antibiotics over the entire ABSSSI treatment course. All four pathways start with vancomycin IV use during a hospital stay. At discharge, patients followed one of four pathways: 1) continue IV vancomycin as an Outpatient Parenteral Antibiotic Therapy (OPAT); 2) switch to oral linezolid; 3) switch to daptomycin; or 4) switch to any oral antibiotic other than linezolid, clindamycin, or TMP-SMX. Health care resource utilization and costs were determined for each pathway. **RESULTS:** A total of 1418 patients met all of inclusion/exclusion criteria. The majority of patients either continued Vancomycin IV (46.5%) or switched to oral linezolid (41.4%) at discharge. Only about 12% of patients were switched to Daptomycin or other non-MRSA active oral antibiotics. The average ABSSSI-related total health care cost was $16,571 for the entire ABSSSI treatment. Total costs were comprised of $12,519 (75.5%) for inpatient cost, $201 (1.2%) for emergency department (ED) visits, $879 (5.3%) for outpatient treatment/office visits, and $1,015(6.1%) for pharmacy claims cost. The costs overall and in various locations of care varied by pathway. **CONCLUSIONS:** Inpatient treatment remains the largest component of total ABSSSI treatment cost. Utilization of linezolid and daptomycin increased the pharmacy or OPAT costs.

PIN59

COMPARISON OF THE HEALTH CARE COSTS AND UTILIZATIONS BETWEEN PATIENTS DIAGNOSED WITH THE HEPATITIS B VIRUS VERSUS THOSE WITHOUT

Xie L[1], Wang L[2], Kariburyo MF[1], Li L[2], Wang Y[1], Baser O[3]
[1]*STATinMED Research, Ann Arbor, MI, USA,* [2]*STATinMED Research, Dallas, TX, USA,* [3]*STATinMED Research/The University of Michigan, Ann Arbor, MI, USA*

OBJECTIVES: To examine the economic burden and health care utilizations of patients diagnosed with the hepatitis B virus (HBV) in the U.S. veteran population. **METHODS:** A retrospective database analysis was performed using the Veterans Health Administration (VHA) Medical SAS datasets from October 1, 2008 to September 30, 2012. Patients diagnosed with HBV were identified using International Classification of Disease 9th Revision Clinical Modification (ICD-9-CM 070.22, 070.23, 070.32, 070.33, V02,61) diagnosis codes. The first diagnosis date was defined as the index date. A group of patients of the same age, region, gender and index year but without HBV infection were identified and matched by baseline Charlson Comorbidity Index (CCI) as the comparison group. A 1-year continuous health plan enrollment was required before and after the index date for both groups. Study outcomes, including health care costs and utilizations, were compared between the HBV and comparator groups using 1:1 propensity score matching. **RESULTS:** A total of 9,718 patients were identified for the HBV and comparison cohorts. After applying a 1:1 matching, a total of 3,093 patients were matched from each cohort, and the baseline characteristics were proportionate. Patients diagnosed with HBV infection were more likely to report higher health care utilizations, including inpatient (28.74% vs. 3.3%, $p<0.01$), emergency room (25.67% vs. 8.3%, $p<0.01$), physician office (98.60% vs. 62.75%) and pharmacy visits (88.23% vs. 63.65%, $p<0.01$). The risk-adjusted health care costs were also higher for patients infected with HBV due to increased inpatient ($10,481 vs. $804, $p<0.01$), emergency room ($382 vs. $80, $p<0.01$), physician office ($4,635 vs. $1,678, $p<0.01$), and pharmacy visits ($1,166 vs. $398, $p<0.01$) resulting in higher total costs ($16,909 vs. $3,045, $p<0.01$) relative to the comparator cohort. **CONCLUSIONS:** During a period of 12 months, VHA patients diagnosed with HBV reported higher health care utilization and costs than their matched controls.

PIN60

A COMPARATIVE STUDY ON THE COST OF ANTIBIOTICS FOR THE YEARS 2011-2012 IN THREE GENERAL HOSPITALS OF GREECE

Gkogkozotou VK[1], Papandreou V[2], Papagiannakopoulou P[3], Asithianakis P[1]
[1]*UNIVERSITY HOSPITAL OF CRETE (PAGNI), CRETE, Greece,* [2]*EVAGGELISMOS HOSPITAL, ATHENS, Greece,* [3]*TZANEIO, PIRAEUS, Greece*

OBJECTIVES: Since Greece came under the regime of IMF and signed the memorandum, several curtailments had to be made to various areas of the public sector. Drug treatment seems to be quite expensive. As part of the strict economic rules, Greek hospitals were obliged to reduce their health care costs. The pharmacy of each hospital incurred considerable weight of this attempt. One of its implemented actions was the drugs' price negotiation with the pharmaceutical companies. **METHODS:** In order to measure the effectiveness of this action, we performed a comparative study of the antibiotics used in 3 hospitals, PAGNI, Evaggelismos and Tzaneio. PAGNI and Evaggelismos are among the 5 biggest hospitals of Greece (pharmaceutical budget around 40M€) while Tzaneio is a small general hospital (PB 6M€). We chose 24 active ingredients (95 different antibiotics) that represent about 1/3 of total hospital antibiotics and 80% of the total antibiotics' budget. We studied their consumption for the years 2011 and 2012 and calculated the costs based on the official drug pricelist and their price after the negotiation. **RESULTS:** From 2011 to 2012 the discounts gained from each hospital were increased. Price negotiation does not apply in prototype drugs that their companies are only obliged to offer a 5% rebate. Unfortunately, these medications are more expensive, represent 36% of the studied antibiotics' cost and their consumption was increased by 20%. But, the discounts for all the studied off-patent drugs and their generics were from 12.8% till 89.9%. Thus, the total cost saving for them was 33.2% at PAGNI, 26.0% at Evaggelismos and 43.1% at Tzaneio. The total benefit for the pharmaceutical expenditure was 3% for both PAGNI and Evaggelismos, and 6% for Tzaneio. **CONCLUSIONS:** Price negotiation is an effective mean of decreasing the cost of off-patent and generic drugs but newer and expensive drugs get doctors' preference, undermining the Pharmacy's cost-saving effort.

PIN61

WHAT ARE THE CLINICAL AND ECONOMIC COSTS AND BENEFITS OF IMPLEMENTING POINT OF CARE TESTS FOR CHLAMYDIA TRACHOMATIS AND NEISSERIA GONORRHOEA IN GENITO-URINARY MEDICINE CLINICS IN THE UNITED KINGDOM?

Turner KM[1], Round J[2], Horner P[1], Macleod J[1], Goldenberg S[3], Deol A[4], Adams EJ[4]
[1]*University of Bristol, Bristol, UK,* [2]*University College London, London, UK,* [3]*Guy's and St Thomas' NHS Foundation Trust, London, UK,* [4]*Aquarius Population Health, London, UK*

OBJECTIVES: To estimate the costs and benefits of patient pathways incorporating a point of care nucleic acid amplification test (POC NAAT) for chlamydia and gonorrhoea in genito-urinary medicine (GUM) clinics in the UK compared with standard off-site laboratory testing. **METHODS:** We simulated 1.2 million men and women GUM clinic attendees based on GUMCAD reports from the UK (2011). A Markov model with Monte Carlo simulation in Microsoft Excel was developed to compare existing standard pathways of testing and treatment for chlamydia and gonorrhoea with a POC NAAT. We conducted sensitivity analyses to evaluate the robustness of the model findings. The primary outcome was the incremental cost-effectiveness ratio (ICER = £/QALY). Secondary outcomes included the number of inappropriate treatments, complications and transmissions averted and change in time from test to treatment. **RESULTS:** The total cost of using the POCT in our cohort was £103.3 million compared with £113.9 million for standard care. The ICER was -£4,182/QALY, making the new pathways cost saving. Nearly 100,000 inappropriate treatments might be avoided by using a POC NAAT. Patients receive diagnosis and treatment on the same day as testing, which may also prevent 162 cases of pelvic inflammatory disease and 17,561 transmissions. **CONCLUSIONS:** Replacing standard laboratory tests for chlamydia and gonorrhoea with a POCT could be cost saving and patients would benefit from more accurate diagnosis and less unnecessary treatment. Overtreatment currently accounts for about a tenth of the reported treatments for chlamydia and gonorrhoea and POC NAATs would effectively eliminate the need for presumptive treatment.

PIN62

COST-EFFECTIVENESS OF CHILDHOOD ROTAVIRUS VACCINATION IN GERMANY

Aidelsburger P[1], Grabein K[2], Boehm K[1], Helbig AK[1], Dietl M[1], Wasem J[2], Koch J[3], Ultsch B[3], Weidemann F[3], Wichmann O[3]
[1]*CAREM GmbH, Sauerlach, Germany,* [2]*University of Duisburg-Essen, Essen, Germany,* [3]*Robert Koch Institute, Berlin, Germany*

OBJECTIVES: Rotavirus (RV) causes highly contagious gastroenteritis especially in children under five years of age. Since 2006, two RV-vaccines are available in Europe (Rotarix® and RotaTeq®). We evaluated the cost-effectiveness of these vaccines for the German health care setting, inter alia to support an informed decision-making concerning a potential vaccination-recommendation. **METHODS:** A Markov Model was developed to evaluate the cost-effectiveness from the statutory health insurance (SHI) (direct costs) and from the societal perspective (SHI plus indirect costs). Health outcomes considered were RV-cases prevented, RV-associated hospitalizations avoided, and quality-adjusted life-years (QALY) gained. RV-incidences were derived from the national mandatory disease reporting system. RV-vaccine efficacy was calculated as pooled estimates based on data from randomized controlled trials. Costs (reference year 2010) were derived from official price catalogues. An annual discount rate of 3% for effects and costs was applied. The first five life-years were considered as model's time horizon. **RESULTS:** The base-case analysis (SHI-perspective) resulted in an incremental cost-effectiveness and cost-utility ratio (ICER) for Rotarix® of € 184 per RV-case prevented, € 2,457 per RV-associated hospitalization avoided, and € 116,973 per QALY gained. For RotaTeq®, the results were slightly higher (€ 234, € 2,622, and € 142,732, respectively). In sensitivity analyses parameter variation showed effects on the ICERs without changing the overall trend. A threshold analysis suggests that cost-saving scenarios are possible with vaccine prices reduced by ~62-66%. When applying base-case scenario results to the 2012 birth-cohort with 80% vaccination coverage, an estimated 206,000-242,000 RV-cases and 18,000 RV-associated hospitalizations can be prevented in this birth-cohort over 5 years for an incremental cost of 44.5-48.2 million Euros. **CONCLUSIONS:** Routine RV-vaccination is expected to prevent a considerable number of RV-cases and RV-associated hospitalizations in Germany. Though, the amount of QALYs gained is low. With current vaccine prices, RV-vaccination is not a cost-saving preventive measure.

PIN63

COST-EFFECTIVENESS ANALYSIS OF 3 CANDINS AND FLUCONAZOLE IN THE TREATMENT OF CONFIRMED INVASIVE CANDIDIASIS IN ADULT NON-NEUTROPAENIC PATIENTS IN SPAIN

Grau S[1], Pozo JC[2], Roma E[3], Salavert M[3], Collados C[4], Egea-García M[4], Mesa FJ[5], Llevat N[5], Barrueta A[5]
[1]*Hospital del Mar (IMIM), Barcelona, Spain,* [2]*Universitary Hospital Reina Sofia, Córdoba, Spain,* [3]*Hospital La Fe, Valencia, Spain,* [4]*Pfizer S.L.U, Alcobendas,, Spain,* [5]*Pfizer S.L.U, Alcobendas, Spain*

OBJECTIVES: To estimate the cost-effectiveness (CE) of the 3 echinocandins (Anidulafungin, Caspofungin and Micafungin) and generic Fluconazole in the treatment of adult non-neutropaenic patients with invasive candidiasis (IC) in a Spanish Intensive Care Unit (ICU) setting. **METHODS:** A 4 arm decision tree model was developed with the 3 echinocandins and generic Fluconazole as first line treatment. In case of treatment failure, a 2nd line treatment was administered (Liposomal Amphotericin-B following the echinocandins and either one of the 3 echinocandins for Fluconazole arm). After 2nd line failure, treatment was discontinued. Total treatment length was 14 days. Efficacy and safety (adverse events/lack of efficacy) parameters where obtained from a mixed-treatment-comparison and a meta-analysis respectively. Efficacy was considered as first line success (Anidulafungin 75.32%; Micafungin 71.65%; Caspofungin 70.62%; and Fluconazole 56.7%). Length of the first and the second line were elicited using experts' opinion through Delphi methodology. Daily drug acquisition costs were considered only. The CE was expressed as an incremental cost-effectiveness ratio (ICER). Univariate sensitivity analyses were also applied and included, length of treatment in 1st or 2nd line and finally drug dosages calculated as per SmPC recommendations according to different patient characteristics. **RESULTS:** Total costs of IC treatment for Anidulafungin, Micafungin, Caspofungin and Fluconazole were €5,552; €5,985; €6,350; €1,654 respectively. Anidulafungin was dominant compared to Micafungin and Caspofungin. Anidulafungin and Micafungin were cost-effective (€20,934; 29.576€ respectively) compared to Fluconazole (CE threshold of €30,000). Sensitivity analyses revealed that ICER was sensitive to increases in the length of the 1st and 2nd line treatments, although Anidulafungin was cost-effective in all scenarios. **CONCLUSIONS:** Based on the model's assumptions, Anidulafungin is cost-saving compared to Micafungin and Caspofungin and cost-effective vs. Fluconazole in the treatment of patients with confirmed invasive candidiasis from a Spanish Hospital ICU perspective.

PIN64

COST-EFFECTIVENESS OF LINEZOLID VERSUS VANCOMYCIN IN THE TREATMENT OF VENTILATOR ASSOCIATED PNEUMONIA IN JAMAICA

Garita M[1], Nicholson A[2], Cuesta G[3], Mould J[4]
[1]*Pfizer Central America and Caribbean, Escazu, San Jose, Costa Rica,* [2]*University Hospital of the West Indies, Kingston, Jamaica,* [3]*Pfizer Central America and the Caribbean, Escazú, San Jose, Costa Rica,* [4]*Pfizer, New York, NY, USA*

OBJECTIVES: The ventilator associated pneumonia (VAP) refers to the pneumonia that appears after 48-72 hours of endotracheal intubation and is the most common nosocomial infections in patients receiving mechanical ventilation. Late-onset VAP is responsible for prolonged ICU stay and higher mortality rates (24 to 50% and can even increase to 76%), which explains the importance of using more effective antibiotics depending on the severity of each case. The aim of this study is to assess the cost-effectiveness (CE) of linezolid against vancomycin in the treatment of VAP, from the public health care perspective. **METHODS:** A cohort of patients with VAP was simulated using a decision-tree model to compare costs and effectiveness of linezolid (600 mg/12 hours) and vancomycin (1 g/12 hours). Effectiveness measures were: microbiological success rates, mortality rates, and ICU and ward LOS. The model used a 12-week time horizon and only direct medical costs were considered (inpatient costs, medication expenses, adverse events costs). Effectiveness and epidemiologic data were retrieved from published literature. Local costs (2013 US$) were gathered from the official databases of Jamaican Health System. Monte Carlo probabilistic sensitivity analysis (PSA) was constructed. **RESULTS:** Linezolid resulted as the most effective and less expensive option for VAP adult patients. Clinical success rate was higher with linezolid (64.4%) against vancomicyn (56.1%). Mean expected ICU LOS was 14 days for linezolid and 17 days for vancomycin, ward LOS was 14 and 24 days with linezolid and vancomycin, respectively. Mortality rate was found lower in the linezolid arm (10.13%) in comparison to vancomycin (15.74%). Overall costs per patient were $36721.65 with linezolid and $40776.82 with vancomycin. In the CE incremental analysis, linezolid appeared as the cost-saving option. PSA outcomes support the robustness of these findings. **CONCLUSIONS:** Linezolid resulted as the cost-saving therapy for treating VAP adult patients in Jamaica.

PIN65

COST EFFECTIVENESS ANALYSIS OF BOCEPREVIR (BOC) ADDED TO PEGIFN/ RIBAVIRIN (P/R) VERSUS PEGIFN/RIBAVIRIN (CURRENT STANDARD OF CARE) FOR THE TREATMENT OF PATIENTS WITH GENOTYPE 1 CHRONIC HEPATITIS C IN GREECE

Athanasakis K[1], Karampli E[1], Retsa MP[2], Theodoropoulou T[2], Kyriopoulos J[1]
[1]*National School of Public Health, Athens, Greece,* [2]*MSD Hellas, Athens, Greece*

OBJECTIVES: Boceprevir plus P/R has demonstrated a superior clinical profile, compared to P/R alone, in the treatment of genotype 1 chronic hepatitis C (G1-CHC) patients. The objective of this study was to evaluate the cost-effectiveness of BOC/P/R therapy for treatment naïve and treatment experienced G1-CHC patients in Greece. **METHODS:** A Markov-model simulating the quality-adjusted life years and corresponding costs of G1-CHC treatment provided the basis of the analyses. The BOC/P/R regimens recommended in the label for treatment naïve and treatment experienced patients were compared to P/R to calculate incremental costs and outcomes. The inputs for the model were derived from post-hoc subset analyses of SPRINT-2 and RESPOND-2 data. Resource use for patient monitoring and treatment of events was elicited via expert panel. Lifetime horizon with 3% discount rate was used and the perspective of analysis was third-party payers. **RESULTS:** BOC-based therapy was projected to reduce liver complications (decompensated cirrhosis, hepatocellular carcinoma, liver transplant and liver–related death) by 44% and 49-53% in treatment naïve and experienced patients, respectively, leading to corresponding gains of 0.87 and 1.25 QALYs per patient. Taking into account medication costs, treatment and management of events, the ICER for BOC-based therapy versus P/R were estimated at 10,003€/QALY and 10,852€/QALY for treatment naïve and experienced patients, respectively. Extensive sensitivity analyses indicated that results were robust. **CONCLUSIONS:** Based on the results of this analysis, the addition of Boceprevir to P/R for treatment of G1 CHC patients can be a cost-effective treatment option in the Greek health care setting.

PIN66

COST PER CURE OF TELAPREVIR AND BOCEPREVIR IN TREATMENT-NAÏVE GENOTYPE 1 HEPATITIS C PATIENTS WITH F2 FIBROSIS IN BRAZIL

Morais AD, Pereira ML
Janssen Cilag Farmaceutica, São Paulo, Brazil

OBJECTIVES: Compare the cost per cure of telaprevir of peginterferon and ribavirin (TVR+PR) compared to boceprevir plus peginterferon and ribavirin (BOC+PR) in the treatment of METAVIR scale F2 patients with previously untreated chronic hepatitis C genotype 1 in the Brazilian public (SUS) and private (SS) health care system. **METHODS:** Treatment costs considered drug acquisition costs of TVR+PR and BOC+PR from a public and private payer perspective in Brazil. The cost/cure was defined as the cost/sustained virological response (SVR) according to the phase 3 trials of TVR and BOC. The SVR rate for TVR+PR was defined as 79% and 49% for PR in patients with F2 fibrosis. Based on the SPRINT-2 trial, the SVR-rate for F2 patients treated with BOC+PR was assumed 57%, average between F0/F1 and F3/F4 patients, compared to 38% for PR. Treatment duration, based on the extended rapid virological response (eRVR), was taken from the respective trials of BOC (eRVR = 44%) and TVR (eRVR = 58%). Deterministic sensitivity analysis was carried out for the eRVR rate. **RESULTS:** In the SUS, TVR+PR had an average treatment cost of R$ 40.093 per F2 fibrosis patient compared to R$ 36.185 with BOC+PR. Considering the SVR rate and the sensitivity analysis, TVR+PR had a cost/SVR of R$ 50.751 (R$ 49.797-R$ 51.705) compared to R$ 63.481 (R$ 61.771-R$ 65.191) with BOC+PR. In the private health care system, TVR+PR had a treatment cost of R$ R$ 88.508 per F2 fibrosis patient compared to R$ 82.518 with BOC+PR. Considering the cost/SVR and sensitivity analysis, TVR+PR had a cost/SVR of R$ 112.036 (R$ 108.253-R$ 115.819) compared to BOC+PR with a cost/SVR of R$ 144.768 (R$ 140.631-R$ 148.905) per F2 patient in the SS. **CONCLUSIONS:** Compared to BOC+PR, TVR+PR was a more cost-effective treatment of F2 fibrosis patients in both public and private health care systems.

PIN67

COST-EFFECTIVENESS OF PEGINTERFERON ALFA AND RIBAVIRIN FOR THE TREATMENT OF CHILDREN AND YOUNG PEOPLE WITH CHRONIC HEPATITIS C FROM THE PERSPECTIVE OF THE NHS IN ENGLAND AND WALES

Lion M[1], McCann E[1], Jiang Y[2]
[1]*MSD Ltd., Hoddesdon, UK,* [2]*Amaris, London, UK*

OBJECTIVES: To evaluate the cost-effectiveness of peginterferon (PEG INF) alfa and ribavirin for the treatment of children and young people ages 3 to 17 years with Chronic Hepatitis C (CHC), from the perspective of the NHS in England and Wales. This analysis was submitted to NICE as part of a submission dossier for the multiple technology appraisal of PEG INF alfa and ribavirin for the respective population. **METHODS:** A Markov model was developed based on previous economic evaluations for treatment of adults with CHC with PEG INF alfa and ribavirin. The model evaluated the cost-effectiveness of PEG INF alfa-2a or alfa-2b and ribavirin, and supportive care, for the treatment of people aged 5 to 17 years. An additional analysis was conducted on 3 and 4 year olds comparing supportive care to PEG INF alfa-2b and ribavirin in line with license. The cost-effectiveness was evaluated using the incremental cost-effectiveness ratio (ICER) from the perspective of the NHS over a lifetime horizon. The results were assessed overall and by age and genotype subgroups. **RESULTS:** The results reported that both combinations of PEG INF alfa and ribavirin dominated supportive care for all patients. Driven by small variation in the comparative efficacy and costs, the comparison between PEG INF alfa-2a and alfa-2b, in combination with ribavirin, showed that PEG INF alfa-2b dominated PEG INF alfa-2a overall and in the following subgroups: 5 to 8 years, 14 to17 years and genotypes 2/3. The ICER for the 9 to13 years subgroup was £4,697. PEG INF alfa-2a dominated PEG INF alfa-2b for the other genotype subgroup **CONCLUSIONS:** The results of the economic evaluation demonstrated that treatment with either combination of PEG INF alfa and ribavirin is a cost-effective treatment option for children and young people aged 3 to 17 years with CHC.

PIN68

COST-EFFECTIVENESS OF 13-VALENT VERSUS 10-VALENT PNEUMOCOCCAL CONJUGATE VACCINE USE IN THE CZECH NATIONAL IMMUNIZATION PROGRAM

Tichopad A[1], Vitova V[1], Roberts CS[2], Hájek P[3]
[1]*CEEOR s.r.o., Prague, Czech Republic,* [2]*Pfizer, New York, NY, USA,* [3]*Pfizer, Praha, Czech Republic*

OBJECTIVES: Streptococcus pneumoniae is presumed to be the major etiology agent responsible for a significant amount of meningitis, bacteremia and sepsis (invasive pneumococcal disease; IPD) as well as Community Acquired Pneumonia (CAP) and Acute Otitis Media (AOM). The Czech Republic (CR), as well as many other European countries have only a limited local evidence on the underlying epidemiology. The objective was to estimate the expected outcomes, costs, cost-effectiveness of the pediatric national immunization program (NIP) with 13-valent pneumococcal conjugated vaccine (PCV13) and 10-valent pneumococcal conjugated vaccine (PCV10) as a comparator among specific populations of children and adults in preventing and reducing the incidence of IPD, CAP and AOM in CR. **METHODS:** A Markov decision-analytic model was developed to examine impacts of infant vaccination with PCV13 versus PCV10. PCV13 direct effectiveness was extrapolated from PCV7 efficacy data from clinical trials, using assumptions regarding serotype prevalence and PCV13 protection against additional serotypes, while indirect (herd) effect was extrapolated from US surveillance data following universal PCV7 use. The local epidemiology and cost data were used to achieve maximum national specificity. **RESULTS:** Model predicts incremental EUR 64.5 million for the PCV13 NIP from the payer's perspective in the 10-year horizon, as compared to PCV10. This would lead to an reduction in IPD, all cause inpatient and outpatient CAP and AOM by approximately 921, 22 900, 56 796 and 40 598 cases, respectively, thus savings EUR 35.4 million. This gives a total cost of EUR 29.0 million in the 10 years. The incremental cost per LYG or QALY gained is estimated as EUR 929 or EUR 1 164, respectively, from the payer's perspective as compared to PCV10. **CONCLUSIONS:** Comparing the national GDP per capita with the WHO

recommendation on health care spending per QALY gained, PCV13 NIP in Czech Republic can be considered cost-effective.

PIN69

ECONOMIC EVALUATION OF FIDAXOMICIN FOR THE TREATMENT OF CLOSTRIDIUM DIFFICILE INFECTIONS (CDI) ALSO KNOWN AS C. DIFFICILE-ASSOCIATED DIARRHOEA (CDAD) IN IRELAND

Van Engen A[1], Casamayor M[2], Loftus F[3], Crimin E[3], Lacey L[4]
[1]*Quintiles, Hoofddorp, The Netherlands,* [2]*Quintiles, Barcelona, Spain,* [3]*Astellas Pharma Co Ltd., Dublin, Ireland,* [4]*Lacey Solutions Ltd., Skerries, Ireland*

OBJECTIVES: Fidaxomicin is the first in a new class of macrocylic antibiotics, indicated in adults for the treatment of Clostridium difficile infections (CDI) also known as C. difficile-associated diarrhoea (CDAD). The study objective was to perform a cost-utility analysis of fidaxomicin for the treatment of CDI compared to oral metronidazole (used to treat initial non-severe CDI and first non-severe recurrence) and oral vancomycin (used to treat severe CDI and any non-severe recurrence beyond the first one). **METHODS:** A Markov model was used to determine the cost-utility of fidaxomicin in the treatment of all adult CDI patients (base case), patients with severe CDI, and patients with initial CDI recurrences, respectively. The cycle length was 10 days. The patient enters the model in the CDI health state and is treated either with fidaxomicin, oral metronidazole or vancomycin for 10 days. The time horizon was one-year. Deterministic and probabilistic sensitivity analyses were performed. Health state utilities were derived from the literature. The perspective was that of the Irish Health Service Executive (HSE). **RESULTS:** In the base case, fidaxomicin was dominant compared to current standard of care, resulting in cost savings of €2,904 and an incremental QALY gain of 0.031. The main drivers of cost-effectiveness were the reduction in rate of recurrence in patients treated with fidaxomicin and the cost of hospitalisation. Fidaxomicin was also found to be dominant for all patient subgroups. The ICERs were highly sensitive to recurrence rates. The probability of the cost-effectiveness of fidaxomicin in all CDI patients at a willingness to pay threshold of €45,000 per QALY gained was estimated to be approx. 82%. **CONCLUSIONS:** Fidaxomicin was dominant compared to current standard of care with an approx. 82% probability of being cost-effective in all CDI patients at a willingness to pay threshold of €45,000 per QALY gained.

A UK CASE STUDY OF SOCIETAL AND HERD-EFFECT IMPACT OF UNIVERSAL MASS INFLUENZA VACCINATION IN THE UNITED KINGDOM

Meier G[1], Van Bellinghen LA[2], Van Vlaenderen I[2]
[1]*GlaxoSmithKline Vaccines, Wavre, Belgium,* [2]*CHESS, Ternat, Belgium*

OBJECTIVES: To demonstrate the impact of influenza vaccination in currently non-recommended populations in the UK. To understand critical elements of influenza infection (herd-effect and productivity losses) and management of disease. Management includes direct medical, non-medical and indirect resources. **METHODS:** A multicohort, static, one-year Markov-model was constructed. Universal influenza mass vaccination of healthy individuals ≥6 months to ≤64 years was applied, using either trivalent (TIV) or quadrivalent (QIV) influenza vaccines. Current vaccination coverage rates for high risk persons were utilized as a proxy. Vaccine efficacy data were derived from Cochrane Databases (TIV) and meta-analyses (QIV). The impact of herd-effect was evaluated by two different estimates from published literature, providing a range of results. A societal perspective was adopted and 2010 was the cost reference year. **RESULTS:** Using the average influenza-B circulation and vaccine matching data of 2000 to 2010, between 71,000-82,000 additional cases will be prevented with QIV versus TIV in one influenza season. QIV is anticipated to prevent more medical visits, complications, and hospitalisations (15,000-17,000); (8,000-9,300) and (889-1,044), respectively. QIV programme costs are higher due to acquisition costs compared to TIV, however influenza treatment and management costs are lower due to fewer cases/complications for direct medical, non-medical and indirect categories (absenteeism/presenteeism), (savings: £4,800,000-£5,700,000); (savings: £215,000-£253,000); (savings: £22,400,000-£26,400,000), respectively. In addition, future productivity losses caused by premature mortality are also minimized with maximal effect with QIV rather than TIV (savings: £5,100,000-£6,700,000). **CONCLUSIONS:** Herd-effect is a well understood and appreciated benefit of vaccinating children and mass vaccination within a population. This model suggests that there are vast benefits in universal mass vaccination of healthy persons in the UK with QIV instead of TIV, due to greater health-related benefits and lower treatment-related costs. However, vaccine acquisition costs need to be considered.

PIN71

THE ECONOMIC ASSESSMENT OF AN ENVIRONMENTAL INTERVENTION: DISCRETE DEPLOYMENT OF COPPER FOR INFECTION CONTROL IN ICUS

Taylor M, Chaplin S
York Health Economics Consortium, York, UK

OBJECTIVES: Health Economics evaluations are typically applied to medications or surgery costs, but this unique study has investigated the economic benefits of discrete deployment of antimicrobial copper alloy touch surfaces in ICUs. Copper/copper alloy surfaces have been shown to act as an adjunct to standard infection control practices in diverse clinical settings, continuously reducing contamination by over 90%. A study by Salgado in 2013 investigated the use of copper surfaces in ICUs and reported a 58% reduction in hospital acquired infections. This study investigates the cost-effectiveness of this intervention. **METHODS:** Following an extensive literature review and use of expert opinion a number of factors have been considered in this evaluation. These are the component costs of the items used in the ICU, the cost of and extra day in bed due to an infection, baseline infection rates and risk reduction of copper items. The model is based on a single room configuration in an intensive care unit with 20 beds in the UK using 6 critical items - bed rails, overbed tray table, chair, call button, data device and IV pole. The model has been created to show the economic impact of an environmental intervention. **RESULTS:** The model predicts the cost of replacing key, frequently-touched surfaces in a 20-bed UK ICU with copper equivalents will be recouped in less than two months. Over 5 years there were 325 fewer infections in the copper arm at a cost per QALY of £262.84. **CONCLUSIONS:** The investigation allowed the derivation of a spreadsheet-based model that uses the best current published information and shows the rapid ROI of a copper intervention. It also calculates the impact on bed days and quality-adjusted life years (QALY). The model is simple, transparent to those with knowledge of spreadsheets, and allows adaptation to specific local settings.

PIN72

COST-EFFECTIVENESS OF A 13-VALENT CONJUGATE PNEUMOCOCCAL VACCINATION PROGRAM IN COPD PATIENTS AGED ≥50 YEARS IN SPAIN: PRELIMINARY RESULTS

Menendez R[1], Rodríguez-GonzálezMoro JM[2], Gros B[3], Echave M[3], Oyagüez I[3], Lwoff N[4], Egea-García M[4], Guijarro P[4]
[1]*Respiratory Infections Health La Fe Research Institute, Valencia, Spain,* [2]*Hospital Gregorio Marañón, Madrid, Spain,* [3]*Pharmacoeconomics & Outcomes Research Iberia, Madrid, Spain,* [4]*Pfizer Spain, Alcobendas, Spain*

OBJECTIVES: Patients with chronic obstructive pulmonary disease (COPD) are at risk of pneumococcal infection. A 13-valent pneumococcal-conjugate vaccine (PCV13) has recently been approved for adult protection against *S. pneumoniae*. This study estimated the clinical and economic consequences of vaccinating COPD patients aged ≥50 years with PCV13 compared to current vaccination recommendations using a 23-valent pneumococcal-polysaccharide vaccine, from the Spanish Healthcare System perspective. **METHODS:** A microsimulation model with a Markov process accounting for risks and costs for invasive pneumococcal disease (IPD) and all-cause nonbacteremic pneumonia (NBP) was developed. Prevalence, mortality rates, vaccination and serotype coverage, and vaccination and disease-related costs (€2013) were based on published data. Vaccines effectiveness was modified by a waning effect over time. Herd-immunity and revaccination were not considered. Outcomes and costs (both discounted at 3%/year) were simulated 100 times with, 1.6 million COPD patients per simulation. Outcomes were pneumococcal cases averted and incremental cost–effectiveness ratio (ICER) in terms of cost per life-year gained (LYG). Sensitivity analyses were performed modifying the time horizon, discount rate and vaccination coverage. **RESULTS:** Over a 5-year period, the use of PCV13 vs current vaccination strategy in adult COPD subjects would prevent 529 IPD cases, 6,329 inpatient-NBP cases, and 697 outpatient-NBP cases. Additionally, 231 IPD and 148 inpatient-NBP related deaths would be averted. The ICER was €24,557/LYG for PCV13 vs current vaccination strategy. In sensitivity analyses, ICER ranged from €26,986/LYG (when changing discount rate from 3% to 5%) to €7,661/LYG (when changing vaccination coverage from 80% to 66%). Using a lifetime horizon 1,271 IPD cases, 10,294 inpatient-NBP cases, and 2,072 outpatient-NBP cases would be prevented, with an ICER of €5,030/LYG. **CONCLUSIONS:** At a willingness-to-pay of €30,000/LYG, PCV13 vaccination in COPD patients aged ≥50 years in Spain is a cost-effective strategy compared to current vaccination recommendations under both 5-year and lifetime time horizons.

PIN73

LINEZOLID FOR THE TREATMENT OF PATIENTS WITH CONFIRMED MRSA NOSOCOMIAL PNEUMONIA IN NANJING, CHINA: A COST EFFECTIVE ALTERNATIVE TO VANCOMYCIN

Tan SC[1], Li Q[2], Chen Y[3], Hájek P[4], Weinstein D[5], Patel DA[6]
[1]*Double Helix Consulting, Asia-Pacific, Singapore, Singapore,* [2]*Jiangsu Province Hospital, Nanjing, China,* [3]*Pfizer Inc., Beijing, China,* [4]*Pfizer, Praha, Czech Republic,* [5]*Pfizer Inc., Paris, France,* [6]*Pharmerit International, Bethesda, MD, USA*

OBJECTIVES: Vancomycin has been the treatment of choice for several years while linezolid is a relatively new alternative in China. Although clinical superiority of linezolid was demonstrated in a recent head-to-head clinical study, economic evaluation comparing the two treatments provides additional useful decision making information. This study aimed to compare the cost-effectiveness of linezolid versus vancomycin in treating confirmed MRSA NP from a payer's perspective in Nanjing. **METHODS:** A cost-effectiveness model primarily driven by the head-to-head clinical data (Wunderink, CID: 2012), was adapted with local published data and expert opinion on resource use and unit costs. The model structure and assumptions were verified to reflect local clinical practice. Both linezolid and vancomycin arms were assumed to have same life expectancy in full health upon discharge. The base case analysis considered 10-day treatment duration for both treatments. Scenario analyses were conducted by varying treatment duration, per day total costs in ICU and general ward, drug acquisition costs, and including costs for managing key adverse events. All costs were reported in 2012 Chinese RMB. **RESULTS:** A higher treatment success rate by 2.7% was predicted for linezolid. Both treatment arms were estimated to have very similar average total costs in the region of RMB 78,800 with the key cost drivers being drug acquisition costs and ICU per day total cost. The ICER for linezolid was RMB 163 for each additional successfully treated patient. Dominance of linezolid attributed to greater treatment success but lower total cost was observed in most of the scenario analyses. The highest ICER was RMB 31,663 in the scenario where the acquisition cost of vancomycin reduced by 20%. **CONCLUSIONS:** Given the estimated low ICERs with dominance in most of the scenario analyses, linezolid can be considered a cost effective option compared to vancomycin in managing confirmed MRSA NP in Nanjing.

PIN74

A COST-EFFECTIVENESS ANALYSIS OF LINEZOLID VERSUS VANCOMYCIN FOR VENTILATOR-ASSOCIATED PNEUMONIA PATIENTS IN COSTA RICA

Garita M[1], Solano A[2], Cuesta G[3], Mould J[4]
[1]*Pfizer Central America and Caribbean, Escazu, San Jose, Costa Rica,* [2]*Hospital Dr. Rafael Ángel Calderón Guardia, San Jose, Costa Rica,* [3]*Pfizer Central America and the Caribbean, Escazú, San Jose, Costa Rica,* [4]*Pfizer, New York, NY, USA*

OBJECTIVES: Ventilator-associated pneumonia (VAP) is the most common nosocomial infection in the intensive care unit (ICU). It's associated with significant morbidity, increasing the ICU and hospital length of stay (LOS), and raising overall costs. Literature suggests that costs could be reduced using the most efficient empiric

therapy. The aim of this study was to assess the cost-effectiveness (CE) of Linezolid against generic Vancomycin as an empiric therapy for VAP patients, from the health care payer's perspective. **METHODS:** A decision-tree model was used to compare costs and effectiveness of Linezolid (600 mg/12 hours) and Vancomycin (1g / 12 hours) (comparator) for a cohort of patients with VAP. Effectiveness measures were: microbiological success rates, mortality rates, ICU and ward LOS and overall costs. Effectiveness and epidemiologic data were collected from published literature. Local costs (2012 US$) were obtained from Costa Rica's Health System official databases. The model used a 12-week time horizon and only direct medical costs were considered (hospital LOS, medication costs, hematologic, gastrointestinal and skin adverse events and lab exams). Monte Carlo probabilistic sensitivity analysis (PSA) was constructed. **RESULTS:** Results showed Linezolid as more effective and less expensive option for VAP. Clinical success rate was higher with Linezolid (64.4%) against Vancomicyn, (56.1%). Mortality was lower with linezolid (10.13% vs 15.74%). Average ICU (and ward) LOS was 18 (9) days with Linezolid and 22 (10) days with Vancomycin. Overall medical costs per patient were $87782.52 with Linezolid and $92771.51 with Vancomycin. CE analyses showed Linezolid is the dominant strategy. **CONCLUSIONS:** This is the first CE study for VAP developed in Costa Rica. Linezolid resulted as the cost-saving option for treating VAP patients in the Costa Rican clinical environment.

PIN75

COST-EFFECTIVENESS OF TELAPREVIR PLUS PEGINTERFERON/RIBAVIRIN (TVR+PR) VERSUS PEGINTERFERON/RIBAVIRIN (PR) IN TREATMENT-NAÏVE GENOTYPE 1 CHRONIC HEPATITIS C PATIENTS WITH F2 FIBROSIS IN BRAZIL

Morais AD, Pereira ML

Janssen Cilag Farmaceutica, São Paulo, Brazil

OBJECTIVES: To compare the cost-effectiveness of telaprevir associated with peginterferon and ribavirin (TVR+PR) compared to peginterferon and ribavirin (PR) alone in the treatment of patients with METAVIR scale F2) fibrosis and with previously untreated chronic hepatitis C genotype 1. **METHODS:** Markov model, Curtis et al 2012, was adapted to a Brazilian public payer perspective. The model estimated chronic hepatitis C disease progression based on transition probabilities for a cohort of patients with F2 fibrosis. Clinical outcomes and drug dosage were taken from the phase-3 trial (Marcellin et al), with the SVR-rate for TVR+PR as 79% and 49% for PR in patients with F2 fibrosis. Drug costs of TVR and PR were gathered from the ministry of health website, www.comprasnet.gov.br. Costs associated with each disease state were gathered from a study by Barros et al. A discount rate of 3.5 % and a lifetime horizon were assumed. **RESULTS:** TVR+PR therapy resulted in higher costs (R$ BRL57,164 vs BRL27,971) and better outcomes (278 cirrhosis avoided per 1,000 patients) compared to PR alone. Treatment with TVR+PR resulted in 19.94 life years gained compared to PR alone with 19.19. TVR+PR was estimated to give a quality adjusted life year (QALY) expectancy of 13.83, 1.16 higher than with PR (12.67 QALYs), resulted in an incremental cost-effectiveness ratio (ICER) of R$23,734 per QALY gained. Compared to PR alone, the treatment with TVR+PR avoided about 11 deaths and 17 liver transplants per 1,000 treated patients. Treatment with TVR+PR resulted in an incremental cost of R$1,595 per liver transplant avoided and R$2,613 per death avoided compared to PR alone. **CONCLUSIONS:** Treating F2 fibrosis patients with TVR+PR was cost-effective compared with PR alone with an ICER below to the WHO recommended threshold. The benefits of TVR+PR treatment were clear with the low incremental cost per death or liver transplant avoided.

PIN76

COST-EFFECTIVENESS OF ANTI-RABIES PROPHYLAXIS AFTER EXPOSURE TO UNOBSERVABLE DOGS IN ERADICATION CONTEXT: THE FRENCH CASE

N'Diaye DS[1], Ribadeau-Dumas F[2], Yazdanpanah Y[3]

[1]*INSERM (French National Institute of Health and Medical Research), Paris, France,* [2]*Pasteur Institute, Paris, France,* [3]*Bichat Claude Bernard Hospital, Paris, France*

OBJECTIVES: WHO recommends Post-Exposure Prophylaxis (PEP) in countries like France, where rabies cases observed are linked to bats or imported. This study aims to assess effectiveness and cost-effectiveness of anti-rabies PEP algorithms in this low rabies risk countries. **METHODS:** A model-based analysis simulated PEP administration incorporating risk of rabies according to exposure categories (CII: minor scratches; CIII: transdermal bite(s)), PEP strategy, and risk of death on car crash in trips to anti-rabies centers. Strategies compared were: A) No PEP for CII and CIII; B) vaccine for CIII only; C) vaccine for CII and CIII; D) vaccine+immunoglobulins for CIII only; E)vaccine for CII and vaccine+immunoglobulins for C III. We simulated the trajectory of 2,807 patients exposed to unobservable dogs in Metropolitan France, in 2011. Model parameters were estimated from French and international literature. The probability that the dog to which the patient was exposed is rabid was $4x10^{-9}$ and the average risk of death on car crash in trips to anti-rabies centers was $7x10^{-7}$. Total vaccine, immunoglobulins and consultation costs for Zagreb regimens (4 vaccine injections) were €160, €700 and €70, respectively. **RESULTS:** Strategy E led to the lowest number of rabies cases ($4.36x10^{-8}$), the highest costs (€2,493,000), but also to $1.74x10^{-3}$ lethal car crashes. Strategy A had the highest number of rabies cases ($5.71x10^{-6}$), but no risk of lethal crash and no costs; therefore it was the most effective and the least costly strategy. In the sensitivity analysis when the probability that the dog is rabid was>$1.4x10^{-6}$, strategy D becomes more effective than strategy A; and when>$1.4x10^{-4}$, strategy B becomes cost-effective (i.e. cost-effectiveness ratio vs. A>3x French GPD=€30,000). **CONCLUSIONS:** In 2011, in France, anti-rabies PEP appears to be less effective and more expensive than No PEP. These model-based results could be used by decision makers to establish national guidelines.

PIN77

AN ECONOMIC MODEL TO COMPARE LINEZOLID AND VANCOMYCIN FOR THE TREATMENT OF CONFIRMED METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS NOSOCOMIAL PNEUMONIA IN GERMANY

Patel DA[1], Michel A[2], Stephens JM[1], Weber B[3], Gao X[1], Charbonneau C[4]

[1]*Pharmerit International, Bethesda, MD, USA,* [2]*Klinikum Hanau GmbH, Hanau, Germany,* [3]*Pfizer, Berlin, Germany,* [4]*Pfizer, Paris, France*

OBJECTIVES: To evaluate economic impact of linezolid (LZD) versus vancomycin (VAN) for treatment of confirmed methicillin-resistant *Staphylococcus aureus*(MRSA) nosocomial pneumonia (NP) in German health care system. **METHODS:** A 4 week decision model was developed capturing 1st and 2nd line therapy. Published literature (primarily Wunderink 2012, reported 54.8% clinical efficacy for LZD vs. 44.9% for VAN in modified Intent-to-Treat population at End of Study for treatment of MRSA NP) and expert opinion provided clinical and resource use data, such as efficacy, mortality, adverse events (AEs), treatment duration, and length of hospital/ICU stay. German cost data was obtained from published literature. Base-case analysis used 10-day treatment duration. In event of treatment failure/severe AEs on 1st-line therapy, drug was switched after 7 days. Costs were reported in 2012 Euros. **RESULTS:** LZD was associated with minimally lower costs (€16,119 vs. €16,144), and greater overall treatment success compared to VAN, resulting in LZD 'dominating' VAN. About 80% of treatment costs were related to hospital stay, primarily ICU (72%). Drug therapy, physician visits, laboratory tests and AEs/treatment failure each account for ≤5% of total costs. Several scenarios were tested by varying treatment duration (7 or 14 days), and varying discontinuation/switch of therapy (at 5 or 10 days). In cases of shorter treatment duration (7 day) or delayed switch of therapy (at 10 day), linezolid continues to 'dominate'. However, with 14 day treatment duration or early switch (at 5 day) linezolid becomes more costly, but still has greater effectiveness resulting in a relatively low Incremental Cost Effectiveness Ratio (ICER) of €8,207 and €2,343 per successfully treated patient. **CONCLUSIONS:** LZD is a cost-effective alternative to VAN for treatment of MRSA-confirmed NP, owing primarily to its higher clinical response rate. Future analyses should use other country costs/resource use data to test result generalizability and assess empiric treatment phase.

PIN78

COST-EFFECTIVENESS OF BOCEPREVIR ADD-ON TREATMENT OF HEPATITIS C VIRUS GENOTYPE 1 PATIENTS IN DENMARK

Ehlers L[1], Ferrante S[2], Kristensen MH[2], Leutscher PDC[3], Chhatwal J[4]

[1]*Aalborg University, Aalborg, Denmark,* [2]*Merck & Co. Inc., North Wales, PA, USA,* [3]*Aarhus University Hospital, Aarhus, Denmark,* [4]*University of Pittsburgh, Pittsburgh, PA, USA*

OBJECTIVES: Despite available treatment options chronic hepatitis C virus (HCV) infection remains a significant disease burden in Denmark, in particular among genotype 1 difficult-to-treat patients The aim of this study was to evaluate the cost effectiveness of boceprevir (BOC), a protease inhibitor, in combination with pegylated interferon *plus* ribavirin (PEG+R), compared to PEG+R alone, among treatment naïve and treatment experienced genotype 1 HCV patients. **METHODS:** A Markov model simulating antiviral therapy and disease progression was developed to estimate the lifetime health care costs and clinical outcomes of alternative treatment strategies. The model simulated the treatment regimens of dual therapy (PEG+R) and triple therapy (PEG+R+BOC), respectively, as recommended in the summary of product (SPC) and the Danish treatment guidelines. Data on clinical efficacy was taken from phase III clinical trials (SPRINT-2 and RESPOND-2). Costs were measured in 2012 Danish Kroner (DKK) and clinical outcomes in quality adjusted life years (QALYs). The incremental cost-effectiveness ratio (ICER) was estimated for treatment naïve and experienced patients. Deterministic and probabilistic sensitivity analyses (PSA) on clinical inputs, costs, health state utility values, and SVR rates were performed to assess the overall decision uncertainty. **RESULTS:** The ICER for PEG+R+BOC therapy versus standard of care with PEG+R was DKK 241.774 for treatment naïve HCV patients and DKK 98.371 for treatment experienced patients. PSA for treatment naïve patients showed a probability of cost-effectiveness of PEG+R+BOC therapy compared to PEG+R of more than 65 % at a willingness-to-pay threshold of DKK 300.000 (approx. £30.000). **CONCLUSIONS:** From a Danish health sector perspective, the model suggests PEG+R+BOC therapy is cost effective in HCV genotype 1 patients to prevent development of late manifestations in the liver, such as cirrhosis and hepatocellular carcinoma (HCC) irrespectively of treatment experience status.

PIN79

COST-EFFECTIVENESS COMPARISON OF GENOTYPE 1 HEPATITIS C VIRUS (HCV) TREATMENTS USING TELAPREVIR (TVR) IN PATIENTS WITH MILD FIBROSIS VERSUS PATIENTS WITH BRIDGING FIBROSIS AND CIRRHOSIS

D'Angelo ER[1], Gonzalez E[2], Sola R[2]

[1]*Janssen-Cilag SA, MADRID, MADRID, Spain,* [2]*Hospital del Mar, BARCELONA, Spain*

OBJECTIVES: To estimate, from a Spanish Healthcare System perspective, the cost-effectiveness of the usage of telaprevir (TVR) with peginterferon and ribavirin (PR) in patients with mild fibrosis (METAVIR F2) vs. patients with bridging fibrosis or cirrhosis (METAVIR scores F3 and F4, respectively). **METHODS:** A decision tree model was developed to assess cost-efficacy of TVR+PR according to the degree of fibrosis and previous response to treatment in patients with HCV Genotype 1. Treatment costs were estimated excluding futility rules but contemplating the potential to shorten treatment in treatment-naïve and relapsers that are either F2 or F3. The efficacy of triple therapy treatment by patient type is derived from the TVR phase III clinical trials. To estimate cost-effectiveness, the following values were calculated for each alternative: the cost per cured patient and the number of cured and not cured patients assuming a fixed budget. **RESULTS:** TVR+PR in F2 patients has a lower cost per cured patient than F3+F4 both in naïve patients (20% less) and in experienced patients (in relapsers: 5% less; in partial responders: 47% less; and in null responders: 39% less). This difference is statistically significant for naïve and partial responding patients. For a 1 million EUR investment in each patient type, resources allocated to F2 patients offers maximum cured patients (94 in F2 vs. 71 in F3+F4) and minimum non-cured patients (37 in F2 vs. 58 in F3+F4). This conclusion stands when different sensitivity analyses are conducted. **CONCLUSIONS:** The usage of TVR+PR in patients with mild fibrosis could be a more cost-effective alternative than in patients with bridging fibrosis or cirrhosis regardless of the patient's previous response to treatment. A long-term cost-effectiveness analysis is required in order to validate this data.

PIN80

COST-EFFECTIVENESS ANALYSIS OF STRIBILD COMPARED TO SIMILAR ANTIRETROVIRAL THERAPIES IN A SPECIALTY RETAIL PHARMACY

Griggs SK[1], Davelis M[2]
[1]*St. Louis College of Pharmacy, St. Louis, MO, USA,* [2]*Schnucks Specialty Pharmacy, Bridgeton, MO, USA*

OBJECTIVES: Approximately 1.1 million people in the U.S. are living with HIV, with 50,000 new infections per year. The FDA approved Stribild™, a once-daily HIV medication, in September of 2012. The primary objective of this study was to assess the cost and disease-related outcomes of Stribild versus guideline-recommended treatment options for HIV patients in a specialty retail pharmacy. A secondary objective was to assess compliance via Medication Possession Ratios (MPRs). **METHODS:** HIV patients who were prescribed one of five antiretroviral regimens in the period from January 1, 2010 to June 21, 2013 and who obtained their medications through Schnucks Specialty Pharmacy were selected via a retrospective chart review. By measuring the direct cost of the medications to the pharmacy and the disease-related outcomes, change in CD4 count and viral load suppression, the cost-effectiveness of Stribild versus its comparators was assessed. **RESULTS:** A total of 92 patients were included in this study: 50 Stribild patients and 42 patients on alternate regimens: 15 Atripla®; 6 Isentress®; 10 Prezista®; and 11 Reyataz®. Incremental Cost-Effectiveness Ratios (ICERs) were conducted between Stribild and the comparators for change in mean CD4 count and percent viral load suppression (<20 copies/ml) achieved. In terms of CD4 count, Stribild was most cost-effective when compared to Prezista and least cost-effective when compared to Isentress. Analyses of viral load suppression indicated that Stribild is more cost-effective than Prezista and Reyataz but less cost-effective than Atripla or Isentress. Mean MPR was greater than 95% for Stribild and three of its comparators (not including Atripla); however, 78 percent of Stribild patients achieved MPR ≥ 95% which demonstrates higher compliance than all comparators except the Isentress patients. **CONCLUSIONS:** The once-daily regimen Stribild appears effective at treating the HIV virus while maintaining compliance for most of its patients; its high cost remains a concern for formulary decision makers.

PIN81

COST-EFFECTIVENESS OF ANTIMICROBIALS AS TREATMENT FOR PATIENTS WITH COMPLICATED SKIN AND SOFT TISSUES INFECTIONS: A COMPARISON BETWEEN CEFTAROLINE, LINEZOLID AND VANCOMYCIN IN THE RUSSIAN HEALTH CARE

Kulikov A, Komarov I
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To estimate the cost-effectiveness of antimicrobials (ceftaroline, linezolid and vancomycin) as treatment for patients with complicated skin and soft tissues infections. **METHODS:** A literature-based cost-effectiveness analysis was developed to estimate the costs of complicated skin and soft tissues infections patients initiating therapy with ceftaroline, linezolid or vancomycin. Direct expenses associated with complicated skin and soft tissues infections and resulting follow-up costs were calculated using general tariff agreement of Russian obligatory insurance system and official national statistics. For reference, accepted exchange rate was 1 EUR = 40 RUB. **RESULTS:** Compared to ceftaroline, linezolid or vancomycin results in increases in drug therapy costs: 77 997 RUB (1 950 EUR) per patient in ceftaroline group (therapy duration – 9 days), 78 816 RUB (1 970 EUR) per patient in vancomycin group (therapy duration – 10 days) and 117 893 RUB (2 947 EUR) per patient in linezolid group (therapy duration – 12 days). The values of cost/clinical cure rate are estimated at 96 055 RUB (2 401 EUR) in ceftaroline group, 98 030 RUB (2 451 EUR) in vancomycin group, and 138 860 RUB (3 472 EUR) in linezolid group per patient. **CONCLUSIONS:** The results of cost-effectiveness illustrate that ceftaroline is dominant in Russian patients with complicated skin and soft tissues infections who are initiating antimicrobials therapy compared with linezolid or vancomycin.

PIN82

ANTIBACTERIAL TREATMENT OF METICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS COMPLICATED SKIN AND SOFT TISSUE INFECTIONS: A COST-EFFECTIVENESS ANALYSIS IN GREECE

Karampli E[1], Ollandezos M[1], Petrakis I[2], Tsoulas C[2], Patel DA[3], Kyriopoulos J[1]
[1]*National School of Public Health, Athens, Greece,* [2]*Pfizer Hellas, Athens, Greece,* [3]*Pharmerit International, Bethesda, MD, USA*

OBJECTIVES: Meticillin-resistant staphylococcus aureus (MRSA) is an important cause of antimicrobial-resistant health care-associated infections worldwide. Its prevalence remains high in the Greek hospital setting. Complicated skin and soft tissue infections (cSSTIs) due to MRSA are associated with prolonged hospitalization, additional costs of care and significant morbidity. The purpose of this study was to conduct a cost-effectiveness analysis of different treatment scenarios in the management of MRSA-cSSTIs, under a third-party payer perspective. **METHODS:** The model was based on a decision tree simulating costs and outcomes for a maximum of 28 days, consisting of empiric, first-line and second-line treatment, for patients with MRSA-cSSTIs. Inpatient and outpatient health care services were included in the analysis. Data on efficacy of the pharmacotherapies under evaluation were derived from a recent meta-analysis (Bassetti et al 2013) and resource use was elicited via an expert panel. Economic results, expressed in Euros (2013), reflect the Greek social insurance setting. **RESULTS:** Three different first→second line treatment scenarios (daptomycin→linezolid, linezolid→daptomycin, vancomycin→linezolid) were evaluated, as recommended by the expert panel. Total management costs per patient were €4,199, €3,809, and €3,900; quality adjusted life years (QALY) gained were 0.058, 0.059 and 0.057 respectively for the above scenarios. The scenario containing first-line linezolid proved to be a dominant therapeutic option vs. the other scenarios (less costly, higher QALYs), whereas first-line daptomycin scenario did not appear to be cost-effective vs. the respective vancomycin scenario (incremental cost-utility ratio €243,932) in the management of MRSA-cSSTIs. Second line oral linezolid was used as continuation treatment after failure/intolerance or switch from intravenous vancomycin and daptomycin. Second line intravenous daptomycin was assumed to be administered via an outpatient parenteral treatment service. **CONCLUSIONS:** Findings suggest that use of first-line linezolid in the management of MRSA-cSSTIs could result in savings for the third-party payer in Greece accompanied by enhanced quality of life results.

PIN83

MATHEMATICAL MODELS OF HEPATITIS B VACCINATION AND SCREENING PROGRAMMES IN THE UNITED KINGDOM: A SYSTEMATIC REVIEW

Keeping ST[1], Allen F[2], Patel A[2], Carroll SM[1], Kilcoyne A[1]
[1]*Sanofi Pasteur MSD, Maidenhead, UK,* [2]*Abacus International, Bicester, UK*

OBJECTIVES: The United Kingdom (UK) has a targeted hepatitis B (HBV) vaccination programme for at-risk patient groups; however such a programme can be challenging to implement. The World Health Organisation (WHO) recommends universal HBV vaccination and this approach has been adopted by most developed countries. A systematic review was conducted to identify UK-based mathematical models for HBV to determine whether current evidence supports the use of a universal vaccination programme versus a targeted approach. **METHODS:** Embase, Medline, Econlit and The Cochrane Library were searched for studies reporting HBV mathematical models (economic or epidemiological) in the UK population. Hand searching of Health Protection Agency and National Institute for Health and Clinical Excellence guidance documents was also performed. Economic models (cost-effectiveness, cost-utility, cost-benefit, cost-consequence) were included if they assessed HBV vaccination or screening programmes. Epidemiological studies were included if they modelled HBV immunity and infection rates. Data were independently extracted and summarised into evidence tables by two reviewers and quality appraisal of included studies was performed. **RESULTS:** Electronic database searches identified a total of 649 citations resulting in 11 relevant publications. Hand searching yielded an additional two publications; a total of 13 included publications representing seven economic evaluations and six epidemiological modelling studies. Overall, there was considerable variation in model methodologies including methods of discounting used, static versus dynamic approaches and sources of model inputs. Only one epidemiological modelling study considered HBV transmission patterns across the UK. **CONCLUSIONS:** Current HBV vaccination policy in the UK is dependent on the demonstration of cost-effectiveness. However, this review highlights some of the limitations inherent in the models which have been used to support policy decisions. Alternative modelling approaches, as well as new data on key inputs, are desirable if the full value of a universal HBV vaccination programme in the UK is to be assessed.

PIN84

COST-EFFECTIVENESS OF ROUTINE INFANT VACCINATION STRATEGIES IN RUSSIA: AN ECONOMIC EVALUATION

Yagudina RI[1], Akimova YI[2]
[1]*Moscow Medical Academy, Moscow, Russia,* [2]*First Moscow medical academy named after I.M. Sechenov, Moscow, Russia*

OBJECTIVES: Today vaccination for children from 0 to 20 months in the Russian Federation is carried mainly by DPT and monovalent vaccines. As a result, a child of this age receives 12 injections. Vaccination against Hib infection so far is only available for children at risk (approx. 20%). Introdution of DTaP-IPV-Hib combined vaccine could reduce the number of injections received by the child and increase the coverage against Hib infection from 20% to 97%. The objective of the present study is to assess the economic evaluation of DTaP-IPV-Hib vaccine introduction into immunization schedule and select the most cost-effective vaccination scheme against Hib infection. **METHODS:** A cost-effectiveness analysis of the DTaP-IPV-Hib vaccine is performed on suggested Markov model. The four vaccination schemes are intercompared : the current immunization program (Scheme0), a 3+1 immunization DTaP-IPV-Hib vaccine (Scheme P), a mixed DTwP /DTaP-IPV-Hib immunization (Scheme mix) and a potential scenario - the current scheme, but with expanded (97%) Hib coverage - Scheme 1. The cohort of infants born in 2011 year is followed over their lifetime. Direct and indirect medical costs are measured from the perspective of the public payer. Outcomes are measured in life years gained (LYG).Exchange rate is 1€ = 41 rub. **RESULTS:** According to the model, total costs of immunization Scheme are: 0 – 4216723519 rub. (102 846 915€), Scheme 1 –4924823829 rub.(120 117 654€), Scheme P -6035132925rub.(147 198 364€), Scheme mix - 4 921 824 835 rub (120 044 508€). The values of cost/LYG are estimated at 4243 198 rub .(103493€) for Scheme 0, 1 224 270rub.(29860€)for Scheme 1, 1500 283 rub. (36592€) for Scheme P, 1223 525rub.(29842€)– for Scheme mix. **CONCLUSIONS:** The introduction of DTaP-IPV-Hib combined vaccine would bring improvement into the Russian immunization program through a Scheme mix.

DIFFERENT DISCOUNTING APPROACHES AND THEIR IMPACT IN ECONOMIC EVALUATION: A PRACTICAL EXAMPLE USING HEPATITIS B VACCINATION

Cure S[1], Bianic F[2], Nandini Kahol D[1], Davie A[1]
[1]*OptumInsight, Uxbridge, UK,* [2]*OptumInsight, Nanterre, France*

OBJECTIVES: To evaluate the impact of different discounting approaches on economic evaluation using an example of Hepatitis B model. Currently, constant discounting rates of 3.5% are applied for costs and outcomes in the UK. This study applied different approaches such as empirical, stepwise and time-shifted discounting in parallel to the constant discounting to identify their respective impact on the cost-effectiveness results with respect to the NICE threshold. **METHODS:** To compare costs and outcomes of a vaccination policy, a Markov model was built for the UK population birth cohort. Patients entered after contracting Hepatitis B and were followed until 80 years old. The health states included chronic carrier phase, immune, compensated and decompensated cirrhosis, hepatocellular carcinoma and death. The different discounting approaches were applied to the costs and health outcomes. The Incremental Cost-Effectiveness Ratios (ICERs) thus obtained were compared. **RESULTS:** The ICER obtained was higher than the NICE threshold of £20,000 to £30,000 per QALY gained

using the constant discounting approach. The empirical , hyperbolic and proportional discounting methods provided ICERs three times higher. The time-shifted and stepwise discounting led to favorable ICERs that were much below the NICE threshold. **CONCLUSIONS:** The use of different discounting approaches had a considerable effect on the cost-effectiveness results. For preventive programs and vaccines constant discounting approach was unfavorable since the health benefits are revealed decades later. Constant discounting could not justify the theory of social and individual time preference. The empirical discounting though discounted the outcomes at a much slower rate in the long term; the approach remained unfavorable owing to the heavy discounting in the short term. The time-shifted and stepwise discounting were feasible for the vaccines as they related to the moment of risk reduction and were persistent with the time-preference theory, respectively.

PIN86

COST-EFFECTIVENESS ANALYSIS OF EMPIRIC LIPOSOMAL AMPHOTERICIN B VERSUS VORICONAZOLE IN TURKEY

Turner SJ[1], Senol E[2], Kara A[3], Al-Badriyeh D[4], Kong DC[5], Dinleyici EC[6]
[1]*Rutgers University, Piscataway, NJ, USA,* [2]*Gazi University, Ankara, Turkey,* [3]*Hacettepe University, Ankara, Turkey,* [4]*College of Pharmacy, Qatar University, Doha, Qatar,* [5]*Monash University, Parkville, Australia,* [6]*Eskisehir Osmangazi University, Eskisehir, Turkey*

OBJECTIVES: A pivotal clinical trial failed to demonstrate non-inferiority of voriconazole (VORI) vs. liposomal amphotericin B (LAMB) for empiric treatment of febrile neutropaenia (FN). This study investigated the cost-effectiveness of the two options from the Turkish health care system's perspective. **METHODS:** A decision-tree analysis was used to capture downstream consequences of each agent. Outcome measures included success, breakthrough fungal infection, persistent base-line fungal infection, persistent fever, premature discontinuation and death. Probability data were extracted from the published clinical trial. Resource consumption and alternative treatment after initial failure with either agent were estimated by an expert panel. Cost was based on 2012 data within Turkey. Deterministic and probabilistic sensitivity analyses were performed to determine the model's robustness. **RESULTS:** Compared to LAMB, VORI was the cost-effective alternative per patient treated and per patient survival (by TL2,523 (approx USD1,396) and TL2,520 (approx USD1,394), respectively). LAMB was preferred when considering the cost per successfully treated patient (TL5,362 difference in favor of LAMB, approx USD2,966). LAMB had a higher likelihood of success (30.57% vs. 26.02%) and lower probability of death than VORI (5.92% vs. 7.95%). Increasing the list cost or length of stay (LOS) of VORI by >32.4% or 1.2 days, respectively, changes the study outcomes. Decreasing list cost or LOS for LAMB by >15.8% or 1.0 days, respectively, resulted in LAMB becoming favorable. Monte Carlo simulation (MCS) of 10,000 subjects, with variability imputed upon the published outcome probabilities, LOS and hospitalization costs, resulted in a 69.4% chance of favoring VORI. **CONCLUSIONS:** VORI appears to be cost-effective when compared to LAMB in the empiric treatment of FN from the Turkish perspective. One-way sensitivity analyses did not change the conclusion with MCS indicating a 69.4% chance of favoring VORI. The outcome was highly sensitive to list cost and LOS.

PIN87

NON-HOMOGENEOUS COST-EFFECTIVENESS MODELING OF A NEW CHG-DRESSING FOR PREVENTING CATHETER-RELATED BLOODSTREAM INFECTIONS FOR PATIENTS IN INTENSIVE CARE UNITS

Maunoury F[1], Motrunich A[1], Ruckly S[2], Timsit JF[2]
[1]*Statésia, Le Mans, France,* [2]*Grenoble University Hospital, Grenoble, France*

OBJECTIVES: Catheter-related bloodstream infection (CRBSI) is a frequent (1-5/1000 catheter-days) and life-threatening complication in intensive care unit (ICU), preventable by systematic use of a new antimicrobial transparent dressing containing a chlorhexidine gluconate (CHG) hydrogel (60% risk reduction in a recent RCT). Our purpose is to evaluate the advantages of routine use of the new CHG-dressing to secure central lines of patients in ICU from the medico-economic viewpoint compared to non-antimicrobial (reference). Both medical and economic criteria are embedded into an analytic decision model to support the choice of the best dressing strategy. **METHODS:** A 30-day ICU-time non-homogeneous markovian model comprises eight states: five combining either occurrence or no-occurrence of: CRBSI, contact dermatitis, and the need of a new central line; one for changing alternative dressing in case of dermatitis and two absorbent states (death and discharge). The probabilities of events derive a multicentre RCT on 1,879 patients. Monte Carlo simulations of 1,000 patients are used for probabilistic sensitivity analysis and 95% confidence intervals (CI) calculations. The final health outcome is the number of CRBSI averted. Costs of ICU stay are updated from estimations of a French study from 2010. This economic evaluation takes into account ICU perspective in France. **RESULTS:** The CHG-dressing prevents 11.75 infections (95% CI: [-19.64; -3.85], number needed to treat=85) for 1,000 patients as estimated via probabilistic cost-effectiveness sensitivity analysis. The mean adjusted cost per patient is $€_{2013}$ 21,391 [95% CI: €20,339; €22,443] for the CHG-dressing group and $€_{2013}$ 20,882 [95% CI: €19,905; €21,859] for the reference dressing. **CONCLUSIONS:** The CHG-dressing, significantly more efficacious to prevent CRBSI when compared to the reference dressing, contributes to preserve patients' health capital at the same cost for the ICU. According to the base case scenario the CHG-dressing is more cost-effective than the reference dressing.

PIN88

COSTS EVALUATIONS OF READY-TO-USE PROPOFOL SYRINGES VERSUS SYRINGES DRAWN FROM VIALS IN CRITICALLY ILL

Devaud JC[1], Eggimann P[2], Voirol P[1], Jolliet P[2], Pinget C[2], Wasserfallen JB[2], Pannatier A[1]
[1]*Lausanne University Hospital (CHUV)/School of Pharmaceutical Sciences, Lausanne, Switzerland,* [2]*Lausanne University Hospital (CHUV), Lausanne, Switzerland*

OBJECTIVES: Primary nosocomial bloodstream infections (BSI) (5-15% of all infections) are associated with increased length of stay and additional hospital costs. Propofol infusions, commonly used for sedation in intensive care units (ICU), are formulated in lipid emulsion which promotes microbial growth. The present study aimed at identifying the probabilities and costs of contamination of syringes of propofol in critically ill patients, and subsequently determining the best strategy for administering propofol. **METHODS:** Costs of propofol-related infection and the different strategies of administration of propofol were computed according to the literature and microcosting method. The additional length of stay in ICU due to major infections related to propofol administration was estimated using the disability model, assuming a cost of CHF 2'118/intensive care unit day (local cost). The cost of each strategy was estimated based on all costs and on the probability of major infections related to propofol administration. **RESULTS:** According to the links found in the literature by genotyping bacteria (syringe-patient), we assumed that a patient has a mean 22.6% risk of developing an infection by a contaminated preparation of propofol. Thus, the ready-to-use syringe and syringes drawn from vials have an infection probability of 0.0014 [0.0009 – 0.0038] and 0.0118 [0.0056 – 0.0181] respectively. Probability of infection and the extended length of stay were the cost-drivers of this analysis. Ready-to-use syringes of propofol saved money, decreasing the cost by at least CHF 251 per sedation. Ready-to-use syringes remained a cost saving strategy when the propofol related infection rate probability according to the literature was as high as 0.38%. **CONCLUSIONS:** Ready-to-use syringes of propofol save money by preventing major infections related to its administration.

PIN89

COST EFFECTIVENESS OF PREPEX DEVICE AND DORSAL–SLIT TECHNIQUE FOR SCALING-UP ADULT SAFE MEDICAL MALE CIRCUMCISION IN HIV PREVENTION IN RURAL CENTRAL UGANDA

Kigenyi O, Kusiima J, Silas I
Makerere University, Kampala, Uganda

OBJECTIVES: Averting 20% of new HIV infections, the country has to achieve 80% national circumcision coverage. Given the inadequacy of human resource at circumcision centers in Uganda, we conducted a study to assess the cost-effectiveness of PrePex device (none surgical) and Dorsal-slit technique (surgical) for scaling-up adult safe medical male circumcision. **METHODS:** In a four weeks cost effectiveness course project during November 2012, we modeled the costs and effects of male circumcision of the 2 commonest strategies (Dorsal-slit technique as standard and PrePex device) used in Uganda. Effectiveness was defined as days of complete healing measured by costs from start of procedure to complete healing. This was the time until end of each procedure when all scores for drainage from incision, epithelialization, granulation of tissue, and edema were zero. We estimated costs and effects from previous studies in developing countries. Direct and indirect costs were included in a cost effectiveness analysis with limited government perspective. Costs for demand creation (training, patient counseling, and promotion campaigns) were excluded. One-way sensitivity analysis was done by varying costs and days of complete healing as main model parameters. Analyses were done using TreeAge Pro-2011 software. **RESULTS:** PrePex (none surgical) utilized $52.13 over the days to complete healing (31 days) compared to dorsal-slit (surgical) utilizing $67.8 over the days to complete healing (23 days). PrePex was less costly ($52) and with lowest adverse-events (0.98) compared to dorsal-slit technique 0.96 adverse-events costing $65.9. PrePex device was mostly not sensitive to changes in costs and days to complete healing. **CONCLUSIONS:** PrePex device was cost-saving and cost effective.

PIN90

COST-EFFECTIVENESS OF CASPOFUNGIN VERSUS VORICONAZOLE FOR EMPIRIC THERAPY IN TURKEY

Turner SJ[1], Senol E[2], Kara A[3], Al-Badriyeh D[4], Kong DC[5], Dinleyici EC[6]
[1]*Rutgers University, Piscataway, NJ, USA,* [2]*Gazi University, Ankara, Turkey,* [3]*Hacettepe University, Ankara, Turkey,* [4]*College of Pharmacy, Qatar University, Doha, Qatar,* [5]*Monash University, Parkville, Australia,* [6]*Eskisehir Osmangazi University, Eskisehir, Turkey*

OBJECTIVES: Two major clinical trials examined the efficacy of caspofungin (CAS) and voriconazole (VORI) for empiric therapy of febrile neutropaenia (FN). We investigated the cost-effectiveness of empiric CAS vs. VORI in FN from the Turkish perspective. **METHODS:** The downstream consequences of CAS or VORI were captured through decision tree analysis. Outcome measures included success, breakthrough fungal infection, persistent base-line fungal infection, persistent fever, premature discontinuation and death. Probability data were extracted from the major studies. An expert panel estimated health care resource consumption and alternative treatment after initial failure with either agent. Cost was based on 2012 data using Turkish Lira (TL). Deterministic and probabilistic sensitivity analyses were performed. **RESULTS:** Compared to VORI, CAS was dominant by TL2,533, TL29,256 and TL2,536 per patient treated, successfully treated and patient survival, respectively (approx. USD1,414, 16,328 and 1,415). CAS had a higher likelihood of success and lower mortality than VOR (34.17% vs. 26.02% and 7.37% vs. 7.95%, respectively). Increasing the list cost or length of stay (LOS) for CAS by >35% or 1.3 days, respectively, changes the study outcomes. A decrease of list cost or LOS for VOR by >32% or 1.2 days resulted in it being favorable. Removing fever resolution as part of the composite outcome afforded a contracted difference (CAS preferred by TL298 and 299 per patient treated and surviving with VORI preferred by TL488 per patient successfully treated). Monte Carlo simulation of 10,000 subjects, with variability imputed on the outcome probabilities taken from the literature, LOS and hospitalisation costs, resulted in a 78.8% chance of favoring CAS. **CONCLUSIONS:** There is a high likelihood of CAS being cost-effective compared to VORI in the treatment of FN in Turkey. Sensitivity analyses highlighted a robust advantage towards CAS. The model is moderately sensitive to changes in LOS or cost of each agent.

PIN91

ECONOMIC ANALYSIS OF PROTEASE INHIBITORS IN FIRST-LINE HAART IN ADULT PATIENTS WITH HIV

Avxentyeva M[1], Goryaynov S[2], Rebrova O[3]
[1]*The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia,* [2]*Autonomous non-profit organization "National Centre for Health Technology Assessment", Moscow, Russia,* [3]*Pirogov Russian National Research Medical University, Moscow, Russia*

OBJECTIVES: To conduct pharmacoeconomic analysis of ritonavir-boosted atazanavir (ATV/r) vs ritonavir-boosted lopinavir (LPV/r) and ritonavir-boosted darunavir (DRV/r) in combination with nucleoside reverse transcriptase inhibitors (NRTIs) in treatment-naïve adult patients with HIV-infection from Russian health care system point of view. **METHODS:** Cost-effectiveness analysis (CEA) with calculation of incremental cost-effectiveness ratio (ICER) was used for comparison of ATV/r with LPV/r. Cost-minimization analysis (CMA) with calculation of cost minimization difference (CMD) was used for comparison of ATV/r with DRV/r. Direct comparison of clinical efficacy and safety of ATV/r vs LPV/r was based on the results of randomized controlled trial (RCT) CASTLE. Indirect comparison of clinical efficacy and safety of ATV/r with DRV/r was performed on the basis of results of RCTs CASTLE and ARTEMIS. Virological response after 96 weeks of treatment and protease inhibitors (PIs)-induced diarrhea were considered as clinical efficacy and safety outcomes, respectively. Direct medical costs were calculated for the hypothetical cohort of 100 patients treated for 96 weeks. **RESULTS:** ATV/r + NRTIs had statistically significant higher rate of virological response after 96 weeks of treatment than LPV/r + NRTIs (risk ratio (RR) = 1.090 [95% CI 1.002; 1.186], p<0.05) with statistically significant lower risk of PI-induced diarrhea (RR = 0.202 [95% CI 0.107; 0.381], p<0.0001). There were no statistically significant difference between combinations ATV/r + NRTIs and DRV/r + NRTIs in terms of rate of virological response and risk of PI-induced diarrhea (RR = 0.981 [95% CI 0.869; 1.107], p=0.77 and 0.543 [95% CI 0.227; 1.296], p=0.17, respectively). ICER for ATV/r vs LPV/r was 4063.58 EUR per one additional patient with virological response. CMD for ATV/r vs DRV/r was 5485.38 EUR per patient. **CONCLUSIONS:** ATV/r is more preferable than LPV/r and DRV/r for administration in combination with NRTIs in treatment-naïve adult patients with HIV infection.

PIN92

TOO EARLY OR TOO LATE? IMPACT OF DIFFERENT HERPES ZOSTER VACCINE'S WANING RATES ON AGE-SPECIFIC INCREMENTAL COST-EFFECTIVENESS RATIO

Ultsch B[1], Weidemann F[1], Reinhold T[2], Siedler A[1], Krause G[3], Wichmann O[1]
[1]*Robert Koch Institute, Berlin, Germany,* [2]*Charite University Medical Center Berlin, Germany, Berlin, Germany,* [3]*Helmholtz Centre for Infection Research, Brunswick, Germany*

OBJECTIVES: Herpes Zoster (HZ) is a painful skin rash that occurs most frequently among the elderly. A vaccine has recently been licensed in Europe to prevent HZ in individuals aged ≥50 years. As of today, the actual annual waning-rate (WR) of vaccine-induced-immunity (VI) is unknown. To investigate the impact of different WRs on the incremental-cost-effectiveness-ratio (ICER) at different ages at vaccination, we performed a health economic analysis for the German statutory-health-insurance setting. **METHODS:** Based on a Markov-model, we compared a HZ-vaccination-strategy to a scenario without vaccination in Germany targeting different cohorts to identify the most efficient age at vaccination (50, 60, or 70 years). A societal-perspective (SP) was considered, country- and age-specific demographic, epidemiological, and cost-of-illness input-data were utilized. We assumed a vaccine-price of 140.48 Euro/dose and 10 year stable VI. Thereafter an exponential waning of VI based on several annual relative WR (0, 2.5, 5, 7.5, 10 and 50%) was assumed. All monetary amounts were in Euro 2010. The cycle-length was a quarter; we considered a lifelong time-horizon. The discount-rate was 3% for outcomes and costs. Results were presented as costs/quality-adjusted life-year (QALY) gained ICERs. **RESULTS:** With annual WR <5% ICERs increase with age at vaccination from 50 (0% WR: 16,567€/QALY gained) to 70 years (0% WR: 37,285€/QALY gained). When WR is ≥5% the vaccination-age-specific ICERs become U-shaped with the minimum ICERs at 60 years (5% WR: 25,474€/QALY gained). With high annual WR (50%) the ICERs at vaccination-age 70 (50,847€/QALY) are lower than ICERs at 50 years (56,871€/QALY). **CONCLUSIONS:** The annual WR has a high impact on vaccination-age-specific ICERs. To obtain lowest ICERs, HZ-vaccine should be given early in life (e.g. 50 years) if WR is low. When annual WR is >4%, the most efficient age at vaccination is 60 years. Evidence on the actual WR after HZ-vaccination has yet to be established.

PIN93

COST-EFFECTIVENESS OF UNIVERSAL VACCINATION AGAINST VARICELLA IN THE NETHERLANDS

de Boer PT, Postma MJ
University of Groningen, Groningen, The Netherlands

OBJECTIVES: The Netherlands has no varicella vaccination in its National Immunization Program (NIP). Although varicella is regarded as a mild disease, implementation of varicella vaccination in the immunization schedule of several countries has shown to be cost-effective. Dutch children are infected with varicella zoster virus at younger age and make less use of the health care system as compared to other European countries. Therefore, a specific cost-effectiveness study of varicella vaccination for The Netherlands is needed. We aimed to estimate the incremental cost-effectiveness ratio (ICER) of universal vaccination of children against varicella in the Dutch NIP as compared with no such vaccination. **METHODS:** A static cohort model was developed to assess the cost-effectiveness of varicella childhood vaccination in the first 30 years. Several vaccination strategies were explored by varying the age of the booster vaccination. Dutch sources of varicella incidence and health care use were combined with vaccine efficacy data from other countries. This study was performed from the societal perspective as well as from the payer's perspective. Results were expressed in euros (€) per quality-adjusted life year (QALY) gained. **RESULTS:** Vaccinating a birth-cohort of 180,000 children could avert 105,091 varicella cases and save 301.1 QALYs and €13.7 million of direct and indirect costs. The optimal vaccinating-strategy from cost-effectiveness point of view was vaccinating at 14 months and 4 years. This scenario resulted in an ICER of €2844/QALY gained from the societal perspective and €40,582/QALY gained from the health care payer's perspective, when a vaccine price of €45 was used. Results were sensitive to vaccine price, waning rate of the second vaccination and indirect costs. **CONCLUSIONS:** Introduction of varicella vaccination in the Dutch NIP would be cost-effective from the societal perspective when a threshold of €20.000/QALY gained was used, which corresponds to the minimum threshold mentioned for the Dutch context.

PIN94

QUADRIVALENT VERSUS TRIVALENT INFLUENZA VACCINE: IS IT GOOD VALUE FOR MONEY?

Barbieri M[1], Patarnello F[2], Boccalini S[3], Silvestri R[2], Lapinet JA[2], Tosatto R[2], Kheiraoui F[4], de Waure C[4], Bonanni P[3], Ricciardi WG[4]
[1]*Centre for Health Economics, York, UK,* [2]*GlaxoSmithKline Italy, Verona, Italy,* [3]*University of florence, Florence, Italy,* [4]*Catholic University of Sacred Heart, Rome, Italy*

OBJECTIVES: To assess the cost-effectiveness of quadrivalent influenza vaccine (QIV) compared to trivalent vaccine (TIV) in the Italian population aged 65 years or more or at high-risk for influenza. **METHODS:** A static and multi-cohort Markov model was modified to simulate the disease process of influenza (type A and B) over a lifetime horizon using annual cycles. Several cohorts based on the Italian population (nine different age-groups and two level of risks: high and low) entered the model and could be vaccinated with QIV or TIV. Vaccine coverage rate, epidemiological and demographic estimates were taken from local statistics, surveillance data and Italian published studies, while circulation of type A versus B virus and type of lineage was taken from Euroflu estimates (from 2003-2004 to 2012-2013). Vaccine efficacy against influenza A and B were taken from 2 meta-analyses of clinical trials. Costs and resource use were based on local tariffs and published estimates (price year 2013). Quality of life scores were obtained from a Spanish study, using the EQ-5D questionnaire. The perspective of the National Health Service (NHS) was used and a 3% discount rate was applied to costs and benefits, according to Italian guidelines. To deal with the issue of uncertainty both deterministic and probabilistic sensitivity analyses were conducted. **RESULTS:** In the basecase, the incremental cost per QALY and per LY saved for QIV versus TIV were €10,940 and €9,452, respectively. The most sensitive parameters were vaccine efficacy and probability of circulation of virus A versus B, but the probabilistic analysis showed that at a threshold of €50,000 per QALY, there was about 90% probability for QIV to be cost-effective. **CONCLUSIONS:** This study suggests that the introduction of QIV at the same level of price of the most recent adjuvated vaccines is likely to be a cost-effective strategy from the perspective of the Italian NHS.

PIN95

VARICELLA VACCINE AS POST-EXPOSURE PROPHYLAXIS – A COST-EFFECTIVENESS ANALYSIS

Chui KS, Wu HL, You J
The Chinese University of Hong Kong, Shatin, Hong Kong

OBJECTIVES: Chickenpox, or varicella, is a highly communicative infectious disease affecting mainly young children. Varicella is self-limiting in the majority of cases, yet serious complications, including secondary bacterial infections of skin and soft tissues, pneumonia and encephalitis, can occur and result in hospitalization. Varicella vaccine is an effective post-exposure prophylaxis (PEP) of chickenpox. This study aimed to analyze cost-effectiveness of PEP using varicella vaccine for pediatric patients from the perspective of public health care provider in Hong Kong. **METHODS:** A decision tree was designed to compare cost and clinical outcomes of PEP with varicella vaccine versus no PEP in pediatric patients (aged 1-18 years old) susceptible to chickenpox with household exposure. Two tiers of outcomes were simulated: 1) Total direct medical cost, and 2) the quality-adjusted life year (QALY) loss associated with chickenpox. Model inputs were retrieved from local epidemiology and medical literature. Sensitivity analysis was performed on all parameters to test the robustness of model results. **RESULTS:** Base-case analysis showed PEP with varicella vaccine to be less costly (expected cost USD320 vs. USD731) with lower QALY loss (0.00423 QALYs vs. 0.01122 QALYs), comparing to no PEP. Sensitivity analysis showed that PEP with varicella vaccine was less costly if PEP effectiveness was >6.2% or chickenpox infection rate without PEP was >8.6%. In 10,000 Monte Carlo simulations, PEP with vaccine was cost-effective in over 99% of the time with mean cost saving of USD611per patient (95% CI USD602-620; P<0.001) and lower mean QALY loss of 0.00809 QALYs (95% CI 0.00802-0.00816 QALYs; P<0.001). **CONCLUSIONS:** Using varicella vaccine as PEP seems to be a cost-saving strategy to avert QALY loss in susceptible pediatric patients exposed to chickenpox in Hong Kong.

PIN96

LONG-TERM OUTCOMES OF SOFOSBUVIR (SOF) FOR THE TREATMENT OF CHRONIC HEPATITIS C INFECTED (CHC) PATIENTS

Cure S[1], Guerra I[1], Dusheiko G[2]
[1]*OptumInsight, Uxbridge, UK,* [2]*Royal free hospital, London, UK*

OBJECTIVES: Sofosbuvir is a uridine analogue polymerase inhibitor. Pan-genotypic efficacy and safety have been demonstrated in four phase III clinical trials of SOF administered with ribavirin (RBV) or with a combination of pegylated interferon alfa and RBV (PR). This analysis evaluated the long-term outcomes of SOF/RBV in treatment-naïve (TN) genotype (GT) 1/4/5/6 and TN, treatment-experienced (TE), interferon ineligible (TNI) GT 2 and 3 patients **METHODS:** A Markov-model followed a cohort of 10,000 patients for a lifetime, with 50% initiating treatment at the compensated cirrhotic stage. In GT 1, 4/5/6 TN patients, SOF/PR for 12 weeks was compared to, telaprevir (TVR) or PR, respectively. SOF/RBV for 12 or 16 weeks for GT 2 and 3, respectively, was compared to no treatment for TNI and TE, and PR for 24 or 48 weeks (PR24/PR48) for TN and TE respectively. SVR 12 weeks have been reported as 90% for TN GT 1 and 97% for GT 4/5/6 patients; 78% for patients with no treatment option (TNI and TE); 97% and 56% for GT 2 and 3 TN; for GT 2 and 3 TE, 86% and 30% with 12-week and, 94% and 62% with 16-week regimens, respectively. **RESULTS:** SOF was shown to be highly effective in preventing advanced liver disease (ALD) and mortality due to HCV across all GTs. This was particularly favorable for patients with no current treatment option (TNI and TE) where up to 7,000 ALD cases can be avoided and more than 200 lives saved. The model demonstrated that in GT 1 and 4/5/6 TN patients, SOF/PR prevented around 5,000 and 900 more ALD cases than PR and TVR treatment arms, respectively. **CONCLUSIONS:** SOF, including within interferon-free regimens, was shown to be highly effective in preventing progression to ALD and reducing HCV-related mortality, particularly in patients with no current treatment option.

ECONOMIC EVALUATIONS OF VARICELLA AND HERPES ZOSTER VACCINATION PROGRAMMES: A SYSTEMATIC REVIEW

Damm O[1], Ultsch B[2], Horn J[3], Mikolajczyk R[3], Wichmann O[2], Greiner W[1]
[1]*School of Public Health, Bielefeld University, Bielefeld, Germany,* [2]*Robert Koch Institute, Berlin, Germany,* [3]*Helmholtz Centre for Infection Research, Braunschweig, Germany*

OBJECTIVES: This systematic review aimed to assess the cost-effectiveness of routine varicella and herpes zoster vaccination in high-income countries. **METHODS:** A PubMed search was performed for identifying English- and German-language publications on economic analysis of varicella and herpes zoster (HZ) vaccination programmes published before May 2013. A study was included if it was a full economic evaluation of a routine childhood or adolescent varicella vaccination programme and/or a HZ vaccination scheme targeting the elderly and if the study reported results for a high-income country as specified by the World Bank. To improve comparability between studies and across countries, all cost estimates were inflated to 2010 values applying country-specific consumer price indices and converted to Euros with the German level of purchasing power using purchasing power parities obtained from the Organisation for Economic Co-operation and Development. **RESULTS:** After the study selection process, 37 model-based studies remained to be included in the review. Routine childhood or adolescent varicella vaccination was cost-effective or cost-saving from a payer perspective and always cost-saving from a societal perspective when ignoring a potential impact on HZ due to exogenous boosting. The inclusion of the impact on HZ led to net QALY losses or incremental cost-effectiveness ratios exceeding commonly accepted thresholds. Additional HZ vaccination could partially mitigate this effect. Results of the studies only focusing on the evaluation of HZ vaccination ranged from EUR 1,200 to 291,240 per QALY in one study assessing multiple scenarios and from EUR 5,572 to 140,125 per QALY across all other studies. **CONCLUSIONS:** While cost-effectiveness of HZ vaccination was strongly dependent on the age of vaccination, cost-effectiveness of varicella vaccination was primarily dependent on the in- or exclusion of the potential impact on HZ. As a consequence, clarification on the role of exogenous boosting is crucial for decision-making regarding varicella vaccination.

PREVENTION OF GRAM-POSITIVE INFECTIONS IN PERITONEAL DIALYSIS PATIENTS – A COST-EFFECTIVENESS ANALYSIS

You J[1], Wong C[1], Luk I[1], Ip M[2]
[1]*The Chinese University of Hong Kong, Shatin, Hong Kong,* [2]*The Chinese University of Hong Kong, Shatin, N.T., Hong Kong*

OBJECTIVES: Gram-positive bacteria cause clinically severe peritonitis and exit-site infection (ESI) in patients on peritoneal dialysis (PD). Incident PD patients are most prone to developing ESI and peritonitis within the first year of dialysis. We investigated the potential costs, quality of life, and clinical outcomes of incident PD patients with or without regular application of mupirocin on exit-site from the perspective of health care provider in Hong Kong. **METHODS:** We designed a decision tree to simulate potential outcomes of incident PD patients with and without regular application of mupirocin over a period of one year. Outcome measures included total direct medical cost per patient, quality-adjusted life-years (QALYs) gained and gram-positive bacterial infection-related mortality rate. Model inputs were derived from literature. Sensitivity analyses evaluated the impact of uncertainty in all model variables. **RESULTS:** In base-case analysis, the mupirocin group showed higher expected QALYs (0.6496 vs. 0.6456), lower infection-related mortality rate (0.18% vs. 1.64%) and lower total cost per patient (USD258 vs. USD1,661) comparing with the control group. Rate of gram-positive bacterial peritonitis without mupirocin and the risk of gram-positive bacterial peritonitis with mupirocin were identified to be potential influential factors. In 10,000 Monte Carlo simulations, mupirocin group was significantly ($p<0.001$) less costly, gained higher QALYs with lower mortality rate 99.9% of the time. **CONCLUSIONS:** Daily application of mupirocin at catheter exit-site during the first 12 months of PD seems to be cost-saving and effective in reducing mortality of PD-related gram-positive infections as well as improving health-related quality of life from the perspective of health care provider in Hong Kong.

COST-EFFECTIVENESS ANALYSIS (CEA) OF LINEZOLID VERSUS VANCOMYCIN IN THE TREATMENT OF NOSOCOMIAL PNEUMONIA CAUSED BY METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS (MRSA-NP) BASED ON A PHASE IV CLINICAL TRIAL: RESULTS FROM FOUR MAJOR CITIES IN CHINA

Wan Y[1], Wang X[2], Wu B[3], Kang H[4], Li Q[5], Chen Y[6], Li JZ[7], Liu S[1], Gao X[1]
[1]*Pharmerit International, Bethesda, MD, USA,* [2]*First Affiliated Hospital of Medical College of Xi'an JiaoTong University, Xi'an, China,* [3]*The 3rd Affiliated Hospital of Sun Yat-sen, Guangzhou, China,* [4]*Chinese PLA General Hospital, Beijing, China,* [5]*Jiangsu Province Hospital, Nanjing, China,* [6]*Pfizer Inc., Beijing, China,* [7]*Pfizer, Inc., San Diego, CA, USA*

OBJECTIVES: To assess the cost-effectiveness of linezolid versus vancomycin in the treatment of NP in four major cities (Beijing, Guangzhou, Nanjing, and Xi'an) in China. **METHODS:** We conducted cost-effectiveness analyses from Chinese payers' perspective piggybacked to a phase IV, randomized, double-blind, multicenter study (Wunderink et al, CID 2012) in MRSA-NP patients (microbiologic confirmed intent-to-treat cohort). Efficacy was measured by treatment success (defined as Cure+Improvement) at the end of study (i.e., 7-30 days after the end of treatment). Direct medical costs from four cities in China (¥, 2012) were calculated from the health care resource use data collected from the trial, including study medication, hospitalization, mechanical ventilation, and continuous renal replacement therapy. Nonparametric bootstrapping method was used to calculate confidence intervals (CI) for costs, efficacy, and incremental cost-effectiveness ratios (ICER). **RESULTS:** Data from 391 patients (186 linezolid, 205 vancomycin) were analyzed. More linezolid patients achieved treatment success vs. vancomycin patients [mean (95% CI)]: 55% (48.3%-61.9%) vs. 45% (38%-52.3%). The total treatment costs of linezolid vs. vancomycin were: ¥79,551(¥72,421-¥86,680) vs. ¥77,587(¥70,656-¥84,519) for Beijing, ¥90,995(¥82,598-¥99,393) vs. ¥89,448(¥81,295-¥97,601) for Guangzhou, ¥82,383(¥74,956-¥89,810) vs. ¥80,799(¥73,545-¥88,054) for Nanjing, and ¥59,413(¥54,366-¥64,460) vs. ¥57,804(¥52,613-¥62,996) for Xi'an. The ICER of linezolid over vancomycin were ¥19,719(-¥143,553-¥320,980), ¥15,532(-¥185,411-¥349,693), ¥15,904(-¥161,935-¥314,987), and ¥16,145(-¥100,738-¥234,412) per additional treatment success for Beijing, Guangzhou, Nanjing, and Xi'an, respectively. Out of 10,000 bootstrap simulations, majority cases had greater efficacies and higher costs for linezolid (in quadrant I of the E-EC plane: Beijing(64%), Guangzhou(59%), Nanjing(61%), Xi'an(66%)), more than one third had greater efficacies and lower costs for linezolid (linezolid dominated vancomycin: Beijing(33%), Guangzhou(38%), Nanjing(37%), Xi'an(32%)); only <2% had greater efficacies and lower costs for vancomycin in all cities (vancomycin dominated linezolid). **CONCLUSIONS:** In this clinical trial population, linezolid appears to be cost-effective from Chinese payers' perspective when compared to vancomycin in treating patients with nosocomial pneumonia caused by MRSA.

PIN100

ECONOMIC EVALUATION OF FLUOROQUINOLONE-BASED REGIMENS FOR THE TREATMENT OF COMMUNITY-ACQUIRED PNEUMONIA IN A MULTI-FIELD HOSPITAL IN RUSSIA

Kozlov RS, Dekhnich AV, Ratchina SA, Belkova YA
Institute of Antimicrobial Chemotherapy, Smolensk State Medical Academy, Smolensk, Russia

OBJECTIVES: Respiratory fluoroquinolones are considered to be an important treatment option in hospitalized adults with community-acquired pneumonia (CAP). We aimed to compare cost-effectiveness of sequential intravenous to oral therapy of CAP with moxifloxacin and levofloxacin ± beta-lactam in a multi-field Russian hospital. **METHODS:** Standard search of prospective randomized clinical trials (RCT) was performed for the period since 1st Jan 1995 till 31st Dec 2012. RCTs quality was assessed by Jadad scale. Three RCTs with direct comparison of moxifloxacin vs. levofloxacin±ceftriaxone in adults with CAP required initial intravenous antimicrobial therapy [Torres A. 2008, File T.M. Jr. 2001, Anzueto A. 2006] were included in the analysis. As similar efficacy and safety was shown between comparators a cost-minimisation model was applied. Original drugs' costs were extracted from hospital receipt notes of three multi-field hospitals and wholesale prices database (www.pharmindex.ru). Cost of therapy was calculated to respective treatment regiments in selected trials: moxifloxacin 400 mg QD vs. levofloxacin 500 mg QD/BID±ceftriaxone 2 g QD for 11 days. Uncertainty was explored in a series of one- and two-way sensitivity analysis. **RESULTS:** The respective total drug therapy costs per patient were as follows: €249 for moxifloxacin vs. €161/€321 for levofloxacin QD/BID and €419/€579 for levofloxacin QD/BID+ceftriaxone. In levofloxacin monotherapy regimens the results were sensitive for IV therapy duration and oral/IV levofloxacin cost. In both levofloxacin+ceftriaxone regimens the results were insensitive to all variables of interest. **CONCLUSIONS:** Moxifloxacin is more cost effective strategy then levofloxacin+ceftriaxone for the treatment of hospitalized adults with CAP. The higher cost-effectiveness for moxifloxacin vs. levofloxacin monotherapy depends on IV therapy duration, levofloxacin regimen and oral/IV levofloxacin cost.

PIN101

ECONOMIC EVALUATION OF CEFTOBIPROLE COMPARED TO A COMBINATION OF LINEZOLID WITH CEFTAZIDIME IN THE MANAGEMENT OF HOSPITALISED PNEUNOMIA IN SCOTLAND

van der Scheer FW[1], Kuessner D[2], de Silva S[3], Posthumus J[2], Bergman G[1]
[1]*Mapi, Houten, The Netherlands,* [2]*Basilea Pharmaceutica International Ltd., Basel, Switzerland,* [3]*Mapi, London, UK*

OBJECTIVES: Ceftobiprole is a new i.v. anti-infective, which has bactericidal activity against difficult to treat Gram-positive (including multidrug-resistant pneumococci and methicillin-resistant Staphylococcus aureus; MRSA) and Gram-negative (including Pseudomonas aeruginosa) bacteria, which are important aetiological agents of nosocomial pneumonia (NP) and hospitalised community-acquired pneumonia (CAP). The objective of this analysis was to estimate the economic value of ceftobiprole (TID) compared to linezolid (BID)/ceftazidime (TID) in the treatment of hospitalised pneumonia patients in Scotland, when coverage of MRSA and Gram-negative pathogens, including P. aeruginosa,is required. **METHODS:** A cost-minimisation analysis, including only direct medical (drug) costs, was considered appropriate since the ceftobiprole phase 3 trials in NP and CAP demonstrated that ceftobiprole is non-inferior to a combination therapy consisting of linezolid and ceftazidime (NP) or ceftriaxone with or without linezolid (CAP). The base case model included drug acquisition, treatment duration, and administration costs. In additional scenario analyses, the cost-minimisation analysis included ICU and total hospitalisation costs as well. The resource use data were derived from the NP trial. **RESULTS:** Treatment with ceftobiprole resulted in a cost-saving of £258 per treated patient compared to linezolid/ceftazidime therapy. While no change in the drug budget is estimated, cost-savings are expected due to less administration time. Scenario analyses evaluated the reduction in length of ICU stay and overall hospital stay that will potentially lead to further cost savings for NHS Scotland (-£2,182 and -£904 per treated patient, respectively). **CONCLUSIONS:** This economic evaluation shows that ceftobiprole is at least a cost-neutral alternative to a combination of linezolid with ceftazidime and provides an effective and safe alternative for hospitalised pneumonia patients in Scotland.

PIN102

COST-MINIMIZATION ANALYSIS OF MARAVIROC VERSUS DARUNAVIR RALTEGRAVIR AND ENFUVIRTIDE FOR CCR5-TROPIC TREATMENT-EXPERIENCED PATIENTS WITH HIV INFECTION IN RUSSIA

Pyadushkina E[1], Omelyanovsky V[2], Avxentyeva M[2], Rebrova O[3], Goryaynov S[1]
[1]*Autonomous Non-profit Organization "National Centre for Health Technology Assessment", Moscow, Russia,* [2]*The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia,* [3]*Pirogov Russian National Research Medical University, Moscow, Russia*

OBJECTIVES: New antiretroviral drugs have a major impact on future treatment options for treatment-experienced HIV-patients with antiretroviral resistance. The

goal of this study was to perform economic evaluation of maraviroc compared with other new antiretroviral agents, such as raltegravir, darunavir and enfuvirtide for treatment-experience patients with HIV infection in Russia. **METHODS:** Indirect comparison was performed to assess the relative clinical efficacy and safety of compared drugs, all in combination with optimized background therapy (OBT). A mathematical model was created in Microsoft Excel software to estimate the direct medical costs of: compared drugs, an average OBT regimen and routine outpatient follow-up (including visits to specialists and diagnostic tests). Drug and medical services cost calculations were based on registered prices from the list of vital and essential drugs and financial standards of regional program of national guarantees for the provision of free medical care to Russian citizens in Moscow in 2012, respectively. The obtained results were tested in sensitivity analysis. **RESULTS:** According to indirect comparison results, there were no statistically significant differences between maraviroc, raltegravir, darunavir and enfuvirtide neither by the undetectable HIV RNA level nor CD4(+) cell-count changes. The rate of adverse events was comparable (except enfuvirtide that has more injection-site reactions). Maraviroc-containing regimen compared with raltegravir-, darunavir- and enfuvirtide-containing regimen is associated with reduced costs and saves an average 177 764.16 rub (€4 209.94), 59 929.92 rub (€1 419.30) and 462 295.92 rub (€10 948.42) per 48 weeks of therapy, and 340 714.64 rub (€8 069.05) and 114 865.68 rub (€2 720.33) and 886 067.18 rub (€20 984.47) per 96 weeks of therapy per patient, respectively. Results were robust in one-way sensitivity analyses. **CONCLUSIONS:** The analysis showed that maraviroc compared with darunavir, raltegravir and enfuvirtide is a cost-saving treatment option for CCR5 tropic treatment-experienced patients in Russia.

PIN103

BOCEPREVIR USE IN FRANCE: A MARKOV MODEL OF DISEASE PROGRESSION AND COST-EFFECTIVENESS FOR CHRONIC HEPATITIS C (VIRUS G1)

Ferrante S[1], Elbasha EH[2], Poynard T[3], Boyaval G[4]
[1]*Merck, Whitehouse Station, NJ, USA,* [2]*Merck Sharp & Dohme Corp., Whitehouse Station, NJ, USA,* [3]*Centre Hospitalier la Pitié Salpêtrière, Paris cedex 13, France,* [4]*MSD France, COURBEVOIE, France*

OBJECTIVES: The addition of boceprevir (BOC) to peginterferon–ribavirin (PR) resulted in significantly higher rates of sustained virologic response in naive or pretreated patients with the chronic hepatitis C virus (HCV) genotype 1 infection, as compared with PR alone. The objective is to project the long-term clinical benefits and estimate the cost-effectiveness of the treatment strategies recommended in the BOC label compared with PR alone. **METHODS:** A Markov model was created to estimate the expected costs and quality adjusted life-years (QALYs) associated with the BOC tritherapy and PR. The model simulates the treatment regimens and the natural history of the chronic HCV to project the lifetime cumulative incidence of advanced liver-related diseases (decompensated cirrhosis (DC), hepatocellular carcinoma (HCC)) and liver transplant. Series of 30 cohorts representing all combinations of pre-specified patient characteristics progress through the model. The baseline characteristics used to define the cohorts are: naive/pretreated, age, gender, baseline fibrosis score and race cohort for the treatment naive population only. Separate analyses were run for naive and pretreated patients. The distribution of baseline fibrosis score for each analysis was based on the subjects enrolled in the clinical trials; the average age and distribution of race cohort were based on French observational study (F. Roudot Thoraval, ADEQUATION, AFEF 2009). The comparator was PR (48 weeks). **RESULTS:** The model predicted relative reductions in patients treated with BOC vs PR alone: 33% and 32% in DC/HCC in naive patients and also 46% and 53% in DC/HCC in pretreated patients. The ICER of BOC-based therapy compared with PR were 15,681€/QALY for naive patients and 10,563€/QALY for pretreated patients. **CONCLUSIONS:** Compared with PR, boceprevir-based treatment is projected to substantially reduce the burden of liver complications associated with the chronic hepatitis C virus genotype 1 and is highly cost-effective if a threshold of 50,000€/QALY is assumed.

PIN104

COST-UTILITY ANALYSIS OF POSACONAZOLE VERSUS FLUCONAZOLE FOR PREVENTION OF INVASIVE FUNGAL INFECTIONS IN PATIENTS WITH GRAFT-VERSUS-HOST DISEASE IN SWEDEN

Lundberg JG[1], Jensen AV[1], Bjorkholm M[2], Hoglund M[3], Akerborg O[4]
[1]*MSD, Sollentuna, Sweden,* [2]*Karolinska University Hospital Solna, Stockholm, Sweden,* [3]*University Hospital, Uppsala, Uppsala, Sweden,* [4]*Optum Insight, Stockholm, Sweden*

OBJECTIVES: In allogeneic transplant (allo-SCT) recipients with graft-versus-host disease (GVHD) the risk of contracting an invasive fungal infection (IFI) is high and antifungal prophylaxis to prevent IFIs is routinely given. Fluconazole, has been standard antifungal prophylaxis in GVHD-patients in Sweden. Recently many Swedish centers have switched from fluconazole, which lacks efficacy against Aspergillus, to posaconazole, for the prevention of IFIs in GVHD-patients receiving moderate to high doses of glucocorticoids. Although, the superior efficacy of posaconazole vs. fluconazole in preventing IFIs have been demonstrated in this clinical setting, the cost-effectiveness of posaconazole vs. fluconazole for GVHD-patients in Sweden has not been established. The aim of this analysis is to estimate the cost-effectiveness of posacoanzole vs. fluconazole prophylaxis in allo-SCT recipients with severe GVHD receiving immunosuppressive therapy in Sweden. **METHODS:** A decision-analytic model was used to determine life-time outcomes of patients with GVHD at high risk of contracting IFIs. The model outcomes were quality adjusted life years (QALYs), costs associated with IFI-prophylaxis and treatment of IFIs and the incremental cost-utility ratio. The efficacy data were gathered from a clinical trial comparing posaconazole with fluconazole prophylaxis in patients with GVHD. The resource use for treatment of IFIs was gathered by expert opinion. Utility, mortality and unit costs were gathered from the literature. To assess the uncertainty of the modeled outcomes a probabilistic sensitivity analysis (PSA) was developed. **RESULTS:** The incremental cost-utility ratio of posaconazole vs. fluconazole for the prevention of IFI in GVHD-patients in Sweden was 541,628 SEK/QALY. The PSA showed a 56.4% probability for a cost per QALY less than 600,000 SEK. **CONCLUSIONS:** Given a willingness-to-pay threshold of 600,000 SEK/QALY, posaconazole is likely to be cost-effective for preventing IFIs in GVHD-patients compared to fluconazole.

PIN105

ECONOMIC EVALUATION OF UNIVERSAL ANTENATAL HIV SCREENING COMPARED WITH CURRENT "AT RISK" POLICY IN ISRAEL

Chowers M[1], Shavit O[2]
[1]*Meir Medical Center, Kfar Saba, Israel,* [2]*Meuhedet Health Fund, Tel-Aviv, Israel*

Israeli ministry of health guidelines for antenatal screening recommend HIV testing only in women belonging to high risk groups. This policy resulted in the last 10 years in an annual average of two infected children from unidentified Israeli women. **OBJECTIVES:** To evaluate an alternative strategy of universal screening using a cost utility analysis. **METHODS:** A budget impact analysis was first conducted to evaluate the cost of introducing universal screening using a payer perspective. Following, a cost-utility analysis (CUA) was carried out to evaluate long term effects of such strategy, compared with current policy. The model was comprised of two steps: a decision tree simulating the period from pregnancy to delivery and a successive Markov model simulating life expectancy of the newborn. Screening test sensitivity and specificity were regarded as 99.94% and 99.5% respectively. Probabilities for having HIV for the low and high-risk populations were based on experts' opinion. They were then adjusted to allow model calibration to reflect real-life finding as presented above. The cost of the screening test was US$ 5.5. Other costs included physician visits, viral load and blood tests, CD4 counts, and medications. QALY weights were 0.83 for HIV and 0.7 for AIDS. **RESULTS:** Probabilities for having HIV for the low and high-risk populations were 0.0215% and 1% respectively. The incremental cost of the universal screening over current policy for an annual cohort of 166,000 Israeli pregnant women was US$1 million, reflecting a cost of $500,000 per a case of an HIV+ baby avoided. For this cohort, an incremental 18 QALYS were projected over a 90 year time horizon with an incremental cost-effectiveness ratio of US$ -30,000. **CONCLUSIONS:** Universal Antenatal HIV screening should be implemented in Israel. The current policy of screening identified high-risk women is both less effective and more costly.

PIN106

HEALTH ECONOMICS ASSESSMENT OF RILPIVIRINE VERSUS COMPARATORS AS FIRST-LINE ANTIRETROVIRAL THERAPIES IN HIV-1 PATIENTS WITH A VIRAL LOAD (VL) ≤100,000 COPIES/ML IN FRANCE

Cognet M[1], Druais S[1], Lahoulou R[2], Havet D[2], Guillon P[2]
[1]*Amaris, London, UK,* [2]*Janssen, Issy-les-Moulineaux, France*

OBJECTIVES: In France, rilpivirine is reimbursed for HIV-1-infected treatment-naïve patients with VL≤100,000 copies/mL for whom the use of efavirenz is not appropriate. This analysis aims to compare costs and outcomes of rilpivirine vs. other third antiretroviral (ARVs) agent recommended in France (in addition to two NRTIS). **METHODS:** A cohort-based Markov model with four therapy lines and six health states based on CD4+ cell-count ranges was developed based on 1-year cycle and a 5-year time horizon. First-line efficacy data at 48 and 96 weeks was first assumed to be similar across treatments, and subsequently set to statistically significantly different (SSD) values from phase-III trial analyses of patients with VL≤100,000 copies/mL. Costs of first-line treatments were obtained from the French National Formulary. Costs associated with subsequent treatments and CD4+ health states were derived from a French cost-effectiveness analysis. Other clinical inputs, HIV-related mortality rates and utility were derived from international publications. Outcomes and costs were discounted at 4%. Robustness of results was assessed using sensitivity analyses (e.g. using efficacy values no SSD). **RESULTS:** All phase-III trials (i.e. ECHO/THRIVE, STARTMRK, CASTLE, ARTEMIS, KLEAN, GEMINI, 2NN) demonstrated a non-inferior antiviral efficacy between arms. In patients with VL≤100,000 copies/mL, response rates were available for rilpivirine (1-year: 90,2%; 2-year: 84,0%), ritonavir-boosted (/r) darunavir (1-year: 79,5%; 2-year: 76,1%), lopinavir/r (1-year: 84,5%; 2-year: 75,2%), atazanavir/r (1-year: 82%; 2-year: 75%), fosamprenavir/r (1-year: 67%) and raltegravir (1-year: 93%). CD4+ cell count changes per mm^3 were available for atazanavir/r (1-year: +179; 2-year: +243), lopinavir/r (1-year: +194; 2-year: +267), rilpivirine (1-year: +185) and raltegravir (1-year: +180). Rilpivirine was the less expensive option in the cost-minimisation analyses and dominated all treatments in the cost-effectiveness analyses when considering SSD efficacy values. **CONCLUSIONS:** The analysis provided health economic results for HIV-1-infected treatment-naïve patients with VL≤100,000 copies/mL favoring rilpivirine over all other ARVs analysed.

PIN107

COST-EFFECTIVENESS OF TELAPREVIR COMBINATION THERAPY COMPARED TO PEGINTERFERON WITH RIBAVIRIN ALONE FOR NAIVE AND TREATMENT EXPERIENCED PATIENTS WITH GENOTYPE 1 CHRONIC HEPATITIS C IN POLAND

Kaczor MP[1], Wójcik R[2], Pawlik D[2], Skrzekowska-Baran I[3], Tronczynski K[3]
[1]*Jagiellonian University Medical College, Kraków, Poland,* [2]*Aestimo s.c., Kraków, Poland,* [3]*Janssen-Cilag Polska, Warszawa, Poland*

OBJECTIVES: To assess the cost-effectiveness of telaprevir (TVR) added to peginterferon and ribavirin (PR) therapy in treatment naive (TN) and experienced (TE) genotype 1 chronic HCV patients in Poland. **METHODS:** Analysis was based on a previously validated Markov model, describing the progression of the disease over a lifetime, adapted to population characteristics specific to Poland and cost parameters obtained via questionnaire studies completed by clinical practitioners. The model comprises the following health states: mild CHC without/with SVR (remission), moderate CHC without/with SVR, cirrhosis without/with SVR, antiviral therapy, decompensated cirrhosis, HCC, liver transplantation, post-liver transplant, CHC related death. The following treatment strategies were considered: PEG++ RBV therapy for 48 weeks; TVR for 12 weeks with PEG+RBV (response-guided therapy in TN and 48 weeks in TE patients). A cost-utility analysis was conducted

to calculate the incremental cost-utility ratio (ICUR) for triple therapy. A subgroup analysis was conducted to evaluate cost-effectiveness of TN patients with IL28B T/T; Scheuer ≥ 2 and in TE patients with Scheuer ≥ 2. **RESULTS:** In the overall TN population, ICUR is 80917 PLN/QALY (»€19736/QALY). ICURs in IL28B T/T and Scheuer ≥ 2 subgroups were 42407 PLN/QALY (»€10343/QALY) and 86984 PLN/QALY (»€21216/QALY), respectively. In the overall TE population, ICUR is 81793 PLN/QALY (»€19950/QALY). For Scheuer ≥ 2 subgroup ICUR = 72448 PLN/QALY (»€17670/QALY). Calculated values are below the cost-effectiveness threshold of 105801 PLN/QALY (»€25805/QALY) in Poland. Results for relapsers, partial responders and null responders are also presented. **CONCLUSIONS:** Based on the cost-utility analysis, telaprevir combination therapy is cost-effective compared to PR alone in Polish settings.

PIN108

COMPARATIVE COSTS ANALYSIS OF CONVENTIONAL STRATEGY VERSUS STEP-DOWN STRATEGY WITH LINEZOLID IN THE TREATMENT OF NOSOCOMIAL PNEUMONIA CAUSED BY GRAM POSITIVE BACTERIA IN MEXICO

Gryzbowski E[1], Peniche-Otero G[1], Herrera-Rojas J[1], Bolaños-Cornejo D[1], Huicochea-Bartelt JL[2], Muciño-Ortega F[2]
[1]*Customized Premium Products S.A. de C.V., Mexico City, Mexico,* [2]*Pfizer S.A. de C.V., Ciudad de México, Mexico*

OBJECTIVES: To estimate the cost difference between use and absence of use of Step-Down Strategy (SDS) with linezolid for treatment of nosocomial pneumonia (NP) caused by Gram Positive Bacteria (GPB) in Mexico, from public health care institution perspective. **METHODS:** To evaluate the potential cost savings between the two strategies, a microcosting was made along three phases: (1) characterization of therapeutic protocol, (2) assessment of resources and (3) estimation of the unit costs of medical care. The temporal horizon of the analysis was set to 14 days. Costs were estimated for the year 2013, expressed in US$ and consider the following medical services: days of hospitalization, consultation with specialists, route of administration, laboratory and imaging tests as well as outpatient control, based on unit costs by level of care reported by Instituto Mexicano del Seguro Social. The frequency of use of these resources were determined from Delphi method with a panel of 10 experienced infectologists. We calculated the differences between average total costs (ATC). The stastistical significance difference between strategies was evaluated by Student's t statistic. **RESULTS:** The ATC of patients using SDS was $10,116, [95%CI $9,344.6 - $10,887.3] and the ATC of patients not using this strategy was $17,251.6 [$16,379.4 - $18,123.8]. The average potential savings due the use of SDS over conventional therapy (only intravenous) are $ 7,135.6, (p<0.001). **CONCLUSIONS:** The use of step down strategy could significantly reduce the costs of treatment of NP in terms of hospitalization, physician visits, laboratory and imaging tests, and drug administration, not as well the resources used in the outpatient control. In a challenging setting of cost containment policies, the use of step down strategy in suitable patients represents the opportunity to invest health care resources in a more efficient way.

PIN109

RESOURCE USE AND OUTCOMES OF PATIENTS TREATED WITH VANCOMYCIN OR LINEZOLID IN A TERTIARY HOSPITAL IN SHANGHAI

Yang Y[1], Ye W[1], Song Y[2], Liu W[1], Wang K[1], Li X[3], Papadimitropoulos M[4], Montgomery W[5]
[1]*Eli Lilly Suzhou Pharmaceutical Co. Ltd. Shanghai Branch, Shanghai, China,* [2]*Department of Pulmonary Medicine, Zhongshan Hospital, Fudan University, Shanghai, China,* [3]*VitalStrategic Research Institute, Shanghai, China,* [4]*Eli Lilly Canada, Toronto, ON, Canada,* [5]*Eli Lilly Australia Pty Ltd., West Ryde, Australia*

OBJECTIVES: Vancomycin and linezolid are amongst the most commonly prescribed antibiotics for hospital-acquired infections in China. The aim of this study is to estimate and compare the baseline characteristics, hospitalization costs, length of stay (LOS), length of therapy (LOT) and all-cause in-hospital mortality of patients treated with vancomycin or linezolid. **METHODS:** Data were extracted from the electronic medical records (EMR) of a tertiary hospital in Shanghai (bed size 1700). The analysis included patients admitted for any underlying cause who received either vancomycin or linezolid between January 2009 and July 2012. Continuous variables were compared with *t* test and *chi-square* for categorical variables. **RESULTS:** Of the total 3234 patients identified, 93.6% were treated with vancomycin (female: 40.6%, mean age: 55.8 years) and 6.4% were treated with linezolid (female: 22.2%, mean age: 62.3 years). Cardiac Surgery was the most frequent admitting department for the both groups, while cardiovascular disease was the top admission reason for the vancomycin group and pulmonary infection for the linezolid group. The average daily dose was 1.6±1.1 g for vancomycin and 1.2±0.5 g for linezolid. The all-cause in-hospital mortality was lower in the vancomycin group compared to the linezolid group (4.2% vs. 21.7%, p<0.001). The vancomycin group had shorter LOS and LOT compared to the linezolid group (23.6±24.4 vs. 37.1±40.8 days, p<0.001; 7.0±8.8 vs. 8.7±10.6 days, p=0.025). The vancomycin group had lower total hospitalization costs, medication costs and antibiotics costs compared to the linezolid group (RMB 68788±64956 vs. 125425±117055, p<0.001; 33258±39792 vs. 70372±69115, p<0.001; 15206±18957 vs. 34681±33184, p<0.001). **CONCLUSIONS:** Vancomycin was more frequently prescribed than linezolid and was more likely to be used in females and younger patients. When compared to those patients treated with linezolid, vancomycin treatment was associated with a shorter LOS and LOT, decreased total hospitalization costs and decreased total medication and antibiotics costs.

PIN110

WHAT CLINICAL BENEFITS COULD BE EXPECTED FROM THE IMPLEMENTATION OF A ROTAVIRUS VACCINATION PROGRAMME IN FRANCE?

Yamin D[1], Remy V[2], Atkins KE[1], Galvani AP[1]
[1]*Yale University, New Haven, CT, USA,* [2]*Sanofi Pasteur MSD, Lyon, France*

OBJECTIVES: Rotavirus vaccines have shown great potential for reducing the disease burden of the major cause of severe childhood gastroenteritis. Real-life observational studies also confirmed the indirect protection provided by rotavirus vaccination in countries where rotavirus vaccination programmes have been introduced. France has not yet implemented such a programme. Previously reported models in France do not include herd protection, thus underestimating the effectiveness of vaccination. Our study uses a dynamic transmission model to account for herd protection and therefore better predict the effect of an oral rotavirus pentavalent vaccination programme in France. **METHODS:** We developed a dynamic model to account for susceptibility of rotavirus infection as a function of both age and the number of previous infections. It was parameterized with French data on rotavirus gastro-enteritis (RVGE) incidence and age-specific contact rates. We evaluated the direct and indirect effects of vaccination on disease incidence and clinical outcomes. A three-dose vaccine course was assumed to be administered to 75% of infant annually. **RESULTS:** Our model predicts that vaccination can reduce the burden of RVGE by 66% in the four years following vaccine introduction, gradually increasing to 73% in the long term for children under 5 years of age. Our calculations show that herd immunity accounts for 11% to 20% of the overall RVGE reduction in children. Incidence in the unvaccinated adult population would also be reduced by more than 40% through herd protection. Vaccination is also predicted to reduce pressure on the health care system with the model estimating an annual reduction of 84% and 82% in the number of hospitalization/nosocomial and outpatient visits for RVGE respectively. **CONCLUSIONS:** The use of dynamic models is critical to account for the indirect effects of rotavirus vaccination via herd protection and thus for policymakers to understand the true effectiveness of a country-wide rotavirus vaccination programme.

PIN111

COSTS ASSOCIATED WITH COLD CHAIN USED TO STORE AND TRANSPORT THERMALLY UNSTABLE ANTIRETROVIRAL DRUGS

Omelyanovsky V[1], Fedyaeva VK[2]
[1]*The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia,* [2]*Fund for the Development of Social Policy and Health Care "Helios", Moscow, Russia*

OBJECTIVES: In Russia free access to high quality health care for patients with AIDS and HIV infections guaranteed by state. Some antiretroviral (ARV) pharmaceuticals need to be transported and stored in special cold chain conditions that significantly increase the burden on the state budget. Use of thermally stable formulation if available may be efficient due to fewer expenses for cold chain provision. To estimate the costs associated with the cold chain conditions in Russian health care. **METHODS:** We calculated the difference in costs associated with ARV drug lopinavir+ritonavir thermally stable and unstable form transporting and storage. Thermally unstable form requires cold chain conditions that drives the cost difference. Costs for additional equipment, electricity, staff salaries were estimated.We used prices and tariffs that were valid in 2011. Calculations were based on the assumption that all eligible registered HIV-infected patients in all regions of Russia receive lopinavir+ritonavir, the number of patients was extracted from state statistics for 2011with a forecast for 2012. **RESULTS:** The difference in annual total costs of shipping toregional centers and storage till the moment patient gets the drug between thermally unstable and thermally stable form is 820,000 Euro. **CONCLUSIONS:** Choice of thermally stable form of ARV drug lopinavir+ritonavir which do not require cold chain conditions of transportation and storage can reduce the economic costs associated with the treatment of HIV infection in Russian health care.

PIN112

RE-ESTABLISHING THE SOCIETAL VALUE OF PEDIATRIC COMBINATION VACCINES

Maman K[1], Zoellner YF[2], Greco D[3], Duru G[4], Sendyona S[1], Remy V[5]
[1]*Creativ-Ceutical, London, UK,* [2]*Hamburg University of Applied Sciences, Hamburg, Germany,* [3]*Centre for Science, Society and Citizenship, Roma, Italy,* [4]*Cyklad Group, Rillieux la Pape, France,* [5]*Sanofi Pasteur MSD, Lyon, France*

OBJECTIVES: Over the past decades, the number of vaccinations recommended for infants has increased significantly, in an effort pursuing wider protection against severe infectious diseases. In their first year, infants would typically get more than 50 injections. The use of combination vaccines provides one solution to the problem of high injection burden but may be undervalued due to the underestimation of vaccine-preventable diseases' seriousness and vaccination benefits. Our objective is to investigate the societal value of pediatric combination vaccines. **METHODS:** A literature search was performed using MEDLINE for relevant articles from 1990 to today, focusing on industrialized countries. A grey literature search on public health websites was used to complement the peer-reviewed literature. **RESULTS:** A total of 86 articles, of which 34 from the peer-reviewed literature, met the inclusion criteria and were analyzed. Many articles presented qualitative argumentation but no quantitative evidence. Public health benefits included improved compliance, timeliness and vaccination coverage thanks to reduced injections and better acceptability by parents. Economic benefits were linked to the improvement of daily practice efficiency through reduced administration burden (less visits, simplified record-keeping, handling, inventory management) and less administration-related errors such as the need for fewer syringes reducing risk of needle-stick injury. Combination vaccines could also enhance efficiency at health care system-level through reduced costs of transport, cold chain, storage and wastage. **CONCLUSIONS:** This review supports the broader value of pediatric combination vaccines which may plausibly generate time and money savings in the short and longer term, and enhance efficiency at both micro and macro levels in the health care system. Findings often stemmed from US settings, the portability to other industrialized countries being therefore plausible but subject to some uncertainty. While there is a paucity of quantitative data to support these arguments, they have significant economic implications and warrant further investigation in future economic evaluations of pediatric combination vaccines.

ADHERENCE INTERVENTIONS TO IMPROVE ADHERENCE TO ANTIRETROVIRAL THERAPY IN LOW INCOME SETTINGS: AN INDIVIDUAL PATIENT DATA NETWORK META-ANALYSIS

Mills EJ[1], Nachega J[2], Lester R[3], Thorlund K[4], Ioannidis J[1], Linnemayr S[5], Gross R[6], Calderone Y[7], Amico R[8], Thirumurthy H[9], Pearson C[10], Remien R[11], Mbuagbaw L[4], Thabane L[4], Chung M[10], Wilson I[12], Liu A[13], Uthman O[14], Ford N[15]

[1]*Stanford University, Stanford, CA, USA,* [2]*Stellenbosch University, Cape Town, South Africa,* [3]*University of British Columbia, Vancouver, BC, Canada,* [4]*McMaster University, Hamilton, ON, Canada,* [5]*RAND Corp, Los Angeles, CA, USA,* [6]*University of Pennsylvania, PA, USA,* [7]*Albert Einstein University, NYC, NY, USA,* [8]*University of Connecticut, CT, USA,* [9]*University of North Carolina, NC, USA,* [10]*University of Washington, Seattle, WA, USA,* [11]*Columbia University, NYC, NY, USA,* [12]*Brown University, Providence, RI, USA,* [13]*UCSF, San Francisco, CA, USA,* [14]*Warwick University, Warwick, UK,* [15]*World Health Organization, Geneva, Switzerland*

OBJECTIVES: To determine the comparative effectiveness of different interventions for improving antiretroviral medication adherence in low-income settings. **METHODS:** We obtained individual patient data from all randomized trials that have evaluated an adherence intervention to promote antiretroviral adherence within low-income countries. We created a treatment network of the differing interventions by pooling the individual patient data from comparable treatments and comparing them across the individual interventions using a Bayesian network meta-analysis approach. Outcomes included self-reported adherence and viral suppression. **RESULTS:** We obtained data on 11 randomized, involving 5432 patients. Interventions included daily and weekly text messaging, calendars, peer supporters, alarms, counseling, and basic clinical care. For self-reported adherence, we found compelling evidence for the role of weekly text messages (Odds ratio [OR] 1.57, 95% Confidence Intervals [CI] 1.22-2.02), counseling (OR 1.43, 95% CI, 1.06-1.94), and peer supporters (OR 1.72, 95% CI, 1.28-2.29). We found no compelling evidence for daily text messaging, alarms, calendars, or unsupported clinical care. Results were similar when using viral suppression as an outcome, although not all trials reported viral outcomes. Treatment supporters (OR 1.36, 95% CI, 1.02-1.82) and weekly text messages (OR, 1.56, 95% CI, 1.01-2.39) were superior to basic clinical care. **CONCLUSIONS:** Using individual patient data allowed us to increase precision to determine what interventions appear to work. Several common recommendations for improving adherence are unsupported by the available evidence. These findings should influence guidance documents on improving antiretroviral adherence in poor settings.

PIN114

HEALTH CARE RESOURCE UTILIZATION AND ADHERENCE TO ANTIRETROVIRAL TREATMENT (ART) BY HIV PATIENTS: AN ANALYSIS WITH THE QUEBEC (CANADA) PUBLIC DRUG PLAN DATABASE

Lachaine J[1], Baril JG[2], Lambert-Obry V[1], Beauchemin C[1]

[1]*University of Montreal, Montreal, QC, Canada,* [2]*Centre de Recherche du CHUM, Montreal, QC, Canada*

OBJECTIVES: Adherence to ART is a key success factor for achieving optimal clinical outcomes in HIV disease. The objective was to assess differences in compliance rates and health care resource utilization between patients receiving a once daily single tablet regimen (STR) vs. a multiple tablets per day regimen (MTR). **METHODS:** This retrospective study included patients covered by the Quebec provincial drug reimbursement program (RAMQ) who have received at least one script for an ART from January 1st, 2006 to June 30th, 2012. For each patient, the index date was defined as the date of the first script for an ART and compliance rates were estimated over a 1-year period. Patients were considered compliant if their medication possession ratio (effective treatment duration over expected treatment duration) was equal or greater to 90%. Medical costs (hospitalizations and ER, outpatient clinic, ICU and physician's visits) were compared between the STR group vs. the MTR group. Regression analyses were performed to assess the relationship between compliance, hospitalization rates and medical costs with the ART regimen, adjusting for age, gender, comorbidities scores, mental disorders diagnosis and drug and alcohol abuses. **RESULTS:** The study included 4,996 HIV patients (mean age: 42.4 years, 74.8% males). A higher proportion of patients were compliant (88.4% vs. 75.8%) in the STR group compared to the MTR group ($p<0.001$). Patients receiving a MTR were 2.0-fold more likely to be non-compliant than patients receiving a STR ($p<0.001$). Moreover, hospitalization rates (25.8% vs. 15.9%, $p<0.001$) and medical costs (CAD$2,785 vs. CAD$1,909, $p=0.008$) were higher for patients receiving a MTR than a STR. Linear regression analyses also showed a positive relationship between MTR (vs. STR) and hospitalization rates ($\beta=0.081$, $p=0.001$) and medical costs ($\beta=0.151$, $p<0.001$). **CONCLUSIONS:** Patients receiving a STR are more compliant than patients on a MTR and have lower hospitalization rates and medical costs.

PIN115

TOBRAMYCIN POWDER FOR INHALATION FOR THE TREATMENT OF CYSTIC FIBROSIS: ANALYSIS OF THE RAMQ DATA

Lachaine J[1], Lapierre ME[1], Beauchemin C[1], Balp MM[2], Calado F[2], Debonnett L[2], Desforges J[3], Sagkriotis A[2]

[1]*University of Montreal, Montreal, QC, Canada,* [2]*Novartis Pharma AG, Basel, Switzerland,* [3]*Novartis Pharmaceuticals Canada Inc, Dorval, QC, Canada*

OBJECTIVES: To describe treatment patterns and measure real-world outcomes with tobramycin powder for inhalation (TIP), tobramycin inhalation solution (TIS), and other tobramycin formulations (OTF), using the provincial public drug reimbursement program database of the *Régie de l'assurance maladie du Québec*(RAMQ). **METHODS:** Patients with a diagnosis of CF covered by the RAMQ drug reimbursement program who had used TIP, TIS, or OTF on at least one occasion during the period from January 1st 2011 to June 30th 2012 were selected. Patient's characteristics, drug utilization patterns and resource utilization were analyzed. **RESULTS:** Data were available for a sample of 244 eligible patients. The average age of the study population was 24.3 years (SD=12.5). While the maximum medication possession ratio (MPR) for alternate month administration is 50%, patients on TIP had an average MPR of 52.8%, while patients on TIS and OTF had an average MPR of 41.4% and 39.7%, respectively. Treatment persistence at 3 months was estimated at 85.5%, 69.0%, and 65.2% for patients on TIP, TIS, and OTF, respectively. Treatment persistence at 6 months was estimated at 78.4%, 62.8%, and 56.5%, respectively for patients on TIP, TIS, and OTF. Higher CF medication treatment costs with TIP were partially offset by lower costs associated with the use of antibiotics, other medications and additional health care resource utilization. The median monthly cost per patient in terms of other medications was of $1,159 (including $79 for other antibiotics), $1,350 ($172), and $1,495 ($240) for patients on TIP, TIS, and OTF, respectively. The median monthly additional health care resource utilization cost per patient was estimated at $56, $188, and $220, respectively for TIP, TIS and OTF cohorts. **CONCLUSIONS:** In a real life setting, TIP was associated with a high level of treatment adherence and limited utilization of additional health care resources.

PIN116

ADHERENCE TO ANTIRETROVIRAL THERAPY AMONG HIV-INFECTED PATIENTS ATTENDING TO A UNIVERSITY INFECTIOUS DISEASES CLINIC IN VENEZUELA

Bastardo YM[1], Castro JS[1], Suarez JA[1], Torres JR[1], Comegna M[2], Damas J[1]

[1]*Universidad Central de Venezuela, Caracas, Venezuela,* [2]*Central University of Venezuela, Caracas, Venezuela*

OBJECTIVES: To determine adherence levels and factors influencing adherence to antiretroviral therapy among HIV-infected patients in Venezuela. **METHODS:** A sample of 46 HIV-infected HIV patients attending an infectious diseases clinic at the Central University of Venezuela were interviewed by the investigators for 20 to 25 minutes. The interview was guided by a structured questionnaire that included questions on sociodemographic and clinical characteristics, medication use, and health behaviors. Adherence was assessed retrospectively based on a 4-day recall as used in Adult AIDS Clinical Trials Group (AACTG) follow up questionnaire. All data analyses were performed using SSPS for Windows Version 19.0. **RESULTS:** Of 46 participants, 30 (65.2%) were male and 16 (34.8%) were female. The mean age was 43.17 years (Range 26-73, SD= 9,790). From 46 participants 69.7% reported adherence $\geq$ 95%. Forgetting to take the medications, alcohol use, and problems with the medications supply were main barriers for adherence in the present study. **CONCLUSIONS:** A group of patients at this clinic reported unsatisfactory adherence. Forgetfulness was reported to be the major cause of non-adherence. Since adherence to antiretroviral therapy in critical to achieve optimal treatment outcomes, health care providers must identify possible barriers to adherence at the earliest and provide appropriate solutions.

PIN117

HEPATITIS C VIRUS INFECTION TREATMENT COMPLETION: AN ANALYSIS OF THE QUEBEC PROVINCIAL REIMBURSEMENT PROGRAM DATABASE

Lachaine J[1], Vachon ML[2], Lambert-Obry V[1], Beauchemin C[1]

[1]*University of Montreal, Montreal, QC, Canada,* [2]*CHUQ, Laval University, Quebec, QC, Canada*

OBJECTIVES: Hepatitis C virus (HCV) infection treatment completion is a key success factor for achieving optimal clinical outcomes. The objective of this study was to assess HCV treatment completion rates in a real life setting. **METHODS:** A retrospective study of the Quebec provincial drug reimbursement program (RAMQ) was conducted using a random sample of patients who filled at least one script at the pharmacy for an HCV medication (pegylated interferon and ribavirin (peg-Riba) +/- boceprevir or telaprevir) from January 2007 to December 2012. Treatment completion rates were calculated at week 12, 24 and 28 according to HCV medication type in order to assess the proportion of patients treated beyond the 12-week futility threshold and the minimal expected treatment duration of 24 weeks (28 weeks for Peg-Riba + boceprevir). **RESULTS:** A total of 1,081 patients who used at least one HCV medication were included in the study. The average age was 46.4 years (SD=10.7) and the proportion of men was higher (64.8%). During the study period, the number of patients who used Peg-Riba only, Peg-Riba + boceprevir and Peg-Riba + telaprevir was 1,029 (95.2%), 50 (4.6%) and 18 (1.7%) respectively. The proportion of patients on Peg-Riba only who completed at least 12 and 24 weeks of treatment was 89.7% and 62.2% respectively. There were 96.0% and 58.0% of patients on Peg-Riba + boceprevir who remained on treatment at week 12 and 28 respectively. The percentage of patients on Peg-Riba + telaprevir on treatment at week 12 and 24 was 50.0% and 11.1%, respectively. **CONCLUSIONS:** The proportion of HCV patients who were still on treatment decreased with time with high discontinuation rates especially after week 12. Treatment completion was not achieved by a significant proportion of patients, regardless of HCV medications.

PIN118

PATIENT SATISFACTION WITH HIV THERAPIES: FOCUS ON ADHERENCE TO TREATMENT

Murray M[1], Dang N[2], Swinburn P[3], Gallop K[3], Lloyd A[3]

[1]*GSK, Brentford, UK,* [2]*ViiV Healthcare, Singapore, Singapore,* [3]*Oxford Outcomes, An ICON plc Company, Oxford, UK*

OBJECTIVES: Over the course of last decade the introduction of highly effective antiretroviral (ARV) therapies has transformed a once life-threatening disease into a chronic condition. However, maintaining patient adherence to therapy, in the long-term, is challenging. Despite the enormous benefits offered by current ARVs, evidence suggests that adherence to treatment regimens remains an issue. Numerous factors have been identified which compromise long-term adherence, including drug-drug interactions, therapy regimen, side-effects, and the overall demands of therapy. The aim of this study is to further understanding of the determinants of treatment satisfaction for HIV patients receiving ARV therapies. **METHODS:** A programme of research was developed in order to firstly establish the relationship between patients' views of their current therapies and the adherence to ARVs.

The initial step involved undertaking a review of published literature detailing HIV patients' experiences of receiving ARV therapy. These findings formed the basis of a meeting of leading European HIV clinical experts, prominent HIV organisation representatives and patients themselves. **RESULTS:** The literature revealed numerous factors such as convenience, tolerability, relationship with physician and disease characteristics which influences patients' satisfaction with treatment. Discussion between the clinicians, representative from patient organisations emphasised the importance of patient preferences as they relate to adherence with HIV therapy. This additional insight emphasised the under-recognised role played by individual differences and therapeutic knowledge in defining attitudes to treatments. **CONCLUSIONS:** Treatment satisfaction is a complex issue. The work undertaken so far has highlighted that despite the advances in ARVs there are still concerns for PLWH. The next stage of research involves undertaking a series of in-depth qualitative interviews with patients across Europe and examining attributes of HIV treatment using the discrete choice experiment methodology.

PIN119

PARENTAL PREFERENCES FOR ROTAVIRUS VACCINATION AND POTENTIAL VACCINATION COVERAGEIN YOUNG CHILDREN: A DISCRETE CHOICE EXPERIMENT

Veldwijk J[1], Lambooij MS[2], Bruijning-Verhagen PCJ[3], Smit HA[3], de Wit GA[4]
[1]*National institute for public health and the environment, Bilthoven, The Netherlands,* [2]*National Institute of Public Health and the Environment, Bilthoven, The Netherlands,* [3]*University Medical Center Utrecht, Utrecht, The Netherlands,* [4]*National Institute for Public Health and the Environment, Bilthoven, The Netherlands*

OBJECTIVES: To determine parental preferences concerning rotavirus vaccination for their newborn baby, and to calculate the potential vaccination coverage for different vaccine scenarios. **METHODS:** A Discrete Choice Experiment (DCE) questionnaire was sent to the parents of 1,250 newborns aged 6 weeks in The Netherlands. The DCE included nine D-efficient designed choice tasks. Panel-mixed-logit models were used to estimate the relative importance of the five included rotavirus vaccine attributes; vaccine effectiveness, frequency of severe side effects, protection duration, location of vaccine administration, out-of-pocket costs. The potential uptake or vaccine coverage was calculated for different vaccine scenarios. **RESULTS:** All attributes showed a significant estimate (P<.05). Parents were more likely to get their newborn vaccinated if the vaccine effectiveness increased, parents preferred a frequency of 1 in 1,000,000 children that suffer from severe side effects over a frequency of 1 in 10,000. Protection duration of 3 years was preferred over 1 year and parents preferred to get their child vaccinated at the GP's office. Finally, increasing out-of-pocket costs were associated with decreased willingness to vaccinate. With respect to the relative importance of these attributes, vaccine effectiveness was most decisive for parents, followed by out-of-pocket costs, protection duration and frequency of severe side effects. Vaccination coverage rates ranged between 22.8% for the least preferred vaccine scenario and 87.5% for the most preferred scenario. **CONCLUSIONS:** When deciding whether to vaccinate their newborn baby against the rotavirus, parents are mostly driven by the effectiveness of the vaccine, the out-of-pocket costs, protection duration and the frequency of severe side effects. Differences in vaccine scenarios resulted in a large range in expected vaccination coverage. Therefore, the context and content of the implementation strategy of the vaccination is expected to strongly affect the vaccination coverage. Specifically requesting an out-of-pocket payment of parents should be considered carefully if a high vaccine coverage is desired.

PIN120

PATIENTS WITH CHRONIC HEPATITIS C VIRUS TREATED WITH SIMEPREVIR ADDED TO PEGINTERFERON AND RIBAVIRIN EXPERIENCED LESS TIME WITH FATIGUE, DEPRESSIVE SYMPTOMS, AND FUNCTIONAL LIMITATIONS: RESULTS FROM PATIENTS IN THE QUEST-1, QUEST-2, AND PROMISE STUDIES

Scott J[1], Gilles L[2], Fu M[3], Brohan E[4], Amatya R[4], Jessner W[2], Beumont-Mauviel M[5]
[1]*Janssen Global Services, LLC, High Wycombe, UK,* [2]*Janssen Research and Development, Beerse, Belgium,* [3]*Janssen Research and Development, Spring House, PA, USA,* [4]*Adelphi Values Ltd., Manchester, UK,* [5]*Janssen Infectious Diseases, Beerse, Belgium*

OBJECTIVES: To examine the value of adding simeprevir (SMV) to peginterferon and ribavirin (PR) for treatment of chronic hepatitis C virus infection using patient-reported outcomes (PRO) and their concordance with virology endpoints and adverse events (AEs). **METHODS:** Patients rated severity of fatigue (FSS), depressive symptoms (CES-D), and impairment in functioning (WPAI:HepC Productivity, Activity, Absenteeism) at baseline and throughout treatment/follow-up in three randomized, double-blind trials comparing addition of SMV or Placebo (PBO) during initial 12 weeks of PR treatment. PR was administered for 48 weeks (PBO group) and either 24 or 48 weeks (SMV group) (response-guided therapy [RGT]). Analysis of pooled data from the trials using a piecewise-linear mixed model compared the area-under-the-curve from baseline to Wk60 (AUC_{60}) between SMV/PR and PBO/PR for each PRO score. Subgroup analyses evaluated impact of Sustained Virologic Response 12 weeks post-treatment (SVR12), fibrosis level, and RGT on PRO scores. **RESULTS:** Of 1178 patients studied, analyses included 768 SMV/PR- and 393 PBO/PR-treated patients. 87.5% of the SMV/PR group met RGT and completed treatment in 24 weeks. Fatigue and anaemia AEs were comparable in both groups but FSS scores show clinically important increases in fatigue, lasting 6.9 weeks longer with PBO/PR ($p < 0.001$). No significant differences were observed for Absenteeism. Mean scores for all other PRO endpoints worsened from baseline to Wk4 in both groups and remained impaired to Wk24 (SMV/PR) and Wk48 (PBO/PR), resulting in significantly lower $AUC_{60}$and fewer weeks with clinically important worsening scores with SMV/PR. PRO scores indicated better outcomes for patients who met RGT criteria or achieved SVR12; differences in PRO scores associated with fibrosis level were only observed in the PBO/PR group. **CONCLUSIONS:** Greater efficacy of SMV/PR enabled reduced treatment duration and less time with PR-related side effects without adding to the severity of side-effects during treatment.

PIN121

PAPER-BASED AND ELECTRONIC ASSESSMENT OF HEALTH-RELATED QUALITY OF LIFE SPECIFIC TO HIV DISEASE: A RELIABILITY STUDY WITH THE PROQOL-HIV QUESTIONNAIRE

Lalanne C[1], Herrmann S[2], Armstrong AR[3], Cheung-Lung C[3], Schwartz Y[4], Chassany O[5], Duracinsky M[6]
[1]*AP-HP, Paris, France,* [2]*Murdoch University, Perth, Western Australi, Australia,* [3]*Assistance Publique-Hopitaux de Paris, Paris, France,* [4]*Inria Saclay-Ile de France, Gif sur Yvette, France,* [5]*University Paris 7, Paris, France,* [6]*Hospital Kremlin Bicetre, Paris, Ile de France, France*

OBJECTIVES: Electronic Patient Reported Outcomes (PRO) provide quick and reliable assessment of patients' health-related quality of life (HRQL). An electronic version of the PROQOL-HIV questionnaire was developed, and its face validity and reliability were assessed using standard psychometric methods. **METHODS:** A total of 70 French outpatients (63% males, mean age 47 years) were recruited. Hard copy and electronic questionnaires were completed in a randomized cross-over design (2-7 day interval). Biomedical data were collected. Questionnaire version and order effects were tested on full scale scores in a two-way ANOVA with patients as random effects. Test-retest reliability was evaluated using Pearson and intra-class correlation coefficients (with 95% confidence interval) for each dimension. Usability testing was carried out from patients' survey reports, specifically: general satisfaction, ease of completion, quality and clarity of user interface (UI) and self motivation for electronic measuring to monitor HRQL in clinical follow-up. **RESULTS:** Questionnaire version and administration order effects (N=58 complete cases) were not significant at the 5% level, nor interacting together (p=0.940). Reliability indices were acceptable, with Pearson correlations above 0.7 and intra-class correlations ranging from 0.696 to 0.926, and scores were not statistically different between the two versions. On 77% of complete surveys, 57% of patients reported being satisfied and interested in electronic assessment of their HRQL in clinical follow up. Individual ratings of PROQOL-HIV user interface (85-100% of positive responses) confirmed UI clarity and usability. **CONCLUSIONS:** The electronic PROQOL-HIV introduces minor modifications compared to the original paper-based version, following ISPOR ePRO Task Force guidelines, and it showed good reliability and face validity. Patients can complete the computerized PROQOL-HIV questionnaire as intended and scores delivered from paper or electronic version share comparable accuracy and interpretation.

PIN122

ATTITUDE OF PARENTS TOWARDS OBLIGATORY AND RECOMMENDED CHILDHOOD VACCINATION

Lehocká L, Malovecká I, Minariková D, Foltan V
Comenius University, Bratislava, Slovak Republic

OBJECTIVES: The immunization is currently one of the most discussed topics in the population and the number of its opponents is increasing. **METHODS:** Opinion, awareness and knowledge of parents (n-parents=240, n-children=463) about childhood immunization through self-reported technique of a questionnaire survey was conducted, with respect of gender, age, education and profession of parents in regard of their professional connection with health care in case of obligatory and recommended childhood vaccination. **RESULTS:** In case of obligatory childhood vaccination all evaluated parameters influence and change opinion, awareness and knowledge of parents. Age ($p<0,01$, Degree of freedom (df)=10, Chi-squared distribution (χ^2)=81,08, table value of Chi-squared distribution ($t\chi^2$)=23,21); gender ($p<0,01$, df=2, χ^2=12,87, $t\chi^2$=9,21); education ($p<0,01$, df=10, χ^2=79,11, $t\chi^2$=23,21); health care profession ($p<0,01$, df=2, χ^2=13,75, $t\chi^2$=9,21. In case of recommended childhood vaccination all analyzed parameters influence and change parents' opinion, awareness and knowledge, except for those working in health care. Age ($p<0,01$, df=5, χ^2=13,29, $t\chi^2$=15,09); gender ($p<0,01$, df=, χ^2=79,82, $t\chi^2$=13,28); education ($p<0,01$, df=4, χ^2=49,10, $t\chi^2$=13,28); health care profession ($0,01<p<0,03$, df=1, χ^2=4,85, $t\chi^2$=6,64). **CONCLUSIONS:** Analysis confirms that age, gender, education and profession connected with health care influence and change parents' opinion, awareness and knowledge about obligatory childhood vaccination. Regarding the recommended childhood vaccination, age, gender and education influence and change parents' opinion, awareness and knowledge, although a profession connected with health care neither influences, nor changes opinion, awareness and knowledge of the parents.

PIN123

MINIMAL IMPORTANT DIFFERENCE (MID) OF RESPONSE TO THE HEPATITIS-C VIRUS PATIENT REPORTED OUTCOMES (HCV-PRO) INSTRUMENT IN A TRIAL OF PEGYLATED INTERFERON/RIBAVIRIN (PEGIFN/RBV) AND DIRECT-ACTING-ANTIVIRALS (DAA)

Baran RW[1], Anderson RT[2], Dietz B[3], Gooch K[1]
[1]*AbbVie, North Chicago, IL, USA,* [2]*Penn State Medical College, Hershey, PA, USA,* [3]*AbbVie GmbH & Co. KG, Ludwigshafen, Germany*

OBJECTIVES: Both chronic HCV infection and current treatments negatively impact patient reported outcomes. PegIFN/RBV-based therapies decrease general HRQoL scores 10%-30% (on SF-36). Psychometric analyses of validity, responsiveness, and MID for the HCV-specific HCV-PRO instrument were performed. **METHODS:** Responses to the HCV-PRO (presented ILC2012), the SF-36, and EuroQol-5D (EQ-5D)+VAS were analyzed in the M11-602 trial of pegIFN/RBV with placebo (n=11) or DAA: ABT-450/ ritonavir (n=24), ABT-072 (n=23), or ABT-333 (n=16). DAAs were administered for 12 weeks, pegIFN/RBV for 48 weeks. PRO instruments were administered at baseline, week 8, end of DAA treatment (EODT), end of pegIFN/RBV treatment (EOT), and posttreatment week 24 (PT24). Convergent validity of HCV-PRO total score (range 0-100) was assessed through correlation (Pearson's) to SF-36 MCS/PCS and EQ-5D VAS scores. Discriminant validity was assessed by dichotomizing HCV-PRO responses on EQ-5D Anxiety/Depression dimension severity (none vs. some) and treatment emergent depression/fatigue adverse events (MedDRA terms). Responsiveness was assessed through analyses of effect size (ES). MID was assessed by standard error of the mean (SEM) and

Receiver Operating Characteristics (ROC) curves correlating HCV-PRO score to MID anchors on SF–36 MCS/PCS and EQ-5D VAS. **RESULTS:** Demographics (N=74): 22% female, 81% white, 51% >50 years of age, 74% Genotype 1a, 69% IL28B non-CC status. Convergent validity: HCV-PRO total score correlations with SF-36 MCS/PCS and EQ-5D VAS scores were 0.64-0.93 (all time points). Discriminant validity: HCV-PRO scores decreased 10-30 points more in subjects impaired by anxiety/depression (EQ-5D) or experiencing depression/fatigue events. ES showed an increasing impact during treatment (-0.66, week 8; -0.76, EODT; –0.93, EOT). At PT24, ES returned to -0.10. SEM and ROC analyses suggested an HCV-PRO MID approximating -10 points. **CONCLUSIONS:** The HCV-PRO is a valid, responsive, disease-specific instrument. In this study, an MID of approximately -10 points was identified. The HCV-PRO may enhance understanding of how HCV treatment impacts function/wellbeing.

PIN124

AN ASSESSMENT OF UNEMPLOYMENT AMONG PEOPLE LIVING WITH HIV/AIDS IN CANADA AND EUROPE

Cline SK[1], Wang S[1], Van Wyk J[2], Baran RW[1], Gooch KL[1]
[1]*AbbVie, North Chicago, IL, USA,* [2]*AbbVie, Maidenhead, UK*

OBJECTIVES: Neurocognitive impairment (NCI), depression, and duration of unemployment have been reported as barriers to obtaining employment among people living with HIV/AIDS (PLWHA) in the US. However, upon return to work, improvements in depression and health-related quality of life (HRQoL) have been observed. The objectives of this study were to examine the burden of unemployment among PLWHA in Canada and Europe by 1.) estimating the number of PLWHA who are unemployed and their duration of unemployment, and (2) determining patient characteristics associated with being unemployed, including NCI, depression, and HRQoL. **METHODS:** Data was derived from CRANIum (sCReen for Anxiety, depression, and Neurocognitive Impairment in HIV+ patients), a multicenter, cross-sectional study of PLWHA in 14 European countries and Canada between 2010 and 2011. Depression was assessed using the Hospital Anxiety and Depression Scale. NCI was assessed using the Brief Neurocognitive Screen, which consists of the Digit Symbol (DS) test and Trail Making tests A and B. HRQoL was assessed using the Medical Outcomes Study HIV Health Survey (MOS-HIV). Logistic regression was utilized in order to determine if these variables, in addition to demographic and clinical variables, were associated with unemployment. **RESULTS:** A total of 2754 PLWHA (mean age = 43; 62% male) were included in these analyses; 960 (35%) were unemployed. Regarding the unemployed, 110 (11%) had been unemployed for < 6 months, 99 (10%) for 6 to 12 months, and 737 (77%) for > 12 months. Logistic regression analyses indicated that NCI, lower scores on the MOS-HIV physical health subscale, previous psychiatric diagnoses, lesser education, Hepatitis B and/or C co-infection, older age and female gender were independently associated with unemployment. Current depression was not associated with unemployment. **CONCLUSIONS:** In tandem with previous reports, results from this multinational study suggest that NCI and HRQoL are salient issues with regards to employment among PLWHA internationally.

PIN125

VALIDATION AND PSYCHOMETRIC EVALUATION OF THE GERMAN-TRANSLATED HEPATITIS C VIRUS PATIENT REPORTED OUTCOMES (HCV-PRO) HEALTH AND WELLBEING INSTRUMENT IN GERMAN HCV-INFECTED PATIENTS TREATED WITH DIRECT ACTING ANTIVIRALS (DAAS) WITH OR WITHOUT RIBAVIRIN (RBV)

Anderson RT[1], Baran RW[2], Xie W[3], Liu Y[2], Dietz B[4], Gooch KL[2]
[1]*Penn State Medical College, Hershey, PA, USA,* [2]*AbbVie, North Chicago, IL, USA,* [3]*AbbVie, Inc., North Chicago, IL, USA,* [4]*AbbVie GmbH & Co. KG, Ludwigshafen, Germany*

OBJECTIVES: Chronic HCV infection and interferon-based treatments negatively impact PROs. The HCV-PRO is a validated disease-specific PRO instrument for patients with HCV. The purpose of this analysis was to ascertain the psychometric properties of the German-translated HCV-PRO. **METHODS:** Responses from German subjects to the HCV-PRO, SF-36v.2, and EQ-5D 5L+VAS were analyzed from the multinational AVIATOR trial of interferon-free oral DAA therapy in Genotype 1 patients. HCV-PRO was translated under Harmonization standards. Approved German-language validated versions of the SF-36 and EQ-5D were included for psychometric comparison. Internal consistency/reliability of HCV-PRO items and total score (range 0–100) were evaluated using Chronbach's alpha. Convergent validity of HCV-PRO total score was assessed through Pearson's correlation to SF-36 MCS/PCS and EQ-5D VAS scores (0.5–0.9 = moderate–strong). Discriminant validity was assessed by dichotomizing HCV-PRO total score on EQ-5D Anxiety/Depression and Pain/Discomfort dimensions by severity (none vs. some). Response range of HCV-PRO total score was examined. Analyses were performed at Baseline, week 8 (Wk8), End of Treatment (EOT), and 24 week follow-up (PTW24). **RESULTS:** Demographics (N=39): 46% female, 97% white, 46% ≥50 years of age, 36% Genotype 1a, 87% IL28B non-CC status. Clinical response was 92.3% of German patients achieving SVR24. Mean HCV-PRO, SF-36 MCS/PCS, and EQ-5D VAS scores were minimally changed during treatment (Wk8, EOT). Cronbach's alpha for HCV-PRO items and total scores over time were 0.92–0.96. HCV-PRO total score exhibited moderate-to-high correlation with SF-36 MCS/PCS and EQ-5D VAS total scores at each time period (r=0.42–0.85), with highest correlation with SF-36 MCS. HCV-PRO mean scores were lower in subjects with anxiety/depression or pain/discomfort vs. none (p<0.01). Mean HCV-PRO score at PTW24 was improved (p=0.038) over baseline. Baseline HCV-PRO floor (0%) and ceiling (10%) scores were acceptable. **CONCLUSIONS:** The German-translated HCV-PRO is a valid, responsive, disease-specific instrument for German-speaking HCV-infected people.

PIN126

REVISED SCORING OF THE WPAI:HEP C IMPROVES ASSESSMENT OF MISSED WORK AND WORK IMPAIRMENT IN HCV CLINICAL TRIALS

Gilles L[1], Peeters M[2], Beumont-Mauviel M[2], Scott J[3]
[1]*Janssen Research and Development, Beerse, Belgium,* [2]*Janssen Infectious Diseases, Beerse, Belgium,* [3]*Janssen Global Services, LLC, High Wycombe, UK*

OBJECTIVES: Trials comparing addition of simeprevir (SMV) or placebo to peginterferon/ribavirin for treatment of chronic hepatitis C virus (HCV) infection found that all patient-reported outcome (PRO) measures except Absenteeism scores from the Work Productivity and Activity Impairment questionnaire for Hepatitis C (WPAI:HepC) showed similar patterns over time and significantly better outcomes for the SMV groups. Absenteeism scores using recommended scoring were available only if a patient was in the workforce at baseline and subsequent study visits. To appreciate movement into and/or out of the workforce in HCV trials, we propose two alternative scores for the WPAI:HepC: Missed Work and Work Impairment. **METHODS:** A total of 711 subjects completed the WPAI:HepC in the QUEST1 and QUEST2 SMV trials during study visits at baseline and throughout treatment and follow-up. The WPAI:HepC assesses whether subjects were in the workforce during the past 7 days; and if so, number of hours missed from work due to HCV or its treatment/number of hours scheduled to work (Absenteeism); and how much productivity was impaired when working (Productivity Impairment). Revised scoring produced Missed Work scores (% hours not working in past week) and Work Impairment (Missed Work x Productivity Impairment) for all subjects at each study visit by setting scores for subjects not in the workforce to 100 (range 0 to 100% Missed Work or Work Impairment). **RESULTS:** WPAI Missed Work score results showed modest differences between treatments but Work Impairment scores were significantly better for the SMV group with a pattern over time consistent with other PRO endpoints in the trials (p=0.034). **CONCLUSIONS:** Methods for evaluating impact of HCV treatment on work life in clinical trials need to provide data for all subjects in order to capture work force participation and productivity when working. Revised scoring of the WPAI:HepC enable more accurate comparison of treatment in clinical trials.

INFECTION – Health Care Use & Policy Studies

PIN127

ASSESSING THE FISCAL CONSEQUENCES OF IMMUNIZING THE FEMALE AND MALE POPULATION AGAINST HUMAN PAPILLOMAVIRUS (HPV) IN GERMANY

Kotsopoulos N[1], Connolly M[1], Remy V[2]
[1]*Unit of PharmacoEpidemiology & PharmacoEconomics, Groningen, The Netherlands,* [2]*Sanofi Pasteur MSD, Lyon, France*

OBJECTIVES: It is well recognized that HPV infection causes a substantial burden in females. The infection also causes a substantial burden in males as it is associated with HPV-related cancers. Traditional economic evaluations focus only on quantifying cost-effectiveness, however, it is increasingly recognized that immunizations may generate broader benefits not captured in cost-effectiveness analysis. This research aimed at developing a government-perspective health investment model to estimate the fiscal impact of immunizing males and females with the quadrivalent HPV vaccine in Germany. **METHODS:** Methodologies from generational accounting, human capital and health economics were combined to estimate the fiscal benefits of HPV immunization. Cohort models were developed simulating the medical costs and average lifetime fiscal transfers between the government and cohorts of 13-year-old immunized and non-immunized individuals. To estimate tax revenue attributed to immunization-related changes in morbidity and mortality, direct and indirect tax rates were linked to differences in age- and gender-specific earnings. **RESULTS:** The lifetime discounted gross tax for the immunized male and female cohorts (n=400,000 each) were €208.7 billion and €130.4 billion, respectively. Over the lifetime of the female and male birth-cohorts, it was estimated that immunization with the quadrivalent HPV vaccine would result in the prevention of 986 female and 296 male HPV-related deaths. Compared to the non-immunized cohorts of 13-year old males and females, the immunized cohorts resulted in higher total net discounted tax by €106.1 million and higher total gross discounted tax by €80.4 million. **CONCLUSIONS:** The combined vaccination of males and females in Germany results in positive lifetime net and gross discounted tax revenues for the government. The vaccination of males and females with the quadrivalent HPV vaccine is likely to have positive effects on public finances and economic growth over subsequent generations.

PIN128

DYNAMIC NETWORK MODEL OF CLOSTRIDIUM DIFFICILE INFECTION TO EVALUATE TREATMENT INTERVENTIONS AND COSTS

Zowall H, Brewer C, Deutsch A
Zowall Consulting Inc., Westmount, QC, Canada

OBJECTIVES: To date, efforts to model Clostridium difficile infection (CDI) have been limited. Most models do not address the contribution of asymptomatic carriers as sources of new infections and are restricted to hospital acquired CDI. We aim to develop a simulation model to systematically examine the dynamic relationship between three major subpopulations of CDI transmission: hospitals, communities, and long-term facilities, to evaluate treatment effectiveness and costs. **METHODS:** We conducted a systematic investigation to determine the key epidemiological factors influencing CDI transmission according to the three major subpopulations: hospitals, communities, and long-term care facilities. We have developed a stochastic agent-tracking meta-population network model of CDI transmission, and identified parameters that would capture transmission from symptomatic and asymptomatic carriers to uninfected individuals among the subpopulations. **RESULTS:** We identified eight infection states: susceptible, gastrointestinal exposure, colonized, diseased, deceased, clinically resolved colonized, relapse of CDI, and cleared. Key parameters include; health outcomes of target populations, time horizon, diagnostic characteristics, treatment effectiveness, transmission rates, susceptibility rates, recurrence rates, and costs. Initial treatments of CDI do not induce a lasting response in 15%-25% of patients. The estimated effectiveness of antibiotic therapy for a first recurrence is 60% and declining with multiple recurrences. Major predictors of recurrences were advanced age and duration of initial hospitalizations. Recurrences of CDI were associated with major increases in hospital LOS and costs. **CONCLUSIONS:** Our dynamic network model of CDI transmission will improve the capacity to project and to quantify the impact of a CDI outbreak in terms of clinical burden and costs.

PIN129

CONSIDERING ECONOMIC ANALYSES IN THE REVISION OF THE PREVENTIVE VACCINATION LAW: A NEW DIRECTION FOR HEALTH POLICY-MAKING IN JAPAN?

Akazawa M[1], Yongue J[2], Ikeda S[3], Satoh T[4]
[1]Meiji Pharmaceutical University, Tokyo, Japan, [2]Hosei University, Tokyo, Japan, [3]International University of Health and Welfare, Otawara City, Tochigi, Japan, [4]Aoyama Gakuin University, Tokyo, Japan

OBJECTIVES: Evidence of a significant vaccine policy shift can be witnessed not only in the number of new vaccines available in Japan but also in the way vaccine policy is being formulated. In 2010, policy makers decided for the first time ever to commission economic analyses as a reference in their consideration of subsidy allocation. This research offers a firsthand account of the recent changes in vaccine policies by examining the decision-making process from the perspective of researchers for economic evaluations. **METHODS:** In order to understand the vaccine policy-making process, we analyzed all the documents that were distributed and discussed during the government committee meetings starting from February 2010 when the revision of the Preventive Vaccination Law was initially proposed to May 2012 when the final recommendations were made. We then created a time-series table to summarize the main issues of the discussions and final conclusions from official reports and other relevant information recorded in the minutes. **RESULTS:** Economic evaluations were conducted for seven vaccines under consideration for the routine immunization program (Hib, PCV for children and adults, HPV, varicella, mumps, hepatitis B). The findings suggested most of them were cost-effective options. However, for the Hib vaccine, the expected savings was less than the additional costs required (23.8 billion yen increased), and for the hepatitis B vaccine, the incremental cost-effectiveness ratio was far beyond the acceptable range (18.3 million yen per QALY). Nevertheless, all the vaccines were equally recommended for inclusion in the routine immunization program. **CONCLUSIONS:** The findings included reasons why policy makers decided to commission economic evidence in the first place, the importance of external influences, the choice of evaluation methods, the extent to which policy makers actually incorporated the economic evidence into new vaccine policies, and the implications of using cost-effectiveness analyses on the future of Japanese health policy-making.

HEPATITIS A VACCINE POLICY PROCESS IN 6 COUNTRIES – FACTORS INFLUENCING POTENTIAL ADOPTION

Foley K[1], Ozawa S[2], Nanni A[3], Durden E[4], Maiese BA[1], Nwankwo C[5], Brodovicz K[6], Acosta CJ[7], Privor-Dumm L[8]
[1]Truven Health Analytics, Cambridge, MA, USA, [2]Johns Hopkins University, Baltimore, MD, USA, [3]Aeras, Rovkville, MD, USA, [4]Truven Health, Austin, TX, USA, [5]Merck & Co., Whitehouse Station, NJ, USA, [6]Merck & Co., North Wales, PA, USA, [7]Hospital Privado de la Comunidad, Mar del Plata, Argentina, [8]Johns Hopkins University, Baltimore, MD, USA

OBJECTIVES: Until recently, there has not been a global focus on getting hepatitis A vaccines on country policy agendas. Using a vaccine policy adoption framework, we sought to identify drivers and barriers of hepatitis A vaccine adoption in six countries. **METHODS:** We applied a four-part framework to identify the public vaccine adoption process and drivers and barriers for hepatitis A vaccine adoption: 1) evidence in support of hepatitis A vaccine adoption; 2) existence of supportive policies; 3) political priority of hepatitis A within the country; and 4) whether or not the stakeholders were empowered and willing to act. Data were collected using a qualitative policy survey and a systematic literature review in Chile, India, Mexico, Russia, South Korea, and Taiwan between November 2011 and June 2012. **RESULTS:** Because hepatitis A is more of a concern during periods of economic transition for most countries, and because it is often perceived as a non-serious illness, countries struggle to align all of the factors necessary for adoption. Even where solid data exist, political support is often waning due to apparent transition to low endemicity for hepatitis A and a reduced threat. Where data are lacking, other vaccines take priority. Where economic studies exist, narrow perspectives fail to capture the broader threat of the disease to regional or country economies. Hepatitis A vaccination policy is further complicated by the fact that as countries transition to lower endemicity, the major threat is in older age groups. This trend leads to a subtle shift in stakeholders from the pediatric vaccine community to those more focused on the adult health community. **CONCLUSIONS:** Although the vaccine adoption process is the same for hepatitis A as for other pediatric vaccines, this study suggests that drivers of hepatitis A vaccine adoption may come from sectors outside the traditional pediatric vaccine community.

PIN131

BARRIERS UNDERLYING LIMITED UTILISATION OF VACCINES THROUGHOUT LIFE (LIFESPAN IMMUNISATION)

Ghosh S[1], Tangari M[1], Baron-Papillon F[2], Sauty E[3], Rodriguez de Azero M[4], Adel Ali K[4]
[1]GfK Bridgehead, London, UK, [2]Sanofi Pasteur MSD, Lyon, France, [3]Merck Vaccines, Courbevoie Cedex, France, [4]Vaccines Europe, European Federation of Pharmaceutical Industries and Associations, Brussels, Belgium

OBJECTIVES: Vaccination constitutes a standard element of public health preventative programmes worldwide; however, majority tend to concentrate on early stages of life, limiting opportunity for other population groups (adolescents, adults and elderly) to fully benefit. The goal of this study was to uncover barriers underpinning limited and inconsistent utilisation of vaccination at all stages of life (lifespan immunisation). **METHODS:** Current access to vaccination was evaluated using publically available government websites in five market archetypes based on purchase and delivery mechanisms. A web-based survey and subsequent in-depth interviews were conducted with 22 country- and European-level vaccine stakeholders to identify perceived barriers. **RESULTS:** Key barriers: constrained finance and competing health care priorities; policy decisions undertaken at disease level; national immunisation programme (NIP) recommendations based on age and risk; poor influence on policy by public health practitioners and lack of vaccination advocacy groups; constrained finances to implement effective immunisation programmes at local level; inadequate data collection and follow-up process at later stages of life; poor awareness of immunisation schedule by health care practitioners (HCPs); lack of structural and operational policies to promote and deliver vaccination at later stages of life; infrequent interactions with the health care system during adult-hood; limited and inconsistent information dissemination by HCPs and government; negative messages on vaccination through media; complacent public attitude towards the risk posed by vaccine preventable diseases. **CONCLUSIONS:** Three main domains of barriers exist: low institutional facilitation to recommend lifespan immunisation as part of NIP; inadequate mechanisms at regional and local level to facilitate citizen access to immunisation / vaccination; low patient demand for immunisation at older stages of life. To overcome these barriers a broad-ranging approach based on awareness is required, which includes providing comprehensive pharmacoeconomic evidence to policy makers and payers, developing information tracking systems that enable follow up, and HCP education to facilitate information dissemination.

PIN132

ECONOMICAL JUSTIFICATION OF THE INNOVATION METHOD OF LABORATORY DIAGNOSTIC OF THE STRUCTURAL AND FUNCTIONAL CHANGES OF SERUM ALBUMIN IN SEPTIC COMPLICATIONS (ATA-TEST)

Vorobiev P[1], Bezmelnitsyna L[1], Krasnova L[1], Muravsky V[2], Davidova T[3], Sytov A[3]
[1]Russian Society for Pharmacoeconomics and Outcomes Research, Moscow, Russia, [2]Albutran, Minsk, Russia, [3]Russian Research Center of Oncology named after N.N. Blochin, Moscow, Russia

OBJECTIVES: The topicality of septic complications (SC) in early period after surgery reminds very high despite the antibiotic prophylaxis. The prediction of SC can be provided by ATA-test (DTE index) by the registration the structural and functional changes of serum albumin. **METHODS:** Prospective observational controlled study of typical practice for cancer patients. Inclusion criteria: cancer patients; age – over 18 years; major operations. Exclusion criteria: inflammation diseases during 3 months before surgery; extended operations on pancreas, liver and bile ducts; renal and/or hepatic failure. ATA-test was made ones a day during 7 days in patients without SC, 14 days – with SC. Data about direct medical costs was collected via medical charts. Analysis was performed with methods of descriptive statistic, parametric and non-parametric criteria. **RESULTS:** Data on 104 patients were obtained: 11 had SC. Ratio (male:female) was 1:1,4. Average age – 61.2±12.5 years. Average level DTE in first 2 hours after surgery in patients with SC was 15.4±7.2%, without SC -31.8±14%, in case SC it didn't increase till normal meanings (40-175%) during 7 days. Direct medical cost of patient with SC – 8838$: 5352$ - cost for medicines, 1949$- hospitalization during 36.5 days (7.5 days in ICU), 1537$-medical services; without SC – 2992$: 534$-medicines, 1309$-hospitalization during 30 days (3 days in ICU), 1149$-medical services. **CONCLUSIONS:** SC can be predicted by ATA-test (DTE index) in first hours after surgery. It provides economy in 10 times for medicines and in 3 times in common direct medical costs.

PIN133

MODELLING STAFF RESOURCE USE IN AMBULATORY HIV CARE

Brennan A[1], Jackson A[2], Horgan M[1]
[1]University College Cork, Cork, Ireland, [2]Cork University Hospital, Cork, Ireland

OBJECTIVES: Information on staff resource requirements for outpatient HIV care is useful for effective planning of the service, especially given the increasing and increasingly complex patient population. The aim of this study was to estimate the staff resources used in the HIV outpatient clinic in Cork University Hospital (CUH). **METHODS:** Staff in the CUH HIV outpatient clinic completed time sheets for 6 consecutive clinics (March-April 2013). Patient identifiable data were not collected, however basic patient characteristics (gender, route of transmission, age > 50 years, Irish nationality, late diagnosis) and clinical information (type of visit and complexity) were included. **RESULTS:** Over the study period 83% (127/153) of doctor visits were timed. 46% of patients were seen by a senior doctor. The average length of time spent with each patient by senior doctors was 14.5 minutes, while NCHDs spent an average of 24.1 minutes per patient. Patient gender, age, route of infection, nationality, late diagnosis and visit type had little impact on the average length of doctor visit, but visit length was affected by doctor type and complexity. In addition, clinical nurse specialists saw 62% of patients, and spent 14.3 minutes on average per patient. **CONCLUSIONS:** Time spent with patients varies with the experience level of the doctor. Visit length was also affected by the individual complexity of the visit. The results of this study will be fed into a wider study estimating the factors influencing the cost of providing ambulatory HIV care in Ireland.

PIN134

UNITED STATES POLICY IMPLICATIONS OF GENERIC SUBSTITUTION OF BRANDED HUMAN IMMUNODEFICIENCY VIRUS MEDICATIONS

Hogue S[1], Brogan A[1], Goodwin B[2]
[1]RTI-Health Solutions, Research Triangle Park, NC, USA, [2]GlaxoSmith Kline, Research Triangle Park, NC, USA

OBJECTIVES: Increasingly, human immunodeficiency virus (HIV) infection is managed as a chronic condition. Payers in the United States (US) typically manage chronic conditions as cost-effectively as possible. One element of cost containment is to institute policies driving utilization of less-expensive generic medications. As generic HIV drugs become available, concerns arise that "de-simplifying" HIV treatment by incentivizing use of generic components of fixed-dose combination (FDC) treatments will impact adherence, resulting in adverse treatment effects. This study evaluated US payers' likelihood to incentivize patients/physicians from branded FDCs toward a combination of generic single-dose drugs. **METHODS:** We conducted targeted research of published literature and payer Web sites to identify information relevant to HIV coverage polices. This informed a discussion guide for one-on-one interviews with 10 payers from US commercial health insurance companies. Participants were recruited to ensure diversity from organizational sizes and geographical regions; interviews were double-blinded (i.e., payer and pharma). **RESULTS:** Payers indicated HIV management is increasingly perceived as

chronic (e.g., diabetes, hypercholesterolemia, schizophrenia) rather than life-threatening and that treatments, while costly, lead to significant savings in medical benefits and ultimately leave medication decisions to specialists. Payers are cautiously examining potential savings and were willing to institute modest management for generics (tier 1) while keeping branded FDCs on preferred tier 2 (branded preferred copay). Payers were unwilling to institute, high cost-sharing co-insurance, prior authorizations, or require failure for members to access branded HIV medications presently or in the near future. **CONCLUSIONS:** Payers recognize the complexity of treating HIV, the role of adherence, the high cost of failure and the public health component of preventing resistance. We found payers to cautiously look at potential cost savings in medication management until all FDC components become generic. We found no widespread desire to drive generic adoption in HIV treatment, and little interest in the "de-simplification" of currently available FDCs.

PIN135

THE HEALTH AND ECONOMIC EFFECTS ON PUBLIC HEALTH DUE TO PATIENTS' DEFAULT IN TUBERCULOSIS TREATMENT IN MALAYSIA

Fun WH[1], Wu DBC[2], Cheong YM[3], Mohd Noordin N[4], Dony JF[5], Lee KKC[3]
[1]*Monash University Sunway Campus, Bandar Sunway, Malaysia,* [2]*Monash University Sunway Campus, Kuala Lumpur, Malaysia,* [3]*Monash University Sunway Campus, Selangor, Malaysia,* [4]*Ministry of Health, Malaysia, Selangor, Malaysia,* [5]*Ministry of Health, Malaysia, Putrajaya, Malaysia*

OBJECTIVES: Inadequate or partial treatment of Tuberculosis (TB) is a known factor that would promote drug resistance, thus increasing the overall cost of TB management. The study objectives are to identify the general characteristics of defaulting patients and to estimate the cost impact on health authorities as compared to non-defaulters. **METHODS:** A retrospective case-control study was carried out in public treatment centres in Selangor, Malaysia. Defaulter is defined as TB patient who has interrupted treatment for two consecutive months or more and did not complete their treatment. All subjects were selected from 2011 TB District Registry database. Patients' medical case notes and baseline characteristics were reviewed and analysed. The direct costs of TB management were estimated from public health cost references. The study was performed from a government's perspective. **RESULTS:** A total of 176 defaulters and 204 non-defaulters were studied. Foreign-born patients showed a higher risk (OR= 5.929; p <0.01) of defaulting treatment. Unemployed patients were also more likely to default treatment (OR=1.521 p>0.05). Defaulters were more likely to default treatment during intensive phase as compared to maintenance phase (68.1% vs. 31.9%; p<0.05). No other significant findings were observed between the two groups including age, ethnicity, severity of x-ray changes, type of TB and overall medical risk factors. Mean cost of the non-defaulter group is higher than the defaulter group due to a complete treatment (RM 1,259.62 vs. RM 575.58; p<0.05). No significant treatment cost difference was observed in foreign-born defaulters as compared to local Malaysians (mean: RM 576.43 vs. RM 573.78; p>0.05). **CONCLUSIONS:** Data from this study suggest TB treatment should be completed to avoid a potential huge waste of resources. More attentions are required for foreign-born defaulters due to overall consequence in public health and management cost. Additional costs would be required if susceptible TB strains of the defaulters turned into more virulent strains.

PIN136

THE DISEASE BURDEN OF INFLUENZA IN GERMANY

Ehlken B[1], Wahle K[2], Hain J[3], Pathak P[4], Anastassopoulou A[3]
[1]*IMS Health, Munich, Germany,* [2]*University of Muenster, Muenster, Germany,* [3]*GlaxoSmithKline GmbH & Co, Munich, Germany,* [4]*IMS Health, Alexandria, VA, USA*

OBJECTIVES: To describe the burden of influenza for children and adults diagnosed with seasonal influenza in Germany. **METHODS:** The study was based on a retrospective database analysis, using a longitudinal electronic medical records database (IMS® Disease Analyzer). Patients with influenza episodes (ICD-10 diagnosis J09-11) being observable 12 months before index date and 1 month afterwards were included. The selection window was May 2010 to April 2012 to cover two influenza seasons. **RESULTS:** A total of 23,068 influenza episodes (19,446 patients) managed by primary care practitioners (PCP) and 7,295 episodes (5,988 patients) managed by pediatricians were eligible. Mean age of patients was 43±20 years in the PCP panel and 7±4 years in the pediatrician panel. The presence of clinical risk factors was documented for 40% of episodes in adults and 31% of episodes in children. The most common risk factors were cardiovascular diseases in adults (28%) and chronic respiratory diseases in children (26%). The presence of risk factors correlated with the number of episodes/patient. Influenza episodes were frequently accompanied by complications (adults: 38%; children: 57%). Bronchitis (adults: 16%, children: 20%) and acute upper respiratory infections (adults: 15%, children: 21%) accounted for the most frequent complications. Mean number of physician visits was 1.2± 0.5 in adults and 1.5±0.8 in children. Nevertheless one in three children (34%) had more than one visit/episode due to complications. About 60% of episodes (adults: 60%; children: 64%) with at least one complication were reported in patients without risk factors. About 50% of patients received drug prescriptions related either to influenza diagnosis or complications. **CONCLUSIONS:** This study demonstrates that in Germany seasonal influenza is associated with a substantial disease burden and considerable resource utilization, which can be preventable by vaccination. The findings may suggest the modification of the current vaccination recommendation for at risk populations.

PIN137

HIV REGULATORY PRACTICES AND THEIR INFLUENCE OVER REIMBURSEMENT DECISIONS

Rubinstein J, Rubinstein E, Jaksa A, Liden D
Context Matters, Inc., New York, NY, USA

OBJECTIVES: This analysis compares the studies that four regulatory agencies used to make their decisions and compares the relationship between the reasons for regulatory decisions and reasons for reimbursement decisions. **METHODS:** The scientific discussions and the studies used to make regulatory decisions for 15 different HIV drugs approved over the last 12 years (2000-2012) were compared for the FDA, EMA, Health Canada and Australia the Australian Therapeutic Goods Administration. The studies used to make regulatory decisions were then compared to the studies used in the reimbursement decisions of France, Scotland, Canada and Australia. **RESULTS:** In all 15 cases reviewed the FDA, EMA and Health Canada used at least one of the same studies to come to their decision and in 13 of the cases Australia also used that same study. In 14 cases the FDA approved the drug before the other regulatory authorities; the longest time before another regulatory agency approved a drug was 15 months for rilpivirine. In six cases the FDA commissioned studies that other regulatory bodies and reimbursement agencies used later. All of the studies were interventional studies. Reimbursement agencies always used studies that were previously cited in regulatory documents. These agencies would also use studies intended for the regulatory approval of another drug as a source for information in a review. **CONCLUSIONS:** Reimbursement agencies and other regulatory agencies are influenced by the FDA in the studies they consider, as illustrated by at least six cases in which other agencies used studies commissioned by the FDA after approval. This influence is easier to see in the last five years, but may be older than that due to improvements in published reports.

PIN138

ATTITUDES, BELIEFS AND BEHAVIOURS OF GENERAL PRACTITIONERS REGARDING VACCINATION: DEVELOPMENT OF A CHARACTERISATION TOOL – QUALITATIVE STEPS

Tugaut B[1], Arnould P[2], Benmedjahed K[1], Coindard G[3], Denis F[4], Duhot D[2], Gallais JL[2], Martinez L[2], Raineri F[2], Seyler D[5], Arnould B[1]
[1]*Mapi, Lyon, France,* [2]*French Society of General Medicine, Issy-les-Moulineaux, France,* [3]*University of Paris-Sud, Le Kremlin-Bicêtre, France,* [4]*University Hospital, Limoges, France,* [5]*International vaccination center, Marseille, France*

OBJECTIVES: General practitioners (GPs) play an essential role in France in the prescription and administration of vaccines. Understanding factors that influence GPs' opinions regarding vaccination would help improve vaccination rate in the general population. The study objectives were to understand and describe GPs' attitudes, beliefs and behaviours regarding vaccination, to develop a self-report tool enabling characterisation of GPs, to assess the prevalence and determinants of vaccination behaviours and to identify the modifiable barriers regarding vaccination. **METHODS:** Focus groups with French GPs (n=36) were conducted following a semi-structured interview guide. Main themes of the guide were identified through a literature review. Qualitative analysis enabled development of a conceptual framework based on the theory of planned behaviour (TPB). Items were then generated based on GPs' quotations. Cognitive debriefing interviews with GPs (n=10) were conducted to assess understanding, acceptability and content validity of the tool. Research methods and results were approved by a committee involving GPs, vaccination and tool development experts. **RESULTS:** Focus groups revealed that GPs' attitudes, beliefs and behaviours regarding vaccination varied depending on target disease and population. GPs were influenced by factors classified in 6 themes: vaccine characteristics, disease characteristics, practical aspects, expected benefits, personal background and relationship with patients. These qualitative findings supported item generation of the tool to capture 39 detailed concepts. The tool was developed to be generic for any disease that could be prevented by vaccination. Comprehension testing to confirm the relevance and understanding of the tool is underway. **CONCLUSIONS:** The tool was developed following rigorous methodology based on documented qualitative research. The TPB seems appropriate for organising qualitative research findings. Characterisation of GPs based on their attitudes, beliefs and behaviours regarding vaccination is expected to predict their intention to vaccinate and thus enable development of efficient programs promoting vaccination. The next step is to perform psychometric validation.

PIN139

A CASE STUDY OF FDA PRACTICES AND ITS INFLUENCE ON REGULATORY AND REIMBURSEMENT DECISIONS FOR DARUNAVIR

Rubinstein J, Rubinstein E, Jaksa A, Jao R, Satyarthi H, Liden D
Context Matters, Inc., New York, NY, USA

OBJECTIVES: It is assumed that agencies influence one another but little has been written on the extent of this influence. This analysis aims to explore how regulatory decisions affect reimbursement decisions within one HIV drug, darunavir. **METHODS:** Documents from the FDA, European Public Assessment Report (EPAR), Health Canada, and the Australian Register of Therapeutic Goods together with the reimbursement decisions from France, Scotland, Canada and Australia were analyzed. The clinical trials found in these documents were compared. **RESULTS:** The FDA approved darunavir ethanolate on June 23, 2006 based on the POWER 1, 2 and 3 clinical trials. After approval, the FDA also required further reports (to be completed by December 31, 2007) on two Phase III studies, ARTEMIS and TITAN. Health Canada approved darunavir on July 28, 2006 and used the POWER studies along with the ARTEMIS and TITAN studies in its decision. The EMA approved darunavir on December 2, 2007 but gave conditional authorization a year earlier. EPAR also used the TITAN and POWER studies to make its decision. The French reimbursement agency used the ARTEMIS and TITAN studies in two recommendations. Scotland and Canada cited the ARTEMIS study in their recommendations. Australia used the POWER and TITAN studies in two recommendations and the ARTEMIS study in its one negative recommendation, citing an inappropriate comparator for the population under review. **CONCLUSIONS:** Studies that required further review by the FDA after approval were key in determining regulatory decisions by Health Canada, EMA and Australia. The reimbursement decisions of France, Scotland, Canada and Australia also relied on these commissioned studies.

PIN140

CLINICAL GUIDELINES EVIDENCE AS A CRITERION FOR CHANGES IN THE LEGISLATION COMBATING TUBERCULOSIS

Stepanenko A, Lishchyshyna O, Melnyk Y
The State Expert Center of the Ministry of Health of Ukraine, Kyiv, Ukraine

OBJECTIVES: Modern medicine provides continuous improvement of diagnosis, treatment and prevention methods in accordance with the requirements of best medical practice. The system of medical care standardization with regard of the evidence-based medicine is focused on developing medical and technological documents that assist a doctor to act effectively in specific clinical situations, avoiding inefficient and false interventions. In view of this, the Ministry of Health of Ukraine has approved the methodology for development of medical and technological documents on the basis of evidence. **METHODS:** Evidence of clinical effectiveness is the main criterion in choosing the treatment methods combating tuberculosis. **RESULTS:** Ukraine has recently introduced the methodology of developing unified clinical protocols of medical care based on adapted clinical guidelines, which in turn are the result of adaptation of the best international practice. In particular, within the project of combating TB the adapted clinical guidelines was developed based on the documents of NICE and WHO. In developing the protocol there identified found differences in the tuberculosis treatment in Ukraine compared to the best practice, which resulted in amendments to the corresponding regulations in health care. **CONCLUSIONS:** Practical recommendations derived from the evidence-based medicine allowed the change of approaches to diagnosis and treatment of tuberculosis in Ukrainian regulations. 3-time examination by sputum smear and culture microscopy is replaced by 2-time, the duration of the basic course of chemotherapy is reduced from 8 to 6 months and its intensity is reduced from 5-component to 4-component treatment for the treatment of new and recurrent cases of tuberculosis with sensitive mycobacteria. In order to integrate these changes into clinical practice local protocols and critical pathways for management of tuberculosis are developing in all health care facilities taking into account peculiarities of the region and available resources of the hospitals.

RESPIRATORY-RELATED DISORDERS – Clinical Outcomes Studies

PRS1
CHARACTERISTICS OF PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) RECEIVING INHALED CORTICOSTEROID/LONG-ACTING β2–SS2-AGONIST (ICS/LABA) FIXED COMBINATION PRODUCTS IN ENGLISH PRIMARY CARE

Blak BT, Rigney U, Emmas C, Hamblin A
AstraZeneca UK Ltd., Luton, UK

OBJECTIVES: ICS/LABA fixed combinations are used in patients with COPD with a history of repeated exacerbations i.e. worsening of disease including infections and who have significant symptoms despite regular bronchodilator therapy. This study describes the characteristics of COPD patients initiating ICS/LABA in English primary care. **METHODS:** Patients with first prescription (index date) of fluticasone/salmeterol (FP/SM) or budesonide/formoterol (BUD/FM) between 01.01.2005-31.10.2011 and a prior COPD record were selected from CPRD primary care records linked to Hospital Episode Statistics. Baseline characteristics prior to first ICS/LABA prescription were described as proportions, means and rates (95%CI). Prior exacerbations were defined as: antibiotic or oral corticosteroid prescriptions or COPD hospitalisation; multiple events within 14 days were treated as one event. **RESULTS:** 26,875 patients age≥40 at index were included with 75.9% initiating FP/SM and 24.1% BUD/FM; mean age 70.3(70.1-70.4) and 69.0(68.8-69.3) years, respectively. In both cohorts 54% were male, approximately 36% current smokers, and 56% past smokers. Pneumonia within 1-year prior to index was slightly higher in FP/SM patients (1.9%(1.9-1.9)) compared to 1.4%(1.4-1.4) in BUD/FM), as was prior mean annual COPD hospitalisation rate (0.17(95%CI:0.16-0.17); 0.11(95%CI:0.10-0.12)). Amongst FP/SM patients 12.7%(95%CI:12.6-12.9) had COPD hospitalisations 1-year prior with 9.2%(95%CI:8.9-9.4) amongst BUD/FM. 37.2%(95%CI:36.7-37.7) of FP/SM patients received tiotropium 1-year prior with 35.4%(95%CI:34.5-36.2) amongst BUD/FM. The majority of patients had received short-acting ß2-agonist; FP/SM patients: 89.8%(95%CI:88.6-91.1), BUD/FM patients: 84.8%(95%CI :82.7-86.8). Proportions receiving inhaled-corticosteroids within 1-year prior was 50.9%(95%CI:50.3-51.6) and 48.0(95%CI:46.8-49.2) for FP/SM and BUD/FM, respectively, oral-steroids figures were 42.2%(95%CI:41.7-42.8) and 39.8%(95%CI:38.8-40.8), respectively, and mean annual exacerbation rate was 2.15(95%CI :2.12-2.18) and 2.02(95%CI:1.96-2.07), respectively, with 75.3%(95%CI:74.2-76.3) and 73.9%(95%CI:72.1-75.7), respectively, having exacerbations. **CONCLUSIONS:** Both groups had similar burden of COPD disease prior to starting fixed combination. The crude prevalences for some baseline characteristics were slightly higher in FP/SM vs. BUD/FM highlighting the need for rigorous propensity score matching in any comparative outcomes research.

PRS2
THE EFFICIENCY OF PREOPERATIVE PHYSIOTHERAPY IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE UNDERGOING OPEN HEART SURGERY

Sió E[1], Bajsz V[1], Mazur M[2], Molics B[3], Boncz I[3], Gombos G[1]
[1]*University of Pécs, Zalaegerszeg, Hungary,* [2]*Zala County Hospital, Zalaegerszeg, Hungary,* [3]*University of Pécs, Pécs, Hungary*

OBJECTIVES: Chronic Obstructive Pulmonary Disease (COPD) associated with heart disease is common; this fact leads to increase the number of postoperative complications. The aim of this study was to evaluate the benefits of preoperative physiotherapy (PT) among patients with COPD. **METHODS:** Thirty-seven patients with COPD were included in the study those who underwent open heart surgery. Group1 (n=17) participated in pre- and postoperative PT while Group2 (n=20) received only postoperative PT. Inclusion criteria: open heart surgery and patients diagnosed with COPD or have FEV_1<80%. Spirometric measurements (vital capacity=VC, forced expiratory volume=FEV_1, maximum expiratory pressure=PEF) performed preoperatively and on the 3rd and 7thpostoperative days. Operative data, duration of mechanical ventilation, average stay of intensive care unit, incidence of atelectasis were also assessed. IBM SPSS Statistics 20 software was used for statistical analysis; t-test and Pearson-correlation was applied (p<0.05). **RESULTS:** VC, FEV_1, PEF showed significantly decrease in Group1 (21.29±13.40%; 19.71±17.96%; 4.18±20.09%) compared to Group2 (34.70±17.54%; 32.85±11.95%; 24.65±21.65%), (p_1=0.013, p_2=0.011, p_3=0.002). Compared to the preoperatively measured, the fail of the three measured respiratory functional values on the 7th postoperative day was significantly smaller in Group1 than Group2 (VC, FEV_1, PEF; Group1: 14.18±12.61%; 12.82±14.31%; -6.29±18.46%; Group2: 25.60±16.11%; 23.05±14.93%; 13.70±19.28%; p_1=0.043, p_2=0.046, p_3=0.004). There was no difference between groups in duration of mechanical ventilation and average stay of intensive care unit. Incidence of atelectasis was 10% in Group1, while 0% in Group2. Pre- and postoperative respiratory functional values did not correlate significantly with extubation time (p>0.05). **CONCLUSIONS:** The applying of preoperative PT to cardiac surgical patients with COPD is effective since the examined respiratory functional values reduced less and increased better in the postoperative period at the preoperatively treated group.

PRS3
RESPIRATORY SYNCYTIAL VIRUS HOSPITALIZATIONS IN THE CANADIAN REGISTRY FOR SYNAGIS (CARESS)

Paes BA[1], Mitchell I[2], Li A[3], Harimoto T[3], Lanctot KL[3]
[1]*McMaster University, Hamilton, ON, Canada,* [2]*University of Calgary, Calgary, Alberta, Canada,* [3]*Sunnybrook Health Sciences Centre, Toronto, ON, Canada*

OBJECTIVES: Paediatric advisory committee guidelines recommend palivizumab prophylaxis for infants at high risk for respiratory syncytial virus (RSV) infection. The objective of this study is to compare the hospitalization rates for respiratory illness (RIH) and RSV-positive hospitalizations (RSVH) among infants who received palivizumab for various indications. **METHODS:** The Canadian Registry for Synagis (CARESS) is a prospective registry of infants who have received ≥1 dose of palivizumab per RSV season across Canada. Demographic data were collected in 32 Canadian national sites during the 2005-2012 RSV seasons. Respiratory illness related hospitalization events were recorded monthly. Standard risk indications that qualified for RSV prophylaxis were categorized as prematurity (≤35 completed weeks gestational age), chronic lung disease or bronchopulmonary dysplasia (CLD), hemodynamically significant congenital heart disease (CHD), and other serious underlying medical disorders (MD). A Cox proportional hazards analysis was conducted to examine differences in hospitalization rates between the indications. **RESULTS:** Of the 13,310 infants enrolled, 8751 were premature, 1048 had CLD, 1414 had CHD, and 2097 qualified with MDs. The overall RIH rate was 6.6% (n=875) with premature infants having a significantly lower rate than the other groups (4.4% vs. 12.2% [CLD], 10.3% [CHD], 10.3% [MD]; B=-0.770, df=1, p<0.0005). Details of hospitalizations did not differ between groups, except the number that were admitted to the Intensive Care Unit which was significantly different between groups (χ^2=11.420, df=3, p=0.010). The overall RSVH rate was 1.55% but was also significantly lower for prematurity (prematurity, 1.36%; CLD, 1.64%; CHD, 2.05%; MD, 2.03%; p<0.0005), with no significant differences between the groups in terms of time to RSV hospitalization (χ^2=1.833, df=3, p= 0.608). **CONCLUSIONS:** RIH and RSVH rates were dissimilar across the groups with premature infants being significantly lower compared to the others. However there were no identified group differences regarding time to first RSVH.

PRS4
THE EFFICACY OF THE EXTRA FRONT LOADING SMOKING CESSATION COUNSELLING SESSIONS ON THE ABSTINENCE RATE COMPARED WITH USUAL CARE USED IN QUIT SMOKING CLINIC IN PENANG, MALAYSIA

Blebil AQ[1], Syed Sulaiman SA[1], Hassali MA[2], Dujaili JA[1], Zin AM[3]
[1]*Universiti Sains Malaysia, Minden, Malaysia,* [2]*Universiti Sains Malaysia, Penang, Malaysia,* [3]*Penang General Hospital, Jalan Residensi, Malaysia*

OBJECTIVES: To assess the impact of the front loading phone calls counselling on the abstinence prevalence at 3 and 6 months after quit date among smokers in Penang, Malaysia. **METHODS:** The study was carried out at Quit Smoking Clinic of two major hospitals in the state of Penang, Malaysia. All the eligible tobacco users who attended the clinics between February 1 and October 31, 2012 were invited. Participants were randomly assigned to receive either the usual care (a combination of nicotine gum for the first 2 weeks and cognitive behaviour therapy); (control group), or the previous combination plus extra counselling sessions through phone calls during the first month of quit attempt (intervention group). **RESULTS:** Two hundred thirty-one subjects were recruited during the period under review. The mean age of starting smoking in the study population was 17.38 ± 3.9 years. The vast majority of our cohort (96.1%) was male. Participants smoked about 14 cigarettes per day on average (mean = 13.78 ± 7.0). At 3 months follow-up point, control group was less likely to quit smoking compared to intervention group but this did not reach statistical significance (OR = 0.669; 95% CI = 0.395-1.133, *P* = 0.86). However, at 6 months, the abstinence rate significantly differed between the standard care and combination of standard care and extra phone calls after verification with exhaled carbon monoxide (48.6% vs. 71.7%, respectively: < 0.001). The control group were significantly less likely to quit smoking (OR = 0.375; 95% CI = 0.217-0.645, P< 0.001). **CONCLUSIONS:** Smoking cessation intervention consisting of phone calls delivered counselling during the first month of quit attempt results in significantly higher abstinence rates compared with a standard care approach. Therefore, the front loading counselling is a promising treatment strategy that should be evaluated further.

PRS5
RESPIRATORY SYNCYTIAL VIRUS HOSPITALIZATION IN INFANTS WITH CONGENITAL AIRWAY ANOMALIES IN THE CANADIAN REGISTRY OF SYNAGIS® (CARESS) FOLLOWING PROPHYLAXIS (2005-2012)

Paes BA[1], Li A[2], Mitchell I[3], Lanctot KL[2]
[1]*McMaster University, Hamilton, ON, Canada,* [2]*Sunnybrook Health Sciences Centre, Toronto, ON, Canada,* [3]*University of Calgary, Calgary, Alberta, Canada*

OBJECTIVES: Palivizumab is recommended for respiratory syncytial virus (RSV) prophylaxis. CARESS tracks palivizumab use and respiratory outcomes in high-risk infants, including those with congenital airway anomalies (CAA). Our objective was to compare hazards for hospitalization for respiratory illness (RIH) and RSV (RSVH) in CAA infants versus those prophylaxed for: 1) other medical disorders (MD) and 2) standard indications (SD). **METHODS:** Infants were prospectively recruited from 32 Canadian sites who received ≥1 dose of palivizumab during the 2005-2012 RSV sea-

sons. Utilization and hospitalization outcomes were collected monthly throughout respective seasons. **RESULTS:** A total of 13,310 infants were enrolled (309 CAA, 1816 MD, 11185 SD). There were statistically significant group differences ($p<0.05$) in: enrolment and gestational age, birth and enrolment weight, proportions of: Caucasians, daycare attendance, smoking exposure, siblings, multiple birth, household crowding, and atopy. Compliance, calculated by inter-dose intervals, was similar across the groups - overall rate 73.2%. CAA infants had a RIH rate of 12.9%; MD (9.9%); SD (5.9%) with significantly increased hazard of hospitalization compared to MD (HR = 1.47, 95%CI: 1.04-2.10, $p = 0.030$) and SD (HR = 1.92, 95%CI: 1.39-2.67, $p < 0.0005$). 40/309 CAA infants were hospitalized for RI, 32 were tested for RSV; 4 were positive (RSVH rate: 1.61% versus 2.06% (MD), 1.47% (SD). By Cox proportional hazard analysis, CAA did not increase hazard of first RSVH compared to MD or SD infants ($\chi^2 = 0.79$, df = 2, $p = 0.67$). After risk factor adjustment for daycare attendance, siblings, smoking exposure and crowding, the model was significant ($\chi^2 = 66.1$, df = 10, $p < 0.0005$); however, individual groups as risk factors remained insignificant ($p = 0.73$). **CONCLUSIONS:** This is the largest report of CAA infants who have received palivizumab world-wide. Despite differences in risk factors, the groups appear to have similar hazards in terms of RSVH.

PRS6

SYSTEMATIC REVIEW OF COLISTIMETHATE SODIUM DRY POWDER AND TOBRAMYCIN DRY POWDER ANTIBIOTICS FOR PSEUDOMONAS AERUGINOSA LUNG INFECTION IN CYSTIC FIBROSIS

Harnan SE[1], Uttley L[1], Cantrell A[2], Taylor CJ[3], Walshaw M[4], Brownlee K[5], Tappenden P[2]
[1]*The University of Sheffield, Sheffield, UK,* [2]*University of Sheffield, Sheffield, UK,* [3]*Sheffield Children's NHS Foundation Trust, Sheffield, UK,* [4]*Liverpool Heart and Chest Hospital NHS Foundation Trust, Liverpool, UK,* [5]*Leeds Children's Hospital, Leeds General Infirmary, Leeds, UK*

OBJECTIVES: To evaluate the clinical effectiveness of colistimethate sodium dry powder for inhalation (DPI) and tobramycin DPI for the treatment of Pseudomonas aeruginosa lung infection in cystic fibrosis. **METHODS:** Electronic bibliographic databases were searched in May 2012 (MEDLINE, MEDLINE in-Process, EMBASE, Cochrane Library databases, CINAHL, Web of Science and Conference Proceedings Citation Index, BIOSIS Previews). Randomised controlled trials were selected for inclusion in the review if they included at least one of the interventions of interest and reported at least one of the following outcomes: rate and extent of microbial response (e.g. sputum density of Pseudomonas aeruginosa); lung function (e.g. forced expiratory volume in one second % predicted (FEV1%); respiratory symptoms; frequency and severity of acute exacerbations; health-related quality of life; and adverse events of treatment (including rate of resistance to antibiotic treatment). **RESULTS:** Three poor to moderate trials were included in the review. Both dry powder formulations were reported to be non-inferior to nebulised tobramycin in terms of clinically relevant changes in FEV1%. However, follow up may not be long enough to detect slowing of the rate of decline in respiratory function and exacerbation rates were not always reported. It was not possible to draw any firm conclusions as to the relative efficacy of the treatments. **CONCLUSIONS:** Whilst both dry powder drugs were reported to be non-inferior to nebulised tobramycin, some results should be interpreted with caution due to the means by which they were analysed, the length of follow up, and concerns about the ability of FEV1% to accurately represent changes in lung health. The clinical trials should have considered FEV1% alongside other clinically relevant outcomes, such as acute exacerbations. This study illustrates the difficulty in assessing new technologies where the evidence base is poor.

PRS7

ASSESSING NON-INFERIORITY OF ACLIDINIUM BROMIDE 400 μG BID VERSUS TIOTROPIUM 18 μG AND 5 μG QD IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) BY MEANS OF A NETWORK META-ANALYSIS

Karabis A[1], Lindner L[2], Prior M[3]
[1]*Mapi, Houten, The Netherlands,* [2]*Almirall UK, Uxbridge, UK,* [3]*Almirall S.A., Barcelona, Spain*

OBJECTIVES: To assess non-inferiority (NI) of aclidinium bromide 400 μg BID (AB400), to tiotropium bromide 18 μg (TIO18) and 5 μg (TIO5) QD in patients with COPD. **METHODS:** A systematic literature search identified 21 RCTs: TIO18 (16 trials), TIO5 (3 trials) and AB400 (2 trials). All trials were analysed using a Bayesian network meta-analysis (NMA) and relative treatment effects between all regimens were obtained for change from baseline (CFB) in FEV_1 trough, SGRQ total score, and TDI focal score, at 24 weeks. The posterior distributions of the relative treatment effects were used to estimate the probability of non-inferiority, based on the NI margins. Two approaches used for margin selection (a) NI_{MCID}: 50% of the Minimum Clinically Important Difference (MCID) (b) NI_{NMA}: 50% of the difference between TIO18 and placebo (PLA), based on the NMA results. AB400 was considered non-inferior if it could maintain at least 50% of this difference with a probability >99%. **RESULTS:** For FEV_1 the MCID is 100mL, while the CFB for TIO18 vs. PLA is 104.1mL giving NI_{MCID}=50mL, NI_{NMA}=52.05mL. AB400 is shown to be non-inferior to TIO5 and TIO18, for both margins. For SGRQ, a change of 4 points is the MCID and CFB for TIO18 vs. PLA is 2.65, thus $NI_{MCID} = 2$ and $NI_{NMA} = 1.325$. AB400 was shown to be non-inferior to TIO5 and TIO18 for both margins. A difference of 1 unit is the MCID for TDI, while the CFB for TIO18 vs. PLA is 0.90 unit, giving $NI_{MCID} = 0.5$, $NI_{NMA} = 0.45$. For these margins, the probability of aclidinium been non-inferior is 97% for the NI_{MCID}, and 96% for the NI_{NMA}. **CONCLUSIONS:** This analysis suggests that treatment with AB400 in COPD is non-inferior to TIO18 and TIO5 with respect to lung function, health status, and to breathlessness with a probability >95%.

PRS8

EFFECTIVENESS OF MONTELUKAST ON ASTHMA CONTROL IN INFANTS: METHODOLOGY OF A CLAIMS DATA STUDY

Belhassen M[1], Tamberou C[1], Laigle V[2], Souchet T[2], Chanut-Vogel C[2], Lamezec L[2], De Blic J[3], Brouard J[4], Fauroux B[5], de Pouvourville G[6], Laforest L[1], Van Ganse E[1]
[1]*University of Lyon, Lyon, France,* [2]*Laboratoires MSD France, Courbevoie, France,* [3]*Necker University Hospital, Paris, France,* [4]*University Hospital Caen, Caen, France,* [5]*Trousseau University Hospital, Paris, France,* [6]*ESSEC, Cergy-Pontoise, France*

OBJECTIVES: Montelukast 4mg (MTL-4) is a recent add-on therapy for young asthmatic children. French regulators have requested real-world evidence on effectiveness of MTL-4 in infants (6-24 months), compared to inhaled corticosteroid (ICS) therapy. National claims data (SNIIR-AM) are now available to public investigators. SNIIR-AM records exhaustive medical resource utilization of the French population, i.e. 65.4 millions. Due to the limited population of infants exposed to MTL-4 from 2010 (i.e. 78 000 children 6-24 months old), SNIIR-AM represents a good tool to investigate its effectiveness. We first tested the feasibility of such a study in a pilot phase conducted on a 1/97th representative sample of the full data set (EGB: Representative Sample of Beneficiaries), to validate identification and evaluation criteria, and to identify potential pitfalls in the methods or insufficient statistical power for groups comparison, in order to take them into account in the finalized version of the protocol. We present hereafter the main conclusions of the pilot project. **METHODS:** We preselected infants receiving ≥ 2 consecutive dispensations of any respiratory drugs (R03 ATC classification) and presenting an initial exacerbation within 6 months following the first dispensing. Asthma exacerbation was identified by asthma-related hospitalizations, dispensing of oral corticosteroids, addition of short-acting beta agonist to existing respiratory therapy, switch to an ICS therapy with higher dosage, or switch to nebulized CS. **RESULTS:** Our sample included 1,149 infants (mean age 13 months, 64% boys). Among them, 51 and 768 were assigned to Montelukast and ICS groups, respectively. Infants with a exacerbation during the 6 months post inclusion were 78.8% and 78.4% in each group, respectively (51% and 62% for oral costicosteroids only). **CONCLUSIONS:** The results of this pilot study support the feasibility of our SNIIR-AM project, regarding inclusion criteria and identification of outcomes. These data allowed us to finalize the SNIIR-AM study protocol that is ongoing.

PRS9

CURRENT CHARACTERISTICS, TREATMENT AND HEALTH CARE CONSUMPTION OF PATIENTS WITH ASTHMA OR COPD IN THE NETHERLANDS

Overbeek JA[1], Driessen MT[2], Penning-van Beest FJA[1], Rutten-van Mölken M[3], Lammers JWJ[4], Herings RMC[1]
[1]*PHARMO Institute for Drug Outcomes Research, Utrecht, The Netherlands,* [2]*GlaxoSmithKline, Zeist, The Netherlands,* [3]*Institute for Medical Technology Assessment, Rotterdam, The Netherlands,* [4]*University Medical Center Utrecht, Utrecht, The Netherlands*

OBJECTIVES: To investigate the characteristics, medication persistence and health care consumption of asthma and COPD patients in The Netherlands in 2011. **METHODS:** Data were obtained from the PHARMO Database Network, including outpatient drug dispensings, hospitalization records and information from general practitioners (GP). From the GP-database, patients with a recorded ICPC-code for asthma or COPD (period 2001-2010) were selected and included if they were continuously registered in 2010-2011 and had ≥1 respiratory dispensing in 2010. Persistence with any respiratory medication was determined among new patients and defined as the number of days of uninterrupted use. **RESULTS:** The study included 6037 asthma and 4489 COPD patients. In 2011, most asthma patients were most often categorized into GINA I (n=1727), female (60%) and had a mean age of 45 (SD±18) years. COPD patients were classified as GOLD II (n = 1485), male (54%) and had a mean age of 67 (SD±11) years. On January 1, 2011, most common used respiratory treatment among asthma patients was fixed-dose combination of LABA+ICS (FDC) (25%), whereas COPD patients mostly either used FDC (14%), LAMA (14%) or both (15%). 30% Of asthma and 16% of COPD patients did not use respiratory medication. Among new asthma patients, after six and twelve months, 22% and 10% of patients were persistent with respiratory medication. These proportions were 42% and 30% for COPD. Most common selected co-morbidities among both groups were hypertension, hypercholesterolemia, and depression. In 2011, asthma patients consulted their GP on average 5.3 times and COPD patients 7.7 times. On average, asthma patients were 0.4 days hospitalized and COPD patients 1.2 days. Cost calculations for health care consumption are available in November. **CONCLUSIONS:** This study provides an overview of the characteristics and health care consumption of asthma and COPD patients in The Netherlands, and emphasizes the need for more research regarding persistence among these patients.

PRS10

ESTIMATION OF THE NUMBER OF CASES OF NOSOCOMIAL PNEUMONIA IN ADULTS CAUSED BY GRAM-POSITIVE BACTERIA IN PUBLIC HOSPITALS IN MEXICO

Gryzbowski E[1], Peniche-Otero G[1], Herrera-Rojas J[1], Bolaños-Cornejo D[1], Huicochea-Bartelt JL[2], Muciño-Ortega E[2]
[1]*Customized Premium Products S.A. de C.V., Mexico City, Mexico,* [2]*Pfizer S.A. de C.V., Ciudad de México, Mexico*

OBJECTIVES: To estimate the number of cases of nosocomial pneumonia (NP) in adults caused by Gram-positive bacteria (GPB) in public hospitals in Mexico. **METHODS:** To estimate the number of hospital discharges for each public institution in ≥ 18 years, databases from the National Health Information System (SINAIS) were consulted. We apply the nosocomial infection (NI) rate (5.97 cases per 100 discharges) issued by Instituto Mexicano del Seguro Social (IMSS) during the period 2011-2012. Through a systematic literature review and critical reading of studies developed in the Mexican setting (using the Critical Appraisal Skills Programme guidelines) we assessed the type of infection and determined the proportion of cases in which microbiological culture was obtained, as well as the proportion giving positive isolates; subsequently, etiologic agent was disaggregated according to their Gram staining characteristics. **RESULTS:** In the year 2011 there were 5,517,139 discharges from public hospitals, applying a rate of 5.97 NI cases/100 discharges, resulted in 329,373 NI cases (16.9% under 18 years and 83.1% in adults). The NP represented 33.2% of NI (90,882 cases), of these, only in 63% of cases a microbiological culture was obtained (57,256) and pathogens were isolated in 87.0% of microbiological cultures (49,813), among these, GPB we identified in 30.4% . According to our estimates the number of cases of adult NP caused by GPB is 15,135 and the pathogens reported were *Staphylococcus aureus* (74.3%), Streptococcus pneumoniae (15.6%), Enterococcus spp. (6.3%) and others (3.8%). **CONCLUSIONS:** In

spite of high heterogeneity found in NI reports (which may decrease the quality of the information recorded), the local data reported in this study can help clinicians in the choice of first line antibiotics in order diminish the probability of unsuccessful treatment and additionally to reduce the emergence of resistant organisms, which could cause negative economic impact in the health care institutions.

PRS11

FACTORS ASSOCIATED WITH COMPLIANCE WITH PALIVIZUMAB PROPHYLAXIS IN THE CANADIAN RSV EVALUATION STUDY FOR SYNAGIS (CARESS) REGISTRY (2005-2012)

Paes BA[1], Li A[2], Yi H[2], Mitchell I[3], Lanctot KL[2]
[1]*McMaster University, Hamilton, ON, Canada,* [2]*Sunnybrook Health Sciences Centre, Toronto, ON, Canada,* [3]*University of Calgary, Calgary, Alberta, Canada*

OBJECTIVES: Palivizumab prophylaxis against respiratory syncytial virus (RSV) is provided monthly during the RSV season. CARESS is a prospective registry of infants who received ≥1 dose of palivizumab across 32 Canadian sites during 7 seasons. The objective is to determine factors associated with palivizumab compliance. **METHODS:** Neonatal and demographic data were collected at enrolment. Palivizumab utilization, compliance, and outcomes related to respiratory illness (RI) and RSV hospitalization were collected monthly. Compliance was defined as receipt of all expected injections at 25–35 day intervals during the RSV season. **RESULTS:** A total of 13,310 infants were enrolled. Infants received 89.0% ± 18.23% of their expected injections and 9745 (73.2%) were administered within appropriate inter-dose intervals.Compliant versus non-compliant infants had a rate of 9.2 RSV and 57.5 RI versus 11.7 RSV and 65.5 RI hospitalizations / 100-patient-years respectively. Compliance differed between prophylaxis indications (χ^2=24.6, p<0.0005); with congenital heart disease the most non-compliant (CHD; n=668, 47.2%), followed by chronic lung disease (CLD; n=470, 44.8%), prematurity (≤35 weeks gestational age; n=3643, 41.6%) and other medical disorders (n=831, 39.6%). A greater proportion of non-compliant infants were Aboriginal (4.8% vs. 2.4%, χ^2=57.8, p<0.0005), attended daycare (4.0% vs. 3.3%, χ^2=5.0, p=0.03), had a mother who smoked (17.1% vs. 12.0%, χ^2=69.0, p<0.0005), and lived with ≥1 smoker (31.7% vs.26.1%, χ^2=49.7, p<0.0005). Significant factors independently associated with compliance (OR, 95%CI) were: maternal education (1.38, 1.22–1.58), Aboriginal descent (0.57, 0.47–0.70), smoke exposure (0.70, 0.52–0.94), CLD (0.74, 0.56–0.99), maternal smoking (0.79, 0.68–1.01), daycare (0.82, 0.68–0.99), and indication for prophylaxis. Compliance by both expected number of injections and inter-dose intervals was associated with lower hazard rates of RI hospitalization (HR=0.86, 95%CI=0.74-0.99, p=0.04). **CONCLUSIONS:** Higher maternal education and lower RI hospitalization was associated with full compliance where as non-compliance was associated with other demographic factors and differed by palivizumab indication.

BUDGET IMPACT ANALYSIS OF A NEW FIXED-DOSE COMBINATION INHALER FOR A CLINICAL COMMISSIONING GROUP WITHIN THE NATIONAL HEALTH SERVICE IN ENGLAND

Dunlop W[1], Heron L[2], Fox G[2], Greaney M[2]
[1]*Mundipharma International Limited, Cambridge, UK,* [2]*Adelphi Values, Bollington, UK*

OBJECTIVES: The economic burden of asthma on the UK National Health Service (NHS) is the largest amongst allergic diseases, costing approximately £800 million per year. Current Global Initiative for Asthma guidelines recommend adding a long acting β2-agonist (LABA) to a low-dose inhaled corticosteroid (ICS) in patients who are on ICS monotherapy and have uncontrolled asthma. The fixed-dose combination of fluticasone propionate and salmeterol (FLUT/SAL), available in a pressurized metered dose inhaler (pMDI) device, is the most commonly prescribed ICS/LABA combination. A new fixed-dose combination of fluticasone propionate and formoterol fumarate (FLUT/FORM) in pMDI is now available. In a 12 week non-inferiority study, FLUT/FORM demonstrated comparable efficacy to FLUT/SAL. This study estimates the budget impact of using FLUT/FORM as an alternative to FLUT/SAL for an average NHS clinical commissioning group (CCG) within England. **METHODS:** Current pMDI prescribing data were taken from a real-world UK patient database (Cegedim Strategic Data). Annual costs to the NHS for drug acquisition, administration, and monitoring were estimated for FLUT/FORM and FLUT/SAL. Annual cost data were used to estimate the potential budget impact for the use of FLUT/FORM versus FLUT/SAL, based on an estimated average population size for a CCG (260,000 persons or 0.41% of the UK population). **RESULTS:** Assuming similar levels of ICS use with both combination regimens, annual drug acquisition costs per person were lower with FLUT/FORM (£411.58) than with FLUT/SAL (£509.06). The difference in acquisition costs and otherwise comparable input costs between the treatments, results in potential annual savings of £61,952.14 for an average CCG, assuming uptake of FLUT/FORM over FLUT/SAL in 50% of existing patients. **CONCLUSIONS:** The comparable efficacy and lower acquisition costs for FLUT/FORM compared to FLUT/SAL make it a cost-saving option, from a NHS England CCG perspective, for the treatment of asthma patients requiring combination maintenance therapy using a pMDI.

PRS13

BUDGET IMPACT ANALYSIS OF STEP-DOWN STRATEGY VERSUS CONVENTIONAL THERAPY IN THE TREATMENT OF NOSOCOMIAL PNEUMONIA CAUSED BY GRAM POSITIVE BACTERIA IN MEXICO

Peniche-Otero G[1], Herrera-Rojas J[1], Gryzbowski E[1], Baeza-Cruz G[1], Huicochea-Bartelt JL[2], Muciño-Ortega E[2]
[1]*Customized Premium Products S.A. de C.V., Mexico City, Mexico,* [2]*Pfizer S.A. de C.V., Ciudad de México, Mexico*

OBJECTIVES: Previous reports of national literature estimated 15,135 cases of nosocomial pneumonia caused by Gram-positive bacteria (GPB) in Mexico, of which approximately 51% (95%CI 43%-59%) are candidates to use the step-down strategy (SDS) with linezolid. The aim of the study was to estimate the budget impact of SDS vs conventional strategy (CS, only intravenous) with linezolid in Mexico, from the perspective of Instituto Mexicano del Seguro Social (IMSS). **METHODS:** Budget impact analysis (BIA) considered direct medical costs of linezolid (intravenous and tablets), length of stay, physician visits, route of administration, laboratory and imaging tests, as well as outpatient control (unit costs extracted from IMSS sources). Costs are expressed in 2013 US$ (1US$:€0.719). The resource use profile was estimated by Delphi method in a panel of 10 experienced infectologists. A BIA considering two scenarios was performed: i) budget impact of use CS in 100% of cases of nosocomial pneumonia caused by GPB (15,135) and ii) budget impact of use of SDS only in candidates (7,718 cases), based on the National budget allocated to health in 2013. **RESULTS:** The per-patient average treatment cost (ATC) of SDS was $10,116 ($9,345-10,887) whereas the per-patient ATC of CS was $17,251 ($16,379-18,124). The scenario i) represents 2.79% of National budget allocated to health, whereas scenario ii) represents 2.19%. This means potential savings of 0.6% of National budget allocated to health ($55,078,697). With these resources, CS treatment could be provided to 3,192 additional nosocomial pneumonia patients caused by GPB in Mexico. **CONCLUSIONS:** In the Mexican setting, SDS with linezolid in suitable patients is an intervention that could promote significant savings regarding the use of only intravenous form of the drug, which represents an opportunity to allocate scarce resources in a more efficient way.

PRS14

POTENTIAL OF OMEGA-3 FATTY ACID IN PARENTERAL NUTRITION IN GERMANY: A BUDGET IMPACT ANALYSIS

Pradelli L, Povero M
AdRes HE&OR, Turin, Italy

OBJECTIVES: The costs to the German hospitals of intensive care (ICU) patients and of surgical patients not admitted to the ICU were estimated in a previous cost-effectiveness analysis of omega-3 FA-supplemented compared to standard PN regimens. The supplementation with Omega-3 FA results in shorter LOS and reduced infection rate, with cost savings for 3,277 € per ICU patient and 1,515 € per not-ICU patients. We aimed to estimate the economic consequences of increasing the rate of omega-3 fatty acids (FA) supplemented parenteral nutrition (PN) regimens in German hospitals **METHODS:** IMS-data recorded about 3 million lipid-containing PN days for Germany; the total number of patients in ICU or in ward receiving PN with lipids was estimated on average PN duration from the cost-effectiveness analysis The costs related to the current use of omega-3 FA (about 29% of total lipid PN days) were compared with those expected with increasing percentages of omega-3 FA-containing PN rates. **RESULTS:** The yearly cost of the patient population (104,022 ICU patients and 427,986 not-ICU patients) treated with current PN regimens mix amounts to about 6 billion Euro. The increase of omega-3 FA-containing PN proportion up to 50% results in a saving of about 210 million Euro (2.7%); the exclusive use of omega-3 FA-containing PN regimes results in savings of 704 million Euro (11.6%). Encouraging omega-3 FA supplemented PN regimens is expected to save costs, because the use is associated with a reduction in hospital LOS (~ 850,000 days saved in the best scenario) and the number of nosocomial infections (~ 40,000 infections avoided in the best scenario). **CONCLUSIONS:** The potential of PN including omega-3 FAs in contributing to an improved quality of care/patient recovery and significant cost savings is not fully exploited in German hospitals.

PRS15

REDUCTION OF COSTS ASSOCIATED WITH A NEW DRY-POWDER INHALER FORMULATION WITH BECLOMETHASONE DIPROPIONATE AND FORMOTEROL COMBINATION FOR THE TREATMENT OF ASTHMA

Sanz-Granda Á[1], Hidalgo A[2]
[1]*Weber Economía y Salud, Majadahonda (Madrid), Spain,* [2]*University of Castilla La Mancha, Toledo, Spain*

OBJECTIVES: A new dry-powder inhaler combination for the treatment of asthma has appeared. The objective of the present study is to analyze the cost impact of the introduction of the new dry-powder inhaler (DPI) –beclomethasone dipropionate with formoterol combination (BEC/FOR) - in the treatment of the moderate to severe persistent asthma **METHODS:** A mathematical model was designed to estimate the financial impact of the partial substitution of DPI budesonide with formoterol (BUD/FOR) and DPI fluticasone propionate with salmeterol (FLU/SAL). Only direct health care costs were considered because the perspective of Spanish National Health Service (NHS) was adopted. The time horizon was four years **RESULTS:** The prevalence is 4.6% and it increases 0.26% yearly. Current annual total cost of treatment with BUD/FOR and FLU/SAL is estimated in around 512; 538; 565 and 591 million € for 2013-2017 respectively. The new total cost is estimated in about 511; 537; 562 and 587 million € with the introduction of BEC/FOR. The major determinants of costs were the exacerbations of asthma (44.5% of total cost), and the antiasthmatic drugs (40.2%). The pharmacological cost of BEC/FOR represented the 37.02% of the total of this option while those of FLU/SAL and BUD/FOR were the 39.75% and 41.27%, respectively. Finally, the introduction of BEC/FOR (share of 2; 4; 9 and 14% for 2013-2017) was associated with a roughly saving of 0.7; 1.2; 2.8 and 4.5 million € in the same time **CONCLUSIONS:** The utilization of beclomethasone dipropionate and formoterol in substitution of fluticasone and salmeterol, and budesonide and salmeterol, all of them as dry-powder inhaled, results in important savings of costs for the NHS

PRS16

THE INFLUENCE OF IMPROVED ADHERENCE AND PERSISTENCE IN CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) COSTS: SYSTEMATIC REVIEW OF THE LITERATURE

Pérez M[1], Dominguez J[1], Armengol S[1], Paz S[2], Lizán L[2]
[1]*Almirall S.A., Barcelona, Spain,* [2]*Outcomes 10, Castellon, Spain*

OBJECTIVES: The lack of treatment adherence and persistence is associated with poor clinical outcomes and higher costs. The aim of this study is to estimate the variation on COPD costs that may take place as a consequence of improving

patients' treatment adherence and persistence. **METHODS:** A systematic review of the literature was performed in MedLine/PubMed, Cochrane Library, ISI WOK, MEDES, IBECS, CSIC, Google Scholar (2002-2012) to identify articles referred to direct COPD cost and treatment persistence and adherence. Based on the direct cost data extracted, the annual cost difference between an adherent and non-adherent and a persistent and non-persistent patient in Spain was estimated. Costs were updated to €, 2012. **RESULTS:** A total of 48 articles were included (9 Spanish; 39 international). The mean annual direct cost of a COPD patient in Spain varies between €301 and €4.226, depending on the publication. Patients' adherence and persistence on COPD treatment and their annual costs was analyzed in 3 articles (no Spanish publications identified). Multiple inhaled treatments and devices of complex use contribute to poor adherence and persistence and to higher medical resources use and more exacerbations. Treatment adherence and persistence implies a 9% and 3% decrease in mean annual direct cost of a COPD patient, respectively, while non-adherence and non-persistence means an increase of 5% and 13%. The difference between the mean annual direct cost associated to adherent and to non-adherent patient varies from €43 to €601 (depending on the selected publication) and rises up to €89 to €1.674 in severe COPD patients. A difference between annual direct cost in persistent and non-persistent patient was estimated in €47 to €666 that reached €99 to €1.855 in severe COPD patients. **CONCLUSIONS:** Treatment adherence and persistence information is scarce. Therapeutic strategies improving patient adherence and persistence may optimize outcomes contribute to COPD costs contain.

PRS17

THE BURDEN OF PNEUMONIA IN MALAYSIA, INDONESIA AND PHILIPPINES

Aljunid S[1], Namaitjiang M[1], Al-Abed A[1], Amrizal M[1], Zafar A[2], De Rosas-Valera M[3], Encluna J[4], Rosminah M[5], Azmi S[6]

[1]*United Nations University International Institute for Global Health (UNU-IIGH), Cheras, Kuala Lumpur, Malaysia,* [2]*International Centre for Casemix and Clinical Coding, UKM Medical Centre, Kuala Lumpur, Malaysia,* [3]*Department of Health Philippines, Manila, Philippines,* [4]*Philippine Health Insurance Corporation, Pasig City, Philippines,* [5]*Universiti Sains Malaysia, Kubang Kerian, Malaysia,* [6]*Azmi Burhani Consulting, Kelana Jaya, Petaling Jaya, Malaysia*

OBJECTIVES: The Casemix databases contain clinical costing information from hospitals in Malaysia, Indonesia and the Philippines. The objective of this study was to determine burden of pneumonia in these three countries. **METHODS:** Pneumonia cases occurring in a single year were identified using ICD10 codes, J10-J18. Patients were further categorized into community-acquired pneumonia (CAP) or hospital-acquired pneumonia (HAP); CAP if they had 1) a primary diagnosis of pneumonia, or 2) secondary diagnosis of pneumonia with primary diagnosis of a respiratory condition; HAP cases had pneumonia in any of the secondary diagnosis fields with non-respiratory primary diagnoses. Descriptive analysis was performed to ascertain patient age groups, mean age, mean length of stay (LOS) and case fatality rates (CFR). **RESULTS:** A total of 15,851 pneumonia cases in year 2010 for Indonesia and Philippines and 2011, for Malaysia were included in the analysis. The mean age of patients was 47.5 years in Malaysia, 36.6 years in Indonesia and 23.5 years in Philippines. There was a preponderance of CAP cases among the very young and the very old while HAP cases were more likely to occur in older persons. The overall CFR of all pneumonia hospitalizations was 11.5% for Malaysia, 5.2% for Indonesia and 3.6% for Philippines. The cost of hospitalization was USD 1,177.50, USD 1,103.80 and USD 254.30 in Malaysia, Indonesia and Philippines respectively. The mean LOS in days was 9.2, 8.0 and 6.6 in the three countries, respectively. **CONCLUSIONS:** Our study is the first to utilize these databases to study and compare the burden of pneumonia across three countries in Asia. The CFR and LOS varied in each of the countries likely due to a variety of reasons including differences in socio-economic conditions, patterns of infection as well as health system differences. In conclusion, pneumonia is significant burden in the South East Asian countries studied.

PRS18

COST AND COST-EFFECTIVENESS ANALYSES FOR MODERATE AND SEVERE COPD PATIENTS TREATED UNIQUELY WITH TIOTROPIUM 18 MCG OD FOR TWENTY-FOUR MONTHS

Povero M[1], Pradelli L[1], Bonadiman L[2], Dal Negro RW[3]

[1]*AdRes HE&OR, Turin, Italy,* [2]*CESFAR e Centro Nazionale Studi di Farmacoeconmia e Farmacoepidemiologia Respiratoria, Verona, Italy,* [3]*U.O.C. di Pneumologia, ULSS 22 Regione Veneto. Ospedale Orlandi, Bussolengo, Verona, Italy*

OBJECTIVES: To evaluate cost and cost-effectiveness of tiotropium monotherapy administered for 24 months (18 mcg die) in patients suffering from mild-to-moderate and severe chronic obstructive pulmonary disease (COPD). **METHODS:** A recent published study showed that tiotropium monotherapy enables a significant minimization of morbidity in two groups of patients corresponding to predicted FEV1 baseline values ≤ 50% (A) and > 50% (B). Clinical outcomes (days in hospital, visits in general ward, cycles of systemic steroids, cycles of antibiotics and maintenance therapy drugs) were evaluated from the Italian NHS perspective. In order to perform cost-effectiveness analysis, FEV1 value, available for each patient, was converted in SGRQ score using a published multivariate linear model; then utilities were obtained through the Ståhl equation. **RESULTS:** Results from comparison between 24 months of standard therapy and subsequent 24 months of tiotropium monotherapy show that hospitalization cost, which represents the driving treatment cost, drops from 74.1% to 67.3% (A) and from 64.5% to 31.6% (B) of the total cost; differently maintenance therapy cost increases but it is more than offset by the savings accruing from the shortening of hospitalization. Furthermore, cost-effectiveness results reveal a mean saving of 216 € (A) and 900 € (B) other than a mean gain of 0.07 QALY(A) and 0.03 QALY(B). Dominance of tiotropium calculated only with patients completing treatment course reveal that in almost 30% (A) and 37% (B) of subjects tiotropium strategy is dominant while only in 2% (A) and 7% (B) of cases are associated to costs increment and worsening on quality of life. **CONCLUSIONS:** These results suggest that adoption of tiotropium as unique treatment in selected mild-to-moderate and severe COPD patients yields significant costs savings and has a beneficial effect on evaluated quality of life.

PRS19

DOUBLING OF HEALTH CARE COSTS AMONG ASTHMA PATIENTS WITH COPD DIAGNOSIS AND ITS ASSOCIATED CO-MORBIDITIES IN A CLAIMS DATABASE IN THE UNITED STATES

Andersson M[1], Gerhardsson de Verdier M[1], Kern DM[2], Zhou S[2], Tunceli O[2], Hackett J[3], Ciaramella G[3], Butler S[3]

[1]*AstraZeneca, Mölndal, Sweden,* [2]*HealthCore, Inc., Wilmington, DE, USA,* [3]*AstraZeneca R&D, Waltham, MA, USA*

OBJECTIVES: To estimate health care costs for asthma patients with and without a COPD diagnosis. **METHODS:** Asthma patients with and without diagnosed COPD were selected from the HealthCore Integrated Research Database covering administrative claims from approximately 27.6 million people in the USA. The index event was a patient's first exacerbation defined as oral corticosteroid prescription fills or emergency department visits or inpatient visits with a primary diagnosis of asthma. Eligibility criteria were ≥1 asthma diagnosis, ≥1 exacerbation and 12 months of continuous health plan enrolment on each side of the index date. Total all-cause and asthma-related direct health care costs for 12 months before and after the index date were calculated for all patients and those with and without a COPD diagnosis. **RESULTS:** A total of 94,883 patients met all eligibility criteria, of these 15,127 (15.9%) had both asthma and COPD diagnoses. The mean patient age was 41.6 years and 62.4% were female. Co-morbid conditions were more common among asthma patients with a COPD diagnosis. Asthma-related direct costs represented 25-30% of all-cause direct health care costs for all patients. Among asthma patients, COPD and its associated co-morbidities roughly doubled all-cause and asthma related direct health care costs: mean annual pre-index all-cause health care costs were $20,012 (COPD diagnosis) versus $8,938 (no COPD diagnosis); mean annual pre-index asthma related costs were $5,623 (COPD diagnosis) versus $2,600 (no COPD diagnosis). Mean annual post-index costs were almost unchanged: all-cause costs of $21,692 (COPD diagnosis) versus $10,787 (no COPD diagnosis) and asthma-related costs of $5,242 (COPD diagnosis) versus $3,016 (no COPD diagnosis). **CONCLUSIONS:** The economic burden of asthma among patients with a COPD diagnosis in a US claims database is twice as high as those without a COPD diagnosis. Further research could adjust for the effects of age on the prevalence of co-morbidities among the different groups.

PRS20

THE IMPACT OF SMOKING ON HOSPITAL COSTS IN TIMES OF CRISIS; AN ADDITIONAL BURDEN TO THE VULNERABLE GREEK HEALTH CARE SYSTEM

Tsalapati K, Athanasakis K, Pavi E, Kyriopoulos J

National School of Public Health, Athens, Greece

OBJECTIVES: Smoking has a tremendous impact on public health and has been a cause of major concern in Greece for more than twenty years. In times of economic recession when household income drops and health spending is decreasing, the demand for health services is transferred to the public sector. In light of the above, the aim of this study was to measure the number of smoking-related hospitalizations and the additional hospital costs for the treatment of smoking-attributable diseases. **METHODS:** A prevalence-based disease specific approach was used for the calculations. Greek-specific smoking-attributable fractions (SAFs) were calculated for all smoking-related diseases, coded according to the International Classification of Diseases ICD-10. Smoking attributable morbidity was obtained by applying the SAFs to all public hospital admissions for 2011. Total hospital costs associated with smoking were calculated by applying the smoking-attributable admissions to each DRG rate. **RESULTS:** For Greece, lung cancer (C33-C34), bronchitis and emphysema (J40-J42, J43) presented the highest disease-specific SAF with a value of 88.4% and 88.1% respectively. In 2011, smoking was responsible for 199,028 hospital admissions (8.9 % of total). Smoking-attributable hospital costs, based on the current pricing DRG system, has reached 400,011,801€ representing 7.7% of public hospital budgets. Ischemic heart disease (I20-I25) was found to be the main cost driver (90.3 million €), followed by other circulatory diseases (I00-I09, I26-I51) (55.8 million€) and pneumonia, influenza (J10-J18) (52.6 million €). **CONCLUSIONS:** Despite evidence of a decreasing trend, smoking is still a considerable public health issue in Greece and has a great impact on public health care system. Vigorous efforts have been implemented to promote a smoke-free environment and to enforce existing anti-smoking legislation however the Greek society still experiences a high proportion of smoking-attributable admissions and hospital treatment costs. The findings of this study further corroborate a call for stronger support of cost-effective tobacco control policies.

PRS21

IMPACT OF CHRONIC PAIN ON HEALTH CARE COSTS IN CHRONIC OBSTRUCTIVE PULMONARY DISEASE AS COMPARED TO OTHER CHRONIC DISEASES

Mapel D, Roberts M, Von Worley A

Lovelace Clinic Foundation, Albuquerque, NM, USA

OBJECTIVES: Surveys have found high rates of pain medication use among COPD patients. However, few data exist on how chronic pain affects health care utilization. We examined how chronic pain affects direct medical costs in COPD and a matched cohort of patients with other chronic diseases. **METHODS:** We conducted a retrospective analysis using claims data from one managed care system. COPD patients were matched by age, sex, insurance type, and encounter type to persons with other chronic conditions but without COPD [Alzheimer's, atrial fibrillation, cancer, kidney disease, acute myocardial infarction, diabetes, heart failure, ischemic heart disease, rheumatoid/osteoarthritis (RA/OA), and stroke]. Chronic pain was indicated by pain-associated diagnoses, procedures for pain interventions, or prescription fills for pain medications. **RESULTS:** The study cohort (7,952 COPD patients, 15,904 non-COPD) was 58% female; mean age, 69. A higher percentage of COPD patients were chronic users of any pain medication (41.2% vs 31.5%, P<0.0001). The only

chronic disease with a greater use of pain medications was RA/OA (44.8% vs 41.2%, P<0.0001). COPD patients had more chronic use of short-acting opioids (24.2% vs. 15.1%, P<0.0001) and long-acting opioids (4.4% vs. 1.9%, P<0.0001). Among COPD patients, those with chronic pain had higher mean annual direct cost [$24,261 vs. $10,390 (p<0.0001)] which was largely attributable to increased hospitalizations (42.7% vs 25.4%, p<0.0001). By comparison, the mean total medical cost for the matched cohort was $17,681 for those with chronic pain compared to $6,543 for individuals without chronic pain (P<0.0001). Pain-related utilization was approximately 20% of COPD patients' annual direct cost. **CONCLUSIONS:** COPD patients have increased prevalence of and utilization for chronic pain as compared to all other chronic illnesses except RA/OA. Individuals with chronic disease and chronic pain have more than double the cost of those without chronic pain, and this difference is even higher among individuals with COPD.

PRS22

COSTS OF COPD IN FRANCE: A NATIONAL DATABASE ANALYSIS

Laurendeau C[1], Chouaid C[2], Roche N[3], Terrioux P[4], Gourmelen J[5], Detournay B[6]
[1]*Cemka-Eval, Bourg la Reine, France,* [2]*CHIC Créteil, Creteil, France,* [3]*APHP, Paris, France,* [4]*Cabinet de Pneumologie Meaux, Meaux, France,* [5]*INSERM, Villejuif, France,* [6]*Cemka, Bourg la Reine, France*

OBJECTIVES: To describe the direct costs to society of COPD per severity grades using the "Echantillon Generaliste de Beneficiaires"(EGB). EGB is a database which contains all health care resources used by a random 1/97 permanent sample of the French population covered by the national health care insurance system. **METHODS:** Several algorithms were developed to identify patients with COPD and to distinguish patients between four severity grades (1-4) based on health care consumption. These algorithms were based on age, rate and history of hospitalizations, treatments and tests received by the individuals. Exacerbations as well as their severity were identified through both antibiotics/corticosteroids drugs prescribed and hospitalizations. Total health care costs were calculated and a case-control approach was then used to estimate the cost of COPD. Exacerbations costs were calculated through a linear regression analysis including age and gender. **RESULTS:** Based on the 10,715 COPD patients identified in the EGB, its prevalence was estimated to 4.2% of the population beyond 40 years. The mean annual overall direct health care cost in this population was estimated to be €9,382. Annual average costs were €7,628; 10,770, 14,979 and 20,747 for severity grade 1-4 (severity data-base defined) respectively. The yearly cost of COPD itself was 5,516€: 45.5% related to hospital care and 20.0% to pharmaceuticals (6.0% to long-acting bronchodilators). The average exacerbation cost was €1,664 (SD: €86.6). The global economic burden of COPD in France was therefore estimated over €7 billions (4% of the national health care expense). **CONCLUSIONS:** Our study provides new solutions to estimate the burden of COPD in France using existing national databases. It confirms that COPD is associated with significant economic burden and the striking direct relationship between the cost of care and severity of the disease.

PRS23

HEALTH CARE RESOURCES UTILIZATION AND ASSOCIATED COSTS IN PATIENTS WITH COPD WITH OR WITHOUT ASTHMA: A RETROSPECTIVE, POPULATION-BASED OBSERVATIONAL STUDY

Sicras A[1], Ibañez J[2], Morejon E[3], Sanchez G[3], Lara N[4], Garcia-Losa M[5]
[1]*Hospital Municipal Badalona, Badalona. Barcelona, Spain,* [2]*Badalona Serveis Assistencials, Badalona, Barcelona, Spain,* [3]*GlaxoSmithKline, Tres Cantos (Madrid), Spain,* [4]*IMS Health, Barcelona, Spain,* [5]*IMS Health, Madrid, Spain*

OBJECTIVES: Chronic Obstructive Pulmonary Disease (COPD) is a highly prevalent chronic inflammatory disease. Some COPD patients show a co-diagnosis of asthma (COPD-A). This real-life observational study assessed the frequency of exacerbations, the use of health care resources and their associated costs in patients with COPD only and COPD-A. **METHODS:** Medical records from 6 Primary Care (PC) and one general hospital were reviewed and data from 2011 were collected from COPD and COPD-A patients aged 40 year or older who met specific inclusion/exclusion criteria. Main study variables were demography, co-morbidities, exacerbations and resources utilization. **RESULTS:** A total of 1210 COPD and 102 COPD-A, mean age (% male) 71.8 (85.5) and 71.2 (65.7) years, respectively, were included. Mean co-morbidity burden was similar in both groups with 7.9 and 7.8 diseases per patient. Most frequent co-morbidities (% in COPD; % in COPD-A) were dyslipidemia (63.0; 60.8) and arterial hypertension (59.5; 62.7) whereas the proportion of exacerbations (%) were 35.0 and 42.2, respectively. Mean number of exacerbations per patient per year was 1.2 in COPD and 1.6 in COPD-A. The frequency of severe exacerbations (%) requiring hospitalizations was 0.4 and 0.7, while those requiring oral corticosteroids was 24.4 and 33.0, respectively. Mean per patient, per year health care resources costs (Euro) were 2152.2 and 2207.5 for PC-associated costs, and 1361.6 and 1754.3 for specialist care-associated costs, respectively. **CONCLUSIONS:** Exacerbations are frequent complications in COPD and COPD-A patients. Both groups show high proportion of co-morbidities and use of health care resources which were higher in the COPD-A group. Health care-related costs are high and are mainly related to hospitalizations and drug therapy.

PRS24

ECONOMIC BURDEN IN DIRECT COSTS OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) IN TURKEY: A PAYOR PERSPECTIVE

Malhan S[1], Polatli M[2], Ozturk C[3], Oksuz E[1], Durgun B[4], Eray O[5], COPD Audit Group, Turkey[6]
[1]*Baskent University, Ankara, Turkey,* [2]*Adnan Menderes University, Aydýn, Turkey,* [3]*Gazi University, Ankara, Turkey,* [4]*GloxoSmithKline, Istanbul, Turkey,* [5]*GlaxoSmithKline, Istanbul, Turkey,* [6]*Adnan Menderes University, Aydin, Turkey*

OBJECTIVES: COPD has a major burden on Turkey's health care system. It leads to high mortality, morbidity and frequent use of health care resources. This study determined the total direct health care costs for the management of COPD patients with differing degrees of disease severity. The study also aimed to find the key cost drivers in the management of COPD in Turkey. **METHODS:** The methodology was based on a study conducted by European Respiratory Society in which Turkey and 11 other countries had been included. COPD patients were recorded from a territary care hospital in 2012. One-year costs were identified by applying cost data to medical information obtained by medical records. The cost analysis was based on cost of illness methodology. Costs included those for medications, laboratory and diagnostic tests, outpatient visits and hospital stays. **RESULTS:** There were 612 patients recruited. Patients were categorized by GOLD classification: 14.29% GOLDI, 15.28% GOLDII, 38.21% GOLDIII, 32.23% GOLD IV. The median of hospitalization day was 9 days. 36.1% of patients were rehospitalized in 90 days. The mortality rate was 3.1% because of exacerbation. The mean total direct costs was €4,135.60 per patient in a year. The total annual cost was correlated with disease severity. Hospitalization contributed the major portion of cost and also correlated with disease severity. The average outpatient cost was € 98.62, hospitalization cost including intervention was €1,548.56, laboratory and diagnostic tests cost were €103,03, comorbidity and complication cost were €1.493,88, medication cost with side effects were €903,59. **CONCLUSIONS:** There is a significant correlation between the cost of COPD and disease severity with hospitalization leading to disease exacerbation being a major contributor to cost. The keys to reducing health care costs lie beneath reducing the frequency of exacerbations and disease severity. As expected, the highest cost component was hospitalization, comorbidity and complication cost respectively.

PRS25

PAEDIATRIC TUBERCULOSIS - COSTS TO THE IRISH HEALTH CARE PAYER

Usher C[1], Adams R[1], Kieran J[2], Walsh C[2], Schmitz S[2], O'Donnell J[3], O'Flanagan D[3], Corcoran B[4], O'Meara M[5], Connolly K[6], Barry M[1]
[1]*National Centre for Pharmacoeconomics, Dublin, Ireland,* [2]*Trinity College Dublin, Dublin, Ireland,* [3]*Health Protection Surveillance Centre, Dublin 1, Ireland,* [4]*National Immunisation Office, Dublin 7, Ireland,* [5]*Department of Public Health, Dublin 1, Ireland,* [6]*National immunisation Advisory Committee, Dublin 1, Ireland*

OBJECTIVES: Ireland currently administers a universal BCG vaccination programme to infants. In order to assess the cost effectiveness of this programme, it is vital to have accurate cost estimates of the burden of tuberculosis (TB) illness in infants. The aim of the current study was to cost the diagnosis and treatment of an episode of the following health states; pulmonary TB, extrapulmonary TB, TB meningitis and latent TB, from the health care payer's perspective. The cost of contact tracing per primary case of TB was also estimated. **METHODS:** Decision trees were constructed to reflect typical episodes of care in the diagnosis and treatment of each health state. Resource use and unit cost data were applied to each node in the decision tree. The probabilities of events occurring were derived from the literature and expert clinical opinion. Main costs included were inpatient medical/surgical costs, pediatrician outpatient appointments, medications, laboratory tests and x-rays. Each health state included a cost for a Directly Observed Therapy programme. Direct medical costs were calculated and the 2012 price year was used. **RESULTS:** The direct medical costs of diagnosing and treating a case of pulmonary TB, extrapulmonary TB, TB meningitis and latent TB were estimated to be approximately €8153, €12224, €15752 and €894 respectively. The main drivers in the costs are the length of hospital stay and the number of pediatrician visits. The cost of contact tracing per primary case of TB was estimated to be approximately €4,248, which was based on a mean number of 9.4 contacts examined per primary TB case. **CONCLUSIONS:** To our knowledge this is the first investigation of costs associated with paediatric TB within the context of the Irish health care setting and will allow for a more robust estimation of the cost effectiveness of BCG vaccination programmes, which will benefit the health care payer.

PRS26

PHARMACOECONOMIC ASSESSMENT OF DIFFERENT TACTICS OF COPD TREATMENT IN RUSSIA

Belevskiy AS
Russian Scientific Research Medical University named Pirogov, Moscow, Russia

OBJECTIVES: Comparative pharmacoeconomic assessment of COPD therapy of patients in GOLD 2-3 stages in Moscow health care system. **METHODS:** Retrospective analysis of 130 cases during 1 year routine practice of patients with COPD in Moscow outpatients departments. Basic therapy strategies were obtaned: 1) monotherapy with indacaterol (14 pts. Low # of pts is because of the product was launched less than year ago); 2) monotherapy by tiotropium (33 pts), 3) fixed combination LABA + ICS (38 pts); 4) tiotropium plus fixed combination of LABA and ICS (45 pts). Cost of illness via calculation of direct medical costs on diagnostic, hospitalization, treatment of main disease and complications based on Federal Standards of COPD treatment and regional tariffs on cervices was estimated. Data on prices on medical products were obtained from State Register of medical products and www.aptechka.ru. **RESULTS:** The most expencive strategy is management of group 4 - 86.5 KRUR/pt/year (1 Euro - 40 RUR) where 67% are costs on base drugs and 31% are hospitalization expenses. Usage of fixed combinations LABA + ICS is comparable with monotherapy by tiotropium, total costs are 47 and 49 KRUR/pt/year accordingly. But if the reason of main part of the costs in group 3 is hospitalization due to exacerbation - 69%, for group 2 - 61% are expenditures on tiotropium. The most preferable is treatment of group 1 - 32847 RUR/pt/year, where 55% - part on indacaterol, 42% - hospital treatment, 3% - urgent care. **CONCLUSIONS:** In spite of high price, indacaterol is the most economic preferable product for basic COPD treatment of patients in GOLD 2-3 stages

PRS27

PREDICTING HEALTH CARE COSTS IN ASTHMA USING THE EQ-5D INDEX SCORE

Gu NY[1], Raisch DW[2], Wu J[3], Gai Y[4], Hay JW[3]
[1]*University of New Mexico, Albuquerque, NM, USA,* [2]*University of New Mexico College of Pharmacy, Albuquerque, NM, USA,* [3]*University of Southern California, Los Angeles, CA, USA,* [4]*Babson College, Babson Park, MA, USA*

OBJECTIVES: To predict health care costs in asthma using the EQ-5D health-related quality-of-life (HRQoL) index score. **METHODS:** We extracted data from the 2000-03 Medical Expenditure Panel Survey (MEPS) on adult respondents who had EQ-5D index scores. Asthma patients were identified using ICD-9 (=493) and self-report on disease (n=3,783). To account for non-random selection of positive spending, the

Heckman two-step selection model was used. The EQ-5D index score was categorized into categories with 0.1 gradations. Marginal effects (ME) were estimated to quantify the marginal changes in costs corresponding to, for instance, 0.1 increments in the EQ-5D index score, or the presence of asthma or asthma treatment. All costs were adjusted to 2003 dollars. **RESULTS:** The EQ-5D index score was a significant predictor of health care costs in all models, as were asthma, asthma treatment and other covariates ($p<0.01$). The Heckman model suggested a significant positive spending bias ($p<0.01$). For the 3 groups considered--non-asthma, asthma and asthma with treatment--the mean EQ-5D index scores were 0.848, 0.755 and 0.706, respectively. The actual mean costs were $2,355, $4,284 and $5,577, respectively. The predicted mean costs using Heckman model were $2,673, $4,431 and $5,618, respectively. On average, a 0.1 unit improvement in EQ-5D score was associated with $502 cost reduction in asthma and $693 cost reduction if asthma patients had treatment ($p<0.01$). However, after adjusting for positive spending bias, the cost reduction was $891 and $961 ($p<0.01$) for these two groups respectively. Greater cost reductions were associated with improving EQ-5D scores at the lower end (<0 to 0.3) and the mid-range (0.5 to 0.7). **CONCLUSIONS:** HRQoL is an important component of health care resource utilization. The findings suggest a significant relationship exists between health care costs and HRQoL data. The EQ-5D significantly predicts costs in asthma and asthma treatment, especially after adjusting non-random positive health care spending.

PRS28

EFFECT OF SMOKING STATUS ON HEALTH CARE COSTS AND RESOURCE UTILIZATION IN PATIENTS WITH CHRONIC-OBSTRUCTIVE-PULMONARY-DISEASE IN CLINICAL PRACTICE: A RETROSPECTIVE NESTED CASE-CONTROL ECONOMIC STUDY

Sicras-Mainar A[1], Rejas J[2], Navarro-Artieda R[3], Ibañez J[4]
[1]*Badalona Serveis Assistencials, Badalona, Spain,* [2]*Pfizer S.L.U., Alcobendas/Madrid, Spain,* [3]*Hospital Universitari Germans Trias i Pujol, Badalona, Barcelona, Spain,* [4]*Badalona Serveis Assistencials, Badalona, Barcelona, Spain*

OBJECTIVES: Chronic-Obstructive-Pulmonary-Disease (COPD) is a prevalent health condition mainly associated with smoking habit, which is considered the reason for higher health care resources utilization and related costs in the National health System. The aim of this study was to analyze and compare health care resource utilization and costs according to smoking status in patients with COPD in clinical practice in Spain. **METHODS:** A retrospective cohort nested case-control study was designed. Cases were current smokers, while two controls (former smokers) per case matched for age, sex, duration of COPD, and burden of comorbidity (number of diagnosis and Charlson index) were included using data from medical records. Non-institutionalized COPD, both genders, 40 years of age and older, seen consecutively over a period of 4 years before the index date and fulfilling eligibility criteria were considered eligible for analysis. Analysis used regression and general linear models with covariates to compare direct and indirect costs and resource utilization. **RESULTS:** A total of 930 COPD medical records were analyzed: 310 corresponding to cases (current smokers) and 630 to controls (former smokers). Mean age was 69.4 years (84.6% male). COPD was more severe in cases; Odds ratio (OR)=1.7 (95% CI 1.1;2.1), and higher percentage of current smokers had exacerbations [OR=2,7 (2.0;3.8)], with 4.2 vs. 1.7 exacerbations per year, respectively, on average ($p<0.001$). Smokers used more physicians visits both at primary care and specialized level, and emergency room as well. Drugs-based therapies were more common in current smokers COPD subjects. As a consequence, smokers had higher average annual health care costs; €3,784 (1,888) vs. €2,302 (2,451) in former smokers ($p<0.001$). **CONCLUSIONS:** COPD smoker patients had more exacerbations and higher severity of disease. Also, used more health care resources, particularly physicians visits and drugs-based therapies resulting in higher health care costs to the national health System.

PRS29

COSTS AND EFFECTIVENESS OF NON-SMOKING CLINIC

Laine J
Pfizer Oy, Helsinki, Finland

OBJECTIVES: In Finland a new Tobacco Act entered into force in October 2010 with the aim of limiting marketing and supply of tobacco products. The long-term objective of the Finnish government is to make Finland tobacco-free by 2040. Several work places and organizations have declared themselves non-smoking. The city of Mikkeli with a population of 55 000, has declared itself a non-smoking city and has established a non-smoking clinic in September 2011. Citizens contacting public health care and willing to quit smoking will be referred to the clinic. **METHODS:** Cross-sectional data was gathered 12 months after the establishment of the clinic. Costs related to investment and clinic's resource utilization were estimated. A health care perspective was applied. **RESULTS:** We studied 74 citizens, who had a least one visit during the first year since the establishment of the clinic. Of them 37% managed to quit smoking. Investment costs related to planning and training of nurses were 168€ per quitter. Operational costs were 141-167€ per quitter. Total costs per quitter were 309-335€. In the future investment costs per customer will decrease as investment costs were nonrecurring. **CONCLUSIONS:** Our results were slightly better than what was achieved in an occupational health care non-smoking project in Finland (37% vs. 31%). In 2010 the average total costs of occupational health care were 340€ per employee in Finland. This is almost the same as the costs per quitter in this study. Cost of cigarettes is about 1800€ per average smoker in Finland. Health care costs related to lung cancer and stroke are about 18500€ per case during the first year. Pharmacological treatment costs about 200-400€ to quitter in average. Investing in smoking clinic is justified from economic and effectiveness point of views. The non-smoking clinic is still in operation.

THE LIST OF MEDICINES FOR COPD TREATMENT IN STATE FORMULARY OF UKRAINE AND RELATED COSTS

Tolubaiev V, Zalis'ka O, Kacheray Y
Danylo Halytsky Luviv National Medical University, Lviv, Ukraine

OBJECTIVES: According to the GOLD-2011 report pharmacotherapy in stable COPD is used to reduce the symptoms, frequency and severity of exacerbations, improve health status and exercise tolerance. **METHODS:** Our aim was to assess the list of medicines, which are available in Ukraine for COPD treatment. We compared the medications included in the State Formulary of Ukraine with the dosage forms and typical doses of COPD medications list provided by GOLD-2011. Also we calculated annual course costs for each drug in different dosage forms. The annual course was considered as amount of medicine for 365 days in appropriate for COPD basis dosing. Information about the medicine prices was obtained from the ukrainian electronic pricing database "MORION". The EUR/UAH exchange rate was 1 EUR = 10.53 UAH (20.06.2013) **RESULTS:** The State Formulary of Ukraine (SFU) contains 19 medicines for INN provided by GOLD-2011: 5 INN are in metered dose inhalers (MDI), 5 - in dry powder inhalers (DPI), 1 - in smart mist inhaler (SMI), 5 solutions for nebulizer and 3 - in tablets. Salbutamol, salmeterol, indacaterol, fluticasone, beclomethasone in DPI are not included in the list of SFU, formoterol in MDI and aminophylline, prednisone in tablets are not included in this list as well. The most expensive drug is tiotropium with annual costs 604.46 EUR for SMI and 533.81 EUR for DPI. The annual costs of salmeterol in MDI and formoterol in DPI are 318.55 and 277.30, respectively. The cheapest medicine is salbutamol in MDI with 22.13 EUR annually but annual costs of salbutamol solution for nebulizer amount 464.48 EUR per year per patient. **CONCLUSIONS:** The State Formulary of Ukraine should be reached by medicines for COPD management recommended by GOLD. Annual COPD basis costs are depending not only from kind of medicine but from it dosage forms as well.

PRS31

COMPARING COSTS AND CONSEQUENCES OF TREATING CHRONIC OBSTRUCTIVE PULMONARY DISEASE WITH BUDESONIDE/FORMOTEROL AND FLUTICASONE/SALMETEROL

Roggeri A[1], Pantaleoni M[2], Pasina C[2], Inzillo V[2], Roggeri DP[1]
[1]*ProCure Solutions sas, Nembro (Bergamo), Italy,* [2]*AstraZeneca Italia, Basiglio (MI), Italy*

OBJECTIVES: Inhaled corticosteroids in fixed combination with long-acting B_2-agonists could prevent and reduce chronic obstructive pulmonary disease (COPD) exacerbations. The aim of this analysis is to compare clinical consequences and direct health care costs related to treatment with budesonide/formoterol and fluticasone/salmeterol for COPD considering the Italian National Health Service (INHS) perspective. **METHODS:** Effectiveness data by the PATHOS study, a population-based, retrospective, observational registry study conducted in Sweden, in terms of reduction in COPD hospitalizations and COPD-related emergency departments (ED) visits were considered in order to estimate the differences in resource consumption between patients treated with budesonide/formoterol versus fluticasone/salmeterol. Base case considers the dosages of the 2 drugs from the PATHOS study, the cost of drugs in charge to INHS, COPD hospitalizations costs from Italian real world data and Italian national tariffs for COPD-related ED visits. **RESULTS:** The real world study PATHOS demonstrated a significant reduction in COPD hospitalizations and COPD-related ED visits with budesonide/formoterol versus fluticasone/salmeterol (-29.1% and -21%, respectively); average dosages reported were 568 mcg/day for budesonide/formoterol (as budesonide dosage) and 783 mcg/day for fluticasone/salmeterol (as fluticasone dosage). In the base case, the treatment for 1 year of 100 patients with budesonide/formoterol lead to a saving of 43.892€ (21.859€ for drugs, 21.864€ for COPD hospitalizations and 169€ for COPD-related ED visits) corresponding to -25.2% compared with fluticasone/salmeterol treatment. In the most conservative sensitivity analysis which consider the DDD dosages for the 2 drugs and COPD hospitalizations and COPD-related ED visits costs from national tariffs, the treatment for 1 year of 100 patients with budesonide/formoterol lead to a saving of 15.523€ (5.754€ for drugs, 9.600€ for COPD hospitalizations and 169€ for COPD-related ED visits) corresponding to -12.5% compared with fluticasone/salmeterol treatment. **CONCLUSIONS:** Treatment with budesonide/formoterol compared to fluticasone/salmeterol could lead to a reduction in direct health care costs with relevant improvement in clinical outcomes.

PRS32

UPDATE ON PHARMACOECONOMICS IN NUTRITION: PARENTERAL GLUTAMINE SUPPLEMENT IN INTENSIVE CARE UNIT PATIENTS

Povero M[1], Zaniolo O[1], Muscaritoli M[2], Eandi M[3]
[1]*AdRes HE&OR, Turin, Italy,* [2]*University La Sapienza, Roma, Italy,* [3]*University of Torino, Torino, Italy*

OBJECTIVES: To re-evaluate the economic consequences of parenteral glutamine supplementation (PGS) in light of the recent metaanalysis confirming that PGS at a dose >0,20 g/kg body weight per day in intensive care unit (ICU) patients is associated with reduced mortality, infection rate (IR) and length of stay (LOS). **METHODS:** A simulation model was updated with the new meta-analysis data and clinical inputs for the control group from Italian ICU population reported in "Progetto Margherita". Costs are evaluated from the perspective of the Italian hospital and derive from official sources. Sensitivity analyses are undertaken to test results' reliability **RESULTS:** PGS is predicted to reduce mortality rates (-29.0%), IR (-21.2%) and overall LOS (-1.07 days/patient), yielding a saving of € 1,047 per patient treated. Treatment costs are completely offset by the reduction in hospital stay costs and antibiotic costs. Probabilistic sensitivity analysis indicates PGS strategy as dominant in more than 90% of cases. **CONCLUSIONS:** Also with contemporary comparative efficacy data is PGS in ICU patients expected to be effective in improving outcomes and containing costs in Italian hospitals providing intensive care.

PRS33

COST-EFFECTIVENESS OF GLYCOPYRRONIUM COMPARED TO TIOTROPIUM IN COPD PATIENTS FROM A SWEDISH SOCIETAL PERSPECTIVE

Costa-Scharplatz M[1], Tambour M[1], Henriksson F[1], Ställberg B[2]
[1]*Novartis, Täby, Sweden,* [2]*Uppsala University, Uppsala, Sweden*

OBJECTIVES: To estimate the cost-effectiveness of a novel LAMA, glycopyrronium (Seebri® Breezhaler), compared with tiotropium (Spiriva®) in COPD patients from a Swedish societal perspective. **METHODS:** A probabilistic Markov model was utilized to

simulate the progressive course of COPD and its impact on quality adjusted life years (QALYs) in moderate to severe patients. Effectiveness was based on initial FEV1 increase included by using patient level improvement in one or more disease severity stages (according to GOLD guidelines) and annualized risk for exacerbation as observed in a 1-year head-to-head randomized controlled trial (GLOW2). Initial FEV1 increase during the first year was followed by a constant decline in FEV1 in subsequent cycles. Based on list prices, annual drug costs were 3'825 Swedish krona (SEK)/447 EUR for glycopyrronium and 5'040 SEK/589EUR for tiotropium. Direct and indirect maintenance and exacerbation costs as well as utilities were extracted from published literature. Primary outcomes were QALYs and societal costs over 3 years, discounting future costs and benefits at 3%. Both one way and probabilistic sensitivity analysis have been performed. **RESULTS:** Over 3 years, glycopyrronium was found to be dominant (i.e. less costly and more effective) compared with tiotropium. Treatment with glycopyrronium resulted in a minor QALY gain of 0.005 compared with tiotropium. Total costs per patient were estimated at 73'752SEK / 8'630 EUR for glycopyrronium and 79'357 SEK /9'286 EUR for tiotropium, resulting in an average cost saving of 5'605SEK /656 EUR per patient after 3 years. Univariate sensitivity analyses showed that base-case results were robust and probabilistic sensitivity analyses resulted in 99% of generated samples with glycopyrronium to be dominant. **CONCLUSIONS:** From a Swedish societal perspective, glycopyrronium was estimated to be cost-effective compared with tiotropium based on the progressive course of COPD and risk for exacerbation in moderate to severe patients as observed in the head-to-head study GLOW2.

PRS34

COST-EFFECTIVENESS ANALYSIS OF CARBAPENEMS IN TREATMENT NOSOCOMIAN PNEUMONIA IN UKRAINE

Iakovlieva L[1], Bezditko N[1], Glumcher F[2], Dubrov F[2]
[1]*National University of Pharmacy, Kharkiv, Ukraine,* [2]*O.O. Bogomolets National Medical University, Kyiv, Ukraine*

OBJECTIVES: To conduct a cost-effectiveness analysis of carbapenems use (imipenem, meropenem, and doripenem) in treatment nosocomial pneumonia. **METHODS:** Cost-effectiveness analysis based on decision-tree model was conducted from patient's (out-of-pocket drugs costs) and state (drugs costs and hospitalization expenses) perspectives. The input data on therapy duration and drugs' doses were retrieved from randomized controlled trials and clinical standards. The drugs doses were equal to: 2.0g /day from imipenem/cilastatin, 3.0g /day for meropenem, and 1.5g/day for doripenem. The model considered that in the case of drugs effectiveness the treatment continued till successful outcome, and in a case of non-effective treatment, the second line therapy (vancomycin or colomycin depending on type of infection) was applied. The data on infections resistance and empirical effectiveness of antibiotics were retrieved from the largest microbiologic study conducted in Ukraine. **RESULTS:** The lowest cost- effectiveness ratio correspond to the initial therapy with imipenem/cilastatin (CER 910$/1158$ vs. 1280$/1648$ for meropenem and 1317$/1712$ for doripenem from state and patient's perspectives accordingly). **CONCLUSIONS:** Thus, empiric therapy with meropenem increases the costs of medical treatment by 29 %, with doripenem – by over 35 %. Sensitivity analysis of the results of calculations versus changes of level of MRSA-resistant and carbapenem-resistant strains demonstrated reliability of the received results.

PRS35

COST-EFFECTIVENESS ANALYSIS OF PALIVIZUMAB AS A PROPHYLAXIS FOR RESPIRATORY SYNCYTIAL VIRUS (RSV) INFECTION IN HIGH-RISK LATE PRETERM INFANTS IN THE NETHERLANDS

Langenfeld MK, Visser S
AbbVie BV, Hoofddorp, The Netherlands

OBJECTIVES: To determine the cost-effectiveness of palivizumab for the prevention of serious lower respiratory tract infection requiring hospitalization caused by RSV compared to no prophylaxis in high-risk infants born at 33-35 weeks of gestational age (wGA) according to the Dutch RISK model. **METHODS:** A decision tree model was developed using data from published literature, palivizumab clinical trials, the Dutch RISK score model, official price/tariff lists and Dutch national population statistic. The comparator was no prophylaxis. The primary perspective of the study was that of the society in The Netherlands. Time horizon was lifetime. The cost valuation is based on the direct health care costs, direct nonmedical costs and indirect costs. Costs were assessed in 2012 Euros. The costs and utilities are discounted by 4% and 1.5%, respectively, from the second year onwards, and no discounting is applied in the first year. **RESULTS:** The base case results show that the use of palivizumab leads to an additional cost of € 4,116, whereas the use of palivizumab leads to a gain of 0.201 life years and 0.265 QALYs. Although the use of palivizumab increases the costs compared with no prophylaxis, palivizumab-treated patients experienced more QALYs and a gain in life years. Subsequently, palivizumab results in an ICER of € 15,520 per QALY gained compared to no prophylaxis. The ICER in cost per LYG is € 20,440. **CONCLUSIONS:** This analysis showed that palivizumab was cost-effective as a prophylaxis against RSV infection requiring hospitalisation in high-risk late premature infants compared to no prophylaxis. Extensive sensitivity analyses and explored scenarios underline the robustness of the demonstrated base case cost-effectiveness.

PRS36

COST-EFFECTIVENESS ANALYSIS OF GLYCOPYRRONIUM BROMIDE IN THE TREATMENT OF CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN SPAIN

Torres C[1], Betoret I[2], Sabater E[1], Figueras M[2], Casado MA[1]
[1]*Pharmacoeconomics & Outcomes Research Iberia, Madrid, Spain,* [2]*Novartis, Barcelona, Spain*

OBJECTIVES: To assess the cost-effectiveness and cost-utility of glycopyrronium bromide versus tiotropium bromide in Chronic Obstructive Pulmonary Disease (COPD) patients, from the Spanish National Health System perspective. **METHODS:** A Markov model was developed to compare glycopyrronium bromide and tiotropium therapies. Progression of a COPD patient cohort was simulated for a 5-year time horizon (3 months-cycle duration). The health states included were defined according to the severity of COPD: mild, moderate, severe, very severe and death (absorbent). Three additional sub-states: without exacerbation, mild and severe exacerbation were considered. The effectiveness of treatment options and utilities for each health state were taken from the literature. Only direct health care costs were considered. Disease management and exacerbation costs were obtained from the literature. Drug costs were calculated based on ex-factory prices with mandatory 7.5% rebate. All costs were updated to €2012. A 3% annual discount rate on costs and health outcomes was applied. Incremental ratios in terms of cost per life-year gained (LYG) and cost per quality-adjusted life-year gained (QALY) of the most effective therapy versus the comparator were calculated. One-way sensitivity analyses were performed modifying the following parameters: time horizon (10 years, lifetime), discount rate (0%, 5%), drug costs (±10%, ±20%) and utilities (±10%). Probabilistic sensitivity analysis (PSA) was also performed. **RESULTS:** At 5 years, glycopyrronium bromide accounted a total cost of €2,225.18 compared to €2,374.81 accounted for tiotropium bromide. Glycopyrronium bromide yielded higher health benefits (4,321 LYG and 3,388 QALY) than tiotropium bromide (4,315 LYG and 3,377 QALY). In all one-way sensitivity analyses performed and in 100% of PSA simulations (1,000 iterations), glycopyrronium bromide compared to tiotropium bromide remained as a dominant strategy. **CONCLUSIONS:** Glycopyrronium bromide therapy in COPD patients is associated to less costs and higher health benefits than tiotropium in Spain.

PRS37

INHALED CORTICOSTEROIDS (ICS) IN TREATMENT OF MODERATE AND SEVERE ASTHMA IN RUSSIAN FEDERATION – COMPARATIVE PHARMACOECONOMIC STUDY

Krysanov I, Tyapkina M
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: We conducted this pharmacoeconomic study to compare mometasone furoate (M/F), fluticasone propionate (F/P) and budesonide (BUD) in treatment of moderate and severe asthma. **METHODS:** Initially we conducted indirect comparison of efficacy and safety of studied therapies through the review of clinical data publications. We used cost minimization and cost effectiveness analysis for the pharmacoeconomic research. In the study we considered the direct costs of the three ICS and additional costs of β2-adregenic agonist (salbutamol). We made calculations of costs for the most common treatment regimens in Russia: M/F 400 µg 1 dose once a day and F/P 125 µg 2 doses twice a day; M/F 400 µg 1 dose twice a day and F/P 250 µg 2 doses twice a day; M/F 200 µg, 400 µg 1 dose twice a day and BUD 200 µg 2 doses twice a day. **RESULTS:** The review of clinical data demonstrated that M/F has similar efficacy to F/P and superior efficacy to BUD. The three ICS have similar safety profile. Use of M/F presents 10105 RUR (316 USD) in direct annual per patient costs for the treatment of moderate asthma and 20210 RUR (632 USD) for severe asthma. Cost minimization analysis showed, that the considered treatment regimens of M/F are cost effective compared to F/P 125 µg and 250 µg. M/F will save the health care system 28 to 50 USD per patient annually, though these results are price sensitive. Cost effectiveness analysis demonstrated that M/F has favorable CER compared to BUD: for 1% of FEV1 increase M/F 200 µg is 12 USD, M/F 400 µg is 24 USD and BUD is 32 USD. These results are insignificantly price sensitive. **CONCLUSIONS:** M/F is the most cost effective of the three ICS as demonstrated by the results of cost minimization and cost effectiveness analyses.

PRS38

THE COST-EFFECTIVENESS OF DRY POWDER ANTIBIOTICS FOR THE TREATMENT OF PSEUDOMONAS AERUGINOSA IN PATIENTS WITH CYSTIC FIBROSIS

Tappenden P[1], Harnan S[1], Uttley L[1], Mildred M[1], Taylor CJ[2], Brownlee K[3], Walshaw M[4]
[1]*University of Sheffield, Sheffield, UK,* [2]*Sheffield Children's NHS Foundation Trust, Sheffield, UK,* [3]*Leeds Children's Hospital, Leeds General Infirmary, Leeds, UK,* [4]*Liverpool Heart and Chest Hospital NHS Foundation Trust, Liverpool, UK*

OBJECTIVES: To evaluate the cost-effectiveness of colistimethate sodium dry powder for inhalation (DPI) and tobramycin DPI versus nebulised tobramycin for the treatment of Pseudomonas aeruginosalung infection in patients with cystic fibrosis. **METHODS:** We developed a state transition model based on transitions between strata of lung function measured in terms of Forced Expiratory Volume in 1 Second (FEV_1) % predicted. Health states representing post-lung transplantation and dead are also modelled. The model was informed by systematic reviews of evidence concerning potential relationships between intermediate and final outcomes. The model assumes that treatment impacts on FEV_1which manifests as changes in health-related quality of life. No survival benefit is assumed due to the absence of robust evidence. Model parameters were informed by two RCTs and best available evidence from the literature. Resource costs associated with drug acquisition, management of exacerbations and nebuliser maintenance were drawn from reference sources and expert opinion. Additional analyses of Patient Access Scheme (PAS) price discounts offered by the manufacturers of both DPI products were also undertaken. **RESULTS:** Colistimethate sodium DPI is expected to produce fewer QALYs than nebulised tobramycin. Based on its list price, nebulised tobramycin is expected to dominate colistimethate sodium DPI. When the PAS is incorporated, the ICER for colistimethate sodium DPI versus nebulised tobramycin is expected to be approximately £288,600 saved per QALY lost. Based on its list price, the ICER for tobramycin DPI versus nebulised tobramycin is expected to be approximately £124,000 per QALY gained. When the proposed PAS is included, tobramycin DPI is expected to dominate nebulised tobramycin. **CONCLUSIONS:** Under their list prices, neither DPI product is likely to represent good value for money given current UK cost-effectiveness thresholds. The price discounts significantly improve the economic attractiveness of both products. The cost-effectiveness of the DPIs against other nebulised antibiotics remains unclear.

PRS39

EMPIRICAL THERAPY FOR RESPIRATORY TRACT INFECTIONS IN AN ERA OF INCREASING ANTIMICROBIAL RESISTANCE: A DECISION AND COST ANALYSIS

Babela R
St. Elisabeth University, BRATISLAVA, Slovak Republic

OBJECTIVES: To analyze the costs of macrolides use compared to cephalosporines for treatment of Acute Bacterial Sinusitis (ABSs) in the era of increasing resistance to *Streptococcus pneumoniae*. **METHODS:** We used a decision analysis model (TreeAge Pro 2013) to perform a cost-minimization and sensitivity analysis to determine what level of macrolide resistance in a community would trigger cephalosporine use. Costs and clinical outcomes of ABSs were extracted from a systematic review of the literature and official local databases. Clinical response was derived from prospective clinical trials, investigations and from clinical experts experience, were we had ≤1 source. **RESULTS:** We have found that the mean cost of empirical treatment with macrolides for ABSs was 79 EUR when community *S. pneumoniae* resistance was at 0%; 77 EUR at 10%; 82 EUR at 20% and 88 EUR at 30%. Cephalosporines were found to be cost-minimizing when the prevalence of macrolide resistance to *S. pneumoniae* exceeded 15%. Sensitivity analysis variables that had a significant impact on our cost-minimization threshold included proportion of macrolide resistance to *S. pneumoniae*, cost of antibiotics and probabilities of clinical cure with antibiotics. **CONCLUSIONS:** We believe we have performed the first cost-based model and sensitivity analysis to determine what level of macrolide resistance in the community could trigger a switch of empirical therapy for ABSs from macrolides to cephalosporines in Slovakia. Our investigation is to our knowledge also locally the first to employ decision analysis to explore the relationship between antimicrobial resistance and clinical decision making in ABSs. From a payer perspective, cephalosporines appears to be a reasonable alternative to macrolides for empirical treatment of ABSs, especially given the current prevalence of macrolides resistance among *S. pneumoniae* in community that reached 30% level, nationwide.

PRS40

ECONOMIC EVALUATION OF MANDIBULAR ADVANCEMENT DEVICE TO TREAT OBSTRUCTIVE SLEEP APNEA

Giannopoulou A[1], Burgers LT[1], van Bruggen MPB[2], de Vries N[3], Redekop WK[1], Rijnsburger A[1]

[1]*Erasmus University Rotterdam, Rotterdam, The Netherlands,* [2]*Philips Research Europe, Eindhoven, The Netherlands,* [3]*St. Lucas Andreas Hospital, Amsterdam, The Netherlands*

OBJECTIVES: In the treatment of obstructive sleep apnea/hyoponea syndrome (OSAHS) moderate patients are primarily offered Continuous Positive Airway Pressure (CPAP). This study aims to assess the cost-effectiveness of mandibular advancement device (MAD), a commonly suggested alternative, as compared to CPAP for moderate OSAHS patients in The Netherlands. **METHODS:** The prognosis of a hypothetical cohort of 50-year-old patients with moderate OSAHS was simulated with a Markov model to estimate the costs and quality-adjusted life-years (QALYs) for both CPAP and MAD. A distinctive factor incorporated in the model was switch of therapy. All input parameters, including the risks of experiencing myocardial infarction, stroke and motor vehicle crashes (MVC) were based on literature and clinical expert opinion. Costs and effects were estimated over a 5-year time horizon using a health care provider perspective and were discounted at a rate of 4% and 1.5%, respectively. Robustness of the results was investigated with several sensitivity and scenario analyses. **RESULTS:** Compared with CPAP, MAD is less expensive (€4,511 vs. €5,302) and only slightly less effective (3.44 vs. 3.49 QALYs) resulting in an incremental cost-effectiveness ratio (ICER) of €15,393 saved per QALY lost. The most influential parameter was the cost of MAD device and its titration. Quality-of-life values, compliance rates, costs and the probabilities of switching treatment, cardiovascular events and MVC were varied in the scenario analyses. Under the majority of the scenarios MAD remained less cost-effective compared to CPAP. **CONCLUSIONS:** Over a 5-year time horizon, MAD therapy may be considered not cost-effective in the treatment of moderate OSAHS patients in The Netherlands. Further research on the impact of both treatments on long-term risks and improvement in the quality of life is required. Similarly, more long-term studies using a uniform compliance definition are needed to inform future cost-effectiveness analyses.

PRS41

INTEGRATING THE LONG-TERM HEALTH BURDEN OF ORAL CORTICOSTEROIDS IN THE COST-EFFECTIVENESS OF OMALIZUMAB

Faria R, McKenna C

University of York, York, UK

OBJECTIVES: Omalizumab offers an alternative to maintenance oral corticosteroids (OCS) in the treatment of severe persistent asthma. Despite widespread recognition of the adverse effects from OCS, there is little quantitative evidence on their health burden or costs. Failing to account for the adverse effects of OCS may underestimate the cost-effectiveness of innovative steroid-sparing medicines such as omalizumab. This study aims to explore the possibilities for integrating evidence on the burden of OCS in cost-effectiveness analysis using omalizumab as a case study. **METHODS:** A model was developed to evaluate the long-term cost-effectiveness of omalizumab in patients requiring maintenance OCS. Costs were from a health service perspective and outcomes were measured as quality-adjusted life years (QALYs). The burden from maintenance use of OCS was quantified with population-based approach, with a decision model and with threshold analysis. **RESULTS:** The incremental cost-effectiveness ratio (ICER) was £37,987 per QALY gained, which is above conventional thresholds used in the UK. Threshold analysis showed that the annual health losses from maintenance use of oral corticosteroids would need to be 0.12 QALYs per year. This is double the quantifiable health losses with the population-based approach and with the decision model and 10% of the health gains achieved with omalizumab. **CONCLUSIONS:** The burden from maintenance OCS can be integrated in cost-effectiveness analysis but the extent to which these estimates account for their full impact on health depends on the approach used and underlying assumptions. The challenges arise from sparse randomised evidence, time lag in the adverse effects and unclear relationship between risk and long-term steroid load. These are empirical questions which can be answered with further research. Such research would be valuable not only for decision making in severe asthma but also for other conditions treated with maintenance OCS.

PRS42

ECONOMIC IMPACT OF A SMOKING CESSATION PROGRAM IN MEXICO: ENROLLING EMPLOYEES AND EMPLOYERS

Huicochea-Bartelt JL, Muciño-Ortega E, Hernandez-Reyes FC

Pfizer S.A. de C.V., Ciudad de México, Mexico

BACKGROUND: Smoking costs at work affect both employers and employees. These costs are a result of a combined loss of productivity, time off work due to illness, smoking breaks and increasing insurance costs. **OBJECTIVES:** This study aims to evaluate the economical impact of a 12 week smoking cessation program with varenicline from an employer perspective in a medium size Mexican-Corporate setting. **METHODS:** A decision tree was built in order to estimate the two endpoints of the program: resource used in terms of costs and productivity gains in labor hours, in a three year horizon. Smokers enrolling in the program were assumed to be the proportion of people who reported being very much indeed interested on quitting smoking in a 2005 UK survey (27%). A promotional cost of a 12 week combo-pack of varenicline was provided by the manufacturer. A literature review was performed in order to obtain smoking specific data of the country and response rates. Labor costs were retrieved from the Mexican National Institute of Statistics and Geography (INEGI). A base scenario of a medium sized company (250 employees) was assumed to show the potential benefits of the program. **RESULTS:** Assuming a 250 employees company and a shared proportion of 50% of the costs of the program between employees and employers, companies would have to invest US$178 per employee only at the first year, and have potential savings of US$228 for each of them after 3 years. At the same circumstances the net productivity gains per programme participant would be in an amount of 70.8 hours. **CONCLUSIONS:** This research showed that if mexican employers invest in a smoking cessation program, significant productivity gains and savings could be reached in a 3 year horizon.

THE RELATIONSHIP BETWEEN TREATMENT SATISFACTION AND ADHERENCE IN COPD PATIENTS IN 5 COUNTRIES

Vietri J[1], Isherwood G[2]

[1]*Kantar Health, Milan, Italy,* [2]*Kantar Health, Epsom, Surrey, UK*

OBJECTIVES: To assess the relationship between treatment satisfaction and adherence in chronic obstructive pulmonary disease (COPD) in European patients, and whether the strength of this relationship varies according to country. **METHODS:** Data were taken from the 5EU (France, Germany, Italy, Spain, and UK) 2011 National Health and Wellness Survey (NHWS), a cross-sectional survey representative of the total adult populations in each 5EU country. The current analysis included all respondents taking one or two treatments for COPD (including chronic bronchitis, COPD, and emphysema; n=914). Satisfaction with medication was measured using a single item per treatment, and averaged for respondents taking two treatments. Adherence was measured using a single 4-item Morisky Medication Adherence Scale (MMAS) for all COPD treatments used. Spearman correlations were used to assess the relationship when adherence was considered as an ordinal variable, and binary logistic regressions were used to assess the relationship between the two constructs when adherence was dichotomized. Regressions included age and gender as covariates. **RESULTS:** Bivariate correlations demonstrated a modest relationship between satisfaction and adherence within COPD patients across the five countries $r_s = .133$, $p<0.001$). The strength of this relationship ranged from a low of $r_s = 0.05$ in France ($p = 0.60$) to a high of $r_s = .37$ in Spain ($p<0.001$). A significant interaction between country and satisfaction confirmed that the relationship varied by country. When the relationship was examined within each country, satisfaction was a significant predictor of adherence only in Spain and the UK (both $p<0.05$). **CONCLUSIONS:** Mean level of adherence to COPD treatments differed across European countries. Higher satisfaction was generally associated with greater adherence, but the strength of this relationship varied. Ensuring treatments are satisfactory to the patient may promote greater adherence, but the strength of the impact is likely to vary across populations.

PRS44

FACTORS RELATED TO ADHERENCE AFTER A MULTIFACTORIAL INTERVENTION TO IMPROVE IT IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD). ICEPOC STUDY

Leiva-Fernandez F[1], Leiva-Fernandez J[2], Prados-Torres D[1], García-Ruiz AJ[3], Barnestein-Fonseca P[1]

[1]*Distrito Sanitario Málaga (SAS), Málaga, Spain,* [2]*Area Sanitaria Málaga Este-Axarquia, Málaga, Spain,* [3]*Malaga University, Malaga, Spain*

OBJECTIVES: To identify factors related to adherence after a multifactorial intervention in patients with COPD. **METHODS:** Design: Randomized Controlled Trial (ISRCTN 15106246) Patients: 146 subjects randomly allocated (random blocks of 4 patients) in two groups (intervention group-IG, control group-CG). Intervention components: 1) Motivational aspects: beliefs-behaviour about COPD (group and individual interviews); 2) Cognitive aspects: information about illness; and 3) Skills: inhaling techniques training. Follow-up: 1 year, 5 visits/group. Primary Outcome: adherence (pill/doses count); Secondary Outcomes: functional status (spirometry), quality of life (Saint George Respiratory Questionnaire-SGRQ); Independent variables: intervention, age, sex, educational level, comorbidity, COPD severity stage (SEPAR guidelines), prescribed medication. Statistical analysis: Four partial logistic regression models, fixed- and random effects estimation, were carried out, a final model was built considering them. Statistical packages SPSS 15.0 and Stata 11.1. **RESULTS:** Predominance of males (91.8%), mean age 69.08 years (CI95%,67.58-70.44); low cultural level (78.1%), 32.2% current smokers (62.84 pack-years [CI95%,55.34-70.34]), Body Mass Index 30.78 kg/m2 (CI95%,28.78-32.78), 81.2% mild-moderate severity stage, predominance of obstructive respiratory pattern; FEV1 (mean)= 67.58% (CI95%,64.58-71.08), 0.87 exacerbations/year [CI95%, 0.68-1.06]. Pharmacological treatment: inhaled-beta2-adrenergic (80.1%); inhaled-anticholinergic (77.4%); inhaled-corticosteroids (70.5%); mucolitycs (11.6%); xanthine (8.2%); oxygen therapy (4.8%); oral-corticosteroids (0.7%). Adherence was 41% (41.2CG/40.8IG).

Both groups were similar at baseline. Drop out was 28.8%. Intention to treat analysis. Adherence increased significantly in IG (p=0.046), NNT=6.37 (CI95%,3.25-142.8). Factors related to adherence: intervention (OR=1.88, CI95%,1.01-3.52), number of exacerbation (OR=0.66,CI95%,0.48-0.91), number of visits to health centre (OR=0.93,CI95%,0.87-1.00), severity (OR=0.677,CI95%,0.43-1.04), number of devices (OR=2.4,CI95%,1.09-5.30), SGRQ-Activity scale (OR=0.978,CI95%,0.95-1.00), SGRQ-Impact scale (OR=1.03,CI95%,1.00-1.06), inhaled-beta2-adrenérgic (OR=0.16, CI95%,0.059-0.43), xanthine (OR=0.199, CI95%,0.05-0.77). Rho coefficient=$6.07x10^{-6}$ (p=0.498). **CONCLUSIONS:** The more adherent patient was that who showed a lower number of visits to health centre, exacerbations, number of devices, level of severity, and impact on daily activities but with higher disease impact. The beta-2-adrenergic and xanthine treatment are associated with no adherence.

PRS45

HOW DO PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) USE THEIR INHALERS? COMMON MISTAKES. TECEPOC STUDY

Leiva-Fernandez F[1], Leiva-Fernandez J[2], Porcel-Martin C[1], Prados-Torres D[1], García-Ruiz AJ[3], Barnestein-Fonseca P[1]

[1]*Distrito Sanitario Málaga (SAS), Málaga, Spain,* [2]*Area Sanitaria Málaga Este-Axarquia, Málaga, Spain,* [3]*Malaga University, Malaga, Spain*

OBJECTIVES: To test the inhaler use in COPD patients. Frequent mistakes. **METHODS:** Design: Cross-sectional study at the beginning of a Multicenter patients' preference trial (ISRCTN15106246) Patients: 465 COPD patients from 9 health care centres, with inhaled treatment, written consent. Non-probabilistic consecutive sampling. Variables: inhaler devices, performance of correct inhalation technique, type of mistakes. Age, sex, Inhalatory pick flow, COPD severity stage, prescribed medication. Basal dyspnea index (BDI). Statistical analysis: Mean, frequency. 95% confidence interval. **RESULTS:** Predominance of males (91.4%), mean age 69.8 years (CI95%,69.00-70.59); FEV1(mean)=55.91%(IC95:53.62-58.2), mixed respiratory pattern (65.9%). Severity stage: 15.7% mild, 44.1% Moderate, 40.3% Severe. Pharmacological treatment: inhaled-beta2-adrenergic (88.8%); inhaled-corticosteroids (76.7%); inhaled-anticholinergic (70.7%); mucolitycs (19.4%); xanthine (7.3%); oral-corticosteroids (1.3%). BDI: grade 2. Inhalation technique: 84.9% had received instruction about inhalation techniques (48.6% from neumologist, 42.1% from general practitioner). The instruction was an explanation without device (59.6%). 67.3% of patients used Handihaler, 54.8% Accuhaler, 31.8% Turbuhaler, 26.9% pressurised metered dose inhaler (pMDI). The 91.3% of patients performed an incorrect inhalation technique with handihaler, 89.5% with Turbuhaler, 85.6% with Accuhaler and 91.7% with pMDI. The most common mistakes in all devices were related to the action consist on: emptying or almost emptying the lungs before activating the spray (79.8%) and holding breath for at least 8-10 seconds or for as long as possible when inhalation is complete (69.5%). The most common mistakes per device were related to: repeating the inhalation with Handihaler (10%), Loading the dispenser correctly in Accuhaler (8.2%) or Turbuhaler (16.6%) and hand-breath coordination in pMDI (52.8%). **CONCLUSIONS:** A high percentage of patients with COPD performed an incorrect inhalation technique although they had been received instruction about this. The most common mistakes are more related to the patient's attitude than to the type of device.

PRS46

TECEPOC STUDY. HOW TO IMPROVE THE INHALATION TECHNIQUES IN PATIENT WITH COPD. THE INFLUENCE OF PREFERENCES

Leiva-Fernandez F[1], Leiva-Fernandez J[2], Porcel-Martin E[1], Vazquez-Alarcon R[1], Martos-Crespo F[3], Barnestein-Fonseca P[1]

[1]*Distrito Sanitario Málaga (SAS), Málaga, Spain,* [2]*Area Sanitaria Málaga Este-Axarquia, Málaga, Spain,* [3]*Málaga University, Málaga, Spain*

OBJECTIVES: to test the efficacy of two educational interventions to improve the inhalation techniques in patients with COPD and the influence of patient' preference. **METHODS:** Design: Multicenter patients' preference trial or comprehensive cohort design ISRCTN15106246. Patients: 465 COPD patients (to detect a difference between groups of 25%, 80% statistical power, 95% confidence level, 40% expected losses), with inhaled treatment, written consent. Non-probabilistic consecutive sampling. Allocation: Patients without strong preferences for a treatment are randomised: RCT group (block randomization), and those with strong preferences are given their choice: PPS group. Variables: Primary outcomes: Performance of correct inhalation technique. Secondary outcomes: Pick flow, dyspnea (Baseline dyspnea index), Functional status (forced spirometry). Interventions: Intervention-A: Written information. A leaflet with the correct inhalation technique for the main inhaler devices used in our area. *Intervention-B:* Intervention-A + individual training (by instructors). Follow-up: 3 month, visits: baseline, 1 month, 3 month. Statiscal analysis: Mean, frequency, 95% confidence interval at baseline. Number Needed to Treat for a benefit (NNT) was calculated. Intention to treat analysis. **RESULTS:** Predominance of males (91.4%), mean age 69.8 years (CI95%, 69.00-70.59); FEV1(mean)=55.91% (IC95%, 53.62-58.2), mixed respiratory pattern (65.9%). Severity stage: 15.7% mild, 44.1% Moderate, 40.3% Severe. Pharmacological treatment: inhaled-beta2-adrenergic (88.8%); inhaled-corticosteroids (76.7%); inhaled-anticholinergic (70.7%); mucolitycs (19.4%); xanthine (7.3%); oral-corticosteroids (1.3%). BDI: grade 2. Primary outcome: better inhalation technique (p=0.002) in the PPS group, NNT=7.4 (IC95%, 4.52-20). Among the RCT cohorts: there was no difference between control and intervention A and there were statistically significative differences between intervention B versus control (p<0.0001), NNT=2.44 (IC95%, 1.87-3.5) and versus intervention A, NNT=2.85 (IC95%, 2.08-4.56). In the PPS cohorts: there was a difference (p<0.0001) between intervention B versus intervention A, NNT=2.33 (IC95%, 1.5-3.2). **CONCLUSIONS:** The performance of a correct inhalation Technique improves with monitor training. The patients' preferences enhance the efficacy of intervention.

PRS47

RELATIONSHIP BETWEEN MEDICATION ADHERENCE AND QUALITY OF LIFE IN COPD – SYSTEMATIC REVIEW

Ágh T[1], Inotai A[1], Bártfai Z[2], Mészáros Á[3]

[1]*Syreon Research Institute, Budapest, Hungary,* [2]*Elizabeth Teaching Hospital and Rehabilitation Institute Sopron, Sopron, Hungary,* [3]*Semmelweis Univesity, Budapest, Hungary*

OBJECTIVES: Adherence and health-related quality of life (HRQoL) are two important indicators in determining success of drug treatments. Although medication adherence and HRQoL have been studied intensively, less is known about the association of these factors. This research aims to undertake a systematic review of the published literature on the relationship of medication adherence and HRQoL in patients with chronic obstructive pulmonary disease (COPD). No comprehensive review has been published in this topic so far. **METHODS:** Peer-reviewed English-language articles that examined the relationship between adherence/compliance/persistence to medication and HRQoL in COPD were identified through database (Medline, EMBASE) searches. Reports until April 2013 were screened. Papers related to oxygen therapy were excluded. **RESULTS:** Of the 243 papers reviewed, eight studies met the inclusion criteria and were analyzed in our systematic review. Evidence suggests that relationship between medication adherence and HRQoL is dual. Non-adherence does not have a clear negative impact on HRQoL. Adherence to medication may affect HRQoL due to more factors, such as effectiveness/efficacy and side effects of the medication, daily life limitation and social stigmatization caused by the therapy. Effect of non-adherence on HRQoL can be derived from the resultant of these factors. Nevertheless, HRQoL may also influence patients' drug use; poor or good HRQoL may trigger non-adherence. Relationship between adherence and HRQoL may differ depend on the duration of the previous therapy (as therapy in newly diagnosed COPD patients may improve HRQoL more than in patients treated previously for longer durations) and on the study design (cross-sectional versus longitudinal follow-up study) as well. **CONCLUSIONS:** Association of medication adherence and HRQoL is multiple. Results from previous studies are limited. Further scientific evaluations are needed to better understand the dynamics between these factors. Such information would be critically important and needs to be considered when integrating adherence into health-economic evaluations.

PRS48

ESTIMATION OF GENERIC UTILITIES IN SPANISH CHRONIC OBSTRUCTIVE PULMONARY DISEASE PATIENTS

Miravitlles M[1], Huerta A[2], Villa G[2], Forne C[3], Cuesta M[3], Brosa M[3], Crespo C[3]

[1]*Hospital Universitari Vall d' Hebrón, Barcelona, Spain,* [2]*GlaxoSmithKline, Madrid, Spain,* [3]*Oblikue Consulting, Barcelona, Spain*

OBJECTIVES: Chronic obstructive pulmonary disease (COPD) is a major public health problem and one of the leading causes of chronic morbidity and mortality worldwide. This study aims at determining generic utilities for Spanish COPD patients stratified by international guidelines GOLD 2006 (airflow limitation) and GOLD 2013 (airflow limitation, exacerbation history and symptoms), and Spanish guidelines GesEPOC (clinical phenotypes). **METHODS:** Multicentre, observational, cross-sectional study, carried out in 15 Pulmonology Spanish public services, including patients aged 40+, diagnosed with COPD, who have not experienced an exacerbation in the previous 2 months and receiving pharmacological treatment for COPD. Utilities were derived from EQ-5D-3L scores. Medians, means and standard deviations (SD) were computed for groups of patients based on GOLD 2006, GOLD 2013 and GesEPOC classifications. Differences in median utilities between groups were assessed by means of Kruskal-Wallis tests. Post-hoc pair-wise comparisons were based on Wilcoxon tests (Bonferroni-adjusted). **RESULTS:** A total of 346 patients were included in the analysis. Statistically significant median differences in utilities by groups of patients were found. GOLD 2006: moderate (n=135, median=0.87, mean=0.81, SD=0.22); severe (n=145, median=0.80, mean=0.71, SD=0.29); very severe (n=66, median=0.67, mean=0.57, SD=0.35); (p<0.001). All pair-wise comparisons were statistically significant (p<0.001). GOLD 2013: group A (n=28, median=0.98, mean=0.94, SD=0.06); group B (n=66, median=0.87, mean=0.80, SD=0.22); group C (n=30, median=0.98, mean=0.87, SD=0.24); group D (n=222, median=0.74, mean=0.66, SD=0.30); (p<0.001). All pair-wise comparisons were statistically significant (p<0.002), excepting groups A and C comparison. GesEPOC: (A) non-exacerbator (n=215, median=0.84, mean=0.78, SD=0.23); (B) overlap COPD-asthma (n=21, median=0.80, mean=0.80, SD=0.19); (C) exacerbator with emphysema (n=46, median=0.74, mean=0.59, SD=0.40); (D) exacerbator with chronic bronchitis (n=64, median=0.74, mean=0.62, SD=0.33); (p<0.001). Pair-wise comparisons between phenotypes A and C (p<0.002) and phenotypes A and D (p<0.001) were statistically significant. **CONCLUSIONS:** Generic utilities are associated with airflow limitation, exacerbation history, symptoms and clinical phenotypes in a sample of Spanish COPD patients.

PRS49

PATIENT-REPORTED OUTCOME (PRO) CLAIMS IN PRODUCTS APPROVED FOR CHRONIC OBSTRUCTIVE PULMONARY DISEASES (COPD) IN EUROPE AND THE UNITED STATES

Caron M, Perrier LL, Acquadro C

Mapi Research Trust, Lyon, France

OBJECTIVES: 1) To identify COPD products approved with a Patient-Reported Outcome (PRO) labeling claim in Europe and the USA, and 2) to list the differences found in Europe vs. the USA in terms of products and labeling. **METHODS:** The search was performed on the FDA- and EMA-approved medicinal product labels and medical reviews/scientific discussions (from January 1995 - February 2013 inclusive). **RESULTS:** A total of 25 COPD products were retrieved: 11 were approved by the EMA and 14 by the FDA. Only three INN were approved by both agencies (aclidinium bromide, indacaterol, and roflumilast), representing 11 products (EMA, n=8; FDA, n=3). Out of the 25 products approved, 15 have a PRO claim (EMA, n=8; FDA, n=7). When focusing on the INN approved by both agencies, the review showed that the FDA and the EMA agreed on the granting of a PRO claim (i.e., "yes" for aclidinium bromide and indacaterol, and "no" for roflumilast). The FDA and the EMA reviewed the same clinical studies. However, the labeling text differs between the agencies. The FDA label of aclidinium bromide does not provide any mention of results measured by the St. George's Respiratory Questionnaire (SGRQ) and the Transition Dyspnoea Index (TDI), while the EMA label does. As for indacaterol, the FDA label does not mention any TDI results, while the EMA label does. Reasons for these discrepancies are found in the FDA medical reviews. The TDI has been assessed as inadequate for use as a CT endpoint. As for the SGRQ, the results met the threshold of clinically meaningful improvement in only

one study. **CONCLUSIONS:** Our review showed that PROs are often included in COPD product labels in Europe and in the USA. Although the FDA and the EMA agree on a general level, the FDA seems more restrictive in the label wording.

PRS50

STUDY OF QUALITY OF LIFE IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE (COPD) AND SYMPTOM ASSESSMENT DIFFERENCES BETWEEN PATIENTS AND FAMILY MEMBERS

Fernández-Lahera J, Gonzalez A, Prados C, F-Bujarrabal J, Martínez A
Hospital Universitario La Paz, Madrid, Spain

OBJECTIVES: To assess the relationship between the questionary of quality of life "COPD assessment test" (CAT) and clinical, functional and comorbidity parameters and compare patient perceptions of symptoms with that of their family members. **METHODS:** We analysed demographic (age, sex, BMI), lung function (FEV_1%) and comorbidity variables (Charlson index) in patients with stable COPD. Patients and family members independently completed the CAT (family members reported their observations of the patient). **RESULTS:** We included 70 patients (83% men, mean age 72±9.4 years, BMI 27.8±4.2 kg/m^2, Charlson index (ChI) 2.41±1.7, mean FEV_1% 57.1±15.1%. Air flow limitation (GOLD): 7 patients (9%) mild, 36 (53%) moderate, 24 (34%) severe and 3 (4%) very severe. There was a significant negative correlation between CAT and FEV_1% (r=-0.265, p<0.0028) but no correlation between CAT and ChI, age or BMI. A comparison of CAT scores between the patients and their family members showed that 61% of the patients underestimated and 33% overestimated their symptoms (CAT scores: 15.5±7.9 (patient) vs. 17.1±7.7 (family) (p<0.038); correlation: (r=0.72; p<0.001). We observed correlations in the 8 CAT items. We found significant differences between the patients and their family members in items 1: coughing (p<0.015), 3: chest tightness (p<0.005) and 6: confidence leaving home (p<0,015) and in overall score (p<0.038). **CONCLUSIONS:** 1. We found a negative correlation between the CAT and FEV_1but not between the CAT and Charlson index. 2. Patients underestimate their symptoms. Cough, chest tightness and confidence leaving home are the issues items that had the greatest discrepancy between patients and family members.

PRS51

COMPARISON OF TREATMENT SATISFACTION IN PATIENTS WITH ASTHMA TAKING LEUKOTRIENE MODIFIERS VERUS THOSE TAKING INHALED CORTICOSTEROIDS

Tomaszewski EL[1], Mendelsohn AB[2], Shah AJ[3]
[1]*Quintiles Outcome, Pittsburgh, PA, USA,* [2]*Quintiles Outcome, Cambridge, MA, USA,* [3]*Quintiles Outcome, Rockville, MD, USA*

OBJECTIVES: To assess treatment satisfaction between patients with self-reported asthma for two classes of asthma treatments, leukotriene modifiers (LM group) and inhaled corticosteroids (IC group), using a novel patient community in the U.S. **METHODS:** Participants were identified via MediGuard, a digital patient platform where patients enroll online to be part of a digital patient community. All information was obtained through participant self-report. Patients were invited to complete the Treatment Satisfaction Questionnaire for Medication (TSQM), a patient reported outcome (PRO) instrument, at random time points between 2009 and 2011. Domain scores of the TSQM were compared between the IC and LM groups using regression analyses, adjusting for age, gender, self-reported severity and number of co-medications. **RESULTS:** A total of 736 patients were included for the IC group, and 647 for LM group. Average ages were comparable (56.3 years (SD=13.8) for IC; 54.9 (13.5) for LM). Both groups were predominantly female (76.3% IC; 83.2%, LM). Effectiveness domain scores were similar between IC and LM groups (p=0.502). LM users reported significantly higher scores (i.e., increased satisfaction) for other domains: side effects (97.1 (SD=0.8) vs. 93.5 (0.7), resp.); convenience (89.2 (0.8) vs. 81.6 (0.7), resp.); global satisfaction (72.3 (1.1) vs. 67.3 (1.0). **CONCLUSIONS:** Patients in the LM group reported higher satisfaction in the convenience and global satisfaction domains than the IC group. Patients in the LM group reported less interference with side effects than the IC group. Providing patients with information on population-based satisfaction scores for these two medications could help inform patients' treatment selection decisions.

PRS52

SYMPTOMS OF COPD IN URBAN RUSSIA AMONG ADULTS 40 YEARS AND OLDER

Vietri J[1], Ertl S[2], Isherwood G[3], Bevelskiy AS[4]
[1]*Kantar Health, Milan, Italy,* [2]*Kantar Health, Moscow, Russia,* [3]*Kantar Health, Epsom, Surrey, UK,* [4]*Russian Scientific Research Medical University, Moscow, Russia*

OBJECTIVES: Chronic obstructive pulmonary disease (COPD) is a major cause of disability worldwide, but awareness of COPD and information regarding the burden of this disease are lacking worldwide, including Russia. The aim of the current study was to assess the prevalence of COPD symptoms (cough with mucous, wheezing, and shortness of breath) among a representative sample of adults aged 40 and above in major cities in Russia. **METHODS:** Data was obtained from the 2011 Russia National Health and Wellness Survey, a cross-sectional survey of the adult population in the city adult population in Russia which includes information on awareness, experience, and diagnosis of medical conditions, health care-related attitudes, demographic characteristics, and health outcomes. The frequency of COPD symptoms was assessed using the Lung Function Questionnaire, and health status was assessed using the SF-12v2. Those experiencing a symptom at least 'sometimes' were compared to those who experienced the symptom 'rarely' or less using independent-samples t-tests. **RESULTS:** A total of 5920 adults aged 40 and older completed the survey. After weighting, 45%, 27%, and 18% reported shortness of breath, coughing up mucous, and wheezing, respectively, and 54% reported at least one symptom. Only 23% of those surveyed were aware of COPD; awareness of COPD was greatest among those with the most symptoms but even among those with all three symptoms, only 31% were aware of the condition. Experience of each symptom was associated with worse mental and physical component summary scores on the SF-12v2, with decrements ranging from 2-6 points depending on the symptom and score considered. **CONCLUSIONS:** Respiratory symptoms are common among adults living in Russian cities, which may indicate high COPD incidence. Awareness of COPD in Russia is lacking. A high proportion of adults aged 40 and older in Russia report frequent respiratory symptoms, and these symptoms are associated with significantly worse health status.

PRS53

THE RELATIONSHIP BETWEEN COPD ASSESSMENT TEST (CAT) AND EQ-5D IN A REAL WORLD PATIENT POPULATION

Wood R[1], Small M[2]
[1]*Adelphi Real World, Bollington, UK,* [2]*Adelphi, Macclesfield, Cheshire, UK*

OBJECTIVES: COPD is a chronic lung disease that has a detrimental effect upon patient's quality of life. The COPD Assessment Tool (CAT) has been developed to measure the impact of the disease. This research explores the relationship between the disease-specific CAT, and the general health related utility measure EQ-5D. **METHODS:** COPD is a chronic lung disease that has a detrimental effect upon patient's quality of life. The COPD Assessment Tool (CAT) has been developed to measure the impact of the disease. This research explores the relationship between the disease-specific CAT, and the general health related utility measure EQ-5D. **RESULTS:** A scatter plot relating CAT score to EQ-5D showed that the relationship is non-linear. Variance of the EQ-5D score increased with CAT score, suggesting the increasing influence of confounding factors for patients reporting a higher CAT score (CAT score range variance: 0-10: 0.013, 11-20: 0.026, 21-30: 0.050 and 31-40: 0.126). A generalized linear model was used to account for the non-linear relationship, and control for confounding influences of age, gender, physician-perceived COPD severity and number of concomitant conditions, with no assumption of constant variance. The relationship between CAT and reversed EQ-5D was positive and significant (coefficient 0.070, p-value <0.0001), illustrating higher CAT score was associated with lower EQ-5D. A one point increase in CAT score resulted in an approximate 7.2% relative decrease in EQ-5D score. Similarly, significant (p-value <0.0001) negative relationships observed for older patients (coefficient 0.016), female gender (coefficient 0.147), greater severity (coefficient 0.469), and a higher number of comorbidities (coefficient 0.070). **CONCLUSIONS:** Increasing COPD impact as measured by the CAT was associated with lower EQ-5D scores. However, the increasing variance of EQ-5D for patients with higher CAT scores demonstrates the need for both COPD impact and overall health status assessment.

PRS54

THE RELATIONSHIP BETWEEN ASTHMA-SPECIFIC QUALITY OF LIFE AND MEASURES OF ASTHMA CONTROL AND GENERIC QUALITY OF LIFE

Stucky B[1], Sherbourne C[2], Edelen MO[2], Eberhart N[2], Lara M[2]
[1]*RAND Corporation, Santa Monica, CA, USA,* [2]*The RAND Corporation, Santa Monica, CA, USA*

OBJECTIVES: Previous research has indicated a strong relationship between asthma symptoms and asthma-specific quality of life (QoL). However, past measures of asthma-specific QoL typically confound symptoms and functional impairment with QoL, which in turn may cause a misleadingly high inter-correlation. The current research uses a newly developed measure of asthma-specific QoL (the RAND-Impact of Asthma on Quality of Life; RAND-IAQL) that controls for asthma symptoms and functional impairment while assessing the degree of asthma impact or burden. Using this new measure, we model the relationship between asthma specific quality of life, generic quality of life, asthma control, and comorbid conditions commonly associated with asthma. **METHODS:** Using a diverse sample of adults with asthma (N=2032), we use structural equation models (SEM) to establish the relationships and suppression effects of asthma control, symptoms, comorbidities (e.g., COPD, Sinusitis), and multiple PROMIS QoL instruments (including anxiety and social QoL) on the prediction of asthma-specific QoL. SEM models will be presented sequentially in order to evaluate the relative utility of increasingly complex models using likelihood ratio tests and changes in the amount of IAQL variance that is accounted for by each added predictor (latent) variable. **RESULTS:** Close fitting SEM models suggest that "interference" caused by asthma, an indicator commonly used to measure asthma control, is most strongly related to asthma-specific QoL. Contrary to the research literature, symptoms of asthma (including shortness of breath, wheezing, and cough) and comorbid diseases are less strongly related to asthma specific QoL than are general assessments of interference and generic measures of anxiety and limitations in social functioning. **CONCLUSIONS:** Asthma-specific QoL is best understood as the degree to which asthma impacts or burdens ones daily life. While asthma symptoms, control, and general QoL are highly inter-correlated, asthma control (primarily interference) is differentially predictive of asthma-specific QoL.

PRS55

THE RAND NEGATIVE IMPACT OF ASTHMA ON QUALITY OF LIFE ITEM BANK AND SHORT-FORMS

Sherbourne C, Stucky B, Edelen MO, Eberhart N, Lara M
The RAND Corporation, Santa Monica, CA, USA

OBJECTIVES: In response to recommendations from the 2010 NHLBI Asthma Outcomes Workshop, we developed a new system for measuring the impact of asthma on quality of life (QoL) that avoids confounding QoL with asthma symptomatology and functional impairment. This presentation summarizes the process of developing and validating an item bank and short-forms that measure patients' perceptions of the impact or bother of asthma on their life. **METHODS:** Focus groups, supplemented by literature review and expert panel recommendations were used to identify key QoL dimensions and develop a pool of items which were refined based on cognitive interviews. Items were field-tested using a diverse national sample of adults with asthma (N=2032). Modern measurement theory was used to develop an item bank and short forms. We validated our short-forms against the Marks AQLQ; ACT; and generic QoL measures. Discriminant validity was examined by evaluating scores from respondents who differed according

to indicators of asthma severity, control, health care utilization and comorbidity. **RESULTS:** A total of 661 QoL statements were identified from focus group transcripts and subsequently used to generate a pool of 112 items in 16 different content areas. Psychometric evaluation of field test data yielded a 65-item unidimensional item bank, 4 and 12-item short forms (alpha = .86 and .93, respectively), and a simulated computer adaptive test suggesting that as few as 5-items are needed to obtain highly precise estimates of the impact of asthma on QoL (IAQL). Our measures correlated highly with Marks' AQLQ and more strongly with the PROMIS global physical than mental scale. IAQL was greater in persons with indicators of more severe asthma, less asthma control, and in persons with greater health care utilization. **CONCLUSIONS:** The RAND-IAQL item bank is a new freely available system for measuring the impact of asthma on Qol that will complement other patient-reported outcomes.

HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE IN NORTH INDIA

Negi H[1], Sarkar M[2], Raval A[3]

[1]*Post Graduate Institute of Medical Education & Research, Chandigarh, India,* [2]*Indira Gandhi Medical College, Shimla, India,* [3]*West Virginia University, Morgantown, WV, USA*

OBJECTIVES: Chronic obstructive pulmonary disease (COPD) is a major health problem in India and constitutes an important cause of mortality and morbidity. A cross sectional study was undertaken to assess health related quality of life (HRQL) and its determinants in COPD patients from India. **METHODS:** A total of 126 patients (73.81% male, 26.19% female) recruited using convenient sampling in a cross-sectional study. Eligible patients assessed for socioeconomic status, anthropometric measures, COPD severity, dyspnea, and health status using a validated Hindi (Regional Language) version of St. George Respiratory Questionnaire (SGRQ). Linear regression model was used to examine association between risk factors and HRQL with adjustment of age and sex. **RESULTS:** Mean total score for SGRQ was 52.66±12.89 showing marked impairment of HRQL. Impairment was associated with the severity of airway obstruction but within each GOLD stage the variation (SD) was wide [Stage I: 47.8±12.3 (n=14); Stage II: 49.28±11.69 (n= 47); Stage III: 53.47±11.69 (n= 44); Stage IV: 61.75±14.14 (n= 21)]. Regression analysis showed that body mass index, Forced expiratory volume in 1 minute (FEV_1), dyspnea grade and depression were associated with poor HRQL. **CONCLUSIONS:** HRQL of COPD patients was significantly impaired across all severities. Marked impairment of HRQL was found even in patients with milder disease.

THE FIRST EXPERIENCES WITH REASSESSMENTS AND APPRAISALS OF CONDITIONALLY APPROVED EXPENSIVE AND ORPHAN DRUGS IN THE NETHERLANDS (2006-2013)

van der Meijden CMJ, Streuper C, Goettsch W

Health Care Insurance Board (CVZ), Diemen, The Netherlands

OBJECTIVES: To provide an overview of the first experiences with reassessments and appraisals of expensive drugs after 4 years of coverage with evidence development (CED) in The Netherlands. **METHODS:** Completed assessments, reassessments and appraisals were summarized. Special attention was paid to the consistency of the conclusions at the initial assessment (T=0) with those at the reassessment (T=4), to the execution of the research proposals, and to the consequences of the reassessments and appraisals. **RESULTS:** From 2006 until 2012, 46 T=0 assessments have been performed: 36 were approved for CED and 10 were declined. By mid 2013, the 4 years' period of CED had ended for 25 drugs. For four drugs, T=4 assessments and appraisals have been completed: omalizumab and ranibizumab for treatment of patients with severe asthma and macula degeneration respectively; and the orphan drugs alglucosidase alfa and agalsidase for treatment of patients with Pompe's disease and Fabry's disease. Based on all the available evidence, conclusions regarding effectiveness were mostly consistent between T=0 and T=4 assessments. However, results from the requested outcomes research studies between T=0 and T=4 were of mixed quality and therefore of limited relevance for the T=4 assessment. Nevertheless, most data from the outcomes research were useful to evaluate appropriate usage in daily practice and resource use. The resource use data was applied in health economic models. In contrast, the input for the clinical effectiveness component in the cost-effectiveness assessment was generally derived from pivotal clinical studies already available at T=0. The T=4 appraisals led to a societal debate on the cost-effectiveness of these drugs. The appraisals resulted in pragmatic solutions like a pay-for-performance agreement and ongoing price negotiations. **CONCLUSIONS:** Outcomes research as part of a CED in The Netherlands has yielded some information regarding the costs and appropriate use in daily practice of expensive drugs. The results from these CED experiments (or lack thereof) have been used in the subsequent negotiations on financial or risk-sharing arrangements.

PRS58

HEALTH TECHNOLOGY ASSESSMENT OF COMPANION DIAGNOSTIC BIOMARKERS AS GATEKEEPERS FOR PERSONALIZED MEDICINE MARKET ACCESS

Spinner DS[1], Ransom JF[2], Culp JL[1], Chawla AS[1], Doyle JJ[3], Faulkner EC[4]

[1]*Quintiles Consulting, Durham, NC, USA,* [2]*Quintiles Consulting, Hawthorne, NY, USA,* [3]*Quintiles, Hawthorne, NY, USA,* [4]*Institute for Pharmacogenomics and Individualized Therapy, Eshelman School of Pharmacy, University of North Carolina, Chapel Hill, NC, USA*

OBJECTIVES: Personalized medicines (PM) are the subset of drug therapies whose efficacy and/or safety can be predicted or monitored based on the status of specific molecular biomarkers. In most cases, access to the applicable biomarker test (also called a companion diagnostic (CDx) if the biomarker/test is regulatory approved and included in the drug label) is critical for early patient access to the specific PM the biomarker status informs. Recent examples of PM and CDx/biomarker test combinations include crizotinib/EML4-ALK test in lung cancer; clopidogrel/CYP2C19 test in cardiovascular disease; natalizumab/ JC virus test in multiple sclerosis; maraviroc/HIV tropism test in HIV infection. To define key evidence required by health technology assessment (HTA) agencies and payers for reimbursement and access decision making, we evaluated global CDx/biomarker test HTAs. **METHODS:** HTA Watch conducted a search of global HTA agency websites for HTAs reviewing CDx/biomarker tests. HTAs were reviewed for key clinical, economic and other evidence criteria scrutinized or raised as concerns by agencies, and potential impacts/correlations of such evidence on agency reimbursement recommendations, distinguishing between true CDx and non-CDx biomarker tests. **RESULTS:** CDx/biomarker tests reviewed by HTA agencies included those used to inform oncology, cardiovascular or infectious disease, neurological disorder, and allergy/asthma treatments. Evidence scrutinized by HTA agencies included demonstration of clinical validity and utility versus competing tests or no test, cost-effectiveness and budget impact associated with implementing CDx testing, size of the responder population and, for solid tumor indications, the practicality of obtaining/availability of sufficient biopsy material for biomarker testing. **CONCLUSIONS:** CDx/biomarker tests are necessary gatekeepers for informing use of PM drugs, especially in early lines of treatment when alternative treatments exist. Since optimal PM market access requires CDx/biomarker test availability it is critical that the value of CDx/biomarkers is demonstrated through evidence development that addresses key HTA agency and payer needs.

PRS59

DIRECT AND INDIRECT BURDEN ASSOCIATED WITH PARENTS WHOSE INFANT HAS BEEN HOSPITALIZED FOR A LOWER RESPIRATORY TRACT INFECTION (LRTI) IN GREECE

Tsolia M[1], Vo P[2], Vlachopioti Z[3], Manthena S[2], Holton MJ[4], Gooch KL[2], Kyriakakis A[5], Koilakou S[5], Kafetzis DA[6]

[1]*Second Department of Paediatrics, University of Athens School of Medicine, P. and A. Kyriakou Children's Hospital, Athens, Greece,* [2]*AbbVie, North Chicago, IL, USA,* [3]*AbbVie Pharmaceuticals S.A, Neo Iraklio, Athens, Greece,* [4]*Lorimer Enterprises Inc., Red Deer, AB, Canada,* [5]*AbbVie Pharmaceuticals S.A, Alimos, Greece,* [6]*Iatriko Kentro Athinon, Private Hospital, Maroussi, Greece*

OBJECTIVES: Severe respiratory infections result in infant hospitalizations for LRTI, of which the most common cause is due to respiratory syncytial virus (RSV). The economic impact of pediatric hospitalizations for respiratory infections is substantial; however the socioeconomic burden it has on parents and caregivers is less understood. **METHODS:** Data was attained from the Parent Burden Study: A prospective multinational study to determine the humanistic and economic burden of infant LRTI hospitalizations during the RSV season. Direct health care resource utilization including length of hospitalization stay (LOS) and intensive care use (ICU) were obtained from medical chart reviews. Indirect economic burden borne by parents were measured in parent surveys administered at the time infants were discharged. Lost work productivity was assessed via the Work Productivity and Activity Impairment questionnaire, specific to caregivers of children hospitalized with respiratory illness. **RESULTS:** A total of 47 infants (35 term, 12 preterm), <1 year of age were included in the Parent Burden Study in Greece. A total of 74% of infants had a confirmed diagnosis of RSV. The mean LOS was 7.50 days (range: 0.66- 40.97, 6.33 days term, 10.91 days preterm). 8.5% (2.9% term and 25% preterm) required ICU admission and 85.1% had supplemental oxygen and/or mechanical ventilation support (80% term, 100% preterm). Among fathers, the average absenteeism (time away from work) was 19.2%, presenteeism (impaired productivity while at work) was 45.6%, and overall work impairment was 55.3%. For mothers, the average absenteeism was 47.0%, presenteeism was 35.0% and overall work impairment was 54.0%. On average, fathers reported 62.1% activity impairment and mothers reported 93.5% due to their child's hospitalization. A total of 51.1% of families required family or arranged childcare to assist siblings during the hospitalization. **CONCLUSIONS:** This study demonstrates, in addition to direct morbidity burden, infant LRTI hospitalizations have a substantial socioeconomic impact on parents and caretakers in Greece.

PRS60

PATTERNS IN ASTHMA MEDICATIONTREATMENT IN THE UNITED STATES

Li Y[1], Suh K[2], Chen W[3], Wei Z[3], Higuchi K[1]

[1]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA,* [2]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA,* [3]*Novartis Pharma Co. Ltd., Shanghai, China*

OBJECTIVES: Despite evidence of medication adherence benefits, many patients do not take their medications as prescribed. The objective of this study was to understand asthma medication treatment patterns among asthma patients in the US by initial asthma treatment medication. **METHODS:** A retrospective database analysis was conducted using Marketscan Commercial and Medicare Supplement Data. Patients were identified between January 1, 2005 through March 31, 2011 based on asthma related hospitalization, emergency room visit or at least 2 office visits at different dates within 1 year. Asthma drug utilization patterns were analyzed among patients aged 12 years or older who were initiated on an asthma medication (without asthma maintenance therapy in the past 12 months) and had at least 24 months traceable insurance coverage information since their initiation of the medication. **RESULTS:** Among the selected patients (n=88,567) being followed up for 24 months, approximately 30% of patients switched treatments at least once regardless of their initial asthma treatment. The three most common medications were montelukast sodium (>90% Singulair), fluticasone propionate and salmeterol (Advair) 250/50mcg and 100/50mcg. One prevalent prescription change was to step down the steroid component. Patients initiating asthma treatment on combination therapy (i.e. Singulair and inhaled corticosteroids) is low (between 0.3% - 1.8%) and switch patterns show that over 50% of patients switch to Singulair monotherapy. Regardless of their initial treatment and medication switches, on average, asthma patients initiate their treatment with 2-3 months days supply; have a gap of over 6 months (~200days) and switch to another treatment. **CONCLUSIONS:** Our results show the high frequency of asthma medication patterns changes. Despite the avail-

ability of prescription of asthma medications, there appears to be an unmet need and further research is necessary.

PRS61

ECONOMIC EVALUATION OF ENHANCED ASTHMA MANAGEMENT: A SYSTEMATIC REVIEW

Yong YV, Shafie AA
Universiti Sains Malaysia, Penang, Malaysia

OBJECTIVES: To evaluate, compare, and assess the quality of the studies on the cost-effectiveness of enhanced management (either as adjunct to usual care or alone) *vs.*usual care alone or none at all. **METHODS:** Scientific databases (ScienceDirect, Wiley Online Library, (EbscoHost – MEDLINE, CINAHL, PSYInfo), (OvidSP – EMBASE, MEDLINE), and Scopus) were searched for published journal articles in English language from year 1990 to 2012, using the search terms "asthma AND (intervene OR manage) AND (pharmacoeconomics OR economic evaluation OR cost effectiveness OR cost benefit OR cost utility)". Hand search was done for local publishings. Only studies with full economic evaluation on enhanced management (either as adjunct to usual care or alone) were included. Selected studies were data abstracted and assessed for their quality of economic evaluation using the Quality of Health Economic Studies (QHES) instrument, and quality of evidence. **RESULTS:** A total of 14 studies were included. There were three distinct modes reviewed: environmental control, self-management, education. Most of the enhanced managements were found to be cost-effective with ICER ranged from dominant to $26700.00 per unit of outcome. Overall, the mean score of QHES was 76.69% (SD 9.26). For the quality of evidence, 'clinical effect sizes, adverse events & complication', baseline clinical data, resourse use, and costs components were ranked mainly 1 or 2 (best or nearly best) in all studies. For 'utilities' component, one study ranked 5 because it used visual analogue scale to obtain patient preference values. **CONCLUSIONS:** Despite the low qualities of the reviewed studies, it overall suggests that enhanced management (either as adjunct to usual care or alone) is mostly cost-effective than the usual care or none at all; environmental control is considered the most cost-effective, and there is also strong evidence for self-management, but provided the mode of it is made available, affordable, and accessible then this shall be worth to be adapted in one's setting.

PRS62

ECONOMIC EVALUATION OF THE IMPACT OF NEW TREATMENT ALTERNATIVES ON MARKET DYNAMICS IN RESPIRATORY DISEASES; A CASE STUDY IN TURKISH HEALTH CARE SYSTEM

Kececioglu S[1], Ulus P[2], Cukadar F[3], Ozkan M[3], Urganci B[3]
[1]*Boehringer Ingelheim Turkey, Istanbul, Turkey,* [2]*Boehringer Ingelheim Turkey, ISTANBUL, TURKEY, Turkey,* [3]*Boehringer Ingelheim Turkey, ISTANBUL, Turkey*

OBJECTIVES: Economic evaluation of the change in market dynamics of a sample ProductA[1] through its inclusion in Therapeutic Equivalence Band (TEB) (with products B[2] and C[3]) between 2010 and 2012 in Turkish health care system. **METHODS:** IMS Dataview was analyzed for 2010-2012 unit sales values (market entry timeline for products A, B, C is 2006, 2009 and 2009, respectively) in the TEB. IMS Medical Index is used for estimating prescription data for the corresponding products. Assumptions on median patient adherence (receipt of prescribed treatment in pharmacy) are applied to prescription data in order to calculate unit sales (prediction). Deviation calculations and sensitivity analysis on market dynamics were performed in Microsoft Excel-2007. **RESULTS:** Deviations between unit sales predictions and realizations for products A, B and C occurred as +11.48%, -5.41% and -20.85% in 2010, -10.16%, +8.14% and -53.87% in 2011 and -31.89%, +28.92% and -67.76% in 2012 respectively. Negative deviation values indicate that receipt of prescription cannot be transformed to receipt of the prescribed product in pharmacy, however positive deviation values correspond to receipt of a product in pharmacy which is different from the content of the prescription. **CONCLUSIONS:** The TEB system allows receipt of a different product than prescription. This study shows alteration of market dynamics in pharmacy as a change from prescribed inhaler option (as negative deviation value), which is linked to receipt of another inhaler option (as a positive deviation value) within the same TEB. Real life data may be collected for further analysis of TEB system in dynamics of corresponding market. [1]Originator treatment in TEB-Novartis-Budesonide(400mcg)&Formoterol(12mcg), [2]Second treatment in TEB-Bilim Pharma, [3]Third treatment in TEB-Abdi Ibrahim Pharma.

ESTIMATES OF PRICE AND INCOME ELASTICITY IN GREECE: GREEK DEBT CRISIS TRANSFORMING CIGARETTES INTO A LUXURY GOOD

Tarantilis F, Athanasakis K
National School of Public Health, Athens, Greece

OBJECTIVES: Greece was long reported to show a smoking prevalence over 40% on adult population, as efforts to constrain smoking were rather ineffective. Following a sharp fall in cigarette consumption for 2012, our objective is to assess smokers' sensitivity to cigarette price and consumer income changes as well as to project health benefits of an additional tax increase. **METHODS:** Analysis includes the conventional model of demand, the myopic addiction model and the rational addiction model. Cigarette consumption for the period 1994-2012 was the dependent variable with Weighted Average Price as a proxy for cigarette price, GDP as a proxy for consumer income and dummy variables reflecting smoking restrictions and antismoking campaigns. Values were computed to natural logarithms and regression was performed. Then, 4 scenarios of tax increase were distinguished in order to calculate potential health benefits. **RESULTS:** Addiction models are unable to provide statistically significant information following a nearly 23.5% drop in consumption during 2012. Short-run price elasticity is estimated at -0.441 and short-run income elasticity is estimated at 1.040. Antismoking campaigns were found to have a statistically significant impact on consumption. Results indicate that, depending on the level of tax increase, annual per capita consumption could fall by up to 607.99 cigarettes; tax revenue could rise by at least €39 million, while up to 595,866 smokers could quit and up to 2,696 smoking related deaths could be averted. **CONCLUSIONS:** Price elasticity estimates are greater than previous studies in Greece and consistent with literature internationally, while income elasticity estimates are far greater. With cigarettes regarded as a luxury good, a great opportunity is presented for decison makers to counter smoking. Increased taxation, along with focused antismoking campaigns, law reinforcement (to ensure compliance with smoking bans) and intensive control for smuggling could inflict a massive blow to the tobacco epidemic in Greece.

PRS64

PREVALENCE OF COMORBIDITIES AMONG CHRONIC COPD PATIENTS IN THE UNITED STATES

Mannino M[1], Higuchi K[2], Tian H[2], Yu TC[2], Suh K[3], Zhou H[4], Li Y[5]
[1]*University of Kentucky, Lexington, KY, USA,* [2]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA,* [3]*Scott & White Health Plan, Temple, TX, USA,* [4]*KMK Consulting Inc., Randolph, NJ, USA,* [5]*Beijing Novartis Pharma Co. Ltd., Shanghai, China*

OBJECTIVES: COPD is the third leading cause of death with increasing mortality while other chronic condition mortality rates are decreasing. This may be due to the fact that COPD is a complex chronic condition with a complicated diagnosis and treatment guideline in an aging patient population with increasing comorbid conditions. The objective of this study was to understand the prevalence of comorbid conditions among COPD patients in the US. **METHODS:** A retrospective database analysis was conducted using Marketscan Commercial and Medicare Supplement Data from year 1/1/2010 to 12/31/2011. Patients were included if they had continuous medical and pharmacy benefits coverage for at least 12 months after their first COPD diagnosis defined as primary or ancillary ICD-9 codes of 491.xx, 492.xx, or 496.xx and were between the ages of 40 and 90 years old at the time of diagnosis. Univariate descriptive analyses were conducted to quantify comorbid disease prevalence. **RESULTS:** Among the selected patients (n=231,827), 95.1% (n=220,519) had medical claims (ICD-9 codes) for diagnoses beyond COPD within 12 months of their COPD diagnosis. The majority of patients were over 65 years old (61.4%, n=135,366). Over 60% (n=130,325) of the patients had more than 3 comorbid conditions. The most common were hypertension (64.9%, n=143,189) (ICD-9 codes 401.xx-405.xx, 415, 416, 416.8, 459.1x and 459.3x), hyperlipidemia (46.5%,n=102,498) (ICD-9 code 272.x), diabetes (27.8%, n=61,225) (ICD-9 code 249.xx, 250.xx, 253.5, 271.4, 357.2, 588.1, 790.29), coronary artery disease (27.4%, n=60,364) (ICD-9 code 414.0x, 414.3, 414.4), and asthma (22.7%, n=50,113) (ICD-9 code 493.xx). **CONCLUSIONS:** Our results show the significant prevalence of comorbid conditions among COPD patients. Further research on comorbid conditions impacting COPD patient treatment adherence, COPD pathogenic pathways and worsening overall prognosis are necessary. More evidence is required to estimate the role of comorbidities in COPD.

SYSTEMIC DISORDERS/CONDITIONS – Clinical Outcomes Studies

EXAMINING THE BURDEN OF ILLNESS OF VETERAN PATIENTS DIAGNOSED WITH OBESITY IN THE UNITED STATES

Wang L[1], Xie L[2], Du J[2], Li L[1], Baser O[3]
[1]*STATinMED Research, Dallas, TX, USA,* [2]*STATinMED Research, Ann Arbor, MI, USA,* [3]*STATinMED Research/The University of Michigan, Ann Arbor, Michigan, MI, USA*

OBJECTIVES: To examine the burden of illness of diagnosed obesity in the U.S. veteran population. **METHODS:** A retrospective database analysis was performed using the Veterans Health Administration (VHA) Medical SAS datasets (01OCT2008-30SEPT2012). Patients diagnosed with obesity were identified (International Classification of Disease 9th Revision Clinical Modification [ICD-9-CM] diagnosis code 278.xx) with the first diagnosis date designated as the index date. A group of patients without obesity but with the same age, region, gender and index year were identified and matched by baseline Charlson Comorbidity Index as a comparator group. The index date for the comparator group was randomly chosen to reduce selection bias. Patients in both groups were required to be at least 18 years old, and have 1 year of continuous medical and pharmacy benefits before and after the index date. Study outcomes, including health care costs and utilizations, were compared between the disease and comparator groups by using 1:1 propensity score matching. **RESULTS:** A total of 1,525,218 patients were identified for the obesity and comparison cohorts. After applying 1:1 matching, a total of 634,257 of patients were included in each group, and the baseline demographic and clinical characteristics were balanced. The obesity cohort had higher percentages of health care utilizations for inpatient (6.21% vs. 2.92%, p<0.01), emergency room (11.96% vs. 7.28%, p<0.01), physician office (99.84% vs. 60.12%, p<0.01), outpatient (99.86% vs. 60.85%, p<0.01), and pharmacy visits (89.01% vs. 61.71%, p<0.01) than the comparator group. Patients diagnosed with obesity also incurred higher expenditures in inpatient ($1,812 vs. $875, p<0.01), emergency room ($117 vs. $69, p<0.01), physician office ($2,936 vs. $1,436, p<0.01), outpatient ($3,288 vs. $1,621) and pharmacy visits ($641 vs. $423, p<0.01) compared to non-obese patients. **CONCLUSIONS:** Study results suggest that patients diagnosed with obesity incurred significantly higher costs and utilizations than non-obese patients.

PSY2

CLINICAL EFFECTIVENESS ANALYSIS OF DEFERASIROX FOR THE TREATMENT OF IRON OVERLOAD DUE TO FREQUENT BLOOD TRANSFUSIONS

Walczak J[1], Lipińska M[1], Jarosz J[1], Moczyński W[1], Ślązak B[1], Laczewski T[2]
[1]*Arcana Institute, Cracow, Poland,* [2]*Novartis Poland Sp. z o.o., Warsaw, Poland*

OBJECTIVES: To compare clinical efficacy and safety of orphan drug deferasirox (DSX) versus deferoxamine (DFO) in the treatment of paediatric patients (age ≤ 18 years) with iron overload from repeated blood transfusions. The underlying conditions requiring transfusion included beta-thalassaemia, sickle cell disease and other congenital and acquired anaemias (myelodysplastic syndromes, Diamond-Blackfan syndrome, aplastic anaemia and other very rare anaemias). **METHODS:** We searched CENTRAL, MEDLINE and EMBASE for relevant randomized controlled trials (RCTs) published up to April 2012. The review was conducted in accordance

with the Cochrane Collaboration guidelines and the Polish Agency for Health Technology Assessment recommendations. Calculations were performed using the StatsDirect®2.6.8 statistical package. **RESULTS:** : As a result of the systematic literature search 2 primary RCTs (subtype II A), satisfying the inclusion criteria were found: Cappellini 2006 (patients with beta-thalassaemia) and Vichinsky 2006 (patients with sickle cell disease). The results of the performed analysis proved that once-daily oral deferasirox showed similar efficacy to parenteral deferoxamine therapy in terms of decreased in LIC (liver iron concentration) and SF (serum ferritin). Treatment adherence was similar in both DSX and DFO groups. Safety analysis showed that deferasirox was safe and well-tolerated therapy. The most frequent adverse events in the deferasirox group were diarrhea, nausea, vomiting, abdominal pain and skin rash. In most cases, analysed adverse events were mild and transient. Discontinuation rates were similar in both DSX and DFO arms. **CONCLUSIONS:** Deferasirox represents an important once-daily oral agent for the treatment of chronic iron overload due to blood transfusions. Once-daily oral deferasirox has acceptable tolerability and similar efficacy to parental deferoxamine in reducing iron burden in transfused paediatric patients. Moreover, deferasirox improves patients' quality of life, may improve patient's compliance with treatment and reduces morbidity and mortality from iron overload.

PSY3

META-ANALYSIS OF EFFICACY OF ROMIPLOSTIM FOR TREATMENT OF IMMUNE IDIOPATHIC THROMBOCYTOPENIA

Aggarwal S, Topaloglu H
Novel Health Strategies, Bethesda, MD, USA

OBJECTIVES: Immune (idiopathic) thrombocytopenia (ITP) is an autoimmune condition characterized by increased platelet destruction and suboptimal platelet production, resulting in low platelet counts (thrombocytopenia). Romiplostim has shown efficacy in increasing platelet counts. The objective of this study was to conduct meta-analysis and present total evidence for Romiplostim for treatment of ITP. **METHODS:** For this meta-analysis we included randomized controlled trials (RCTs) evaluating Romiplostim for the treatment of ITP. We included RCTs that compared romiplostim versus placebo for management of ITP, had a treatment duration of at least 24 weeks, were doubleblind (patients and investigators blinded) and reported data on platelet response. A systematic literature search for Etanercept trials was undertaken for the databases Pubmed, Embase, Biosis, Google Scholar, and Cochrane. Data was collected for the study size, interventions, year, and the two outcomes overall and durable platelet response rate. For meta-analysis, random effects and fixed effects models were used to obtain cumulative statistics. **RESULTS:** Two RCTs with a total of 125 patients were identified. The pooled response rates for Romiplostim for overall platelet response rate were 82% (95% CI 73%-90%); and for durable platelet response rate were 48% (95% CI 26%-71%). The pooled response rates for placebo for overall platelet response rate were 7% (95% CI 0%-15%), and for durable platelet response rate were 2% (95% CI 0%-4%). For overall platelet response rate the cumulative relative risk with placebo versus Romiplostim was 0.09 (95% CI 4%-14%). For durable platelet response rate, the cumulative relative risk with placebo versus Romiplostim was 0.03 (95% CI 0%-6%). **CONCLUSIONS:** Meta-analysis shows Romiplostim offers patients with Immune idiopathic thrombocytopenia an effective therapeutic option for increasing platelet counts.

PSY4

BIS SENSOR VERSUS CONVENTIONAL ANESTHETIC MONITORING: SYSTEMATIC REVIEW ON PATIENT-ORIENTED OUTCOMES

Nobre MRC, Costa FM
InCor - HCFMUSP, São Paulo, Brazil

OBJECTIVES: Adult patients who receive general anesthesia may not remain totally unconscious during surgery despite of anesthetics and analgesics care received. The retention of memory due to intraoperative awareness may cause serious clinical complications, requiring 1071 patients monitored to prevent the occurrence of one event. The proper conventional maintenance of general anesthesia is assessed with clinical signs or expired gases (ETAC/ETAG/ETCO2). Bi-Spectral Index Monitoring or BIS Sensor is a neurophysiological evaluation system that continually analyzes EEG to determine the level of intraoperative awareness. **METHODS:** We have made a literature search in PubMed to identify systematic reviews and randomized controlled trials that studied level of consciousness intraoperative or postoperative memory when used these alternatives of anesthetic monitoring. **RESULTS:** We have found nine RCT and two systematic reviews published until April 2013 and conducted our own meta-analysis on seven trials. Two studies were excluded from the synthesis for not presenting the outcome of primary interest. Three RCT of moderate heterogeneity showed no difference in the occurrence of intraoperative awareness between the BIS group and the ETAC/ETAG/ETCO2 group. The quality of evidence was considered high in one study, moderate and low in the others (26,490 patients, I2 = 45.9%, RR = 1.28, 95% CI = 0.54 to 3.03, p = 0.57). Four clinical monitoring control group studies with no heterogeneity showed that the sensor BIS was more effective, requiring between 71 and 167 patients monitored for an event of intraoperative awareness avoided. The quality of evidence of the studies was considered high (7,779 patients, I2 = 0.0%, RR = 0.42, 95% CI = 0.27 to 0.65, p = 0, 0.0001). **CONCLUSIONS:** Clinical trials published until April 2013 showed favorable results in patient-oriented outcomes of BIS group when compared to clinical monitoring group but not to ETAC/ETAG/ETCO2 group.

PSY5

MORTALITY AND SURVIVAL IN INOPERABLE OR RESIDUAL/RECURRENT CHRONIC THROMBOEMBOLIC PULMONARY HYPERTENSION (CTEPH): A SYSTEMATIC LITERATURE REVIEW

Byrnes MJ[1], Ashaye AO[1], Iheanacho I[2], Travers K[1], Sikirica M[3]
[1]*Evidera, Lexington, MA, USA,* [2]*Evidera, London, UK,* [3]*Global HEOR, Bayer HealthCare Pharmaceuticals, Berlin, Germany*

OBJECTIVES: CTEPH is a progressive and commonly fatal disease. A systematic literature review was conducted to synthesize evidence on mortality and survival in patients with inoperable CTEPH or residual/recurrent pulmonary hypertension (PH) after pulmonary endarterectomy (PEA). **METHODS:** Using specific search terms, we systematically searched for MEDLINE- and EMBASE-indexed studies on the epidemiology of CTEPH in various regions (including Western Europe, North America, New Zealand, or Australia) without temporal limits. Among these studies, we identified those that reported mortality and/or survival for patients with inoperable CTEPH or residual/recurrent PH post-PEA. These studies then underwent analytical narrative synthesis. **RESULTS:** In all, 71 articles met the criteria for acceptance into the review. Of these, 21 described mortality or survival in patients with inoperable CTEPH or residual/recurrent PH post-PEA. The proportion of patients with inoperable disease was 27%–41% in seven registries and retrospective studies in Europe. The proportion of patients who underwent PEA was 59%–69% in two Canadian studies and 10%–65% (median 50%) in 11 European studies. Among studies with ≥18 months of follow-up, mortality was higher in patients with inoperable CTEPH (13.4%–58%, with seven of 10 studies reporting mortality rates of 13.3%–21.4%) than among those with residual/recurrent PH post-PEA (7.4% after a mean follow-up of 50 months). Overall survival was lower among patients with inoperable CTEPH than among those with residual/recurrent PH post-PEA. Survival rates for inoperable CTEPH were 73%–93% at one year (10 studies), 41%–88% at three years (nine studies), and 53%–88% at five years (five studies). In contrast, patients with residual/recurrent PH post-PEA had five-year survival rates of 89.9%–100% (three studies). **CONCLUSIONS:** Inoperable CTEPH carries a particularly poor prognosis, with survival rates lower even than those for patients who have residual/recurrent PH following PEA.

PSY6

ANALYSES ADJUSTING FOR SELECTIVE CROSSOVER SHOW IMPROVED OVERALL SURVIVAL WITH DECITABINE COMPARED WITH TREATMENT CHOICE IN DACO-016 PHASE III TRIAL

Tomeczkowski J[1], Güntert A[1], Thilakarathne P[2], Diels J[2], Xiu L[3], Tapprich C[1]
[1]*Janssen-Cilag GmbH, Neuss, Germany,* [2]*Janssen Pharmaceutica, Beerse, Belgium,* [3]*Janssen-Cilag Limited, Raritan, NJ, USA*

OBJECTIVES: Among patients with acute myeloid leukemia (AML), the DACO-016 randomized study showed reduction in mortality for DACOGEN®(decitabine, DAC) compared with treatment choice (TC): at primary analysis the Hazard Ratio (HR) was 0.85 (95% CI: 0.69- 1.04; stratified log-rank p=0.108). With two interim analyses, 2-sided alpha was adjusted to 0.0462. With one year additional follow-up the HR reached 0.82 (nominal p=0.037). These data, together with significant outcomes in secondary endpoints and a positive benefit-risk resulted in approval of DACOGEN in the EU, however not in the US. With the primary analysis only showing a strong trend, the French Haute Autorité de Santé negated a mortality benefit. Though prespecified, the log-rank test could be considered not optimal to assess the observed survival difference because of the non-proportional hazard nature of the survival curves. We applied the Wilcoxon test as a sensitivity analysis. **METHODS:** Patients (age ≥ 65 years, ineligible for chemotherapy) were randomized to DAC (N=242) or TC (N=243). For testing the observed treatment effect, Wilcoxon-test is considered more powerful in the context of non-proportional hazard curves compared to the log-rank test, as the former assigns more weight to earlier events. **RESULTS:** A total of 108 (44.4%) patients in the TC arm and 91 (37.6%) patients in the DAC arm selectively crossed over to subsequent disease modifying therapies at progression, which might impact the survival beyond the median with resultant converging curves (and disproportional hazards). The Wilcoxon-test stratified by baseline age, cytogenetic-risk and ECOG performance status showed a significant improvement in OS with DAC (7.7 [6.2; 9.2] months) versus TC (5.0 [4.3; 6.3] months) (p=0.0456). **CONCLUSIONS:** Wilcoxon-test indicated significant increase in survival for DAC vs TC in patients with AML compared to log-rank test at primary analysis.

SYSTEMIC DISORDERS/CONDITIONS – Cost Studies

PSY7

BUDGET IMPACT ANALYSIS OF DEFERASIROX IN THE TREATMENT OF NON TRANSFUSION DEPENDENT THALASSEMIA IN GREECE

Masoura P[1], Murphy DR[1], Chatzikou M[2], Alexopoulos ST[1], Magestro M[3]
[1]*Heron Evidence Development Ltd., London, UK,* [2]*Novartis (Hellas) S.A.C.I., Athens, Greece,* [3]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA*

OBJECTIVES: Deferasirox is an oral iron chelator that has demonstrated efficacy in reducing excess liver iron concentration (LIC) in iron overloaded non-transfusion dependent thalassemia (NTDT) patients. This analysis estimated the budget impact of reimbursing deferasirox in Greece. **METHODS:** An open cohort budget impact model was developed from the Greek health care system perspective over 5 years. Comparators included deferoxamine, deferiprone, and combination therapy (deferoxamine plus deferiprone). NTDT prevalence, drug acquisition and administration costs were from Greece (2013 €). No discounting was applied. Deferasirox clinical inputs were derived from the THALASSA trial. Rate of reduction in LIC (decrease of 26%) was applied each year for deferasirox. This was assumed the same for all comparators. Patients remained on treatment until the 3 mg Fe/gr dw discontinuation threshold for LIC was reached. Treatment was reinitiated when LIC increased above 5 mg Fe/gr dw. Base case starting age was 10 years. Sensitivity analysis was performed on key model inputs. **RESULTS:** A total of 280 patients with NTDT were estimated to be treated with iron chelation per year. With no deferasirox, total drug acquisition and administration costs were € 3,545,406 and € 11,889,133, respectively. With the introduction of deferasirox, acquisition costs increased by 62% to € 5,738,323 and administration costs decreased by 58% to € 4,993,474. Total expenditure decreased by over 30% representing cost savings of € 4,702,742 over 5 years. Results were sensitive to acquisition costs, administration costs for deferoxamine, treatment efficacy and discontinuation threshold. **CONCLUSIONS:** Reimbursement of deferasirox in NTDT resulted in cost savings to the Greek health care system.

Avoidance of administration costs for infused treatments could offset the higher acquisition cost for deferasirox. Additional data is required to confirm efficacy of other treatments in patients with NTDT.

PSY8

THE BUDGET IMPACT OF QUTENZA® FOR THE TREATMENT OF NEUROPATHIC PAIN IN SWEDEN

Chambers C[1], Nordling S[2], Smith D[3], Bentley A[3]
[1]*Astellas, Chertsey, UK,* [2]*Astellas Pharma, Kastrup, Denmark,* [3]*Abacus International, Bicester, UK*

OBJECTIVES: Neuropathic pain (NP) is a common disorder which can be chronic, severe, and disabling and is associated with reductions in quality of life and considerable costs. Current first-line treatments for NP include tricyclic antidepressants and anti-convulsants. QUTENZA® is a cutaneous patch that allows rapid dermal delivery of capsaicin directly to the source of pain. The objective of this analysis is to estimate the burden of NP, current treatment costs and the budget impact of introducing QUTENZA® for the treatment of peripheral NP in non-diabetic adults in Sweden. **METHODS:** We constructed a budget impact calculator to estimate the impact of introducing QUTENZA® for 100 people in Sweden. Drug costs for each management strategy are annual costs, based on estimated market shares, and range from SEK 231 to SEK 5,806 (with SEK 3,909 for QUTENZA®). We assumed a 50% uptake of QUTENZA® and a 50% reduction in the use of concomitant medication in the model, based on evidence from real-world data. **RESULTS:** For a NP population of n=100, the cost of current prescribing was estimated at SEK 1.00 million. The cost of alternative prescribing including QUTENZA® was estimated at SEK 1.01 million. The annual cost of treating a patient with QUTENZA® was estimated as SEK 11,941. The estimated cumulative budget impact by year (for 100 patients, with the market share rising from 10% in Year 1 to 100% in Year 5) ranged from SEK 9,664 in Year 1 to SEK 67,949 in Year 5. **CONCLUSIONS:** The introduction of QUTENZA® results in a budget impact of SEK 67,949 for 100 patients over 5 years. This represents a minimal additional expenditure and could be considered good value for money given the added benefits for patients with NP in Sweden.

PSY9

PHARMACOECONOMIC ANALYSIS OF ANTI-INHIBITOR COAGULANT COMPLEX (AICC) IN THE TREATMENT OF INHIBITOR HEMOPHILIA

Yagudina R, Kulikov A, Zinchuk I, Molchanova N
First Moscow State Medical University named after I. M. Sechenov, Moscow, Russia

OBJECTIVES: To identify the dominant scheme of inhibitor hemophilia bypassing agents therapy (comparing three regimens: Eptacog alfa monotherapy, combination therapy «Eptacog alfa + AICC» and «AICC + Eptacog alfa»). **METHODS:** Based on the crossover clinical research FENOC (Jan Astermark, Sharyne M., Donfield, 2007) the annual cost of treatment by bypassing agents in mild, moderate, severe and life-threatening bleeding is estimated. The analysis of the direct and indirect costs is conducted. Direct costs include the cost of bypassing agents therapy, the cost of emergency medical care, the cost of inpatient and outpatient treatment. Indirect costs include cost of patient's disability, GDP losses caused by mortality and disability, and sick-pay. Value of bypassing agents on demand therapy in three dosing schemes is identified: monotherapy Eptacog alfa (there is no alternative treatment), «Eptacog alfa + AICC» (after the first episode of bleeding no response patients to treatment from Eptacog alfa to AICC transferred) and «AICC + Eptacog alfa» (after the first episode of bleeding no response patients to treatment from AICC to Eptacog alfa transferred). **RESULTS:** Based on the clinical study FENOC, indicated that there is no significant difference in efficacy AICC and Eptacog alfa therapy in patients susceptible to this treatment. An analysis of the direct and indirect costs shows that the costs of the annual course of treatment of 142 patients in Russia are 66 mil EUR, 60,7 mil EUR and 53,1 mil EUR for treatments Eptacog alfa monotherapy, «Eptacog alfa + AICC» and «AICC + Eptacog alfa» schemes respectively. **CONCLUSIONS:** It is determined that the regimen «AICC + Eptacog alfa», will reduce reduces costs relative to the current treatment regimen for 12,9 mil EUR (19,54%) or provide additionally treat of 34 patients of this disease.

PSY10

POTENTIAL FINANCIAL IMPACT OF SUGAMMADEX IN ANAESTHETIC DEPARTMENTS: A BUDGET IMPACT ANALYSIS ON POTENTIALLY SHORT PROCEDURES REQUIRING NEUROMUSCOLAR BLOCKADE

Povero M, Pradelli L
AdRes HE&OR, Turin, Italy

OBJECTIVES: To evaluate the economic impact on Italian NHS of using sugammadex within anaesthetic departments instead of neostigmine. **METHODS:** The number of procedures using neuromuscular blockings agents (NMBA) potentially eligible for sugammadex was elaborated by hospital discharge data available in Italy for the year 2010. Reduction in postoperative residual curarisation (PORC) rate and saved time allocated to extra procedures were taken from two recent meta-analyses. Costs considered in the analysis were drugs acquisition costs (sugammadex and neostigmine) and PORC management costs. **RESULTS:** Overall annual costs of sugammadex and neostigmine usage result about 34.5 and 31.6 Million Euro, respectively. Sugammadex prevents 99% of PORC episodes on 428,995 procedures; this is associated with savings of more than 30 Million Euro. Also the saved time in surgery procedures due to sugammadex results in an annual savings of 154,867 (36.1%) hours that could be used for further procedures. **CONCLUSIONS:** Sugammadex radically reduces PORC episodes during post-operative and it allows for shorter operating room occupation.

PSY11

THE BUDGET IMPACT ANALYSIS OF DEFERASIROX FOR THE TREATMENT OF IRON OVERLOAD DUE TO FREQUENT BLOOD TRANSFUSIONS IN CHILDREN AND ADOLESCENTS (AGE ≤18 YEARS)

Walczak J[1], Obrzut G[1], Sołtys E[1], Laczewski T[2]
[1]*Arcana Institute, Cracow, Poland,* [2]*Novartis Poland Sp. z o.o., Warsaw, Poland*

OBJECTIVES: The purpose of the budget impact analysis (BIA) was to estimate financial consequences of deferasirox (DSX) reimbursement within the health care treatment programme (HTP) on the budget of the National Health Fund (NHF) in Poland. **METHODS:** BIA was performed for a 2-year time horizon (July 2012 - June 2014) from the Polish public payer perspective. The target population qualified to the HTP programme were children and adolescents (age ≤18 years) with iron overload due to frequent blood transfusions. The population was estimated on the basis of medical expert opinion. Two scenarios were compared: the "existing scenario" – without reimbursement of DSX (only standard of care with deferoxamine (DFO) was available) and the "new scenario" – DSX reimbursed as part of HTP. In the analysis, only direct medical costs were included: costs of drugs and their administration, costs of monitoring and costs of blood transfusions. It was assumed that the cost of deferoxamine was included in the cost of hospitalization procedures related to chelation therapy. Due to the lack of available data on adverse events (AE) incidence during therapy with deferasirox or deferoxamine, the costs of AE's treatment were not considered. The calculations were performed in Microsoft Office Excel. **RESULTS:** NHF annual expenditures related to the introduction of deferasirox reimbursement will increase by PLN 454 thousand in the first year and by PLN 434 thousand in the second year of reimbursement compared with the "existing scenario." **CONCLUSIONS:** The positive reimbursement decision for DSX enables patients with iron overload access to safe and effective therapy. Deferasirox therapy will allow young patients to go back to normal functioning in their families and in society. The positive reimbursement decision will also contribute to improving the quality of life, self-esteem and emotional state of the patients.

PSY12

PHARMACOECONOMIC STUDY OF NUTRITION SUPPORT (NS) USAGE DURING INTENSIVE TREATMENT

Metelkin I, Yagudina R, Kulikov A
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To undertake a comparative analysis of 2 methodologies of intensive treatment (IT) , precisely: IT without NS and IT taking into account NS handling. **METHODS:** Pharmacoeconomic analysis "budget impact" was provided. Only direct costs were taken into account: expenses for drug therapy, hospitalization (intensive care unit and medical division) and late complications (pneumonia, sepsis, catheter and wound infection) treatment. Effectiveness data was taken from Russian clinical trial: Popov T.S., Shestopalov A.E., Tsvetkov D.S., Nechaev D.S., Kuz'min M.A. Nutrition Day in intensive care units of the Russian Federation. National association of parenteral and enteral nutrition – Moscow (Russia), 2011. Four types of NS were compared: IT without NS; IT + enteral nutrition (EN); IT + parenteral nutrition (PN) and IT + combined nutrition (CN). **RESULTS:** When carrying out comparative pharmacoeconomic study all calculations were made for 3 groups of patients depending on their health condition: lightly-severe, moderately severe and severe. According to the results of calculations transfer of patients from IT without NS to IT carrying out NS leads to reduction of total expenses, therefore economy of money for the state. Independent from patient health condition – the greatest economy of money arises when EN is used during IT. Further on degree of expressiveness of positive economic effect there is PN and the least NS economic type is CN. **CONCLUSIONS:** The results received during the study were analyzed and the rating of NS types, which were taking part in the research, from the point of view of their clinical efficiency and economic effectiveness for the state budget, was made.

PSY13

A BUDGET IMPACT MODEL FOR NOVOSEVEN FOR THE MANAGEMENT OF BLEEDING EPISODES IN PATIENTS WITH HAEMOPHILIA A TREATED WITH INHIBITORS

Kaskens L[1], Martial L[1], Montoro Ronsano JB[2], Ramirez de Arellano A[3], Darba J[4]
[1]*BCN HEALTH, Barcelona, Spain,* [2]*Hospital Vall D'Hebron, Barcelona, Spain,* [3]*Novo Nordisk Pharma, Madrid, Spain,* [4]*Universitat de Barcelona, Barcelona, Spain*

OBJECTIVES: To demonstrate the economic impact of using NovoSeven compared to Feiba for the initial treatment of mild to moderate bleeding episodes in patients with haemophilia A with inhibitors. **METHODS:** A budget impact model was developed based on a previous economic evaluation to calculate the annual budget impact and the treatment cost per episode according to the different treatment strategies. The model presents the costs of the strategies to treat a mild to moderate bleeding episode with up to three lines of treatment, in which the impact parameters are the weight of the patient, the dose, the efficacy and the costs of medication and administration. Three treatment strategies were used: strategy 1: NovoSeven - NovoSeven - NovoSeven, strategy 2: Feiba - NovoSeven - NovoSeven and strategy 3: Feiba - Feiba - NovoSeven. Costs per episode and annual costs were calculated based on local input data on costs and resources and the perspective used was of the Spanish National Health Service (NHS). **RESULTS:** Total costs per patient for one bleeding episode were €10,253, €11,852 and €12,042 for strategies 1, 2 and 3, respectively. Lower total costs per patient with NovoSeven are due to a reduced need for further treatment and associated hospitalisation. Only using NovoSeven saves €23,985 compared to strategy 2 and €26,842 compared to strategy 3 annually. **CONCLUSIONS:** The use of NovoSeven in all three lines of treatment in patients with in haemophilia A compared to using Feiba in the first line of treatment and in the first and second line of treatment saves €1,599 and €1,789 respectively per bleeding episode. This is mainly due to reduced need for further treatment and associated hospitalisation with NovoSeven. Annual cost savings using only NovoSeven are the consequence of lower drug cost and higher treatment efficacy with NovoSeven.

PSY14

PHARMACOECONOMIC EVALUATION OF INTRAVENOUS FERRIC CARBOXYMALTOSE AND IRON SUCROSE IN CORRECTION OF PREOPERATIVE ANAEMIA IN PATIENTS UNDERGOING MAJOR ELECTIVE SURGERY

Gorokhova SG, Ryazhenov VV, Emchenko IV
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To assess the cost-effectiveness of ferric carboxymaltose (FCM) and iron sucrose (IS) in the correction of iron-deficiency anaemia (IDA) before elective major surgery in non-cardiac surgical patients and predict potential budget expenses for the day care services and blood transfusions. **METHODS:** The pharmacoeconomic model was developed based on the data from multicentre prospective study (E. Bisbe et al., 2011) on the efficacy of FCM and IS for correcting preoperative anaemia in patients undergoing major elective non-cardiac surgery. The cost-effectiveness of two intravenous iron formulations was measured as total costs of medicines and day care services per one patient attained iron replenishment or per one patient without IDA at the end of treatment. Budget impact analysis included expenses for the day care services and blood transfusion procedures during intraoperative and/or postoperative period. Sensitivity analysis was performed by including in the model of iron sucrose similars (ISSs). It was considered that treatment with ISSs requires dose increase up to 120-135% of dose of the original IS (E. Lee et al., 2013; J. Rottermbourg et al., 2010). **RESULTS:** The clinical efficacy of FCM was higher compared to that of IS, this was also reflected in better pharmacoeconomic profile of FCM. The CERs were 14,473.61 RUB and 15,222.83 RUB per one patient attained iron replenishment in the FCM and IS groups, respectively. Treatment with FCM was associated with 2.5-fold lower costs of day care services and 2.7-fold lower expenses for blood transfusion procedures. Additional expenses for the day care services were required for patients received ISSs due to increased frequency of injections; this was resulted in the highest CERs in the ISS group. **CONCLUSIONS:** The present study has demonstrated that administration of FCM is economically effective strategy to replenish body iron stores and correct IDA in surgical patients.

PSY15

COST ANALYSIS OF A FIBRIN SEALANT PATCH FOR MILD, MODERATE AND PROBLEMATIC SOFT TISSUE SURGICAL BLEEDING: A HOSPITAL PERSPECTIVE

Corral M[1], Ferko N[2], Hollmann S[2], Delatore P[3], Jamous N[4], Brown ST[2], Rubinger D[2]
[1]*Ethicon Biosurgery, Somerville, NJ, USA,* [2]*Cornerstone Research Group, Burlington, ON, Canada,* [3]*Ethicon, Inc, Somerville, NJ, USA,* [4]*Ethicon Biosurgery, Norderstedt, Germany*

OBJECTIVES: Although there are several hemostats available, drawbacks include limitations with efficacy on first attempt and sub-optimal ease-of-use. Literature suggests that more efficacious hemostats may avert hospital resources and offset upfront acquisition costs. A study was conducted to estimate the cost impact of a novel fibrin sealant patch (i.e., EVARREST™) versus standard of care (SoC) in mild-moderate and problematic soft tissue surgical bleeding. **METHODS:** An economic model was developed to quantify 30-day cost impact of EVARREST from a U.S. hospital perspective. Key resources, collected from two trials, included quantity of initial treatment and re-treatment, operating time, hospitalization, transfusion risk, amount transfused, and ventilator utilization. SoC was composed of Surgicel (mild-moderate bleeding) or Surgicel (88%) and conventional methods (12%) (problematic bleeding). The primary analysis included resources clinically related to the significant hemostasis benefit of EVARREST vs. control (i.e., initial and re-treatment, operating time and transfusion). A secondary analysis included all resources collected. Published data on U.S. costs were applied to resource use. **RESULTS:** In problematic bleeding, the primary analysis predicted that EVARREST is cost-savings for the hospital vs. SoC (-$462 USD per patient) with robust one-way sensitivity results (range: -$199 to -$6,212 USD). In mild-moderate bleeding, EVARREST acquisition cost is partially offset with a cost impact of $507 USD per patient (sensitivity range: $175 to $851 USD). Secondary analyses predicted further resource reduction with EVARREST leading to cost-savings (-$5,096 USD per patient) or reduction in cost impact ($233 USD per patient) for problematic and mild-moderate bleeding respectively. **CONCLUSIONS:** This analysis suggests that the hospital cost impact of EVARREST depends on type of bleed. In problematic soft tissue bleeding, EVARREST may result in important cost savings for hospitals, in addition to meeting an important unmet need. Further study in additional populations may be required to confirm findings.

PSY16

COST ANALYSIS OF BYPASSING AGENT PROPHYLAXIS TREATMENT VERSUS ON-DEMAND THERAPY IN HEMOPHILIA A WITH INHIBITOR IN SPAIN

Villarrubia R[1], Oyagüez I[1], Alvarez MT[2], Mingot E[3], Parra R[4], Casado MA[1]
[1]*Pharmacoeconomics & Outcomes Research Iberia, Madrid, Spain,* [2]*Hospital Universitario La Paz, Madrid, Spain,* [3]*Hospital Regional Universitario Carlos Haya, Malaga, Spain,* [4]*Hospital Universitari Vall d'Hebron, Barcelona, Spain*

OBJECTIVES: To estimate the treatment cost of prophylaxis and acute breakthrough bleeds with Activated Prothrombin Complex Concentrate (aPCC) versus on-demand therapy with recombinant Factor VIIa (rFVIIa) for severe hemophilia A (HA) with inhibitor patients, from the Spanish Healthcare System perspective. **METHODS:** A cost-analysis model was used to compare annual cost per patient of aPCC prophylaxis versus rFVIIa on-demand treatment. Cost estimation included prophylaxis pharmaceutical costs (aPCC), on-demand pharmaceutical treatment for bleedings, bleeding events management (excluding factor), surgeries and HA management. Prophylaxis regimen was 75.72IU/kg three times per week. Total dosage for each hemorrhagic event was 673.46µg/kg for rFVIIa and 233.13U/kg for aPCC, annual number of bleedings was 25 for on-demand therapy and 8 for prophylaxis, assuming 69% reduction due to prophylaxis. A baseline bleeding management cost (€2,971) was estimated based on resource use provided by an expert panel for four bleeding sites (joints [62.5%], muscle and soft tissue [28.6%], mucous membranes [3.6%] and other sites [5.4%]). Drug (ex-factory price with mandatory 7.5% rebate) and unitary costs (€, 2013) were obtained from local databases. **RESULTS:** Estimated annual treatment cost of prophylaxis with aPCC (€523,473) was lower than on-demand treatment with rFVIIa (€622,183). Based on the total agent consumption (789,109IU [aPCC] and 1,050,067µg [rFVIIa]) the pharmaceutical cost accounted for €496,350 for aPCC (14.6% on-demand bleedings and 85.4% prophylaxis) compared to €543,866 for rFVIIa (average bleeding cost of €9,062 [aPCC] and €21,556 [rFVIIa]). Yearly bleedings cost was €23,770 for aPCC versus €74,963 for rFVIIa. A baseline cost for HA management (€2,645) and an average cost of surgeries (€708/year) were estimated for both strategies. Results for sensitivity analyses showed cost-savings ranging from €22,525 to €996,384 of prophylaxis with aPCC vs. on-demand with rFVIIa. **CONCLUSIONS:** Three times/week aPCC prophylaxis could reduce 16% the total treatment cost of severe HA with inhibitor, saving up to €98,000/patient/year.

PSY17

RELATIONSHIP BETWEEN BODY MASS INDEX AND HEALTH CARE COSTS BY PLACE OF SERVICE IN EMPLOYED ADULTS

Abouzaid S[1], Kleinman NL[2], Andersen L[2], Wang Z[1], Powers A[1]
[1]*Eisai Inc., Woodcliff Lake, NJ, USA,* [2]*HCMS Group, Cheyenne, WY, USA*

OBJECTIVES: While previous studies have shown that overweight and obesity are associated with higher costs, less is known about health care costs by place of service (POS) at various levels of BMI. This study measures the impact of BMI as a continuous variable on health care cost at different places of service. POS categories include: pharmacy, doctor's office, inpatient hospital, outpatient hospital or clinic, emergency department, laboratory, and other. **METHODS:** Using 2003-2012 retrospective data from large employers throughout the United States, employees' BMI values were calculated using health risk appraisal data. All study employees were >=18, had >=12 months of health plan coverage after their index BMI screening date, and had no medical claims indicating pregnancy. Employees with BMI<18 (1st percentile) or BMI>47 (99thpercentile) were excluded. Generalized additive models on 12-month post-index POS costs produced estimates of the nonlinear relationship between BMI and cost after controlling for age, gender, marital status, race, salary, zip-code region and index year. **RESULTS:** This study included 71,633 eligible employees; 32.0% were female. The average BMI, age and annual salary were 27.3, 39.8 years and $81,382, respectively. Costs increased significantly with BMI in each POS (P<0.001). Total adjusted annual per-employee health care cost estimates at BMI values of 25, 30, 35, and 45 were $3043, $3932, $4357, and $7248, respectively. Cost estimates by POS at these BMI values were: Pharmacy ($706, $903, $1106, $1372), Inpatient ($398, $678, $643, $2440), Outpatient ($799, $1057, $1113, $1516), Office ($939, $1044, $1174, $1495), Emergency ($131, $159, $200, $186), Laboratory ($34, $38, $46, $43), and Other ($35, $53, $74, $196), respectively. **CONCLUSIONS:** Employees with higher BMI levels incurred more cost at each of the 7 places of service. Because of the high prevalence of overweight and obesity, these costs represent a significant burden for US employers.

PSY18

COHORT ANALYSIS ASSESSING HEALTH CARE COSTS ASSOCIATED WITH OBESITY AT VARIOUS PLACES OF SERVICE IN EMPLOYED ADULTS

Abouzaid S[1], Kleinman NL[2], Andersen L[2], Wang Z[1], Powers A[1]
[1]*Eisai Inc., Woodcliff Lake, NJ, USA,* [2]*HCMS Group, Cheyenne, WY, USA*

OBJECTIVES: This study determines the distribution of health care costs by place of service (POS; pharmacy, doctor's office, inpatient hospital, outpatient hospital or clinic, emergency department, laboratory, and other) among employees based upon body mass index (BMI). **METHODS:** Using 2003-2012 retrospective data from large employers throughout the US, employees' BMIs from health risk appraisal data defined three main cohorts (BMI<27 [normal weight], 27<=BMI<30 [overweight] and BMI>=30 [obese]). The 27<=BMI<30 cohort was further divided into 3 comorbidity subcohorts: those without diabetes, hypertension or dyslipidemia (NonT2DHtnDys), those with hypertension or dyslipidemia without diabetes (HtnDys), and those with diabetes with or without hypertension or dyslipidemia (T2D). All eligible employees were aged>=18, had >=12 months post-index health plan coverage, and had no pregnancy claims. Annual post-index costs were compared between cohorts and between subcohorts using two-part regression modeling, controlling for age, gender, marital status, race, salary, region, and index year. **RESULTS:** This study included 39,696 (BMI<27), 14,281 (27<=BMI<30), and 18,801 (BMI>=30) eligible employees, with total adjusted health care costs of $3,191, $3,695, and $4,844, respectively. Employees with higher BMI were significantly more likely to incur health care costs in every POS category. Obese employees (BMI>=30) had particularly high inpatient costs compared to other cohorts, averaging twice the cost of the BMI<27 cohort ($919 vs. $431, P<0.05). Total costs among subcohorts of 27<=BMI<30 were $2,863 (NonT2DHtnDys), $5,271 (HtnDys), and $7,594 (T2D). NonT2DHynDys employees had significantly lower health care cost than other subcohorts in every POS category. The T2D subcohort had significantly higher pharmacy, inpatient, doctor's office, laboratory and other health care costs when compared to HtnDys. **CONCLUSIONS:** Employees with higher BMI incurred higher average health care costs than other employees at all places of service. Comorbidities, particularly diabetes, exacerbate health care costs of overweight employees. This represents a significant economic burden for US employers given the high prevalence of overweight and obesity.

PSY19

HAEMOPHILIA A: ANNUAL COST COMPARISON BETWEEN FL-RFVIII AND BDD-RFVIII IN FRANCE: WE SHOULD COMPARE THE COST PER PATIENT INSTEAD OF THE PRICE PER UNIT

Haarmann H[1], Epstein J[2], Grumel O[3]
[1]*Baxter Healthcare, Opfikon, Switzerland,* [2]*Baxter BioScience, Westlake Village, CA, USA,* [3]*Baxter France, Maurepas, France*

OBJECTIVES: Hemophilia A is rare bleeding disorder where patients have defective or deficient levels of coagulation factor VIII (FVIII). Recombinant FVIII (rFVIII) are manufactured to treat the patients, either as a full-length rFVIII (FL-rFVIII) molecule replicating natural human FVIII or with the B-domain deleted (BDD-rFVIII). It has been suggested that Deletion of B domain had been implemented to improve production profitability. However, this deletion has been shown to induce increase factor consumption by 32.8% in the US (Epstein 2011) and also may increase the risk of developing inhibitors for previously treated patients (PTP) Hazard Ratio=10.8 (Aledort 2011). Both differences can have an important impact on patient health and on the national health care budget. **METHODS:** A Excel-based decision tree model had been developed to compare the overall cost to treat severe haemophilia A patients from a health care system perspective with the most used FL-rFVIII and

BDD-rFVIII in Europe. Clinical data are from the published literature. Pharmacy cost of rFVIII, immune tolerance induction (ITI) and bypassing agents for patients who developed inhibitors are considered from French health care perspective. **RESULTS:** Both products are listed and reimbursed at similar unit price whereas the overall cost to treat a patient with BDD-rFVIII is higher considering the increased consumption on prophylaxis and the risk of developing an inhibitor for PTPs. This may be translated into an increase cost of 36% over 1 year and 40% over 3 years when treating children and adult PTPs with prophylaxis. **CONCLUSIONS:** The cost study confirms the cost advantage of rFVIII (FL-rFVIII) as well as the need to compare the rFVIII based on the overall cost and not on the price per unit.

PSY20

COST OF ILLNESS OF NEUROPATHIC PAIN IN SPAIN IN 2012 FROM A SOCIETAL PERSPECTIVE

Ruiz L[1], Liedgens H[2], Obradovic M[2]
[1]*Adelphi Real World, Bollington, UK,* [2]*Grünenthal GmbH, Aachen, Germany*

OBJECTIVES: To quantify the total societal costs of Neuropathic Pain (NP) in Spain following a bottom-up prevalence approach. **METHODS:** The sample was drawn from the 2012 Adelphi NP Disease Specific Programme, a cross-sectional survey of 413 primary care physicians and specialists and their consulting patients across the EU5. Physicians completed patient record forms for 826 patients in Spain including patients' socio-demographic information, treatment history and resource utilization. Additionally, 577 patients voluntarily completed another questionnaire that included the Work Activity and Productivity Impairment Questionnaire (WPAI). Health-related costs were collected and adjusted to 2012 prices when needed. For professional caregivers' costs and work losses, Spanish average salaries were used. **RESULTS:** The 826 patients included accounted for a total of € 2,676,893.83, an average of € 3,240.79 per patient, with 72% (€2,350) of these being health related costs, including drugs (50%), consultations (11%), surgical (9%) and non-surgical (2%) procedures. Working losses related with patients' sick leave (as reported by doctors) accounted for 17% (€555) of the costs and professional caregiving added up to 10% of the total costs. The results were extrapolated to national prevalence figures of 2012 excluding patients assumed to be non-treated. The societal costs for 2012 were: health-related costs €514,583,543, work losses €119,417,964 and professional caregivers €72,204,921. Additionally, 91% of the caregivers were non-professional. 191 (33%) of the 577 patients completed the WPAI with an Overall Work Impairment score of 55%. Finally, 183 (33%) of the patients stated that NP prevented them from working at some point, with 26 patients stating this was "permanently". **CONCLUSIONS:** The economic impact associated with Neuropathic Pain (NP) implies substantial annual costs to the Spanish National Health Service of more than €500 Mio. and a large burden on patients' lives and their families. The results shown here suggest that an important part of the real cost is still hidden.

PSY21

EXPLORING THE BURDEN OF ILLNESS OF HEREDITARY ANGIOEDEMA IN THE UNITED KINGDOM

Helbert M[1], Drogon E[2], Mannan A[2], Holbrook T[3], Murray H[3], Piercy J[3]
[1]*Manchester Royal Infirmary, Manchester, UK,* [2]*ViroPharma Europe, Maidenhead, UK,* [3]*Adelphi Real World, Bollington, UK*

OBJECTIVES: Hereditary angioedema (HAE) is a rare but potentially life-threatening condition with intermittent and unpredictable oedema affecting the larynx, abdomen and extremities. This study aims to define the burden of HAE in England and Scotland as published data are limited. **METHODS:** A comprehensive, cross-sectional, retrospective study of the burden of HAE (type I and II) in England and Scotland. Three data collection methods: 1) secondary care data identified using Hospital Episode Statistics based on D.84.1 diagnostic code (defects in complement system, C1-esterase inhibitor deficiency); 2) primary care data accessed through The Health Improvement Network (THIN) database using C-376-000 HAE diagnostic code. Both database analyses identified patients diagnosed ≤10 years and include all episodes ≤2years. Costs were calculated using most up-to-date best-matched HRG tariffs. 3) Primary research in five secondary care centres in England and Scotland collecting information on >100 patients (>18 years) via medical records ≤2years, matched with patient self-completion questionnaires and centre interviews. Selected centres represent different approaches to HAE management to ensure a national representative sample. **RESULTS:** Data collection from all three phases of the study is on-going. Early results from 1) indicate 1,174 HAE patients admitted to hospitals in England, for any reason, in the past two years. Mean length of stay, including day cases, was 2.8 days. The annual total cost of secondary care in England was £3,227,149, corresponding to per HAE patient cost of £2,749. **CONCLUSIONS:** This is the first comprehensive UK HAE cost of illness study, providing a comprehensive understanding from both NHS and patient perspectives. Important insight into patient demographics, pathway of care, treatment patterns, and any regional or sub-population differences in the standard of care will be provided, helping to raise disease awareness in the UK.

PSY22

ADRENAL INSUFFICIENCY: BURDEN OF DISEASE IN FRANCE IN 2011

Bourguignon S[1], Reznik Y[2], Chenuc G[3]
[1]*Stratégique Santé, Evry Cedex, France,* [2]*Caen Hospital, CAEN, France,* [3]*Capionis, Paris, France*

OBJECTIVES: Adrenal insufficiency (AI) is a rare disease caused by a deficiency in hormone synthesis by adrenal glands, due to either the destruction of the glands (primary AI: PAI) or hypothalamic / pituitary causes (secondary AI: SAI). Patients are treated with hormone replacement therapy, mainly hydrocortisone. Our aim was to assess the cost of AI management in France **METHODS:** We used data from the French National Health Insurance (Social security) on patients who benefited from a long duration disease status N°31 for their AI in 2011 (primary and secondary combined) on the one hand, and the results of a Delphi Panel survey on the other hand. This survey, involving 15 endocrinologists from academic hospitals, was designed to better understand the patients' pathway in the absence of guidelines. An epidemiological approach on the prevalence of the disease has led to a cost study using a "top-down" method. Sensitivity analyses were conducted on the following cost parameters: medical and drugs costs in primary care, costs of public and private hospitalizations - chosen according to their weight in the pathway described by the Delphi Panel. **RESULTS:** The social security paid a total of € 5,612,842 for 1377 AI patients in 2011. The annual cost per patient is therefore € 4,076, including 62% for primary care expenses, 29% for public hospital expenses and 9% for private hospital. The total population with AI is estimated between 26,000 and 30,000 patients, leading to a total cost ranging from € 106M and € 122M. A 1% reduction in hospital spending would generate a gain of € 430,000 to € 500,000 per year. **CONCLUSIONS:** Despite AI concerns few patients, significant costs are borne by Social Security. An increased compliance and a better management of symptoms such as fatigue could help optimizing this cost.

PSY23

ECONOMIC BURDEN OF PATIENTS WITH PAINFUL DIABETIC NEUROPATHY IN EUROPE: A SYSTEMATIC LITERATURE REVIEW

Alleman CJM[1], Westerhout KY[1], Hensen M[1], Stoker MJ[2], Chambers C[3], Long SK[2], van Nooten FE[2]
[1]*Pharmerit International, Rotterdam, The Netherlands,* [2]*Astellas, Leiden, The Netherlands,* [3]*Astellas, Chertsey, UK*

OBJECTIVES: Painful diabetic neuropathy (PDN) is a complication of diabetes mellitus. The aim of this research was to describe the epidemiology and economic burden resulting from PDN in Europe. **METHODS:** A systematic literature review was performed according to a pre-defined search strategy and review criteria in Embase and PubMed from 2003 to 2012. Conference proceedings and Health Technology Assessment (HTA) organizations' websites were also searched from 2010 to 2012. **RESULTS:** In total, 23 original studies were identified that covered either epidemiology (n= 16) or economic burden (n=7) for PDN patients in Europe. 13 - 26% of European diabetes patients are reported to develop PDN. Health care costs per PDN patient were between €2,441 and €2,963 *per annum* in UK and Spanish studies, respectively. Inpatient care, medical visits and drug costs accounted for the majority of the total costs, although drug costs can vary widely depending on the choice of medication. Health care costs for PDN lead to a high total economic burden for European countries. Considering the identified prevalence data and cost estimates, the estimated total annual health care burden for the UK would be approximately €1.7 billion, from a payer perspective. In addition, PDN is significantly associated with disruptions in employment status and productivity loss, primarily driven by impairment while working (presenteeism), resulting in average European per-patient productivity losses of € 10,484 *per annum*. Pain severity highly influences economic outcomes: higher severity has been linked to significant increases in resource use, productivity losses and health care costs. **CONCLUSIONS:** The large number of PDN patients combined with the cost per patient results in a high economic burden of PDN for European countries. More severe pain results in increased resource use and costs for payers and society; therefore, more effective PDN treatments will lead to patient as well as economic benefits.

PSY24

COST OF OBESITY AND ECONOMIC VALUE OF OBESITY SURGERY FOR TURKEY (CEVOS-T)

Kockaya G[1], Tatar M[2], Ergin G[3], Atikeler K[2]
[1]*Covidien, Istanbul, Turkey,* [2]*Hacettepe University, Ankara, Turkey,* [3]*Polar Health Economics Consultancy, Ankara, Turkey*

OBJECTIVES: Obesity and its comorbidities are among the primary challenges that health systems face globally. Obesity is rapidly becoming a problem in Turkey as well. Recent research has revealed that 30.3% of the population is obese(20.5% of males, 41% of females) of which 2.9% of the obese population is classified under the morbid obese category. The 2003 Burden of Disease Study also concluded that 26.006 deaths for males and 31.136 deaths for females could be averted by decreasing the ratio of obese population. **METHODS:** The objective of this study is to find out the economic impact of obesity with its possible economic benefits of obesity surgery for Turkey. **RESULTS:** Literature search and expert panel are the main methodologies used in the study. A comprehensive literature search was undertaken with key words in PubMEd to find out the extent of obesity and its comorbidities and treatment methods in Turkey. Cost of obesity for Turkey was calculated depending on the published literature. An expert panel questionnaire form was designed after the literature search aiming at finding the cost. The form was sent to the experts in advance and a panel discussion was undertaken to reach a consensus. After the consensus building phase the economic benefits of obesity surgery were estimated based on the price tariff declared by the Social Security Institution(SGK). **CONCLUSIONS:** Cost of obesity for Turkey was estimated as US$ 787.184.000 for 2012. It was the 1.05% of gross domestic product of Turkey. SGK pays US$ 1707 weighted average for obesity surgery. It was estimated that return of investment on obesity surgery can be possible after the third year of surgery. The study indicated that obesity has a great impact to Turkish economy. On the other hand, obesity surgery can have a positive impact with its economic benefits to Turkish health system.

PSY25

A SYSTEMATIC LITERATURE REVIEW ON THE EPIDEMIOLOGY AND ECONOMIC BURDEN OF ANAEMIA ASSOCIATED WITH CHRONIC KIDNEY DISEASE

Rizzo M[1], Iheanacho I[1], van Nooten FE[2], Goldsmith D[3]
[1]*Evidera, London, UK,* [2]*Astellas, Leiden, The Netherlands,* [3]*Guy's Hospital London, London, UK*

OBJECTIVES: The epidemiological and economic burden associated with anaemia in patients with chronic kidney disease (CKD) in Europe has not been explored recently using systematic literature review (SLR) methods. Therefore, an SLR was conducted to assess these topics. **METHODS:** A systematic search was conducted of MEDLINE- and EMBASE-indexed literature on anaemia in CKD from 2007 to 2012 for publications on epidemiology and economic burden. Data from included articles were abstracted into a pre-designed template and synthesised using qualitative methods. **RESULTS:** The review identified 19 studies reporting on epidemiology and nine on economic burden. The prevalence of anaemia among patients with CKD varied widely by setting, being generally lower in those from the general population and

primary care (range: 1.0%–9.4%) than in general hospitals (range: 5.8%–43.3%), and highest in specialist nephrology settings (range: 16.0%–97.6%). Also, prevalence rates increased with the CKD stage (1–2: 14.1%–27.9%; 3: 25.5%–91.1%; 4: 36.0%–85.5%; 5: 97.6%). The cost of managing anaemia per patient per year varied across studies from £2,616 (2006–2007 Great British Pounds; GBP) to £3,740 (2006 GBP) in the UK, to €5,617 in France (cost year not reported). One study reported that the overall cost of managing anaemia was highest in patients with CKD Stage 3 compared with other stages (3: £4,162,056 vs. 4–5: £243,288; 2006–2007 GBP). Another study reported higher costs per patient per annum for individuals with lower haemoglobin (Hb) levels (Hb >12 g/dL: €2,418; Hb <10 g/dL: €13,005; cost year not reported). Among patients with CKD, those with anaemia were more likely to be hospitalised (61% vs. 50% of those without anaemia). **CONCLUSIONS:** Anaemia is a highly prevalent condition in CKD across treatment settings in Europe, and the limited evidence available suggests it is associated with a substantial economic burden.

PSY26

MODELLING THE PREDICTIVE VALUE OF PAIN INTENSITY ON COSTS AND RESOURCES UTILIZATION IN PATIENTS WITH PERIPHERAL NEUROPATHIC PAIN

Pérez C[1], Navarro A[2], Saldaña MT[3], Wilson K[4], Rejas J[5]
[1]*Pain Clinic, Hospital de la Princesa, Madrid, Spain,* [2]*Primary Care Health Centre Puerta del Ángel, Madrid, Spain,* [3]*Primary Care Health Centre Raíces, Castrillón, Asturias, Spain,* [4]*Pfizer Inc., Walton Oaks, UK,* [5]*Pfizer S.L.U., Alcobendas/Madrid, Spain*

OBJECTIVES: Peripheral neuropathic pain (PNP) implies a significant economic burden that results in major health care and indirect costs. The aim of the present analysis was modelling the association and predictive value of pain intensity on costs and resources utilization (health care and non-health resources) in patients with chronic PNP treated in routine clinical practice conditions in Spain. **METHODS:** Secondary economic analysis based on data from a multicenter, observational and prospective cost-of-illness study in patients with chronic PNP refractory to previous treatment. Data on resources utilization and pain intensity was collected at baseline and 12 weeks after starting a new treatment. Pain intensity was measured using the 0-100 mm Visual Analogue Scale (VAS) of the Short Form McGill Pain Questionnaire. Univariate and multivariate linear regression models were fitted to identify independent predictors of costs and health care and non-health care resources utilization. **RESULTS:** A total of 1703 patients were included in the current analysis. Pain intensity was an independent predictor of total costs ([Total costs(Euros)] = 35.6 x [VAS pain intensity] + 214.5; coefficient of determination [R^2]=0.19, p<0.001), direct costs ([Direct costs(Euros)] = 10.8 x [VAS pain intensity] + 257.7; R^2=0.06, p<0.001) and indirect costs ([Indirect costs(Euros)] = 24.8 x [VAS pain intensity] – 43.4; R^2=0.19, p<0.001) related to chronic PNP in the univariate analysis. Pain intensity remain significantly associated with total costs, direct costs and indirect costs after adjustment by other covariates in the multivariate analysis (p<0.001). The impact of pain intensity on health care and non-health care resources utilization accounted for such findings. **CONCLUSIONS:** Pain intensity predicts the health care and non-health care resources utilization, and costs related to chronic PNP. Management of patients with drugs associated with a higher reduction of pain intensity will have a greater impact on the economic burden of that condition.

PSY27

RESOURCE UTILIZATION AND COSTS ASSOCIATED WITH RITUXIMAB TREATMENT IN PATIENTS WITH PEMPHIGUS AND PEMPHIGOID: A COMPARISON OF 6 MONTHS BEFORE AND 6 MONTHS AFTER TREATMENT

Heelan K, Shear N, Knowles S, Hassan S, Mittmann N
Sunnybrook Health Sciences Centre, Toronto, ON, Canada

OBJECTIVES: Pemphigus and pemphigoid are a rare group of potentially fatal diseases, causing blistering on mucosal and epidermal surfaces. Long-term treatment with systemic corticosteroids and immunosuppressive agents such as intravenous immunoglobulin (IVIg) are usually required. Rituximab (RTX) is increasingly being used for autoimmune bullous dermatoses (AIBD) and has shown to be effective, however, in Canada, RTX is not approved for AIBD. Given the potential cost associated with the use of RTX, there is a need to quantify the issues around accessing it for AIBD patients. **METHODS:** Resources (e.g., treatment, lab costs, procedures, access to health care providers) associated with 89 AIBD patients were collected and quantified 6 months prior and 6 months post RTX initiation. Costs of adverse events secondary to standard treatment (e.g., steroid adverse effects such as diabetes, cataracts, osteoporosis etc) and costs of medications used to prevent steroid adverse effects (e.g., proton pump inhibitors, bisphosphonates) were not calculated. Unit costs (2013 $CAN) were applied to the resources. Overall cohort costs pre and post RTX, as well as cost per patient, were calculated. Cost drivers were identified. **RESULTS:** The overall cohort cost for 6 months pre-RTX was $3.7million (M), and 6 months post was $2.6M (30.3% decrease). IVIg was shown to be the main cost driver. 6 months pre-RTX, 157 months of IVIG was used ($3.6M) compared to 71 months ($1.6M) 6 months post. The cost associated with access to health care resources significantly reduced from $46,715 vs. $22,978, and fewer visits to the dermatologist were required (377 vs. 256 visits). A decrease was also observed in the cost of specialist consultations required ($5,807 vs. $3,234) and other treatment/medication use ($64,548 vs. $48,045). The cost per patient decreased ($41,497 vs. $28,923). **CONCLUSIONS:** RTX is effective in reducing the number of resources and costs associated with treatment of AIBD.

PSY28

HEALTH AND SOCIAL CARE RESOURCE USE BY INDIVIDUALS WITH FRAGILE X SYNDROME: RESULTS OF TWO DELPHI PANELS

Barry SJ[1], London P[2], Bostock T[1], Adlard N[3], Lakhdari K[4], Aubertin G[5], Burge P[6], Corbin JF[7], Gagnon S[7], Hassiotis A[8]
[1]*Optum, Burlington, ON, Canada,* [2]*Optum, Chicago, IL, USA,* [3]*Novartis Pharmaceuticals UK, Surrey, UK,* [4]*Novartis Pharmaceuticals Canada, Montreal, QC, Canada,* [5]*University of British Columbia, Victoria, BC, Canada,* [6]*Queen's University, Kingston, ON, Canada,* [7]*University de Sherbrooke, Sherbrooke, QC, Canada,* [8]*University College London, London, UK*

OBJECTIVES: To estimate health and social care resource use in treating individuals with Fragile X Syndrome (FXS) in Canada and the United Kingdom (UK). FXS is the most common inherited form of intellectual disability (ID) worldwide; however its impact on resource use is not well documented. **METHODS:** Delphi panels were formed to generate consensus-based estimates of resource use. Panelists from multiple disciplines were recruited (7 panelists in Canada, 6 in UK) and a questionnaire developed to obtain estimates from each panelist by 2 age groups, 2 severity levels and 24 service types for each of 9 items from the Aberrant Behavior Checklist (ABC) a proxy completed instrument to rate maladaptive behaviors of individuals with ID. A factor weight was estimated to differentiate costs by gender and a self-declared confidence score (1 – 5) was reported for each ABC item. Mean total service counts and coefficients of variation (CV) were calculated to assess variance between panelists and between rounds. Initial results were reviewed with panelists in a facilitated group discussion after which the questionnaire was repeated. Final data were based on the second round of estimation. **RESULTS:** Comprehensive resource data were collected for both countries. There was lower variance and higher confidence in both countries in round 2 compared to 1. Rounds 1 and 2 means (CV) for Canada were [6,723 (0.69) 8,575 (0.52)] and for UK were [6,953 (0.96) 6,023 (0.76)]. The average level of self-declared confidence increased from 2.6 to 3.3 in Canada and from 2.6 to 2.8 in the UK. **CONCLUSIONS:** The study generated comprehensive resource use data for treating individuals with FXS in Canada and the UK. Credible and validated estimates were generated through group discussion and refinement of initial estimates. The resulting data will be important in performing economic evaluations of treatments for patients with FXS.

PSY29

IMPACT OF BARIATRIC SURGERY ON OBESE PATIENTS MANAGEMENT AND RELATED COSTS: A FRENCH NATIONAL CLAIMS DATABASE ANALYSIS OVER THE PERIOD 2005 -2011

Czernichow S[1], Emery C[2], Fagnani F[2], Gourmelen J[1], Szwarcensztein K[3], Lafuma A[2]
[1]*INSERM, Villejuif, France,* [2]*Cemka Eval, Bourg La Reine, France,* [3]*ETHICON SAS, Issy les Moulineaux, France*

OBJECTIVES: To gain an understanding of the impact of bariatric surgery on the current medical management of obese patients. **METHODS:** The EGB database is a 1/97 representative sample (around 600,000 individuals) of the national claims database covering the whole French population including outpatients and inpatient care. Adult patients treated for the first time over the period 01/01/2007 to 31/12/2009 by bariatric surgery were identified through related procedures and obesity ICD-10 codes. A cohort of patients was constituted with a 2-year follow-up before and after the index procedure date (T). Reimbursed medical consumption over this 4-year period was recorded and presence of co-morbidities was identified through ICD-10 codes, reimbursement of specific drugs or procedures. **RESULTS:** A total of 350 patients meeting the selection criteria were identified in the database with a mean age of 38.9 (+/- 11.3) years, 83.4% female and 69.7% had a BMI in the range 40-50. The distribution of patients according to bariatric procedure was gastric banding (62.6%), gastric by-pass (19.7%), sleeve gastrectomy (16.6%) and bilio-pancreatic diversion (1.1%). The annual per capita reimbursed health expenses evolved from 2.633€ (+/-3.124€) in Year (T-2), to 3.557€ (+/-3.380€) in Year (T-1), to 4.240€ (+/-3.840€) in Year (T+1) (excluding procedure cost) to 3.755€ (+/-5.037€) in Year (T+2). In 39% of patients those costs decreased between T-2 and T+2, (>5%) and the only two variables significantly explaining this decrease were the reduction of consumption for anti-Diabetes and/or anti-Hypertension drugs. Most items of medical consumption increased over the period pre and post procedure but started to decrease in Year T+2. **CONCLUSIONS:** The visits for preparing bariatric surgery were probably an opportunity for those patients to benefit from a general check-up which has generated extra short term medical consumption. Additional research with longer follow up could better capture the benefits of bariatric surgery on medical consumption.

PSY30

COST-CONSEQUENCE ANALYSIS OF A TREATMENT STRATEGY INCLUDING PONATINIB COMPARED TO A TREATMENT STRATEGY INCLUDING ONLY THE 2ND GENERATION TYROSINE KINASE INHIBITORS (2G TKIS), DASATINIB OR NILOTINIB, IN RESISTANT PATIENTS WITH PHILADELPHIA CHROMOSOME-POSITIVE (PH+) LEUKEMIA, IN ITALY

Chiroli S[1], Furneri G[2], Pane F[3]
[1]*1ARIAD Pharmaceuticals (Europe) Sárl, Lausanne, Switzerland,* [2]*Italian National Research Center on Aging, Ancona, Italy,* [3]*Università Federico II, Napoli, Italy*

OBJECTIVES: To assess treatment cost and duration (months) of major cytogenetic response (MCyR) using ponatinib in patients intolerant or resistant to 2G TKI, compared to treating with only 2G TKIs, in patients with Ph+ leukemia, in Italy. **METHODS:** A 3-year Markov model with 1-year cycles simulated patients with Ph+ leukemia to estimate outcomes in those eligible for ponatinib therapy, defined as 1) 2G TKI-resistant, 2) 2G TKI-intolerant if imatinib is not clinically appropriate, or 3) with T315I mutation. Eligible patients received treatment sequences including 2G TKIs and ponatinib in the ponatinib arm and 2G TKI only in the comparator arm. Patients without MCyR by 12 months were switched to the next therapy line until TKI options were exhausted, then to best supportive care. MCyR rates for 2G TKI or ponatinib were estimated from clinical trial data and expert opinion. Patients were assumed to accrue MCyR months until estimated treatment failure. Monthly treatment costs reflect approved EU dosing and list prices; cost of ponatinib was assumed equivalent to the US. **RESULTS:** We estimated 184, 280, and 360 ponatinib-eligible patients in years 1-3, respectively. Treating ponatinib-eligible Ph+ leukemia patients with 2G TKIs yielded a 3-year cost of €58.51 million and a total of 2,536 months in MCyR, at an average cost of €23,068/MCyR month. Using ponatinib in eligible patients cost €79.54 million and provided 5,649 months in MCyR, at an average cost of €14,079/MCyR month. **CONCLUSIONS:** The treatment strategy includ-

ing ponatinib provided more than double (2.2-fold) the MCyR months at 36% higher cost compared to the 2G TKI strategy. The average cost/MCyR month with ponatinib was lower than the average cost/MCyR month with 2G TKIs. While there are limitations with the methology and assumptions of the model, this analysis suggests treatment with ponatinib may provide good value for ponatinib-eligible Italian patients.

PSY31

EVALUATION OF THE COST-EFFECTIVENESS OF THE CAPSAICIN PATCH QUTENZATM FOR THE TREATMENT OF PERIPHERAL NEUROPATHIC PAIN IN THE UNITED KINGDOM

Trueman D[1], Poole CD[2], Chambers C[3], Odeyemi I[4], Currie C[2]
[1]*Abacus International, Bicester, UK,* [2]*Cardiff University, Cardiff, Wales, UK,* [3]*Astellas Pharma Europe Ltd., Staines, UK,* [4]*Astellas Pharma Europe Ltd., Staines, UK*

OBJECTIVES: To estimate the cost-effectiveness of using the capsaicin patch QUTENZATM prior to use of more costly neuropathic pain medications for individuals with peripheral neuropathic pain (PnP). **METHODS:** A decision tree and Markov model was developed using inputs from a prospective, observational study. This study provided estimates of clinical efficacy, health utility and resource use. The model considered two treatment strategies: 1. a capsaicin patch followed by pregabalin and then a subsequent last-line therapy, and 2. no exposure to a capsaicin patch. A systematic review and meta-analysis were used to estimate the effectiveness of pregabalin. Response was defined as a ≥50% reduction in pain at week-8. Patients who responded were assumed to experience pain relief and increase in health-related quality of life until the resolution of pain (or death). Non-responders were assumed to switch therapy, and individual's that failed last-line therapy were assumed to experience baseline pain (unless resolution of pain or death). Costs were based on published sources. The primary outcome was the incremental cost-effectiveness ratio (ICER). The perspective was the UK National Health Service and personal social services. **RESULTS:** Key parameter estimates derived from the observational study were: the probability of response for capsaicin patch (29.5%), the mean number of patches per application (1.5), the mean time to retreatment (218 days), The baseline EQ-5D score was 0.370; response was associated with an increase in EQ-5D utility of 0.353 from baseline. The base-case ICER was £2,292 per quality-adjusted life-year (QALY). This varied by time horizon. Probabilistic sensitivity analysis suggested that over a lifetime horizon, a treatment strategy placing capsaicin patches before pregabalin had a 99.9% probability of being cost effective at a willingness-to-pay threshold of £20,000. **CONCLUSIONS:** The capsaicin patch used before pregabalin was a highly cost-effective treatment in the management of peripheral neuropathic pain.

PSY32

COST EFFECTIVENESS OF INDUCTION ANESTHETIC AGENTS

Nagappa AN[1], Karthik R[1], Prabhu N[2], Umesh G[3]
[1]*Manipal University, MCOPS, Manipal, India,* [2]*Manipal Univiersity, Manipal, India,* [3]*Manipal University, Manipal, India*

OBJECTIVES: To evaluate the cost effectivenss of Thiopentone and Propofol for over night induction anesthesia in a tertiary care hospital. **METHODS:** A prospective observational study in which the patients scheduled for general anaesthesia were adminsitred EQ5D 5L(Qol question aire) after six hour and 24 hours of administering Induction Aneasthesia. Kuppuswamy scale was applied to asses the socioeconomic status along with the demographic detials **RESULTS:** The average of EQ5D5L scores for Propofal was 14.2 and for Thiopentone 16.0. The cost of the Propofol brand used in hospital were 250INR and 260INR. Thiopentone , only one brand was avialable costing 62 INR. The Propofol was the most commonly used induction anesthetic and it costs more than 4 times of Thipentone. The patients socioeconomic categorirzation based on Kuppuswmy Scale revealed nearly 50% of patients belonged to lower middle class and 35% middle class and rest of the patients to Upper class. Incremental cost effectivness ratio for Thiopentone agianst Propofol was found to be -110; **CONCLUSIONS:** The Propofol although expensive does not offer any advantage over the Thiopentone as for quality of life among patients who under went induction anethesia

PSY33

COST-EFFECTIVENESS ANALYSIS OF CYSTEAMINE IN THE TREATMENT OF PATIENTS WITH CYSTINOSIS – A RARE DISEASE

Walczak J[1], Stelmachowski J[1], Obrzut G[1], Hubert A[2]
[1]*Arcana Institute, Cracow, Poland,* [2]*Orphan Europe, Paris La Défense, France*

OBJECTIVES: To perform a cost-effectiveness analysis (CEA) of cysteamine in the treatment of infantile cystinosis vs. control group consisting of patients who had been given only conservative and symptomatic treatment (CaST). **METHODS:** Markov model was developed in TreeAge Pro 2009. The model evaluated the costs and health outcomes of cysteamine treatment at a dose of 1.30 g/m^2/day compared with the use of CaST. The model distinguished two populations, depending on the time of initiation of the treatment (before the age of two – P1 and after the age of two – P2, which implies worse prognosis for the time of occurrence of end stage renal disease (ESRD)). The CEA was conducted from both a common payer perspective (a patient and a public payer) and a public payer perspective. The time horizon of the analysis covered the period from the age of one or four (depending on the start of cysteamine therapy) to fifty (currently, the oldest living patients with cystinosis reach the fifth decade of life). The main measures of the outcomes in the CEA were life-years gained (LYG) and life-years gained to the onset of ESRD. **RESULTS:** From the common payer perspective the cost per LYG was PLN 95,337 and PLN 192,272, respectively for the population P1 and P2. Cost of LYG to the onset of ESRD was PLN 33,317 and PLN 64,163, respectively for populations P1 and P2. The results obtained from the public payer perspective did not differ significantly from the results obtained from the common payer perspective. **CONCLUSIONS:** Cysteamine treatment of patients with cystinosis vs. therapy involving only CaST is more expensive, however produces better health outcomes. Regarding the acceptability threshold in Poland cysteamine therapy can be considered a cost-effective technology compared with CaST in patients who began treatment before the age of two.

PSY34

COST-EFFECTIVENESS OF SUGAMMADEX FOR ROUTINE REVERSAL OF NEUROMUSCULAR BLOCKADE, WITH EXTUBATION AT A TOF RATIO OF 0.9, IN ANAESTHETISED PATIENTS UNDERGOING ELECTIVE SURGERY IN ENGLAND AND WALES

Praet C[1], D'Oca K[1], O'Regan C[1], Insinga RP[2], Maiese EM[3]
[1]*MSD Ltd., Hoddesdon, UK,* [2]*Merck & Co. Inc., Upper Gwynedd, PA, USA,* [3]*Merck & Co, Inc., Whitehouse Station, NJ, USA*

OBJECTIVES: To assess the cost-effectiveness of sugammadex compared with neostigmine + glycopyrrolate as a reversal agent for moderate and deep rocuronium or vecuronium-induced neuromuscular blockade (NMB) in the elective setting in England and Wales, when extubation occurs at a train-of-four (TOF) ratio of 0.9. **METHODS:** A decision tree comparing the cost-effectiveness of sugammadex versus neostigmine + glycopyrrolate when reversing moderate or deep NMB induced by commonly used neuromuscular blocking agents (NMBAs) (atracurium/rocuronium/vecuronium) was developed. Extubation was modelled to occur at a TOF ratio of 0.9, as may happen when using objective NMB monitoring to determine when to safely extubate. Time to recovery was used to calculate the cost of patients recovering in theatre based on both the average cost per minute of theatre time, and operating room (OR) staff costs per minute. Effectiveness was measured by the number of prolonged paralysis cases prevented by each treatment regimen. **RESULTS:** Reversal of moderate NMB: when considering average cost per minute of theatre time, results show that sugammadex strategies are dominant compared with all assessed comparators. When considering OR staff cost per minute, results show that rocuronium with sugammadex is dominant over all assessed comparators, with the exception of atracurium with neostigmine + glycopyrrolate (ICER< £100). Reversal of deep NMB: when considering either costing scenario, results show that sugammadex strategies are dominant over all assessed comparators, with the exception of atracurium with neostigmine + glycopyrrolate (ICER < £330). **CONCLUSIONS:** In clinical settings where extubation occurs at a TOF ratio of 0.9, and time savings may be realized for all OR staff, under both moderate and deep NMB scenarios in the elective surgery setting, sugammadex is either dominant or shows reasonable levels of cost-effectiveness (with low ICERs <£330 when not dominant against neostigmine+ glycopyrrolate), whilst also filling an unmet need for deep NMB reversal.

PSY35

COST-EFFECTIVENESS ANALYSIS OF A VACCINATION PROGRAMME FOR THE PREVENTION OF HERPES ZOSTER AND POST-HERPETIC NEURALGIA IN ADULTS AGED 50 AND OVER IN GERMANY

Largeron N[1], Préaud E[1], Boehm K[2], Aidelsburger P[2], Anger D[3], Bianic F[3]
[1]*Sanofi Pasteur MSD, Lyon, France,* [2]*CAREM GmbH, Sauerlach, Germany,* [3]*OptumInsight, Nanterre, France*

OBJECTIVES: A vaccine is licensed in Europe for the prevention of Herpes Zoster (HZ) and postherpetic neuralgia (PHN) in adults aged ≥50 years. The objective of this study was to assess the cost-effectiveness of a vaccination programme in Germany in this population. **METHODS:** An existing European Markov Model was adapted to the German health care setting and cost-effectiveness outcomes were assessed from the statutory health insurance (SHI) and from the societal perspective. The Markov Model compares a HZ vaccination policy for adults aged ≥50 years with a no vaccination policy. Health states considered are healthy, HZ, PHN, healthy post-HZ and death. HZ and PHN states are further split by pain severity (mild, moderate or severe). Model outcomes include cost/HZ case avoided, cost/PHN case avoided and cost/quality-adjusted life year (QALY) gained. Additionally we assessed the number needed to vaccinate (NNV) to avoid one case of HZ or PHN. Input data were obtained from German data sources, international and German study results as well as published literature. Discounting was done in accordance to guidelines from the German Institute for Quality and Efficiency in Health Care (IQWiG). **RESULTS:** Preliminary results of the base-case analysis show incremental cost-effectiveness and cost-utility ratios (ICER) in amount of € 2,223 per HZ case avoided and € 22,923 per QALY gained from a payer perspective. In sensitivity analyses discount rates, vaccine prices and no hospitalization assumption showed a major impact on the results. **CONCLUSIONS:** Our cost-effectiveness analysis shows that a HZ vaccination policy for adults aged ≥50 years in Germany could provide public health and economic effects in the German health care system.

PSY36

THE POTENTIAL OF A REDUCTION IN THE RISK OF OPIOID-RELATED FRACTURES TO DRIVE THE COST-EFFECTIVNESS OF AN ANALGESIC

Cawson M[1], Knight C[2], Hirst M[3], Dunlop W[3]
[1]*RTI Health Solutions, Manchester, UK,* [2]*RTI Health Solutions, Sheffield, UK,* [3]*Mundipharma International Limited, Cambridge, UK*

OBJECTIVES: An increased risk for fractures has been observed in patients treated with opiates, possibly resulting from falls related to central nervous system effects, such as dizziness. Observational data suggest that the semisynthetic opioid, buprenorphine, may be associated with a lower fracture risk than some other opiates such as tramadol. Our objective was to perform a preliminary analysis to explore whether a buprenorphine-class drug has the potential to be cost-effective due to a reduced risk for fracture. **METHODS:** Decision-analytic modeling was used to project fracture-related outcomes and costs over 1 year. Quality-adjusted life-years (QALYs) and costs (in 2012 pounds sterling) were estimated from a health service perspective. Odds ratios for forearm, hip, and spine fractures, by drug, estimated from real-world hospital discharge data (Vestergaard et al., 2006), were applied to the risk for fracture in the general population.

Drug costs were based on the 10-µg per hour buprenorphine patch and the equivalent tramadol dose (2013 British National Formulary listings). Fracture costs were from a recent National Institute of Health and Care Excellence submission; utility weights were obtained from the literature. **RESULTS:** For a population of 100,000, the model predicted a reduction in the number of additional fractures (forearm, hip, or spine) associated with analgesic use from over 2,000 for patients treated with tramadol to under 20 for patients treated with buprenorphine. An estimated £5.5 million was saved and over 1,300 QALYs were gained. In sensitivity analysis, buprenorphine was dominant in most analyses and most sensitive to treatment duration. The cost-effectiveness estimate was below £20,000 per QALY in all scenarios. **CONCLUSIONS:** Our preliminary analysis suggests that buprenorphine has the potential to be dominant and cost-effective, compared with tramadol.

PSY37

COST-EFFECTIVENESS OF ENZYME REPLACEMENT THERAPY (ERT) WITH ALGLUCOSIDASE ALFA IN CLASSIC-INFANTILE PATIENTS WITH POMPE DISEASE

Kanters TA[1], Plug I[2], Rutten-van Mölken MPMH[1], Redekop W[1], Van der Ploeg AT[2], Hakkaart L[1]

[1]*Erasmus University Rotterdam, Rotterdam, The Netherlands,* [2]*Erasmus University Medical Center, Rotterdam, The Netherlands*

OBJECTIVES: Infantile Pompe disease is a rare metabolic disease. Enzyme replacement therapy (ERT) has proven to have substantial effects on survival in infantile Pompe disease. However, costs of therapy are very high. This paper assesses the cost-effectiveness of ERT in infantile Pompe disease. **METHODS:** A patient simulation model was used to compare costs and effects of ERT with costs and effects of supportive therapy (ST). The model was filled with data on survival, quality of life and costs. For both arms of the model, data on survival were obtained from international literature. In addition, survival as observed among 20 infantile Dutch patients, who all received ERT, was used. Quality of life was assumed to be the same in both groups and was measured using the EQ-5D. Costs included the costs of ERT, which depend on a child's weight, and costs of health care use, informal care and infusions. A lifetime time horizon was used, with semi-annual time cycles. **RESULTS:** On average, ST receiving patients were modelled not to survive the first half year of life; whereas the life expectancy in the ERT patients was modelled to be almost 14 years. Lifetime incremental QALYs were 6.7. Incremental costs were estimated to be € 7.0 million, consisting for 95% of treatment costs. The incremental costs per QALY were estimated to be € 1.0 million. The incremental cost per life year gained was estimated to be € 0.5 million. **CONCLUSIONS:** In 2012, the Dutch health care insurance board advised the Minister of Health to reimburse enzyme replacement therapy in Pompe disease, despite its unfavorable ICER. Other factors, such as the rarity of the disease, equity considerations, and the relatively modest budget impact have probably played a role in this decision. These and other factors could be incorporated in a formal multi-criteria decision analyses.

PSY38

COST-EFFECTIVENESS AND COST-UTILITY ANALYSIS OF BELIMUMAB FOR THE TREATMENT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN PORTUGAL

Gouveia M[1], Borges M[2], Augusto M[2], Costa J[2], Treur M[3], Lopes S[4]

[1]*Católica Lisbon School of Business and Economics, Lisbon, Portugal,* [2]*Center for Evidence Based Medicine, Faculty of Medicine, University of Lisbon, Lisbon, Portugal,* [3]*Pharmerit International, Rotterdam, The Netherlands,* [4]*GlaxoSmithKline Portugal, Algés, Portugal*

OBJECTIVES: To estimate the incremental cost-effectiveness (ICER) and cost-utility ratio (ICUR) of belimumab compared to standard care (SC) for the treatment of patients with Systemic Lupus Erythematosus (SLE) in Portugal. **METHODS:** A lifetime microsimulation model represented the complex and multidimensional course of SLE, based on long term data from a US cohort of SLE patients. The analysis was undertaken using a societal perspective with 5% discount rates for costs (direct and indirect costs), and effects [Life Years Gained (LYG) and QALY (Quality Adjusted Life Years)]. The model was calibrated with the phase III BLISS trials data, and UK utility values. The ICER and ICUR were estimated by comparison of SC *vs*SC with belimumab, with a lifetime analytic horizon. Belimumab non-responders were discontinued after 6 months and belimumab treatment was maximized at 3 years. **RESULTS:** The model demonstrated that adding belimumab to SC to treat SLE patients with high disease activity, positive anti-dsDNA antibodies, and low complement (C3, C4) levels, would result in a potential gain of 0.41 life-years, and 0.32 QALYs. Incremental costs were€ 8,400, resulting in an ICER of €20,649/LYG and ICUR of €25,917/QALY for the base case scenario. ICER and ICUR are insensitive to the follow-up treatment costs of SLE, and wastage of drug; moderately sensitive to duration of treatment, and waning time; and very sensitive to discount rates, and exclusion of indirect costs. The probabilistic sensitivity analysis reveals a cost-effectiveness probability of 59% for a €30,000/QALY threshold, and a median ICUR of €27,932/QALY (95% confidence interval: €14,215/QALY - €52,279/QALY). **CONCLUSIONS:** The analysis suggests that adding belimumab to SC for SLE patients with high disease activity, positive anti-dsDNA, and low complement levels, is cost-effective, presenting an ICER and ICUR below the commonly used threshold. This study is funded by GlaxoSmithKline, protocol #HO-13-13626

PSY39

THE COST OF PRODUCING A UNIT OF BLOOD IN HOSPITALS: A NATIONWIDE ECONOMIC ANALYSIS FOR THE CASE OF GREECE

Fragoulakis V[1], Stamoulis K[2], Grouzi E[3], Maniadakis N[1]

[1]*National School of Public Health, Athens, Greece,* [2]*National Blood Centre (EKEA), Athens, Greece,* [3]*Transfusion Service of "Agios Savvas" Regional Cancer Hospital, Athens, Greece*

OBJECTIVES: To estimate the cost of producing a unit of blood from a NHS and societal perspective in Greece. **METHODS:** In line with the official guidelines, the cost of blood production accounted only for the resources expended for collection, processing, laboratory testing, storage, as well as the indirect donor's productivity loss. Hence, the cost associated to donor recruitment, pre-transfusion preparation, transfusion administration, follow up management of adverse events, and other long-term relevant costs were not taken into consideration. Two separate questionnaires were used to collect data regarding: personnel time, annual blood quantities collected, percentage of wastage, consumables utilization, institutional overheads, information technology expenditure, medical equipment utilized, nuclear acid tests, other laboratory tests and indirect costs. Data gather by 53 hospitals across the country. An economic model was build using also economic data collected by the National School of Public Health and the Ministry of Health. All data referred to the year 2012. **RESULTS:** The cost distribution was positively skewed (skewness:1.530). The unweighted mean cost of collecting a blood unit was estimated at €146.43 (*standard deviation*: +€28.18, *min/max*: €110.25-€240.84). In addition, the indirect cost of donors' loss of productivity was estimated at €33,70 (+€49,23). Major cost component appears to be the cost of personnel, which was estimated at €46.86 (+€24.86, €16.49-€132.59), accounting for 32.0% of the total direct cost. The average of blood unit wastage was estimated at 4.90%. There were not differences between the cost of producing a unit of blood in Athens compared with the rest of the country (Man-Whitney test, p-value: 0.341). **CONCLUSIONS:** This study indicates that the cost of producing a cost of blood isn't insignificant. These figures need to be complemented with those concerning the cost of transfusion to have a full picture of producing and using a cost of blood locally.

PSY40

BURDEN OF CYSTIC FIBROSIS IN THE RUSSIAN FEDERATION

Holownia M[1], Krasnova L[2], Vorobiev P[2]

[1]*Russian Society for Pharmacoeconomis and Outcomes Research, Moscow, Russia,* [2]*Russian Society for Pharmacoeconomics and Outcomes Research, Moscow, Russia*

OBJECTIVES: The significance of cystic fibrosis associated with early disability, the need for long-term regular treatment and follow-up and is associated with high costs. Data reflecting the socio-economic burden of cystic fibrosis in Russia is low, which dictates the need for clinical and economic studies, for example – this study. **METHODS:** An assessment of the burden of cystic fibrosis with the use of tobramycin inhalation solution from different manufacturers and powder inhaled tobramycin (Tobi Podhaler) for the treatment of Pseudomonas infections in patients with cystic fibrosis. The study took into account only the direct medical costs of one patient based on standards of outpatient and inpatient care for patients with cystic fibrosis. **RESULTS:** The burden of cystic fibrosis with the use of tobramycin powder for inhalation Tobi Podhaler with the time horizon of 10 years is reduced faster than in similar groups of patients: the point of profitability is on the eighth year of treatment when compared with tobramycin-Gobbi and a 9-year - with Bramitobom, when the use of Tobi Podhaler requires less cost to 46,372 USD and 50,138, respectively. **CONCLUSIONS:** Additional costs are difficult to calculate due to the fact that tobramycin solution for inhalation requires compliance with "cold chain" at all stages of the life cycle of the product: transportation, storage at the distributor and at the pharmacy, storage at home. Thus, obtained data in controlled efficacy studies of tobramycin solution in actual practice, may be significantly lower.

PSY41

QUALITY OF LIFE BENEFITS AND COST IMPACT OF PROLONGED RELEASE OXYCODONE/NALOXONE VERSUS PROLONGED RELEASE OXYCODONE IN PATIENTS WITH MODERATE TO SEVERE PAIN AND OPIOID-INDUCED CONSTIPATION DESPITE THE USE OF 2 LAXATIVES: A UK COST UTILITY ANALYSIS

Dunlop W[1], Neufeld K[2]

[1]*Mundipharma International Limited, Cambridge, UK,* [2]*Mundipharma Research GmbH & Co, Limburg, Germany*

OBJECTIVES: To evaluate the cost-effectiveness of prolonged release oxycodone/naloxone combination tablets [OXN; naloxone is added to counteract opioid-induced constipation (OIC)] in patients who are constipated despite the use of two laxatives, compared with prolonged release oxycodone (OXY) alone. **METHODS:** A model used data from one phase II randomised, controlled trial (RCT) in patients with moderate/severe cancer pain and a pooled analysis of two phase III RCT's in patients with moderate/severe non-cancer pain. A subgroup of patients with OIC who had failed on two or more laxatives at screening was applied in the analysis (n=178). The drug cost for pain therapy was combined with laxative costs and other resources to calculate the cost difference between OXN and OXY. Quality-adjusted life-year (QALY) gains were calculated by mapping Bowel Function Index scores to EQ-5D utility values. Deterministic sensitivity analyses were performed. The analysis was conducted from the perspective of the UK National Health Service (NHS). **RESULTS:** The incremental cost of OXN vs. OXY was £409.60 for the average treatment duration of 301 days. OXN gave an incremental QALY gain of 0.0524. The estimated incremental cost-effectiveness ratio (ICER) was £7,821.80 for OXN vs. OXY. The ICER remained below £30,000 for all sensitivity analyses, with OXN dominating OXY in some scenarios when higher constipation unit costs were applied. **CONCLUSIONS:** Patients treated with OXN experienced a quality of life gain, and OXN had an ICER considerably below thresholds normally regarded as cost-effective in the UK (£20,000 – 30,000/QALY). More research is required into the cost of treating OIC, with OXN dominating OXY (total cost saving to the NHS and quality of life benefit) in sensitivity on OIC unit costs. OXN is therefore estimated to be a cost-effective option for treating patients with moderate to severe pain and OIC, who are constipated despite the use of two laxatives.

PSY42

COST-EFFECTIVENESS OF PLERIXAFOR (PXF) FOR STEM CELL MOBILIZATION IN LYMPHOMA (NHL/HL) AND MULTIPLE MYELOMA (MM) PATIENTS IN POLAND

Kaczor MP[1], Wójcik R[2], Pawlik D[2], Glasek M[3], Pieczonka A[3], Lis J[3]

[1]*Jagiellonian University Medical College, Kraków, Poland,* [2]*Aestimo s.c., Kraków, Poland,* [3]*Sanofi, Warsaw, Poland*

OBJECTIVES: To assess cost-effectiveness of PXF, used in combination with G-CSF versus standard mobilization options used alone, to enhance mobilization of haematopoietic stem cells to the peripheral blood for collection and subsequent autologous transplantation (auto-HCT). Target population, as defined by Polish opinion leaders, are patients with NHL/HL or MM whose cells mobilize poorly, i.e. predicted poor mobilizers (peripheral blood CD34+ cell count <10/mL) and proven poor mobilizers (failure of previous mobilizations). **METHODS:** PXF is an add-on therapy to currently reimbursed standard mobilization (SM) options: G-CSF or chemotherapy plus G-CSF. Two scenarios were compared: with and without PXF. Analysis was performed using a Markov decision model, developed in *TreeAge Pro 2013*. A probabilistic (Monte Carlo simulation) model with time-dependent transition probabilities included initial cycle, during which the individual undergoes mobilization and auto-HCT if cell collection is successful, and four mutually exclusive health states: progression-free survival (remission and durable remission – lymphomas only), further treatment after progression, palliative treatment/observation and death. A one-year Markov cycle length was used with half-cycle correction. Baseline cohort characteristics, disease progression and utility estimates were obtained from systematic literature review and questionnaire study among Polish clinical practitioners. The analysis was conducted from the Polish public payer, patients, and societal perspective, over a lifetime horizon. Discount rates were 5% (costs) and 3.5% (outcomes). **RESULTS:** The mean QALY gain were 7,378 (PXF) and 6,452 (SM). The mean costs were 188,404 PLN (€45,019) (PXF) and 157,073 PLN (€37,532) (SM). Base-case incremental cost-utility ratio (ICUR) in NHL/HL/MM population was 33,821 PLN/QALY (€8,082). Probability of PXF being cost-effective in Poland when compared to SM is 99,8% (current threshold of 105,801 PLN/QALY (€25,281)). **CONCLUSIONS:** Based on accepted cost/QALY threshold values in the Polish settings, PXF was proved to be cost-effective option for NHL/HL/MM patients with poor response to SM regimens.

PSY43

COST-UTILITY ANALYSIS (CUA) OF BELIMUMAB (BEL) IN THE TREATMENT OF ADULT PATIENTS WITH ACTIVE, AUTOANTIBODY-POSITIVE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

Walczak J[1], Kopel J[1], Sołtys E[1], Dziurda D[2]
[1]*Arcana Institute, Cracow, Poland,* [2]*GSK, Warszawa, Poland*

OBJECTIVES: To estimate the cost-utility of BEL treatment of patients with SLE as an add-on therapy to intensive standard of care (SOC) vs. SOC in Poland. **METHODS:** The general population considered in the analysis were patients with SLE with significant disease activity, who met criteria of SLE diagnosis and were ineffectively treated with SOC. CUA was performed from the public payer perspective. The lifetime horizon was assumed. The decision model was developed in *MS Excel* and adjusted to Polish conditions. The calculations were performed using Monte Carlo microsimulation. The model included data from international clinical studies and Polish data on costs and resource utilization. Direct medical costs were included: costs of drugs, administration, diagnostic, monitoring and *costs related to disease activity*. Results were calculated for two patients populations: target population 1 (TP1) - patients with positive anti-dsDNA, low complement and ≥10 scores in SELENA-SLEDAI scale and target population 2 (TP2) - patients with positive anti-dsDNA, low complement, ≥6 scores in SELENA-SLEDAI scale and necessity of corticosteroids use. **RESULTS:** CUA results showed that BEL compared to SOC is more costly however, also more effective therapy. The ICUR was 113,986 PLN/QALY and 108,744 PLN/QALY, respectively for TP1 and TP2. Obtained results are placed slightly above the Polish acceptability threshold. Additional health effects related to BEL treatment instead of SOC were noticed both in LYG and QALY (0.432 and 0.4 LYG; 0.322 and 0.294 QALY, respectively for TP1 and TP2). Moreover, the model suggests lower frequency of cardiovascular events, and also pulmonary and renal complications in BEL arm. **CONCLUSIONS:** Since there is currently no effective treatment option of SLE in Poland, reimbursement of belimumab will give patients an access to a safe and effective therapy, which allows them to return to active life and career and also to improve their quality of life.

PSY44

COST-UTILITY ANALYSIS OF DEFERASIROX FOR THE TREATMENT OF IRON OVERLOAD DUE TO FREQUENT BLOOD TRANSFUSIONS IN THE CHILDREN AND ADOLESCENTS

Walczak J[1], Sołtys E[1], Obrzut G[1], Laczewski T[2]
[1]*Arcana Institute, Cracow, Poland,* [2]*Novartis Poland Sp. z o.o., Warsaw, Poland*

OBJECTIVES: To estimate the cost-utility of deferasirox (DSX) treatment of iron overload due to frequent blood transfusions in children and adolescents in Polish conditions. **METHODS:** Clinical effectiveness data were taken from previously performed systematic review of deferasirox for the treatment of pediatric patients (age ≤ 18 years) with iron overload due to frequent blood transfusions. The way of administration of chelation therapy (parenteral vs. oral) significantly affects patients' functionality and quality of life. Therefore it was decided to perform a cost-utility analysis. Analogous to other economic studies, it was assumed that patient survival was the same for both compared interventions: deferasirox and deferoxamine (DFO). In the analysis a simple decision model was developed. The calculations were performed using Monte Carlo microsimulation technique (100,000 trials). Only direct medical costs were included in the analysis: costs of drugs and their administration, costs of monitoring and costs of blood transfusions. The time horizon of the analysis was one-year period. Two perspectives were considered: a public payer (National Health Fund, NHF) and the patient and NHF perspective. The measure of effects was QALY (quality adjusted life years). **RESULTS:** The results showed that DSX compared to current standard treatment of iron overload due to frequent blood transfusions (DFO) in the children and adolescents is more costly however also more effective therapy from both considered perspectives. The ICUR (incremental cost-utility ratio) of replacing DFO by DSX was 26,180 PN/QALY from NHF perspective. The results from both patient and NHF perspective was similar. **CONCLUSIONS:** With reference to the acceptability threshold in Poland the oral chelation therapy in the population of children and adolescents with iron overload due to frequent blood transfusions with deferasirox is cost effective intervention when compared with deferoxamine.

PSY45

COST-EFFECTIVENESS OF SAPROPTERIN VERSUS PHENYLALANINE FREE DIET IN PATIENTS WITH PHENYLKETONURIA IN EGYPT

ElSisi G[1], Elmahdawy M[1], Abaza S[2], Shalakani A[3]
[1]*Central Administration for Pharmaceutical Affairs, Cairo, Egypt,* [2]*Roche, Cairo, Egypt,* [3]*Ministry of Health, Cairo, Egypt*

OBJECTIVES: Phenylketonuria (PKU) is an orphan disease with incidence rate 1:5000 in Egypt. Cost-effectiveness of Sapropterin versus Phenylalanine (PHE) free diet in PKU patients from the insurer perspective was evaluated over a time horizon of 10 years. **METHODS:** A cohort Markov chain model with six health states: healthy, mild PKU, controlled mild PKU, classical PKU, controlled classical PKU and death was identified based on the process of the disease. The length of a cycle was set at one year. The transition probabilities were derived from updated, previously published studies in Egyptian patients with PKU. Relative risk of Sapropterin and utilities were derived using international published sources. Direct Medical costs were obtained from the Ministry of Health mandatory Tarrif in Egypt. All costs and effects were discounted at 3.5% annually. All costs were reported in Egyptian pounds of the financial year 2013. Deterministic sensitivity analysis was conducted. **RESULTS:** Total costs for Sapropterin and PHE free diet were 304.1687 EGP and 188.6498 EGP respectively. QALYs for Sapropterin and PHE free diet were 0.00566 and 0.00547 respectively. The incremental cost-effectiveness ratio (ICER) for Sapropterin versus PHE free diet was 602,933 EGP/QALY. Sapropterin is not cost effective because it is more than 3 times GDP/capita in Egypt (57,566 EGP). The ICER was most sensitive to the utility of the states 'classical PKU' and 'controlled classical PKU'. **CONCLUSIONS:** World Health Organization recommends that interventions that cost more than 3 times GDP/capita for one Disability Adjusted Life Year (DALY) avoided should not be reimbursed. Despite the difference between DALY and QALY, one can assume they are similar to be able to put a value on the outcome. Sapropterin doesn't represent a good value for money compared to PHE free diet in the Egyptian PKU patients.

PSY46

A COST-UTILITY ANALYSIS OF LIGHTERLIFE TOTAL AS A TREATMENT FOR OBESITY IN THE UNITED KINGDOM

Lewis L[1], Taylor M[2]
[1]*York Health Economics Consortium, University of York, York, UK,* [2]*York Health Economics Consortium, York, UK*

OBJECTIVES: LighterLife Total (LLT) is a weight loss programme for the obese (BMI ≥30kg/m2) combining a very low calorie diet (VLCD) with weekly support groups for behaviour modification. This study evaluated the cost-effectiveness of LLT compared with dietary and surgical interventions. This is the first study assessing the cost-effectiveness of a VLCD. **METHODS:** A cohort model was developed to assess the reduction in BMI in the first 12 months following intervention with LLT, gastric banding, gastric bypass, Weight Watchers, Counterweight, Slimming World and no treatment, and the subsequent yearly BMI increase. Published all cause-mortality was applied by age and BMI. Co-morbidity prevalence (diabetes, colorectal cancer, CHD) was applied by BMI. Costs were applied for each intervention and for co-morbidities, from a UK health care perspective. Utilities were calculated by BMI with an additional decrement for co-morbidities. A 10 year time horizon was used. Analyses were run for two subgroups: BMI 30-40 in and BMI >40. **RESULTS:** BMI 30-40: compared against no treatment, Counterweight, Weight Watchers and Slimming World, LLT was associated with higher costs, but also greater QALYs and was cost-effective against all, with incremental cost-effectiveness ratios of £14,937, £16,004, £16,182, and £19,840, respectively. BMI >40: compared against no treatment LLT incurred higher costs, but also greater QALYs and was cost-effective (ICER = £5,349). LLT was less effective than banding and bypass. The budget impact of uptake of LLT across the UK was assessed for both BMI 30-40 and BMI >40 groups. **CONCLUSIONS:** BMI 30-40: LLT was more costly than dietary interventions, but lead to increased QALYs and was estimated to be cost-effective. BMI >40: LLT resulted in a lower initial BMI reduction than gastric banding and bypass. LLT was estimated to be cost-effective against no treatment in both groups.

PSY47

FULL COST OF PLASMA FROM VOLUNTARY NON REMUNERATED DONORS IN ITALY

Zaniolo O[1], Povero M[1], Gandini G[2], Aprili G[2], Eandi M[3]
[1]*AdRes HE&OR, Turin, Italy,* [2]*University of Verona, VERONA, Italy,* [3]*University of Torino, Torino, Italy*

OBJECTIVES: In Italy, within the legal mandate to pursue national self-sufficiency of secondary blood products, the Regions are starting to organize trade to offset need/availability unbalances. Therefore the determination of the full cost to the Regions of plasma collection and handling is needed. **METHODS:** Plasma is obtained from voluntary, non-remunerated donors either from full blood or from apheresis, and is collected either directly in facilities of the Regional Health Services, or indirectly through the net of donors' associations before being delivered to the transformation industry for processing. Amount and costs of materials and activities needed for collecting, producing, validating, and distributing plasma were obtained from the transfusional medicine department of the Verona province, Veneto Region. Attributable overhead expenses are assumed at 15% of direct cost. When plasma is collected as part of the whole blood or from multicomponent apheresis, common costs are attributed basing on the commercial value of single components, taken as proxy of the willingness-to-pay for them. In an alternative scenario, only product-specific costs are attributed to plasma recovered from whole blood donations, for which the driving need is the supply of red blood cells. **RESULTS:** Total cost per liter of plasma sent for processing is estimated in 114 and 286 euros, respectively, for collection from whole blood and apheresis. Given the current mix of plasma origin, the weighed mean cost of plasma to the Regions before processing charges is estimated in 157 €. When plasma recovered from whole blood donations is considered by-product, its cost per liter sent to industry is estimated in 27 €, and the corresponding weighed mean cost in 92 €. **CONCLUSIONS:** The Italian donor-based system, in addition to

its ethical and social values, supplies plasma at a lower or comparable cost than commercially available.

PSY48

INDIRECT COSTS OF SYSTEMIC LUPUS ERYTHEMATOSUS-RELATED ABSENTEEISM IN POLAND: AN ANALYSIS BASED ON SOCIAL INSURANCE INSTITUTION DATA

Golicki D[1], Karczewicz E[2], Zalewska H[2], Dziurda D[3], Gryglewicz J[3], Gierczynski J[3]
[1]*Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland,* [2]*Department of Statistics and Actuarial Forecasts, Social Insurance Institution (ZUS), Warsaw, Poland,* [3]*Institute of Health Care Organizations, Lazarski University, Warsaw, Poland*

OBJECTIVES: To estimate indirect costs of systemic lupus erythematosus (SLE) in Poland, based on absenteeism in the workplace data derived from Department of Statistics of the Social Insurance Institution (ZUS). **METHODS:** Available insurance information consisted of data on: (1) sick leaves, (2) short-term inability to work - on the basis of decisions authorizing rehabilitation services (3) long-term inability to work – on the basis of medical certificates awarded because of incapacity for work. To calculate indirect costs we used three parallel alterations of the human capital approach (HCA) method - based on: the average monthly gross earnings, Gross Domestic Product (GDP) per capita or gross value added per 1 employee (adjusted by a factor of marginal productivity of labor). **RESULTS:** In 2010, in patients with SLE in Poland, sick leaves, short-term and long-term inability to work were responsible for: 1897, 596 and 27 012 months of absenteeism, in 1600, 112 and 2481 persons, respectively. The total number of 2459 years of lost productivity corresponded to indirect costs of: 100,421,579 PLN, 97,215,041 PLN or 161,743,804 PLN, based on average earnings, GDP per capita or adjusted gross value added per employee, respectively. **CONCLUSIONS:** Two of the three approaches, in addition - the most frequently mentioned in the literature, indicated the indirect costs of systemic lupus erythematosus in Poland at around 100 million PLN per year. Our estimates of indirect costs may be undervalued because it did not include the cost of lost productivity due to premature mortality in the course of SLE, and the costs associated with a reduction in the efficiency of the work done despite of the disease (preseenteism).

PSY49

CHARACTERIZING DISEASE BURDEN IN AN ULTRA-RARE DISEASE IN THE UNITED STATES: TRANSTHYRETIN (TTR) AMYLOIDOSIS PATIENTS & CAREGIVERS

Stewart M[1], Loftus J[2], Lenderking WR[3], Murphy BR[3], Alvir J[4], Roberts L[5], Shaffer S[5], Cicchetti MJ[6], Gleeson S[5]
[1]*Pfizer, Inc, Groton, CT, USA,* [2]*Pfizer Ltd., Tadworth, UK,* [3]*Evidera, Lexington, MA, USA,* [4]*Pfizer, Inc., New York, NY, USA,* [5]*Evidera, Bethesda, MD, USA,* [6]*Pfizer, Inc., Groton, CT, USA*

OBJECTIVES: TTR amyloidosis, a progressive, degenerative ultra-rare genetic disease, can cause familial amyloid polyneuropathy (TTR-FAP) and cardiomyopathy (TTR-CM), requiring substantial caregiver support. This study evaluated the burden of illness on patients' and caregivers' work productivity, health care resource use (HCRU), and health-related quality of life (HRQoL). **METHODS:** An online survey including the Work Productivity & Activity Impairment (WPAI) questionnaire, EQ-5D, & HCRU questions recruited TTR-FAP and TTR-CM patients and caregivers through two U.S.-based patient advocacy groups. **RESULTS:** Thirty-three TTR patients (26 males) and 18 caregivers (7 males) completed the survey. Most were aged over 60; mean disease duration was approximately 6 years (patients) or 5 years (caregivers with disease). Most patients and caregivers had a college degree. Generally caregivers (77.8%) were the primary caregiver for their patient; 61.1% also had amyloidosis. Unemployment was high in patients with TTR-FAP (42.9%), TTR-CM (60.0%), both TTR-FAP/CM (71.4%); only 33.3% of caregivers reported working part/full-time. Employment was highest for TTR-FAP patients (n=10), yet 11.8% missed work, 32.2% were impaired at work and 38.5% reported overall work impairment due to TTR. Liver transplant, the primary treatment option, occurred in 42.4% patients and 18.2% caregivers with disease. A majority of patients reported outpatient visits to health care providers in the past 3 months for disease: 85.7% TTR-FAP, 100% TTR-CM, and 85.7% for TTR-FAP/CM. Hospitalization rates ranged from 14.3-30.0% across all patient groups, with 14.3-23.8% for emergency visits. EQ-5D Index scores for patients were 0.80 (SD=0.14) with transplant, and 0.68 (SD=0.16) without transplant. Caregivers with disease and transplant had lower EQ-5D Index scores (M=0.14, SD=0.35) than those without transplant (M=0.41, SD=0.32). The pattern was similar for EQ-5D VAS results for patient and caregiver groups. **CONCLUSIONS:** TTR amyloidosis is associated with substantial disruption in employment rates, work productivity, high levels of resource use, and poor HRQoL for patients and caregivers.

PSY50

RESOURCE CONSUMPTION EVALUATION ASSOCIATED WITH RITUXIMAB ADMINISTRATION IN PORTUGAL

Pereira C[1], Santos A[2]
[1]*Roche Farmacêutica Química, Lda., Amadora, Portugal,* [2]*Prime Focus Health, Paço de Arcos, Portugal*

OBJECTIVES: Determine the costs associated with rituximab intravenous (iv) preparation and administration in follicular non-Hodgkin lymphoma (NHL) and estimate the difference *versus* rituximab subcutaneous (sc) formulation, considering material resources (MR) consumption and health care professionals (HCP) time spent in each procedure. Patient's and chair time savings in hospital Day Care Unit (DCU) were also estimated. **METHODS:** Rituximab iv data was collected, between November 2012 and January 2013, through face to face interviews with pharmacists and DCU nurses responsible for the preparation and administration in each hospital. The HCP time cost was calculated by multiplying their income per hour by the average time spent on each procedure; MR costs were determined based in official databases or in "table values" provided by the manufacturers. Rituximab sc administration time was based in the respective pivotal clinical trial - SABRINA (BO22334). **RESULTS:** Ten hospitals from mainland Portugal were included, with a weekly average of 7 NHL patients treated with rituximab iv. The HCP average overall active time spent with rituximab iv preparation and administration, per treatment cycle, was about 89 minutes *versus* 16 minutes estimated for sc. An average overall cost reduction of 93% was estimated with sc *versus* iv (3€ *versus* 45€, respectively). DCU chair time capacity could be increased by 3 and 7 fold if one considers combination or maintenance therapy, respectively, with rituximab sc *versus* iv, due to SC much faster administration. Rituximab sc reduces the overall time patients spend in an infusion chair by 95% (7 min with sc *vs.*143 min with iv). **CONCLUSIONS:** Rituximab sc formulation potentially offers significant resource (material and HCP time) savings, improves hospital organization and provides clear benefits for patients regarding time saved and administration convenience. Ultimately, rituximab sc increases hospital efficiency that's critical in the current economic climate.

SYSTEMIC DISORDERS/CONDITIONS – Patient-Reported Outcomes & Patient Preference Studies

PSY51

THE ASSOCIATION BETWEEN SEVERITY OF 'AVERAGE' PAIN (NPRS) AND THE EQ-5D INDEX IN PATIENTS WITH NEUROPATHIC PAIN

Chambers C[1], Odeyemi I[2], Currie C[3], Poole CD[3]
[1]*Astellas Pharma Europe Ltd., Staines, UK,* [2]*Astellas Pharma Europe Ltd., Staines, UK,* [3]*Cardiff University, Cardiff, Wales, UK*

OBJECTIVES: Pain is an important driver of health-related utility. Our purpose was to characterise the association between pain severity and the EQ-5D index. **METHODS:** Paired values for the Numerical Pain Rating Scale (NPRS) average pain score (previous 24 hours) and the EQ-5D index were available from a prospective, non-interventional study of people with neuropathic pain treated with an 8% capsaicin patch (Qutenza™). The NPRS records pain on an integer scale between 0 and 10 units, representing no pain and worst imaginable pain, respectively. The EQ-5D index is derived from impairment level (none/moderate/severe) across five domains (Mobility, Self-care, Usual activities, Pain & discomfort, Anxiety & depression), and values health-related utility on a scale of 1 to 0, meaning perfect health and death, respectively. Generalized linear mixed models with a normal probability distribution, identity link function, and a first-order autoregressive covariance structure were tested to determine the relationship between EQ-5D index score (scale) and NPRS average 24 hour pain score (ordinal). **RESULTS:** For the purposes of this preliminary analysis, 170 patients with NP contributed 353 combined observations from baseline observation and follow-up assessments at week-8 and week-12. The GLMM model that best fitted the data (smallest Information criterion) had one random effect (subject + intercept) and one fixed effect (NPRS + intercept). The fixed-effects coefficients were: (Intercept) 0.728 + (NPRS1: β 0.000; 95%CI -0.0186, 0.186) + (NPRS2: -0.045;-0.205,0.116) + (NPRS3: -0.075;-0.227,0.078) + (NPRS4: -0.207;-0.364,-0.049) + (NPRS5: -0.181;-0.338,-0.024) + (NPRS6: -0.315;-0.471,-0.159) + (NPRS7: -0.323;-0.478,-0.167) + (NPRS8: -0.458;-0.618,-0.299) + (NPRS9: -0.638;-0.825,-0.451) + (NPRS10: -0.740; -0.927,-0.553). Predicted utility was highly correlated (R^2=0.753) with observed utility. Mean squared error for predicted utility was 0.033 (sd 0.052). **CONCLUSIONS:** Neuropathic pain was highly correlated with utility with a difference of around 0.8 utility units across the NPRS range. All domains of the EQ-5D differed across the NPRS.

PSY52

MEASURING PROS THAT MATTER TO BARIATRIC AND BODY CONTOURING SURGERY: THE BODY-Q

Pusic A[1], Cano S[2], Scott A[1], Tsangaris E[3], Klassen A[3]
[1]*Memorial Sloan-Kettering Cancer Center, New York, NY, USA,* [2]*ScaleReport, Stotfold, United Kingdom,* [3]*McMaster University, Hamilton, ON, Canada*

OBJECTIVES: Health care payers are interested in funding bariatric surgery because it resolves a range of obesity-related health problems. However, following weight loss, many patients are left with unsightly excesses of skin and require body-contouring surgery. Our team has developed a new PRO instrument (i.e., the BODY-Q) to measure satisfaction and quality of life of bariatric and body-contouring surgery patients. Unlike existing PRO instruments, the BODY-Q is composed of scales that measure appearance-related concerns, which is an important reason why patients seek treatment. The BODY-Q also stands apart as it the only PRO instrument designed to measure change in patients concerns throughout the entire weight loss journey. **METHODS:** We followed international guidelines for the development of a PRO instrument. This abstract presents Phase I results, i.e., qualitative phase. Patient stories were used to develop a conceptual framework covering the key concerns of patients, and to develop a set of preliminary items. Items were grouped into clinically meaningful scales and instructions and four-point response options were developed. The scales were refined by obtaining feedback from a sample of surgical experts and patients. **RESULTS:** From 59 patient interviews, we developed a conceptual framework. Over 3,500 preliminary items were developed and used to inform the following 17 independently functioning scales: 1) appearance scales measuring the body, abdomen, upper arms, buttocks, inner thighs, hip and outer thighs, skin and scars; 2) quality of life scales measuring body image, sexual, psychological and social wellbeing, physical function and symptoms; and 3) process of care scales measuring satisfaction with information, doctor and office staff. **CONCLUSIONS:** Phase II involves a multicentered field-test in Canada and the USA. Rasch Measurement Theory analysis will be used to determine which items to retain in each scale based on their performance against a standard set of psychometric criteria.

PSY53

THE USE OF PREFERENCE BASED MEASURES IN HAEMOPHILIA: IS THE CURRENT EVIDENCE BASE USEFUL FOR EVIDENCE BASED DECISION MAKING?

Tolley K[1], Miners A[2], Brazier J[3], Pericleous LM[4], Sharma T[4], Petersen J[4], Lonergan T[5]
[1]*Tolley Health Economics, Buxton, UK,* [2]*London School of Hygiene and Tropical Medicine, London, UK,* [3]*University of Sheffield, Sheffield, South Yorkshire, UK,* [4]*Novo Nordisk A/S, Soborg, Denmark,* [5]*Tolley Health Economics, Derbyshire, UK*

OBJECTIVES: To identify and evaluate the published evidence base on the use of preference based measures for assessing haemophilia related outcomes, and to discuss their limitations and gaps for evidence based decision making. **METHODS:** A systematic review was carried out for 25 year time period 1988 to 2013 to investigate preference based evaluations of treatments and/or outcomes related to haemophilia. The search terms included:utility, QALY, standard gamble, time-trade-off, contingent valuation, conjoint analysis, and discrete choice. **RESULTS:** The search identified 22 original peer reviewed articles, covering a range of countries and treatments. There were 7 cost-utility analyses, and 7 studies reporting use of the EQ 5D to determine utility values for haemophilia health states. Two studies, both from Canada, were vignette type studies that directly assessed utilities for treatment related health states. The EQ 5D studies produced reasonably consistent utilities, whereas the vignette studies produced variable results. Six studies were conjoint analysis and/or willingness to pay studies and focused on the value of attributes of new treatments. As is typical of studies in rare diseases, there were limitations in all studies related mainly to small sample sizes, uncontrolled designs and potentially confounding factors. The main evidence gaps were a lack of preference/utility data for caregivers, or the direct impact of bleeding on utilities, and only one study used a generic measure other than the EQ 5D (the SF-6D) to generate utilities for haemophilia health states. **CONCLUSIONS:** Given that haemophilia is a rare condition, there is a reasonably large evidence base of preference based studies for potential use in evidence based decision making. However, the limitations and gaps in the studies identified mean that there are still limitations in the evidence base to support a comprehensive assessment of the value of new interventions for haemophilia.

PSY54

PATIENTS AT THE CENTER OF REGULATORY DECISIONS: USING STATED-PREFERENCE DATA TO HELP REGULATORS ANSWER DIFFICULT QUESTIONS

González JM[1], Johnson FR[1], Fairchild A[1], Irony T[2], Ho M[2]
[1]*RTI Health Solutions, Research Triangle Park, NC, USA,* [2]*US Food and Drug Administration, Silver Spring, MD, USA*

OBJECTIVES: In collaboration with FDA's Center for Devices and Radiological Health (CDRH), we developed and administered a best-practice discrete-choice experiment (DCE) survey to elicit preferences for outcomes associated with using weight-loss devices to demonstrate how DCE data can help determine meaningful benefits for regulatory decisions involving serious side-effect risks. **METHODS:** An online DCE questionnaire was administered to adult residents of the United States who reported having or having had a body mass index (BMI) of at least 30 kg/m^2. Respondents evaluated constructed hypothetical weight-loss devices with different features identified with the help of clinicians at CDRH. Weight-loss devices were defined in terms of device effectiveness, device-related risks of side effects, surgery requirements for implantation, and diet restrictions. An efficient experimental design ensured that device profiles provided the necessary statistical information to identify the choice-model parameters. Random-parameter choice models produced preference weights indicating the strength of preference for device features. These weights were used to calculate the maximum acceptable risk of dying or minimum required weight loss associated with various device profiles. **RESULTS:** A total of 540 respondents completed the online survey. Results from the study show that respondents had well-defined, plausible preferences for different outcomes associated with weight-loss devices. Internal validity tests, including a scope test of sensitivity to absolute risk levels, indicated the data are of high quality. Preference results were used to construct an Excel-based tool that calculates the necessary benefits to offset the device-related risks with confidence intervals for any device that can be described by features included in the study design. **CONCLUSIONS:** Results confirm the feasibility of using DCE methods to evaluate patients' tolerance for weight-loss device risks, as well as the feasibility of constructing a policy-relevant decision aid that makes this information accessible to regulators.

PSY55

HEALTH RELATED QUALITY OF LIFE BY LINE OF THERAPY IN IMATINIB-RESISTANT OR IMATINIB-INTOLERANT PATIENTS WITH CHRONIC MYELOID LEUKEMIA TREATED WITH BOSUTINIB MEASURED BY EQ-5D

Whiteley J[1], Reisman A[1], Shapiro M[2]
[1]*Pfizer Inc, New York, NY, USA,* [2]*Pfizer Inc, Cambridge, MA, USA*

OBJECTIVES: Bosutinib a dual Src/Abl tyrosine kinase inhibitor (TKI) demonstrated efficacy in a phase 1/2 study of patients with relapsed/refractory Chronic Myeloid Leukemia (CML). Health utilities were reported in the imatinib IRIS study, but there is limited information from relapsed/refractory CML patients. The objective was to evaluate the effect of bosutinib on health utilities in patients with CML after failure with imatinib. **METHODS:** Evaluation of patient HRQoL was an exploratory objective in the clinical trial measured using the EQ-5D, which consists of 5-items: mobility, self-care, usual activities, pain/discomfort and anxiety/depression. Each item ranges from 1 ("no problems") to 3 ("extreme problems"). The EQ-5D was completed at weeks 4, 8, 12 and every 12 weeks thereafter, as well as treatment completion and scored according to the UK tariff. **RESULTS:** Of the N=570 patients included in the trial, 288 were second line chronic phase (CP 2L) CML, 118 were third line CP patients (3L), 76 were accelerated phase (AP) and 64 blast phase (BP). For 2L patients, the mean utility score at baseline was 0.83 (SD 0.21), and was maintained throughout the course of the study demonstrating a significant improvement at week 36 (mean change from baseline 0.04, p=0.01). For 3L patients, the mean utility at baseline was 0.80 (SD 0.22), and maintained throughout the study. There were no statistically significant differences from baseline through week 36 in health utility in 3L patients. The mean utility at baseline for advanced patients was 0.78 (SD 0.28) for AP and 0.66 (SD 0.30) for BP patients and was maintained throughout the study. **CONCLUSIONS:** These data suggest that relapsed/refractory CML patients treated with bosutinib maintain their quality of life throughout the trial regardless of the line of treatment or phase of disease. These results highlight the value of capturing patient HRQoL in CML treatment.

PSY56

A SYSTEMATIC REVIEW ON THE EFFECT OF BEHAVIORAL VERSUS SURGICAL INTERVENTION ON OBESE PATIENTS' PSYCHOLOGICAL WELL-BEING

Fortier KJ, Kiss N
Oxford Outcomes, Morristown, NJ, USA

OBJECTIVES: Approximately 400 million people worldwide are considered obese as defined by the World Health Organization. In Europe, 15.5% of adults have a body mass index of ≥30 kg/m^2. Diabetes, heart disease, and stroke, are among the most common obesity-related comorbidities. Furthermore, obesity has also been found to cause depression and emotional distress, negatively affecting the quality of life of obese patients. With obesity at the forefront of many social and health care dialogues, treatment guidelines currently suggest exercise (often linked with changes in diet) or weight loss surgery to effectively treat obesity. This review seeks to understand which of these two types of interventions, exercise or surgical, have a greater impact on obese patients' emotional and psychological well-being. **METHODS:** A systematic review of peer-reviewed literature was conducted to identify RCTs and observational studies that measure any type of emotional or psychological change in patients who underwent either of the interventions of interest for weight loss: exercise or weight loss surgery. Embase and Medline databases were searched for articles published from 2004 to 2013. Search terms were used to identify studies that assessed psychological well-being of obese patients who either exercised or underwent weight loss surgery. **RESULTS:** The search identified 40 studies, of which 11 measured relevant interventions and measures of psychological well-being. Of those, 9 investigated patients undergoing bariatric surgery, while only 2 explored exercise interventions. All of the studies indicated improvements in patients' emotional health, except for 1 bariatric surgery study, where patients were shown to have no change in symptoms after weight loss plateaued. **CONCLUSIONS:** While both interventions, when they lead to weight loss, seem to result in improvements in patients' psychological well-being, there is limited data to conclude whether one intervention is more effective in improving psychological well-being. Further study is needed, especially for exercise interventions.

PSY57

OBESITY TRENDS 2006-2012 IN THE UNITED STATES: RESULTS FROM THE NATIONAL HEALTH AND WELLNESS SURVEY

Pomerantz D[1], Wang Z[2], Annunziata K[3], Gupta S[1], Martinez-Triggs C[1]
[1]*Kantar Health, Princeton, NJ, USA,* [2]*Eisai Inc., Woodcliff Lake, NJ, USA,* [3]*Kantar Health, New York, NY, USA*

OBJECTIVES: According to the Centers for Disease Control and Prevention, there were dramatic increases in the obesity rates in the US since 1980s which reached a plateau after 2003[1]. The objectives of this study were to examine obesity trends across US adults from 2006-2012 by various gender/age groups and changes in activity impairment. **METHODS:** Results were from the US National Health and Wellness Survey, a nationally representative, online survey. Respondents were age ≥ 18 years, and results were weighted/projected to reflect the gender, age, and race/ethnic proportions, as determined by the Current Population Survey (US Census Bureau). This analysis focused on adults age ≥ 20 by BMI Class 1 (BMI>=30 & <35 kg/m^2), Class 2 (BMI>=35 & <40 kg/m^2), and Class 3 (BMI>=40 kg/m^2). Activity impairment was assessed from the Work Productivity and Activity Impairment Questionnaire. **RESULTS:** The proportions of adults age 20+ with Class 1, Class 2 and Class 3 obesity levels have slowly declined from 2006 to 2012 (Class 1: 19.3% in 2006 to 18.4% in 2012; Class 2: 9.2% in 2006 to 8.2% in 2012; Class 3: 7.3% in 2006 to 6.7% in 2012). This is consistent across most age/gender subgroups, except in the group of men age 60+, which showed increases of Class 2 (7.5% to 8.2%) and Class 3 obesity (3.7% to 4.6%); Activity impairment declined along with the decline of obesity prevalence (men and women), though women reported greater impairment than men in the corresponding BMI Class. **CONCLUSIONS:** The data suggested a slight decline in obesity prevalence and improvement in activity function in the US population recently. However, obesity remains a pandemic with tremendous health and economic burden and calls for continuous effort in education, prevention and management. PSY58

THE IMPACT OF INCREASING PAIN SEVERITY ON IMPAIRMENT OF REGULAR DAILY ACTIVITIES

Poole CD[1], Chambers C[2], Odeyemi I[3], Currie C[1]
[1]*Cardiff University, Cardiff, Wales, UK,* [2]*Astellas Pharma Europe Ltd., Staines, UK,* [3]*Astellas Pharma Europe Ltd., Staines, UK*

OBJECTIVES: To evaluate to what extent pain severity was associated with impairment of regular daily activities other than paid work. **METHODS:** Study data originated from a prospective, non-interventional study of people with NP treated with the capsaicin patch QUTENZA™. Repeated observations from baseline- and 12-week follow-up assessments for the Numerical Pain Rating Scale (NPRS) 'average pain in the last 24 hours' score, and the Activity Impairment (AI) score from the Work Productivity Activity Index (WPAI-NP) were analysed. The NPRS subjectively records pain on a scale between 0 (no pain) and 10 (worst imaginable pain). The WPAI-NP Activity Impairment Index measured the extent to which NP affected regular daily activities from 0% (no effect) to 100% (complete prevention). Generalized linear mixed models (GLMM; SPSS v20), with a normal probability distribution, identity link function, and a first-order autoregressive covariance structure were tested to determine the relationship between WPAI-NP-AI (scale) and NPRS (ordinal). **RESULTS:** A total of 171 patients with NP contributed 253 combined observations from baseline and week 12 follow-up assessment. Mean age at baseline was 59.4 years (sd 14.9) and 44% of subjects were male. The GLMM model that best fitted the data (smallest information criterion) had one random effect (subject+intercept) and two fixed effects (Sex+NPRS+intercept). The significant (p<0.05) fixed-effects coefficients were: (Intercept) 14.2+(Male: β -7.0; 95%CI -13.5,-0.5)+(NPRS3: 24.4;9.0,39.8)+(NPRS4:9.4;13.5,45.3)+(NPRS5:36.5;21.2,51.8)+(NP

RS6:43.7;28.5,60.0)+(NPRS7: 46.3;31.1,61.5)+(NPRS8: 58.5;42.6,74.4)+(NPRS9:2.0;44.2, 79.8)+(NPRS10:72.2;54.7,89.7). The estimated marginal mean WPAI-NP-AI increased linearly from 10.1% at NPRS 0 to 84.8% at NPRS 10. Predicted WPAI-NP-AI was highly correlated with observed values (R-squared=0.889); mean absolute error (predicted-observed) was 9.6 (sd 6.9). **CONCLUSIONS:** In people with chronic NP, increasing pain severity was associated with a linear increase in impairment of regular daily activities other than paid work. Interventions that reduce pain are likely to improve functioning.

PSY59

HEALTH-RELATED QUALITY OF LIFE IN BRAZILIAN OBESE PATIENTS SUBMITTED TO BARIATRIC SURGERY: A SYSTEMATIC LITERATURE REVIEW

Vasconcellos JF, Fernandes RA, Takemoto M, Amaral LM, Silva MA, Haas LC, Menezes LP
ANOVA, Rio de Janeiro, Brazil

OBJECTIVES: Bariatric surgery is the best long-term treatment for morbid obesity with clinical improves, like reductions in blood pressure, glucose and lipids levels. However postoperative complications and psychosocial issues may impact quality of life (QoL). This study aims to assess health-related quality of life (HRQoL) in Brazilian obese patients submitted to bariatric surgery. **METHODS:** A systematic review was conducted by April 2013 through Cochrane Collaboration, Medline, EMBASE, and Lilacs databases. Studies that described QoL in Brazilian obese patients were included in this review. Bariatric Analysis and Reporting Outcome System (BAROS), Moorehead-Ardelt quality of life questionnaire II (M-A-QoLQII), Abbreviated WHOQoL questionnaire and Short Form-6D (SF-6D) were used to evaluate the behavior of patients who underwent bariatric surgery in relation to QoL domains. **RESULTS:** Seven studies met eligibility criteria. In all studies, individuals presented body mass index (BMI) $\geq$ 40kg/m^2 or $\geq$ 35 kg/m^2 associated with comorbidities. Patients reported their self-esteem (SE), physical activity (PA), social relations (SR), disposition to work (DW) and sexual activity (SA), after bariatric surgery. According to the M-A-QoLQII, three studies showed HRQoL improvement in 28.9%, 39.5%, 28.4%, 30% and 25.6% of patients for SE, PA, SR, DW and SA, respectively. And 68.9%, 50.6%, 53.1%, 52.2%, 45.6% of patients guaranteed greatly improved regarding those parameters, respectively. After weight loss, bariatric surgery was effective to improve QoL in PA domain. Besides, when compared to patients submitted to medical treatment, patients who underwent surgical procedure presented an improvement of 93% in HRQoL, contrasting with 65.4% of the medical cohort ($p<0.001$). Only one study measured QoL before and after bariatric surgery: SF-36 domains and M-A-QoLQII showed that post-surgery results were invariably better than pre-surgery ones ($p<0.001$ for all domains). **CONCLUSIONS:** The present review demonstrated the potential QoL improvements in Brazilian patients after bariatric surgery, in addition to clinical benefits.

PSY60

STUDY OF QUALITY OF LIFE AND COSTS FOR CML PATIENTS IN BULGARIA

Kamusheva M[1], Vulchanova T[2], Georgieva SS[3], Chervenkova N[4], Krusteva I[5], Camurjieva A[6], Stoimenova A[1], Petrova G[1]
[1]*Medical University, Faculty of Pharmacy, Sofia, Bulgaria,* [2]*University chematology hospitals, Hospital pharmacy, Sofia, Bulgaria,* [3]*Aleksandrovska Hospital, Sofia, Bulgaria,* [4]*University hospitals Plovdiv, Hospital pharmacy, Plovdiv, Bulgaria,* [5]*University hospitals Pleven, Hospital pharmacy, Pleven, Bulgaria,* [6]*Military University Hospital, Hospital pharmacy, Sofia, Bulgaria*

OBJECTIVES: To analyze the cost of therapy for patients with chronic myeloid leukemia (CML) and their quality of life. **METHODS:** It is retrospective as regard to cost and prospective as regard to quality of life analysis. Five university hospitals in four major cities treating all 320 CML-patients are included for the period 2011-2012. Information is collected from the patients' records about the health care resources used as medicines for CML, additional therapy, hospitalizations and physicians visits. The assessment of health related quality of life is conducted with validated for the country SF-36 questionnaire. **RESULTS:** A total of 164 (51.2%) men and 156 (48.75%) women, average age 53.96±15.41 were observed. The average CML pharmacotherapy monthly cost is 5976.4 BGN, the average total pharmacotherapy cost for additional diseases is 566.27 BGN and the average additional costs for physicians' visits and hospitalization is equal to 1504.69 BGN. The most expensive CML therapy is with Dasatinib 7771.20 BGN and the cheapest is Imatinib therapy equal to 5245.15 BGN. The most common additional diseases are cardiovascular (68%), followed by endocrine (29%). There is significant correlation between overall assessment for quality of life and average total additional costs – the higher assessment for QoL, the lower costs for hospitalization and visits. With the significantly highest score is the scale Bodily pain, followed by Physical functioning, and the lowest are Vitality, energy or fatigue and Role limitation. In most of patients on Imatinib (77.9%) are recorded good hematological responses and 66.7% are with major molecular response. **CONCLUSIONS:** CML is a disease consuming significant health care resources especially for major pharmacotherapy with TKIs. Infrequent physicians' visits and rarer hospitalizations generate higher assessment of quality of life.

PSY61

TREATMENT SATISFACTION AND ITS ASSOCIATION WITH HEALTH OUTCOMES IN PATIENTS WITH NEUROPATHIC PAIN

Holbrook T[1], Obradovic M[2], Liedgens H[2]
[1]*ADELPHI REAL WORLD, MACCLESFIELD, UK,* [2]*Grünenthal GmbH, Aachen, Germany*

OBJECTIVES: Neuropathic pain (NP) is a chronic progressive disease which is hard to control. This analysis investigates patients' satisfaction with pain therapy and its relationship with pain severity and health related quality of life (HRQoL). **METHODS:** Data were drawn from the 2012 Adelphi NP Disease Specific Programme, a cross-sectional study involving 413 primary care physicians and specialists across Europe. Physicians provided detailed records for 3956 NP patients, of which 1568 patients voluntarily completed EQ-5D and Brief Pain Inventory questionnaires. HRQoL was measured via the EQ-5D, satisfaction via a three-option question answered by the patient, and pain via the Brief Pain Inventory (BPI) interference score. Boxplot analyses were used to compare outcomes across satisfaction groups. **RESULTS:** Only 64 (4.08%) were satisfied with their treatment, and 1504 (95.92%) not satisfied. A positive relationship was observed between satisfaction and HRQoL, with the most satisfied group recording a 31.62% higher EQ-5D score (mean 0.75 vs. 0.57, $p<0.01$) relative to the next most-satisfied group. A negative relationship was observed between satisfaction and pain, with the most satisfied patient group scoring 30.89% lower pain scores (mean 3.40 vs. 4.91, $p<0.01$). **CONCLUSIONS:** Most neuropathic pain patients are not satisfied with their current pain therapy. This analysis suggests a negative relationship between treatment satisfaction and reported pain severity as well as a clear positive relationship between treatment satisfaction and health related quality of life. The results highlight the need for a more targeted treatment of neuropathic pain patients.

PSY62

PROFILE OF BACK PAIN SUFFERERS ACROSS 5EU COUNTRIES

Annunziata K[1], Isherwood G[2], Sternbach N[1]
[1]*Kantar Health, New York, NY, USA,* [2]*Kantar Health, Epsom, Surrey, UK*

OBJECTIVES: According to the Pain in Europe Study, about one in five EU adults have chronic pain. Back pain / lower back pain is among the most commonly cited location of pain.[1] Additionally, research has suggested that pain has a negative impact on sufferer mental health, employment, sleep and personal relationships.[2] This analysis profiles and compares adults experiencing back pain to adults without pain across 5EU. **METHODS:** Results were taken from the 2011 5EU National Health and Wellness Survey, a nationally representative, self-administered survey. Respondents were adults age 18 and over from France, Germany, Italy, Spain and UK. This analysis focuses on adults diagnosed with back pain or experienced pain as a result of back problem in the past month- ("patients with back pain"). Quality of life was measured using the SF12v2 scale. Activity impairment was measured using the Work Productivity and Activity Impairment scale. **RESULTS:** Out of the total sample of n=57,512, ~10% (n=5,984) have back pain. Relative to adults without pain, back pain sufferers are older on average (48.9 vs. 46.3), more likely to be women (57% vs. 48%), and obese (27% vs. 16%). Their overall mental and physical quality of life scores are significantly lower (43.2 vs. 47.9, $p < 0.001$ and 40.3 vs. 50.9, $p < 0.001$). In addition, back pain sufferers are exhibited more work impairment (absenteeism and presenteeism) and activity impairment, and utilized health care resources to a greater extent than non-sufferers (i.e., greater physician visits, hospitalization, and ER). All these results are notably higher among back pain patients treated with a prescription. **CONCLUSIONS:** Considering the prevalence of back pain among adults, the level of work impairment and quality of life limitations impacts a substantial portion of adults in the 5EU population. Improvements in treatment of back pain are needed to reduce this burden.

PSY63

EVALUATING WILLINGNESS-TO-PAY THRESHOLD FOR SUGAMMADEX REVERSAL OF ROCURONIUM-INDUCED NEUROMUSCULAR BLOCKADE: A CONTINGENT VALUATION SURVEY

Song HJ[1], Han E[2], Kang SH[3], Lee EK[4]
[1]*SungKyunKwan University, Suwon, South Korea,* [2]*Gachon University, Incheon, South Korea,* [3]*MSD, Seoul, South Korea,* [4]*Sungkyunkwan University, Suwon, South Korea*

OBJECTIVES: Reversal of the residual effect of rocuronium or vecuronium by neostigmine may be slow and associated with side-effects. Sugammadex, a selective relaxant binding agent, encapsulates rocuronium to provide for a rapid reversal of residual neuromuscular blockade. Also, postoperative residual neuromuscular block can reduce delay of awakening, recovery, and dissatisfaction of patient. The aim of this study is to evaluate the willingness-to-pay (WTP) of sugammadex for effectiveness and safety using a contingent valuation method. **METHODS:** A total of 505 adult general population and 60 experts (anesthesiologist and surgeon) participated in a face-to-face survey. The respondents were surveyed separately each scenario of moderate and deep blocks for surgery. The scenario was designed to provide information concerning reversal time on neuromuscular block, adverse reaction of PRNB, and quality of surgery or recovery. The out-of-pocket WTP for sugammadex was utilized open answer. **RESULTS:** In general population, WTP values for sugammadex were 81,768 Korean won (KRW) in moderate block and 128,622 KRW in deep block. The same sample answered 89,017 KRW and 141,536 KRW for WTP for their family members in moderate block and deep block, respectively. Experts were estimated the WTP of 99,417 KRW in moderate block and 153,250 KRW in deep block. For patients, experts suggested that 82,517 KRW and 132,517 KRW were appropriate WTP. The WTP was statistically significantly higher in the general population who had been taken operation and older than their counterparts. **CONCLUSIONS:** The WTP for sugammadex was ranged the 81,768 to 99,417 KRW in moderate block, and the 128,622 to 153,250 KRW in deep block. The WTP of general population for their family members was higher than the WTP for their own, and the expert's WTP was higher than their patients.

LIKELIHOOD OF USE AND PERCEPTION TOWARDS BIOSIMILARS IN RHEUMATOID ARTHRITIS ARENA: SURVEY OF RHEUMATOLOGISTS IN EUROPEAN UNION, BRAZIL, JAPAN AND CHINA

Narayanan S[1], Liu L[2]
[1]*Ipsos Healthcare, Gaithersburg, MD, USA,* [2]*Pfizer Inc. and Weill Medical College of Cornell University, New York, NY, USA*

OBJECTIVES: To assess rheumatologist perception towards biosimilars and the likelihood of use of biosimilars to manage RA patients in the EU, Brazil, Japan and China. **METHODS:** A multi-country cross-sectional survey was conducted in top-5 EU countries (UK/Germany/Spain/France/Italy), Brazil, Japan and China in April/May 2013 using an online physician panel in the respective geographies; rheumatologists were randomly selected for survey participation to be geographically representative in select countries/regions. Surveys assessed the rheumatologist perceptions of biosimilars in terms of factors that would prevent them from using

biosimilars among their biologic-eligible RA patients, and their likelihood of use of biosimilars. Descriptive statistics are reported. **RESULTS:** A total of 173 rheumatologists participated in the survey. Years of experience practicing rheumatology was: <=1yr:0%, 2-5yrs:6%, 6-10yrs:17%, 11-20yrs:42%, >20yrs:32%. Geographic distribution of rheumatologists was: 5EU-58%, Brazil-23%, Japan-11% and China-9%. Mean RA patient-volume/year was 291 (5EU-329, Brazil-259, Japan-232 and China-189). Overall, 47% of rheumatologists reported that they would prescribe a biosimilar to their eligible RA patients "definitely or highly likely" (5EU:58%, Brazil:21%, Japan:47%, China:47%); 51% of rheumatologists reported that they would try using biosimilars for 1-2 yrs among a small group of patients in their practice before starting to use it in a majority of biologic-eligible RA patients in their practice (5EU:60%, Brazil:33%, Japan:42%, China:47%). The top-5 factors that would prevent them from using biosimilars were diverse across the countries (Overall/5EU/Brazil/Japan/China): Doubts in similarity to original molecule 60%/63%/67%/47%/33%), inadequate safety/efficacy profile/data (53%/51%/51%/58%/60%), lack of long-term data (46%/51%/41%/32%/40%), lack of national guidelines recommending the use of biosimilars (37%/39%/31%/32%/47%) and lack of data from local country/market (31%/23%/41%/42%/47%). **CONCLUSIONS:** Across markets, over half of the rheumatologists expressed concerns/reservations towards prescribing biosimilars to their eligible RA patients. While payer organizations look to biosimilars to contain costs and make medicines more affordable to RA patients in need, potential barriers to biosimilar adoption may exist.

PSY65

BARRIERS TO BIOLOGIC THERAPY USE FOR AUTOIMMUNE DISORDERS IN EMERGING MARKETS

Gross HJ[1], Vietri J[2]

[1]*Kantar Health, Princeton, NJ, USA,* [2]*Kantar Health, Milan, Italy*

OBJECTIVES: Biologic therapy is increasingly used to treat autoimmune disorders in developed markets, but usage is still low in emerging markets. This analysis was conducted to identify factors associated with current use of biologic medication among patients with autoimmune disorders in emerging markets. **METHODS:** Data were from the Brazil, China, and Russia National Health and Wellness Surveys, cross-sectional surveys representative of the total adult population (Brazil) or urban adult population (China and Russia) in each country, conducted in 2011 and 2012. Respondents self-reporting physician diagnosis of ankylosing spondylitis, Crohn's disease, psoriasis, psoriatic arthritis, rheumatoid arthritis, or ulcerative colitis and using a prescription medication (Rx) for at least one of those conditions were included; patients with missing data for any covariate were excluded. Binomial logistic regression included the following predictors: age, sex, country, income, Charlson Comorbidity Index (CCI), body mass index (BMI), monthly out of pocket (OOP) costs for Rxs, fear of needles, condition severity, length of diagnosis, and type of treating physician. **RESULTS:** Of 1,507 respondents included in the analysis, 300 (19.9%) were using a biologic. Of those, 82.0% (n=246) were in China. Relative to China, patients were less likely to use biologics in Brazil (OR 0.21; 95% CI: 0.13, 0.36) and Russia (OR: 0.29, 95% CI: 0.18, 0.46; ps<0.001). Higher CCI was associated with use of biologics (OR: 1.18, 95% CI: 1.10, 1.26; p<0.001), as were higher OOP costs (OR: 2.37, 95% CI: 1.04, 5.42; p<0.05) compared to no OOP costs. Fear of needles was positively associated with biologic use (OR: 1.57, 95% CI: 1.18, 2.09; p<0.01). No other covariates were significant. **CONCLUSIONS:** Country was by the strongest predictor of biologic use in patients with autoimmune conditions in emerging markets, but higher costs and more comorbidities were associated with biologic use across emerging markets.

PSY66

DISEASE STATUS, TREATMENTS AND OUTCOMES OF PATIENTS WITH ANKYLOSING SPONDYLITIS RECEIVING THEIR FIRST BIOLOGIC IN THE UNITED STATES AND EUROPEAN UNION

Narayanan S[1], Baskett A[2], Lu Y[2], Hutchings R[2]

[1]*Ipsos Healthcare, Gaithersburg, MD, USA,* [2]*Ipsos Healthcare, London, UK*

OBJECTIVES: To compare the disease status, treatments and outcomes of patients with AS receiving their first biologic in UK, Germany, France, Italy and Spain (5EU) with the US. **METHODS:** A multi-country multi-center medical chart-review study of AS patients was conducted between October-December 2012 among physicians (rheumatologists: 5EU: 97%, US: 99%) in hospitals and private practices to collect de-identified data on AS patients who were recently treated with a biologic as part of usual care. Physicians were screened for duration of practice and patient volume and recruited from a large panel to be geographically representative in each country. Eligible AS patient charts (>2) were randomly selected from a sample of prospective patients visiting each center/practice during the screening period. Physicians abstracted patient diagnosis, treatment patterns/dynamics and patient symptomatology/disease status/outcomes. **RESULTS:** Seven hundred and ninety seven eligible AS patient charts (5EU:613, US: 184) were abstracted; 701 (5EU:549, US: 152) patients were on their first biologic (mean-age: 5EU:42.5yrs/US:42.4yrs; female: 5EU:16.2%/US:17.1%). Time-to-1st biologic from diagnosis (5EU:55.3months/US:46.8months) and time-on-current biologic (5EU:31.7months/US:44.3months) differed between regions. Top-2 biologic treatments observed were – adalimumab (5EU:43%/US:35%) and etanercept (5EU:30%/US:41%). Among the top-3 reasons for biologic treatment initiation, 'mechanism of action' & 'improve signs/symptoms' were observed in both 5EU and US, whereas 'positive personal experience' (5EU) and 'prevention of structural damage' (US) were also observed. Key lab measures documented were: ESR (5EU:17.4mm/h, US:20.9mm/h) and CRP (5EU:8.8mg/dl, US:2.7mg/dl). Current disease severity per physician-judgment (mild:moderate:severe) was: 5EU-63%:32%:6%, US-62%:34%:5%. Among patients with available data, current HAQ (5EU:1.3, US:0.8), BASDAI (5EU:2.9, US:3.4), VAS provider score (5EU:2.9, US:2.5), VAS patient score (5EU:3.0, US:2.7), Swollen Joint Count (5EU:1.3, US:0.5), and Tender Joint Count (5EU:2.0, US:0.9) differed across regions. **CONCLUSIONS:** Among AS patients receiving their first biologic, disease severity differed between 5EU and US, with patients in 5EU with relatively higher burden and poorer outcomes.

PSY67

VARIATIONS IN TREATMENT PATTERNS AND DISEASE SEVERITY AMONG PATIENTS WITH PSORIASIS RECEIVING THEIR FIRST BIOLOGIC IN EUROPEAN UNION

Narayanan S[1], Franceschetti A[2]

[1]*Ipsos Healthcare, Gaithersburg, MD, USA,* [2]*Ipsos Healthcare, London, UK*

OBJECTIVES: To assess the treatment patterns and current disease severity of patients with PsO receiving their first biologic in 5EU, namely, UK, Germany (DE), France (FR), Italy (IT) and Spain (SP). **METHODS:** A multi-country multi-center medical chart-review study of PsO patients was conducted among dermatologists in hospitals/private practices to collect de-identified data on patients who were recently treated with a biologic as part of usual care. Physicians were screened for practice-duration (3-30 yrs) and patient-volume (incl.>2PsO biologic patients/month) and recruited from a large panel to be geographically representative in each country. Physicians abstracted charts of next five consecutive biologic patients within each center/practice. Physicians abstracted patient diagnosis, treatment patterns/dynamics and patient symptomatology/disease severity. Results from patients on first biologic treatment were analyzed. **RESULTS:** In 4Q2012, 225 physicians abstracted 924 eligible PsO patient charts; 690 (75%) were on their first biologic (mean-age:46.9yrs, female:36%). Geographic distribution-UK:18%, DE:21%, FR:19%, IT:21%, SP:21%. Time-to-1st biologic from diagnosis (months)/time-on-current biologic (months) varied- UK:140/17, DE:119/10, FR:138/15, IT:103/18, SP:127/17. Top-4 first-line biologic treatments observed were etanercept, adalimumab, infliximab and ustekinumab. Treatment experience prior to first biologic varied dramatically (not mutually exclusive): Immunomodulators-UK:92%,DE:51%,FR:68%,IT:73%,SP:76%; phototherapy-UK:55%,DE:71%,FR:59%,IT:32%,SP:37%; topicals-UK:41%,DE:69%,FR:46%,IT:43%,SP:39%; retinoids-UK:29%,DE:30%,FR:34%,IT:42%,SP:40%; fumerates-UK:13%,DE:69%,FR:0%,IT:1%,SP:0%; corticosteroids-UK:2%,DE:32%,FR:10%,IT:14%,SP:10%; Average # of flares in the past yr were: UK-1.0,DE-1.3,FR-1.1,IT-1.0,SP-1.6. Mean current PASI scores were: UK-8,DE-20,FR-12,IT-18,SP-11. Current disease severity per physician judgment was (remission/mild/moderate/severe): UK-45%/25%/20%/10%, DE-26%/19%/21%/35%, FR-42%/34%/15%/9%, IT-39%/19%/31%/11%, SP-44%/29%/26%/2%. Mean number of treatments prior to first biologic varied by current disease severity (remission/mild/moderate/severe): UK-2.7/3.1/2.6/3.1, DE-3.0/3.7/2.7/4.1, FR-2.2/2.6/2.2/2.4, IT-2.2/2.2/2.3/2.1, SP:2.4/2.2/2.3/2.3. **CONCLUSIONS:** Among PsO patients receiving their first biologic, treatment patterns and disease severity varied across 5EU, with patients in Germany disproportionately experiencing higher disease burden. Factors influencing the observed variations in care and optimal therapeutic approaches (including treatment sequencing) aligned with clinical guidelines to decrease patient disease burden warrants scrutiny.

PSY68

PHARMACOTHERAPY COSTS OF MULTIPLE MYELOMA IN THE CZECH REPUBLIC: A RETROSPECTIVE ANALYSIS

Baloghova K[1], Fuksa L[2]

[1]*Masaryk University, Brno, Czech Republic,* [2]*General Health Insurance Company of the Czech Republic, Praha, Czech Republic*

OBJECTIVES: In the Czech Republic there are three modern molecules available for the treatment of multiple myeloma: bortezomib, thalidomide and lenalidomide. In order to better understand this evolving specific market, analysis of consumption trends has been conducted with emphasis on the molecules' mutual influence. **METHODS:** Time-consumption curves of bortezomib, lenalidomide and thalidomide since 2009, based on the economic data of the General Health Insurance Company of the Czech Republic, were analyzed. While there was reimbursement for thalidomide in the first line treatment and bortezomib in the second line in 2009, we focused on and evaluated the impact of the launch of lenalidomide in 2009 (as a second line treatment). We also investigated the extension of reimbursement of bortezomib for the use in the first line in 2010. **RESULTS:** The introduction of lenalidomide (2009) led to a rapid decline in thalidomide consumption within the next year, in contrast to bortezomib, the consumption of which appeared unaffected. Furthermore, also the consumption of thalidomide decreased profoundly following the extension of reimbursement conditions of bortezomib (2010). The overall relative reduction in thalidomide consumption observed within the two years between 2009 and 2011 was 70%. **CONCLUSIONS:** The presented retrospective analysis shows that the impact of myeloma treatment on payers' financial budgets has increased nearly 3-times in the last four years. The extension of reimbursement of bortezomib had a clear impact on the consumption of thalidomide, which was its supposed comparator in the first line therapy. However, it appears that even though the introduction of lenalidomide did also significantly affect the consumption of thalidomid, it had no apparent impact on the use of bortezomib.

PSY70

APPETITE SUPPRESSANTS: A DRUG UTILISATION STUDY

Truter I

Nelson Mandela Metropolitan University, Port Elizabeth, South Africa

OBJECTIVES: To determine the prescribing and cost of appetite suppressants in a defined private sector patient population, as well as the prescribing of other medicines to the patient sample. **METHODS:** A retrospective drug utilisation study was conducted on a medical insurance claims database in South Africa for 2010 and 2011. No clinical information was available in the database. **RESULTS:** In 2010, 37 patients (86.49% females) were prescribed 44 appetite suppressants at a total cost of R9813.39, of which 75.0% were for phentermine. The average age of patients was 40.95 (SD=12.37) years. In 2011, 27 patients (77.78% females) received 42 prescriptions for appetite suppressants at a total cost of R9967.73. The average age of patients was 40.04 years (SD=10.41) (females: 37.95 (SD=7.76) years; males 47.33 (SD=10.52) years). Most products (80.95%) were for phentermine, followed by d-norpseudoephedrine (14.29%) and diethylpropion (4.76). Prescribing patterns in 2010 and 2011 were similar. Appetite suppressants are strictly regulated in South Africa.

In 2011, a total of 630 products (all therapeutic classes) were prescribed. The most often other prescribed classes in 2011 were gastrointestinal tract products (14.60%), cardiovascular agents (11.11%) and antimicrobial products (9.52%). The most frequently prescribed subclasses were HMG-CoA reductase inhibitors (statins), analgesic combinations, non-selective COX-inhibitors and selective serotonin re-uptake inhibitors. The total amount claimed from the medical insurance scheme for all the products was R73013.71, however, only R37553.24 was paid out. Appetite suppressants were excluded from patients' medical insurance benefits. **CONCLUSIONS:** A limited number of strictly regulated appetite suppressants were prescribed. Appetite suppressants that patients can buy over-the-counter were not included in this study. Pseudoephedrine has recently been rescheduled to be more strictly controlled due to its abuse potential. Further consumer studies on appetite suppressants which include clinical information will provide a useful insight into the role of these products in weight loss efforts.

PSY71

ANALYSIS OF THE REIMBURSED PSORIASIS MARKET IN HUNGARY BETWEEN 2007 AND 2011

Ecseki A, Nagy ZB, Becsi R, Gerencsér Z, Rozsa P, Toth I
MediConcept Ltd., Budapest, Hungary

OBJECTIVES: Psoriasis is a chronic skin disease of scaling and inflammation, typically characterized by erythematous papules and plaques with a silver scale. In Hungary, approximately 150.000 – 200.000 people are affected. We sought to evaluate the available reimbursed psoriasis treatment options, the economic impact of the disease, and in general we attempted to see beyond the market trends and patients characteristics observed in the analysed dataset. **METHODS:** Data were derived from the nationwide dataset of the Hungarian National Health Insurance Fund Administration, the single health care financing agency of Hungary. Data were evaluated according to sex, age, geographical region, type of care and specialty of the prescribing physician. The analysis covers data of all reimbursed pharmaceuticals and other medical services between 1 January 2007 and 31 December 2011. **RESULTS:** The median age was between 51 and 55 years. A bimodal age of onset has been recognised in several large studies, but in this patient cohort people between the ages of 30 and 69 were overrepresented. We found no significant deviation between counties, but there is a clear seasonality in the data. During each year of the analysed period the number of patients who redeemed at least one reimbursed drug fell short compared to the prevalence based estimates. At any given time close to 80% of the patients did not receive any reimbursed treatment and the number of sold packages continuously decreased over the 5-year period. The introduction of biologic treatments also significantly affected the market. **CONCLUSIONS:** To our knowledge, no systematic empirical research exists addressing the question of how psoriasis market changed over the time in Hungary. The data suggest relatively poor adherence to treatment regimens frequently seen and documented in other studies as well.

PSY72

UTILIZATION PATTERNS FOR TREATMENT WITH STRONG OPIOIDS FOR CHRONIC BACK PAIN IN GERMANY

Theidel U[1], Mittendorf T[1], Mueller-Schwefe GHH[2], Ueberall MA[3]
[1]*Herescon GmbH, Hannover, Germany,* [2]*Deutsche Gesellschaft für Schmerzmedizin e.V., Oberursel, Germany,* [3]*Institut für Neurowissenschaften, Algesiologie und Pädiatrie, Nuernberg, Germany*

OBJECTIVES: Although opioids are a well-accepted and effective method for pain management, it is still a challenge for physicians to find adequate treatment schemes in non-malignant pain. Inadequate treatment might impact quality of life and induce social and psychological problems. Aim of this survey was to describe treatment patterns of chronic back pain (CBP) in Germany. **METHODS:** In a cross-sectional, non-interventional survey n=4,283 German physicians were asked to report experiences with strong opioids in CBP. Statistical analysis was performed to analyze relationships between strong opioids and potential side effects. **RESULTS:** The majority of physicians (54.4%) at least partly accept strong opioid therapy in CBP noting treatment benefits in 69.6%. Most prescribed therapies are non-opioids like NSAIDs/COX-2 (55.1%) and physiotherapy (47.7%). 22.7% of all CBP receive strong opioids (26.0% fentanyl, 19.9% oxycodone/naloxone, 17.8% oxycodone, 13.9% hydromorphone, 13.8% burprenorphine, 13.7% morphine, 7.3% tapentadol, 1.8% L-methadone). 16.5% are treated in monotherapy, 23.6% with multimodal treatment. 67.5% show a reduction in pain intensity ≥50%. 25.8% need strong opioids for longer than 12 months. 26.2% need an increased dosage. Furthermore, 20.2% of patients experience a decrease in efficacy, which leads to opioid rotation (15.1%). 23.4% have persistent side effects (25.3% never, 46.4% temporary) wherefore 16.1% switch and 15.2% withdraw the treatment. Most side effects are observed near start of therapy, with constipation being the most common and resistant side effect (49.1%). After treatment discontinuation, pain status is considerable worsened in 34.3%. Correlation analysis shows that morphine has the highest probability of side effects when compared to oxycodone and oxycodone/naloxone. **CONCLUSIONS:** Although physicians see the medical need, CBP patients seem not to be overly treated with strong opioids. Obviously, morphine is not the treatment of first choice. Treatments chosen strongly depend on physician specialty. As anticipated, constipation is the most common and resistant side effect.

PSY73

VARIABILITY OF CLINICAL PRACTICE FOR BARIATRIC SURGERY IN SPAIN

Espallardo O, Busutil R
Johnson & Johnson Medical, Madrid, Spain

OBJECTIVES: Geographical variations in medical practice are expected to be small when the evidence about a particular technology is abundant. This would be the case of bariatric surgery (BS), which has been demonstrated to be an effective intervention to promote weight-loss in patients with indications for this procedure (PWI). Moreover, BS has recently proven to be cost-effective and drive long-term savings, compared to a "do-nothing" intervention, for the Spanish National Health System. The objective of this research is to analyze the differences in adoption of BS among the different Spanish Autonomous Communities (Regions). **METHODS:** Ecologic design. A retrospective analysis of the Spanish 2011 Health System Survey was conducted to estimate the prevalence of adult PWI for BS in each Region. The results were therefore extrapolated to the total regional adult population reported by the National Institute of Statistics for 2011. The total number of bariatric surgeries by Regions during 2011were retrieved from the database of the National Health Ministry (ICD-9-CM: 44.31, 44.39, 44.38, 44.95 and 44.69) **RESULTS:** Variation in the annual provision of BS was large, ranging from 0.81% of patients with indication for Murcia, to 0.11% in Navarra. For the rest of Regions, the percentage of PWI operated in 2011 was: Madrid=0.62%; Castilla y León=0.60%; Aragón=0.35%; Cataluña=0.33%; Pais Vasco=0.32%; Com. Valenciana=0.30%; Cantabria=0.30%; Canarias=0.30%; Extremadura=0.23%; Galicia=0.22%; Asturias=0.19%; Andalucía=0.18%; Castilla La Mancha=0.15%; Baleares=0.14% and La Rioja=0.13%. **CONCLUSIONS:** These results raise the hypothesis that living in a certain Region may strongly affect the probability of a PWI receiving BS. In such case, this variability should be tackled, particularly in a country where most patients are supposed to have access to this treatment without any copayment. Further research with more accurate estimations and multilevel analysis models would be desirable to confirm these results.

PSY74

PIVOTAL STUDIES OF ORPHAN MEDICINAL PRODUCTS – AN ANALYSIS OF QUALITY OF CLINICAL EVIDENCE

Picavet E[1], Cassiman D[2], Hollak CEM[3], Maertens J[2], Simoens S[1]
[1]*KU Leuven, Leuven, Belgium,* [2]*University Hospital Leuven, Leuven, Belgium,* [3]*University of Amsterdam, Amsterdam, The Netherlands*

OBJECTIVES: Recent debate on the long-term effectiveness of some orphan medicinal products (OMPs) led us to question whether the initial standards for clinical evidence for OMPs, set by EMA at the time of marketing authorization, are too low. Therefore, the aim of this study was to quantitatively evaluate the characteristics and quality of clinical evidence that is presented for OMPs to obtain marketing authorization in Europe. **METHODS:** We quantitatively assessed the characteristics and quality of clinical evidence of the pivotal studies of 64 OMPs as described in the European Public Assessment Report and/or the Scientific Discussion document prepared by the Committee for Human Medicinal Products of the EMA using a new and validated instrument. **RESULTS:** The 64 OMPs were altogether authorized for 78 orphan indications, for which 117 studies were identified as 'pivotal' or 'main' studies. In approximately two thirds of the studies, the allocation was randomized (64.8%) and a control arm was used (68.5%). Half of the studies applied some type of blinding. Only a minority (26.9%) of the studies included a Quality-of-Life (QoL) related endpoint, of which a third claim an improvement in QoL. Upon analyzing the quality of reporting, we found that some aspects (i.e. the endpoints, the sampling criteria, and the interventions) are well described, whereas other items (i.e. a description of the patients and of potential biases) are not reported for all studies. **CONCLUSIONS:** In conclusion, the pivotal studies that are the basis for marketing authorization of OMPs are a cause for concern, as they exhibit methodological flaws. Additionally, there are shortcomings in the reporting of those studies that complicate the interpretation. A more demanding regulatory process for OMPs is needed to guide evidence-based clinical decision-making.

PSY75

HOW TO DETERMINE SIZE OF PATIENT POPULATION WHEN THE RIGHT DATA ISN'T THERE?

Stuchiner A
PAREXEL, New York, NY, USA

OBJECTIVES: As costs of health care continue to rise, payers need to quantify the potential patient population for a new treatment. In the case of a novel treatment for intractable pain that would be for end of life cancer patients, it was necessary to consider alternative methods for calculating the potential patient population size. This study determined different approaches for identifying patient subpopulations in cancer for 'end-of-life' pain therapies **METHODS:** PAREXEL conducted a literature search on the number of cancer pain patients with intractable pain. Data was found on cancer patients with pain but not those at the end of their lives with intractable pain. Alternative measures were considered, and cancer mortality data was identified as a surrogate for end of life cancer patients. The WHO's guidelines on cancer pain estimate that 10 to 25% of cancer pain patients have intractable pain. Based on such surrogate measures, we were able to determine an estimated number of cancer patients with intractable pain at the end of their lives. **RESULTS:** Prior to this study, the target patient population was estimated to be 156,000 in the US and an equivalent number in Germany, UK, Spain and France. However, based on the surrogate measures, the results were much lower: 30,000 in the US and 31,000 in the 4 EU countries. These numbers were validated by interviewing 22 pain clinicians in the US and EU and 23 payers in the US and EU. **CONCLUSIONS:** By providing payers with accurate estimates of potential patient populations they will be better able to determine the cost implications of covering novel treatments. Given that the care provided to patients at the end of their lives is usually significantly higher than at any other time, treatments for end of life care have economic implications for payers.

PSY76

COST-MINIMIZATION OF MABTHERA INTRAVENOUS VERSUS SUBCUTANEOUS ADMINISTRATION

Bax P, Postma MJ
University of Groningen, Groningen, The Netherlands

OBJECTIVES: To identify and compare all costs related to preparing and administrating MabThera for the intravenous and subcutaneous formulations in Dutch hematological patients. The a priori notion is that the costs of subcutaneous MabThera

injections are lower compared to intravenous infusion due to potential lower time investments, shorter pharmacy preparation time, less patient chair time and less spillage. **METHODS:** We use a prospective, observational, bottom up, micro-costing approach aiming at the inclusion of 50 patients with hematological disease. Primary cost outcomes comprise the labor costs for nurses and pharmacists/pharmacy technicians, materials, hourly daycare costs and drug spillage costs. Exact timings are measured using stopwatches, dosing and spillage is measured using registered MabThera volumes in the Hospital Pharmacies' registrations and materials are exactly numbered and labeled. List prices are used for materials and MabThera costs, hourly nurse and pharmacy time is costed according to salaries, and day-care is costed using the Dutch guideline for costing research in health care. Anticipating positive outcomes of the currently ongoing non-inferiority study, efficacy of MabThera along both administration routes was implicitly assumed similar; additionally parity pricing is assumed. **RESULTS:** Interim results based on 24 patients included so far indicate that extra costs of intravenous infusion over subcutaneous injections are on average €175 per administration. This difference is primarily constituted by €100 lower daycare costs related to shorter chair time for subcutaneous as compared to intravenous administration. **CONCLUSIONS:** Our interim cost-minimization analysis suggests that subcutaneous injection of MabThera involves lower administration costs than intravenous infusion. With similar efficacy assumed, cost savings can be achieved at no expense of health, by including subcutaneous MabThera injections in the Dutch reimbursement system. Notably, over a full course of administrations (8 cycli) cost savings may easily surpass €1000 per patient per year.

PSY77

IS IT WORTH HAVING ORPHAN DRUG STATUS IN GERMANY POST-AMNOG?

Radicek S, Obradovic M, Rauland M

GfK Bridgehead, Nuremberg, Germany

OBJECTIVES: To review the assessments of benefit for orphan drugs within the early benefit assessment process after implementation of AMNOG in Germany. **METHODS:** Secondary research was used in this study. **RESULTS:** In contrast to other pharmaceuticals, by law, the benefit of orphan drugs (ODs) is proven by market authorization. No assessment vs. an appropriate comparator as defined by G-BA will be conducted, provided the revenue is less than 50 mio. EUR based on pharmacy retail prices including VAT over the past twelve months. IQWiG only assesses the accuracy of the number of patients and the therapy costs stated in the value dossier, while GB-A defines the extent of the benefit based on the Phase III data submitted with the abbreviated dossier. Seven ODs have been assessed by G-BA since implementation of AMNOG in 2011. Only one OD has received considerable benefit status in one patient subgroup, whilst two ODs have been classified as not quantifiable, and the other ODs assessed so far have been granted only a minor benefit. Prices have been negotiated for only 2 ODs so far: For Pirfenidon, with an unquantifiable benefit, a rebate of 11% was applied, while Tafamidis, with a minor benefit, received a rebate of 24.5%. **CONCLUSIONS:** There is a clear benefit for ODs (with annual sales of less than 50 mio EUR) in terms of reduced administrative burden and costs associated with the abbreviated value dossier submission. Furthermore, the OD status and the absence of a comparative added benefit assessment warrant a benefit score, whereas 60% of the non-orphan pharmaceuticals failed to prove an additional benefit vs. the defined comparator. As only two orphan drugs have completed price negotiations, it is very difficult to estimate, whether OD status will have a positive impact on future pricing opportunities after AMNOG.

PSY78

COST-EFFECTIVENESS OF SCHOOL-BASED HEALTH PROMOTION IN CANADA: A LIFE-COURSE MODELING APPROACH

Tran B[1], Ohinmaa A[1], Kuhle S[2], Johnson JA[1], Veugelers P[1]

[1]*University of Alberta, Edmonton, AB, Canada,* [2]*Dalhousie University, Halifax, NS, Canada*

OBJECTIVES: The Alberta Project Promoting active Living and healthy Eating (APPLE) Schools has been recognized as a "best practice in preventing childhood obesity. To inform decision making on the expansion and resource allocation for such school-based program like the APPLE Schools, we evaluated its cost-effectiveness and return-on-investment following a life-course approach. **METHODS:** We developed a state transition model to represent the life-time progression of weight status of three groups of children who were obese, overweight or normal weight at 11 years. The model quantified impacts of the intervention in terms of prevented excess weight cases, improved quality-adjusted life years (QALY), and avoided health care costs. Both costs and QALYs were estimated to their present value using 3% discount rate. **RESULTS:** The incremental cost-effectiveness ratio (ICER) of the APPLE Schools program was CA$ 15,833 per 1 QALY gained, and CA$ 24,359 or 11,047 per 1 obese or overweight case prevented in adult population. Every 1,000 children intervened; the program costs CA$190,000, and the estimated saving in the health care costs is about CA$ 2.3 million, that is equivalent to a benefit-cost ratio of 13:1. The sensitivity analyses showed that the incremental cost-effectiveness of the APPLE Schools program was robust against variations of program costs and model parameters. **CONCLUSIONS:** The APPLE Schools program is a cost-effective intervention for obesity prevention, and promises substantial return on investment. Expanding the coverage and allocating resources towards school-based programs is central to the fight against obesity epidemic in Canada.

PSY79

PAYER ASSESSMENT AND REIMBURSEMENT POLICY FOR RARE DISEASES: A REVIEW OF THE LITERATURE

Hutchings A[1], Palaska C[2], Schey C[2], Pericleous L[3], Petersen J[4]

[1]*Global Market Access Solutions, London, UK,* [2]*Global Market Access Solutions, St Prex, Switzerland,* [3]*Novo Nordisk A/S, Søborg, Denmark,* [4]*Novo Nordisk A/S, Soborg, Denmark*

OBJECTIVES: To review the published literature to identify: a) the most frequently cited challenges relating to payer assessment and reimbursement of rare disease treatments (including orphan drugs), and b) to review author recommendations to improve the assessment of these treatments. **METHODS:** A systematic literature review of Medline and EMBASE databases was conducted for the period 2000 - 2013. The search sought to identify papers on the topic of assessment and reimbursement policy for rare diseases. Health policy studies, commentaries, and review articles were included. Clinical or economic studies of specific drugs or diseases were excluded. Information was extracted on assessment and reimbursement challenges and author recommendations for addressing these issues. **RESULTS:** The literature review identified 726 papers; 49 met the inclusion criteria. The most frequently identified issues included multiplicity of orphan indications (34/49), high per-patient cost (32/49), and the difficulty in undertaking robust clinical and economic evaluations given limited evidence (32/49). Several authors commented on limitations of current health technology appraisal processes. The issue of equity and societal preference for funding rare diseases was highlighted in almost half of the papers (22/49). Lack of availability of alternative treatments was also considered an important factor. Suggestions for improvements to the assessment and reimbursement process included: greater use of registries (22/49), adjustment to preference weights used in cost effectiveness analysis (19/49) and conditional reimbursement and risk-sharing-schemes (12/49). Some authors advocated alternative pathways for assessing rare disease treatments including a specific approach utilising multi-criteria decision analysis. **CONCLUSIONS:** The debate on payer policy in rare diseases has grown in the last 5 years as concerns have increased about patient access to new medicines. While there is some consistency in the literature, there is as yet little consensus on how policy should be changed to address these issues.

PSY80

A SYSTEMATIC REVIEW OF THE EFFECTIVENESS OF TAXES IN PREVENTING OBESITY TRENDS

Maniadakis N[1], Kourlaba G[2], Kapaki V[1], Damianidi L[3]

[1]*National School of Public Health, Athens, Greece,* [2]*National and Kapodistrian University of Athens School of Medicine, Athens, Greece,* [3]*Ludwig Maximilian University (LMU), Munich, Germany*

OBJECTIVES: Obesity prevalence is increasing worldwide, a worrying trend as it relates to many diseases and imposes significant direct and indirect health care costs. The purpose of the present study was to assess the impact of taxation policies upon the consumption of Sugar Sweetened Beverages (SSBs) and High in Fat Sugar and Salt (HFSS) foods and ultimately caloric intake and weight outcomes. **METHODS:** The review identified relevant papers from web-based searches in comprehensive databases such as: Pubmed, Web-of-Science, Cochrane Library, Ag Econ, Econlit and National Agricultural library. Searching was conducted with all potential combinations of various relevant for the purposes of the study financial, nutritional, and outcome terms. Thereafter, abstracts were reviewed and studies were selected based on predefined criteria. The search included studies published from 1990 up to February of 2013 in English language. The characteristics and the results of the selected studies were extracted in a special form and consequently were reviewed and synthesized, based on the methodological design. **RESULTS:** A total of fifty five studies were finally included in the review. Several different types of studies showed a reduction in purchases and consumption of SSBs or HFSS foods when prices increase due or not due to taxation, but the subsequent effect upon total caloric intake was much smaller. A few studies which report weight outcomes, indicate that they are either insignificant or very small in magnitude to cause any public health improvements. **CONCLUSIONS:** The effectiveness of taxation policies to curb obesity levels is doubtful and the desired objectives not easily attainable, mainly because of the complex nature of consumer behavior and the impact of substitution effects, for which there is limited evidence to date. There is need to investigate in more depth the potential underlying mechanisms and the links between price increase policies, obesity and public health outcomes.

PSY81

MANAGED ENTRY AGREEMENTS AND ORPHAN DRUGS: A EUROPEAN COMPARATIVE STUDY (2006-2012)

Morel T[1], Arickx F[2], Befrits G[3], Siviero PD[4], van der Meijden CMJ[5], Xoxi E[4], Simoens S[1]

[1]*KU Leuven, Leuven, Belgium,* [2]*NIHDI, Brussels, Belgium,* [3]*Dental and Pharmaceutical Benefits Agency, Stockholm, Sweden,* [4]*Italian Medicines Agency (AIFA), Rome, Italy,* [5]*Health Care Insurance Board (CVZ), Diemen, The Netherlands*

OBJECTIVES: To identify, describe and classify managed entry agreements (MEAs) applied to orphan drugs by national payers and to analyse their practice in Europe. **METHODS:** To identify and describe MEAs, national HTA and reimbursement decisions on orphan drugs across seven European countries were reviewed and their main characteristics extracted. To fill data gaps and validate the accuracy of the extraction, collaboration was sought from national payers. To classify MEAs, a bespoke taxonomy was implemented. Identified MEAs were analysed and compared by focusing on five key themes, namely by describing the MEAs in relation to: drug targets and therapeutic classes, geographical spread, type of MEA applied, declared rationale for setting-up of MEAs, and evolution over time. **RESULTS:** Forty-two MEAs for 26 orphan drugs, implemented between 2006 and 2012 and representing a variety of MEA designs, were identified. Italy was the country with the highest number of schemes (n=15), followed by The Netherlands (n=10), England and Wales (n=8), Sweden (n=5) and Belgium (n=4). No MEA was identified for France and Germany due to data unavailability. Antineoplastic agents were the primary targets of MEAs. 55% of the identified MEAs were performance-based risk-sharing arrangements; the other 45% were financial-based. Nine of these 26 orphan drugs were subject to MEAs in two or three different countries, resulting in 24 MEAs. A total of 60% of identified MEAs focused on conditions whose prevalence is inferior to 1 per 10,000. **CONCLUSIONS:** This study confirmed that a variety of MEAs were increasingly used by European payers to manage aspects of uncertainty associated with the introduction of orphan drugs in the health care system, and which may be of a clinical, utilisation, or budgetary nature. It remains unclear whether differences in the use of MEAs reflect differences in how 'uncertainty' and 'value' are perceived across health care systems.

PCN1
A LITERATURE REVIEW ON THE HUMANISTIC AND ECONOMIC BURDEN OF MINERALOCORTICOID EXCESS SYNDROME
Langham S[1], Ralston S[1], Webb IJ[2], Lin HM[2]
[1]PHMR Associates, London, UK, [2]Millennium: The Takeda Oncology Company, Cambridge, MA, USA
OBJECTIVES: Notable side effects of abiraterone for advanced prostate cancer are oedema, hypertension, and hypokalemia, constituting a mineralocorticoid excess syndrome (MES). Although abiraterone is co-administered with prednisone to minimise MES symptoms, they remain a burden requiring concomitant therapies to manage each toxicity and/or treatment with costly mineralocorticoid receptor antagonists. A literature review was conducted to assess the impact of MES symptoms on health-related quality of life (HRQoL) and health care costs in patients across a number of disease areas. **METHODS:** Outside prostate cancer, MES is a broad syndrome which is best characterised as bilateral primary aldosteronism (PA). Electronic databases were searched for data on the economic and humanistic burden of MES (or its symptoms in combination) and/or PA. **RESULTS:** Even though no studies were identified in a specific prostate cancer population, nine studies found humanistic burden and three of the economic burden related to MES (PA) in the literature. Patients with MES (PA) had significantly impaired HRQoL (measured by SF36 and SF12) compared with the general population, especially on physical domains, general health perceptions, and vitality. Patients also exhibited greater levels of anxiety, depression and somatization. Use of mineralocorticoid receptor antagonists was associated with reduced HRQoL. Despite sparse direct economic data on MES, hypertension and oedema were associated with increased health care resources and costs. Chronic oedema was additionally associated with hospitalisation and lost productivity. **CONCLUSIONS:** MES symptoms can significantly impair HRQoL and may increase resource use. The impact of these symptoms in an advanced prostate cancer population is likely to be exacerbated, as many of these elderly patients already have serious co-morbidities. Further research is required to determine the incidence and severity of MES in patients receiving abiraterone in actual clinical practice and the impact these symptoms have on health care resource use and the well-being of patients with prostate cancer.

PCN2
BISPHOSPHONATES-ASSOCIATED OSTEONECROSIS OF JAW IN CANCER PATIENTS: A META-ANALYSIS
Lin HC[1], Lin SJ[1], Chan AL[2]
[1]Kaohsiung Medical University, Kaohsiung, Taiwan, [2]Min-Sheng General Hospital, Taoyuan, Taiwan
OBJECTIVES: This meta-analysis aims to assess the incidence of osteonecrosis of the jaw(ONJ)associated with bisphosphonates in cancer patients. **METHODS:** The published literature was systematically searched and reviewed using MEDLINE and the Cochrane Central Register of Controlled Trials on 30 April 2013. Any randomized controlled trial assessing the role of bisphosphonates in cancer patients and clearly mentioned the event of ONJ were eligible for inclusion. Studies that included specific risk estimates were pooled using a random-effects model. The quality of these studies were assessed with RevMan statistical software (version 5.0). **RESULTS:** Eight of 21 randomized controlled clinical trials were included. Thirteen studies were excluded due to no cases of osteonecrosis of jaw were reported. A total of 13,399 patients were collected in eight studies, 6686 patients were assigned to bisphosphonates group and 6713 were assigned to control group. Twenty-eight cases (28/6686,0.42%) of ONJ were reported in bisphosphonates group. No patient was reported in control group. Risk ratio was used to estimate the risk of osteonecrosis of the jaw associated with bisphosphonate. Pooled results showed very lower risk of ONJ associated with bisphosphonates 5.61 (95% CI: 1.90, 16.52). No heterogeneity was found in our study. **CONCLUSIONS:** Although the risk ratio of ONJ associated with the use of bisphosphonates is low in our study, we still need to suggest physicians to make a particular concern on using bisphosphonates in cancer patients. We suggest that a large and well design of risk of ONJ as primary endpoint, prospective multi-center studies should be conducted in the future.

PCN3
SKELETAL-RELATED EVENTS HAVE A SIGNIFICANT IMPACT ON HEALTH-RELATED QUALITY OF LIFE IN MEN WITH METASTATIC CASTRATION RESISTANT PROSTATE CANCER (MCRPC) FOLLOWING DOCETAXEL THERAPY FAILURE
Ivanescu C[1], Phung D[2], Holmstrom S[2]
[1]Quintiles, Hoofddorp, The Netherlands, [2]Astellas Pharma Global Development, Leiden, The Netherlands
OBJECTIVES: Patients with mCRPC are at risk of experiencing skeletal-related events (SREs), defined as pathologic fracture, spinal cord compression, and the need for radiotherapy or surgery to bone. We examined the immediate impact of an SRE on patients' HRQoL. **METHODS:** Data were obtained from the AFFIRM study, a phase 3 trial of enzalutamide vs. placebo in patients with mCRPC. Only patients experiencing any type of SRE were included in the analysis (*n=284*). For patients with multiple SREs, only the first event was used. HRQoL was assessed at baseline and at fixed intervals throughout the study until treatment discontinuation using the FACT-P (Functional Assessment of Cancer Therapy–Prostate) instrument. We used linear mixed-effects models to model each patient's longitudinal trajectory of FACT-P outcomes before the first SRE and to estimate how far the post-SRE value of HRQoL deviated from that trajectory. **RESULTS:** SREs were associated with a deterioration of HRQoL with an adjusted mean change of -6.93 (95% CI: [-9.92; -3.95]) of the FACT-P total score for any SRE. The largest impact was observed in subjects with spinal cord compression, which induced a mean decrease in the FACT-P total score of -9.68 (95% CI: [-16.10; -3.27]); pathological bone fractures and radiation or surgery to bone determined changes in FACT-P total score of -7.61 (95% CI: [-16.79; 1.56]) and -6.68 (95% CI: [-10.25; -3.11]), respectively. The standardized effect size was moderate (any SRE: -0.32; spinal cord compression: -0.49; pathological bone fracture: -0.35; radiation or surgery to bone: -0.30). **CONCLUSIONS:** Consistent with previous analyses in metastatic prostate cancer [Weinfurt K.P., et al. Annals of Oncology 2005;16: 579–584], our findings demonstrate that SREs lead to significant functional declines in patients' daily lives. Therefore, any therapy reducing or delaying the occurrence of SREs should also reduce the effects of SREs on HRQOL.

PCN4
CAN ADMINISTRATIVE DATA PREDICT CHEMOTHERAPY ADVERSE EVENTS?
Pearce AM, Haas M, Viney R
University of Technology, Sydney, Ultimo, Australia
OBJECTIVES: The rates of adverse events (AEs) are an important component of chemotherapy cost effectiveness. However, AE rates in clinical practice are difficult to obtain. This study aimed to determine whether Australian administrative data could identify the incidence of selected chemotherapy AEs. **METHODS:** The Elements of Care study (EoC) was a prospective cohort of individuals in New South Wales undergoing chemotherapy for breast, colorectal or lung cancer. Primary data, including AEs experienced, was collected through questionnaires and medical record review. Linked administrative data of prescriptions and medical services for each participant were available from the Pharmaceutical Benefits Scheme (PBS) and Medicare Benefits Schedule (MBS). This data was used to identify if an individual was treated for one of the selected AEs (diarrhoea, vomiting, anaemia and neutropenia) in the three days after a chemotherapy dose. These proxy-identified AE rates were compared with the self-reported AE rates using 2x2 contingency tables, with significance of any differences calculated using odds ratios and chi-square statistics. **RESULTS:** There were 482 individuals in EoC. The proxy identified much lower rates of AEs than were self-reported, capturing 30% of self-reported cases of nausea and vomiting, 1.3% of self-reported diarrhoea, and less than 1% of self-reported anaemia and neutropenia. Additional analyses did not identify a pattern in the grade of AEs or type of treatment received that the proxy was more likely to identify. **CONCLUSIONS:** Overall there was poor concordance between the two measures of AE rates. This may be due to low treatment rates for AEs, poor capturing of AE treatments by the proxy, or over-reporting of adverse event by participants. Regardless, it would appear that administrative data such as the MBS and PBS are not suitable for estimating the incidence of AEs in clinical practice, and bottom up data collection techniques such as EoC are essential.

PCN5
EVALUATION OF THE BURDEN OF ILLNESS OF SKIN CANCER AMONG VETERAN PATIENTS UNITED STATES
Wang L[1], Dysinger AH[2], Xie L[2], Du J[2], Huang A[1], Baser O[3]
[1]STATinMED Research, Dallas, TX, USA, [2]STATinMED Research, Ann Arbor, MI, USA, [3]STATinMED Research/The University of Michigan, Ann Arbor, Michigan, MI, USA
OBJECTIVES: To evaluate the burden of skin cancer among U.S. veteran patients. **METHODS:** Patients diagnosed with skin cancer were identified (International Classification of Disease 9th Revision Clinical Modification [ICD-9-CM] diagnosis code 232.xx) using the Veterans Health Administration (VHA) Medical SAS datasets from October 1, 2009 to September 30, 2011. The first diagnosis date was defined as the index date. A comparison group of patients without skin cancer of the same age, region, gender and index year were identified and matched on baseline Charlson Comorbidity Index with a randomly chosen index date to minimize selection bias. Patients in both groups were required to be at least 18 years old and have 1 year continuous health plan enrollment pre- and post-index date. Follow-up health care costs and utilizations were compared between the two groups after using 1:1 propensity score matching adjusting baseline characteristics. **RESULTS:** A total of 12,504 patients were identified for the skin cancer and comparison cohorts. After 1:1 propensity score matching, each group included 4,400 patients with well-balanced baseline demographic and clinical characteristics. Patients diagnosed with skin cancer had higher percentages of inpatient (5.75% vs. 2.64%, p<0.01), emergency room (11.89% vs. 6.50%, p<0.01), physician office (99.95% vs. 66.70%, p<0.01), outpatient (99.95% vs. 67.41%, p<0.01), and pharmacy visits (91.89% vs. 71.30%, p<0.01). Patients in the skin cancer cohort also incurred higher expenditures in inpatient ($1,494 vs. $555, p<0.01), emergency room ($108 vs. $60, p<0.01), physician office ($4,486 vs. $1,480, p<0.01), outpatient ($4,780 vs. $1,639) and pharmacy visits ($707 vs. $429, p<0.01) than patients in the comparison group. **CONCLUSIONS:** Study results suggest that cancer patients diagnosed with skin cancer incurred significantly higher costs and health care resources compared to patients without.

PCN6
EVALUATION OF THE BURDEN OF ILLNESS OF COLORECTAL CANCER AMONG VETERAN PATIENTS IN THE UNITED STATES
Wang L[1], Xie L[2], Li L[1], Wang Y[2], Kariburyo MF[2], Baser O[3]
[1]STATinMED Research, Dallas, TX, USA, [2]STATinMED Research, Ann Arbor, MI, USA, [3]STATinMED Research/The University of Michigan, Ann Arbor, Michigan, MI, USA
OBJECTIVES: To examine the economic burden and health care utilizations of colorectal cancer patients in the U.S. veteran population. **METHODS:** A retrospective database analysis was performed using the Veterans Health Administration Medical SAS datasets (01OCT2008-30SEP2012). Patients (≥18 years of age) diagnosed with colorectal cancer (International Classification of Disease 9th Revision Clinical Modification ICD-9-CM codes 153.xx, 154.xx) were identified. The first diagnosis date was designated as the index date. A comparator group was created by categorizing patients without colorectal cancer but of the same age, region, gender and index year, and matching them by baseline Charlson Comorbidity Index. The index date for the comparison group was selected randomly to minimize selection bias. Continuous medical and pharmacy benefits for 1 year pre- and 1 year post-index date were required. One-to-one propensity score matching (PSM) was used to compare the health care costs and utilizations during the follow-up period between

the colorectal cancer and comparison groups, adjusted for baseline demographic and clinical characteristics. **RESULTS:** A total of 75,208 patients were identified for the colorectal cancer and comparison cohorts. After 1:1 PSM, 24,053 patients were matched from each group, and the baseline characteristics were proportionate. Patients diagnosed with colorectal cancer had more health care utilization including inpatient (20.40% vs. 2.61%, p<0.01), emergency room (ER) (15.32% vs. 6.06%, p<0.01), outpatient (99.60% vs. 64.31%, p<0.01) and pharmacy visits (88.30% vs. 66.20%, p<0.01). The higher health care utilization resulted in increased health care costs, including high inpatient ($9,867 vs. $795, p<0.01), ER ($158 vs. $61, p<0.01), outpatient ($5,020 vs. $1,585, p<0.01), pharmacy ($1,345 vs. $523, p<0.01) and total costs ($16,232 vs. $2,903, p<0.01) for patients diagnosed with colorectal cancer compared to patients in the comparison group. **CONCLUSIONS:** Veteran patients diagnosed with colorectal cancer incurred significantly higher health care utilization and costs over a 1-year period compared to patients without colorectal cancer.

PCN7

EVOLUTION OF MOLECULAR DIAGNOSTIC TEST USAGE IN SOLID TUMOURS IN WESTERN EUROPE: AMBITION STUDY (ANALYSIS OF MOLECULAR BIOMARKER TESTS IN ONCOLOGY)

Ricarte C[1], Bruce A[2], Anger C[2]
[1]*IMS Health, La Défense, France,* [2]*IMS Health, London, UK*

OBJECTIVES: The development of targeted therapies has changed the paradigm of cancer management necessitating the use of robust biomarkers to identify eligible patients. This study aims to evaluate trends in molecular diagnostic test (MDT) uptake across various solid tumors. **METHODS:** This study used IMS Oncology Analyzer™, a patient database collected through a quarterly physician panel survey. This database provides comprehensive insight into cancer care. Selected patients were at advanced/metastatic stages and diagnosed with breast (BC), stomach (SC), non-small cell lung cancer (NSCLC) or colorectal cancer (CRC) and receiving chemotherapy. MDT uptake was analyzed from time 0 (year of the European Medicines Agency –EMA– approval of the associated targeted therapy) until 2012. The analysis was done on 5 EU countries (France, Germany, Italy, Spain and UK). **RESULTS:** Trastuzumab was approved in HER2+ BC by the EMA in 2000 and had a line extension in 2004. In metastatic BC, the proportion of HER2-tested patients in 2004 was 60% (787/1,320) versus 94% (1,351/1,430) in 2012. Following further approval in 2010 for use in HER2+ advanced SC, HER2-testing grew from 17% (176/1,015) to 50% (501/993) between 2010 and 2012 in this population. In the year that Gefitinib gained EMA approval in EGFR+ NSCLC (2009), 8% of advanced NSCLC patients (280/3,465) were EGFR-tested. This proportion increased to 56% (2,092/3,708) in 2012. Panitumumab and Cetuximab obtained EMA approval for KRAS-wild type CRC in 2007 and 2008 respectively. In 2009, 42% (1,183/2,843) of metastatic CRC patients were K-RAS-tested and 62% (1,782/2,873) in 2012. **CONCLUSIONS:** The use of MDTs has become increasingly important in oncology as more targeted therapies are launched. While consistent growth in testing is established, differences exist in the delay to achieving routine testing of patients. Further observation of MDT usage is required, considering national health guidelines, to better understand movement towards personalized cancer management.

PCN8

A LESSON LEARNT FROM AVASTIN®: - BEVACIZUMAB INDUCED HYPERTENSION AS A PREDICTIVE BIOMARKER OF PATIENT RESPONSE IN OVERCOMING REGULATORY AND HEALTH TECHNOLOGY ASSESSMENT (HTA) HURDLES

Fowler RC, Street-Docherty LM, Morrison S
GfK Bridgehead, Melton Mowbray, UK

BACKGROUND: The high cost of VEGF-targeted anti-angiogenic therapies within a financially strained health-system, makes reimbursement decisions a potentially limiting factor for new compounds. Failure to demonstrate adequate clinical benefit and cost-effectiveness in HER-2 negative metastatic breast cancer resulted in significant regulatory and health technology assessment (HTA) challenges. There is increasing expectation for new drugs to have companion diagnostics that identify likely patient responders, with growing support for using biomarkers to inform treatment decisions **OBJECTIVES:** The purpose of this study was to critically examine published literature on trials incorporating biomarkers related to VEGF inhibition across different cancer indications, to explore their value as predictive, prognostic, pharmacological or surrogate response biomarkers **METHODS:** A search with a strict set of inclusion criteria was used to review the current literature. Information was gathered for 13 biomarkers that have been explored for anti-VEGF therapy and a database was compiled housing raw experimental data for comparison. Each biomarker was critically evaluated and ranked accordingly, to validate their potential as predictive, prognostic, pharmacodynamic and surrogate endpoint markers for bevacizumab-based therapies, with consideration for likely regulatory, clinical and payer acceptance. **RESULTS:** A total of 222 published studies were incorporated into the analysis. Plasma VEGF-A, PlGF and soluble VEGFR-1/VEGFR-2 demonstrated value as pharmacodynamic biomarkers with limited prognostic value. CECs and CA19-9 showed prognostic and predictive value under restricted indications. Blood pressure demonstrated superiority in its ability to predict response to bevacizumab. **CONCLUSIONS:** The evidence suggests the incorporation of biomarkers in clinical trial design must be tailored to the drug and the cancer indication to which the therapy is applied. The potential for blood pressure as a biomarker of response to bevacizumab has been highlighted. Bevacizumab-induced hypertension should therefore be considered as a key candidate for future biomarker-driven trials, increasing the likelihood of test-treatment acceptance by key regulatory and HTA stakeholders.

PCN9

PREGNANCY AFTER BREAST CANCER IN 2000-2002 AND 2010-2012: A RETROSPECTIVE DATABASE ANALYSIS

Kalousidou N[1], Waehlert L[1], Rex J[2], Kostev K[2], Ziller V[3]
[1]*Fresenius University of applied sciences, Idstein, Germany,* [2]*IMS Health, Frankfurt am Main, Germany,* [3]*Philipps-University of Marburg, Marburg, Germany*

OBJECTIVES: Women of childbearing age with a diagnosis of breast cancer often want to conceive a child after treatment. Some reports found that pregnancy does not increase the risk of cancer recurrence after successful treatment. These reports and positive changes in the survival rates of breast cancer patients can impact the decisions of patients and physicians. The goal of this study was to estimate the number of women who survived breast cancer and subsequently became pregnant and to determine the time between the cancer diagnosis and pregnancy in the time periods between 2000-2002 and 2010-2012, respectively. **METHODS:** This retrospective study analysed longitudinal routine care data collected by gynaecologists in Germany (IMS® Disease Analyzer). Data from women aged 20-45 with a pregnancy within 10 years after the first breast cancer diagnosis from 102 gynaecological practices in Germany (Disease Analyzer database; 01/1992 to 12/2012) were analysed. **RESULTS:** In the time period 2000-2002, 65 (projected to national level: 4615) women became pregnant after a breast cancer diagnosis; this number increased to 114 (projected to national level: 8094) between 2010-2012. The mean age did not significantly change between 2000-2002 and 2010-2012 (33.8 (SD: 6.0) and 34.2 years (SD: 6.1)). The time between the first breast cancer diagnosis and pregnancy identification was 896 days (SD: 690) in 2000-2012 and 552 days (SD: 696) in 2010-2012 (p<0.01). **CONCLUSIONS:** This retrospective analysis showed that the number of pregnancies following breast cancer diagnosis has significantly increased in the last 10 years. More over, the time to pregnancy has become significantly shorter. This is indicative of the positive and hopeful developments for young women affected by breast cancer. Further studies on this important research topic are necessary.

PCN10

EVALUATION OF VARIABLE RELEVANCE AND ACCESSIBILITY TO SUPPORT PERSONALIZED MEDICINE IN BREAST CANCER

Udomaksorn S[1], Stenehjem D[2], Welch B[1], Cheng Y[1], Anderson L[2], Colonna S[2], Neumayer L[2], Brixner D[1]
[1]*University of Utah, Salt Lake City, UT, USA,* [2]*University of Utah/University of Utah Hospitals & Clinics, Salt Lake City, UT, USA*

OBJECTIVES: About 1 in 8 U.S. women will develop invasive breast cancer during their lifetime. Response to treatment varies among women depending on several factors. This work identified and prioritized the essential variables to implement personalized cancer treatment, and determined the feasibility of obtaining these variables from available data sources toward a real time clinical decision aid. **METHODS:** A focus group of 10 breast cancer clinicians was conducted to determine possible variables for inclusion into the clinical dashboard. An electronic 3-categorical scale (must have, would like to have, unnecessary) survey was conducted among a broader group of breast cancer clinicians. Variables were classified by category and mention frequency (Mode). The accessibility of these variables from two separate cancer care databases was evaluated by data querying, text search and electronic chart review and categorized as available, difficult to access, or unavailable. **RESULTS:** Ten clinicians identified 67 possible variables for inclusion into the dashboard. According to the broader electronic survey 25 clinicians determined 39 "must have" variables with 9 patient specific variables (e.g. age at diagnosis, comorbidities, hormone replacement use, cancer history); 13 tumor specific variables (e.g. clinical stage at diagnosis, histologic grade, laterality) and 17 timeline related variables (e.g. date and type of surgery, chemo/endocrine/targeted therapies received by date, chemotherapy regimen and cycle information, overall survival). 34 of identified "must have" variables were accessible from at least one of available databases. Of the relevant variables five may be difficult to access, including BRCA testing and status, performance status, date and site of recurrence, disease free survival and treatment delay. **CONCLUSIONS:** Breast cancer clinicians identified 39 essential variables, the majority of which can be obtained from currently available databases and then uploaded into a clinical dashboard to support personalized medicine at the point of care for patients with breast cancer.

PCN11

AN INDIRECT TREATMENT COMPARISON OF THE EFFICACY OF EVEROLIMUS (AFINITOR®) AND FULVESTRANT FOR THE TREATMENT OF HORMONE RECEPTOR POSITIVE (HR+) HER2 NEGATIVE (HER2–) ADVANCED OR METASTATIC BREAST CANCER

Chandiwana D[1], Vieira J[1], Granville J[2], McCool R[2], Fleetwood K[3]
[1]*Novartis Pharmaceuticals UK Limited, GB- Frimley/Camberley, UK,* [2]*York Health Economics Consortium Ltd., York, UK,* [3]*Quantics Consulting Ltd., Edinburgh, UK*

OBJECTIVES: To indirectly compare the efficacy (progression free survival (PFS)/time to progression (TTP) and overall survival (OS) of everolimus plus exemestane (EVE+EXE) with fulvestrant in patients with hormone receptor positive, HER2 negative advanced or metastatic breast cancer. **METHODS:** A systematic search of the Cochrane Library and other resources was undertaken to identify reviews and clinical trials reporting interventions for metastatic breast cancer that would allow an indirect comparison of fulvestrant and EVE+EXE. A Bayesian fixed effect model was used with exemestane adopted as the base treatment for the model because it provided the most information in the network. The basic parameters of the model are the log hazard ratios with respect to exemestane for PFS/TTP and OS from the included studies. In the absence of full networks for TTP/PFS, these outcomes were assumed to be the same measure in a disease with short survival times. **RESULTS:** Six trials contributed to a network for PFS/TTP and five to a network for OS. Because the comparator treatment was used as the base treatment, a HR > 1 indicates that the comparator is less effective than everolimus. For PFS/TTP, EVE+EXE performed better than fulvestrant 250mg (HR 2.13 Credible interval (CI):1.72 to 2.63) and 500mg (HR 1.69 CI: 1.30 to 2.22). This difference was statistically significant. For OS, EVE+EXE performed better than fulvestrant 250mg (HR 1.36 CI: 0.95 to 1.97) and 500mg (HR 1.15 CI: 0.76 to 1.75) but the difference was not statistically significant. A complete statistical assessment of heterogeneity for PFS/TTP and OS was not possible because of data limitations. **CONCLUSIONS:** EVE+EXE confers better PFS/TTP benefit in HR+ HER2-ve metastatic breast cancer when indirectly compared with fulvestrant 250mg

or 500mg. The indirect analysis did not show a statistically significant difference in OS between everolimus compared with fulvestrant.

PCN12

SMALL MOLECULE TARGETED THERAPIES FOR THE SECOND LINE TREATMENT OF METASTATIC RENAL CELL CARCINOMA (MRCC): A SYSTEMATIC REVIEW AND INDIRECT COMPARISON OF SAFETY AND EFFICACY

Dranitsaris G[1], Schmitz S[2], Broom RJ[3]
[1]University of Ioannina, Ioannina, Greece, [2]Trinity College, Dublin, Ireland, [3]Auckland City Hospital, Auckland, New Zealand

OBJECTIVES: Patients with mRCC and a good performance status typically receive an anti-VEGFR TKI (sunitinib or pazopanib) as initial therapy. Upon disease progression or intolerance, there are four orally-administered agents approved in the 2nd - line setting (including cytokine-refractory). However, head to head comparative trial data are limited. In the absence of such data, mixed treatment comparison (MTC) models are a widely accepted statistical method for generating comparative effectiveness information. In this study, an indirect comparison on the safety and efficacy was undertaken between axitinib, sorafenib, pazopanib and everolimus for 2nd - line therapy in advanced RCC. **METHODS:** A systematic review of major databases was conducted from January 2005 to June 2013 for randomized controlled trials evaluating at least one of the four agents in 2nd- line mRCC. Bayesian MTC models were fitted to assess comparative effectiveness based on multiple endpoints: tumour response, progression free survival (PFS), grade III/IV toxicities such as diarrhea, fatigue, hand foot skin reaction, rash and stomatitis as well as treatment discontinuations. **RESULTS:** A total of four randomized trials meeting the inclusion criteria were appropriate for the statistical pooling exercise. All four agents seem able to induce tumour shrinkage and provide patients with a clinically meaningful PFS benefit. Axitinib was superior to pazopanib (HR = 0.64; 95%CrI: 0.42 to 0.96) and sorafenib (HR = 0.70; 95%CrI: 0.57 to 0.87) in terms of PFS. However, patients receiving axitinib would be at an elevated risk for fatigue and to a lesser extent, stomatitis. **CONCLUSIONS:** Keeping in the mind the caveats associated with cross-trial comparisons, axitinib appears to provide superior PFS benefits relative to pazopanib and sorafenib. However, this is at a cost of a higher frequency of some dose-limiting toxicities. Everolimus, an mTor inhibitor, is mechanistically distinct from the other agents evaluated and would be a useful option post anti-VEGFR TKI failure.

PCN13

TARGETED THERAPY IN TRIPLE-NEGATIVE METASTATIC BREAST CANCER (TNBC) - A SYSTEMATIC REVIEW AND META-ANALYSIS

Clark OAC[1], Engel T[1], Paladini L[1], Ferreira MBA[2]
[1]Evidencias, Campinas, Brazil, [2]Roche, São Paulo, Brazil

OBJECTIVES: To perform a systematic review and meta-analysis of all randomized controlled trials comparing the efficacy of targeted therapy to conventional CT in patients with metastatic Triple-Negative Breast Cancer (TNBC). **METHODS:** Several databases were searched, including MEDLINE, EMBASE, LILACS, and CENTRAL. The primary endpoint was progression-free survival (PFS). We performed a meta-analysis (MA) of the published data. The results were expressed as Hazard Ratio (HR) or Risk Ratio (RR), with their corresponding 95% confidence intervals (CI 95%). **RESULTS:** The final analysis included 12 trials comprising 2,054 patients with TNBC. It was evidenced studies with conventional CT plus targeted therapy including bevacizumab (Bev), sorafenib (Sor), cetuximab and iniparib. The PFS was higher in patients who received Bev plus CT compared to CT alone in previously untreated patients with TNBC (fixed effect: HR=0.62; CI 95%=0.51-0.75; p<0.00001). The PFS was also higher in one study with Bev plus CT in previously treated patients (fixed effect: HR=0.49; CI 95%=0.33-0.74; p=0.0006). Sor plus CT was available in first-line and second-line. The PFS was higher in the group with Sor versus CT alone (fixed effect: HR=0.69; CI 95%=0.49-0.98; p=0.04) and iniparib plus CT (fixed effect: HR=0.75; CI 95%=0.62-0.90; p=0.002). **CONCLUSIONS:** Bev, Sor and iniparib, when associated with the conventional CT, demonstrated gains in the PFS of patients with TNBC.

PCN14

ABIRATERONE AND ENZALUTAMIDE FOR THE TREATMENT OF METASTATIC CASTRATION-RESISTANT PROSTATE CANCER (MCRPC) POST CHEMOTHERAPY: AN INDIRECT COMPARISON AND BUDGET IMPACT ANALYSIS

Li T[1], Thompson M[2], Todd M[1], Yu M[1], Kheoh T[1], Saadi R[1]
[1]Janssen Global Services LLC, Raritan, NJ, USA, [2]Cornerstone Research Group, Burlington, ON, Canada

OBJECTIVES: Abiraterone and enzalutamide are two new treatment options for patients with mCRPC after docetaxel-based chemotherapy. This study aims to understand the relative clinical and economic value of these therapies. **METHODS:** Two pivotal clinical trials were conducted to evaluate abiraterone and enzalutamide in post-docetaxel treatment of mCRPC: Study COU-AA-301 for abiraterone and the AFFIRM trial for enzalutamide. The PICO (population, intervention, comparison, and outcomes) construct was employed to assess the comparability of the trials, followed by an indirect treatment comparison (ITC) using the Bucher method and a mix treatment comparison using Bayesian statistics. An economic evaluation was performed based on the ITC results. **RESULTS:** Several key differences were identified between the COU-AA-301 and AFFIRM trials. First, the studies used different comparators. Abiraterone plus prednisone was compared with prednisone alone, while enzalutamide was compared with placebo. Second, the endpoints rPFS, PSA progression, and PSA response were defined differently between trials, and thus were not included in the analysis. To address the difference in comparators, the ITC was performed using data from COU-AA-301 and subjects receiving corticosteroids concurrently in the AFFIRM trial. OS was significantly improved with both abiraterone and enzalutamide (3.9 and 3.2 months respectively). The ITC results were HR = 0.949 (95% CI: 0.712-1.26) for abiraterone versus enzalutamide using the Bucher method, and HR = 0.948 (95% CI: 0.711-1.26) using the Bayesian method. Using the US price for abiraterone and enzalutamide (approved in the US only), and assuming 25% of patients received therapy following docetaxel, cost savings from using abiraterone would be >$10K/patient/year or $49.0M/year nationally. **CONCLUSIONS:** Differences in study design should be addressed when conducting an ITC. The evidence from this ITC shows that abiraterone and enzalutamide have similar efficacy in OS in mCRPC post chemotherapy. However, abiraterone is cost saving compared to enzalutamide in this analysis.

PCN15

DIFFERENCES IN MEDICAL COST AND SURVIVAL BETWEEN TRIAL AND NON-TRIAL PATIENTS WITH ACUTE MYELOID LEUKAEMIA – A UK POPULATION-BASED PROPENSITY ANALYSIS

Wang HI[1], Aas E[2], Roman E[1], Howell D[1], Painter D[1], Smith A[1]
[1]University of York, York, UK, [2]University of Oslo, Oslo, Norway

OBJECTIVES: Information about acute myeloid leukaemia (AML), including the costs of treatment and survival-estimates, are usually derived from clinical trial data. However, it is not known whether this information is generalizable to non-trial patients. This study was carried out to evaluate the differences in medical costs and survival between trial and non-trial patients with AML; and hence assess the external validity of trial data to the general patient population. **METHODS:** The Haematological Malignancy Research Network (HMRN, www.hmrn.org) is an established population-based patient cohort that registers around 2000 newly diagnosed patients each year. All adults (≥18) newly diagnosed with AML between September 2004 and August 2007 and treated with induction intent were included. Patients were followed until August 2012, and the comparative outcomes were medical costs and survival. Standard statistical analyses were used to measure unadjusted difference in outcomes, and propensity score analyses were applied to measure differences by adjusting for baseline imbalance in pre-treatment characteristics between trial and non-trial patients. **RESULTS:** Overall, 173 patients treated with induction intent were included, of which 106 were trial and 67 non-trial. Trial participation was associated with younger age, fewer comorbidities, better prognosis, and being treated at teaching hospitals. Before controlling for patients' characteristics, trial patients had better survival and incurred higher costs (p<.0001 for both). After controlling for patients' characteristics by carrying out propensity score analyses, these differences remained significant in both survival (median survival 28.7 vs. 8 months; p<.0001) and medical costs (mean costs £84,497 vs. £49,624; p<.0001). **CONCLUSIONS:** For AML patients treated with induction intent, significant differences were observed in treatment costs and survival according to trial status, both before and after controlling for patients' pre-treatment characteristics. Data generated solely from clinical trials may therefore not be generalizable to non-trial patients and should be treated with some caution when used to facilitate decision-making.

PCN16

THE EFFECT OF POSITIVE MARGINS ON OUTCOMES IN BREAST CANCER

Ling CS[1], Weisgerber-Kriegl UM[2], Njue A[1], Heyes AE[1], Kaye JA[3]
[1]RTI Health Solutions, Manchester, UK, [2]F. Hoffmann-La Roche Ltd., Basel, Switzerland, [3]RTI Health Solutions, Waltham, MA, USA

OBJECTIVES: To review the data available on excision margins following breast-conserving therapy (BCT), focusing on definitions of positive and clear margins, percentage of operations resulting in positive margins, the effect of positive margins on future treatment, and the relationship between positive margins and disease-free and overall survival. **METHODS:** Targeted searches of PubMed were conducted using a predefined search strategy. Data from robust systematic reviews and/or meta-analyses were given priority. **RESULTS:** Definitions of positive and negative margins are variable, but typically a clear margin of 2 mm is considered acceptable. Most studies indicate positive margins in 20%-40% of patients after wide local excision. Guidelines recommend that patients with positive margins after BCT undergo repeat surgery, and in surveys, most physicians said they would recommend re-excision when there is tumour within 1 mm of the margin. In the identified studies, 20%-30% of patients underwent re-excision and approximately 2% had multiple re-excisions (two or more); 10%-15% of patients who initially had lumpectomy later had a mastectomy. There is a significant association between margin status and local recurrence (in a recent meta-analysis, the odds ratio was 2.42 for positive vs. negative margin status; 95% confidence interval, 1.94-3.02; P<0.001). However, among patients with a clear margin, width is not clearly related to risk of local recurrence. Four studies that assessed the effect of margin status on overall or disease-specific survival were identified, three reported a significant association (e.g., cause-specific survival at 12 years significantly associated with margin status, P<0.001). **CONCLUSIONS:** Definition of adequate margins remains controversial. None-the-less, final margin status is a key prognostic factor following BCT. The data identified suggest that an intervention that reduces the rates of positive margins during BCT may have the potential to improve outcomes and reduce the burden on patients and health care providers.

PCN17

A MIXED TREATMENT COMPARISON (MTC) TO COMPARE PROGRESSION FREE SURVIVAL (PFS) ASSOCIATED WITH DIFFERENT CHEMOTHERAPY REGIMENS FOR PLATINUM-SENSITIVE OR PARTIALLY PLATINUM-SENSITIVE RECURRENT ADVANCED OVARIAN CANCER

Edwards SJ, Barton S, Thurgar E, Wakefield V, Karner C, Trevor N
BMJ Group, London, UK

OBJECTIVES: This research was conducted during a review of the manufacturer's submission (MS) to the NICE Single Technology Appraisal programme for bevacizumab, a vascular endothelial growth factor (VEGF) inhibitor. Bevacizumab in combination with gemcitabine/carboplatin has recently been licensed for use in patients with platinum-sensitive or partially platinum-sensitive recurrent advanced ovarian cancer. This research compared this new triple therapy with treatments used in clinical practice in the UK: platinum monotherapy, gemcitabine/carboplatin, paclitaxel/carboplatin, pegylated liposomal doxorubicin hydrochloride (PLDH)/carboplatin. **METHODS:** Randomised controlled trials (RCTs) for inclusion were identified using the MS for bevacizumab. RCTs were assessed for comparability based on patient population, disease severity, platinum sensitivity, and treatments received. An MTC was conducted using a Bayesian Markov chain Monte Carlo simulation.

Fixed and random effects models were explored with results reported for the best fitting model. Hazard ratio (HR) was chosen as the summary statistic. **RESULTS:** The network of 6 RCTs formed a linear series of "steps", which facilitated comparison of all chemotherapy regimens of interest. The fixed effects model was the best-fitting model. There was reasonable agreement between the number of unconstrained data points, residual deviance and pair-wise results, suggesting a coherent network. Using bevacizumab/gemcitabine/carboplatin as the baseline, the results for PFS for the other chemotherapy regimens were: platinum monotherapy (HR 2.92, 95% Credible Interval [CrI]: 2.10 to 3.96), gemcitabine/carboplatin (HR 2.09, 95% CrI: 1.65 to 2.60), paclitaxel/carboplatin (HR 2.16, 95% CrI: 1.50 to 3.01), PLDH/carboplatin (HR 1.77, 95% CrI: 1.20 to 2.51); where a HR>1 favours bevacizumab/gemcitabine/carboplatin and a HR<1 favours the comparator. **CONCLUSIONS:** This research suggests bevacizumab in combination with gemcitabine/carboplatin may offer significantly longer PFS compared with other chemotherapy options available in the UK.

PCN18

EFFICACY OF BRENTUXIMAB VEDOTIN AND OTHER TREATMENTS IN PATIENTS WITH RELAPSED OR REFRACTORY (RR) SYSTEMIC ANAPLASTIC LARGE-CELL LYMPHOMA (SALCL): A SYSTEMATIC REVIEW

Bonthapally V[1], Yang H[2], Macalalad AR[2], Wu EQ[2], Lutes R[3], Shonukan O[1], Chi A[3], Huebner D[3]

[1]*Millennium: The Takeda Oncology Company, Cambridge, MA, USA,* [2]*Analysis Group, Inc., Boston, MA, USA,* [3]*Takeda Cambridge US, Cambridge, MA, USA*

OBJECTIVES: Brentuximab vedotin (ADCETRIS®), a CD30-targeted antibody-drug conjugate, has conditional approval in Europe for the treatment of adult patients with RR sALCL. This systematic review summarized the efficacy of other treatments for RR ALCL, for comparison with brentuximab vedotin. **METHODS:** A systematic literature review identified studies published between 1993 and February 2013 reporting efficacy of treatments in adult patients with RR ALCL, or more generally with RR peripheral T-cell lymphoma (PTCL) including ≥1 ALCL patient. Five databases were included: EMBASE, MEDLINE, and the WHO ICTRP; reviews published since 2011 were also searched manually for additional studies. English publications reporting complete remission/response (CR) rate and/or 2-year overall survival (OS) in RR ALCL/PTCL populations were included. Publications of principal treatment with bone marrow transplantation or radiotherapy were excluded. CR rates and 2-year OS, from the identified studies and from the brentuximab vedotin single-arm phase 2 trial in sALCL (SG035-0004), were summarized. **RESULTS:** Of 1653 publications screened, 12 studies were eligible for inclusion; all were phase 1 or 2 or unspecified prospective non-randomized studies. For these studies, the CR rates were 0–28% in RR PTCL patients (n=4–130 PTCL; median age 36–69 years; n=1–41 ALCL), and for the 6 studies that also reported CR outcomes in the subset of RR ALCL patients (n=13–130 PTCL; median age 47–69 years; n=2–41 ALCL), the CR rates were 0–33% in RR ALCL patients. For RR ALCL patients treated with brentuximab vedotin in SG035-0004 (n=58 sALCL; median age 52 years) the CR rate was 59%. The 2-year OS ranged from 7–33% in the 5 identified studies that reported OS, compared with 63% with brentuximab vedotin in SG035-0004. **CONCLUSIONS:** The CR rate and 2-year OS for brentuximab vedotin in RR sALCL appear to exceed that of other therapies in RR ALCL/PTCL.

PCN19

A COMMUNITY-BASED, CASE-CONTROL STUDY EVALUATING MORTALITY REDUCTION FROM GASTRIC CANCER BY ENDOSCOPIC SCREENING IN JAPAN

Hamashima C[1], Ogoshi K[2], Okamoto M[3], Shabana M[4], Kishimoto T[3], Fukao A[5]

[1]*National Cancer Center of Japan, Tokyo, Japan,* [2]*Niigata Cancer Center Hospital, Niigata, Japan,* [3]*Tottori University, Yonago, Japan,* [4]*San-in Rosai Hospital, Yonago, Japan,* [5]*Yamagata University, Yamagata, Japan*

OBJECTIVES: Although gastric cancer has decreased in the last three decades, it is still the second leading cause of cancer death worldwide. In Asian countries, the burden of gastric cancer has remained, and screening is still expected to prevent gastric cancer death. In order to evaluate reduction of mortality from gastric cancer by endoscopic screening, a community-based, case-control study was conducted in Japan. **METHODS:** Case subjects were defined as persons who had died of gastric cancer between 2003 and 2006 in four cities, Tottori Prefecture, and between 2006 and 2010 in Niigata City, Japan. Up to six control subjects were matched by sex, birth year (±3 years), and residence of each corresponding case from population lists in the study areas. Controls were required to be disease-free at the time when the case was diagnosed gastric cancer. The odds ratios were calculated for those who had ever participated in endoscopic screening or radiographic screening before the reference date when the case was diagnosed gastric cancer, compared with persons who had never participated in any screening. Conditional logistic-regression models for matched sets were used to estimate the odds ratios and 95% confidence intervals. **RESULTS:** There were 288 males and 122 females for case subjects, with 2,292 matched control subjects. Compared with those who had never been screened before the date of diagnosis of gastric cancer in cases, the odds ratios within 48 months from the diagnosis date were 0.703 (95% confidence interval :0.497-0.996) for endoscopic screening and 0.860 (95% confidence interval :0.631-1.171) for radiographic screening. **CONCLUSIONS:** The result suggests a 30% reduction from gastric cancer mortality by endoscopic screening compared to no screening within 48 months before the diagnosis date of gastric cancer.

PCN20

BENEFIT OF ADDING PANITUMUMAB TO FOLFOX4 IN PATIENTS WITH KRAS/NRAS WILD-TYPE (WT) METASTATIC COLORECTAL CANCER (MCRC): A NUMBER-NEEDED-TO-TREAT (NNT) ANALYSIS

Douillard JY[1], Sienna S[2], Davison C[3], Braun S[4], Sidhu R[5]

[1]*ICO René Gaudducheau, St Herblain, France,* [2]*Ospedale Niguarda Ca' Granda, Milan, Italy,* [3]*Amgen Ltd., Cambridge, UK,* [4]*Amgen (Europe) GmbH, Zug, Switzerland,* [5]*Amgen Inc., Thousand Oaks, CA, USA*

OBJECTIVES: To calculate NNTs for panitumumab+FOLFOX4 vs FOLFOX4 alone (PRIME study) to achieve one objective response (OR rate [ORR] analysis) or prevent one disease progression (PFS analysis) or death (OS analysis) at 6/12 or 12/24 months. **METHODS:** In PRIME, 1183 patients with previously untreated mCRC were randomised. Using data from an exploratory analysis conducted when 80% of patients had died, NNTs (Bender. Encyclopedia of Biostatistics, Second Edition; Volume 6, pp3752-61) were retrospectively calculated in patients with *KRAS/NRAS* WT (n=505; exons 2-4 assessed) mCRC overall and in the ECOG performance score 0/1 (n=473) subgroup. ORR and PFS events were defined using RECIST. **RESULTS:** In the overall *KRAS/NRAS* WT population, 59.3% vs 45.6% of patients receiving panitumumab+FOLFOX4 vs FOLFOX4 alone, respectively, achieved an OR; NNT(95% CI) in the ORR analysis was 7.3(4.5-19.9). In the ECOG 0/1 subgroup, 61.3% vs 46.4% of those receiving panitumumab+FOLFOX4 vs FOLFOX4 alone, respectively, had an OR; the NNT(95% CI) was 6.7(4.2-16.5). For the PFS overall population analysis, the HR(95% CI) was 0.74(0.62-0.90); HR(95% CI) for the ECOG 0/1 subgroup was 0.72(0.59-0.88). NNTs(95% CI) in the overall population at 6 and 12 months were 12.8(8.3-34.1) and 9.2(5.7-25.9), respectively; corresponding values for the ECOG 0/1 subgroup were 11.9(7.9-27.8) and 8.4(5.3-20.8). For the OS overall population analysis, the HR(95% CI) was 0.76(0.63-0.93); HR(95% CI) for the ECOG 0/1 subgroup was 0.74(0.60-0.90). NNTs(95% CI) in the overall population at 12 and 24 months were 16.8(10.4-57.1) and 10.4(6.2-37.1), respectively; corresponding values for the ECOG 0/1 subgroup were 16.0(10.3-44.1) and 9.4(5.9-27.2). **CONCLUSIONS:** In these analyses NNTs for PFS, OS and particularly ORR were low, reflecting the high therapeutic benefit of adding panitumumab to FOLFOX4 in patients with *KRAS/NRAS* WT mCRC. Limitation by ECOG score 0/1 further lowered NNTs for PFS and OS.

PCN21

INDIRECT COMPARISON ANALYSIS TO EVALUATE THE CLINICAL EFFECTIVENESS OF TRASTUZUMAB EMTANSINE (T-DM1) VERSUS OTHER TREATMENTS FOR HER2-POSITIVE METASTATIC BREAST CANCER (MBC)

Benito Garcia E[1], Hersberger V[1], Takyar S[2], Moser A[1]

[1]*F. Hoffmann-La Roche Ltd., Basel, Switzerland,* [2]*Heron Health, Chandigarh, India*

OBJECTIVES: T-DM1, an antibody-drug conjugate which combines the antitumor properties of trastuzumab (H) with the cytotoxic agent DM1, is approved for the treatment of patients with MBC previously treated with trastuzumab+taxane. We compared the clinical effectiveness of T-DM1 versus all available therapies used in the treatment of unresectable HER2-positive locally advanced breast cancer (LABC) or MBC. **METHODS:** This systematic review (SR) and indirect treatment comparison (ITC) included all published data between January 1, 1998 and December 20, 2012. Studies were chosen in accordance with conventional methods for performing and reporting SRs and ITCs (i.e., Cochrane Handbook for SRs, PRISMA, ISPOR guidelines, and major HTA agencies). Eligible trials were controlled trials of treatments for unresectable HER2-positive LABC or MBC that had progressed after treatment with combination of trastuzumab+taxane in the adjuvant or MBC setting. Progression had to have occurred after the most recent treatment for LABC or MBC or within 6 months after treatment for early-stage disease. **RESULTS:** Seven RCTs and two non-randomized controlled trials (n-RCTs) met the inclusion criteria. Of the seven RCTs, five had a common comparator, being eligible for the ITC. The other two RCTs and two n-RCTs did not have a common comparator and were thus not included in the ITC. T-DM1 was the only treatment to demonstrate statistically significantly longer overall survival (OS) and progression-free survival (PFS) when directly compared to capecitabine+lapatinib, and when indirectly compared to capecitabine+trastuzumab (PFS HR [95% CI]: 0.53 [0.32, 0.86], p=0.01; OS HR [95% CI]: 0.56 [0.35, 0.91]; p=0.01) and capecitabine monotherapy (PFS HR [95% CI]: 0.36 [0.25, 0.51]; p<0.0001); OS (HR [95% CI]: 0.53 (0.39, 0.72); p=0.0009). **CONCLUSIONS:** In this ITC, T-DM1 was associated with longer OS and PFS versus capecitabine+trastuzumab and capecitabine monotherapy in patients with HER2-positive LABC or MBC with disease progression after treatment with trastuzumab+taxane.

PCN22

SECOND-LINE TREATMENT OF METASTATIC COLORECTAL CANCER (MCRC): A SYSTEMATIC LITERATURE REVIEW (SLR) AND FEASIBILITY ASSESSMENT OF CONDUCTING INDIRECT TREATMENT COMPARISON (ITC) ANALYSIS

Xu Y[1], Martin AL[1], Ross S[2], Knopf KB[3], Strand L[1], Iqbal SU[4], Joulain F[5], Jasso Mosqueda JG[6], Fahrbach K[1]

[1]*Evidera, Lexington, MA, USA,* [2]*SDRoss Consulting, Cohasset, MA, USA,* [3]*Pacific Hematology Oncology Associates, San Francisco, CA, USA,* [4]*Sanofi, Cambridge, MA, USA,* [5]*Sanofi, Chilly-Mazarin, France,* [6]*Sanofi, CHILLY-MAZARIN Cedex, France*

OBJECTIVES: To investigate the efficacy and safety of second-line chemotherapy in mCRC and to determine the feasibility of relative efficacy between treatments using indirect or mixed treatment comparisons. **METHODS:** An SLR on randomized trials published from 1992–2012 was performed. EMBASE, PubMed, CENTRAL databases were consulted. Manual searches (including ASCO and ESMO abstracts) were also conducted. Eligible studies evaluated second-line clinical efficacy and safety endpoints in mCRC. **RESULTS:** Twenty-seven trials with patients enrolled ranging from n=33–1,226 were identified. Patients were markedly diverse in terms of ECOG, EGFR, or *KRAS* status, and prior treatment exposures: oxaliplatin (k=9), irinotecan +/- 5-FU (k=5), bevacizumab (k=7), and 5-FU (k=22). On-study treatments and comparators were also diverse: FOLFIRI alone (t=6) or with panitumumab (t=2) or aflibercept (t=1); FOLFOX4 alone (t=6) or with bevacizumab (t=1); bevacizumab alone (t=1) or with chemotherapy (t=2); irinotecan alone (t=19) or with FOLFOX4 (t=2) or cetuximab (t=1); and miscellaneous other regimens (t=19). Study methodologies varied in analysis populations (ITT [k=24] vs. per protocol or not reported [k=3]), primary efficacy outcomes (OS, PFS, and/or tumor response, as variably measured), follow-up durations, and timing of outcomes measurements. Preliminary network diagrams to assess feasibility of meta-analyses for ITC revealed only a single study for each treatment comparison of interest. Assumptions of comparability of apparently diverse patients, past and current treatment regimens, and comparator arms would be necessary to pool treatment groups for meta-analysis of treatment effectiveness across studies and hence, is not feasible. Given the lack of SOC treatments used in many trials, introducing such assumptions will compromise the evidence-based criteria for quantitative clinical data syntheses for indirect or mixed treatment

comparisons. **CONCLUSIONS:** Current standards around second-line treatment of mCRC have evolved over time. The substantial clinical, methodological, and statistical heterogeneity in the available data prevents evidence-based quantitative comparisons of treatment outcomes at this time.

PCN23

COMPARISON BETWEEN EVEROLIMUS (AFINITOR®) AND CHEMOTHERAPY AGENTS (CAPECITABINE, DOCETAXEL AND DOXORUBICIN) FOR THE TREATMENT OF HORMONE RECEPTOR POSITIVE (HR+) HER2 NEGATIVE (HER2–) ADVANCED OR METASTATIC BREAST CANCER

Vieira J[1], Chandiwana D[1], Taylor M[2], Lewis L[3]
[1]*Novartis Pharmaceuticals UK Limited, GB- Frimley/Camberley, UK,* [2]*York Health Economics Consortium, York, UK,* [3]*York Health Economics Consortium, University of York, York, UK*

OBJECTIVES: This study compares everolimus (EVE) versus the most commonly used chemotherapy agents in UK clinical practice (capecitabine [CAPE], docetaxel [DOC] and doxorubicin [DOX]) in patients with hormone receptor positive, HER2 negative advanced or metastatic breast cancer with the purpose of determining the effect of everolimus versus chemotherapy through the derivation of hazard ratios (HR). **METHODS:** A systematic review of the literature was performed to find evidence that could link EVE with chemotherapy (CAPE, DOC and DOX) in terms of progression-free survival (PFS) and overall survival (OS). No head-to-head trials comparing EVE versus chemotherapy were found, the only study that linked hormonal therapy with chemotherapy for treatment of metastatic breast cancer was Wilcken *et al.* (2003). Wilcken *et al.* identified three studies which compared OS for tamoxifen versus chemotherapy. None of the studies identified in the systematic review reported PFS. The link between EVE versus chemotherapy through Wilcken *et al.*(2003) was established via tamoxifen (using Bucher methods), so it was assumed that PFS for chemotherapy would be the same as PFS for everolimus versus tamoxifen (TAM) from the TAMRAD trial. **RESULTS:** HR for everolimus versus tamoxifen for PFS from the TAMRAD trial is 0.54. For OS, Wilcken et al. derived a HR for chemotherapy versus tamoxifen of 0.94. To calculate the HR for OS for everolimus vs tamoxifen the inverse was applied to the OS HR from the TAMRAD trial (0.45), hence (1/0.45)=2.22. The HR for OS for everolimus versus chemotherapy is therefore (0.94x2.22)=2.09. Because a class effect was assumed for the three chemotherapy agents, these HRs were applied to capecitabine, docetaxel and doxorubicin equally. **CONCLUSIONS:** Compared with the most commonly used chemotherapy agents in UK clinical practice (CAPE, DOC and DOX), everolimus has a lower risk of death as demonstrated by the HRs derived.

PCN24

TREATMENTS FOR EGFR MUTATION POSITIVE NSCLC – A NETWORK META-ANALYSIS

Fonseca T[1], Lungershausen J[2], Wallenstein G[3], Stammberger U[3], Bertwistle D[1], Griebsch I[2]
[1]*IMS Health, London, UK,* [2]*Boehringer Ingelheim Pharma GmbH, Ingelheim am Rhein, Germany,* [3]*Boehringer Ingelheim Pharma GmbH & Co.KG, Ingelheim, Germany*

OBJECTIVES: Lung cancer is the most common cause of cancer-related deaths world-wide. Afatinib is a novel, potent, irreversible ErbB family blocker. In EGFR mutation-positive locally advanced and metastatic non-small cell lung cancer, afatinib shows superior effectiveness as a 1st-line treatment compared to standard-of-care chemotherapy. To date, no head-to-head trial results exist to compare the efficacy of afatinib to reversible EGFR TKIs, gefitinib or erlotinib. The analyses presented here attempt to fill this gap by means of a network meta-analysis (NMA). **METHODS:** A systematic literature review (2002-2012) identified the best available evidence. Results from afatinib's pivotal trials (LUX-Lung 3, LUX-Lung 6) were added. A NMA following a Bayesian approach (in WinBUGS) was applied to estimate the relative treatment effects between afatinib, gefitinib and erlotinib. Outcomes of interest were progression free survival (PFS) and overall survival (OS). For PFS, results by investigator review were considered as not in all trials PFS was assessed independently. Versus erlotinib, afatinib's results in the two most common EGFR mutations studied in erlotinib trials were considered. Sensitivity analyses were performed to confirm the robustness of results. **RESULTS:** Twenty studies, including LUX-Lung 3 and LUX-Lung 6, were included; 19 reported OS, 14 reported PFS. Results from random effects models are reported. All comparisons versus reversible TKIs favoured afatinib, although in most analyses the upper credible interval limit exceeded 1. The estimated probability of afatinib being best regarding PFS in all mutations was 80% compared to 17% for erlotinib and 3% for gefitinib, and was 43% regarding OS compared to 13% for gefitinib and 3% for erlotinib. **CONCLUSIONS:** Afatinib consistently showed superior efficacy versus chemotherapy in the pivotal trials. In the absence of head-to-head trial results versus reversible TKIs, the NMA results suggest also potential superiority of afatinib for both PFS and OS when compared to erlotinib and gefitinib.

PCN25

QUALITY INDICATORS OF THE FOURTH SCREENING ROUND (2008-2009) OF THE HUNGARIAN ORGANIZED, NATIONWIDE BREAST CANCER SCREENING PROGRAMME

Boncz I[1], Dobrossy L[2], Péntek Z[3], Kovács A[2], Budai A[2], Vajda R[1], Sebestyén A[4]
[1]*University of Pécs, Pécs, Hungary,* [2]*National Public Health and Medical Officers Service (ÁNTSZ), Budapest, Hungary,* [3]*MaMMa Healthcare Ltd., Budapest, Hungary,* [4]*National Health Insurance Fund Administration, Pécs, Hungary*

OBJECTIVES: Organized, nationwide screening for breast cancer with mammography started in Hungary in January 2002. Women in the age group 45-65 years are the target population and 2 years screening interval is applied. The aim of this study is to evaluate the quality indicators of the 4th screening round (2008-2009). **METHODS:** The data derive from the financial database of the National Health Insurance Fund Administration (NHIFA) covering the period of 2008-2009. We calculated the following indicators: recall rate of women who underwent mammography examinations, attendance of re-called women, proportion of women referred to surgery, proportion of women who underwent surgery compared to referred women, proportion of benign and malignant cases. **RESULTS:** In 2008-2009 there were 477904 screening mammography examinations in Hungary. 5.15 % of participating women were re-called. The attendance of re-called women was 92.25 %. Altogether 2092 women (9.7 %) were referred for breast surgery but only 1485 women (71.0 %) underwent surgery. Histological examination confirmed 281 benign (18.9 %) and 1204 malignant (81.1 %) cases. **CONCLUSIONS:** The quality indicators of the Hungarian organized mammography screening program met the recommendations of international professional guidelines. However, in addition to current indicators, new ones should be introduced in order to provide a more comprehensive monitoring of the program.

PCN26

THE ATTENDANCE OF THE FOURTH SCREENING ROUND (2008-2009) OF THE HUNGARIAN ORGANIZED, NATIONWIDE BREAST CANCER SCREENING PROGRAM

Boncz I[1], Dobrossy L[2], Péntek Z[3], Kovács A[2], Budai A[2], Vajda R[1], Sebestyén A[4]
[1]*University of Pécs, Pécs, Hungary,* [2]*National Public Health and Medical Officers Service (ÁNTSZ), Budapest, Hungary,* [3]*MaMMa Healthcare Ltd., Budapest, Hungary,* [4]*National Health Insurance Fund Administration, Pécs, Hungary*

OBJECTIVES: Organized, nationwide screening for breast cancer with mammography started in Hungary in January 2002. Women in the age group 45-65 years are the target population and 2 years screening interval is applied. The aim of this study is to analyze the attendance rate of the 4th screening round (2008-2009). **METHODS:** The data derive from the financial database of the National Health Insurance Fund Administration (NHIFA) covering the period of 2008-2009. We calculated two attendance indicators. The up-take of the program means the percentage of women aged 45-65 who, having been sent an invitation for screening, attend a screening unit and undergo mammography in response to that invitation. We defined coverage as the ratio of women in the age group 45-65 years having either a screening mammography or a diagnostic mammography. **RESULTS:** In 2008-2009 there were 477904 screening mammography cases and 1204893 diagnostic mammography examinations in Hungary. We found 49.4 % and 41.5 % up-take in 2008 and 2009 respectively; and 45.0 % combined rate for 2008/2009. The screening coverage was 31.2 % and the diagnostic coverage was 20.4 %, while the total coverage (screening and diagnostic) was 50.1 %. **CONCLUSIONS:** The attendance of the Hungarian organized breast cancer screening program – compared to the previous period before the implementation of the organized screening program – is promising, although to achieve the expected results in mortality decrease a further improvement of both the uptake and coverage is necessary.

PCN27

RACIAL DISPARITIES IN DIFFUSION, COMPARATIVE MORBIDITY, AND DISEASE CONTROL OF INTENSITY-MODULATED RADIATION THERAPY COMPARED TO CONFORMAL RADIATION THERAPY FOR LOCALIZED PROSTATE CANCER

Cobran EK[1], Overman R[2], Carpenter WR[3], Godley PA[4], Chen R[5]
[1]*University of North Carolina at Chapel Hill, Gillings School of Global Public Health and School of Medicine, UNC Lineberger Comprehensive Cancer Center, Chapel Hill, NC, USA,* [2]*University of North Carolina at Chapel Hill, Eshelman School of Pharmacy, Division of Pharmaceutical Outcomes and Policy, Chapel Hill, NC, USA,* [3]*University of North Carolina at Chapel Hill, Gillings School of Global Public Health Department of Health Policy and Management, Chapel Hill, NC, USA,* [4]*University of North Carolina at Chapel Hill, School of Medicine, Division of Hematology/Oncology, Chapel Hill, NC, USA,* [5]*University of North Carolina at Chapel Hill, School of Medicine, Department of Radiation Oncology and Urology, Chapel Hill, NC, USA*

OBJECTIVES: Recent advances in prostate cancer radiation therapy (RT) technology have led to the development of costlier treatments such as intensity-modulated radiation therapy (IMRT) compared to the prior standard, conventional radiation therapy (CRT). This study examines the two treatment modalities to determine if racial disparities in morbidity and disease control may be explained by differential use of IMRT versus CRT. **METHODS:** A population-based study was conducted using Surveillance, Epidemiology, and End Results (SEER)-Medicare linked data from 2000 through 2009 for patients with non-metastatic prostate cancer. Adjusted Cox Proportional Hazards models were conducted, adjusting for demographic and clinical characteristics. Results are presented as (Adjusted Hazard Ratio [95% Confidence Interval]). In subjects without prior morbidity at RT, the rate of recurrence, hip fracture, erectile dysfunction, disorders related to gastrointestinal, and urinary (incontinence and non-incontinence) morbidity were compared by race with IMRT as the referent group. **RESULTS:** Approximately 10,976 men [524 African-American (AA) CRT; 423 AA IMRT; 4,746 Caucasian CRT; 5,283 Caucasian IMRT] met study eligibility. Diffusion of IMRT was slower among AA compared to Caucasians ($p<0.001$). Caucasians receiving CRT were at a greater risk for hip fracture [1.29; (1.16, 1.43)], cancer recurrence [1.13; (1.04, 1.23)], or urinary incontinence [1.09; (1.01, 1.19)] than those receiving IMRT. No estimates comparing AA CRT recipients to AA IMRT recipients reached statistical significance, though cancer recurrence, erectile dysfunction, and gastrointestinal morbidity rates were greater for CRT subjects **CONCLUSIONS:** There were no statistically significant racial disparities in morbidity and disease control related to differential use of IMRT versus CRT. However, diffusion of IMRT was significantly slower among AA. Future research should include more years of follow-up data and a larger sample of AA in order to understand whether measured differences in treatment diffusion achieve clinical significance sufficient to explain a portion of the racial disparity in prostate cancer mortality.

PCN28

OFF-LABEL TRASTUZUMAB USAGE IN BREAST CANCER PATIENT IN TURKEY

Kockaya G[1], Tanyeri P[2], Buyukokuroglu ME[2], Yenilmez FB[3], Durmus D[4], Vural IM[4], Akbulat A[4], Artiran G[4], Gursoz H[4], Kerman S[4]
[1]*Health Economics and Policy Association, Ankara, Turkey,* [2]*Sakarya University, Sakarya, Turkey,* [3]*Hacettepe University, Ankara, Turkey,* [4]*Turkish Medicine and Medical Device Agency, Ankara, Turkey*

OBJECTIVES: Off-label use of medications is extremely common especially in oncology. The aim of this study is to help update the guidelines and determine pharmaceuticals and off-label indications in breast cancer. **METHODS:** This study involved patients (n=1317) with metastatic breast cancer with tumors that were defined as human epidermal growth factor receptor 2, ErbB-2 positive who received trastuzumab or other medicine application off-label usage in Turkey. During this period using trastuzumab was licenced only for 9 weeks, not for 52 weeks in Turkey. A computer search was performed using the TITCK's (Turkish Drug and Medical Devices Institution) database. The patient base was searched for off-label medicine applications between 1 June 2008 to 1 June 2010. **RESULTS:** The average age were 49.02 ± 10.46. Overall, 85 % of applications were approved in generally 8 or 9 weeks period. It was found that the Marmara Region had the highest application percentage (33.26 %) and then the Central Anatolia Region (27.9 %). Evaluated on the base of cities Istanbul, Ankara and Izmir had the most applications with 29.6 %, 19.2 % and 15.7 % respectively. University hospitals were created the most of the applications (81.1%), other applicaitons were from education & research hospitals (10.2 %) and private hospitals (5.9 %). Off-label drug usage in breast cancer medication, physicians were preferred trastuzumab, trastuzumab+vinoralbin and lapatinib. **CONCLUSIONS:** Trastuzumab had the highest percentage in all off-label medicine applications for breast cancer usage. On the other hand, 85 % of all trastuzumab off-label usage applications were approved. The reason of 15 % of trastuzumab applications is needed to be investigated further.

ASSESSMENT OF PATIENT POPULATION WITH NSCLC BY STAGE, ECOG-PS, EGFR MUTATION STATUS AND LINE OF THERAPY IN GERMANY

Schmidt U[1], Drechsler M[1], Assmann G[1], Kempel A[2]
[1]*Boehringer Ingelheim, Ingelheim, Germany,* [2]*Pharmametrics GmbH, Freiburg, Germany*

OBJECTIVES: To assess the patient population with advanced non-small cell lung cancer (NSCLC) with EGFR (epidermal growth factor receptor) positive mutation in Germany who are eligible for tyrosine-kinase inhibitor (TKI) therapy. An accurate assessment of the relevant patient population provides the basis for budget impact analyses in health technology assessments. **METHODS:** A systematic literature review was conducted. In addition, data from various cancer registries, cohort studies and surveillance studies were analyzed and compared with the findings in the literature. **RESULTS:** In a first step the proportion of patients with NSCLC was determined. Data was further differentiated by histologic subgroup (adenocarcinoma, large-cell carcinoma, squamous carcinoma and other carcinoma). The analysis revealed that the proportion of adenocarcinoma among the group of NSCLC has increased in Germany, especially among women from about 40% in 2000 to over 58% in 2009, in men from 28% to almost 40%, respectively. The proportion of patients with locally advanced or metastatic NSCLC (stage IIIb/IV) ranged between 51%-70%. The proportion of patients harbouring an EGFR mutation ranged between 5%-17%, differing by histologic subgroup, with the highest EGFR mutation rates (9%-26%) in patients with adenocarcinoma. The distribution of patients by ECOG (Eastern Cooperative Oncology Group) Performance Status (PS) showed that at diagnosis 63%-92% had an ECOG-PS 0-1. On average, first line therapy was received by over 80% of patients, while only 52%-65% underwent second line therapy and third line therapy was received by 15%-25% only. **CONCLUSIONS:** By analyzing all available data it is possible to provide good estimates of the relevant patient population. Although significant advances have been made in reporting and data collection for relevant patient subgroups related to NSCLC, there still is a large lack of representative data on a national level in Germany.

PCN30

ESTIMATING PREVALENCE OF PROSTATE CANCER CLINICAL STATES USING A DYNAMIC PATIENT PROGRESSION MODEL

Dass RN[1], Wheatley Price P[1], Goosey R[2], Spencer M[3], Prütz C[1], Ahlgren G[4], Berruti A[5], Ford D[6], Hamberg P[7], Klier J[8], Ribal MJ[9], Schrijvers D[10], Wolff JM[11], Durand A[1]
[1]*Janssen-Cilag Limited, High Wycombe, UK,* [2]*Kantar Health, Epsom, UK,* [3]*Janssen, High Wycombe, UK,* [4]*Skanes University Hospital, Malmö, Sweden,* [5]*University of Brescia, Brescia, Italy,* [6]*Queen Elizabeth Hospital Birmingham UK, Birmingham, UK,* [7]*Sint Franciscus Gasthuis & Prostate Cancer Center Rotterdam, Rotterdam, The Netherlands,* [8]*UPK (Urologische Partnerschaft Köln), Köln, Germany,* [9]*Hospital Clinic, University of Barcelona, Barcelona, Spain,* [10]*Ziekenhuisnetwerk Antwerpen-Middelheim, Antwerp, Belgium,* [11]*AKH Viersen, Viersen, Germany*

OBJECTIVES: Prostate cancer (PC) is the most common solid neoplasm in Europe. Accurate estimates of prevalence and patient flow through PC states are necessary to analyse disease burden and the health economic impact of novel therapies. This study presents a dynamic patient progression model (PM) estimating the population size of 13 PC clinical states across 8 European countries (EU8; Belgium, France, Germany, Italy, The Netherlands, Spain, Sweden, and UK). **METHODS:** A dynamic PM was developed using a 27-year time horizon to estimate the prevalence and progression of PC from diagnosis through possible death, using a sequence of 13 Markov clinical states (5 non-metastatic and 8 metastatic). Incidence data were taken from local country registries from 1993 to 2012, and a simple growth model was used to forecast incidence rates to 2020 and beyond. PM flow structure, probabilities of prevalence, progression, and mortality per clinical state were determined using a Delphi panel of PC experts from the EU8 countries and based on published literature and local research. **RESULTS:** A consensus of expert opinion was reached on the clinical states and flow rates of patients with PC in Europe. This resulted in a refined PM with new clinical states that represent the current treatment paradigm for PC. The PM also estimated growth in prevalence and mortality of future PC patient populations across 13 different clinical states of PC from 2012 to 2020. Five-year prevalence rates from the PM were in agreement with those from the GLOBOCAN 2008 project. **CONCLUSIONS:** The PM obtained by consensus of expert opinions provided patient prevalence and mortality estimates for 13 distinct PC clinical states. The PM and patient flow rates provide a representative simulation of the local environment, which can be used to assess PC disease burden, health economic impact, and cost of PC care in the EU.

PCN31

THERAPY SEQUENCES IN MULTIPLE MYELOMA – A CLINICAL MODEL STUDY IN REGARDS OF A GERMAN COST CONTEXT

Wirth D[1], Loellgen N[2], Knop S[3]
[1]*Janssen, Neuss, Germany,* [2]*Janssen-Cilag, Neuss, Germany,* [3]*Universitätsklinikum Würzburg, Würzburg, Germany*

OBJECTIVES: With a vast number of possible treatment options for Multiple Myeloma patients, it is unclear in which combination and sequencing compounds should be used to achieve prolonged overall survival. This question cannot be timely answered with an RCT, a health economic model (1) was used to approximate for OS and adopted for a German cost setting. **METHODS:** Using a combination of meta-analysis and -regression, the possible overall survival of different therapy sequences is approximated in a Markov model. Data source for this model is a systematic literature research covering 2008-2012, identifying a total of 68 studies and 11.115 patients in Multiple Myeloma. From each study treatment arm, response per therapy and therapy line was extracted. Subsequently, a regression analysis was used to specifically determine the "time to next treatment (TTNT)". TTNT is used in our model study to reflect the positive correlation of response to therapy and disease progression, which has shown to be highly related (2-5). Using TTNT, the model can now demonstrate which sequence of therapies in 1st, 2nd and 3rd line will total to a possible OS of a patient. **RESULTS:** We analyzed 13 sequences from over 200 theoretical combinations, based on their German approval. Early usage of new compounds results in a prolongation of overall survival of at least 6 months, compared to the standard therapy with melphalan/prednisone (6), with minimal possible OS between 3.98 and 5.06 years. Cost data from Germany were included to amount costs of therapy for a complete sequence. For the sequences presented, costs range between 69.000 and 135.000 €. The majority of those costs accrue from drugs, not from other resources. **CONCLUSIONS:** An important topic of modeling approaches is to show both internal and external validity, which is both needed to validate the prognoses. The external validation is currently undertaken using data from cancer registries and non-interventional studies.

PCN32

THE ESTIMATED SURVIVAL OF PATIENTS WITH DOUBLE REFRACTORY CHRONIC LYMPHOCYTIC LEUKAEMIA; A REANALYSIS OF NICE TA202 USING BAYESIAN METHODOLOGY TO MODEL OBSERVED DATA

Almond C[1], Stevens JW[2], Ren K[2], Batty A[1]
[1]*BresMed, Sheffield, UK,* [2]*University of Sheffield, Sheffield, UK*

OBJECTIVES: Standard therapy for chronic lymphocytic leukaemia (CLL) is fludarabine, followed by alemtuzumab. Patients resistant to both treatments (double refractory (DR)-CLL) receive best supportive care (BSC). Ofatumumab is licensed for the treatment of DR-CLL, but was not recommended by the National Institute for Health and Care Excellence (NICE technology appraisal 202 (TA202)). There is little clinical data for BSC in DR-CLL. TA202 identified a single-arm study of ofatumumab and an observational study of BSC. Survival for BSC in TA202 was modelled by fitting a Weibull distribution to data for ofatumumab non-responders. The effects of ofatumumab were estimated by assuming a proportional hazards model. The objective of this study was to investigate the potential sources of survival data for BSC, and the impact of the choice of survival distributions used in TA202 on the cost-effectiveness of ofatumumab. **METHODS:** Individual patient-level data was reconstructed from Kaplan-Meier curves using a published algorithm. Plausible survivor functions were fitted to the data using Markov chain Monte-Carlo simulation. Goodness-of-fit to the observed data was assessed using deviance information criterion and the clinical plausibility of extrapolations using subjective opinion. The cost-effectiveness model from TA202 was reproduced including alternative survival data. **RESULTS:** A Weibull distribution provided the best fit to the data and was most clinically plausible. If proportional hazards were assumed (as in TA202) the incremental cost-effectiveness ratio (ICER, incremental cost per life year gained) was £52,400, similar to £49,252 reported in TA202. Relaxing the assumption of proportional hazards increased the ICER to £85,618. **CONCLUSIONS:** The best fitting and most clinically plausible model was a Weibull distribution, giving results consistent with TA202; however both the use of a subgroup of a single arm trial and of data from multiple studies has a high level of uncertainty. Relaxing the assumption of proportional hazards increased the ICER.

PCN33

AFLIBERCEPT + FOLFIRI (AF) VERSUS. PLACEBO + FOLFIRI (PF) IN METASTATIC COLORECTAL CANCER (MCRC): MEAN OVERALL SURVIVAL (OS) IN A "BETTER RESPONDERS" PATIENT POPULATION OF THE VELOUR TRIAL

Joulain F[1], Naoshy S[2], Chau I[3], Iqbal SU[2], Bridgewater J[4]
[1]*Sanofi, Chilly-Mazarin, France,* [2]*Sanofi, Cambridge, MA, USA,* [3]*Royal Marsden Hospital, Sutton, Surrey, UK,* [4]*University College Hospital, London, UK*

OBJECTIVES: The VELOUR trial demonstrated significant survival benefit for aflibercept plus FOLFIRI (5-fluorouracil-leuocovorin-irinotecan) versus FOLFIRI alone in mCRC patients previously treated with oxaliplatin. Multivariate analysis identified a subset of "better responder" patients who derive sustained benefit with AF, which includes patients who did not experience an early relapse directly from adjuvant setting (10% of patients included in VELOUR) and with either ECOG PS0 or (PS1 and ≤1 metastatic site). Median OS was significantly improved in AF arm: 16.2 versus 13.1 months for PF (adjusted HR = 0.73 [95% CI: 0.61–0.86]). Mean survival estimation can render a more meaningful estimate for long-term benefit of interventions and can be effectively applied to clinical and economic decision support. Our objective was to derive mean OS for the "better responders" subgroup in VELOUR. **METHODS:** As survival probability at the end of the follow-up period was 21% in AF vs 8% in PF, mean OS was estimated by extrapolating the KM curve using a survival function over a 15-year period. Five standard parametric distributions were tested: exponential, Weibull, lognormal, loglogistic and Gompertz. Goodness-of-fit of distributions was evaluated by Akaike's Information Criteria (AIC), Bayesian Information Criteria (BIC) and graphical methods. **RESULTS:** Of the 1226 patients enrolled in VELOUR, 404

(66.0%) AF patients and 406 (66.1%) PF patients were classified in "better responders" subgroup. Lognormal and loglogistic distributions were the 2 distributions providing the best fit to the observed OS data, with very similar and good fit. Mean OS over 15-years using loglogistic distribution was 24.8 vs. 18.6 months for AF and PF, respectively. **CONCLUSIONS:** Post-hoc analysis suggested that the "better responders" subgroup of patients within VELOUR derived enhanced survival benefit with the AF combination. The results highlight the therapeutic benefit of AF in clinically relevant patient subpopulations.

PCN34
FACTORS DRIVING INEQUALITY IN PROSTATE CANCER SURVIVAL: A POPULATION BASED STUDY
Burns R[1], Sharp L[2], Sullivan FJ[3], Deady S[2], Drummond FJ[2], O'Neill C[1]
[1]NUI Galway, Galway, Ireland, [2]National Cancer Registry Ireland, Cork, Ireland, [3]Prostate Cancer Institutue, Galway, Ireland
OBJECTIVES: As cancer control strategies have become more successful, issues around survivorship have become increasingly important to researchers and policy makers. The aim of this study was to examine the role of a range of clinical and socio-demographic variables in explaining variations in survival after prostate cancer diagnosis, paying particular attention to the role of health care provider(s) (i.e. private vs. public) and socio-economic status. **METHODS:** Data were extracted from the National Cancer Registry Ireland, for patients diagnosed with prostate cancer from 1998-2009 (N=26,183). A series of multivariate Cox and logistic regression models were used to examine the role of health care provider and socio-economic status (area-based deprivation) on survival, controlling for age, stage, Gleason grade, marital status and region. Survival was based on all-cause mortality. **RESULTS:** Individuals who were treated in a private care setting were more likely to have survived than those who had not, when other factors were controlled for. A socio-economic gradient was evident with respect to marital status, region of residence, clinical stage and Gleason grade. The effect of socio-economic status was modified by health care provider, such that risk of death was higher in those of lower socio-economic status for men treated by public, but not private, providers. **CONCLUSIONS:** The role of health care provider (a proxy for voluntary private insurance) and socio-economic status in survival of men with prostate cancer may give rise to equity concerns regarding the operation of the Irish health care system and warrants further investigation.

PCN35
CONDITIONAL SURVIVAL (CS) PROBABILITIES FOR ADVANCED MELANOMA PATIENTS TREATED WITH IPILIMUMAB: MODEL BASED ANALYSIS
Lee D[1], Kotapati S[2], Gueron B[3], Bapat U[4], Batty AJ[1]
[1]BresMed, Sheffield, UK, [2]Bristol-Myers Squibb Pharmaceuticals, Wallingford, CT, USA, [3]Bristol-Myers Squibb, Rueil Malmaison, France, [4]Bristol-Myers Squibb Pharmaceuticals, Uxbridge, UK
OBJECTIVES: There are few treatments available for advanced melanoma and survival rates are low. While the incidence of the disease continues to rise, only two new treatments have come to the market recently: ipilimumab and vemurafenib. Ipilimumab is indicated in Europe for the treatment of advanced melanoma in adults who have received prior therapy. Ipilimumab has demonstrated a statistically significant improvement in overall survival in 2 Phase III RCTs. Prolonged survival (>2 years in some patients) has been shown (MDX020 & 024). **METHODS:** Data from the MDX010-20 trial, which was conducted in previously treated patients with a maximum follow up duration of 55 months, was used to develop an economic model for health technology assessment in England & Wales. This model has been used to predict the conditional survival (CS) of patients treated with ipilimumab (based on both ipilimumab containing arms) compared to gp100 – the active control. The model used patient level Kaplan–Meier data for the first 18 months, parametric curves fitted to the patient level data from 18 months to 5 years, and published AJCC registry data beyond 5 years. **RESULTS:** The curves were a good fit to the MDX010-20 trial data (MAE 0.003) and consistent with published Phase II data (which provides a longer time horizon). Given an ipilimumab patient has survived 2 years, the modelled probability of being alive at 5 years is 67% (49%,79%) (gp100: 15% [9%,21%]) and at 10 years is 54% (39%, 63%) (gp100: 2% [1%,3%]). **CONCLUSIONS:** The model shows that a substantial proportion of patients treated with ipilimumab surviving to 2 years are likely to have sustained survival benefits: more than 50% of ipilimumab patients surviving to 2 years are alive at 10 years, with 29% remaining alive at 20 years. This level of sustained survival is not shown by gp100 patients.

PCN36
ESTIMATING AND MODELING LONG TERM SURVIVAL IN LUNG CANCER USING MIXTURE PARAMETRIC MODELS
Sánchez L[1], Luaces P[1], Viada C[1], Galan Y[2], Ballesteros J[3], Rodríguez PC[1], Crombet T[1], Lage A[1]
[1]Center of Molecular Immunology, Havana, Cuba, [2]Cuban National Cancer Registry, Havana, Cuba, [3]University of the Basque Country UPV/EHU, Leioa, Spain
OBJECTIVES: To ascertain the existence of several populations regarding overall survival (OS) in patients with advanced non-small-cell lung cancer (NSCLC). **METHODS:** Data of OS from the Cuban National Cancer Registry (CNCR) and from Cuban multicentre trials of immunotherapy were analysed with a lognormal mixed model assuming 1 to 6 underlying populations. The Bayesian Information Criterion (BIC) was used to select the best model fitted to the data in all cases. **RESULTS:** The CNCR provided data for 31133 patients diagnosed with lung cancer since January 1998 until December 2008. Of those, 7286 patients presented stages IIIb-IV of NSCLC at diagnosis and were selected for analysis. The immunotherapy Cuban trials provided data for more than 750 patients enrolled in 8 trials conducted since 1997 until 2010. The mixed model applied to CNCR data separated 4 populations: very high risk (OS mean time = 0.62 months, 23% of the sample); high risk (OS mean time = 3.1 months, 34%); medium risk (OS mean time = 9.2 months, 35%); and low risk (OS mean time = 29.1 months, 8%). Results for clinical trials separated 2 populations for controls and 3 populations for the immunotherapy groups. For controls a population of medium risk (OS mean time = 11.6 months, 61%) and other of low risk were obtained (OS mean time = 31.7 months, 38%). For NSCLC patients with immunotherapy a population of medium risk (OS mean time = 11.2 months, 55%); a population of low risk (OS mean time = 23.8 months, 33%); and another of very low risk or long-term survival were obtained (OS mean time = 55.5 months, 12%). **CONCLUSIONS:** Our analyses support the existence of several populations regarding OS among advanced stage lung cancer.

PCN37
SURVIVAL ANALYSIS USED IN COMPANY SUBMISSIONS TO THE NATIONAL CENTRE FOR PHARMACOECONOMICS, IRELAND
McCullagh L, Barry M
National Centre for Pharmacoeconomics, Dublin, Ireland
OBJECTIVES: Many company submissions received by Health Technology Assessment (HTA) Agencies evaluate the cost effectiveness of interventions which impact on survival. An accurate estimate of the survival benefit is required to calculate a reliable estimate of cost effectiveness. Generally the relevant trial data is immature and must be extrapolated. Many extrapolation models are available. Model choice is critical; different models can lead to different cost effectiveness results. The objectives were to review the methods/justification of the survival analysis used in company submissions to the National Centre for Pharmacoeconomics (NCPE). A further aim was to develop NCPE Guidance for the future handling of survival analysis. **METHODS:** Relevant submissions to the NCPE (economic evaluations which had dealt with advanced and/or metastatic cancer) were reviewed to determine the methods/justification of the survival analysis used. **RESULTS:** Twelve submissions were evaluated. Appropriately, the mean overall survival (OS) had been estimated and used in eight cases (67%). Median OS estimates had been estimated/used in three (25%). It was unclear which measure had been used in the remaining submission. The submissions which had used mean OS estimates were further investigated. Parametric model-based extrapolation techniques had been used to calculate the mean estimates in all eight. The most popular parametric models were the Weibull (n=3) and the loglogistic (n=3). The methods used to fit the parametric models varied. Most commonly the model was fitted using individual patient-level data. Some justification for the choice of extrapolation technique was offered in five submissions; AIC +/or BIC were estimated in three and visual inspection was reported in two. **CONCLUSIONS:** Survival analysis has not been conducted appropriately in all HTAs. Justification of the choice of model is not always offered. Moving forward, NCPE Guidance is required to ensure that survival analysis using patient-level data is conducted appropriately. These will be presented.

CANCER – Cost Studies

PCN38
BUDGET IMPACT OF METASTATIC CASTRATE-RESISTANT PROSTATE CANCER (CRPC) TO GERMAN PAYERS
Jensen IS[1], Wu C[1], Cyr PL[1], White RE[2]
[1]PriceSpective LLC, Cambridge, MA, USA, [2]Teva, Inc, Horsham, PA, USA
OBJECTIVES: The 2010 Urological Association Guidelines for Management of Castrate-Resistant Prostate Cancer (CRPC) recommend docetaxel plus prednisone for first-line chemotherapy for symptomatic metastatic CRPC patients who have progressed from hormone therapy. Since 2010, several CRPC agents with better tolerability and longer survival have launched. These improved therapies are causing a shift in practice. The aim of our analysis was to 1) quantify the 3-year mCRPC budget impact for the German health system based on the practice shift, and 2) estimate the cost per additional month of progression-free survival (PFS). **METHODS:** A conceptual decision analytic model was developed for the German health system to estimate the impact on direct medical costs of a therapy shift in CRPC over three years. Guideline recommended regimens were represented in model with three lines of therapies: palliative, abiraterone, enzalutamide, docetaxel and cabazitaxel. Progression in therapy was measured as the duration of PFS. A targeted literature search identified US per-patient-per-month costs of docetaxel treated patients (hospitalization=€954, ambulatory=€765, ER=€32, MD=€318) and were adapted to the German health system by applying a published purchase price parity factor. Drug costs were based on Ex-factory pricing. Adverse event rates were used as a proxy to derive relative resource utilization of other treatments. Utilization of CRPC regimens was informed by interviews with EU opinion leaders. **RESULTS:** The shift in practice pattern is expected to increase the German health system's 3-year budget by €23 million. The additional cost/month of PFS is estimated to decrease by €99/month from €4,659 for current treatment mix to €4,560 for future treatment mix by year 3. **CONCLUSIONS:** From the German health system's perspective, a change in practice pattern will result in an increase in total budget of €23 million. The reduction in cost/month of PFS of €99/month indicates the shift in practice will use more efficient therapies.

PCN39
ECONOMIC IMPACT OF DENOSUMAB FOR SKELETAL RELATED EVENT PREVENTION IN PATIENTS WITH PROSTATE CANCER AND BONE METASTASIS FROM A UNITED STATE MANAGED CARE ORGANIZATION PERSPECTIVE
Arellano J[1], Cristino J[2], Chen K[3]
[1]Amgen Inc., Thousand Oaks, CA, USA, [2]Amgen (Europe) GmbH, Zug, Switzerland, [3]Amgen, Inc., Thousand Oaks, CA, USA
OBJECTIVES: To evaluate clinical and economic impact of increasing denosumab use compared to zoledronic acid (ZA) in PrCa patients with BM to a MCO. **METHODS:** An economic model was developed to estimate clinical and economic impact to a 1-million-member US MCO of introducing denosumab as bone targeting agent (BTA) for prevention of SREs in PrCa patients with BM. Total number of patients receiving BTA was estimated based on disease prevalence and treatment eligibility in this population. The real-world SRE rates in ZA-treated patients were derived from a large commercial database and used together with the trial-

based treatment effect for denosumab versus ZA to estimate the denosumab SRE rate. Total number of SREs, total SRE management medical cost, BTA drug cost, and total cost were calculated. The impact of denosumab per-member-per-month (PMPM) at increasing utilization rates was assessed by comparing to a scenario without denosumab, i.e., all patients received ZA and reported. Additionally, impact of annual increase in denosumab use was conducted. **RESULTS:** A total of 63 PrCa patients with BM received BTA. In the scenario where all eligible patients receiving ZA, an annual total number of SREs was 120. An annual denosumab use of 20%, 35% or 45% resulted in 4.2%, 7.4%, and 9.5% reduction in total SREs and 5.3%, 9.3%, and 11.9% reduction in medical costs of managing SREs, compared to all patients receiving ZA. The drug cost was partially offset by the reductions in the medical cost and the increase in total cost was minimal (1.2%-2.7%). The PMPM ranged $0.002-$0.005. Consecutive-year analysis showed $0.001 increase in PMPM with 10% denosumab utilization increase. **CONCLUSIONS:** Due to superior efficacy of denosumab versus ZA in SRE prevention in PrCa patients with BM, increased denosumab use results in medical cost reduction in a US MCO. Overall, denosumab provides additional clinical value with limited budget impact.

PCN40

BUDGET IMPACT ANALYSIS OF IPILIMUMAB FOR THE TREATMENT OF ADVANCED MELANOMA IN THE VENETO REGION, ITALY

Adami S[1], Aiello A[2], Palozzo AC[3], Magrì MR[2], Visentin E[2], Chiarion V[4], Michelon A[2], Alberti C[5], Maran PR[2], Saugo M[6], Scroccaro G[1]

[1]*Regione Veneto, Venezia, Italy,* [2]*UVEF Regional Drug Coordination Centre, Verona, Italy,* [3]*Venetian Oncology Institute, Padova, Italy,* [4]*Venetian Oncology Instituite, Padova, Italy,* [5]*Azienda Ospedaliero Universitaria di Verona, Verona, Italy,* [6]*Regione Veneto, Padova, Italy*

OBJECTIVES: Ipilimumab is the first drug to be licensed in Italy for the treatment of advanced melanoma in adults who have received prior therapy. This study aims to estimate the budget impact of ipilimumab in patients who live in the Veneto Region. **METHODS:** Our analysis was performed from the perspective of the Italian health care system. Two scenarios were analyzed: one with the optimization of vials and the other without. Only drug acquisition costs (measured in euro) were considered into the analysis. All costs were referred to year 2013. **RESULTS:** Based on the incidence and mortality rates of the last three years, a total of 80 adult patients were assumed to be elegible for the treatment in the Veneto Region. The cost per mg of ipilimumab was €53,70: one 10 ml vial contains 50 mg of ipilimumab and one 40 ml vial contains 200 mg of ipilimumab. The recommended induction regimen is 3 mg/kg administered intravenously every 3 weeks for a total of 4 doses. The costs per patient of one year's therapy with ipilimumab ranged from €45.108 with vial optimization (considering 4-5 patients infused at the same time - average weight 70 kg) to €53.700 without. The Veneto Region identified a single center for the preparation/administration of treatment to minimize drug waste and to reduce the yearly treatment cost per patient, with a saving of €8.592 per patient/year. Applied to whole elegible patients (average weight 70-75 kg), it allows to obtain savings up to €430.000-690.000 per year. **CONCLUSIONS:** High prices for new cancer drugs are a growing concern to payers, given the large number of cancer drugs in development and the limited health care resources. Vial optimization may be an useful strategy to decrease waste, maximizing the use of health care resources and ensuring that eligible patients are treated.

PCN41

ECONOMIC EVALUATION OF EPOETIN ALFA HEXAL (BINOCRIT) COMPARED TO DARBEPOETIN ALFA (ARANESP) IN THE TREATMENT OF CHEMOTHERAPY INDUCED ANEMIA (CIA) IN GERMANY

Turner M[1], Walsh K[1], Whitehouse J[2]

[1]*Sandoz Biopharmaceuticals, Holzkirchen, Germany,* [2]*GfK Bridgehead, Melton Mowbray, UK*

OBJECTIVES: To compare the budget requirements of utilizing epoetin alfa Hexal vs. darbepoetin alfa in the German health care system **METHODS:** Anemia is a common side effect observed in patients receiving myelosuppressive chemotherapy. The purpose of this pharmacoeconomic analysis was to evaluate the cost-effectiveness of the short-acting biosimilar ESAs epoetin-alfa Hexal (EA) 30,000 or 40,000 IU weekly (QW) versus long-acting erythropoiesis-stimulating agent (ESA) darbepoetin alfa (DA) 150 mcg weekly (QW) and 500 mcg once every 3 weeks (Q3W) for the treatment of CIA. A budget impact model was constructed employing a payer perspective, per patient plus 5 year time horizon. The treatment period considered was based on 12 weeks and was aligned with routine chemotherapy regimen administration. Model inputs included: medical treatment, outcomes, and health care service utilization from published clinical studies and summary of product characteristics recommendation. Effectiveness of therapeutic alternatives was determined by comparing hemoglobin maintenance rates. Initial treatment with biosimilar epoetin α 30,000 IU or 40,000 IU per week has been shown to produce a similar Hb response. Costs included only drug acquisition costs and reflect 2013 data. The analysis was performed from the perspective of the German health care system. **RESULTS:** The average expected pharmaceutical costs per patient were €4,843 for DA Q3W, €4,383 for DA QW and €2,944 for EA 30,000IU QW, €3,946 for EA 40,000IU QW. Cost-savings associated utilizing with utilizing Epoetin Alfa Hexal 30-40,000 are 11-49% to DA QW and were 23-64% relative to DA 3QW. **CONCLUSIONS:** In the treatment of CIA among cancer patients in Germany, epoetin alfa Hexal is projected to provide more efficient use of health care resources compared to alternative treatment strategies with darbepoetin alfa.

PCN42

A BUDGETARY IMPACT ANALYSIS MODEL FOR EVEROLIMUS IN THE TREATMENT OF ER+ HER2- METASTATIC BREAST CANCER IN ENGLAND AND WALES

Taylor M[1], Lewis L[2], Vieira J[3], Chandiwana D[3]

[1]*York Health Economics Consortium, York, UK,* [2]*York Health Economics Consortium, University of York, York, UK,* [3]*Novartis Pharmaceuticals UK Limited, GB- Frimley/Camberley, UK*

OBJECTIVES: Whilst the cost-effectiveness of everolimus + exemestane (EVE+EXE) versus placebo + exemestane (PBO+EXE) in patients with ER+ HER2- metastatic breast cancer has been demonstrated elsewhere, this is the first analysis to assess the implications for health spending at a population level. **METHODS:** The model uses a cumulative cohort approach, allowing incident patients to enter the model each year over a five-year period. The incident population was based on several factors: (i) the female population aged >15 years; (ii) the proportion of those women with advanced invasive breast cancer; (iii) the proportion who are post-menopausal; (iv) the proportion who are hormone receptor positive; (v) the proportion who are HER2-; (vi) the proportion with asymptomatic visceral disease, and (vii) the proportion for whom hormonal therapy is appropriate. Finally, the cohort was filtered to show those who had previously relapsed or progressed on NSAI. 'Per patient' treatment and adverse event costs were generated based on treatment-specific progression-free survival curves, and multiplied by the number of patients expected to receive each treatment according to market share data and likely uptake rates. An incremental analysis was performed, where two scenarios were compared: (i) a world without EVE+EXE, and (ii) a world with EVE+EXE. **RESULTS:** It is expected that a total of 1,052 patients will be eligible to receive EVE+EXE over a five-year period. In a 'world without EVE+EXE', the total five year cost was estimated as £1,652,904. Assuming an annual uptake rate of 10%, in a 'world with EVE+EXE' the total cost over the same period was expected to be £2,271,606. Therefore, the incremental cost associated with the introduction of EVE+EXE in England and Wales is £618,702 over five years. **CONCLUSIONS:** EVE+EXE was associated with modest increased health care costs but has, separately, been demonstrated to lead to incremental health benefits compared with other treatments.

PCN43

INCORPORATING STAKEHOLDER INPUT INTO BUDGET IMPACT MODELS TO COMPARE STEM CELL MOBILIZATION STRATEGIES

Jensen IS[1], Halbert RJ[2], Grosvenor A[3], Schwartz EL[4], Rossi DG[5], Naoshy S[6], Iqbal SU[6], Xiao Z[6], McSweeney PA[7]

[1]*PriceSpective LLC, Cambridge, MA, USA,* [2]*ICON, PriceSpective LLC, El Segundo, CA, USA,* [3]*PriceSpective, London, UK,* [4]*PriceSpective LLC, San Diego, CA, USA,* [5]*Medica Spedali Civili, Brescia, Italy,* [6]*Sanofi, Cambridge, MA, USA,* [7]*Colorado Blood Cancer Institute (CBCI) and The Rocky Mountain Blood and Marrow Transplant Program, Denver, CO, USA*

OBJECTIVES: There is a dearth of published health economic evidence on stem cell (SC) mobilization that can be leveraged effectively for transplant center decision making. Our objective was to develop representative budget impact models (BIM) for key decision makers to estimate the total financial impact of adopting plerixafor for SC mobilization patients undergoing autologous peripheral stem cell transplantation (ASCT) for multiple myeloma and lymphoma. The BIMs were developed for EU5 (France, Germany, Italy, Spain, UK) and United States (US). **METHODS:** Prior to BIM development, in-depth interviews were conducted in EU5 (n=33) and US (n=20), to determine the most influential decison maker(s) for choosing a mobilization regimen. The choice of inputs and outputs that are critical for the adoption of plerixafor at the hospital level, were determined. Additionally, the BIM was developed using inputs from published literature and market research. **RESULTS:** Primary research revealed that the center director and treating physician are the most influential decision makers, while hospital administrators, transplant coordinators, pharmacy directors, and apheresis directors have a more limited role. There was consensus on inputs critical for assessment: clinical (drug/regimen utilization, apheresis days, and success/failure rates) and economic (mobilization costs; drug costs; apheresis cost and hospitalization costs). Model outputs include: first mobilization success and total mobilization budget impact. Interviews with clinical experts, and primary literature review determined that the relevant mobilization regimen comparators for the models are Granulocyte-Colony Stimulating Factor (G-CSF) alone, G-CSF and plerixafor, G-CSF and chemotherapy mobilization with cyclophosphamide and the triple regimen G-CSF, chemotherapy mobilization and plerixafor. **CONCLUSIONS:** Conducting primary interviews with key stakeholders and using the latest clinical practice information for critical inputs/outputs is essential for developing a representative model that is applicable to decison makers.

BREAST CANCER SCREENING PROGRAM IN THE BASQUE COUNTRY: COSTS AND HEALTH BENEFITS ASSESSMENT THROUGH DISCRETE EVENT SIMULATION

Arrospide A[1], Mar J[1], Comas M[2], Rue M[3], Larrañaga N[4], Acaiturri T[5], Sarriugarte G[6]

[1]*Hospital Alto Deba, Mondragon, Spain,* [2]*IMIM- Institut de Recerca Hospital del Mar, Barcelona, Spain,* [3]*Biomedical Research Institute of Lleida (IRBLLEIDA), University of Lleida. Red de Investigación en Servicios de Salud en Enfermedades Crónicas (REDISSEC), Lleida, Spain,* [4]*Basque Government, Donostia, Spain,* [5]*Hospital de Cruces, Barakaldo, Spain,* [6]*Direccion Territorial de Sanidad de Bizkaia, Bilbao, Spain*

OBJECTIVES: In the Basque Country (Spain), mammographies have been done in biennial basis to women in their fifties and sixties since 1996. The main objective of this project was the evaluation of the impact of the Screening program in terms of costs and health in the Basque women population since 1996. **METHODS:** A discrete event simulation model was built to represent the natural history of breast cancer in women invited to the breast cancer screening program in the Basque Country. The disease progress was described in three main states (healthy, preclinical and clinical) in the model. We assumed all women would be diagnosed at the beginning of the clinical stage unless it had been diagnosed previously through the screening program. The data collected among the 15 years when the screening program was held allowed model's validation. In order to compare the economic impact of these scenarios mammography and treatment costs – depending on the diseasestage at diagnosis – were included. The health impact assessment was based on quality adjusted life expectancy of cancer patients. **RESULTS:** Since the screening program started working, 8,925 cancers were detected among 313,475 women who attended the screening which represents the 76% of the invited ones. 60% of the diagnosed cancers were detected through the screening program. All the mammographies carried out during the evaluated years costed 46 million Euros. Each cancer detected in the screened scenario costs 29,581.06€, in the

background scenario the cost was 29,639.22€. In terms of total costs the background scenario had a lower cost on average until the year 2009. **CONCLUSIONS:** Early detection of breast cancer improves survival prognosis and decreases treatment costs for each detected cancer. In the future, the costs of the early detection program will be balanced by the savings in treatment costs.

PCN45

ESTIMATING THE BUDGET IMPLICATIONS OF RADIUM RA 223 DICHLORIDE IN CASTRATION-RESISTANT PROSTATE CANCER PATIENTS WITH NON-VISCERAL BONE METASTASES TREATED IN INFUSION CENTERS IN THE UNITED STATES

Hansen RN[1], Seal B[2], Wen L[2], Valderrama A[3], Sullivan SD[4]
[1]*University of Washington, Pharmaceutical Outcomes Research and Policy Program, Seattle, WA, USA,* [2]*Bayer HealthCare Pharmaceuticals, Inc., Pine Brook, NJ, USA,* [3]*Bayer, Cedar Grove, NJ, USA,* [4]*School of Pharmacy, University of Washington, Seattle , WA, USA*

OBJECTIVES: Metastatic prostate cancer (MPC) results from the spread of cancer to distant parts of the body and is associated with markedly decreased survival. First line therapy for prostate cancer involves androgen deprivation, however most MPC patients progress in spite of castration levels of testosterone. A recently approved infusion product, Radium Ra 223 dichloride (Radium-223), has been introduced in the U.S. market adding to concerns about the costs for end-stage treatments. We sought to estimate the budget impact of Radium-223 on infusion center expenses in the U.S. **METHODS:** We developed a financial model to estimate budget impact from a hospital-based infusion center perspective. Using data from the U.S. Census, SEER, and the Premier Perspective Database, we estimated the eligible population using a theoretical hospital's catchment area. We modeled use, treatment costs and reimbursement for three radiopharmaceuticals (Radium-223, Samarium-153, and Strontium-89) and two common chemotherapies (docetaxel and cabazitazel) in terms of drug cost, infusions, and laboratory monitoring. Reimbursement for these treatments was estimated at both commercial and Medicare rates using the Average Sale Price and relevant Common Procedural Technology codes. We calculated total cost and reimbursement for one year with the current utilization from Premier and then estimated the incremental net budget impact associated with adoption of Radium-223 at 1, 3, and 5% of patients. **RESULTS:** In a catchment area of 1 million lives, an estimated 45 MPC patients with non-visceral bone metastases would be treated with current agents and incur approximately $500,000 in treatment costs for radiopharmaceuticals and chemotherapy. Adding Radium-223 to the treatment mix and assuming adoption rates of 1% to 5%, the annual net impact on the infusion center budget would range from $600 to $3,000. **CONCLUSIONS:** Radium-223 presents a new treatment option for MPC patients with non-visceral bone metastases and a positive net impact for infusion centers.

PCN46

ESTIMATING THE BUDGET IMPACT OF ADDING AVASTIN (BEVACIZUMAB) TO FRONT LINE TREATMENT FOR ADVANCED OVARIAN CANCER IN BRAZILIAN SUPPLEMENTARY HEALTH CARE SYSTEM

Tsuchiya CT, Buschinelli CT, Maximo MFM, Tobaruella FS, Gonçalves TM
Roche Brazil, São Paulo, Brazil

OBJECTIVES: Ovarian cancer (OC) is one of the most lethal gynecologic cancers worldwide. According to Brazilian Institute of Cancer (INCA), 6,190 new OC cases were estimated in 2012. During the last 15 years, carboplatin plus paclitaxel (CP) has been established as front-line (FL) standard of care therapy for advanced ovarian cancer, with no significant advances in treatment ever since. Bevacizumab (Bev) in combination with CP was approved in Brazil for FL treatment of advanced epithelial OC on May/2013. Therefore, this study aimed to estimate the economic impact of bevacizumab reimbursement for advanced OC in Brazilian Supplementary Healthcare System. **METHODS:** The potential number of eligible patients for CP + Bev in FL therapy for advanced OC was estimated following an epidemiologic approach. It was assumed that Supplementary Healthcare System attendance accounts for 40% of all patients. Additional drug costs and infusion fees were evaluated. The ex-factory price (VAT 18%) and labeled dose were considered. Average therapy duration of CP + bevacizumab was 15 months based on GOG-0218 trial. Costs were reported in Brazilian Reais (BRL1.00≈USD0.44; Jun/2013). A total health assistance budget of BRL 88.1 billion was forecasted for 2013, based on the last updated data from Brazilian National Regulatory Agency for Private Health Insurance and Plans (ANS). **RESULTS:** A total of 1,287 eligible cases in CP + Bev FL therapy for advanced OC are expected in 2013 in the private setting. Adding bevacizumab to the treatment of all these potential patients would yield an increase of BRL 267 million, corresponding only to an increment around 0.30% on health assistance expenses. **CONCLUSIONS:** Treating all eligible FL advanced OC patients with CP + Bev will potentially result in a low impact in Supplementary Healthcare System budget, associated to unprecedented clinical benefits for this population with a high medical unmet need.

PCN47

THE FRENCH PUBLIC HEALTH CARE SYSTEM: AN ORIGINAL WAY FOR COST SAVING

Karouby D[1], Bocquet F[2], Chevalier D[3], Paubel P[4]
[1]*CHRU STRASBOURG, Strasbourg, France,* [2]*Agence Générale des Produits de Santé, Paris, France,* [3]*Groupe Hospitalier Paris Saint Joseph, Paris, France,* [4]*Paris Descartes University, Paris, France*

OBJECTIVES: The patent expiries of leading biologic products and development of biosimilars create opportunities for cost saving. The french public health policies has established a complementary means encouraging heathcare facilities (HF) to save money : the "écart médicament indemnisable" (EMI). We explored the evaluation of EMI on the erythropoietic factors class. **METHODS:** We've carried out a comparative study in french HF, representing about 65% of national hospital beds, on the price of erythropoietic factors. The data have been collected on procurement procedures operative as at January 1, 2012. **RESULTS:** A total of 25 care facilities or group of care facilities agreed to participate in the study. The overall sales turnover reached 15 millions euros (M€). All HF granted a discount from 5% to 69% on the prices fixed by negociation between the Comité Economique des Produits de Santé and the manufacturers. The average discount ranges from 11% to 73%. The average EMI varies between 1.42 and 2.69 € excluding value added tax (EVAT) per 1000 international units and between 0.09 and 0.22 € EVAT per microgram according to the medicinal product. The average amount refunded to HF can be estimated at january 1, 2012 at 3.37 M€, or 22.6% of the total budget. We assessed annual prices trends based on starting dates of contract, and we could figure out EMI trends. According to the product, the EMI quickly decline, remain broadly stable or increase. **CONCLUSIONS:** Many of top-selling biologics are due to lose patent protection over the next years. The emergence of competition in pharmaceutical market contributes to better control expenditure in our health system. The great potential for cost savings concerning erythropoietic factors in our study could be investigated in other class of medicinal products.

PCN48

BUDGET IMPACT ANALYSIS OF FENTANYL BUCCAL TABLET FOR THE TREATMENT OF CANCER BREAKTROUGH PAIN

Darba J[1], Kaskens L[2], Sánchez-de la Rosa R[3]
[1]*Universitat de Barcelona, Barcelona, Spain,* [2]*BCN HEALTH, Barcelona, Spain,* [3]*TEVA Pharma, Madrid, Spain*

OBJECTIVES: To assess the economic impact of Fentanyl Buccal Tablet for the management of breakthrough cancer pain (BTcP) in Spain **METHODS:** A 4-year budget impact model was developed for the period 2012-2015 for patients with BTcP from the perspective of the Spanish National Health System. BTcP products included in this model were rapid onset opioids containing fentanyl products (buccal, sublingual, or nasal transmucosal). Prevalence data on cancer, BTcP, opioid use and number of BTcP episodes were obtained from literature. Input data on direct medical resources associated with opioid use and opioide-induced side effects (OISEs) were obtained by consulting experts in oncology from different Spanish hospitals. Resource utilisation included drugs, medical and emergency visits, other non-pharmacological treatments and the treatment of OISEs. Unit costs were obtained from literature and a 3% discount rate was applied to costs. Based on the unit costs for drugs and medical resources the annual BTcP treatment costs per patient associated with each product were determined, to estimate the overall budget impact based on the total treatment population and the percentage of drug utilisation associated with each product **RESULTS:** Patients treated with oral opioids for BTcP was estimated at 23,291 in 2012 with an increase up to 23,413 in 2015. The average annual budget savings with an increase of Fentanyl Buccal Tablet, Fentanyl Sublingual Tablet and Intranasal Fentanyl Spray and a decrease of Oral Transmucosal Fentanyl Citrate, was estimated at €2.6 million over the next four years **CONCLUSIONS:** The increase in the use of Fentanyl Buccal Tablet leads to overall savings in the budget impact for the Spanish NHS. Although the economic impact of BTcP treatment showed to increase over the next four years due to population growth the average annual cost per patient reduced with €29 by the increase in the use of Fentanyl Buccal Tablet.

PCN49

ECONOMIC IMPACT OF DENOSUMAB FOR SKELETAL RELATED EVENT PREVENTION IN PATIENTS WITH BREAST CANCER AND BONE METASTASIS FROM A UNITED STATE MANAGED CARE ORGANIZATION PERSPECTIVE

Chen K[1], Arellano J[2], Cristino J[3]
[1]*Amgen, Inc., Thousand Oaks, CA, USA,* [2]*Amgen Inc., Thousand Oaks, CA, USA,* [3]*Amgen (Europe) GmbH, Zug, Switzerland*

OBJECTIVES: To evaluate clinical and economic impact of increasing denosumab use compared to zoledronic acid (ZA) in BrCa patients with BM to a MCO. **METHODS:** An economic model was developed to estimate clinical and economic impact to a 1-million-member US MCO of introducing denosumab as bone-targeting agent (BTA) for prevention of SREs in BrCa patients with BM. Total number of patients receiving BTA was estimated based on disease prevalence and treatment eligibility in this population. The real-world SRE rates in ZA-treated patients were derived from a large commercial database and used together with the trial-based treatment effect for denosumab versus ZA to estimate the denosumab SRE rate. Total number of SREs, total SRE management medical cost, BTA drug cost, and total cost were calculated. The impact of denosumab per-member-per-month (PMPM) at increasing utilization rates was assessed by comparing to a scenario without denosumab, i.e., all patients received ZA. Additionally, impact of annual increase in denosumab use was conducted. **RESULTS:** A total of 122 BrCa patients with BM received BTA. In the scenario where all eligible patients receiving ZA, an annual total number of SREs was 155. An annual denosumab use of 20%, 35% or 45% resulted in 4.5%, 7.9%, and 10.2% reduction in total SREs and 5.7%, 10.1%, and 12.9% reduction in medical costs of managing SREs, compared to all patients receiving ZA. The drug cost was partially offset by the reductions in the medical cost and the increase in total cost was minimal (2.4%-5.5%). The PMPM ranged $0.008-$0.017. Consecutive-year analysis showed $0.004 increase in PMPM with 10% denosumab utilization increase. **CONCLUSIONS:** Due to superior efficacy of denosumab versus ZA in SRE prevention in BrCa patients with BM, increased denosumab use results in medical cost reduction in a US MCO. Overall, denosumab provides additional clinical value with limited budget impact.

PCN50

POTENTIAL LONG-TERM COST SAVINGS DUE TO SIGNIFICANT CLINICAL BENEFIT OF OBINUTUZUMAB (GA101) IN COMBINATION WITH CHLORAMBUCIL IN PREVIOUSLY UNTREATED CHRONIC LYMPHOCYTIC LEUKEMIA

Walzer S[1], Tournier C[2], Marino JP[3], Mueller E[4], Duong M[3]
[1]*MArS Market Access & Pricing Strategy UG (h.b.), Weil am Rhein, Germany,* [2]*F. Hoffmann-La Roche, Basel, Switzerland,* [3]*Hoffmann-La Roche Limited, Mississauga, ON, Canada,* [4]*Analytica LA-SER International Inc., Loerrach, Germany*

OBJECTIVES: Obinutuzumab is the first, glycoengineered type II antibody demonstrating increased Antibody-Dependent Cell-Mediated Cytotoxicity (ADCC) and

direct cell death compared with rituximab (Rtx) and is pending regulatory approval (in combination with chlorambucil (Clb)) for the treatment of patients with previously untreated chronic lymphocytic leukemia (CLL). Obinutuzumab+Clb has shown >85% reduction in the risk of progression, relapse or death in comparison to treatment with Clb alone (HR 0.14), a broadly accepted treatment option for many patients with co-existing medical conditions. In a majority of markets the health economic consequences will be assessed in terms of affordability. **METHODS:** A health economic model was developed analyzing the cost impact of obinutuzumab on further lines of treatment due to the number of reduced refractory patients compared to Clb and Rtx. Market share information for obinutuzumab, ofatumumab, Rtx, Clb and Bendamustine and the different relevant combinations were entered for Germany and Canada (Ontario province only). **RESULTS:** Based on a 39% reduction in numbers of refractory patients treated with obinutuzumab+Clb compared to Rtx+Clb cost savings per year per patient (PYPP) for further line treatments in Canada (Ontario) range between Ca$950 and Ca$3,091, which leads to maximum cost savings for the whole eligible population (401 patients) up to $Ca1,239,491. In Germany the cost savings range PYPP between €2,556 and €8,318, which leads to maximum cost savings for the whole eligible population (1,302 patients) up to €10,830,036. The big difference in the cost savings PYPP between the two countries is mainly due to the different market share assumptions for ofatumumab. Key cost drivers were treatment duration and price/cost of further line treatments. Scenario analyses on cost, efficacy and market share data confirmed these findings. **CONCLUSIONS:** Obinutuzumab+Clb shows significant patient-relevant clinical benefits and potential cost savings in further line treatments in patients with previously untreated CLL.

PCN51

PHARMACOECONOMIC ASPECTS OF CHRONIC PAIN MANAGEMENT IN RUSSIAN CANCER PATIENTS

Ryazhenov VV[1], Gorokhova SG[1], Emchenko IV[1], Matveev NV[2]
[1]*I.M. Sechenov First Moscow State Medical University, Moscow, Russia,* [2]*N.I. Pirogov Russian National Research Medical University, Moscow, Russia*

OBJECTIVES: To assess the cost-effectiveness of the new transdermal therapeutic system (TTS) of fentanyl and subcutaneous injections (SIs) of morphine hydrochloride in the treatment of chronic pain and predict potential budget impact of the implementation of fentanyl TTS in routine clinical practice. **METHODS:** The pharmacoeconomic model was developed based on the results of Russian observational study, included 45 patients with terminal cancer: 25 patients received fentanyl TTS and 20 – SIs of morphine. At the first stage, the cost-effectiveness ratios (CERs) of therapies during the first month was measured as total costs of medicines and expenses for ambulance services for acute pain relief per one patient without side-effects. At the second stage, the CERs of therapies during subsequent three months was measured as costs of medicines per one unit of pain intensity (PI) reduction (visual pain scale). **RESULTS:** During the first month of therapy the frequency of ambulance use was significantly lower in patients received fentanyl TTS (0.32 vs 1.05 per one patient per week in the morphine group), this was reflected in lower total costs (12 611, 42 RUB and 23,037.54 RUB per one patient, respectively). Patients in the fentanyl TTS group were less likely to have side effects. The estimated CERs for fentanyl TTS and SIs of morphine were 13,001.46 RUB and 27,756.07 RUB per one patient without vomiting and 23,354.47 RUB and 82,276.93 RUB per one patient without constipation, respectively. Long-term treatment with fentanyl TTS was resulted in decreased PI as compared to SIs of morphine. The three-month CERs were 4,897.05 RUB and 7,869.30 RUB per one unit of PI reduction, respectively. **CONCLUSIONS:** The present study has demonstrated that administration of new transdermal therapeutic system of fentanyl has the better cost-effectiveness profile in the treatment of Russian cancer patients.

PCN52

BUDGET IMPACT OF LIPEGFILGRASTIM FOR THE MANAGEMENT OF CHEMOTHERAPY-INDUCED NEUTROPENIA

Montouchet C[1], Ruff L[1], Cerchiari A[2], Plich A[2]
[1]*Medaxial Group, London, UK,* [2]*Teva Pharmaceuticals Europe B.V, Utrecht, The Netherlands*

OBJECTIVES: Chemotherapy-induced neutropenia (CIN), a commonly-occurring adverse event in cancer patients undergoing chemotherapy, and particularly febrile neutropenia (FN), have potentially life-threatening and costly consequences. The standard of care for patients at risk of FN comprises prophylactic administration of recombinant granulocyte colony-stimulating factor (G-CSF) with pegfilgrastim, a long-acting formulation of G-CSF, and the most widely used in Europe. Lipegfilgrastim is a novel, pegylated and glycosylated long-acting G-CSF designed for use in the same patient population as pegfilgrastim. We developed a model to estimate the economic impact over five years of managing G-CSF-eligible chemotherapy patients at risk of FN with lipegfilgrastim rather than pegfilgrastim in Scotland. **METHODS:** The eligible patient population was estimated based on cancer incidence in Scotland and current uptake of G-CSF by patients initiating chemotherapy to prevent neutropenia. Drug, monitoring and event costs were taken from the British National Formulary, Unit Costs of Health and Social Care and Scottish National Tariff. As lipegfilgrastim was shown to be non-inferior to pegfilgrastim (in a phase III study in breast cancer patients), the efficacy and safety of pegfilgrastim and lipegfilgrastim were assumed to be identical. Non-statistically significant trends towards fewer neutropenic events and dose modifications with lipegfilgrastim were explored in scenario analyses. **RESULTS:** The model estimated that 315 patients currently receive pegfilgrastim annually. A progressive increase in lipegfilgrastim uptake was associated with cost savings ranging from £2,814 in year 1 to £16,883 in year 5, totalling £61,904 over five years. Savings were attributable to the low drug acquisition cost of lipegfilgrastim. Using event rates from the pivotal phase III breast cancer study, scenario analyses suggested that using lipegfilgrastim instead of pegfilgrastim generated savings of £145,312, avoided 81 neutropenic events (including 11 occurrences of FN) and 50 dose modifications, and caused 34 additional treatment-emergent adverse events. **CONCLUSIONS:** Lipegfilgrastim was cost-saving compared with pegfilgrastim.

PCN54

SAFETY PROFILE AND COSTS OF RELATED ADVERSE EVENTS OF TRASTUZUMAB EMTANSINE COMPARED TO OTHER REGIMENS IN THE CANADIAN HEALTH CARE SYSTEM

Piwko C[1], Prady C[2], Yunger S[3], Moser A[4], Le P[1], Vicente C[1]
[1]*PIVINA Consulting Inc., Mississauga, ON, Canada,* [2]*Centre de sante et du service sociaux Champlain-Charles-Le Moyne, Greenfileld Park, QC, Canada,* [3]*Hoffmann-La Roche Limited, Mississauga, ON, Canada,* [4]*F. Hoffmann - La Roche Ltd., Basel, Switzerland*

OBJECTIVES: Trastuzumab emtansine (T-DM1) is an antibody–drug conjugate comprised of the microtubule inhibitory cytotoxic agent DM1 and trastuzumab which, in addition to its antitumor properties, targets T-DM1 to HER2–overexpressing cells. The overall safety profile of T-DM1 was investigated in the phase III EMILIA trial (comparing T-DM1 [n=496] to capecitabine plus lapatinib [CAP+LAP, n=495]) in patients with HER2-positive locally advanced or metastatic breast cancer (MBC) previously treated with trastuzumab and a taxane, and the phase II TDM4450g trial (comparing T-DM1 [n=67] to trastuzumab plus docetaxel [TRAZ+DOCE, n=70]) in patients with previously untreated MBC. Both trials demonstrated clinically meaningful differences between T-DM1 and its comparators. The objectives were to estimate and compare the Canadian costs of managing the treatment-related adverse events (AEs) of T-DM1 as reported in the two trials, from the perspective of Canadian public payers. **METHODS:** An Excel based spreadsheet model was utilized for the analysis. Costing information was obtained from the literature, clinical experts, and Canadian standard costing sources. Costs were reported as 2012 CAD. The AEs that were considered were all treatment-related grade ≥3 AEs as well as grade 2 AEs that occurred in ≥5% of patients in both arms of either study. **RESULTS:** The management of treatment-related AEs as reported in the EMILIA trial resulted in higher per patient costs ranging from $3,060 - $10,499 for CAP+LAP versus $1,376 - $2,463 for T-DM1, yielding savings of $1,684-$8,036. In the TDM4450g trial, the management of treatment-related AEs resulted in higher per patient costs ranging from $5,124 - $27,617 for TRAZ+DOCE versus $798 - $2,215 for T-DM1, yielding savings of $4,326-$25,402. **CONCLUSIONS:** This analysis demonstrated that utilizing T-DM1 for the management of HER2-positive metastatic breast cancer results in significant cost savings of related AEs management due to the improved safety profile compared to CAP+LAP and TRAZ+DOCE.

PCN55

A COST-ANALYSIS OF STEREOTACTIC RADIOTHERAPY IN LUNG CANCER

Perrier L[1], Morelle M[2], Pommier P[2], Plommet N[1], Beckendorf V[3], Mahé MA[4], Lartigau E[5], Boisselier P[6], Bondiau PY[7], Touboul E[8], Peignaux Casasnovas K[9], Gassa F[2], Dussart S[2], Claude L[2]
[1]*Cancer Centre Léon Bérard, Lyon, France,* [2]*Leon Berard Cancer Centre, Lyon, France,* [3]*Cancer Center Alexis Vautrin, Vandoeuvre-les Nancy, France,* [4]*Institut de Cancerologie de l'Ouest - René Gaudducheau, Saint - Herblain, France,* [5]*Centre Oscar Lambret, Lille, France,* [6]*Cancer Center Val d'Aurelle-Paul Lamarque, Montpellier, France,* [7]*Centre Antoine Lacassagne, Nice, France,* [8]*Hospital Tenon, Paris, France,* [9]*Centre Georges-François Leclerc, Dijon, France*

OBJECTIVES: Stereotactic radiation therapy is an innovative technique with high therapeutic potential due to excellent local control and increased survival rate. A cost analysis investigating stereotactic radiation therapy modalities either with linear accelerator (Cone Beam Computed Tomography (CBCT), Exac-trac) or Cyberknife was conducted. **METHODS:** The cost-analysis was performed prospectively based on a multicenter study. Patients included were treated for lung carcinoma (T1-T2, N0, M0). Cost calculations were strictly based on a micro costing approach according to the hospitals' point of view. Only direct costs were taken into account. Productivity losses of personnel involved in the process, costs of administrative personnel, costs of logistics and general management were not taken into account. Time horizon included radiation therapy (preparation for radiation therapy and the fraction itself). All costs were given in 2011 euros. Uncertainty was captured by one-way and probabilistic sensitivity analyses using a non-parametric bootstrap method. **RESULTS:** 113 patients were enrolled in 11 French centers from April 2009 to December 2011. 98 economic questionnaires were exploitable. The costs of preparation for stereotactic radiation therapy were 430€ (SD: 101€) with Cyberknife and 433€ (SD: 199€) with linear accelerator. When required, costs of implementation of fiducial markers with one/two days of inpatient care were 1,619€. The costs of stereotactic radiation therapy (all fractions included) were 1,811€ (SD: 760€) with Cyberknife and 817€ (SD:403€) with linear accelerator. Costs per fraction were 550€ (SD: 224€) with Cyberknife and 201€ (SD: 97€) with linear accelerator. Depreciation periods of the accelerator played a major role in costs. **CONCLUSIONS:** This is to our knowledge the first study highlighting costs incurred by different stereotactic radiation therapy modalities in lung cancers. Cost-effectiveness studies have to be conducted in order to shed further light on which modality to focus on.

PCN56

COST OF ADVERSE EVENTS DURING TREATMENT WITH EVEROLIMUS PLUS EXEMESTANE OR SINGLE-AGENT CHEMOTHERAPY IN PATIENTS WITH ADVANCED BREAST CANCER

Campone M[1], Yang H[2], Faust E[2], Kageleiry A[2], Signorovitch J[2], Zhang J[3], Gao H[3]
[1]*Institut de Cancérologie de l'OUEST, Saint Herblain-Nantes Cedex, France,* [2]*Analysis Group, Inc., Boston, MA, USA,* [3]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA*

OBJECTIVES: Everolimus plus exemestane (EVE+EXE) recently received approval for the treatment of patients with HR+/HER2- advanced breast cancer that recurs or progresses during/after non-steroidal aromatase inhibitors. This study was designed to evaluate the expected costs of managing adverse events during EVE+EXE therapy and single-agent chemotherapy in the western European region. **METHODS:** An economic model was developed to estimate per-patient cost of managing adverse events for patients receiving EVE+EXE or chemotherapies. Adverse event rates for EVE+EXE were collected from the phase III BOLERO-2 trial. Adverse event rates for capecitabine, docetaxel, and doxorubicin chemotherapies were collected from published clinical trial data. Grade 3/4 adverse events with at least 2% prevalence during any of these treatments were included in the study. The adverse event rate

estimates do not count multiple episodes of the same event. Costs of managing each adverse event were obtained from the literature and averaged across western European countries (UK, Germany, France, Italy, Belgium, Spain, Sweden, and Switzerland), where available. The costs were inflated to 2012 Euros (€). **RESULTS:** Expected per-patient costs of managing adverse events within the first year of treatment among patients with advanced breast cancer receiving EVE+EXE were €730. Among patients receiving capecitabine, docetaxel, or doxorubicin as single-agent chemotherapy, expected per-patient costs were €1721, €2390, and €1230, respectively. The most costly adverse event for patients treated with EVE+EXE was anemia (€152 per patient). The most costly adverse event for patients treated with capecitabine, docetaxel, or doxorubicin was lymphocytopenia (€861 per patient), neutropenia (€821 per patient), and leukopenia (€382 per patient), respectively. **CONCLUSIONS:** Expected costs of managing adverse events in patients with HR+/HER2- advanced breast cancer receiving EVE+EXE are about one-half to one-third of the costs for those receiving chemotherapies. This economic consideration can have important implications for health care spending in the advanced breast cancer setting.

PCN57

ECONOMIC IMPACT MODEL OF LIPEGFILGASTRIM TO PREVENT NEUTROPENIA IN CANCER PATIENTS IN SPAIN

Sánchez-de la Rosa R, García-Bujalance L
TEVA Pharma, Madrid, Spain

OBJECTIVES: To estimate the economic impact of managing chemotherapy patients at risk of neutropenia and eligible to receive Granulocyte-Colony Stimulating Factor (G-CSF) with lipegfilgatrim (LONQUEX, a new long-acting G-CSF) rather than pegfilgastrim in Spain. **METHODS:** Both the BIA and CMA were conducted from the Spanish-payer's perspective: they included direct drug cost, administration, neutropenic events and adverse event costs, but did not consider indirect costs. The drug acquisition cost of lipegfilgatrim used in the model was based on the anticipated price of lipegfilgatrim at the time of launch in Spain. All costs were expressed in EUROS-2013. A range of sensitivity, scenario and threshold analyses were performed. An additional analysis was performed within the BIA to explore the trend towards fewer dose modifications in the lipegfilgatrim arm of the XM22-03 trial. **RESULTS:** The CMA shows that treating a patient with lipegfilgatrim instead of pegfilgrastim resulted in a cost saving of 650,06€. At the population level, the BIA predicts that cost savings could range from 113.166€ in year 1 to 678.995€ in year 5, totaling to 2.489.648€ over five years. Furthermore, the BIA shows a potential to avoid 50 dose modifications with the use of lipegfilgatrim instead of pegfilgrastim. The model is most sensitive to the cost of pegfilgrastim and lipegfilgatrim, but results are robust, with the model estimating cost savings over a wide range of inputs. When the trend towards decreased NE and increased AE with lipegfilgatrim vs pegfilgrastim reported in the XM22-03 trial is explored, cost savings was about 30% compared to the default scenario, reaching 3.208.619 €., mainly due to decreased NE costs **CONCLUSIONS:** Lipegfilgatrim is cost-saving compared with pegfilgrastim. These savings are confirmed across a wide range of input values.

PCN58

THE RELATIVE ECONOMIC VALUE OF IPILUMUMAB IN COLOMBIA

Garrido S[1], Juarez-Garcia A[2], Hernández-Rivera G[2], Donato BMK[3]
[1]*Bristol-Myers Squibb Company, Lima, Peru,* [2]*Bristol-Myers Squibb Company, Mexico City, Mexico,* [3]*Bristol-Myers Squibb Company, Wallingford, CT, USA*

OBJECTIVES: There are relatively few treatment options for pre-treated metastatic melanoma (MM) patients. Clinicians have recently been provided access to a new option, ipilumumab that has demonstrated long-term survival benefits, in a subset of patients. Karweit J and colleagues (2012) present data to support the use of mean OS for agents with a right-skewed survival curve, where a subset of patients respond to treatment with long term survival -as is the case for ipilimumab. The research presents data for several oncology agents: ipilimumab for MM, bevacizumab for non-small cell lung cancer, sorafenib for hepatocellular carcinoma, lenalidomide for multiple myeloma, trastuzumab for metastatic breast cancer and vemurafenib for MM. The data reveals a greater mean OS improvement than median OS improvement, since mean OS accurately captures the complete survival benefits. In this analysis we select agents from the Krweit J et al study and who have received regulatory authorization in Colombia, to compare their relative economic value. **METHODS:** The economic value of each asset is presented in terms of cost per month of mean OS within the Colombian health care payer perspective. The analysis uses the cost to treat to mean progression of each asset divided by the months of mean overall survival improvement using current list prices of assets. **RESULTS:** Ipilimumab in comparison to bevacizumab, sorafenib, trastuzumab, sutinib, lenalidomide, and vemurafenib demonstrates a clinical and economic relative value. The cost per mean overall survival month gained for ipilumumab ($39,344,362 COP) is below the average of the comparator assets (range from $60,226,690 to $20,166,226). **CONCLUSIONS:** The relative clinical and economic value of ipilumumab in the context of a variety of oncologic assets is clearly documented. This data provides health care decision makers critical data when determining coverage of oncologic treatments.

PCN59

EXAMINING THE BURDEN OF ILLNESS OF VETERAN PATIENTS WITH PROSTATE CANCER IN THE UNITED STATES

Wang L[1], Xie L[2], Kariburyo MF[2], Li L[1], Wang Y[2], Baser O[3]
[1]*STATinMED Research, Dallas, TX, USA,* [2]*STATinMED Research, Ann Arbor, MI, USA,* [3]*STATinMED Research/The University of Michigan, Ann Arbor, Michigan, MI, USA*

OBJECTIVES: To examine the economic burden and health care utilizations of prostate cancer patients in the U.S. veteran population. **METHODS:** Patients diagnosed with prostate cancer (ICD-9: 185.xx) were identified from the U.S. Veterans Health Administration (VHA) Medical SAS dataset from October 1, 2009 through September 30, 2011. The first diagnosis date was defined as the index date. A comparator group was created by identifying patients without prostate cancer but with the same age, region, gender, index year, and matched baseline Charlson Comorbidity Index. The index date for the comparator group was randomly chosen to reduce selection bias. A 1-year continuous health plan enrollment was required before and after the index date for both groups. Study outcomes, including health care costs and utilizations, were compared between the disease and comparator groups using 1:1 propensity score matching (PSM). **RESULTS:** Eligible patients (N=384,596) were identified for the prostate cancer and comparison cohorts and after applying PSM, a total of 112,693 patients were matched from each group and the baseline characteristics were well-balanced. Patients diagnosed with prostate cancer were more likely to be hospitalized (75.41% vs. 2.46%, p<0.01), and report more emergency room (9.30% vs. 5.45%, p<0.01), outpatient (99.77% vs. 61.15%, p<0.01) and pharmacy visits (85.65% vs. 63.77%, p<0.01). Patients diagnosed with prostate cancer also incurred higher costs for inpatient ($2,216 vs. $695, p<0.01), emergency room ($92 vs. $51, p<0.01), outpatient ($3,364 vs. $1,462, p<0.01), pharmacy ($582 vs. $413, p<0.01) and total costs (6,162 vs. $2,571, p<0.01) compared to the comparator group. **CONCLUSIONS:** Patients diagnosed with prostate cancer were associated with a higher burden of illness compared to their matched controls during a period of 12 months.

PCN60

COST OF CARE WITH EVEROLIMUS VERSUS AXITINIB FOR SECOND-LINE METASTATIC RENAL CELL CARCINOMA PATIENTS IN CANADA

Perrin A[1], Chua A[1], Wang X[2], Hurry M[3]
[1]*LA-SER Analytica, New York, NY, USA,* [2]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA,* [3]*Novartis Pharmaceuticals Canada Inc., Dorval, QC, Canada*

OBJECTIVES: Everolimus and axitinib are approved to treat patients with metastatic renal cell carcinoma (mRCC) following failure on various first-line therapies. This analysis assessed the cost of care with everolimus versus axitinib for second-line mRCC patients from a Canadian payer perspective. **METHODS:** Costs considered in this analysis included those related to drug acquisition and adverse events (AEs). Drug acquisition costs were based on the Ontario wholesaler price. Adverse event costs were based on the Ontario Case Costing Initiative and literature. Drug costs, adjusted for dose intensity, and AE costs, based on daily incidence rates, accrued for the duration of treatment in each arm; the sums of these costs were compared across treatments. The mean dose intensities, treatment durations and rates of AEs in the treatment arms were the calculated from trial data. Scenario analyses are presented to estimate the range of costs within the treatment arms. Costs are presented in 2011 Canadian dollars. **RESULTS:** In the base case analysis, the total cost of treatment with everolimus was estimated to be $24,931 while the total cost of treatment with axitinib was $39,010. The primary driver of the cost discrepancy was axitinib's high dose intensity, resulting in high drug acquisition costs. Despite analysis limitations, the trend of the results remained consistent across scenario analyses. When treatment duration was estimated from median progression-free survival estimates in each study's post-sunitinib populations, the total cost of treatment with everolimus was $8,339 less than with axitinib. Sensitivity analyses that assumed equivalent treatment durations between each arm also demonstrated lower overall treatment costs for everolimus patients. **CONCLUSIONS:** The analysis demonstrates that everolimus provides a less costly treatment option than axitinib for patients requiring second-line therapy. Significant uncertainty remains regarding axitinib's treatment duration and dosing, which could result in higher costs to the health care system compared to everolimus.

PCN61

RELATIVE CLINICAL AND ECONOMIC VALUE OF IPILIMUMAB IN MEXICO

Juarez-Garcia A[1], Donato BMK[2], Appiani C[1], Davila A[1], Hernández-Rivera G[1]
[1]*Bristol-Myers Squibb Company, Mexico City, Mexico,* [2]*Bristol-Myers Squibb Company, Wallingford, CT, USA*

OBJECTIVES: Ipilumumab is a clinically proven treatment option for pre-treated metastatic melanoma (MM). Ipilumumab has clearly demonstrated survival benefit, that is prolonged in a proportion of the responding patients. Karweit J and colleagues (2012) demonstrated that mean overall survival (OS) can be particularly useful for agents with a right-skewed survival curve where a subset of patients respond to treatment with long term survival. The research has demonstrated that several agents, including ipilimumab for MM, bevacizumab for non-small cell lung cancer, sorafenib for hepatocellular carcinoma, lenalidomide for multiple myeloma and trastuzumab for metastatic breast cancer (among others) have shown greater mean OS improvement than median OS improvement, reflecting the long term survival benefit for some patients. In this analysis we select oncologic agents that have demonstrated mean OS benefit in the above mentioned study and have received license in Mexico. We compare the relative economic value delivered by each asset, which broadly represent the therapeutic oncologic class. **METHODS:** The economic value of the analogues is estimated for the Mexican private perspective in terms of cost per month of mean OS versus comparators. The analysis relies on the cost to treat to mean progression by the months of mean OS improvement. **RESULTS:** Cost per month of OS for ipilimumab ($15,993 USD) when compared to bevacizumab, sorafenib, trastuzumab, sunitinib, lenalidomide and vemurafenib is below the average relative cost of the assets (range from $35,871 to $9,845 USD). **CONCLUSIONS:** This study demonstrates that ipilimumab is a competitive asset in terms of value for money. The analysis allows to evaluate within a clear and robust analytical framework, the reimbursement decisions across the oncologic therapeutic class in Mexico.

PCN62

COSTS OF PILOT PROGRAMS EMPLOYING ALLIED HEALTH PROFESSIONALS WITHIN THE CENTERS FOR POPULATION HEALTH AND HEALTH DISPARITIES

Walton S[1], Johnson TJ[2], Li CC[2], Joyce B[3]
[1]*University of Illinois at Chicago, Chicago, IL, USA,* [2]*RUSH, Chicago, IL, USA,* [3]*University of Illinois Chicago, Chicago, IL, USA*

OBJECTIVES: To measure the costs of two pilot interventions within the National Institutes of Health-funded Centers for Population Health and Health Disparities (CPHHD) designed to improve health outcomes in medically underserved commu-

nities through the utilization of allied health professionals. **METHODS:** Two local CPHHD programs with prospective randomized controlled trial designs (a virtual team care intervention aimed at reducing depressive symptoms in older adults with depression and cardio-metabolic syndrome, and a patient navigator program to increase mammography screening for breast cancer) provided the underlying data for this analysis. The programs collected detailed resource use data along with several clinical measures. Costs were measured from a payer perspective. The navigator program involved in-person or remote navigator consultations, and costs were based on a wage rate of $15 per hour. The depression program involved multiple services and all costs reflected institution-specific billing data. **RESULTS:** There were 949 patients in the patient navigator intervention. On average, these patients received 8.28 minutes of navigator services per patient over the phone and 1.23 minutes via in-person visits, translating to a per-patient cost of $2.38. For the six patients enrolled in the team care intervention for depression, resources used included social worker case management and individual psychotherapy, translating to program costs of $145 per patient over 12 months. Spillover health care service costs were similar between the intervention and control groups (intervention = $55 per patient, control = $64 per patient). **CONCLUSIONS:** Costs are an important consideration for evaluating pilot, team-care based interventions to improve patient health. The two programs evaluated here offer insight into the potential impact of interventions that employ allied health professionals and demonstrate a relatively low cost per patient. Future work will examine these costs in comparison with measured effects of the program.

PCN63

ASSESSING THE BURDEN OF CAREGIVING FOR PATIENTS WITH LUNG CANCER IN EUROPE

Goren A[1], Gilloteau I[2], Penrod JR[2], Jassem J[3]
[1]*Kantar Health, New York, NY, USA,* [2]*Bristol-Myers Squibb, Princeton, NJ, USA,* [3]*Medical University of Gdansk, Gdansk, Poland*

OBJECTIVES: To investigate the self-reported burden imposed by care of lung cancer (LC) patients in the European Union (EU). **METHODS:** The study included respondents to the 2010 and 2011 EU National Health and Wellness Survey from France, Germany, Italy, Spain, and the UK who reported being caregivers for a relative with LC versus respondents who did not report being caregivers for a relative with any condition (control). Outcome measures included Short Form (SF)-6D health state utilities and mental and physical health status (all derived from the SF-12v2), stress-related comorbidities, health care resource use during the past 6 months, and work/activity impairment during the past week using the Work Productivity and Activity Impairment (WPAI) questionnaire. Productivity losses were converted into costs using the human capital method by applying median hourly wages per country (from Eurostat 2006 personal income inflated to 2010) to the total number of hours lost using results from WPAI. Multivariable analyses were used to test the potential impact of LC patient caregiving on health care resource use and work/activity impairment, as well as costs specifically associated with work impairment. **RESULTS:** A total of 107 caregivers for patients with LC and 103,868 non-caregivers were identified. Compared with non-caregivers and adjusting for covariates, caregivers had higher mean levels of impaired presenteeism (27.1% vs. 14.8%), overall work impairment (32.4% vs. 18.0%), and activity impairment (32.8% vs. 21.8%; all $p<0.005$); higher odds of impact across all measures of the WPAI including absenteeism (all $p<0.01$); and higher annual costs associated with impaired presenteeism (€5,672 vs. €3,429) and overall work impairment (€6,905 vs. €4,147; both $p<0.05$). Health care resource utilization and mean level of absenteeism did not differ significantly. **CONCLUSIONS:** LC patient caregiving in the EU is associated with significantly higher work/activity impairment and related costs relative to non-caregivers. Costs associated with LC caregiver burden deserve further attention.

PCN64

DIRECT MEDICAL COSTS (DMC) OF TREATING CHRONIC LYMPHOID LEUKEMIA (CLL) PATIENTS IN THE PUBLIC HEALTH CARE SYSTEM IN BRAZIL: RESULTS FROM A RETROSPECTIVE ANALYSIS OF AN ADMINISTRATIVE DATABASE

Asano E, Pereira ML
Janssen-Cilag Farmaceutica, Sao Paulo, Brazil

OBJECTIVES: To determine direct medical costs of treating patients with Chronic Lymphoid Leukemia (CLL) from the Brazilian Public Healthcare System perspective. **METHODS:** A retrospective longitudinal analysis of the Government administrative claims database (Datasus) was performed. Eligibility criteria were patients starting CLL (ICD-10 code C911) chemotherapy from Jan/2008 to Dec/2011, with complete information and no inconsistency in date of birth, gender. Outpatient and inpatient databases were combined through deterministic linkage. Outcome was direct medical costs (DMC), calculated as the sum of the medical claims for each patient included in the analysis, for a maximum period of 5 years or death or loss of follow-up, whichever comes first. DMC was categorized in chemotherapy, hospitalizations, and other outpatient costs. **RESULTS:** From 5100 patients with CLL identified in the database, 613 met eligibility criteria. Median follow-up time was 25 months. This population cohort had 54% males with average age at start of treatment of 66.4 ± 11.7 years. Patients received an average of 12.0 ± 9.4 months of chemotherapy treatment, with 71% of them treated by one type of chemotherapy regimen. Total DMC in this population was R$ 7,021,631.48 (average cost of R$ 6,404.52 ± 6,133.37 per patient-year), from which R$ 5,384,552.12 (77%) are related to chemotherapy, R$ 1,062,978.98 (15%) to hospitalizations and R$ 574,100.38 (8%) to other outpatient costs. Outpatient laboratory exams accounted for 6% (R$ 397,050.07) of total DMC. 30 (5%) patients underwent radiotherapy treatment, with total costs of R$ 53,944.96 (<1% of DMC). A total of 862 hospitalizations were identified in 287 (46.8%) patients, with an average cost of R$ 1,233.15 ± 3,879.86 per hospitalization. **CONCLUSIONS:** Patients with CLL represent a significant economic burden to the public health system. Chemotherapy and hospitalization costs accounts for more than 90% of the total costs.

PCN65

REAL WORLD MANAGEMENT AND COSTS IN UNRESECTABLE METASTATIC MELANOMA (MM) PATIENTS: UPDATE OF A PILOT STUDY BASED ON AN INSTITUTIONAL PATIENT REGISTRY

Strens D[1], Specenier P[2], Peeters M[2]
[1]*Realidad, GRIMBERGEN, Belgium,* [2]*University Hospital Antwerp, Edegem, Belgium*

OBJECTIVES: To assess the management and associated lifetime costs in MM patients as from the diagnosis of unresectable metastatic disease until death. **METHODS:** A retrospective patient chart review was performed at the Antwerp University Hospital to obtain data on medical consumption related to the management of unresectable MM (uMM). A complete registry of all melanoma patients who visited the hospital between 2007 and May 2013 was compiled. Eligible for this retrospective chart review were patients with uMM with sufficient data available and who deceased before May 2013. Data on demographics, disease characteristics and management of uMM were collected. Direct costs were calculated by multiplying each item of resource use with its unit cost (2013, €) using the Belgian public health care payer's perspective (PHCP) and patient's perspective. Average (bootstrap 95%CI) overall costs per patient were calculated. **RESULTS:** Out of 338 registered melanoma patients, 35 were eligible and included in this chart review. The median overall survival time (OS) in all patients was 6.2 months. 88.6% (n=31) of patients were treated by systemic treatment(s) of which 17% (n=6) received up to 4 different treatment lines. Ten patients received "new drugs": ipilimumab (1 to 4 cycles): 10; vemurafenib: 2. Fifty-six (41%) of the 137 hospitalizations were for treatment administration. The mean overall cost per patient was €43,429 (bootstrap 95% CI: 33,372 - 54,351), of which € 42,367 (95%CI: 32,481 - 52,976) was reimbursed. The PHCP cost was driven by systemic treatments costs (46% of cost). Mean PHCP cost was € 87,468 (95 % CI: 77,372-97,307) for patients treated with "new drugs" versus € 24,327 (95 % CI: 18,617 - 30,634) for patients not treated with "new drugs". Median OS was 9 and 4.9 months, respectively. **CONCLUSIONS:** Management of uMM results in considerable costs for the PHCP, mainly driven by systemic treatment costs.

PCN66

MANAGEMENT COSTS OF THE FIRST FIVE YEARS AFTER DIAGNOSIS IN BREAST CANCER BY STAGE IN FRANCE

Atsou K[1], Bardoulat I[1], Colin X[1], Lemasson H[1], Ricarte C[2], Maurel F[2], Ajjouri R[3], Lançon F[3]
[1]*IMS Health, La Défense Cedex, France,* [2]*IMS Health, La Défense, France,* [3]*Institut National du Cancer, Boulogne Billancourt cedex, France*

OBJECTIVES: Few recent data are available on breast cancer treatment costs, especially by stage of the disease at diagnosis. This study was designed to estimate the management costs in breast cancer for the first 5-year period following diagnosis. Costs have been distinguished by stage of severity. **METHODS:** A patient-level analysis was performed from a French physician survey database, collecting data on patient demographics, cancer history from diagnosis and treatment patterns. Data were extracted for all breast cancer cases with at least 1 year of follow-up after diagnosis using data collected from 2011 to 2012. Cost analyses were conducted from a health care payers' perspective adjusting for stage (stages I-IV) at diagnosis and year from diagnosis. **RESULTS:** A total of 1,157 patients were included in the analysis. The stages at diagnosis distribution was respectively from stage I to IV 29.7%, 39.2%, 15.0% and 16.1%. The mean (SD) age at inclusion was 62.5 (12.4) and the mean (SD) time from diagnosis was 5.0 years (5.1). The mean annual cost (SD) over the 5-year period after diagnosis was ranging from 4,293€ (9,526€) for stage I to 12,111€ (19,070€) for stage IV. The mean (SD) annual costs for the 1st year after diagnosis were estimated at 11,647€ (9,883€), 13,226€ (11,575€), 17,254€ (14,535€) and 24,003€ (24,888€), respectively for stage I to IV at diagnosis. The main cost contributors in early stages were radiotherapy and surgery while cytotoxic treatments, hormonotherapy and supportive care droved it for the late stage. The mean annual costs for the following years after diagnosis (2nd to 5thyear) decreased, ranging from 1,827€ (8,964€) for Stage I to 5,370€ (10,662€) for stage IV. **CONCLUSIONS:** : The mean annual cost was strongly related to the clinical stage at diagnosis and the year from diagnosis. These estimates could be useful to populate models that explore impact of treating and preventing breast cancer.

PCN67

THE HUMANISTIC AND ECONOMIC BURDEN OF VENOUS THROMBOEMBOLISM IN CANCER PATIENTS: A SYSTEMATIC REVIEW

Kourlaba G[1], Relakis J[2], Kontodimas S[3], Holm MV[4], Maniadakis N[2]
[1]*National and Kapodistrian University of Athens School of Medicine, Athens, Greece,* [2]*National School of Public Health, Athens, Greece,* [3]*LEO Pharmaceutical Hellas S.A., Athens, Greece,* [4]*LEO PHARMA, Copenhagen Area, Denmark*

OBJECTIVES: To systematically review the humanistic and economic burden of cancer-related venous thromboembolism (VTE). **METHODS:** A literature search was carried out on Pubmed, Cochrane Central Register of Controlled Trials, Econlit, Science Direct, JSTOR, Oxford Journals and Cambridge Journals. The search was limited to humanistic studies published from January 2000 to December 2012. Additional studies were also identified by searching reference lists of relevant published reviews and included studies. The identified studies were independently reviewed by two reviewers against pre-determined inclusion and exclusion criteria. A quality assessment of the selected studies was also conducted by using standard methods . The data of selected studies were extracted onto a data extraction form and consequently synthesized. **RESULTS:** Fifty five studies were included in our review. It was found that cancer patients experience between 2-fold and 20-fold higher risk of developing VTE in comparison to non-cancer patients. Cancer patients are more likely to experience a VTE event in the first 3 or 6 months after cancer diagnosis and the onset of chemotherapy. Additionally, an increased risk of VTE in patients with distant metastases and certain types of cancer (i.e. pancreatic or lung) was identified. VTE strongly affects the prognosis of cancer patients as it has been found that it is a leading cause of death in this group of patients. The annual average total cost for cancer patients with VTE was found to be almost 50% higher compared to that of cancer patients without VTE

in the USA in 2002. Inpatient care costs accounted for more than 60% of total cost. **CONCLUSIONS:** Although the economic impact of the VTE in cancer patients as well as the impact of VTE on patients' quality of life is not well studied, the present review demonstrate that there is a substantial humanistic and economic burden associated with VTE in cancer patients.

PCN68

A MICRO-COSTING OF THE INPATIENT MANAGEMENT OF FEBRILE NEUTROPENIA IN THE IRISH HEALTH CARE SETTING

McCullagh L[1], O'Brien C[2], Fogarty E[1], Walsh C[3], Dempsey O[3], Barry M[1], Kennedy MJ[2]
[1]*National Centre for Pharmacoeconomics, Dublin, Ireland,* [2]*St James's Hospital, Dublin, Ireland,* [3]*Trinity College Dublin, Dublin, Ireland*

OBJECTIVES: Febrile neutropenia (FN) is a potentially life-threatening complication of chemotherapy which generally prompts immediate hospitalisation. The study objective was to evaluate the resource use and cost of hospitalisation for FN within the Irish Health care setting. Micro-costing techniques were used. The health payer perspective was adopted. **METHODS:** This was a single centre study. Adult cancer patients undergoing chemotherapy, who were subsequently admitted for FN, were identified prospectively. Patient medical records were reviewed retrospectively. **RESULTS:** Patient demographics and resource utilisation data (pertaining to the management of FN) were obtained from a cohort of 32 patients (69% female, mean age = 58.8 years). Twenty-five percent of patients had more than one FN episode. In total, 42 FN episodes were captured; 60% of episodes had occurred within the first two cycles of chemotherapy. The bootstrap estimation was used to determine mean hospital length of stay (LOS) with standard deviation (± SD) and mean costs (± SD). The mean LOS was 7.3 (± 0.5) days. The mean cost per FN episode was €8,915 (± 718). The major cost driver was hospital bed-stay (mean cost of €6,851 (± 549)). Other cost drivers included antibacterial treatment at €760 (± 156), laboratory investigations at €538 (± 47) and the requirement for blood bank products at €525 (± 189). **CONCLUSIONS:** To our knowledge, this is the first investigation of the cost of chemotherapy induced FN within the context of the Irish Health care setting. Our results will be used in cost-effectiveness analyses of novel chemotherapeutic agents and interventions which prevent or treat FN.

PCN69

THE COST OF NSCLC IN FRANCE

Martin M[1], Mcguire A[2], Marty R[3], Lenz C[4]
[1]*OptumInsight, Uxbridge, Middlesex, UK,* [2]*London School of Economics, London, UK,* [3]*HEVA HEOR, Lyon, France,* [4]*Pfizer, Berlin, Germany*

Though lung cancer, and the most common subtype, non-small cell lung cancer (NSCLC), occur frequently, there are limited data quantifying the economic burden of these cancers in Europe.**OBJECTIVES:** To describe the burden of NSCLC in three European countries using patient-level data from commercially available health care data. **METHODS:** Patient-level data were obtained for France from the PMSI (French National discharge database; containing data from publicly-funded hospitals) from 2008 to 2011 while excluding patients with a prior-hospitalization for lung cancer in the preceding 24-month period (2006-2007). As NSCLC does not have a separate ICD-10 code, expert opinion was used to eliminate patients diagnosed with non-NSCLC, based on particular procedures and tests. Hospital resource use was valued using French DRG tariffs. Chemotherapy regimens were valued using official rates. **RESULTS:** A total of 61,144 patients were identified with lung cancer in 2008. 19,099 were excluded because of prior lung cancer diagnoses. Of this cohort of 42,043 patients, 25,054 were exclusively treated in the public setting; 15,061 were identified as NSCLC and were considered in this analysis. Hospital-related costs cumulated over the follow-up period were estimated at €337,382m, with chemotherapy costs representing 9%. Mean cumulated hospital-related cost per-patient were estimated at €22,401 over the follow-up period. Terminal care represented a mean per-patient cost of €10,440. Adverse events triggering hospital-expenses represented a mean per-patient cost of €5,694. Patients ≤ 55 years incurred higher costs per-person over the follow-up period than patients >55 years; €25,386 vs. €21,368. These extra costs were mostly driven by chemotherapy costs(€13,287 vs. €10,561). Patient with metastases incurred higher costs over the follow-up period than patients without these, €23,118 vs. €21,934. **CONCLUSIONS:** This is one of the first analyses quantifying the economic burden of NSCLC. The burden for France is substantial. Subsequent analyses will allow for comparisons of this burden across other countries.

PCN70

CHEMOTHERAPY TREATMENT PATTERNS, HEALTH CARE COSTS, AND MORTALITY OF LUNG CANCER PATIENTS IN TAIWAN – A LONGITUDINAL STUDY BETWEEN 2000 AND 2008

Liang FW[1], Chen SY[2], Tsai CF[1], Jen MH[3], Li CY[1], Wasiak R[3], Boulanger L[2], Lu TH[1]
[1]*National Cheng Kung University, Tainan City, Taiwan,* [2]*Evidera, Lexington, MA, USA,* [3]*Evidera, London, UK*

OBJECTIVES: To examine chemotherapy treatment patterns, health care costs, and mortality of lung cancer patients in Taiwan. **METHODS:** This study analyzed medical and pharmacy claims from a random sample of one million taken from all beneficiaries covered under Taiwan's national health insurance in 2000. Newly diagnosed lung cancer patients between 2000 and 2008 (first observed diagnosis as the index date) were identified based on medical claims with associated diagnoses. Patients were followed until death or the end of 2008. Per patient per month [PPPM] total health care costs (in USD) and median survival were reported. Chemotherapy treatment patterns during the follow-up were examined. **RESULTS:** This study included 3,343 lung cancer patients (mean age: 67.1 years; 34.5% female; 35.4% secondary lung cancer). Median survival was 8.1 months. PPPM costs were $2,322 USD (interquartile range $450-$2,902). Lifetime costs from diagnosis among those who died during the study period were $12,788 USD (interquartile range $2,674-$17,546). Of the 1,633 patients who received chemotherapy during the follow-up, 375 received only one chemotherapy agent (gemcitabine 35.7%, vinorelbine 20.5%, platinum-based agents 20.3%, UFUR 8.3%, taxanes 7.7%, etoposide 7.5%). Close to three quarters (74.8%) of treated patients received combination therapy with platinum-based agents. Of 1,221 patients treated with platinum-based combination therapy, the therapy most commonly used includes gemcitabine (37.5%), taxanes (21.5%), and vinorelbine (18.2%), while 21.4% of patients received two or more other agents. We observed longer median survival in patients with a higher number of chemotherapy agents received. **CONCLUSIONS:** Lung cancer patients in Taiwan incurred considerable health care costs after diagnosis. More than half of patients were treated with chemotherapy, in particular with multiple chemotherapy agents. Future research comparing cost-effectiveness among different treatment options is warranted.

PCN71

AUSTRALIAN STANDARD COSTS AND CONSEQUENCES OF FOUR CHEMOTHERAPY ADVERSE EVENTS

Pearce AM, Haas M, Viney R
University of Technology, Sydney, Ultimo, Australia

OBJECTIVES: This work aimed to develop rigorous models of the Australian costs of four common chemotherapy adverse event (diarrhoea, vomiting, anaemia and neutropenia), which provide standard cost estimates and can be used in future models of chemotherapy cost effectiveness. **METHODS:** Decision analytic modelling was used to identify the costs and consequences of AEs. These are not only stand alone models, but also form decision tree sections to be incorporated into larger models of chemotherapy cost effectiveness. Model structures are based on best-practice clinical pathways, and incorporate efficacy of side effect treatment, quality of life and chemotherapy dose. Literature reviews identified clinical inputs. Costs of treatment were obtained from standard Australian sources such as the Pharmaceutical Benefits Schedule. The perspective was the Australian health care system. One-way sensitivity analyses explored uncertainty in the models. **RESULTS:** The base case average cost per patient of diarrhoea ranged from $19 (mild AE) to $4,821 (severe AE); those for anaemia ranged from $51 (mild AE) to $17,100 (moderate AE) depending on the type of chemotherapy and anaemia treatment. Vomiting prevention base case costs ranged from $0.84 (low risk chemotherapy) to $157.55 (high risk chemotherapy requiring breakthrough and refractory management). Neutropenia base case costs ranged from $2,235 (outpatient management) to $12,054 (intensive care required). Where possible, the impact on quality of life and chemotherapy total dose was also modelled. Estimates of AE costs vary widely in the literature, however our estimates appear consistent with studies of similar methodology. **CONCLUSIONS:** The four models presented represent best-practice modelling techniques for chemotherapy AEs. Each has been designed to enable either the results or the model structure to be incorporated into larger models of chemotherapy cost effectiveness. This allows model builders to incorporate rigorous, Australian-specific estimates of the costs and consequences of chemotherapy AEs into models of chemotherapy cost effectiveness.

HORMONAL RECEPTOR POSITIVE, HER2 NEGATIVE METASTATIC BREAST CANCER (MBC HR+HER2-): PRE AND POST-PROGRESSION COSTS UNDER THE PUBLIC HEALTH CARE SYSTEM (SUS) AND SOCIETAL PERSPECTIVES IN BRAZIL

Haas LC[1], Fernandes RA[1], Bines J[2], Caldas A[3], Valentim J[3]
[1]*ANOVA, Rio de Janeiro, Brazil,* [2]*Clementino Fraga Filho Hospital, Federal University of Rio de Janeiro, Rio de Janeiro, Brazil,* [3]*Novartis Biociências SA, São Paulo, Brazil*

OBJECTIVES: To estimate direct medical costs and productivity costs of hormonal receptor positive, HER2 negative metastatic breast cancer (MBC HR+ HER2-) under the public health care system (SUS) and societal perspectives in Brazil, being MBC cost data very scarce in Brazil so far. **METHODS:** A systematic literature review was performed in the following databases: Cochrane, MEDLINE via Pubmed, LILACS, EMBASE and CRD until FEB 2013. Gray literature was also included. National guidelines search and expert validation was carried out specifically for the direct medical cost estimations. Direct medical costs were stratified as pre and post-progression costs and terminal costs. Pre and post-progression costs considered outpatient, inpatient and monitoring costs. For post-progression, metastasis treatment costs were also estimated, including bone, lung, liver and brain metastasis. For the productivity costs, the Human Capital method was chosen. Days of absenteeism were obtained from the literature and a Markov model was used to estimate the loss of productivity in 1 year (as the mean age of MBC in Brazil is 59 and official retirement at 60 years of age). Unit costs were obtained from Brazilian official lists and IBGE (income). All costs are expressed in 2012 Brazilian Real (BRL). **RESULTS:** Pre, post-progression and terminal costs of MBC HR+HER2-were estimated in BRL308, BRL731 and BRL4.164 respectively, under SUS perspective. Post-progression metastasis treatment costs presented an average of BRL12.047 under SUS perspective. The productivity costs were estimated in BRL26.056 under the societal perspective considering the available treatments at SUS for MBC HR+HER2- patients. **CONCLUSIONS:** MBC HR+HER2- post-progression costs impose a significant economic burden under SUS perspective as well as productivity losses to the society. Novel therapies that postpone progression in those patients may reduce costs associated.

PCN73

ESTIMATING THE COST OF HPV-RELATED DISEASES IN TURKEY: A DELPHI APPROACH

Bakir M[1], Ayhan A[2], Arvas M[3], Kose MF[4], Gungor M[5], Ortac F[6], Ozgul N[7], Yuce K[7], Ergun T[1], Gungor E[5], Altundag O[2], Saka G[8]
[1]*Marmara University School of Medicine, Istanbul, Turkey,* [2]*Baskent University School of Medicine, Ankara, Turkey,* [3]*Istanbul University Cerrahpasa School of Medicine, Istanbul, Turkey,* [4]*Bahcesehir University School of Medicine, Istanbul, Turkey,* [5]*Acibadem University School of Medicine, Istanbul, Turkey,* [6]*Ankara University School of Medicine, Ankara, Turkey,* [7]*Hacettepe University School of Medicine, Ankara, Turkey,* [8]*Merck Sharp Dohme, Istanbul, Turkey*

OBJECTIVES: Very limited data is available on the cost and burden of HPV-related diseases in Turkey. The aim of our analysis is to evaluate the corresponding cost through understanding the current clinical practices, use of resources and treat-

ment algorithms based on expert opinion. **METHODS:** This study uses the Delphi method to reach experts' consensus on the clinical practices currently being used in Turkey. Delphi method has been widely used in medical areas where empirical data is scarce. The survey developed for this study includes questions to understand the clinical resource use in order to calculate the associated costs. Although the panelists' answers are unlikely to change after the second iteration according to the literature, a three-iteration panel was needed to reach a consensus in practice. The consensus is then used to calculate the cost of an episode of care for genital warts (GW), CIN 1, CIN 2/3, different cervical cancer stages from the payer's perspective. **RESULTS:** TDP-HPV included a total of 10 experts, including gyneco-oncologists, dermatologists and a medical oncologist. The cost of a GW episode of care is approximately USD 263.58 to the government. CIN 1 cases are only treated if the disease persists for 2 years, which happens in about 5% of cases. The cost of a CIN 1, CIN 2/3 episode of care is calculated as USD 127, USD 262 to the government, respectively. The cervical cancer (CC) stages are divided into local CC, regional CC, and distant CC. The costs associated with these states are USD 1,340, USD 4,345, and USD 8,150. **CONCLUSIONS:** Early diagnosis and treatment is crucial from the cost perspective too as a more severe disease costs more. GWs are sometimes left out when HPV-related diseases are considered. However, this study mentions that GW presents a serious burden to the society.

PCN74

COSTS OF HER 2 NEGATIVE, HORMONAL RECEPTOR POSITIVE, METASTATIC BREAST CANCER (MBC-HR+) TREATED WITH EVEROLIMUS (EVE) + EXEMESTANE (EXE) IN THE BRAZILIAN PRIVATE SYSTEM (BPS): A REAL WORLD (RW) AND PUBLISHED LITERATURE ANALYSIS

Clark OAC[1], Paladini L[1], Engel T[1], Caldas A[2], Valentim J[2]
[1]*Evidencias, Campinas, Brazil,* [2]*Novartis Biociências SA, São Paulo, Brazil*

OBJECTIVES: EVE in association with aromatase inhibitor was recently approved by ANVISA (Brazilian Regulatory Agency) for MBC-HR+ patients. EVE redefines the role of endocrine therapy in MBC-HR+ reversing endocrine resistance. The aim of this study is to determine the costs associated to the introduction of EVE + EXE for the Brazilian private system population. **METHODS:** A previous study from real-world (RW) data between 2011-12 (large private database of medical claims for chemotherapy (CT), Evidencias Database) and published data identified MBC-HR+ patients and evaluated costs of treatments and adverse events (AEs), by a micro-costing approach. Patients were divided into three groups, according to metastasis: bone exclusive (B), Visceral exclusive (V) and Bone plus Visceral (BV). For this study the financial impact of the adoption of EVE+EXE was calculated in this population, based on the previous findings. Direct medical costs of EVE, hormones, CT, hospitalization, supportive care, radiation, monitoring and AEs were considered. A cohort of 100 patients with MBC-HR+ was simulated in a decision tree to obtain the costs for each group and the mean cost/ patient. Costs were estimated in 2013 Brazilian Real (R$). **RESULTS:** RW data showed the following distribution of patients: B 38%, V 42% BV 20%. Lengths of treatment (months) were B 25.1-30, V 16.1; BV 14-19.6. Mean costs/patient/group, before EVE+EXE adoptions, were B R$135.744 (US$67,872), V R$129.079 (US$64,539) and BV R$117.172 (US$58,568). If EVE+EXE substituted 80% or 50% of the current treatments, the incremental percentage of costs would be B (5%; - 9%), V (5,7%; -16%) and BV (22%; 14%). Costs with AEs were at least 50% lower with the use of EVE+EXE. **CONCLUSIONS:** EVE adoption in association with EXE may be cost saving for some groups of MBC-HR+ patients. For other groups, the incremental cost is not superior to 22%.

PCN75

ESTIMATED COSTS OF HER2-POSITIVE METASTATIC BREAST CANCER FOR PATIENTS INITIATING AN ORAL ANTICANCER TREATMENT: RESULTS FROM A FRENCH PROSPECTIVE OBSERVATIONAL STUDY

Woronoff-Lemsi MC[1], Chaix-Couturier C[2], Durand-Zaleski I[3], Espié M[4], Lortholary A[5], Merrouche Y[6], Flinois A[7], Chabernaud H[8], Benjamin L[9]
[1]*Department of Pharmacy, Besançon Cedex, France,* [2]*Conseil Chaix-Couturier, Meudon, France,* [3]*Hôpital Henri Mondor, Créteil, France,* [4]*Hôpital Saint Louis, Paris, France,* [5]*Catherine de Sienne, Nantes, France,* [6]*Institut de Cancérologie Lucien Neuwirth, Saint Priest en Jarez, France,* [7]*Kantar Health, Paris, France,* [8]*Kantar Health, Montrouge, France,* [9]*GlaxoSmithKline, Marly le Roi, France*

OBJECTIVES: To assess the cost of HER2-positive (HER2+) metastatic breast cancer (mBC) for patients initiating an oral anticancer treatment (OAT) from the perspective of the French National Health Insurance (NHI). **METHODS:** A prospective observational multicenter study was conducted among 284 HER2+ mBC patients treated by 68 oncologists initiating a treatment containing an OAT between March 2011 and February 2012. Costs data were available for 199 patients. Clinical characteristics, treatment patterns, quality-of-life, adherence and health care resources data were collected. Health care resource use data on hospitalization, medical consultation, drug and radiation-therapy were reported by oncologists at treatment initiation and after each 3-month period during a 9 months maximum period. Cost estimations were based on unit costs from national databases (French Diagnosis Related Group cost database and NHI database for drug unit cost). **RESULTS:** A total of 109 patients (55%) received an OAT only and 90 (45%) received oral and intravenous (IV) drugs. Thirty patients (15%) were treated with radiation therapy and 43 patients (22%) with hormonal-therapy in addition to chemotherapy. The overall average cost of management per patient was 28,482€ ± 14,914 for all patients, 19,412€ ± 9,462 for patients with an OAT only and 39,467€ ± 12,770 for patients with oral and IV drugs. Drug costs were 27,669 € ± 14,976 and they represented 97% of the total hospital cost of management (hospitalizations, consultations and drugs). **CONCLUSIONS:** This prospective observational study conducted among HER2+ mBC patients shows that the route of drug administration has an impact on treatment costs. Nevertheless, the study design does not allow concluding that OAT were associated with lower costs and cost savings. These finding however warrants further exploration within the context of micro-costing studies from the hospital and community perspective in order to better understand the health care resources used that are required to manage patients treated with OAT.

PCN77

INPATIENT HOSPITAL COSTS OF FEBRILE NEUTROPENIA (FN) AS A CONSEQUENCE OF CHEMOTHERAPY (CHT) FOR BREAST CANCER (BC) AND NON-HODGKIN LYMPHOMA (NHL) IN SWITZERLAND

Mattli R, Pletscher M, Eichler K, Wieser S
Winterthur Institute of Health Economics, Zurich University of Applied Sciences, Winterthur, Switzerland

OBJECTIVES: FN can be a serious complication of CHT, increasing mortality risk and health care costs. Incidence and inpatient hospital costs of FN in Switzerland are currently not reported; therefore this study aimed to: 1. Estimate the number of FN-related hospitalizations. 2. Assess inpatient hospital costs per FN event in Switzerland. **METHODS:** The main data source was MedStat, a comprehensive database of all Swiss hospitalizations from 1997-2010. BC and NHL cases were identified from ICD-10-GM codes. Hospitalizations for FN were identified by a simultaneous code of BC or NHL and neutropenia. Incident cases of cancer were identified as patients treated in 2010 for the first time since 2002. Results were compared to data from the Foundation National Institute for Cancer Epidemiology and Registration (NICER). Cost data stems from the cantonal hospital of Winterthur. **RESULTS:** Using MedStat data, 645 male and 557 female NHL patients and 6'391 female BC patients were hospitalized in 2010 for the first time. Corresponding annual incidence data from NICER were 780 male and 688 female NHL patients and 5'388 female BC patients. The proportion of hospitalizations due to FN was 8.2% (190/2'311) among male and 6.0% (123/2'063) among female NHL patients, and was 2.6% (255/9'650) among female BC patients. In-hospital mortality of FN cases was 9.5% for men and 5.7% for women with NHL, and 4.3% for BC. Median inpatient treatment costs for an FN event were CHF 8'399 (mean: CHF 14'006) in NHL and CHF 4'208 (mean: CHF 10'020) in BC. Nursing time was the most important cost component and length of stay was the most important driver of total inpatient cost. **CONCLUSIONS:** 3% to 8% of all hospitalizations in NHL and BC patients were due to FN. Our results suggest that FN leads to considerable risk of death and incurs high in-hospital care cost in Switzerland.

PCN78

COST ASSESSMENT OF METASTATIC AND NON-METASTATIC CASTRATION-RESISTANT PROSTATE CANCER PATIENT-MANAGEMENT IN SPAIN

Morote J[1], Cozar JM[2], Duran I[3], Gomez Veiga F[4], Leon L[5], Maroto P[6], Miñana B[7], Solsona E[8], Oyagüez I[9], Casado MA[9], Roldán C[9], Gutierrez L[10], Hechmati G[11]
[1]*Vall d'Hebron Hospital. Universitat Autónoma de Barcelona, Barcelona, Spain,* [2]*Hospital Virgen de las Nieves, Granada, Spain,* [3]*Hospital Universitario Virgen del Rocío, Sevilla, Spain,* [4]*CHUAC "A Coruña University Hospital, A Coruña, A Coruña, Spain,* [5]*Hospital Clinico Universitario Santiago, Santiago de Compostela, Spain,* [6]*Htal Sant Pau, Barcelona, Spain,* [7]*Hospital Morales Meseguer, Murcia, Spain,* [8]*I.V.O, Valencia, Spain,* [9]*Pharmacoeconomics & Outcomes Research Iberia, Madrid, Spain,* [10]*Amgen S.A., Barcelona, Spain,* [11]*Amgen (Europe) GmbH, Zug, Switzerland*

OBJECTIVES: To compare annual management costs of castration-resistant prostate cancer (CRPC) patients at high risk of developing bone metastases (BM) versus those that already had BM in Spain. **METHODS:** An expert panel of 5 urologists and 3 oncologists from Spanish health centres was asked to estimate the mean annual resource use in the management of non-metastatic CRPC patients and in the first, second and subsequent years after developing BM. Hospital resources were stratified into four major categories: 1) general resources [medical visits, diagnostic and monitoring procedures, hospital admission and surgeries], 2) hormone therapy, 3) chemotherapy and 4) analgesic treatments. The last three categories included: drug costs, adverse event (AE) management-costs and pre-medication costs. Skeletal-related events (pathological fracture, radiation or surgery to bone and spinal cord compression) often suffered by BM patients were excluded from the analysis as Spanish cost-related data had recently been published. Unit costs (€, 2013) for each identified resource were obtained from a national cost-database. **RESULTS:** Total management-related annual costs for non-metastatic CRPC patients were €2,691.57; €978.51 were hormone therapy drug costs, €11.10 analgesics costs and €243.55 AE management costs. No chemotherapy was administered in these patients. Annual management cost for BM patients was €6,000.37 the first year, €14,468.35 the second year and €14,313.87 in subsequent years. Hormone therapy drug costs accounted for €946.67, €948.13 and €948.13 in the first, second and subsequent years, while chemotherapy costs accounted for €1,892.21 (32.2%); 9,485.41 (66.2%) and €9,143.92 (64.4%), respectively. Analgesic costs increased from €597.29 (first year) to €915.16 and €1,031.20 (second and subsequent years) and AE management costs increased from €595.63 (first year) to €758.58 (second year) and €732.14 (subsequent years). **CONCLUSIONS:** CRPC patients with BM had higher management costs than non-metastatic patients especially after the first year of treatment, which was mainly due to chemotherapy drug costs.

PCN79

ECONOMIC BURDEN OF TOXICITIES ASSOCIATED WITH ADVANCED MELANOMA TREATMENTS IN FRANCE, ITALY, THE NETHERLANDS, AND SPAIN

Bilir SP[1], Zhao Z[2], Wehler EA[3], Munakata J[1], Barber B[2]
[1]*IMS Health, San Francisco, CA, USA,* [2]*Amgen Inc, Thousand Oaks, CA, USA,* [3]*IMS Health, Alexandria, VA, USA*

OBJECTIVES: Little is known about costs of managing adverse events (AEs) associated with currently-available therapies in advanced melanoma. This study identifies and estimates the costs of these AEs in France (FR), Italy (IT), The Netherlands (NL), and Spain (ES). **METHODS:** A comprehensive literature search was conducted to identify common grade 3/4 AEs from product labels and published phase II/III advanced melanoma studies in PubMed, conference abstracts, and European treatment guidelines. Resource utilizations for the management of each type of AE in typical inpatient/outpatient treatment setting were determined via in-depth interviews with 5 melanoma clinicians in each country. Outpatient and inpatient 2012 costs were then estimated for each type of AE by applying country-specific tariffs, except in Spain where costs were obtained from government database or best published sources. **RESULTS:** Most frequent grade 3/4 AEs associated with chemotherapies included neutropenia, vomiting, and anemia. Vemurafenib was commonly associated with cutaneous squamous cell carcinoma (CSCC)/keratoacanthoma, rash, and

elevated liver enzymes, while dabrafenib was most often associated with CSCC and pyrexia. The most common AEs associated with trametinib were hypertension and rash. Common ipilimumab AEs were immune-related diarrhea/colitis, dyspnea, anemia, vomiting, and less frequently, hypophysitis. In the outpatient setting, the most costly AEs per incident included anemia (€1,431, €1,309, €1,276; ES, IT, FR) and CSCC (€1,058; NL). Other costly outpatient treatments include those for hypophysitis (€463, €449, €321; NL, ES, IT), febrile neutropenia (€593, €430; IT, ES), and CSCC (€483, €292; ES, IT). In the inpatient setting, the most costly AEs per hospitalization per country were hypophysitis (€10,189; ES), elevated liver enzymes (€6,868; FR), anemia (€2,826, €2,628; NL, IT). Additional inpatient treatments with high costs were diarrhea (€4,083; ES), neutropenia (€2,322; IT) and vomiting (€2,036; NL). **CONCLUSIONS:** Costs of managing AEs can be substantial, and effective new treatments with reduced AE profiles would be valuable.

PCN80

THE COST OF TREATING SQUAMOUS CELL CARCINOMA OF THE ANUS (SCCA) IN ENGLAND: RESULTS FROM AN EMPIRICALLY CALIBRATED MODEL

Keeping ST, Carroll SM

Sanofi Pasteur MSD, Maidenhead, UK

OBJECTIVES: Squamous cell carcinoma of the anus (SCCA) generally requires a number of complex interventions as part of a multidisciplinary approach to treatment. This research aimed to combine available data on disease progression and treatment in order to estimate the average cost of treating a case of SCCA in England. **METHODS:** Data on primary treatment, disease progression and follow-up were obtained from the Association of Coloproctology of Great Britain and Ireland's anal cancer position statement, supplemented by expert opinion where necessary. First, decision trees were constructed to estimate the costs of diagnosis, staging and primary treatment. A Markov model was then developed to simulate disease progression and follow-up based on the mode of primary treatment (combined modality therapy versus radiotherapy alone). Values for unknown parameters were jointly selected from within plausible ranges and model outputs for each simulation were then compared to empirical data on overall mortality and locoregional relapse. Goodness of fit was estimated using ordinary least squares. All costs applied to treatments and interventions were taken from the 2010/11 National Tariff, with the 2010/11 Reference Costs used for off tariff payments. A one-way sensitivity analysis was also performed. **RESULTS:** The cost of treating a case of SCCA was estimated to be in the range of £16,448-£16,630 when future inflation was taken into account, and £16,278-£16,455 when it was not. In the one-way sensitivity analysis, the adjusted value ranged between £14,309-£23,264 (unadjusted £14,139-£23,077), with the results most sensitive to changes in the mode of admission for primary treatment and the costs of staging/diagnosis. **CONCLUSIONS:** Despite limitations in the approach resulting from a lack of available data, these results indicate that the cost of treating SCCA is significant. Further observational work is required in order to verify these findings.

PCN81

ECONOMIC BURDEN OF TOXICITIES ASSOCIATED WITH ADVANCED MELANOMA TREATMENTS IN THE UNITED STATES

Bilir SP[1], Zhao Z[2], Wehler E[3], Munakata J[1], Barber B[2]

[1]*IMS Health, San Francisco, CA, USA,* [2]*Amgen Inc, Thousand Oaks, CA, USA,* [3]*IMS Health, Alexandria, VA, USA*

OBJECTIVES: Information on the costs of managing adverse events (AEs) associated with currently-available treatment regimens in advanced melanoma is limited. This study identifies treatment-related AEs associated with commonly-used regimens recommended in US guidelines, and estimates the costs of treating these AEs in the US. **METHODS:** Grade 3 and 4 AEs were identified by a comprehensive literature search of product labels and published English-language phase II/III advanced melanoma studies in PubMed, conference abstracts, and NCCN guidelines. In-depth interviews with 5 US melanoma clinicians were performed to obtain resource utilization and treatment setting information for managing each type of AE. Costs (2012$) were then estimated for each type of AE in outpatient and inpatient settings, using Medicare reimbursement rates for the outpatient setting, and Healthcare Utilization Project estimates for the inpatient setting. **RESULTS:** The most common grade 3 and 4 AEs associated with chemotherapy regimens included neutropenia, vomiting, and anemia. Cutaneous squamous cell carcinoma (CSCC)/keratoacanthoma, rash, and elevated liver enzymes were most common AEs associated with vemurafenib, while CSCC and pyrexia were most often associated with dabrafenib. The most common AEs associated with trametinib were hypertension and rash. Common ipilimumab AEs included immune-related diarrhea/colitis, dyspnea, anemia, and vomiting, and less frequent hypophysitis. The highest cost per incident in the outpatient setting among these AEs was neutropenia ($2,039), followed by CSCC ($369), vomiting ($342), and dyspnea ($222). The highest costs per hospitalization were for CSCC ($18,906), followed by hypophysitis ($15,721) and febrile/afebrile neutropenia ($11,125). Other costly AEs in the inpatient setting include hypertension ($8,113), diarrhea ($6,881), dyspnea ($6,826), vomiting ($6,046), anemia ($6,014), and elevated liver enzymes ($5,942). All hospitalizations due to AEs were more than $4,000 per incident. **CONCLUSIONS:** The costs of managing treatment-related AEs in advanced melanoma are considerable, and there is need for effective treatments with improved toxicity profiles.

PCN82

HEALTH ECONOMIC EVALUATION OF A COMPLEMENTARY BIOMARKER FOR HYPOTHETICAL PROSTATE CANCER SCREENING IN GERMANY

Meier F[1], Niederländer CS[2], Djanatliev A[3], Gantner-Bär M[3], Höllthaler J[4], Voigt W[4], Schöffski O[1], Kolominsky-Rabas PL[2], Emmert M[1]

[1]*Friedrich-Alexander-University Erlangen-Nuremberg, Nuremberg, Germany,* [2]*Centre for Health Technology Assessment (HTA) and Public Health (IZPH), University of Erlangen-Nuremberg, Erlangen, Germany,* [3]*University of Erlangen-Nuremberg, Erlangen, Germany,* [4]*Siemens AG, Erlangen, Germany*

OBJECTIVES: Prostate cancer (PCA) is the most common cancer in men worldwide. However, there is disagreement about the benefits of existing screening programs. This is mainly due to low specificity of currently utilized biomarkers. This can lead to both inappropriate medical treatment and increasing costs of care. For the future, many biotechnological developments are promising, but not all will be affordable for routine screening. The question is how much a complementary biomarker to prostate-specific antigen (PSA)-test may cost which would be applied to avoid false-positive results. **METHODS:** Conduct of a hybrid discrete-event and system-dynamics simulation by applying AnyLogic. Based on clinical guidelines and expert knowledge, a hypothetical PCA screening workflow was developed and supplemented by a proposed innovative biomarker. Demographic and patient behavior information, disease related data on incidence as well as sensitivity and specificity of PSA, digital-rectal examination and prostate biopsy were further implemented in the model. Economic consequences were calculated by considering costs for examinations, biopsy diagnosis and complications. **RESULTS:** In Germany, annual screening would be recommended for 18.8 million men aged ≥45 years. Assuming a biomarker specificity of 80%, approximately 70% of prostate biopsies could be avoided. This could lead to a reduction of biopsy caused complications. Regarding the latter, mean costs of 204.17€ were calculated. Due to prevented check-ups and biopsy-complications, cost neutrality for the supposed biomarker will be reached when applying a price of 48.50€. **CONCLUSIONS:** A complementary biomarker could lead to more precise diagnosis and additional value for patients and health insurance funds. Although the price may not be high, an implementation may nevertheless be feasible for companies due to the high number of examinations. Funded by the German Federal Ministry of Education and Research (BMBF) as part of the National Cluster of Excellence Medical Technology - Medical Valley EMN (Project grant No. 01EX1013B).

PCN83

RESOURCE USE AND COST OF DIAGNOSIS AND MANAGEMENT OF BREAST CANCER BY STAGE IN AN IRISH TEACHING HOSPITAL

Tierney P[1], Tilson L[2], Barry M[2], Bennett K[3]

[1]*National University of Ireland, Galway, Ireland,* [2]*National Centre for Pharmacoeconomics, Dublin, Ireland,* [3]*Trinity Centre for Health Sciences, Dublin, Ireland*

OBJECTIVES: To estimate the cost of diagnostic investigation and treatment for breast cancer in an Irish teaching hospital from a health payer perspective. **METHODS:** Retrospective population based resource utilisation data for n=611 patients treated for primary breast cancer in a university teaching hospital in Ireland were available for the period 2009-2011. Health care resource use included diagnostic investigations and all treatments. Unit costs for diagnosis & surgical procedures, laboratory tests, and radiotherapy were derived from DRG costs, hospital finance departments, clinical opinion and literature review. Chemotherapy costs were estimated from local hospital protocols, pharmacy departments and clinical opinion. Associated pharmaceutical cost, including oral hormonal therapy, were estimated from the HSE Primary Care Reimbursement Services claims database. Overall and mean costs by stage of breast cancer are presented with bootstrap 95% confidence intervals (CIs). **RESULTS:** Total cost of diagnosis, treatment and follow-up was estimated at €15.2 million over the 3 year period, with an average cost of €24,863 per patient (95% CI; €22,628, €27,197). Chemotherapy and other pharmaceuticals accounted for 47%, radiotherapy 19%, surgery 19%, diagnostics 5%, radiology 2% and follow-up 8% of total expenditure. The biological agent trastuzumab accounted for 43% of total pharmaceutical expenditure. Costs varied by stage at diagnosis. The average cost per patient by stage at diagnosis was estimated as follows; Stage 1 (n = 186) €23,821 (95% CI; €20,113, €27,846); Stage 2 (n=248) €24,919 (95% CI; €21,358, €28,626); Stage 3 (n=121) €30,172 (95% CI; €25,434, €35,366); Stage 4 (n=56) €16,570 (95% CI; €7,964, €25,836). **CONCLUSIONS:** This study demonstrates the value of using existing data from national and local databases in estimating the cost of diagnosis and management of breast cancer from a health payer perspective and highlights the impact of trastuzumab on overall costs.

PCN84

ANALYSIS OF PUBLIC AND PRIVATE HOSPITAL DATABASES (PMSI) 2010 / 2011 TO ESTIMATE THE FREQUENCY AND ASSOCIATED COSTS FOR FEBRILE NEUTROPENIA IN FRANCE

Vainchtock A[1], Cohen S[2], Durand-Zaleski I[3]

[1]*HEVA, LYON, France,* [2]*Amgen S.A.S., Neuilly-sur-Seine, France,* [3]*Hôpital Henri Mondor, Créteil, France*

OBJECTIVES: To estimate the frequency and costs of hospital stays for cancer patients receiving cytotoxic chemotherapies inducing febrile neutropenia (FN), in public and private hospitals in France. **METHODS:** The French Hospital National Database (PMSI) is a comprehensive claims database which includes information on diagnoses an procedures and allows record linkage. Hospital stays for patients admitted with hematologic or solid tumors in 2010/2011 were extracted and an *ad hoc*algorithm selected those for which the primary admission reason was FN, as well as those due to an infectious syndrome resulting from FN. Economic valuations were based on 2010 public national tariffs and National Scale Costs (ENCC). **RESULTS:** A total of 14,685 hospital stays were analyzed (3,776 stays for the treatment of hematologic tumors and 10,909 for solid tumors) corresponding to 10,721 patients treated for FN (2,386 patients first treated for hematologic tumor and 8,343 first treated for solid tumor). The proportions of patients hospitalized for FN were 12.2% for hematologic tumors and 7.0% for solid tumors. The average length of stay was 7 days for patients with hematologic tumors and 6.5 days for patients with solid tumors. In the sub analysis, non-Hodgkin's lymphoma (11.7%) and lung cancer (11.8%) were, respectively, the most common hematologic and solid tumor types in patients hospitalized for FN. The mean costs of treatments associated with FN per patient were 7,820.67€ for hematologic tumors, 4,907.83€ for solid tumors and, in the sub-analysis, 6,816€ for non-Hodgkin's lymphoma and 4,907€ for lung cancer. **CONCLUSIONS:** The PMSI is a useful source to estimate the treatment costs associated with FN in France. In 2010/2011, febrile neutropenia induced a total of 14,685 stays and a total cost of 59.6 million euros for the Statutory Health Insurance.

PCN85

THE ANALYSIS OF COSTS AND REIMBURSEMENTS FOR LUNG CANCER TREATMENT IN THE CZECH REPUBLIC

Rogalewicz V[1], Simrova J[2], Vojtisek R[3], Bartak M[4]

[1]*Czech Technical University in Prague, Kladno, Czech Republic,* [2]*University Hospital Plzen, Plzen - Lochotin, Czech Republic,* [3]*University Hospital Plzen, Plzen - Lochotin, Czech Republic,* [4]*J.E. Purkyně University, Usti nad Laben, Czech Republic*

OBJECTIVES: Lung cancer is the most frequently diagnosed oncologic disease worldwide, annually diagnosed in nearly 1.4 million patients. In 2010, the incidence in men was 89.7 per hundred thousand people (in 1996, it was 102.3), while in women 35.2 (against 22.9 in 1996). The severity of the disease is also reflected by the high mortality rate, which was 74.8 per hundred thousand people in men and 27.4 in women in 2010. **METHODS:** Identifying the costs spent by a clinic/hospital is difficult in the Czech Republic, as the majority of hospitals work with cost related data in the "confidential" mode. The costs were estimated and verified based on expert opinions of pulmonologists, oncologists, head physicians and staff members of technical and economic departments of five pneumo-oncologic centres and university hospitals in this study. **RESULTS:** Totally 32 procedures (process maps) were identified in lung cancer treatment (10 in diagnostic, 22 in therapeutic processes). Each procedure consists of diagnostics, therapy and subsequent monitoring of patients. Costs for respective steps were assessed, and total costs for each therapeutic scheme were calculated. **CONCLUSIONS:** The calculations imply that treatment costs significantly differ depending on the selected diagnostic/ therapeutic procedure. The setting of the reimbursement system generates different stimuli for providers who may reach both positive and negative balances. This fact may have an effect on economic results leading, in its consequence, to the preference of alternatives more suitable in terms of reimbursement regardless of the optimum procedures for a specific patient.

PCN86

TREATMENT PATTERNS AND COSTS ASSOCIATED WITH CHRONIC LYMPHOCYTIC LEUKEMIA CHEMOTHERAPY UNDER THE BRAZILIAN PRIVATE HEALTH CARE PERSPECTIVE: A RETROSPECTIVE ANALYSIS OF THE ORIZON DATABASE

Ferreira CN[1], Paloni EDMP[1], Asano E[2], Santana CFSD[1], Pereira ML[2]

[1]*ORIZON - Companhia Brasileira de Gestão de Serviços, Sao Paulo, Brazil,* [2]*Janssen-Cilag Farmaceutica, Sao Paulo, Brazil*

OBJECTIVES: To identify the chemotherapeutic treatment patterns and associated costs in patients with chronic lymphocytic leukemia (CLL) in the Private Healthcare System. **METHODS:** A retrospective analysis of the Orizon database, containing inpatient and outpatient claims data of a pool of 102 HMOs (34% of the total Private Health System), from January 2009 to December 2012 was conducted. Eligibility criteria were patients starting CLL (ICD-10 code C911) chemotherapy treatment from April 2009 to December 2012. This cohort of patients was followed until December 2012, death or loss of follow-up. Chemotherapy regimens were identified based on the agents reported in the claims. Line of treatment was defined based on meaningful interruption (>6 months) and/or change in the chemotherapy regimen. Descriptive statistics (average, standard deviation and percentage) of treatment regimens, duration of treatment and costs were performed. **RESULTS:** A total of 163 patients representing 859 cycles of chemotherapy met eligibility criteria; 43.6% of the patients underwent more than one line of treatment, with total chemotherapy costs of R$84,979.63 per patient. The three most widely used chemotherapy regimen were: fludarabine, cyclofosfamide and rituximab (FCR), used in 81 (54.9%) patients with average treatment duration of 3.54 cycles and total costs of R$69,241.91 per patient; rituximab monotherapy, used in 44 (27.0%) patients, with average treatment duration of 4.05 cycles and total costs of R$59,543.12 per patient; and fludarabine and cyclofosfamide (FC), used in 19 (11.7%) patients, with average duration of 2.22 cycles and total costs of R$7,075.95 per patient. Chemotherapy drugs accounted for 72.8% of the total costs, followed by other medicines (11%), disposable devices (5.5%) and hospital facility fees (5.0%). **CONCLUSIONS:** FCR is the standard of care in CLL patients treated in the Brazilian Private Health System, and almost half of the patients undergo more than one treatment line, creating a significant financial burden to private payers.

PCN87

COST OF CANCER IN THE AUSTRIAN HOSPITAL SETTING

Walter E[1], Said M[1], Bauer M[1], Gastl G[2], Samonigg H[3]

[1]*Institute for Pharmaeconomic Research, Vienna, Austria,* [2]*Medical University of Innsbruck, Innsbruck, Austria,* [3]*Medical University of Graz, Graz, Austria*

OBJECTIVES: In Austria, 38,000 people are yearly diagnosed with cancer, which is the world's leading cause of death (Austria: 19,547), followed by heart disease and stroke. Advances in early detection, prevention and treatment have led to decreasing cancer death and more favorable outcomes. Moreover, significant increases in the cost of cancer care have come in parallel with these advances. The cost factor related to modern cancer treatment is increasingly a matter of debate. Hence, the aim of the analysis was to evaluate the cost of cancer expressed as reimbursed lump-sums of the DRG system, number of inpatients stays and Length-of-Stay (LOS) in the inpatient setting to bring more transparency in the discussion and bridge the information-gap. **METHODS:** We performed a retrospective claim-based analysis with Austrian DRG-System (LKF Leistungsorientierte Krankenanstaltenfinanzierung) data. The DRG-System is based on ICD-10 codes. Payment consists of one or several case-based lump-sums. Our analysis included all cancer hospital admissions. The cost-evaluation is based on the refunded lump-sums of the DRG-System for the year 2011. **RESULTS:** In 2011, 353,883 inpatient stays with a diagnosis of cancer were monitored. Hospital stays due to cancer accounts for 14% of the entire inpatient stays in Austria. The average LOS in cancer patients was 4.35 days and was associated with average costs per stay of 3,730 Euros. Compared with the total number of admissions these numbers are below average (LOS: 5.43; costs per stay: 3,949 Euros). Furthermore, cancer patients received medical services to the value of 927 million Euro or 14.2% of total reimbursed lump-sums (6.53 billion Euros) in Austria. 224 million Euros fall upon medical tumour therapy. With regard to monoclonal antibody therapies, 56 million Euros was refunded. **CONCLUSIONS:** The current development in modern cancer therapies leads to efficient treatment pathways expressed in higher survival rates, reduced hospital days and an improved quality-of-life.

PCN88

COST-ANALYSIS IN THE TREATMENT OF PATIENTS AFFECTED BY MALIGNANT ASCITES IN ITALY

Teruzzi C[1], Mantuano M[1], Colombo GL[2], Bruno GM[3], Di Matteo S[3]

[1]*Temas. A Quintiles Company, Milan, Italy,* [2]*University of Pavia, Pavia, Italy,* [3]*S.A.V.E. Studi Analisi e Valutazioni economiche, Milan, Italy*

OBJECTIVES: The objective of this project was to identify the treatment cost of malignant ascites from the Italian NHS perspective through a cost-analysis. Three reference centers in Italy contributed to this study during year 2012. **METHODS:** Three centers (Scientific Institute of Romagna for Cancer Studies and Treatment-I.R.S.T; Medical Oncology Unit of San Gerardo Hospital; Department of Gynecology of University Hospital Agostino Gemelli) were chosen due to the fact that they treat a representative sample of patients with malignant ascites in Italy. Each center was asked to complete three case report forms: the first identifying the costs for the pre-procedure diagnostic tests, the second identifying the specific procedure costs (paracentesis) and the third identifying the specific costs due to treatment of complications. All these reports had to be completed for the last 5 patients diagnosed with malignant ascites in order to prevent selection bias. A total cost for each patient was calculated by DRG analysis (standard cost – tariff). The DRG analysis assessed: day hospital, admission number, hospitalization, number of hospitalization days, principal diagnosis, main procedure/intervention, number of paracentesis procedures performed on the same patient with the same diagnosis, DRG type, DRG code, refund value for day hospital/ refund value for ordinary hospitalization. **RESULTS:** The analysis shows an average cost of € 1,464.42 per patient with malignant ascites using the DRG reimbursement rate (minimum value: €1,405.63; maximum value: €1,525.37). Analysis using DRG with complications resulted in a mean value of €1,524.84 (minimum value: €1,429.69; maximum value: €1,625.55). The key cost driver of malignant ascites treatment was the paracentesis procedure. **CONCLUSIONS:** The economic impact of paracenteses is high, especially when procedures must be repeated. The reduction in the number of paracenteses could reduce the costs while improving the QoL of the patients.

PCN89

ECONOMIC EVALUATION OF AN ELECTRICAL IMPEDANCE SPECTROSCOPY (EIS) DEVICE USED AS AN ADJUNCT TO COLPOSCOPY

Bessey A, Whyte S, Minton J, Chilcott J

University of Sheffield, Sheffield, UK

OBJECTIVES: Colposcopy is an essential part of the screening process for the prevention of cervical cancer by diagnosing and treating precancerous lesions known as cervical intra-epithelial neoplasia (CIN). The objective of this study was to assess the cost and health impact of using an electrical impedance spectroscopy (EIS) device to aid in the diagnosis of precancerous lesions compared to standard colposcopy. A threshold for the EIS device that resulted in a similar sensitivity and higher specificity than standard colposcopy was used. **METHODS:** Two models to assess the cost and health impacts were developed; a short term model representing the initial colposcopy treatment pathway and a longer term Markov model that included colposcopy follow-up. Sensitivity and specificity of colposcopy were derived from the EpiCIN trial of the EIS device. Two referral thresholds were defined in the analysis, the threshold for 'See and Treat' on colposcopic impression alone (CI) and a lower threshold for referral for biopsy to determine disease presence (DP) prior to treatment. Costs of colposcopy were estimated using data from Sheffield Teaching Hospitals. Different colposcopy clinic scenarios were modelled to represent the different ways colposcopy clinics manage patients. Health related quality of life (HRQoL) decrements were applied for colposcopy, biopsy and treatment. One-way sensitivity analyses were also conducted. **RESULTS:** The analysis suggests that the use of the EIS device can result in fewer biopsies being taken, a reduction in overtreatment with an associated small improvement in HRQoL, and a lower colposcopy cost per woman with CIN2+ treated for some colposcopy clinic scenarios. The results are sensitive to changes in colposcopy costs. **CONCLUSIONS:** The use of the EIS device with a higher specificity and similar sensitivity to standard colposcopy has the potential to lead to a reduction in the colposcopy cost per woman with CIN2+ treated for some clinic scenarios.

PCN90

ESTIMATION OF THE EPIDEMIOLOGICAL AND ECONOMIC IMPACT OF THE QUADRIVALENT HPV VACCINATION IN GIRLS AND BOYS IN SPAIN

Bosch X[1], Cortés Bordoy J[2], Gil de Miguel A[3], López Belmonte JL[4], Bresse X[5], Serip S[6], Nieves D[6]

[1]*Catalan Institute of Oncology, Barcelona, Spain,* [2]*Gynaecological Oncology Centre, Palma de Mallorca, Spain,* [3]*Universidad Rey Juan Carlos, Alcorcon, Spain,* [4]*Sanofi Pasteur MSD, Madrid, Spain,* [5]*Sanofi Pasteur MSD, Lyon, France,* [6]*Oblikue Consulting, Barcelona, Spain*

OBJECTIVES: To estimate the epidemiological and economic benefits of a quadrivalent HPV vaccination in girls and boys compared with vaccination only in girls in Spain. **METHODS:** A population-based compartmental dynamic transmission model of HPV developed in the US was partially adapted to the Spanish setting updating epidemiological data of HPV related diseases, the vaccination coverage and direct costs of the diseases. The analysis was performed from the National Health System (NHS) perspective. The strategy of cervix cancer screening (CCS) and vaccination of only girls from 11 to 26 years (S1) was compared to CCS and vaccination of girls and boys from 11 to 26 years (S2) with the quadrivalent vaccine. Assuming the duration of protection against vaccine HPV types is lifetime, the results over a 100-year time horizon, were estimated applying a discount of 3% on costs. In order

to assess the uncertainty on the parameters, univariate sensitivity analyses were performed. **RESULTS:** At 100 years, compared to only screening for cervix cancer, S2 scenario reduced 73% of the genital warts cases, 92% of the cancer cases in women and 87% of the cancer cases in men; while S1 strategy only reduced 56%, 87% and 63% the cases of the different diseases, respectively. S2 strategy was less costly compared with S1: during the first 10 years reduced more than €25 million for the NHS and more than €282 million over 100 years. The savings over 100 years varied between €141 million and €1,268 million when considering a 5% or 0% discount, respectively. **CONCLUSIONS:** Vaccinating boys and girls between 11 and 26 years would significantly reduce the epidemiological and economic burden of HPV related diseases in Spain.

PCN91

COMPARATIVE COST-CONSEQUENCE ANALYSIS OF THE BIVALENT AND QUADRIVALENT VACCINES AGAINST HPV IN SPAIN

López Belmonte JL[1], Cortés Bordoy J[2], Gil de Miguel A[3], Bresse X[4], Serip S[5], Nieves D[5], Bosch X[6]

[1]*Sanofi Pasteur MSD, Madrid, Spain,* [2]*Gynaecological Oncology Centre, Palma de Mallorca, Spain,* [3]*Universidad Rey Juan Carlos, Alcorcon, Spain,* [4]*Sanofi Pasteur MSD, Lyon, France,* [5]*Oblikue Consulting, Barcelona, Spain,* [6]*Catalan Institute of Oncology, Barcelona, Spain*

OBJECTIVES: To compare the impact of the quadrivalent (QV) (HPV 6/11/16/18) and bivalent (BV) (HPV 16/18) vaccines against HPV in Spain. **METHODS:** A population-based compartmental dynamic transmission model of HPV developed in the US was partially adapted to Spain updating epidemiological data of HPV related diseases, the vaccination coverage and direct costs of the diseases. The reduction of the number of cases related to HPV and savings associated with the following strategies were compared: A) cervix cancer screening (CCS) of women between 25-65 years, every 3-5 years and a vaccination program of girls between 11-26 years with the QV vaccine; B) CCS+BV vaccine. The analysis was performed from the National Health System (NHS) perspective, costs were discounted by 3% and the time horizon was 100 years. Univariate sensitivity analyses were performed to assess the uncertainty on the parameters. **RESULTS:** At 100 years, considering the current indications of the vaccines, lifetime protection against HPV vaccine types and 20 years of cross-protection, both strategies reduced 208 cases of vulvar and vaginal cancers and 22,796 cases of CIN2+. The strategy CCS+QV vaccine reduced 18,689 additional cases of genital warts due to the protection against 6/11 HPV types, but 4 less cases of cervix cancer and 359 less cases of CIN2+ due to better cross-protection of the BV vaccine. Nevertheless, savings accumulated during 100 years due to the reduction of genital warts cases (€215.7 million) compensated the cost associated to cervix cancers and CIN2+ that the BV vaccine additionally reduced (€3 and €27.1 million, respectively). Therefore, during 100 years the QV vaccine saves €185.4 million more than the BV vaccine. The sensitivity analyses confirmed the stability of the results. **CONCLUSIONS:** The QV vaccine provides higher cost savings to the NHS compared to the BV vaccine due to the additional efficacy against HPV 6/11 types.

PCN92

ONE LINE DOES NOT MAKE A PICTURE: REAL-WORLD COST-EFFECTIVENESS OF MULTIPLE MYELOMA TREATMENTS USING A FULL DISEASE MODEL

Blommestein H[1], Verelst S[2], de Groot S[1], Huijgens P[3], Sonneveld P[4], Uyl-de Groot C[1]

[1]*Erasmus University, Rotterdam, The Netherlands,* [2]*Erasmus MC, Rotterdam, The Netherlands,* [3]*VU University Medical Center, Amsterdam, The Netherlands,* [4]*Erasmus University Medical Center, Rotterdam, The Netherlands*

OBJECTIVES: As with many types of cancer, treatment of multiple myeloma (MM) is characterised by sequential treatment lines consisting of innovative expensive drugs such as thalidomide, bortezomib and lenalidomide. While cost-effectiveness of single treatments has been studied, a full disease model evaluating treatments sequentially is currently lacking, consequently, high uncertainty exists on incremental cost-effectiveness ratios. Therefore, we aimed to take a look at the big picture and calculate real-world costs and effects for commonly used treatment pathways for MM. **METHODS:** We developed a patient-level simulation (PLS) for elderly (>65) MM patients diagnosed since 2004. Real-world data (N=621) including patient and disease characteristics, treatment information as well as resource use was collected from hospital registrations and medical files. Five treatment categories per line were observed resulting in 19 commonly used treatment pathways. Parametric survival models including patient characteristics such as age, performance status, comorbidities and laboratory values were used to predict time to an event, i.e. the start of a new treatment or death. Logistic regression determined which of the two competing events occurred. The sensitivity of parameters was explored through sensitivity analyses. **RESULTS:** In total, the costs and effects of 19 treatment pathways were calculated. Depending on the treatment sequencing, total costs ranged from €40,810 (Melphalan/Prednison-Thalidomide-Other) to €132,613 (Bortezomib-Lenalidomde-Other) while overall survival ranged from 28 to 50 months for Bortezomib-Lenalidomide-Thalidomide and Lenalidomide-Bortezomib-Other, respectively. Costs per quality-adjusted-life-year (QALY) were between €21,881 (Melphalan/Prednison-Thalidomide-Other) and €57,743 (Bortezomib-Lenalidomide-Other). Compared to real-world prescription, QALYs could be increased at a cost of €33,785 per QALY (Lenalidomide-Thalidomide-Other). **CONCLUSIONS:** The cost-effectiveness of 19 treatment pathways for MM patients was calculated and revealed that real-world treatment could be improved at a cost of €33,785 per QALY. Our PLS model proved to be a reliable and robust approach to study entire treatment pathways for MM.

PCN93

COMPARATIVE EFFECTIVENESS OF CONSERVATIVE THERAPY VERSUS CYSTECTOMY FOR NON-MUSCLE INVASIVE BLADDER CANCER PATIENTS

Dinh T

Archimedes Inc., San Francisco, CA, USA

OBJECTIVES: Non-muscle invasive bladder cancer (NMIBC) is a complex disease with wide variation in risks of recurrence and progression, treatment efficacy and complications, and patient co-morbidities. To assist in medical decision making from clinical and cost perspectives, we have developed a simulation model that synthesizes the evidence on NMIBC using the Archimedes Model platform. **METHODS:** The NMIBC model consists of a patient generation component in which virtual patients are constructed from SEER case listings; a natural history component that captures recurrence, progression, and bladder cancer mortality; a health care component that captures the effects of treatments, tests, and surveillance; and a cost component that tracks the costs relevant to bladder cancer care. Using this model, we performed a 5-year virtual clinical trial of 350 NMIBC patients with demonstrated Bacillus Calmette-Guerin failure, randomized to either immediate cystectomy or conservative treatment with Mitomycin C (MMC) intravesical therapy. The model is integrated within the Archimedes Model platform, which captures the effects of both NMIBC and patient co-morbidities. This model, validated against 5 published studies, gives recurrence and progression rates within ±20% of published results. **RESULTS:** The virtual clinical trial shows a 5-yr cystectomy rate of 51% in the MMC arm, with an average delay to cystectomy of 0.84 yr (median 0.44 yr). The immediate cystectomy arm saves 0.26 life years (LY) and $5598 in total bladder cancer cost per patient compared to the MMC arm. **CONCLUSIONS:** We have constructed a dynamic, quantitative model of NMIBC that can predict clinical and economic outcomes and help optimize treatment and surveillance guidelines. The virtual clinical trial quantifies LY and cost outcomes for immediate cystectomy versus conservative therapy, and provides a valuable tool for trial design and health economic analyses.

PCN94

THE COST-EFFECTIVENESS OF BENDAMUSTINE-RITUXIMAB VERSUS FLUDARABINE-RITUXIMAB FOR PATIENTS WITH INDOLENT NON-HODGKIN'S LYMPHOMA (INHL) WHO HAVE PROGRESSED FOLLOWING TREATMENT WITH RITUXIMAB OR A RITUXIMAB-CONTAINING REGIMEN IN COLOMBIA

Bertwistle D[1], Munakata J[2], Wehler E[3], Leyva V[4], Ariza JG[5], Zambrano C[5], Gonzalez L[6]

[1]*IMS Health, London, UK,* [2]*IMS Health, San Francisco, CA, USA,* [3]*IMS Health, Alexandria, VA, USA,* [4]*IMS Health, Mexico City, Mexico,* [5]*Janssen Cilag, Bogotá, Colombia,* [6]*Janssen, Raritan, NJ, USA*

OBJECTIVES: To determine the cost-effectiveness of bendamustine-rituximab (Ben-R) versus fludarabine-rituximab (Fdb-R) in patients with iNHL who have progressed following treatment with rituximab or a rituximab-containing regimen in Colombia. **METHODS:** An economic model was constructed from the Colombian health system perspective, with a 35-year (lifetime) horizon and a discount rate of 3%. The model included three health states, progression-free (PF), progressive disease (PD), and death, which were associated with utility weights of 0.81, 0.62 and 0, respectively. Clinical inputs (response rates, Kaplan-Meier curves, hazard ratios (HRs) and adverse event rates) were from the Stil NHL 2-2003 study. Resource use data were from interviews with three Colombian hematologists treating iNHL patients. Unit costs were from ISS and SISPRO report and were expressed as 2013 Colombian Pesos. Univariate and probabilistic sensitivity analyses were conducted to determine the key drivers of cost-effectiveness, and uncertainty around the results, respectively. **RESULTS:** Total lifetime cost of Ben-R was $291,192,912 and total cost of Fdb-R was $260,463,392. Ben-R patients accrued more LYs (6.47 vs. 5.15), QALYs (4.66 vs. 3.56), and PFLYs (3.57 vs. 2.05) compared to Fdb-R patients. The ICERs were $23,286,360 (cost per LY), $27,956,124 (cost per QALY) and $20,259,063 (cost per PF LY). Univariate sensitivity analysis revealed that the ICER per LY was most sensitive to the PFS and OS HRs for Ben-R vs Fdb-R, the number of treatment cycles, and the cost of bendamustine. Probabilistic sensitivity analysis with 1,000 iterations estimated that Ben-R had a 52% chance of being cost-effective, compared to Fdb-R, at a willingness to pay (WTP) of $59M per LY, rising to a plateau of about 93% at a WTP of $175M and above. **CONCLUSIONS:** At a willingness-to-pay of $59M (three times the GDP per capita of Colombia) Ben-R is a cost-effective alternative to Fdb-R.

PCN95

COST-EFFECTIVENESS OF THE OPTICAL IMAGING AGENT HEXAMINOLEVULINATE FOR PATIENTS WITH NON-MUSCLE INVASIVE BLADDER CANCER

Marteau F[1], Kornowski A[1], Bennison C[2], Tempest MJ[2], Mariappan P[3], Witjes JA[4]

[1]*Ipsen Pharma SAS, Boulogne-Billancourt, France,* [2]*Pharmerit Ltd., York, UK,* [3]*Western General Hospital, Edinburgh, UK,* [4]*Radboud University Medical Centre, Nijmegen, The Netherlands*

OBJECTIVES: Hexaminolevulinate (HAL) is an optical imaging agent used as an adjunct to white light cystoscopy (WLC) in the diagnosis and management of non-muscle invasive bladder cancer (NMIBC). The objective of this study was to model the cost-effectiveness of HAL-assisted blue light cystoscopy (HAL-BLC) compared to WLC alone when used at initial transurethral resection of bladder tumours (TURB) from the perspective of the National Health Service (NHS) in England and Wales using available clinical data. **METHODS:** A two-part model was developed to estimate the incremental cost-effectiveness of HAL-BLC at initial TURB for patients positively diagnosed in the outpatient setting with NMIBC over a lifetime horizon. This consisted of a short-term decision tree, which estimated the outcome of the outpatient diagnostic procedure and inpatient TURB, and a Markov cohort model, used to extrapolate long term outcomes. Clinical effectiveness evidence on recurrence was taken from a recent meta-analysis of NMIBC with HAL-BLC, costs were derived from NHS reference costs, and utilities and disease evolution were from the literature. **RESULTS:** Despite additional treatment and equipment costs, base case results suggest that HAL-BLC is a dominant strategy as an adjunct to WLC compared to WLC only, when used at initial TURB for patients diagnosed with NMIBC. HAL-BLC is expected to be associated with 0.060 incremental QALYs and cost-savings of £391 per patient resulting from fewer recurrences and fewer associated surgical procedures (33 avoided TURBs/149 positively-diagnosed patients), in turn due to improved completeness of lesion resection and better tumour staging. Probabilistic sensitivity analyses indicated that HAL-BLC was dominant in 91.9% of iterations. **CONCLUSIONS:** HAL-BLC as an adjunct to WLC was shown to be a domi-

nant strategy over WLC alone when used at initial TURB for patients diagnosed with NMIBC in England and Wales, with improved patient outcomes and cost-savings expected to offset investment in HAL.

UNCERTAINTY AND COST-EFFECTIVENESS ANALYSIS OF THE SEQUENTIAL APPLICATION OF TYROSINE KINASE INHIBITORS FOR THE TREATMENT OF CHRONIC MYELOID LEUKEMIA

Rochau U[1], Sroczynski G[1], Wolf D[2], Schmidt S[3], Jahn B[4], Conrads-Frank A[4], Stenehjem D[5], Brixner D[6], Radich J[7], Gastl G[3], Siebert U[8]

[1]*UMIT - University for Health Sciences, Medical Informatics and Technology/ ONCOTYROL - Center for Personalized Cancer Medicine, Hall in Tyrol/ Innsbruck, Austria,* [2]*Medical University Innsbruck/ University of Bonn, Innsbruck/ Bonn, Austria,* [3]*Medical University Innsbruck, Innsbruck, Austria,* [4]*UMIT - University for Health Sciences, Medical Informatics and Technology, Hall in Tyrol, Austria,* [5]*University of Utah/ University of Utah Hospitals & Clinics, Salt Lake City, UT, USA,* [6]*UMIT - University for Health Sciences, Medical Informatics and Technology/ ONCOTYROL - Center for Personalized Cancer Medicine/ University of Utah, Hall in Tyrol/ Salt Lake City, UT, Austria,* [7]*Fred Hutchinson Cancer Center, Seattle, WA, USA,* [8]*UMIT – University for Health Sciences, Medical Informatics and Technology / ONCOTYROL / Harvard University, Hall i. T./ Innsbruck / Boston, Austria*

OBJECTIVES: Currently, there are several tyrosine kinase inhibitors (TKI) approved for the treatment of chronic myeloid leukemia (CML). The aim of our study was to evaluate the long-term cost-effectiveness of different therapy regimens for CML focusing on the evaluation of the uncertainty using probabilistic sensitivity analysis (PSA). **METHODS:** We performed a cost-effectiveness analysis using a state-transition Markov model. The model evaluates seven treatment strategies including different combinations of TKIs as well as chemotherapy or stem cell transplantation. For model parameters, we used published trial data, and Austrian clinical, epidemiological, and economic data from the Austrian CML registry, statistical and economic databases. We performed a cohort simulation over a lifelong time horizon, adopted a societal perspective with an annual 3% discount rate. We conducted extensive uncertainty analyses and contrasted different methodological approaches to define parameter uncertainty distributions from our source data. We compared the base-line derived from the mean parameter values with the mean outcomes of all PSA scenarios. **RESULTS:** In the base-case efficiency frontier, nilotinib without second-line TKI resulted in an ICUR (1) of 118,600 €/QALY compared to the baseline strategy imatinib without second-line TKI. Imatinib followed by nilotinib after failure yielded an ICUR (2) of 123,900 €/QALY compared to nilotinib without second-line TKI. Nilotinib followed by dasatinib after failure resulted in an ICUR (3) of 149,400 €/QALY compared to imatinib followed by nilotinib after failure. The remaining strategies were excluded due to absolute or extended dominance. The PSA resulted in ICURs of (1) 116,200 €/QALY (2) 130,300 €/QALY and (3) 130,300 €/QALY. **CONCLUSIONS:** Based on our analysis, we recommend imatinib followed by nilotinib as the most cost-effective treatment strategy including a second-line TKI. Mean results from PSA show only small deviation from the base-case analysis. When new path to cure data are available, results will need to be updated.

PCN97

A SYSTEMATIC REVIEW AND CRITICAL APPRAISAL OF ECONOMIC EVALUATIONS OF RADIOTHERAPY FOR CANCER

Barbieri M[1], Weatherly H[1], Sculpher MJ[1], Ara R[2], Basarir H[2]

[1]*Centre for Health Economics, York, UK,* [2]*University of Sheffield, Sheffield, UK*

OBJECTIVES: To review published cost-effectiveness studies which evaluate radiotherapy in individuals with breast, cervical, colorectal, head and neck, or prostate cancer. To compare the economic methods used with the guidelines used in the appraisal programme for the National Institute of Health and Care Excellence (NICE) in the UK. **METHODS:** Systematic searches of seven databases (Medline, EMBASE, CDSR, NHSEED, HTA, DARE and EconLit) were conducted in July 2012. In addition, research registers, the NICE website and conference proceedings were searched. Studies that reported results of economic evaluations of radiotherapy interventions in terms of incremental quality adjusted life-years or life-years for individuals diagnosed with cancers were included. The quality of these studies was assessed in terms of meeting, essential, preferred and UK NICE-specific requirements for economic evaluations. **RESULTS:** Twenty-nine studies satisfied the inclusion criteria (breast=14, colorectal=2, prostate=10, cervical=0, head and neck=3). The majority (13) of the studies were set in the US with just 2 conducted in the UK. Considering essential methodological criteria, only 3 (10%) studies used estimates for clinical effectiveness which were identified by systematic literature review. Just a quarter (8/29) used health related quality of life data from patients with the particular cancers. While the majority of studies used one-way sensitivity analyses, only a third (10/29) reported the results of a full probabilistic sensitivity analysis. Additional essential criteria such as the use of an appropriate horizon, a clear description of both the comparators and the patient group indication were generally satisfied. However, as only 2 of the studies were conducted in the UK, the majority of the UK NICE specific requirements were not met. **CONCLUSIONS:** This review indicates there is little robust evidence of the cost-effectiveness of radiotherapy interventions in these cancers and very little evidence which could be used to support decision making in the UK.

PCN98

SELECTIVE INTERNAL RADIOTHERAPY (SIRT) USING RESIN YTTRIUM-90 MICROSPHERES FOR CHEMOTHERAPY-REFRACTORY METASTATIC COLORECTAL CANCER: AN ITALIAN COST-EFFECTIVENESS ANALYSIS

Cosimelli M[1], Golfieri R[2], Pennington B[3], Sennfält K[4]

[1]*Regina Elena National Cancer Institute, Rome, Italy,* [2]*Sant'Orsola-Malpighi Hospital, Bologna, Italy,* [3]*BresMed, Sheffield, UK,* [4]*Sirtex Medical Limited, North Sydney, Australia*

OBJECTIVES: SIRT using resin microspheres of yttrium-90 can be used to treat liver metastases resulting from colorectal cancer (CRC). A retrospective cohort study found a survival advantage from SIRT compared to standard care in chemotherapy-refractory patients. This study was used in combination with other sources to model the cost-effectiveness of SIRT vs best supportive care (BSC) in this indication. **METHODS:** A state-transition model was developed, with three health states, based on survival outcomes from a retrospective cohort study in chemotherapy-refractory mCRC comparing yttrium-90 resin microspheres (SIR-Spheres; Sirtex, Sydney, Australia) *vs.* BSC. The model was developed from the perspective of the National Health Service in Italy. The model included costs for treatment acquisition, pre-treatment work-up and delivery of microspheres, and chemotherapy received in addition to, instead of, or after, SIRT. In addition costs of managing AEs and a cost of death were included. Costs were obtained from the University Hospital in Bologna, Agenzia Italiana del Farmaco, and the literature. Utility data was not available from the study, so was taken from a recent NICE economic evaluation in the same indication. **RESULTS:** SIRT increased survival resulting in a life-year gain of 1.35 (2.12 vs 0.98) life years and a quality-adjusted life year (QALY) gain of 0.83 (1.52 vs 0.70). The costs of SIRT, monitoring and further treatment were greater in the SIRT arm with partial cost-offset through a reduction in adverse events. Overall, SIRT lead to an increase in costs of €24,626 (€39,973 vs €15,347), resulting in a cost/QALY of €29,850. Probabilistic sensitivity analysis showed a 97% chance of SIRT being cost-effective at a threshold of €50,000/QALY. **CONCLUSIONS:** The analysis demonstrates that SIRT using resin yttrium-90 microspheres has the potential of being a cost-effective option in the treatment of patients with chemotherapy-refractory liver metastases resulting from colorectal cancer.

PCN99

THE COST-EFFECTIVENESS OF BENDAMUSTINE VERSUS FLUDARABINE FOR THE FIRST-LINE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN MEXICO

Bertwistle D[1], Munakata J[2], Wehler E[3], Leyva V[4], Valencia A[5], Hernandez A[5], de la Torre L[5], Gonzalez L[6]

[1]*IMS Health, London, UK,* [2]*IMS Health, San Francisco, CA, USA,* [3]*IMS Health, Alexandria, VA, USA,* [4]*IMS Health, Mexico City, Mexico,* [5]*Janssen, Mexico City, Mexico,* [6]*Janssen, Raritan, NJ, USA*

OBJECTIVES: To determine the cost-effectiveness of bendamustine versus fludarabine for the first line treatment of CLL in Mexico. **METHODS:** An economic model was constructed from the Mexican public payer perspective, with a 25-year (lifetime) horizon and a discount rate of 5%. The model included three health states, progression-free (PF), progressive disease (PD), and death. Clinical inputs (Kaplan-Meier curves, response rates, hazard ratios (HRs) and adverse event (AE) rates were from a phase 3 trial comparing bendamustine and chlorambucil, and from a network meta-analysis. Resource use data were from interviews with Mexican hematologists treating CLL. Resource use for PF patients was weighted based on treatment response. Unit costs were obtained from Mexican Social Security Institute (IMSS) and were expressed in 2013 Mexican Pesos. Univariate and probabilistic sensitivity analyses were conducted to determine the key drivers of cost-effectiveness, and the uncertainty around the results, respectively. **RESULTS:** Total lifetime costs for bendamustine and fludarabine were $660,796 and $536,068, respectively. Bendamustine patients accrued more LYs (6.83 vs. 5.98), QALYs (5.13 vs. 4.25), and PF LYs (2.97 vs. 1.13) compared to fludarabine patients. The ICERs were $146,848 (cost per LY), $142,853 (cost per QALY) and $67,647 (cost per PF LY). Univariate sensitivity analysis revealed the cost per LY ICER was most sensitive to number of bendamustine cycles, the PFS for bendamustine vs. chlorambucil and the cost of bendamustine. Probabilistic sensitivity analysis with 1,000 iterations predicted bendamustine had a 48% chance of being cost-effective, compared to fludarabine, at a willingness to pay (WTP) of $125,000. **CONCLUSIONS:** At a WTP of $125,000 (GDP per capita of Mexico) bendamustine is cost effective versus fludarabine.

PCN100

COST-EFFECTIVENESS OF INDUCTION TREATMENT WITH BORTEZOMIB ADDED TO THALIDOMIDE AND DEXAMETHASONE IN NEWLY DIAGNOSED MULTIPLE MYELOMA PATIENTS ELIGIBLE FOR AUTOLOGOUS STEM CELL TRANSPLANTATION IN GERMANY

van Beurden-Tan C[1], Rosiñol L[2], Diels J[3], Wirth D[4], Chirita O[5], Lahuerta JJ[6], Gaugris S[5], Marsh S[5], San Miguel J[7], Spencer M[5], Treur M[1], Bladé J[2]

[1]*Pharmerit International, Rotterdam, The Netherlands,* [2]*Hospital Clínic de Barcelona, Barcelona, Spain,* [3]*Janssen Pharmaceutica, Beerse, Belgium,* [4]*Janssen, Neuss, Germany,* [5]*Janssen, High Wycombe, UK,* [6]*Hospital Universitario 12de Octubre, Madrid, Spain,* [7]*Hospital Clínico Universitario de Salamanca, Salamanca, Spain*

OBJECTIVES: To estimate the cost-effectiveness of bortezomib, thalidomide, and dexamethasone (VTD) induction therapy, versus TD alone in newly diagnosed multiple myeloma (ndMM) patients eligible for autologous stem cell transplantation (ASCT) in Germany. **METHODS:** A life-time Markov model with monthly cycles is used to model disease progression and generate cost per quality-adjusted life years (QALY). It includes five health states; four of which are related to the lines of treatment, and death. Patients enter the first line state at randomisation and receive induction usually followed by ASCT. Patients can move to the next line upon progression or die within a line, until they enter the final (4+) line where they remain until death. Transition probabilities are derived from multi-state survival analysis of patient level data from the PETHEMA-trial for first line, the APEX-trial for second and third line, and an observational data set (eVOBS) for further lines. The model uses ASCT and time dependent utilities from the literature and trial estimated grade ≥3 adverse events (AEs) associated disutilities to calculate the QALYs. Cost estimates related to treatments, transplant and AEs are based on German specific sources. A payer's perspective is chosen. Discount rates of 3% for both cost and utilities are applied. **RESULTS:** Total life years of 6.38 VTD and 5.06 for TD with first line duration of 50.47 versus 32.85 months respectively. Incremental costs of VTD versus TD are 22,179€ [95%CI:6,950€;33,528€] and incremental QALYs are 0.72 [95%CI:0.33;1.20], resulting in an ICER of €30,655 per QALY gained. The univariate analyses show that the model is most sensitive

to induction cost and percentage transplants. At a willingness-to-pay threshold of 35,000€ per QALY gained, VTD has a 57.1% probability to be cost-effective in this setting. **CONCLUSIONS:** VTD induction is a cost-effective strategy for ndMM patients eligible for ASCT in Germany compared to TD.

PCN101

A COST-EFFECTIVENESS ANALYSIS OF CISPLATIN PLUS PEMETREXED DOUBLET INDUCTION TREATMENT FOLLOWED BY PEMETREXED MAINTENANCE COMPARED WITH BEVACIZUMAB PLUS CISPLATIN PLUS GEMCITABINE TRIPLET INDUCTION TREATMENT FOLLOWED BY BEVACIZUMAB MAINTENANCE FOR NON-SQUAMOUS NSCLC IN SWEDEN

Bryden PA[1], Kumar G[1], Winfree KB[2], Boye ME[2], Taipale K[3], Thompson R[4], Borgeke H[5]
[1]*Oxford Outcomes Ltd., Oxford, UK,* [2]*Eli Lilly and Company, Indianapolis, IN, USA,* [3]*Eli Lilly and Company, Helsinki, Finland,* [4]*Eli Lilly and Company, Windlesham, Surrey, UK,* [5]*Eli Lilly and Company, Stockholm, Sweden*

OBJECTIVES: This analysis compares the cost effectiveness (CE) of an induction and maintenance sequence of a cisplatin plus pemetrexed (cis+pem) doublet followed by pemetrexed, with that of a bevacizumab (7.5mg or 15mg) plus cisplatin plus gemcitabine (bev+cis+gem) triplet followed by bevacizumab (7.5mg or 15mg) for the treatment of non-squamous non-small cell lung cancer (NSCLC) in Sweden. **METHODS:** As no head-to-head trial data are available comparing these relevant regimens in the first-line induction and maintenance treatment settings, decision modelling and evidence synthesis were used to estimate CE. A series of network meta-analyses were performed to obtain hazard ratios for overall survival (OS) and progression-free survival (PFS) for each induction and maintenance comparator, and odds ratios for response for induction comparators. Bevacizumab doses were pooled in the meta-analyses. The CE model was structured using an area-under-the-curve approach. Costs and benefits were discounted at 3% per annum, consistent with Swedish practice. **RESULTS:** Cis+pem induction followed by pemetrexed maintenance was associated with a higher median PFS, OS, total life-years gained and quality-adjusted life-years (QALYs) than the bevacizumab triplets. Total costs were 416,478Kr for the bev(7.5mg)+cis+gem induction triplet plus bevacizumab 7.5mg maintenance sequence, 478,862Kr for the cis+pem doublet followed by pemetrexed maintenance sequence, and 541,677Kr for the bev(15mg)+cis+gem induction triplet followed by bevacizumab 15mg maintenance sequence. Total QALYs were 0.73 and 0.97 for the bevacizumab triplets and pemetrexed induction and maintenance sequence. The incremental cost-effectiveness ratio (ICER) of cis+pem followed by pemetrexed compared with bev(7.5mg)+cis+gem followed by bevacizumab 7.5mg was 260,831Kr (30,477Euro). The higher bevacizumab dose of 15mg was dominated by the cis+pem followed by pemetrexed sequence. The results of the probabilistic analysis support these results. **CONCLUSIONS:** The results of the CE analysis suggest that cis+pem doublet induction followed by pemetrexed maintenance is a cost-effective treatment sequence compared with the bevacizumab options for NSCLC in Sweden.

PCN102

A COST-EFFECTIVENESS ANALYSIS OF AXITINIB AND SORAFENIB FOR 2ND LINE TREATMENT OF ADVANCED RENAL CELL CARCINOMA AFTER FAILURE OF CYTOKINES IN THE UNITED STATES

Stillman IO[1], Ambavane A[1], Cislo P[2]
[1]*Evidera, Lexington, MA, USA,* [2]*Bayer Pharma AG, Montville, NJ, USA*

OBJECTIVES: To assess the cost-effectiveness of axitinib compared to sorafenib from the perspective of a US third-party payer for second-line treatment of patients with advanced RCC who failed cytokines. **METHODS:** Phase III AXIS trial reported that axitinib increased median progression free survival (PFS) compared to sorafenib (12.0 vs. 6.6 months, p<0.0001), while overall survival (OS) showed no difference (29.4 vs. 27.8 months, p=0.144) in patients failing treatment with cytokines. A cohort partition model was constructed to estimate direct medical costs and health outcomes, discounted at 3.0% per annum. Patients were apportioned into 3 health states (progression-free, progressed and dead) based on OS and PFS Kaplan-Meier curves from the AXIS trial. Active treatment was applied until progression, followed by best supportive care (BSC) thereafter. The wholesale acquisition costs and adverse event (AE) costs were obtained from published sources. AE rates and utility values were informed by the AXIS trial. US administrative claims data (MarketScan®) was analyzed to estimate routine care costs. Probabilistic sensitivity analysis (PSA) was conducted. **RESULTS:** The total per-patient lifetime costs were estimated to be $242,750 for axitinib and $168,880 for sorafenib and 84% of the cost difference was due to the higher total medication cost of axitinib. The quality-adjusted life-years (QALY) gained on axitinib vs. sorafenib was 1.3 vs. 1.2 and the incremental cost-effectiveness ratio (ICER) was $683,209/QALY. 100% of the PSA iterations showed that axitinib was more expensive than sorafenib and the QALY difference between axitinib and sorafenib was no greater than 0.7. **CONCLUSIONS:** For post-cytokine subgroup, axitinib resulted in an ICER > $650,000/QALY versus sorafenib due to high drug costs and lack of OS benefit, indicating that axitinib may not present good value for money as 2nd line treatment of advanced RCC when compared to sorafenib in the US.

PCN103

COST-EFFECTIVENESS OF COBAS® EGFR MUTATION TEST VERSUS SANGER SEQUENCING IN THE TREATMENT OF LOCALLY ADVANCED OR METASTATIC NSCLC: A PAYER PERSPECTIVE IN THE UNITED KINGDOM

Towse A[1], Gavaghan M[2], Strunz-McKendry T[3], Garfield S[2], Poulios N[4]
[1]*Office of Health Economics, London, UK,* [2]*GfK Bridgehead, Wayland, MA, USA,* [3]*Roche Diagnostics Limited, West Sussex, UK,* [4]*Roche Molecular Diagnostics, Pleasanton, CA, USA*

OBJECTIVES: We explored the cost-effectiveness of using the CE-IVD marked cobas® EGFR Mutation Test versus Sanger sequencing for identifying EGFR mutations in locally advanced or metastatic NSCLC patients from a UK payer perspective. **METHODS:** A decision-tree model was developed to compare testing methodologies and resulting treatment pathways in a hypothetical NSCLC population in the UK with a baseline EGFR mutation prevalence of 16.6%. Model inputs included parameters describing mutation testing accuracy, treatment response (EGFR inhibitor, standard chemo therapy or best supportive care) and adverse events arising from treatment. Inputs were based on published literature and costs in the NHS in England and Wales. The model examined cost-effectiveness over the patients' lifetime. A one-way sensitivity analysis was conducted. **RESULTS:** Using £32,500/QALY as a threshold, the cobas EGFR Mutation Test was cost-effective at an incremental cost per QALY gained of £18,394 for the target population as a result of better test accuracy and lower detection limit relative to Sanger sequencing. The cobas EGFR Mutation test was able to correctly identify more patients with EGFR mutations (lower rate of false negatives) and more appropriately direct patient treatment than Sanger sequencing. **CONCLUSIONS:** The cobas EGFR Mutation Test, by correctly identifying more patients for proper treatment, can be considered a cost-effective strategy for identification of EGFR mutations in locally advanced or metastatic NSCLC patients from a UK payer perspective.

PCN104

A CRITICAL APPRAISAL OF COST-EFFECTIVENESS ANALYSES OF HUMAN PAPILLOMAVIRUS TESTING IN CERVICAL SCREENING: MAKING APPROPRIATE COMPARISONS AND USEFULLY INTERPRETING RESULTS

O'Mahony J[1], Naber S[2], de Kok IMCM[2]
[1]*Trinity College Dublin, Dublin, Ireland,* [2]*Erasmus Medical Centre, Rotterdam, The Netherlands*

OBJECTIVES: To critically appraise published cost-effectiveness analyses (CEAs) of human papillomavirus (HPV) testing in cervical screening regarding the appropriateness of comparisons between strategies and the usefulness of the interpretation of cost-effectiveness estimates. **METHODS:** The PubMed database was searched for relevant CEAs of cervical screening using HPV testing. The identified CEAs were carefully appraised for their quality of analyses, reporting and interpretation of results. Specific examples of modelling shortcomings were selected as illustrations of what to avoid when estimating the cost-effectiveness of HPV-based screening. **RESULTS:** The review identified 29 relevant CEAs. Regarding basic errors, 11 of the 29 calculated the incremental cost-effectiveness ratios (ICERs) either partly or completely incorrectly. Ten studies failed to fully report costs and effects; either simply reporting ICERs or depicting a cost-effectiveness plane. Regarding more fundamental errors, 23 failed to include sufficient screening interval comparators against which to meaningfully estimate ICERs; effectively leading to average cost-effectiveness ratios being mistakenly identified as ICERs, which biases cost-effectiveness ratio estimates downwards. Finally, none of the studies gave specific consideration to the magnitude of the change in costs and effects of adding HPV testing to a given strategy, either with a simple graphical interpretation or with a formal interpretation using the net benefit framework. **CONCLUSIONS:** Model specification is typically the most difficult part of a model-based CEA, whereas simulating relevant strategies is relatively straightforward once the model is built. Similarly, once results have been generated, their correct presentation and interpretation is relatively straightforward. However, this analysis shows that these relatively easy aspects of CEA are being performed poorly in the HPV screening literature. Consequently, a few simple improvements to basic aspects of CEAs of HPV-based screening could greatly enhance the usefulness of such analyses to decision makers.

PCN105

COST-EFFECTIVENESS OF EML4-ALK FUSION TESTING AND FIRST-LINE CRIZOTINIB TREATMENT FOR PATIENTS WITH ADVANCED ALK POSITIVE NON-SMALL CELL LUNG CANCER IN A PUBLICLY FUNDED SYSTEM (ONTARIO, CANADA)

Djalalov S[1], Beca J[1], Hoch JS[2], Krahn MD[3], Tsao MS[4], Cutz JC[5], Leighl N[4]
[1]*St. Michael's Hospital, Toronto, ON, Canada,* [2]*University of Toronto, Toronto, ON, Canada,* [3]*Toronto Health Economics and Technology Assessment (THETA) Collaborative, Toronto, ON, Canada,* [4]*Ontario Cancer Institute, Toronto, ON, Canada,* [5]*McMaster University, Hamilton, ON, Canada*

OBJECTIVES: ALK-targeted therapy with crizotinib offers significant improvement in clinical outcomes for the treatment of EML4–ALK fusion positive NSCLC. We estimated the cost-effectiveness of EML4-ALK testing in combination with first-line crizotinib for ALK positive NSCLC in Ontario. **METHODS:** A cost-effectiveness analysis was conducted, using a Markov model from the Canadian public health (Ontario) perspective and a lifetime horizon in Stage IV NSCLC patients with non-squamous histology. Transition probabilities and mortality rates were calculated from the Ontario Cancer Registry and Cancer Care Ontario New Drug Funding Program (CCO NDFP). Costs were obtained from the Ontario Case Costing Initiative, CCO NDFP, University Health Network and the literature. Population-based ALK testing included initial IHC testing followed by FISH confirmation for positive cases. **RESULTS:** The strategy of genomic testing linked to targeted crizotinib treatment gained 0.11 QALYs compared to no testing or crizotinib treatment in the advanced non-squamous NSCLC population. The incremental cost was CAD $4,179 per patient compared to the previous standard of care without ALK testing; the incremental cost-effectiveness ratio for the base case was $392,538 per QALY. The incremental cost and ICER for crizotinib therapy in known ALK positive advanced NSCLC patients was $96,554 and $254,617/QALY. The cost of testing was less relevant to the ICER at a biomarker frequency of 7% and higher. The major drivers of cost-effectiveness are drug cost and low biomarker frequency in the population. **CONCLUSIONS:** EML4–ALK genomic testing in combination with crizotinib treatment for all Stage IV non-squamous NSCLC patients is not cost-effective in the setting of high drug costs and a low biomarker frequency in the general population. Modifying these key drivers will be important in improving the cost-effectiveness and accessibility to novel therapies with major clinical benefit in advanced NSCLC.

PCN106

OVERVIEW ON COST-EFFECTIVENESS RESULTS OF DECISION-ANALYTIC STUDIES FOR THE TREATMENT OF MULTIPLE MYELOMA

Rochau U[1], Jahn B[2], Qerimi V[3], Kluibenschaedl M[2], Kurzthaler C[2], Conrads-Frank A[2], Willenbacher W[4], Gastl G[4], Siebert U[5]

[1]*UMIT - University for Health Sciences, Medical Informatics and Technology/ ONCOTYROL - Center for Personalized Cancer Medicine, Hall in Tyrol/ Innsbruck, Austria,* [2]*UMIT - University for Health Sciences, Medical Informatics and Technology, Hall in Tyrol, Austria,* [3]*UMIT - University for Health Sciences, Medical Informatics and Technology/ Ss. Cyril and Methodius University in Skopje, Hall in Tyrol/ Skopje, Austria,* [4]*Medical University Innsbruck, Innsbruck, Austria,* [5]*UMIT – University for Health Sciences, Medical Informatics and Technology / ONCOTYROL / Harvard University, Hall i. T./ Innsbruck / Boston, Austria*

OBJECTIVES: To provide an overview on published decision-analytic models evaluating treatment strategies for multiple myeloma (MM) focusing on the cost-effectiveness results. **METHODS:** A systematic literature search was performed in the electronic databases Pubmed, NHS EED and the Tufts CEA Registry to identify studies evaluating MM treatment strategies using mathematical decision-analytic models. To meet the inclusion criteria, models were required to compare different treatment strategies, to be published as full text articles in English, and comprise relevant clinical health outcomes over a defined time horizon and population. We used evidence tables to summarize methodological characteristics and economic results. For comparability, all economic results were transferred into 2012 US Dollar. We used Purchasing Power Parity to convert the currency into US Dollar of the same year. For converting US Dollar from step one into US Dollars 2012, we used Consumer Price Index rates for the relevant year. **RESULTS:** We found eleven decision-analytic modeling studies. Economic evaluations were included in all studies. Eight studies reported cost-utility results. The modeling approaches applied included a decision tree model, Markov cohort model, discrete event simulations, partitioned survival analyses and area under the curve models. Time horizons ranged from seven years to lifetime. Half of the models chose the perspective of the health care system, while other perspectives were societal, third party payer and government payer. Among others, two studies reported cost-effectiveness of autologous transplantation vs. standard-dose melphalan with an ICER of $31,263 /life-year gained (LYG) and $36,778/LYG. One study reported that bortezomib vs. lenalidomide plus dexamethasone is cost saving, while another comparable study reported an ICUR for lenalidomide plus dexamethasone vs. bortezomib of $22,301/QALY. **CONCLUSIONS:** We identified several well-designed cost-effectiveness/cost-utility models using a broad variety of different modeling approaches. Results of most of the studies were not comparable due to different treatment strategies, target population and settings.

ECONOMIC EVIDENCE OF SURGICAL PROCEDURES IN CANCER: A SYSTEMATIC LITERATURE REVIEW

Ara R[1], Basarir H[1], Keetharuth A[1], Weatherly H[2], Barbieri M[2], Sculpher MJ[2]

[1]*University of Sheffield, Sheffield, UK,* [2]*Centre for Health Economics, York, UK*

OBJECTIVES: To examine the empirical and methodological cost-effectiveness evidence of surgical interventions for breast, colorectal, and prostate cancer. **METHODS:** Systematic searches of seven databases including MEDLINE, EMBASE, CDSR,HTA, DARE, EconLit and NHSEED, research registers, the National Institute of Health and Care Excellence (NICE) website and conference proceedings was conducted in April 2012. Studies were included if they evaluated the cost-effectiveness of a surgical procedure in either breast, colorectal or prostate cancer and reported cost per quality adjusted life-year or cost per life-year results. The quality of the studies included was assessed in terms of meeting essential, preferred, and UK specific requirements for economic evaluations. **RESULTS:** The 17 (breast=3,colorectal=7,prostate=7) studies which satisfied the inclusion criteria covered a broad range of settings with 9 set in European and 8 in non-European locations. Just a third (11/17) was published within the last 10 years. In terms of the essential quality criteria; the populations, interventions and comparators were generally well defined. However, very few studies were informed by the results of literature reviews or synthesised clinical evidence. Although the interventions had potential differential effects on recurrence and mortality rates, some studies used relatively short time horizons. Although univariate sensitivity analyses were reported in all studies, less than a third characterised all uncertainty with a probabilistic sensitivity analysis. While a third of studies incorporated patients' health-related quality of life data, only 4 of the 17 studies used social tariff values. **CONCLUSIONS:** There is very little recent robust evidence describing the cost-effectiveness of surgical interventions in these indications. Many of the more recent publications did not satisfy the essential methods requirements, such as using synthesising clinical evidence informed by a systematic literature review. Given the ratio of potential benefit and harm associated with surgery in cancer, there is an urgent need to conduct additional robust economic evaluations in this area.

PCN108

ABIRATERONE ACETATE VERSUS ENZALUTAMIDE FOR METASTATIC CASTRATION-RESISTANT PROSTATE CANCER POST CHEMOTHERAPY: COST EFFECTIVENESS ANALYSIS

He J, Li T, Saadi R

Janssen Global Services LLC, Raritan, NJ, USA

OBJECTIVES: With approvals of abiraterone acetate (AA) and enzalutamide (ENZA) in the past 2 years, the treatment landscape has shifted dramatically for metastatic castration-resistant prostate cancer (mCRPC) patients who failed docetaxel-based chemotherapy. There is increasing interest in the relative cost-effectiveness of these therapies. The objective of this study was to assess the cost-effectiveness of AA versus ENZA among individuals with mCRPC post chemotherapy from a payer perspective. **METHODS:** A survival-based Markov cohort model consisting of 3 health states, progression-free, progressed, and dead, was developed to project over 10 year period. Progression between states was determined by overall survival (OS) and radiographic progression free survival (rPFS). An indirect treatment comparison was conducted to determine the relative efficacy of AA and ENZA (data reported separately). Utilities were mapped from FACT-P to EQ-5D based on a review of the literature. Drug acquisition costs in the US were used since ENZA was approved only in the US at the time of analysis. Costs of scheduled and unscheduled follow-up visits were obtained from the Centers for Medicare Services Drug Payment Table and Physician Fee Schedule and represented in 2013 US dollars. Average wholesale prices for a 30-day supply of AA and ENZA were $7,674 and $8,940, respectively. One-way sensitivity analyses were performed against all probability, utility, and cost values incorporated into this cost-effectiveness model. **RESULTS:** In this analysis, AA provides substantial saving with $13,322 per patient versus ENZA. The main drivers of the model are drug costs, health utility values, and efficacy (OS and rPFS). The robustness of the results was supported by sensitivity analyses. **CONCLUSIONS:** Given similar OS benefits, AA is cost saving compared with ENZA for the treatment of patients with mCPRC post-docetaxel based on US data.

PCN109

COMPARATIVE STUDY OF THE COST-EFFECTIVENESS OF TRASTUZUMAB IN THE TREATMENT OF BREAST CANCER IN DIFFERENT COUNTRIES

Rabbani S[1], Ardam A[1], Salamzadeh J[2]

[1]*Shahid Beheshti University of Medical Sciences, tehran, Iran,* [2]*Shahid Beheshti University of Medical Sciences, Tehran, Iran*

OBJECTIVES: Pharmacoeconomic evaluations are more critical in developing countries in which economic effects of new and expensive therapies have significant impact on patients, insurance companies and the health systems. Since cost-effectiveness studies are too costly and time consuming, in these countries new medications are often being used in daily practice before being well documented as cost-effective interventions. This would force health organizations to perform comparative studies as alternatives to cost-effectiveness analysis. Trastuzumab, an anti-cancer monoclonal antibody which was approved by FDA in 1998, is an expensive medicine introduced to the Iranian pharmaceutical market since 2003, with an annual usage cost of 308,352,730,640 Rials ($ US 25,000,000) in 2010. **METHODS:** A systematic review on electronic medical databases including the Cochrane, CRD, EMBASE, HEED, MEDLINE, and PubMed, covering the years 2000 to 2009, was performed using relevant key words to extract publications investigating cost-effectiveness and efficacy of trastuzumab in breast cancer treatment. The Incremental Cost-Effectiveness Ratios (ICERs) were compared with a criterion introduced by WHO. **RESULTS:** The reported ICERs were between $90,118/QALY to $217,264/QALY and $13,361/QALY to $65,250/QALY in metastatic and adjuvant breast cancer therapy, respectively. The metastatic ICERs were 8 to 20 folds of the GDP per Capita in Iran whereas the adjuvant phase ICERs were 1.2 to 6 folds of it. Sensitivity analysis showed the results are more sensitive to discount rate, drug regimen cost, duration of survival benefits, as well as the risk of relapse and metastasis. **CONCLUSIONS:** Trastuzumab therapy in metastatic breast cancer cannot be cost effective in Iran, however as adjuvant therapy it is still a challenging issue. Unlimited access to this medicine would not be rational and recommendations with an approach to optimize its usage, e.g. administration in younger patients with poor prognosis and higher risk of relapse or using clean rooms to reduce drug wasting, are strongly advised.

PCN110

THE COST-EFFECTIVENESS OF BENDAMUSTINE-RITUXIMAB VERSUS FLUDARABINE-RITUXIMAB FOR PATIENTS WITH INDOLENT NON-HODGKIN'S LYMPHOMA (INHL) WHO HAVE PROGRESSED FOLLOWING TREATMENT WITH RITUXIMAB OR A RITUXIMAB-CONTAINING REGIMEN IN MEXICO

Bertwistle D[1], Munakata J[2], Wehler E[3], Leyva V[4], Valencia A[5], Hernandez A[5], de la Torre L[5], Gonzalez L[6]

[1]*IMS Health, London, UK,* [2]*IMS Health, San Francisco, CA, USA,* [3]*IMS Health, Alexandria, VA, USA,* [4]*IMS Health, Mexico City, Mexico,* [5]*Janssen, Mexico City, Mexico,* [6]*Janssen, Raritan, NJ, USA*

OBJECTIVES: To determine the cost-effectiveness of bendamustine-rituximab (Ben-R) versus fludarabine-rituximab (Fdb-R) in patients with iNHL who have progressed following treatment with rituximab or a rituximab-containing regimen in Mexico. **METHODS:** An economic model was constructed from the Mexican public payer perspective, with a 35-year (lifetime) horizon and a discount rate of 5%. The model included three health states, progression-free (PF), progressive disease (PD), and death, which were associated with utility weights of 0.81, 0.62 and 0, respectively. Clinical inputs (response rates, Kaplan-Meier curves, hazard ratios (HRs) and adverse event rates) were from the Stil NHL 2-2003 study. Resource use data were from interviews with Mexican hematologists treating iNHL patients. Unit costs were obtained from Mexican Social Security Institute (IMSS) and were expressed as 2013 Mexican Pesos. Univariate and probabilistic sensitivity analyses were conducted to determine the key drivers of cost-effectiveness, and uncertainty around the results, respectively. **RESULTS:** Total cost of Ben-R was $1,726,828 and total cost of Fdb-R was $1,640,024. Ben-R patients accrued more LYs (5.82 vs. 4.73), QALYs (4.22 vs. 3.29), and PF LYs (3.37 vs. 1.96) compared to Fdb-R patients. The ICERs were $79,890 (cost per LY), $92,788 (cost per QALY) and $61,486 (cost per PF LY). Univariate sensitivity analysis revealed that the ICER per LY was most sensitive to the PF survival (PFS) and overall survival (OS) HRs for Ben-R vs Fdb-R and the use of bone marrow transplants in the PD state. Probabilistic sensitivity analysis with 1,000 iterations estimated that Ben-R will be cost effective over 90% of the time at a willingness-to-pay threshold of $125,085. **CONCLUSIONS:** At a willingness-to-pay of $125,085 (GDP per capita of Mexico) Ben-R is cost effective versus Fdb-R.

PCN111

A COST-EFFECTIVENESS ANALYSES OF USING SUNITINIB (SU) IN FIRST LINE OF METASTATIC RENAL CANCER IN ROMANIAN JURISDICTION

Berghea F[1], Skoupa J[2], Ciuleanu T[3], Miron L[4], Stanculeanu DL[5], Jinga D[6], Dediu M[5], Mateescu DN[7], Hájek P[8], Bradatan B[9], Xuan J[10]

[1]*Carol Davila University Of Medicine and Pharmacy, Bucharest, Romania,* [2]*ISPOR Chapter Czech Republic, Prague 7, Czech Republic,* [3]*Ion Chiricuta Clinic, Cluj, Romania,* [4]*Oncology Institute, Iasi, Romania,* [5]*"Alexandru Trestioreanu" Oncology Institute, Bucharest, Romania,* [6]*University Hospital, Bucharest, Romania,* [7]*Diagnosis & Treatment Oncology Center, Brasov, Romania,* [8]*Pfizer, Praha, Czech Republic,* [9]*Pfizer, Bucharest, Romania,* [10]*Pfizer, Inc., New York, NY, USA*

OBJECTIVES: In Romania the estimated incidence of metastatic renal cancer (mRCC) is about 1500 cases; less than 400 patients receive full reimbursement for

their therapy. Our objective was to assess the cost-effectiveness of Sunitinib (SU) in the first-line treatment of mRCC patients in comparison with Bevacizumab (BEV) + IFN- and Sorafenib (SO) -at the level of 2011 year- based on the latest clinical evidence. **METHODS:** A Markov model (comprised of four states: 1st line treatment, 2nd line, Best Supportive Care and Death) was validated in several countries and was adapted for the Romanian jurisdiction. The model was set to 6 weekly cycles for a period of 10 years, which corresponds with a lifetime length scenario. Costs for medication and application were derived from hospital databases, expert panels and structured interviews. Experts that managed more than 60% of all local mRCC were consulted. These experts identified several scenarios related to outpatient and inpatient treatment decisions predominantly based on social reasons; all these scenarios have been tested. A WHO methodology was used to set a threshold of price per QALY (3 x local GDP) **RESULTS:** Cost per cycle in 1st line was lower than both 2nd line and BSC – consistent with other international findings. Neutropenia, proteinuria and heart failure have been identified as the most costly adverse events. The QALYs for SU was 1.86 compared to BEV 1.7 and SO 1.69. Incremental cost per QALY SU versus SO was 14.000 EURO and, respectively, -141.000 EURO versus BEV. **CONCLUSIONS:** Sutent is cost effective versus SO and dominant to BEV in the treatment of mRCC in the study settings. The model was very sensible to price of medication and cost of BSC.

PCN112

THE POTENTIAL COST-EFFECTIVENESS OF OBINUTUZUMAB (GA101) IN COMBINATION WITH CHLORAMBUCIL IN CHRONIC LYMPHOCYTIC LEUKEMIA

Walzer S[1], Becker U[2], Samanta K[3], Wiesner C[2], Mueller E[4]
[1]*MArS Market Access & Pricing Strategy UG (h.b.), Weil am Rhein, Germany,* [2]*F. Hoffmann-La Roche Ltd., Basel, Switzerland,* [3]*Roche Products Limited, Welwyn Garden City, UK,* [4]*Analytica LASER International Inc., Loerrach, Germany*

OBJECTIVES: Obinutuzumab is the first, glycoengineered type II antibody demonstrating increased Antibody-Dependent Cell-Mediated Cytotoxicity (ADCC) and direct cell death compared with rituximab, and is pending regulatory approval (in combination with chlorambucil (Clb)) for the treatment of patients with previously untreated chronic lymphocytic leukemia (CLL). Obinutuzumab+Clb has shown a > 85% reduction in the risk of progression, relapse or death in comparison to treatment with Clb alone (HR 0.14, 95% CI 0.09-0.21, p <.0001), a broadly accepted treatment option for many patients with co-existing medical conditions. The cost-effectiveness of this innovative therapy will need to be assessed in countries using incremental cost-effectiveness thresholds to make reimbursement decisions. **METHODS:** A four-state Markov lifetime model from the UK NHS perspective was developed for patients with existing medical conditions utilizing the patient-level information from the underlying clinical trial comparing obinutuzumab+Clb versus rituximab+Clb and versus Clb alone (CLL11 trial). Transition probabilities from PFS to progression were derived from this study's data. Post-progression survival was estimated using published data and was part of the sensitivity analyses. Cost data (e.g. administration and adverse events), utilities and the prices for rituximab and Clb were retrieved for the UK. As obinutuzumab is not yet approved a range of price assumptions of similar innovative oncology therapies has been applied. **RESULTS:** Based on this early evaluation, obinutuzumab+Clb showed a cost per QALY in the base case analysis of £18,000 to £19,000 when compared to Clb and £29,000 to £32,000 when compared to rituximab+Clb. Probabilistic and deterministic sensitivity analyses confirmed these findings. **CONCLUSIONS:** Obinutuzumab+Clb showed significant patient-relevant clinical benefits and might be a potential cost-effective therapy in comparison to the current standard of care and could hence support access for a maximum number of patients with previously untreated CLL.

PCN113

COST-EFFECTIVENESS OF BREAST CANCER SURVEILLANCE BY LIFETIME RISK IN WOMEN AGED LESS THAN 50 YEARS

Teljeur C, Harrington P, Murphy L, Ryan M
Health Information and Quality Authority, Dublin, Ireland

OBJECTIVES: National programmes of breast cancer screening are common for women over the age of 50 at average risk. For women aged less than 50, surveillance may be offered to those at elevated risk either due to family history or because of identified genetic risk factors, such as a BRCA1 mutation. The lifetime risk for these women is not known with certainty. The purpose of this study was to examine the cost-effectiveness of different screening strategies as a function of lifetime risk. **METHODS:** A Markov model was developed to evaluate the cost-effectiveness of different MRI- and digital mammography-based surveillance strategies between the ages of 30 and 49. Costs and benefits were calculated to life expectancy. The perspective was that of the publicly funded health care system in Ireland. Lifetime risk of developing breast cancer was varied between 4% and 94%. A cost-effectiveness threshold of €45,000/QALY was applied. **RESULTS:** The probability of cost-effectiveness increased with increasing lifetime risk. For women at moderate risk (i.e. lifetime risk of between 17% and 30%), cost-effectiveness was only achieved with annual surveillance from the age of 40 to 49 when lifetime risk reached 28% to 30%. For women with high familial risk, cost-effectiveness was achieved for surveillance from the age of 40 to 49. For women with a BRCA1 mutation, surveillance from the age of 40 to 49 was cost-effective for all levels of lifetime risk, while MRI from age 30 was only cost-effective for a lifetime risk of over 65%. **CONCLUSIONS:** Risk levels for breast cancer encompass wide ranges of lifetime risk. The cost-effectiveness of different surveillance strategies is sensitive to lifetime risk and suggests the need for individualised surveillance programmes.

PCN114

COLLABORATIVE CARE FOR DEPRESSION MANAGEMENT IN CANCER: A COST-EFFECTIVENESS ANALYSIS

Duarte A[1], Walker S[1], Richardson G[1], Walker J[2], Sharpe M[2], Sculpher MJ[3]
[1]*University of York, York, UK,* [2]*University of Oxford, Oxford, UK,* [3]*Centre for Health Economics, York, UK*

OBJECTIVES: Collaborative care interventions for comorbid depression have demonstrated their beneficial impact on health outcomes. Depression in cancer patients is associated with decreased quality of life, and poorer health outcomes. Therefore, there may be considerable gains in the adequate treatment of depression in oncology patients. We explored the cost-effectiveness of a collaborative care intervention specifically developed for the treatment of depression in cancer patients compared to usual practice. **METHODS:** A cost-effectiveness analysis comparing a collaborative care intervention for depression management, Depression Care for People with Cancer (DCPC), in addition to usual care with usual care alone, based on data from the second Symptom Management Research Trials in Oncology (SMaRT-2). SMaRT-2 was a large (n=500), multicentre study, in depressed patients with a relatively good cancer prognosis, in a secondary care setting. Outcomes included costs expressed as UK sterling in 2010-11 prices and health outcomes in quality-adjusted life-years (QALYs), estimated from a National Health Service and Personal Social Services perspective. Scenario analyses were performed to determine the impact on cost-effectiveness of alternative costing assumptions, and uncertainty was characterised through cost-effectiveness acceptability curves and probabilities of cost-effectiveness at key cost-effectiveness thresholds. **RESULTS:** DCPC in addition to usual care was associated with greater costs, but also improved health outcomes. DCPC was found to be cost-effective at accepted cost-effectiveness thresholds. Results were robust across alternative scenarios, with probabilities of cost-effectiveness higher than 90% for cost-effectiveness thresholds ranging between £20,000-30,000 per QALY. **CONCLUSIONS:** Compared to usual care, DCPC in addition to usual care is likely to be cost-effective at current UK cost-effectiveness thresholds. This contributes to the growing evidence on the cost-effectiveness of collaborative care interventions for the treatment of comorbid depression. Future research will use a decision modelling approach to extrapolate trial-based results across a longer time horizon, and incorporate other relevant sources of evidence.

PCN115

PHARMACOECONOMIC EVALUATION OF ABIRATERONE ACETATE VERSUS CABAZITAXEL IN THE TREATMENT OF METASTATIC CASTRATION-RESISTANT PROSTATE CANCER IN KAZAKHSTAN

Kostyuk A, Almadiyeva A
National Center for Health Development, Astana, Kazakhstan

OBJECTIVES: The purpose of this study was to explore the cost-effectiveness of abiraterone acetate (abiraterone) vs. cabazitaxel in metastatic castration-resistant prostate cancer (mCRPC) patients who progressed after docetaxel in Kazakhstan. **METHODS:** Since no head-to-head trial data were not available for Abiraterone against cabazitaxel, indirect profitability model was developed using clinical data (progression-free survival (PFS), overall survival (OS), adverse events (AEs)) from the pivotal Phase 3 clinical trials COU-AA-301 (Abiraterone) and TROPIC (cabazitaxel). The basic assumption in the model was that the two comparator arms in the trials were "palliative" and are therefore equivalent. Using the resources, in particular for controlling the adverse events was calculated based on data Kazakhstan. For validation purposes, a secondary analysis was conducted using international resources use data. The analysis used a local expenditures 2011-2012, undiscounted. Hospitalization, day hospital visits, medications, and laboratory tWe developed a Markov microsimulation model with a lifetime horizon and a direct health-care cost perspective. The patient history was recorded and was used in calculations of transition probabilities, utilities, and costs. ests were taken from the public officially published rates. The cost of purchasing drugs came from recent price lists . Calculations were based on the average duration of treatment for each agent. **RESULTS:** The total cost of treatment was lower for Abiraterone compared with cabazitaxel. Higher costs for the purchase of medicines for Abiraterone were offset by lower administrative expenses and lower AE management costs. Results were confirmed by secondary analysis. All sensitivity analyzes from the point of view of the model parameters and modeling assumptions are consistent with the expected findings, which confirmed both internal and external consistency of the model. **CONCLUSIONS:** Abiraterone is a potentially cost-effective option compared with cabazitaxel in the health care system in Kazakhstan.

PCN116

REDUCING THE LENGTH OF ANTIBIOTIC PROPHYLAXIS IN CLINICAL CONDITIONS

Djozic M[1], Jovic R[1], Tomic Z[2], Sabo A[2]
[1]*University of Novi Sad, Faculty od Medicine, Clinical Center of Vojvodina, Novi Sad, Serbia and Montenegro,* [2]*University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia and Montenegro*

OBJECTIVES: The aim of this study was to evaluate duration and cost of prophylactic use of antibiotics, as well as occurrence of postoperative infection in the patients (pts) with laryngeal and pharyngolaryngeal carcinoma during 2005 and 2010. **METHODS:** Histories from 87 pts (2005) and 92 pts (2010) who were treated during the year 2005 and 2010 from laryngeal and pharyngolaryngeal carcinoma at the ENT Clinic, Clinical Center of Vojvodina, Novi Sad, Serbia, have been used. All pts received triple drug therapy perioperatively. Since 2009, additional hygienic measures and education of staff (in terms of the proper use of antibiotics) have been taken to improve hospital treatment. From the patients' histories, we followed: average length of hospital stay,average length of administrating antibiotics, occurrence of infection or other postoperative complication (fistula) and the price of used antibiotics. **RESULTS:** During 2005, antibiotics were administrated as follows: aminoglycosides (amikacin) 2x500mg during 10 days, cephalosporin (cefazolin amp. 2x1g, cefrtriakson 2x1g) 10 days, metronidazole (solutio) 3x500mg 10 days.During 2010, same anibiotics were administerd for an average of 3 days. The average length of hospital stay was in 2005. was 13.5 days, x+/- SD=13.5+/-4.2, and in 2010 was 11.18 days, x+/- SD=11.18+/-5.9. The average length of administrating antibiotics was 9.4 days in 2005 (x+/- SD=9.4+/-1.1) and in 2010 was 3.4 days (x+/- SD=3.4+/-1.7). Occurrence of infection was in 4 pts (2005) and 6 pts (2010). The cost of used antibiotics in 2005.was 775748 dinars (9320 euros), and in 2010. was 366159 dinars (3698euro). **CONCLUSIONS:** With reducing the length of administrating same antibiotics, after additional hygienic and educative measures have been taken, it is possible to significantly reduce the length of hospital stay (while the number of postoperative infections is not significantly increased) and cost of used antibiotics, which altogether leads to reduction of overall cost of hospital treatment.

PCN117

SELECTIVE INTERNAL RADIOTHERAPY (SIRT) USING RESIN YTTRIUM-90 MICROSPHERES FOR CHEMOTHERAPY-REFRACTORY METASTATIC COLORECTAL CANCER: A UK COST-EFFECTIVENESS ANALYSIS

Bester L[1], Wasan H[2], Sangro B[3], Kennedy A[4], Pennington B[5], Sennfält K[6]
[1]*University of New South Wales, Darlinghurst, Australia,* [2]*Hammersmith Hospital, London, UK,* [3]*Clinica Universitaria de Navarra, Navarra, Spain,* [4]*Sarah Cannon Research Institute, Nashville, TN, USA,* [5]*BresMed, Sheffield, UK,* [6]*Sirtex Medical Limited, North Sydney, Australia*

OBJECTIVES: Treatment options for chemotherapy-refractory liver metastases resulting from colorectal cancer are limited. The safety and efficacy of SIRT using resin yttrium-90 microspheres was studied in this population. The objective of this analysis was to assess the cost-effectiveness of SIRT compared to best supportive care (BSC) from the perspective of the UK NHS. **METHODS:** A state-transition model was constructed, based on survival curves from a retrospective cohort study of yttrium-90 resin microspheres (SIR-Spheres; Sirtex, Sydney, Australia) *vs.* BSC in chemotherapy-refractory mCRC. The model included costs for treatment acquisition, pre-treatment work-up and delivery of microspheres, and chemotherapy received in addition to, instead of, or after, SIRT. In addition, costs of managing AEs and a cost of death were included. Costs were microcosted using NHS reference costs and the British National Formulary 64. Utility data were taken from a recent NICE economic evaluation in metastatic colorectal cancer. **RESULTS:** The results showed an increase in survival for patients receiving SIRT compared to BSC (2.09 *vs.* 0.97 years), with a corresponding increase in quality adjusted life years (1.50 vs 0.69). The associated costs were £35,487 *vs.*£12,730 for SIRT and BSC, respectively. The additional costs were due to the SIRT treatment and the cost associated with extension to life. The cost per QALY was £28,216 (cost per life year £20,323). The results were robust to alternative assumptions tested in scenario analyses; survival functions, utilities or the time spent pre- and post-progression. However, one-way sensitivity analysis showed results were most sensitive to the parameters for the survival functions. Data shown here were also consistent with published clinical studies. **CONCLUSIONS:** The analysis demonstrates that SIRT using resin yttrium-90 microspheres has the potential of being a cost-effective option in the treatment of patients with chemotherapy-refractory liver metastases resulting from colorectal cancer.

PCN118

PHARMACOECONOMIC ANALYSIS OF INTRAVENOUS TEMOZOLOMIDE FOR THE TREATMENT OF NEWLY DIAGNOSED GLIOBLASTOMA MULTIFORME IN RUSSIA

Krysanov I, Krysanova V
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To perform comparative pharmacoeconomic analysis of concomitant, adjuvant and second-line intravenous temozolomide (ITMZ) for the treatment of newly diagnosed glioblastoma multiforme versus initial radiotherapy and second-line therapy with ITMZ. **METHODS:** Analysis of the published clinical trials was conducted to evaluate comparative efficacy and safety of the studied therapy options. Direct medical costs included drug therapy and hospital treatment. All prices were for Moscow region, year 2013. Expected difference in direct medical costs was calculated in Excel based model. For the cost-effectiveness analysis, survival was expressed as 2.5 years restricted mean estimates from EORTC-NCIC study. The incremental cost-effectiveness ratio (ICER) was estimated. One-way sensitivity analysis was made. **RESULTS:** According to published trials the treatment of newly diagnosed glioblastoma multiforme with ITMZ was associated with a significant improvement in overall survival. The difference in 2.5 years restricted mean survival between the treatment arms was 0.25 life-years and the ICER was 76,982.6 USD per life-year. The one-way sensitivity analysis showed that the results are more sensitive to the variations of key model parameter, such as price of ITMZ. **CONCLUSIONS:** The concomitant, adjuvant and second-line ITMZ was more effective and economically justified treatment option for patients with newly diagnosed glioblastoma multiforme.

PCN119

COST-EFFECTIVENESS OF BENDAMUSTINE VERSUS FLUDARABINE FOR FIRST-LINE TREATMENT OF CHRONIC LYMPHOCYTIC LEUKEMIA (CLL) IN COLOMBIA

Bertwistle D[1], Munakata J[2], Wehler E[3], Leyva V[4], Ariza JG[5], Zambrano C[5], Gonzalez L[6]
[1]*IMS Health, London, UK,* [2]*IMS Health, San Francisco, CA, USA,* [3]*IMS Health, Alexandria, VA, USA,* [4]*IMS Health, Mexico City, Mexico,* [5]*Janssen Cilag, Bogotá, Colombia,* [6]*Janssen, Raritan, NJ, USA*

OBJECTIVES: To determine the cost-effectiveness of bendamustine versus fludarabine for first line treatment of CLL in Colombia. **METHODS:** An economic model was constructed from the Colombian health system perspective, with a 25-year (lifetime) horizon and a discount rate of 3%. The model included three health states, progression-free (PF), progressive disease (PD), and death. Clinical inputs (Kaplan-Meier curves, response rates, hazard ratios (HRs) and adverse event (AE) rates) were from a phase 3 trial comparing bendamustine and chlorambucil, and from a network meta-analysis. Resource use data were from interviews with three Colombian hematologists treating CLL. Resource use for PF patients was weighted based on treatment response. Unit costs were from ISS and SISPRO report and were expressed in 2013 Colombian Pesos. Univariate and probabilistic sensitivity analyses were conducted to determine the key drivers of cost-effectiveness, and the uncertainty around the results, respectively. **RESULTS:** The total lifetime costs for bendamustine and fludarabine were $61,982,845 and $20,432,209, respectively. Bendamustine patients accrued more LYs (7.52 vs. 6.50), QALYs (5.61 vs. 4.60), and PF LYs (3.09 vs. 1.14) compared to fludarabine patients. The ICERs were $40,530,919 (cost per LY), $41,117,127 (cost per QALY) and $21,264,817 (cost per PF LY). Univariate sensitivity analysis revealed the cost per LY ICER was most sensitive to progression-free survival and overall survival HRs for bendamustine vs. fludarabine, the number of treatment cycles, and the cost of bendamustine. Probabilistic sensitivity analysis with 1,000 iterations predicted bendamustine had a 71% chance of being cost-effective, compared to fludarabine, at a willingness to pay (WTP) of $59M per LY, rising to a plateau of about 80% from a WTP of $80M and greater. **CONCLUSIONS:** At current WTP of $59M (three times Colombian GDP per capita) bendamustine is a cost effective alternative to fludarabine.

PCN120

COST-EFFECTIVENESS OF CABAZITAXEL IN MHRPC IN TURKEY

Yesil A[1], Sahin T[1], De Geer A[2], Kim K[3], Topcu T[1]
[1]*Sanofi Turkey, Istanbul, Turkey,* [2]*OptumInsight Life Sciences, Stockholm, Turkey,* [3]*OptumInsight, Stockholm, Sweden*

OBJECTIVES: To determine the cost-effectiveness of cabazitaxel, based mainly on the TROPIC trial in 2nd line treatment of mHRPC relative to the standard of care at the time of launch of the drug. **METHODS:** A Markov model was developed to comprise set of different health states each associated with costs, effects and probabilities of moving to other state. In simulation, a cohort of defined patients are run through the model during the time period of choice, it's assumed that transitions between states only occurs at equidistant time-points and the interval is called a cycle. Because of the relatively short survival time of mHRPC patients, cycle length in the model was set at 3 weeks, corresponding to the length of one chemotherapy administration cycle. Transition rates between different states representing mHRPC disease progression were estimated based on progression of disease and survival rates from the TROPIC trial. **RESULTS:** According to the approved labeling in Turkey, a subgroup of patients with ECOG PS 0-1 and measurable disease at baseline was identified on TROPIC results with a secondary analysis. The result of this analysis shows a similar OS outcomes with decreased death rates. Cabazitaxel was cost-effective compared mitoxantrone with cost per LYG of TRY66,862 given the threshold of TRY68,409 per LYG for the subgroup of the patients at ECOG PS 0-1 and with measurable disease at baseline. Although there has been no formal threshold for the cost-effectiveness ratio in Turkey, a threshold of TRY68,409 per LY gained was assumed based on WHO-CHOICE criteria (3xGDP percapita). **CONCLUSIONS:** It is difficult for the results of the analysis to be interpreted because there is no official cost-effectiveness threshold in Turkey. However, from the WHO perspective; results showed that cabazitaxel is a cost-effective treatment with all ICER values compared to mitoxantrone, below TRY68,409.

PCN121

EVALUATING THE COST EFFECTIVENESS OF GENE EXPRESSION PROFILING AND IMMUNOHISTOCHEMISTRY TESTS

Rafia R[1], Ward SE[1], Scope A[1], Wyld L[2]
[1]*University of Sheffield, Sheffield, UK,* [2]*Royal Hallamshire Hospital, Sheffield, UK*

OBJECTIVES: Gene expression profiling (GEP) and expanded immunohistochemistry (IHC) tests aim to improve decision-making relating to adjuvant chemotherapy for women with early breast cancer (EBC) at intermediate or high risk of recurrence following primary surgery. **METHODS:** A probabilistic model was developed to evaluate the cost effectiveness of treatment guided using the OncotypeDx and IHC4 tests compared with current clinical practice in England and Wales. Analysis was undertaken for women with oestrogen receptor positive (ER+), lymph node negative (LN–), and HER2– EBC from a NHS perspective. In the comparator arm, cancer registry data was used to inform the proportion of patients receiving chemotherapy under current practice. In the intervention arm (new test in addition to current practice) patients were classified into different risk categories based on the result of the new test. The likelihood of receiving chemotherapy was dependent on this classification. The natural history of breast cancer was then simulated using a state transition Markov model, taking into account the reduction in the risk of recurrence associated with chemotherapy. **RESULTS:** The economic analysis suggested that treatment guided using IHC4 has the most potential to be cost-effective at a threshold of £20,000 per QALY gained; however the evidence base to support IHC4 needs further research to confirm the analytical validity of the test and to clarifiy the cost of the test in clinical practice. OncotypeDX has a more robust evidence base, but further evidence on the impact on decision making in the UK and the predictive ability of the test in an ER+, LN-, HER- population receiving current treatment regimens is needed to confirm whether or not it constitutes a cost-effective option in the UK. **CONCLUSIONS:** GEP and IHC tests have the potential to constitute a cost effective option in the UK, but further research is needed to confirm this finding.

PCN122

PHARMACOECONOMIC ANALYSIS OF USING APREPITANT PLUS STANDARD ANTIEMETIC THERAPY FOR PREVENTION OF NAUSEA AND VOMITING ASSOCIATED WITH HIGHLY AND MODERATELY EMETOGENIC CANCER CHEMOTHERAPY IN RUSSIA

Krysanov I, Krysanova V
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To perform comparative pharmacoeconomic analysis of aprepitant plus standard antiemetic therapy – 5-hydroxytriptamine-3 antagonist and corticosteroid - for prevention chemotherapy-induced nausea and vomiting (CINV) versus standard antiemetic therapy. **METHODS:** Analysis of the published clinical trials was conducted to evaluate comparative efficacy and safety of three-drug combination. Cost-effectiveness analyses was performed. Direct medical costs of treatment with studied drugs were considering for each option: cost for 1-cycle and 6-cycle cancer chemotherapy (CCT) with highly emetogenic drugs and for 1-cycle and 4-cycle CCT with moderately emetogenic drugs for 1 patient. The calculation of costs was based on drugs' prices from the List of Vital and Essential Drugs in Moscow region. The incremental cost-effectiveness ratio (ICER) was estimated. One-way sensitivity analysis was made. **RESULTS:** According to published trials the using aprepitant plus standard antiemetic therapy in patients receiving highly and moderately emetogenic chemotherapy was associated with a significant improvement in control of CINV. The ICER was 593.7 USD per 1-cycle and 2906.6 USD per 6-cycle CCT with highly emetogenic drugs for 1 patient. The ICER was 852.7 USD per 1-cycle and 4570.1 USD per 4-cycle CCT with moderately emetogenic therapy. The one-way sensitivity analysis showed that the results are more sensitive to the variations of

aprepitant price. **CONCLUSIONS:** The using aprepitant plus standard antiemetic therapy was more effective and economically justified treatment option for prevention of nausea and vomiting associated with highly and moderately emetogenic cancer chemotherapy.

PCN123

ECONOMIC EVALUATION OF FULVESTRANT 500 MG VERSUS GENERIC NON-STEROIDAL AROMATASE INHIBITORS IN PATIENTS WITH ADVANCED BREAST CANCER IN NORWAY

Ekman M[1], Jacob J[1], Bjørheim J[2]
[1]*AstraZeneca Nordic-Baltic, Södertälje, Sweden,* [2]*AstraZeneca Nordic-Baltic, Oslo, Norway*

OBJECTIVES: In Norway, breast cancer represented 23% of all new cancer cases between 2004 and 2008, and was a leading cause of mortality representing 13% of all cancer deaths. The objective of this study was to perform an economic evaluation of fulvestrant 500 mg compared with anastrozole and letrozole used as second line endocrine therapies in the treatment of advanced breast cancer in post-menopausal women in Norway. **METHODS:** The economic analysis was conducted by using a simulation model estimating progression-free survival, overall survival and associated costs and utility gains over the expected lifetime of the patients. As there are no head-to-head trials comparing fulvestrant 500 mg with aromatase inhibitors, the clinical evidence for the comparative effectiveness was obtained from a network meta-analysis. The economic evaluation was conducted from a health care perspective, with costs and resource use based on published sources and expert assessment. **RESULTS:** The cost-effectiveness ratio of fulvestrant 500 mg versus anastrozole 1 mg was 36,000 EUR per quality-adjusted life year (QALY), with incremental costs of 9,600 EUR and incremental QALYs of 0.27. The cost-effectiveness ratio of fulvestrant 500 mg versus letrozole 2.5 mg was 62,000 EUR per QALY, with incremental costs of 21,000 EUR and incremental QALYs of 0.34. In the sensitivity analysis the results were stable for variations of key parameters, such as the time horizon, the hazard ratios for overall survival, the choice of parametric distribution for progression-free survival and the discount rate. **CONCLUSIONS:** Given an informal cost-effectiveness threshold of around 70,000 EUR/QALY in Norway, the results of the economic evaluations suggest that fulvestrant 500 mg is a cost-effective treatment compared with alternative treatments such as anastrozole and letrozole. These findings indicate that fulvestrant 500 mg is a valuable treatment option for patients with advanced breast cancer in Norway.

PCN124

COST-EFFECTIVENESS OF THE SYSTEMATIC IDENTIFICATION AND TREATMENT OF COMORBID MAJOR DEPRESSION FOR PEOPLE WITH CHRONIC DISEASES: THE EXAMPLE OF CANCER

Walker S[1], Walker J[2], Richardson G[1], Palmer S[1], Wu Q[1], Gilbody S[1], Martin P[3], Holm Hansen C[3], Sawnhey A[3], Murray G[3], Sculpher MJ[4], Sharpe M[2]
[1]*University of York, York, UK,* [2]*University of Oxford, Oxford, UK,* [3]*University of Edinburgh, Edinburgh, UK,* [4]*Centre for Health Economics, York, UK*

OBJECTIVES: Comorbid major depression occurs in approximately ten percent of people suffering from a chronic medical condition such as cancer. A 'collaborative care' approach can be used to systematically identify and treat comorbid major depression. However, we lack information on cost-effectiveness of overall approach as economic evaluations published to date have focused solely on the treatment stage. We therefore aimed to use the best available evidence to estimate the cost-effectiveness of the whole approach (both systematic identification and systematic treatment) compared with usual practice, for patients attending specialist cancer clinics. **METHODS:** A cost-effectiveness analysis using a decision analytic model structured to reflect both the identification and treatment processes. Evidence was taken from reviews of relevant clinical trials and from observational studies, together with data from a large depression screening service. Sensitivity and scenario analyses were undertaken to determine the effects of variations in depression incidence rates, time horizons, patient characteristics and alternative estimates of treatment effect. Probabilistic sensitivity analysis was also undertaken. **RESULTS:** Systematic depression management generated more costs than usual practice, but also more quality adjusted life years (QALYs). The incremental cost-effectiveness ratio was £11,765 per QALY and the probabilities of systematic depression management being cost-effective at thresholds of £20,000 and £30,000 per QALY were 0.998 and 1 respectively. Findings were robust to tests of variation in key model parameters. **CONCLUSIONS:** A combined approach to the systematic identification and treatment of comorbid major depression in cancer patients is likely to be cost-effective at widely accepted threshold values. Systematic depression management may be a better way of generating QALYs for cancer patients than some existing medical and surgical treatments. It could potentially be applied to other chronic medical conditions.

PCN125

PET-BASED RADIOTHERAPY TREATMENT PLANNING IS HIGHLY COST-EFFECTIVE COMPARED TO CT-BASED PLANNING: A MODEL-BASED EVALUATION

Bongers ML[1], Coupe VMH[1], De Ruysscher D[2], Lambin P[3], Oberije C[3], Uyl-de Groot CA[4]
[1]*VU University Medical Center, Amsterdam, The Netherlands,* [2]*University Hospitals Leuven/KU Leuven, Leuven, Belgium,* [3]*MAASTRO Clinic, Maastricht, The Netherlands,* [4]*Erasmus University Rotterdam, Rotterdam, The Netherlands*

OBJECTIVES: PET-based radiotherapy planning for selective lymph node irradiation is an example of the current tendency to individualize treatment in cancer. We evaluated the cost-effectiveness of individualized radiotherapy planning, comparing PET-CT-based to CT-based radiotherapy treatment planning in non-small cell lung cancer. **METHODS:** Our analysis uses a previously developed decision model. The model was based on data for 200 NSCLC patients with inoperable stage I-IIIB, provided by the Maastro Clinic. Transition rates in the model were estimated by multi-state statistical modelling and include the impact of patient and tumour features on disease progression. Resource use estimates, costs and utilities were obtained from the database of the Maastro Clinic, the literature and Dutch guidelines. Primary outcomes were the difference in life years (LY), quality adjusted life years (QALY), costs and the incremental cost-effectiveness and cost-utility ratio (ICER and ICUR) of PET-CT versus CT based radiotherapy planning. Model outcomes were obtained from averaging the outcome for 50 000 simulated patients. To present uncertainty, a probabilistic sensitivity analysis was done. In scenario analyses, we explored the effect of varying the input parameters for costs and QALYs and the effect of changing the assumptions regarding the multi-state model. **RESULTS:** The incremental costs of PET-CT based planning were € 534 (95% CI: €-4670 – €6080) for 0,43 incremental LYs (95% CI: 0,31 – 0,52) and 0,33 QALYs gained (95% CI: 0,26 – 0,45). The base-case scenario resulted in an ICER of € 1242 per LY gained and an ICUR of € 1618 per QALY gained. The probabilistic sensitivity analysis gave a 41% probability that PET-CT based planning improves health outcomes at reduced costs and a 59% probability that PET-CT based planning is more effective at slightly higher costs. **CONCLUSIONS:** PET-based radiotherapy planning for non-small cell lung cancer is highly cost-effective compared to CT-based planning.

PCN126

COST-EFFECTIVENESS OF SYSTEMATIC TESTING FOR LYNCH SYNDROME IN PATIENTS NEWLY DIAGNOSED WITH COLORECTAL CANCER IN THE UNITED KINGDOM

Huxley N[1], Snowsill T[1], Hoyle M[1], Jones-Hughes T[1], Coelho H[1], Cooper C[1], Frayling I[2], Hyde C[1]
[1]*University of Exeter Medical School, Exeter, UK,* [2]*University Hospital of Wales, Cardiff, UK*

OBJECTIVES: The cost-effectiveness of genetic testing for Lynch Syndrome for patients newly diagnosed with colorectal cancer in the UK has not previously been estimated. Therefore, the cost-effectiveness of nine testing strategies were simultaneously compared using a detailed and rigorous mathematical model. **METHODS:** In the base case analysis, probands were tested only if aged 50 or below. Testing strategies included use of family history, tumour-based tests and genetic testing. The clinical pathways of thousands of individual patients diagnosed with colorectal cancer (CRC) and their relatives were simulated. For each person, the total costs and quality-adjusted life years (QALYs) were calculated using methodology recommended by the National Institute of Health and Care Excellence (NICE). Simulated clinical events included incidence of CRC and endometrial cancer (EC); surgery for CRC and EC, colonoscopies (including bleeding and perforation), mortality from CRC, EC, colonoscopy and background causes. A proportion of people diagnosed with Lynch Syndrome were assumed to receive prophylactic hysterectomy and to undergo biennial colonoscopies (assumed to reduce the incidence and stage of colorectal cancer). The costs of treating patients with CRC with surgery, chemotherapy, radiotherapy, stoma care and palliative care were captured. Similarly, the costs of treating patients with EC with chemotherapy and radiotherapy were included. **RESULTS:** The life expectancies of probands and relatives with Lynch Syndrome are estimated to increase by up to 1.6 years, depending on the strategy for genetic testing. All testing strategies are predicted to offer good value for money versus no testing, with all incremental cost-effectiveness ratios below the UK basic cost-effectiveness threshold of £20,000 per QALY. Universal genetic testing is predicted to offer poor value for money versus targeted genetic testing. **CONCLUSIONS:** Results suggest that targeted genetic testing for Lynch Syndrome for patients with newly diagnosed CRC in the UK is a good use of limited financial resources.

PCN127

COST-EFFECTIVENESS ANALYSIS OF CAPSULE ENDOSCOPY IN SCREENING FOR COLORECTAL CANCER IN JAPAN

Sakamaki H[1], Tajiri H[2], Inoue S[3]
[1]*Meijo University, Nagoya, Japan,* [2]*Jikei University School of Medicine, Tokyo, Japan,* [3]*CRECON Research & Consulting INC., Tokyo, Japan*

OBJECTIVES: The PillCam COLON2 is a colon capsule endoscopy (CCE) that makes a minimally-invasive colonoscopy possible and is expected to improve detailed examination rate which have been identified as a problem concerning a population-based colorectal cancer (CRC) screening system in Japan. The objective of this analysis was to evaluate the cost-effectiveness of CCE if newly introduced into the current population-based CRC screening system in Japan. **METHODS:** The subject of this analysis was a sequential screening system for which CCE has been incorporated (immunochemical fecal occult blood test (IFOBT) → detailed examination by CCE → detailed examination by colonoscopy) and the comparator was the conventional sequential screening system (IFOBT → detailed examination by colonoscopy). The target population includes asymptomatic adults aged 40 years old and a lifelong simulation was conducted using a Markov model which consists of 8 states, no polyp, adenomatous polyp (≤ 5mm, 6-9mm and ≥ 10mm), localized CRC, regional CRC, distant CRC and death. The efficacy measures were life year and quality-adjusted life year (QALY). The analysis was conducted from the perspective of the payer and only direct medical costs were considered. **RESULTS:** The incremental cost effectiveness ratio (ICER) observed when incorporating CCE into the conventional screening system was €59,911 per QALY, €25,060 per QALY and €14,905 per QALY when assuming a 10%, a 20% and a 30% improvements in detailed examination rates (1 Euro=128 JPY). Therefore, the introduction of CCE was determined to be cost-effective if the detailed examination rate increased by 20% or more relative to current rate with CCE introduction. **CONCLUSIONS:** Based on this analysis, the introduction of CCE into the conventional population-based screening system in Japan is shown to be cost-effective. The cost-effectiveness of CCE is primarily dependent on the degree of improvement in the current detailed examination rate.

PCN128

COST-EFFECTIVENESS OF FIRST-LINE TREATMENT OF ADVANCED METASTATIC NON SMALL CELL LUNG CANCER- A SYSTEMATIC REVIEW OF ECONOMIC MODELS

Eijgelshoven I[1], Verduyn SC[1], Bhatti T[2], Bexelius C[2], Jansen JP[3]
[1]*Mapi, Houten, The Netherlands,* [2]*F. Hoffmann-La Roche Ltd., Basel, Switzerland,* [3]*Mapi / Tufts University School of Medicine, Boston, MA, USA*

OBJECTIVES: To summarize the modeling methods used in published cost-effectiveness evaluations of first-line treatment for advanced NSCLC patients. **METHODS:** To identify relevant studies, a systematic literature search was performed in Medline®, EMBASE®, Medline-In-Process and the CRD database from 2000 to 2013. In addition, Technology Appraisals (TA) were identified by searching the NICE, SMC and pCODR websites. Studies were included for review based on the following pre-defined criteria; 1) description of cost-effectiveness or cost-utility analysis; 2) inclusion of a comparison of drug interventions in first-line treatment of advanced NSCLC patients; and 3) results were expressed as cost per LY or QALY gained. **RESULTS:** Out of 1009 unique citations, 21 publications and 18 TA met the inclusion criteria. The identified cost-utility and cost-effectiveness analyses were all performed from a payer perspective for a variety of countries in Europe, Asia and North America. The economic value of targeted therapies for first-line and maintenance treatment for advanced NSCLC patients were evaluated for different subpopulations according to histology type (non-squamous, squamous). The most commonly used modeling approach was the state-transition model with health states reflecting stable disease, progression, and death. Transitions between these health states were based on either fixed or time varying transition probabilities. Cost-effectiveness analyses that were based on a synthesis of clinical efficacy evidence primarily relied on the constant hazard ratio assumption. The impact of structural modeling assumptions on cost-effectiveness findings was frequently not reported. **CONCLUSIONS:** Based on a review of published cost-effectiveness evaluations, it was concluded that the rational for certain modeling choices are frequently not provided. In particular, choices pertaining to methods for clinical evidence synthesis and the impact on cost-effectiveness findings need to be justified in a more structured way.

PCN129

COST-MINIMIZATION ANALYSIS (CMA) OF DIFFERENT STRATEGIES TO TREAT NEWLY DIAGNOSED LOCALLY CONFINED LOW-RISK PROSTATE CANCER (LCLRPC) IN GERMANY: RESULTS OF THE HAROW STUDY

Schädlich PK[1], Baranek T[2], Häussler B[1], Weißbach L[3]
[1]*IGES Institut GmbH, Berlin, Germany,* [2]*CSG - Clinische Studien Gesellschaft mbH, Berlin, Germany,* [3]*Stiftung Männergesundheit - Foundation for Men's Health, Berlin, Germany*

OBJECTIVES: The optimal treatment choice for the about 64,000 men diagnosed with prostate cancer each year in Germany still remains unclear. The objectives therefore were to estimate and compare costs under day-to-day conditions of caring for men in Germany with newly diagnosed LCLRPC using hormonal therapy (HT), active surveillance (AS), radiotherapy (RT), operation (OP), or watchful waiting (WW) – HAROW. **METHODS:** The long-term observational multi-centre HAROW study combined data collection from urologists (clinical data; utilized outpatient medical services, OMS) and from patients (employment status, QoL by EQ-5D, numerous health resource use items). Resource use was valued by year 2010 official prices in €. Direct costs (DC) were given by hospital treatment, OMS and drugs, inpatient rehabilitation, patients' co-payments. Indirect costs (IC: sick leave, premature retirement, premature mortality) were estimated by 2010 gross domestic product/capita/day. Costs and quality-adjusted life-years (QALYs) were discounted by 3% per annum. Strategies without significant differences in QALYs/patient-year (PY) were compared by cost-minimization analysis (CMA) using mean costs/PY, remaining strategies by cost-utility analysis. **RESULTS:** From 07/2008 to 03/2013, 3063 LCLRPC patients (T1a–T2c, N0, M0; 67.3±7.5 years) were included from 257 urologists: AS n=452, RT n=378, HT n=210, HT+RT n=80, combination therapy (CT) n=137, OP n=1647, other therapy (OT) n=18, WW n=141. Observation period: average 1.9 years, maximum 4.6 years. From the societal perspective (DC+IC), HT+RT had the lowest cost/PY (€1033), followed by AS (€1265), RT (€1313), WW (€1316), HT (€1522), CT (€3209), OT (€5705), and OP had highest cost/PY (€6656). From the perspective of DC, WW showed he lowest cost/PY (€894), followed by RT (€905), HT+RT (€987), AS (€1014), HT (€1169), OT (€2176), CT (€2204), and OP had highest cost/PY (€5374). **CONCLUSIONS:** The HAROW study provides meaningful results on costs of different LCLRPC treatment strategies under day-to-day conditions of care in Germany to support decision making.

PCN130

HEALTH TECHNOLOGY ASSESSMENT OF CONTRAST-ENHANCED ULTRASOUND (CEUS) TECHNIQUES

Dozsa C[1], Nagy J[2], Borcsek B[3]
[1]*University of Miskolc, Miskolc, Hungary,* [2]*Medience Ltd., Tokol, Hungary,* [3]*Med-Econ Ltd., Veroce, Hungary*

The second generation of contrast-enhanced ultrasound (CEUS) techniques combines the advantages of ultrasound techniques and the additional information provided by the contrast agent. **OBJECTIVES:** To prove that sulphur hexafluoride microbubbles contrast agent used for CEUS is as effective in detecting and analyzing abnormal-looking areas in the liver as currently used imaging techniques (contrast-enhanced CT and MRI: CECT and CEMRI), however the costs of CEUS are considerably lower. **METHODS:** Cost-minimization analysis was based on literature review (last 5 years MEDLINE research, evidence level 1++) and on Hungarian financing data. National medical protocols were also considered. **RESULTS:** Average cost per patient of CEUS was 64,5 EUR, while costs of currently used techniques were 129 EUR. According to the literature 70% of currently used CT and MRI techniques could be replaced by CEUS. Results made it evident that the equally effective contrast-enhanced ultrasound technique is more cost-effective than the currently used contrast-enhanced CT and MRI techniques. Health technology assessment suggested that the change for the new technology would save 64 509 million EUR for the National Health Insurance Fund at the end of the third year of application, counting with 5000 cases. **CONCLUSIONS:** The widespread use of cost-effective CEUS technology is highly recommended as it is an evidently cost-saving technique from the insurer's point of view. Further assessment is recommended to measure clinical parameters, burden of radiology and other quality of life parameters of patients, possibly by using a control group if this is ethically viable.

PCN131

COST-EFFECTIVENESS OF BENDAMUSTINE-RITUXIMAB IN FIRST-LINE INDOLENT NHL: A PATIENT-LEVEL SIMULATION

Dewilde S[1], Woods B[2], Castaigne JG[3], Parker C[2], Dunlop W[3]
[1]*SHE, Brussels, Belgium,* [2]*Oxford Outcomes, Oxford, UK,* [3]*Mundipharma International Limited, Cambridge, UK*

OBJECTIVES: To evaluate the cost-effectiveness of bendamustine-rituximab (B-R) compared with standard of care as first-line treatment for patients with advanced indolent non-Hodgkin's lymphoma (NHL) in England and Wales. **METHODS:** A patient-level simulation was adapted from the model used by the University of Sheffield School of Health and Related Research (ScHARR) in a health technology appraisal of rituximab for first-line treatment of follicular lymphoma (the most common type of indolent NHL). This approach allowed modelling of the complex treatment pathways in indolent NHL; specifically, first-line maintenance and second-line treatment choice could be modelled as a function of patient age, and prior treatment choice and outcome. Data from a Phase 3 randomised, open-label trial by the Study group indolent Lymphomas (StiL) in Germany were used to compare B-R with CHOP-R (cyclophosphamide, doxorubicin, vincristine, prednisone, rituximab). The relative efficacy of CHOP-R and CVP-R (cyclophosphamide, vincristine, prednisone, rituximab) was estimated as per the original ScHARR approach. The analysis was conducted from the perspective of the National Health Service, using a lifetime time horizon. One-way sensitivity and scenario analyses were conducted, including one using recently published randomised trial data comparing CVP-R with CHOP-R. **RESULTS:** The base-case deterministic incremental cost-effectiveness ratio (ICER) was £5,249 per quality adjusted life year (QALY) for B-R *vs.* CHOP-R, and £8,092 per QALY for B-R *vs.* CVP-R. The alternative scenario using direct data comparing CVP-R with CHOP-R more than halved the ICER for B-R *vs.* CVP-R to £3,468. Owing to its better toxicity profile, B-R reduced the cost of treating adverse events by over £1,000 per patient *vs.* CHOP-R. None of the one-way sensitivity or scenario analyses increased the ICER above £20,000. **CONCLUSIONS:** The ICERs for B-R *vs.* CHOP-R and CVP-R were below the thresholds normally regarded as cost-effective in England and Wales (£20,000 – 30,000 per QALY).

PCN132

COST-UTILITY OF GRANULOCYTE-COLONY STIMULATING FACTORS (G-CSFS) FOR PRIMARY PROPHYLAXIS (PP) OF CHEMOTHERAPY INDUCED FEBRILE NEUTROPENIA (FN) IN BREAST CANCER PATIENTS IN THE NETHERLANDS

Somers L[1], Timmer-Bonte JNH[2], Gelderblom H[3]
[1]*OncoLogX bvba, Wuustwezel, Belgium,* [2]*Alexander Monro Breast Cancer Hospital, Bilthoven, The Netherlands,* [3]*Leiden University Medical Center, Leiden, The Netherlands*

OBJECTIVES: To assess number needed to treat to avoid an episode of FN (NNT) and cost-utility in The Netherlands of PP with once-per-cycle pegfilgrastim vs. no prophylaxis and vs. PP with daily G-CSF filgrastim (11-days as per label or 6-days suboptimal use) for reducing FN incidence in women with primary breast cancer receiving high risk chemotherapy for FN (e.g. TAC, a frequently used reference regimen in The Netherlands). **METHODS:** A decision-analytic model was constructed from health care-payer perspective. Costs were from official list prices (April 2013) or literature and included drugs, drug administration and FN-related medical costs and hospitalisations. Effectiveness inputs in terms of relative risk reduction (RRR) for FN were based on a recent meta-analysis. Survival and utility inputs were modeled from available data for breast cancer patients in the US and the UK. Outcomes included NNT and incremental cost effectiveness ratio (ICER) as cost per quality-adjusted life-year gained (QALY). Univariate sensitivity analyses evaluated the robustness of the model. **RESULTS:** NNT with pegfilgrastim PP was lowest at 4.4, with filgrastim 11-days at 5.6 and filgrastim 6-days at 13.4. In terms of cost-utility, pegfilgrastim PP was dominant vs. 11-days filgrastim PP and was considered cost-effective vs. no prophylaxis (€29,896/QALY) and vs. PP with 6-days filgrastim (€7,615/QALY). In a scenario analysis reducing the prices of daily G-CSFs by 40%, pegfilgrastim PP remained cost-effective. The sensitivity analyses revealed that most sensitive variables were FN effectiveness (relative risk reductions), incremental survival assumptions and cost of G-CSFs, and overall the model was robust to sensitivity analyses. **CONCLUSIONS:** In a Dutch setting, pegfilgrastim PP offers a cost-effective approach to PP of FN. In the cost-utility analysis pegfilgrastim PP was dominant vs. 11-days filgrastim PP and cost-effective vs. no prophylaxis and 6-days filgrastim PP.

PCN133

COST-EFFECTIVENESS ANALYSIS OF ABIRATERONE ACETATE AS SECOND LINE TREATMENT FOR METASTATIC CASTRATION-RESISTANT PROSTATE CANCER AFTER DOCETAXEL TREATMENT IN JAPAN

Shibahara H[1], Shiroiwa T[2], Nakamura K[1], Shimozuma K[1]
[1]*Ritsumeikan University, Kusatsu, Japan,* [2]*National Institute of Public Health, Saitama, Japan*

OBJECTIVES: Abiraterone acetate improves overall survival of patients with metastatic castration-resistant prostate cancer (CRCP). The NICE in the UK has recommended abiraterone as a second line treatment for CRCP after docetaxel. Ministry of Health, Labour and Welfare (MHLW) has begun to discuss whether or how to use cost-effectiveness data for reimbursement or pricing. The purpose of this study is to evaluate cost-effectiveness of abiraterone plus prednisolone compared to prednisolone alone in Japan. **METHODS:** Cost-effectiveness analysis was performed using a Markov model (TreeAge Pro 2013) based on data from the randomized control trial (COU-AA-301 study) and literature review conducted from the public health care payer's perspective. The (1) abiraterone (1,000 mg once daily and orally) plus prednisolone (5 mg twice daily and orally) was compared with (2) prednisolone alone. The base case was assumed to be a 69 year-old man with metastatic CRPC. The model used a time horizon of 10 years. Outcomes were measured in quality-adjusted life years (QALYs), and incremental cost-effectiveness ratio (ICER) was calculated. MHLW has yet to approve abiraterone due to the delay in development, and drug cost was estimated based on prices in the UK and the US. Both cost and outcomes were discounted at a 2% annual rate based on Japanese guidelines for eco-

nomic evaluation. Sensitivity analyses were conducted to explore the uncertainties surrounding the assumptions. **RESULTS:** Abiraterone plus prednisolone indicated higher QALYs than prednisolone alone, though it was more expensive. In the base-case analysis, ICER for abiraterone plus prednisolone exceeded JPY 10 million (EUR 80,000) per QALY gained. The one-way sensitivity analysis for discount rate (0 to 4%) showed no affects on the results. **CONCLUSIONS:** The present study concludes that the ICER may be more than JPY 10 million. Further deliberate discussion on cost-effectiveness of abiraterone in Japan is needed to consider the Japanese price and clinical outcomes.

PCN134

ECONOMIC EVALUATION OF HPV VACCINATION PROGRAM IN SOUTH KOREA

Kim J, Kim Y, Ahn J, Kim Y, Park J
National Evidence-based Healthcare Collaborating Agency (NECA), Seoul, South Korea

OBJECTIVES: To assess the cost-effectiveness of a national HPV vaccination program that vaccinates 12 year-old girls with cervical cancer screening and the only current cervical cancer screening. **METHODS:** We analyzed the effect of HPV infection reduction by HPV vaccination on reduction of CIN and cervical cancer and finally conducted cost-utility analysis applying QALYs to which takes into account life span expansion and the quality of life. With the societal perspective, patient time costs, caregiver costs, and transportation costs were all considered as well as medical costs. Markov model was used with one year cycle and life time analysis period. Markov states in this model were classified well, HPV infection, CIN 1, CIN 2/3, cervical cancer (initial cancer), follow-up cervical cancer, recurrent/persistent cancer, follow-up recurrent/persistent cancer and death. The HPV infection was limited to infections caused by HPV specific types 16 and 18. **RESULTS:** When HPV vaccination program is introduced to 12-year old cohort, it was indicated that cervical cancer patients with HPV vaccination program would be 2,042 patients and cervical cancer patients with present screening program 3,709. It results that cervical cancer patients would be decreased to 1,667 by HPV vaccination. From this, it was estimated that all the cohorts would get an additional life expectancy of 1,648 LYG and quality adjusted life years of 1,849 QALYs. According to cost-utility analysis result, additional 1849 QALYs cost KRW 59.8 billion when HPV vaccination program implement, and the incremental cost-utility ratio was estimated to be KRW 32 million per a QALY. Considering the threshold of Korean cost-effectiveness, the vaccination program is decided not to be cost-effective. **CONCLUSIONS:** Though the HPV vaccination program for 12-year old girls was not cost-effective at the current condition of Korea, it is advisable to consider that cost-effectiveness varies sensitively.

PCN135

COST UTILITY ANALYSIS OF EVEROLIMUS IN THE TREATMENT OF METASTATIC RENAL CELL CANCER IN THE NETHERLANDS

Mihajlović J, Minović I, Bruinsma A, Postma MJ
University of Groningen, Groningen, The Netherlands

OBJECTIVES: Metastatic renal cell cancer (mRCC) is becoming an important part of Dutch health care expenditure due to expensive pharmaceutical options for disease control and lack of adequate prevention methods. New targeted therapeutics, such as sunitinib, sorafenib and everolimus, have recently emerged with relevant benefits on progression-free survival (PFS) for mRCC patients. This study aims to assess the cost-effectiveness of the most recent of these introductions, i.e. everolimus, in comparison to best supportive care in second line treatment of mRCC patients in The Netherlands. **METHODS:** A Markov model was designed in line with Dutch treatment protocols. Transitions between health states were modeled by time-dependent probabilities extracted from published Kaplan-Meier curves for PFS and overall survival (OS). The cohorts were followed over 18 cycles, each cycle lasting 8 weeks. Annual discount rates of 1.5% for health and 4% for costs were applied and a health-care perspective was taken. One-way and probabilistic sensitivity analyses (PSA) were performed to test the robustness and uncertainty around the base-case estimate. **RESULTS:** The incremental cost-effectiveness ratio (ICER) for everolimus was esimated at €92,258/QALY. Sensitivity analysis identified the hazard multiplier, an estimate of OS gain, as the main driver of everolimus' cost-effectiveness. Through PSA a wide 95% confidence interval around the base-case ICER estimate was revealed (€49,677 - €453,941/QALY). Additionally, at the threshold of three times GDP per capita (€95,700 in The Netherlands) everolimus had a 54% probability of being cost-effective. **CONCLUSIONS:** The base-case ICER was just below the upper cost-effectiveness limit recommended by WHO, indicating that everolimus might be a cost-effective option in the Dutch setting. However, reasonable uncertainty of the main finding resulted from everolimus' unpredictable gain in OS. Efforts should be undertaken to perform an integral assessment of the economic attractiveness of all current and new therapeutics in mRCC.

PCN136

COST-UTILITY ANALYSIS (CUA) OF DIFFERENT STRATEGIES TO TREAT NEWLY DIAGNOSED LOCALLY CONFINED LOW-RISK PROSTATE CANCER (LCLRPC) IN GERMANY: RESULTS OF THE HAROW STUDY

Schädlich PK[1], Baranek T[2], Häussler B[1], Weißbach L[3]
[1]*IGES Institut GmbH, Berlin, Germany,* [2]*CSG - Clinische Studien Gesellschaft mbH, Berlin, Germany,* [3]*Stiftung Männergesundheit - Foundation for Men's Health, Berlin, Germany*

OBJECTIVES: The optimal treatment choice for preserving quality of life (QoL) of the about 64,000 men diagnosed with prostate cancer each year in Germany still remains unclear. The objectives therefore were to estimate cost utility under day-to-day conditions of caring for men in Germany with newly diagnosed LCLRPC using hormonal therapy (HT), active surveillance (AS), radiotherapy (RT), operation (OP), or watchful waiting (WW) – HAROW. **METHODS:** The long-term observational multi-centre HAROW study combined data collection from urologists (clinical data; utilized outpatient medical services, OMS) and from patients (employment status, QoL by EQ-5D, numerous health resource use items). Resource use was valued by year 2010 official prices in €. Direct costs (DC) were given by hospital treatment, OMS and drugs, inpatient rehabilitation, patients' co-payments. Indirect costs (IC: sick leave, premature retirement, premature mortality) were estimated by 2010 gross domestic product/capita/day. Costs and quality-adjusted life-years (QALYs) were discounted by 3% per annum. Strategies with significantly different QALYs/patient-year (PY) were compared by CUA, remaining strategies by cost-minimization analysis. **RESULTS:** From July 2008 to March 2013, 3063 LCLRPC patients (T1a–T2c, N0, M0; 67.3±7.5 years) were included from 257 urologists: AS n=452, RT n=378, HT n=210, HT+RT n=80, combination therapy (CT) n=137, OP n=1647, other therapy (OT) n=18, WW n=141. Observation period: average 1.9 years, maximum 4.6 years. From the societal perspective (DC+IC), AS and RT each dominated HT, i.e. there were savings/PY (€257 and €208) and QALYs gained/PY (0.0811 and 0.0587) with AS and RT, respectively, versus HT. When comparing OP to HT, there were additional cost (DC+IC) of €5134/PY and 0.0784 QALYs gained/PY for OP versus HT leading to €65,525 per QALY gained. **CONCLUSIONS:** The HAROW study provides meaningful results on cost utility of AS, OP, RT, and HT as LCLRPC treatment strategies under day-to-day conditions of care in Germany to support decision making.

PCN137

A COST-UTILITY ANALYSIS OF EVEROLIMUS PLUS EXEMESTANE FOR THE TREATMENT OF ER+ HER2- METASTATIC BREAST CANCER IN THE UNITED KINGDOM

Taylor M[1], Lewis L[2], Vieira J[3], Chandiwana D[3]
[1]*York Health Economics Consortium, York, UK,* [2]*York Health Economics Consortium, University of York, York, UK,* [3]*Novartis Pharmaceuticals UK Limited, GB- Frimley/Camberley, UK*

OBJECTIVES: This study evaluated the cost-effectiveness of everolimus + exemestane (EVE+EXE) versus placebo + exemestane (PBO+EXE) in patients with ER+ HER2- metastatic breast cancer in the UK. Whilst the effectiveness of treatment has been demonstrated previously, this is the first analysis to assess the cost of the intervention alongside those benefits. **METHODS:** A Markov model was developed to compare treatment with EVE+EXE versus PBO+EXE in patients with ER+ HER2- metastatic breast cancer over a lifetime time horizon (UK health care perspective). Follow-up data on progression-free survival and overall survival were taken from the BOLERO II trial. Weibull functions were used to extrapolate trial data beyond the follow-up period. Utilities from published sources were combined with trial data to calculate quality-adjusted life years (QALYs) associated with each treatment. Drug costs (list prices) and background health state costs (i.e. non-intervention costs) were applied to calculate incremental costs offset. **RESULTS:** Over a ten year time horizon, EVE+EXE led to a life expectancy of 3.27 years, compared to 2.41 for PBO+EXE. EVE+EXE resulted in 1.91 QALYs, compared to 1.31 for PBO+EXE. Therefore, the incremental gains in life years and QALYs were 0.85 and 0.60 respectively. Drug costs were £22,074 and £628 for the two arms respectively, whilst non-drug costs were £22,332 and £21,108 respectively. Therefore, the EVE+EXE arm had an incremental cost of £22,670. The incremental cost per QALY was, therefore, £37,719 over a ten-year time horizon. Probabilistic sensitivity analysis demonstrated that, at a threshold of £30,000 per QALY gained, EVE+EXE had a 27.3% likelihood of being cost-effective. At a threshold of £55,000 per QALY gained, the likelihood of cost-effectiveness was 77.4%. **CONCLUSIONS:** EVE+EXE was associated with increased health care costs, but was also estimated to lead to health gains in terms of both LYs and QALYs.

PCN138

COST-EFFECTIVENESS OF GEMCITABINE PLUS CISPLATIN VERSUS GEMCITABINE ALONE FOR TREATMENT OF ADVANCED BILIARY TRACT CANCER IN JAPAN

Arakawa I[1], Uemura S[1], Murasawa H[1], Inoue T[2]
[1]*Teikyo Heisei University, Tokyo, Japan,* [2]*Tokyo Women's Medical University, Tokyo, Japan*

OBJECTIVES: Gemcitabine plus cisplatin is a common use for chemotherapy patients with advanced biliary tract cancer in Japan. This study aims to assess the cost-effectiveness of this combination therapy compared to monotherapy for biliary tract cancer in Japan. **METHODS:** A Markov model of three states and monthly transmissions was constructed based on a phase II trial. Transition probabilities between states were derived from the trial conducted by Valle, J. et al (2010). and converted to appropriate parameters for input into the model. The associated cost components, obtained from literature published in Japan, were inpatient, outpatient, and medication for biliary tract cancer as well as those for palliative care. We estimated cost-effectiveness per quality-adjusted life year (QALY) at a time horizon of thirty two months. An annual discount for cost and outcome was not considered. **RESULTS:** The model demonstrate no statistical significance in the hazard ratio of 0.625, as compared to an actual ratio of 0.63 (95% confidence interval: 0.51–0.77) retrieved from the clinical trial. The base case outcomes indicated that combination therapy would be more cost-effective than monotherapy when the incremental cost-effectiveness ratio (ICER) was approximately 720,000 YEN per QALY gained, retrospectively. A tornado diagram depicting the deterministic sensitivity analysis of the ICER revealed that the death rate resulting from the combination therapy influenced the base case, but robustness of the base case was identified. A probabilistic analysis resulting from 5,000 Monte Carlo simulations demonstrated efficacy at willingness to pay (WTP) thresholds of 5,000,000 YEN per QALY gained in approximately 95% of the population. **CONCLUSIONS:** In Japan, combination therapy is a cost-effective treatment option for advanced biliary tract cancer.

PCN139

HEAD TO HEAD ECONOMIC EVALUATION OF TWO GENOMIC PROFILES OF RECURRENCE RISK FOR BREAST CANCER, MAMMAPRINT VERSUS ONCOTYPE DX, IN SPAIN

Crespo C[1], Seguí MÁ[2], Cortés J[3], Lluch A[4], Brosa M[5], Becerra V[6], Chiavenna SM[6], Gracia A[6]
[1]*University of Barcelona, Barcelona, Spain,* [2]*Corporación Sanitaria Parc Taulí, Sabadell, Barcelona, Spain,* [3]*Hospital Universitario Vall d'Hebron, Barcelona, Spain,* [4]*Hospital Clínico Universitario, Valencia, Spain,* [5]*Oblikue Consulting, Barcelona, Spain,* [6]*Ferrer Internacional, Barcelona, Spain*

OBJECTIVES: Cost effectiveness analysis of MammaPrint in the diagnosis of early breast cancer from the Spanish NHS perspective. **METHODS:** Markov model

assuming a 60-year-old women cohort with negative-lymph node, positive estrogen receptors and negative HER2 breast cancer. Costs and effects of the treatment by identifying recurrence risk using A!O, MammaPrint or OncotypeDX were compared at 5 years, 10 years and lifetime horizons. Probability of low or high risk of recurrence by A!O was fixed 50/50 (ratios between 40/60 and 60/40 for sensitivity analysis). Risks predicted by OncotypeDX and MammaPrint were assumed to be the same. Cost of chemotherapy (2.825€), recurrence (6,357€) and other direct health care costs were derived from local data. Three health states (free of recurrence, recurrence, death) were defined in a given period of time. **RESULTS:** A total of 31% patients required adjuvant chemotherapy with MammaPrint classification (36.6% with OncotypeDX, 56.3% with A!O). MammaPrint showed a life expectancy of 23.55 years at lifetime Differences in chemotherapy costs, worse prognosis rates and a higher cost of the genomic profile (3,200€ vs. 2,675€) explained higher cumulative costs for OncotypeDX over both alternatives at any time. MammaPrint instead of OncotypeDX showed savings of at least 1,273€ after 5 years. MammaPrint resulted dominant (less costly and more effective) against OncotypeDx at any time horizon and would be cost-effective from the 6th year versus A!O (43,912€, 6,169€ and 287€ per QALY gained at 5, 10 years and lifetime; 30,000€/QALY gained threshold assumed). Sensitivity analysis confirmed base case results with MammaPrint remaining cost-effective until a willingness-to-pay threshold below 275€/QALY gained. Utility of recurrence, age at baseline and probability of A!O low risk were the key drivers at 10 years. **CONCLUSIONS:** MammaPrint in predicting risk of recurrence in these patients and avoiding chemotherapy overtreatment is a dominant strategy over OncotypeDX and it is highly cost-effective against A!O.

PCN140

EARLY-STAGE ECONOMIC EVALUATION OF STRATIFIED MEDICINE IN MULTIPLE MYELOMA

Gaultney JG[1], Redekop WK[1], Sonneveld P[2], van der Holt B[3], Uyl-de Groot C[1]
[1]*Erasmus University Rotterdam, Rotterdam, The Netherlands,* [2]*Erasmus University Medical Center, Rotterdam, The Netherlands,* [3]*Erasmus University Medical Center, Clinical Trial Center, Rotterdam, The Netherlands*

OBJECTIVES: The clinical utility of biomarkers is often uncertain and difficult to demonstrate in an experimental setting. Modeling techniques can be used at the preclinical phase to evaluate their potential therapeutic and economic value. In multiple myeloma (MM), subgroup analyses of pivotal trials show that only patients presenting with adverse prognostic biomarkers demonstrate significantly improved survival with bortezomib-based versus some alternative therapies. A cost-utility analysis was conducted to evaluate the potential value of a risk-stratified treatment (RST) approach versus uniform treatment (UT) in Dutch daily practice MM. **METHODS:** A Markov-type decision analytic model compared total health benefits and costs for two strategies: 1) UT where all patients received the standard of care consisting of bortezomib induction/maintenance and 2) RST where treatment was stratified according to clinical and tumor biomarkers only, molecular biomarkers only, or any biomarker. In RST, high-risk patients received bortezomib while other patients received chemotherapy and thalidomide. Input data originated from clinical trials, literature reviews, observational studies and national tariffs. Various sensitivity and scenario analyses were performed. **RESULTS:** RST dominated UT, with average health gains of 0.007-0.059 LYs (0.009-0.040 QALYs) and cost-savings of €1,842-€4,924 depending on detection method. A scenario analysis for RST where all high-risk patients received an experimental treatment increased health by 0.40 LYs (0.30 QALYs) and costs by €2,567 compared to UT. Influential parameters included the price of bortezomib and survival and quality-of-life-related parameters. **CONCLUSIONS:** An economic evaluation of biomarkers in the preclinical development phase provided evidence that RST in MM may improve health outcomes and lower costs. Modeling techniques made it feasible to assess the circumstances under which RST would be promising and hence guide the prioritization of designing experimental studies to evaluate clinical utility. These findings should encourage payers and users to support the clinical development and adoption of RST approaches in MM.

PCN141

COST-UTILITY OF ACTIVE SURVEILLANCE FOR THE TREATMENT OF LOCALIZED PROSTATE CANCER IN THE CONTEXT OF THE GERMAN HEALTH CARE SYSTEM

Koerber F[1], Waidelich R[2], Stollenwerk B[1], Rogowski W[1]
[1]*Helmholtz Center Munich, Neuherberg, Germany,* [2]*University of Munich, Munich, Germany*

OBJECTIVES: There is an on-going debate about whether to perform surgery on early, localized prostate cancer and put up with common long term side effects of prostatectomy like incontinence and erectile dysfunction. Alternatively such patients could be closely monitored and counselled (active surveillance). This study investigates the cost-utility of active surveillance compared to radical prostatectomy. **METHODS:** A Markov model comparing prostatectomy and active surveillance over a lifetime horizon was programmed in TreeAge. Comparative disease specific mortality was based on the Scandinavian Prostate Cancer Group trial and a review and meta-analysis of comparative effectiveness studies. Resource use was identified via national treatment guidelines and expert interviews covering in-patient, out-patient, medication, aids & remedies as well as out of pocket payments. Utility values were literature-based and used as factor weights to age specific German HRQoL values. Uncertainty is assessed deterministically and probabilistically. **RESULTS:** Our results suggest that active surveillance is a cost saving treatment strategy generating more QALYs at reduced overall costs. The probability of developing metastases under AS and the probability of recurrence as well as utility weights of patients under AS and after prostatectomy were major drivers of cost-effectiveness. Monte Carlo simulation suggests that PE is likely to become at willingness to pay thresholds > €400,000. **CONCLUSIONS:** Active surveillance is likely to be a cost effective treatment option from the perspective of the German Statuary Health Insurance. An improved way of identifying cancers with a high probability of progression could favour active surveillance more clearly. It is not clear yet how the use of individual utilities for side effects would alter the results.

PCN142

AN OVERVIEW OF DOMESTIC CANCER DRUGS IN TURKEY: 2008-2012

Vural EH, Safak Yilmaz E, Vural IM, Dogan E, Akbulat A, Gursoz H, Kerman S
Turkish Medicines and Medical Devices Agency, Ankara, Turkey

OBJECTIVES: Cancer is among the most common causes of death in Turkey. Cancer diagnosis and treatment management were substantially improved by the Ministry of Health. Generic market and price movements of different kinds of drug groups show different characteristics. In this study we aimed to demonstrate the impact of domestic manufacture of cancer drugs on import cancer drug sales in Turkey in terms of both boxes and cost sale trend analysis between 2008 and 2012. **METHODS:** This study was designed as an observational, retrospective study. Domestic oncology drugs were chosen from the base oncology drug groups. The sales data of the domestic oncology drugs and both original and generic import drugs which have the same active ingredient with the domestic drugs was obtained from the Information Medical Statistics (IMS) database from September 2007 to July 2012. Sales data is evaluated with segmented regression analysis for interrupted time series. **RESULTS:** Oncology drug sales report showed that the market share of domestic products increased approximately 38% at 2012 from 0,5% at 2008. Before the cut point, there was a statistically significant increase in the sales level of import oncology drugs, but after the cut point sales trend showed a statistically significant decrease. Import oncology drugs' unit price per box decreased from 196.5TL between September 2007 and October 2008 to 172.6TL between November 2008 and July 2012. But domestic oncology drugs' unit price per box was 91.8TL between November 2008 and July 2012. **CONCLUSIONS:** In conclusion, domestic drug manufacturing has important contributions to a country's economy including low drug prices, supplying for the domestic consumption, creation of employment opportunities and also as export potentials. Price cut in 2009 and 2011 in Turkey and "Reference Pricing System" should be taken into consideration for this price change evaluation in the case of domestic product manufacturing.

PCN143

SHORT-TERM DISABILITY (STD) ASSOCIATED WITH SKELETAL RELATED EVENTS (SRES) IN COMMERCIALLY INSURED PATIENTS WITH BONE METASTASES (BM) SECONDARY TO SOLID TUMORS

Qian Y[1], Song X[2], Zhang K[2], Balakumaran A[1], Arellano J[1]
[1]*Amgen Inc., Thousand Oaks, CA, USA,* [2]*Truven Health, Cambridge, MA, USA*

OBJECTIVES: Patients with BM frequently experience SREs including pathological fracture, surgery or radiation to bone, or spinal cord compression .The study objective was to estimate STD (work hour loss) and associated costs in patients with SREs in a population with BM secondary to solid tumors. **METHODS:** Patients with diagnosis of solid tumors and BM were extracted from MarketScan® Health Productivity and Management Database and Commercial Database in 2002-2010. Eligible patients were 18-64 year-old full-time employees, had STD benefit eligibility, and had ≥6 months continuous pre-index enrollment (pre-period) and ≥1 month follow-up. For SRE patients, index date was the first SRE claim. For patients without SREs, index date was assigned per the distribution of index dates from SRE patients. Monthly STD hours and costs associated with STD were estimated during the first (up to) 6 months and the first (up to) 12 months. Generalized linear models estimated the marginal impact of having SRE on STD hours and associated costs, controlling for baseline STD hours and patients' characteristics. **RESULTS:** A total of 854 patients with SREs and 701 patients without SREs were included, with a mean age of 52.1 and 51.6 years, respectively. 52.2% of SRE patients reported STD during the 6-month follow-up, compared with 19.1% of patients without SREs. For SRE patients, the mean STD hours were 21.2 per month in pre-period and 61.3 during follow-up. The hours for patients without SREs were 8.6 and 14.4, respectively. Multivariate analysis indicated that SREs were associated with significantly increased STD hours (39.4 per month) and associated costs ($613 per month) during the 6-month follow-up period. Results from the 12-month follow-up period were similar. **CONCLUSIONS:** SREs were associated with significantly increased STD hours and associated costs. Therapies that prevent or delay the development of SREs may reduce work loss and costs associated with it.

PCN144

ECONOMIC ACTIVITY OF CANCER SURVIVORS IN POLAND

Macioch T, Hermanowski TR
Medical University of Warsaw, Warsaw, Poland

OBJECTIVES: Although cancer is one of the leading causes of mortality worldwide, the number of cancer survivors is constantly growing due to improved treatment. Growing number of cancer survivors goes in line with trends to increase retirement age and this together leads to increase number of cancer survivors at economically active age. The aim of this study was to analyze economic activity of cancer survivors in Poland. **METHODS:** Data on disability (the number of medical certificates awarded because of incapacity for work) due to cancer and other diseases were retrieved from the Social Insurance Institution annual report for the year 2009. Data included the number of medical certificates issued for the first time and the number of certificates reissued, their periods of validity, age of population and disability severity (complete or partial inability to work, inability of independent existence). **RESULTS:** Cancer was the second (after cardiovascular diseases) cause of medical certificates issued for the first time because of incapacity to work and account for 22% of all certificates awarded for the first time. However, the number of certificates reissued was significantly lower – cancer accounted for 7% of all certificates reissued (cardiovascular diseases still accounted for the largest number of certificates reissued – 25%). The mean age of population with cancer was above the mean age of overall population with medical certificates awarded because of incapacity to work, however lower than those for cardiovascular or pulmonary diseases. Significant differences in disability severity structure exist. Significant higher percentage of cancer patients were judged as either incapable of independent existence (19.9%-24.9% compare to 4.4%-6.5% in overall population) or complete incapable to work (45.9%-71.1% compare to 23.4%-32.9% in overall popula-

tion). **CONCLUSIONS:** Disability in cancer survivors is very common and is more severe than in other diseases.

PCN145
IMPACT OF NURSING AND PHARMACY CARE BETWEEN CAPECITABINE AND 5-FLUORURACIL REGIMENS IN THE MANAGEMENT OF ADVANCED ESOPHAGO-GASTRIC CANCER IN HONG KONG
Lee VWY[1], Yao R[2], Yip E[2], Law K[3], Tang G[3], Zhou KR[1]
[1]*The Chinese University of Hong Kong, Hong Kong, Hong Kong,* [2]*Princess Margaret Hospital, Kowloon, Hong Kong,* [3]*Queen Elizabeth Hospital, Kowloon, Hong Kong*
OBJECTIVES: To compare the possible time savings from reduction of nursing and pharmacy time to manage advanced esophago-gastric cancer (AEGC) patients using capecitabine-based regimens versus traditional 5-FU based intravenous (IV) chemotherapy in the Hong Kong public hospital setting. **METHODS:** This was a time-and-motion study conducted in 2 public hospitals of Hong Kong based on the simulation of previously data on both capecitabine-based regimen (XELOX and XP) and IV 5-FU-based regimen (FOLFOX and FP). The preparation, dispensing and administration time for XELOX, XP, FOLFOX and FP were compared. The capital item utilization including hospital bed, infusion pump etc and length of patient attendance were recorded. Each subject was based on 24-week cycle in the analysis. The projected cost saving in nursing and pharmacy time was estimated if all AEGC in Hong Kong were prescribed capecitabine-based regimen. **RESULTS:** The average nursing time for FOLFOX and FP was 83.7 and 83.4 minutes versus XELOX and XP was 33.7 and 39.8 minutes respectively. The average pharmacy dispensing time for FOLFOX and FP was 25.3 and 71.4 minutes versus XELOX and XP was 18.7 and 19.9 minutes respectively. The total time saved for each patient for a 24-week cycle in FOLFOX versus XELOX was 734.8 minutes in nursing and 154.0 minutes in pharmacy as well as in FP versus XP was 182 minutes in nursing and 269.2 minutes in pharmacy. Nursing and pharmacy could potentially spare 3.3 full time equivalent (FTE) and 1.5 FTE if all AEGC patients were converted to capecitabine-based chemotherapy. **CONCLUSIONS:** Capecitabine-based chemotherapy regimens saved in both nursing and pharmacy time as compared to traditional 5-FU based IV chemotherapy in the Hong Kong public hospital setting.

PCN146
WORKFORCE PARTICIPATION AND PRODUCTIVITY LOSSES AFTER HEAD AND NECK CANCER
Pearce AM[1], Timmons A[1], Hanly P[2], O'Neill C[3], Sharp L[1]
[1]*National Cancer Registry Ireland, Cork, Ireland,* [2]*National College of Ireland, Dublin, Ireland,* [3]*NUI Galway, Galway, Ireland*
OBJECTIVES: There has been no estimate of the productivity losses associated with head and neck cancer (HNC) conducted using bottom-up data, or beyond premature mortality. The aim of this work is to investigate workforce participation, and estimate the productivity losses associated with temporary and permanent work absence, reduced work hours, and premature mortality in individuals with HNC in Ireland. **METHODS:** Survey data were collected from a cancer registry identified cohort of individuals in Ireland diagnosed with head and neck cancer between January 1994 and December 2011. Data collected included employment status at time of diagnosis and workforce participation patterns following diagnosis. These data were combined with population-level survival estimates and national wage data to estimate the value of temporary and permanent work absence, reduced work hours and premature mortality using a Human Capital Approach. **RESULTS:** Of the survey respondents, 276 were in paid work at the time of diagnosis. 88% had time off following diagnosis, with 63% of these returning to work. The mean (median) time off work was 9 months (6 months), range of 0 to 65 months. Seventy percent of individuals returning to work reported reducing the hours they worked, by an average of 20 hours per week. Preliminary results show the average productivity losses per person associated with temporary and permanent work absence and reduced work hours are €222,000. Productivity losses associated with premature mortality and the results of sensitivity analyses to test discount and wage growth rates will also be presented. **CONCLUSIONS:** Head and neck cancer and its treatment can have a profound impact on workforce participation. This affects not only the individuals' and their families, but also society in terms of productivity costs. These costs should be considered in economic evaluations of cancer treatments and health service delivery in this population.

PCN147
HOSPITAL RESOURCES CONSUMPTION ASSOCIATED WITH TRASTUZUMAB TREATMENT IN BREAST CANCER IN PORTUGAL
Andrade S[1], Santos A[2]
[1]*Roche Farmacêutica Quimica, Amadora, Portugal,* [2]*Prime Focus Health, Paço de Arcos, Portugal*
OBJECTIVES: Determine the costs associated with the preparation and administration, considering the material resources (MR) consumption and time spent by the health care professionals (HP), of Her2 positive breast cancer treatment with trastuzumab intravenous (iv) and to estimate the difference compared with a subcutaneous (sc) formulation. **METHODS:** Data were collected in face to face interviews with the pharmacist and nurse responsible for the preparation and administration of trastuzumab in each hospital. The cost of the HP time was calculated by multiplying the value of each HP hour by the average time of each procedure; MR costs were determined based on the values presented in official sources or in price table provided by the manufacturer. **RESULTS:** Five public and two private Hospitals from mainland Portugal, with an average of 12 patients with HER2 + breast cancer treated with trastuzumab iv, per week, participated in the study. The average time spent by the HP in trastuzumab preparation and administration was 79 minutes for iv and 18 minutes for sc. Per treatment cycle, the estimated average overall cost of each treatment was €43.22 (HP - €26.01; MR - €17.21) for iv, and €3.18 (HP - €3.13; MR - €0.05) for sc. Considering the total course of treatment (18 cycles), the treatment with trastuzumab iv is estimated at €777.96 versus €57.19 on sc treatment. **CONCLUSIONS:** Trastuzumab sc formulation would potentially allow savings of approximately €720 per patient, and provide an important benefit to the patients. Trastuzumab sc would also contribute to maximize the efficiency and effectiveness of health resources. This study presents a limitation regarding the subjectivity inherent to costs determination based on answers given by the HP. Moreover values may be underestimated due to lack of information regarding fixed costs.

PCN148
RESOURCE USE OF NON-SMALL CELL LUNG CANCER IN SLOVAKIA
Ondrusova M[1], Psenkova M[1], Berzinec P[2], Basso F[3]
[1]*Pharm-In Ltd., Bratislava, Slovak Republic,* [2]*Specialized Hospital of St Zoerardus Zobor, Nitra, Slovak Republic,* [3]*Boehringer Ingelheim GmbH, Vienna, Austria*
OBJECTIVES: Data on economic burden of advanced or metastatic non-small cell lung cancer (NSCLC) are lacking in Slovakia. Therefore, the objective of this cost of illness study was to measure the resource utilisation and the costs associated with treating advanced or metastatic NSCLC in Slovakia and provide a basis for cost-effectiveness evaluations. **METHODS:** The project was run in two phases: in the first phase an Expert panel took part in the survey and developed the diagnostic and treatment algorithms to reflect the local medical practice and quantify the use of resources associated with anticancer drug treatment, management of adverse events and best supportive care. Then, in the second step, 2012 management costs were applied to the resources. All types of health care used in the NSCLC management were evaluated (outpatient and inpatient visits, diagnostics, prescription drugs and examinations). The analysis was performed from the Slovakian health insurance perspective reflecting direct medical costs only. The structure of cost data follows the requirements of pharmaco-economic modelling in NSCLC. **RESULTS:** Monthly costs of advanced or metastatic NSCLC management during the active treatment (before progression) count for €1055.67, during the disease progression €1101.21 and on the best supporting care €1561.22. The most frequent regimens were cisplatin+gemcitabine (20.6%) and cisplatine+pemetrexed (19.1%) in the first line, erlotinib (49.1%) in the second line and gemcitabine (29.6%) in the third line. The most costly side effects were renal toxicity (€1060.85), febrile neutropenia (€902.92), hemoptysis (€717.08), anaemia (€668.84), pain (€631.34), leukopenia/neutropenia (€629.58), dyspnoe (€628.35), thrombocytopenia (€578.60), nausea/vomiting (€562.72) and fatigue (€523.19). **CONCLUSIONS:** Cost-effectiveness must be demonstrated in order to get reimbursement in Slovakia and local resource use data are key drivers for health economic modelling and can guide resource allocation decisions in NSCLC. This study provides important information to support these decisions.

CANCER – Patient-Reported Outcomes & Patient Preference Studies

PCN149
ADHERENCE RATES FOR INTRAVENOUS CHEMOTHERAPY REGIMENS TO TREAT COLON CANCER
Seal B[1], Asche CV[2], Shermock KM[3], Anderson S[1], Cameron J[1]
[1]*Bayer HealthCare Pharmaceuticals, Inc., Pine Brook, NJ, USA,* [2]*University of Illinois College of Medicine, Peoria, IL, USA,* [3]*The Johns Hopkins Medical Institutions, Baltimore, MD, USA*
OBJECTIVES: It is widely thought that adherence rates to intravenous (IV) chemotherapy regimens for colon cancer are high. However, there are no known formal assessments of this issue. **METHODS:** A retrospective analysis was performed using the Optuminsight Oncology claims database. Patients aged 18 years and older, diagnosed with CRC between July 1, 2004 and December 31, 2010, who were insured by a commercial health plan were included in the study. Adherence to the following IV chemotherapy regimens was assessed using the National Comprehensive Cancer Network (NCCN) guidelines as the standard for expected cycle/regimen duration: FOLFOX, FOLFOX+bevacizumab, FOLFIRI, and FOLFIRI+bevacizumab. Adherence was assessed using the medication possession ratio (MPR), calculated as the number of days a patient was covered by their chemotherapy regimen, according to NCCN guidelines, divided by the number of days elapsed from the first to the last infusion of that regimen. **RESULTS:** A total of 46,941 chemotherapy cycles in 6,880 patients were analyzed. Overall, adherence rates to IV chemotherapy was fairly high, with mean MPR ranging between 0.84 and 0.88 for these regimens. However, a substantial proportion of patients for each regimen experienced low adherence. Twenty five percent of patients receiving FOLFOX, FOLFOX+bevacizumab, and FOLFIRI+bevacizumab regimens experienced MPR<0.8. Additionally, approximately 35% of patients receiving FOLFIRI experienced an MPR<0.8. At least 10% of patients receiving FOLFOX regimens had an MPR less than 0.7; while at least 10% of patients receiving FOLFIRI regimens had an MPR of less than 0.6. **CONCLUSIONS:** Although overall rates of adherence were fairly high, a substantial subpopulation experienced low adherence to each of these IV regimens per NCCN guideline recommendations. The reasons for the low adherence rates need to be explored as this could have an impact on efficacy. These results also highlight the drawback of relying solely on summary statistics at the population level.

PCN150
PERSISTENCE IN PATIENTS WITH BREAST CANCER TREATED WITH TAMOXIFEN OR AROMATASE INHIBITORS- ANALYSIS BASED ON ONCOLOGY ANALYZER DATABASE
Schmidt N[1], Haas G[1], Mergenthaler U[1], Kostev K[1], Hadji P[2]
[1]*IMS Health, Frankfurt am Main, Germany,* [2]*Department of Gynecology, Endocrinology and Oncology, Phillips-University of Marburg, Germany, Marburg, Germany*
OBJECTIVES: Lack of non-compliance is often underestimated in breast cancer treatment. The aim of our study was to analyze the persistence with tamoxifen (TAM) and aromatase inhibitors (AI) in women with breast cancer (BC) and to identify reasons of treatment discontinuation and determinants of non-persistency. **METHODS:** We used data of the Oncology Analyzer database, which includes individual information on patient history related to the treatment of patients across all cancer types. This enables a complete overview of cancer patient care from diagnosis onward, facilitating research in areas such as treatment changesn, dosing and regimen compliance, market sizing and off-label use. We identified 7063 breast cancer patients with a start of TAM or AI therapy from 1990 until 2011 and with a treatment duration of at least 365 days. **RESULTS:** After

one year of follow up, 11.2% of TAM, and 18.4% of AI treated patients discontinued their treatment. In these patients with , the reasons for stopping were: progressive disease including local and distant progression (68.1%), side effects (15.5%), patient's choice (8.6%) and other reasons (7.8%). The multivariate hazard ratios of the cox regression models showed that patients younger than 50 were most likely to discontinue initial therapy when compared with the reference group of women over 70 years of age (HR: 2.30, p=0.01). In contrast, patients treated in gynaecologist or oncologist practice had significantly longer persistence than patients who obtained their prescriptions in general hospital or academic cancer facility (HR: 0.47, p=0.02). Additionally, patients with therapy initiation in gynecological practices had significantly longer persistence than in oncological practice (HR: 0.68, p=0.04). Additionally, metastases were associated with strongly increased risk of treatment discontinuation (HR: 3.81, p<0.01). **CONCLUSIONS:** The proportion of breast cancer patients with therapy discontinuation within first year after therapy start is high and needs to be significantly increased to improved outcome in clinical practice.

PCN151

HEALTH STATE UTILITY VALUES IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS

Chevalier J[1], Le Lay K[2], de Pouvourville G[1]

[1]*ESSEC Business School, Cergy-Pontoise Cedex, France,* [2]*Boehringer Ingelheim France, Paris Cedex 13, France*

OBJECTIVES: Lung cancer has an important impact on Health related Quality of Life (HRQoL). LUCEOR2 is a multi-country prospective study which aimed to measure HRQoL and EQ-5D utility values in Non Small Cell Lung Cancer patients (NSCLC). Previous results presented utility values calculated on the whole LUCEOR2 population and on the French subgroup using the UK tariff for the EQ-5D. Our aim was to calculate utility values with the French tariff for the application in French cost-effectiveness studies. **METHODS:** Data from the LUCEOR2 study that included all patients from participating countries which provided a meaningful sample size for data analysis. Patients were stratified in 7 health states defined by the response of treatment (progressive or stable) and the line of treatment (1st, 2nd, 3rd/4thand BSC). EQ-5D health states were valued using the French tariff. **RESULTS:** A total of 319 patients were recruited in LUCEOR2, HRQoL were available for 258 of them (73 in France). Mean utilities for progression-free patients on 1st, 2nd and 3rd/4th lines were 0.690 (n=116; standard deviation [sd]: 0.258), 0.697(n=46; sd: 0.221) and 0.609(n=25; sd: 0.324) respectively. For patients with progressive disease, values were 0.608(n=26; sd: 0.237), 0.550(n=17; sd: 0.353) and 0.418(n=21; sd: 0.399). Overall, patients with progressive disease had lower mean utility than patients with stable disease (0.530 vs. 0.682 ; p=0.001). Utilities calculated using the French EQ-5D tariff are lower than the utilities calculated using the UK tariff. **CONCLUSIONS:** This study presents the French utility values for patients with NSCLC. It demonstrates the impact of the disease on the HRQol. Further investigations will be made on the potential differences in scores between countries.

PCN152

ESTIMATING HEALTH STATE UTILITIES FOR PATIENTS WITH RELAPSED/ REFRACTORY (R/R) HODGKIN LYMPHOMA (HL) AND SYSTEMIC ANAPLASTIC LARGE-CELL LYMPHOMA (SALCL) IN MEXICO AND BRAZIL

Shingler S[1], Swinburn P[1], Lloyd A[1], Bonthapally V[2]

[1]*Oxford Outcomes, An ICON plc Company, Oxford, UK,* [2]*Millennium: The Takeda Oncology Company, Cambridge, MA, USA*

OBJECTIVES: Benefits of treatment can be measured by utility values. Health utilities typically range between 0 (dead) and 1 (full health) and reflect health-related quality of life (HRQL) in a given health state. Societal values for health states can be captured using the time trade-off (TTO) methodology. Currently, no values exist for health states depicting stages of R/R HL and sALCL for Latin American countries. The aim of this study was to collect utility values from members of the public in Mexico and Brazil for R/R HL and sALCL health states. **METHODS:** Health states were developed using recognized methods, including a literature review, patient and clinician interviews, and cognitive debriefing. States included stages of R/R HL and sALCL (complete response [CR], partial response [PR], stable disease, and progressive disease), and adverse events (AEs) including B-symptoms, acute/chronic graft-versus-host disease (GVHD), and grade I/II or grade III peripheral sensory neuropathy (PSN). Members of the public in Mexico (n=100) and Brazil (n=101) valued each health state using the TTO methodology. **RESULTS:** Participants showed a clear preference for the treatment response states; CR was valued as the state least likely to affect HRQL, with utility gains of 0.13–0.14 over stable disease. The experience of any AE was associated with a large decline in quality of life. The most burdensome AEs were acute GVHD and grade III PSN. Experiencing acute GVHD gave a disutility from stable disease of 0.190 (for Brazil) and 0.125 (for Mexico). Only minor discrepancies existed between the mean utilities for the two countries, the largest being for PR (Mexico, 0.633; Brazil, 0.717). **CONCLUSIONS:** Societal valuation of health states for R/R HL and sALCL revealed the notable perceived benefit of a treatment response and the significant disutility associated with AE experience. Utility values for Mexico and Brazil were broadly consistent.

PCN153

UTILITY VALUES FOR PATIENTS WITH ADVANCED GASTROINTESTINAL STROMAL TUMORS (GIST) TREATED WITH REGORAFENIB VERSUS PLACEBO IN THE PHASE III GRID TRIAL

Connolly M[1], Currie C[2], Chang J[3]

[1]*Unit of PharmacoEpidemiology & PharmacoEconomics, Groningen, The Netherlands,* [2]*Cardiff University, Cardiff, Wales, UK,* [3]*Bayer HealthCare, Montville, NJ, USA*

OBJECTIVES: To estimate utility values by health states for regorafenib and placebo-treated subjects from the phase-3 *GIST – Regorafenib In Progressive Disease* (GRID) trial, and test the assumption that utility values remained constant over successive cycles of treatment in the same health state. **METHODS:** The GRID study included a double-blinded phase, plus an open-label regorafenib phase for those whose disease progressed. The EQ-5D index was evaluated using paired-samples comparison as the primary analysis, and repeated measures as a sensitivity analyses. **RESULTS:** A total of 185 subjects were included; 63% males, with an overall average age of 58 years; 55% received study treatment as 3rd-line, the rest as 4th-line or later. 67% were randomized to receive regorafenib as initial double-blind therapy. Average utility at baseline was 0.767 units. There were no differences in baseline characteristics or EQ-5D for either treatment arm, or those whose disease progressed. The paired-samples analysis compared progression-free EQ-5D index versus any first, post-progression assessment. Of those with available data (N=77) there was a difference of -0.120 units (p=0.001). In the repeated analysis, the Δ-EQ-5D between progression-free disease and disease progression (in double-blind phase) was -0.041 units (p=0.051). The mean EQ-5D index following discontinuation of open-label treatment due to secondary progression was much lower, with a difference of -0.231 units (p<0.001). Whilst adjusting for disease status and treatment, the cycle number did not significantly influence the EQ-5D index (p=0.341). **CONCLUSIONS:** Heath-related utility remained stable over successive treatment cycles after controlling for disease status and treatment type, suggesting that for subjects treated with regorafenib who remained progression-free, that active treatment did not lead to deterioration in utility. Due to the cross-over design, the repeated measures analysis did not contain a homogenous, group of people whose disease had progressed. Thus, the paired-sample analysis provides a better estimate of utility.

PCN154

ASSOCIATIONS BETWEEN OVERALL CARE EXPERIENCE RATINGS AND UTILITY AND PSYCHOLOGICAL WELL-BEING IN MEN RECENTLY DIAGNOSED WITH PROSTATE CANCER: FINDINGS FROM A POPULATION-BASED STUDY

Hennessy M, O'Leary E, Comber H, Drummond FJ, Sharp L

National Cancer Registry Ireland, Cork, Ireland

OBJECTIVES: Patient experience is increasingly recognised as an important measure of quality of care. A few studies have suggested that patients who report higher levels of satisfaction with care also have higher quality-of-life and higher psychological wellbeing, and are more likely to cooperate with treatment. In Ireland, this area is under-researched. The PiCTure 2 study aimed to assess the care experiences of men recently diagnosed with prostate cancer – the most common cancer among men in Ireland - and investigate associations between experiences and health-related quality-of-life (utility) and psychological wellbeing (depression, anxiety and distress). **METHODS:** Men diagnosed with invasive prostate cancer (ICD10 C61) 5-20 months prior to study commencement were identified through the National Cancer Registry. The patient experience questionnaire was based on the Prostate Care Questionnaire (Baker et al. 2007), modified for Ireland. Utility and psychological wellbeing were assessed using the EQ5D-5L and Depression Anxiety and Stress Scale (DASS-21). The questionnaire was administered by post to 2,180 men during January-April 2013. EQ5D-5L responses were converted to EQ5D-3L health states and valued with UK valuations. **RESULTS:** A total of 1499 valid questionnaires were received (response rate=70%). Men rated their overall care very highly; however, there were variations with those (i) further from diagnosis, (ii) in poorer health, (iii) younger, (iv) with third level education and (v) with private health insurance significantly more likely to report poorer care experiences. Almost half of men reported maximum utility scores; one-fifth had depression, one-fifth anxiety and one-eighth stress. Lower global experience scores were significantly associated with lower utility values and poorer psychological well-being (p<0.001). **CONCLUSIONS:** While men recently diagnosed with prostate cancer report quite high overall care experience ratings, variations were reported and associations with lower utility and psychological well-being were observed. These results provide further rationale for initiatives to improve quality of care.

PCN155

UTILITY MAPPING OF THE EORTC QLQ-C30 ONTO EQ-5D IN PATIENTS WITH SOFT TISSUE SARCOMA

Amdahl J[1], Manson SC[2], Isbell R[2], Chit A[3], Delea TE[4]

[1]*PAI, Brookline, MA, USA,* [2]*GlaxoSmithKline, Uxbridge, UK,* [3]*GlaxoSmithKline, Mississauga, ON, Canada,* [4]*Policy Analysis Inc. (PAI), Brookline, MA, USA*

OBJECTIVES: The European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire Core 30 (EORTC QLQ-C30) is one of the most commonly used quality of life instruments in clinical trials of anti-cancer agents. Here we present an algorithm for mapping between the QLQ-C30 and EQ-5D preferences in an adult population with advanced soft tissue sarcoma (aSTS) who participated in the PALETTE trail, building upon mapping work performed in other tumours. **METHODS:** Data from the PALETTE trial assessing pazopanib versus placebo for the treatment of aSTS (n=369) was used, where EQ-5D was assessed at baseline and week 4, and the QLQ-C30 at baseline plus weeks 4, 8 and 12. Ordinary least squares (OLS) and generalised linear model regression using a generalised estimating equations (GLM/GEE) approach was employed with the EQ-5D disutility value as the dependent value. A variety of model forms were tested with different link functions and error term distributions, as well as using two stage models and including factors other than QLC-C30 terms (i.e., age, sex, ECOG status). **RESULTS:** There was relatively little variability in the root mean square error (RMSE) and R-squared across 28 different models tested, with the RMSE ranging from 0.16 to 0.18 and the R-squared ranging from 0.54 to 0.63. Using GLM/GEE vs. OLS, adding non QLQ-C30 terms, two-stage models, and squared terms for QLQ-C30 scores all improved R^2, albeit slightly. All the models overestimated the disutility for assessments with zero disutility and underestimated the disutility for assessments with large disutilities, as has commonly been reported for such algorithms. **CONCLUSIONS:** The mapping algorithms tested had reasonable predictive validity. These algorithms were used in cost-effectiveness evaluations of pazopanib in aSTS patients and may be useful for future cost-effectiveness evaluations of other therapies for this indication.

PCN156

COMPARATIVE RESPONSIVENESS OF DIRECT AND MAPPED SF-6D PREFERENCE-BASED MEASURES IN COLORECTAL CANCER

Wong CKH[1], Mulhern B[2], Wan YF[1], Lam CLK[1]
[1]*The University of Hong Kong, Hong Kong Island, Hong Kong,* [2]*University of Sheffield, Sheffield, UK*

OBJECTIVES: This study examined the responsiveness of preference-based measures based on the anchor of self-reported change in general health condition of patients with colorectal cancer (CRC). **METHODS:** A baseline sample of 333 patients was recruited at the specialist outpatient clinic of academic teaching hospital in Hong Kong between September 2009 and July 2010, and was surveyed prospectively at 6-month follow-up. SF-6D preference-based indices were derived from the generic SF-6D measure ($SF\text{-}6D_{Direct}$), from the Short Form-12 Health Survey ($SF\text{-}6D_{SF\text{-}12}$) and also mapped from the condition-specific Functional Assessment of Cancer Therapy-Colorectal ($SF\text{-}6D_{FACT\text{-}C}$). The responsiveness of three measures was assessed using the internal responsiveness and external responsiveness. The 95% bias-corrected and accelerated bootstrapping confidence intervals were performed to compare the internal responsiveness statistics measured by standardized effect size, standardized response mean, and responsiveness statistic. External responsiveness was evaluated by receiver operating characteristic (ROC) curve analysis that examined the ability to detect score changes with global health condition changes or discriminate between the worsened and unchanged/improved groups. **RESULTS:** Over half of patients reported no change in global health condition based on the self-reported anchor, whilst 15.1% and 32.9% of patients rated better and worse in current health condition compared to baseline respectively. In worsened group, internal responsiveness was satisfactory for the $SF\text{-}6D_{Direct}$ and $SF\text{-}6D_{FACT\text{-}C}$ preference-based indices. The $SF\text{-}6D_{SF\text{-}12}$ and $SF\text{-}6D_{FACT\text{-}C}$ indices were significantly more responsive to detect positive changes than the $SF\text{-}6D_{Direct}$ index in improved group. The $SF\text{-}6D_{Direct}$ and $SF\text{-}6D_{FACT\text{-}C}$ indices were more externally responsive based on ROC curve. The $SF\text{-}6D_{FACT\text{-}C}$ index was generally more responsive to changes in health status compared with other indices. **CONCLUSIONS:** Direct SF-6D measure was more responsive than mapped preference-based measures in improved group but the direction was reversed in worsened group. Use of a preference-based index mapped from a condition-specific measure captures both negative and positive important changes in HRQOL score among CRC.

PCN157

QUALITY OF LIFE IN PATIENTS WITH METASTATIC COLORECTAL CANCER (MCRC): A UTILITIES STUDY IN THE UNITED KINGDOM AND THE NETHERLANDS

Stein D[1], Joulain F[2], Iqbal SU[3], Naoshy S[3], Muszbek N[4], Payne KA[1], Ferry DR[5]
[1]*Evidera, Dorval, QC, Canada,* [2]*Sanofi, Chilly-Mazarin, France,* [3]*Sanofi, Cambridge, MA, USA,* [4]*Evidera, London, UK,* [5]*The Dudley Group NHS Foundation Trust, Dudley, UK*

OBJECTIVES: To elicit utility values from EQ-5D for patients with various stages of mCRC. **METHODS:** An observational cross-sectional study consisting of one-time EQ-5D completion at enrollment was conducted in five hospitals in The Netherlands and the United Kingdom (UK). Patients were categorized into stable or progressed cohorts based on investigator assessment. Patients with mCRC were eligible if on second or subsequent lines of treatment or best supportive care [BSC], received prior oxaliplatin, no prior irinotecan, and had Eastern Cooperative Oncology Group (ECOG) performance status scores of 0-2 at second line initiation similar to the VELOUR trial. Chart data on patient demographics, clinical history, prior/current treatments, serious adverse events (SAEs) were collected. Average utilities were estimated; uni- and multivariate analyses were conducted. **RESULTS:** A total of 75 patients were enrolled, 42 patients stable on second line or third line following an AE on second line and 33 progressed patients. Mean age was 63 (standard deviation [SD]=10); 52% male. Most patients in the stable (98%) and progressed (88%) cohorts had ECOG scores of 0-1 at enrollment. 7% and 15% of patients in stable and progressed cohorts respectively had ongoing SAEs at enrollment. Mean utility scores were 0.741 (SD=0.230) and 0.731 (SD=0.292) for stable and progressed patients respectively. Higher proportions of patients reported increased anxiety/depression (36% vs. 12%) and fewer problems with daily activities post-progression (64% vs. 38%). 83% and 42% of patients in stable and progressed cohorts respectively, were on treatment at enrollment. **CONCLUSIONS:** While the majority of the stable cohort had good performance status and few SAEs ongoing at enrollment, utility values were not much higher compared to the progressed cohort. Higher values in the progressed cohort may be attributed to exclusion of patients in palliative care centers, radiological versus symptomatic disease progression and patients remaining on treatment, having few SAEs and good performance status at enrollment.

PCN158

UTILITY VALUES USED IN NATIONAL INSTITUTE FOR HEALTH AND CARE EXCELLENCE (NICE) TECHNOLOGY APPRAISALS OF MEDICINES FOR 4 METASTATIC CANCERS

Burke MJ[1], Sidhu R[2], George E[2]
[1]*National Institute for Health and Care Excellence, Manchester, UK,* [2]*National Institute for Health and Care Excellence, London, UK*

OBJECTIVES: National Institute for Health and Care Excellence (NICE) considers the quality-adjusted life year (QALY) to be the most appropriate generic measure of health benefit that reflects both mortality and health-related quality of life effects. The QALY is the sum of a person's length of life in each health state multiplied by a quality-adjustment weight (that is, utility value) associated with that health state. Cost-effectiveness results are often sensitive to the choice of utility value, but relevant and comparable utility values are not always available leading to debate about the most appropriate utility values to include. The objective of the research was to review the health-related utility values used in economic models across NICE technology appraisal guidance for 4 metastatic cancers. **METHODS:** A cross-sectional review of manufacturer submissions and reports produced by independent academic groups was carried out to identify the health-related utility values used. Information relating to the methods used to elicit utility values that were selected for use in cost-effectiveness analyses were compared with methods specified by NICE as the reference case in its 2004 and 2008 Methods Guides. The review focused on guidance published before June 2013 for medicines treating metastatic breast cancer, metastatic colorectal cancer, metastatic hormone-refractory prostate cancer and metastatic non-small-cell lung cancer. Nineteen technology appraisals published between March 2002 and August 2012 met the inclusion criteria. **RESULTS:** Common themes or variations that exist between utility values selected by manufacturers and independent academic groups for each metastatic cancer and between the 4 metastatic cancers were analysed. The research also explored the methodological issues that were considered by the Appraisal Committee relating to the selection of utility values. **CONCLUSIONS:** Therefore, this research provides insight to the methodological considerations regarding incorporation of utility values that have informed health technology assessment decision-making in England for 4 metastatic cancers.

PCN159

PATIENTS' AND CAREGIVERS' PREFERENCES FOR BONE METASTASES (BM) TREATMENTS IN THE UNITED STATES

Qian Y[1], Mohamed AF[2], Hauber AB[2], Collins H[1], Hechmati G[3], Gatta F[3], Arellano J[1]
[1]*Amgen Inc., Thousand Oaks, CA, USA,* [2]*RTI Health Solutions, Research Triangle Park, NC, USA,* [3]*Amgen (Europe) GmbH, Zug, Switzerland*

OBJECTIVES: Patients with BM from solid tumors often experience skeletal-related events [SREs]; commonly defined as pathologic fracture, radiation or surgery to bone, and spinal cord compression. Several bone-targeted agents are approved for the prevention of SREs. This study evaluated US patients' and caregivers' preferences in relation to available treatment options in the US. **METHODS:** Adults with or adult caregivers of patients with a self-reported physician diagnosis of BM from a solid tumor completed a web-enabled discrete-choice experiment survey comprising a series of 10 choices between pairs of hypothetical medication profiles. Each profile included 6 medication attributes within a pre-defined range (primarily based on prescribing information and real-world practice): months until first SRE (10, 18 and 28 months); months until worsening of pain (3, 6, 10 months); annual risk of osteonecrosis of the jaw (ONJ; 0%, 1%, 5%); annual risk of renal impairment (0%, 4%, 10%); mode of administration (subcutaneous injection, 15-minute infusion, 120-minute infusion); and monthly out-of-pocket cost to patients ($25, $75, $150, $330). Choice questions were based on an experimental design with known statistical properties. The survey was pretested with 15 patients and 11 caregivers using open-ended interviews. A separate main-effects random parameters logit model was estimated. **RESULTS:** In total, 187 patients and 197 caregivers completed the survey. Among the attribute levels included, out-of-pocket cost to patients, risk of renal impairment, and months until first SRE were most important to both patients and caregivers. For those attributes, better outcomes were preferred to worse outcomes ($p<0.05$) except that risk of renal impairment between 4% and 10% was not significant for patients; costs between $25 and $75 were not significant for either group. **CONCLUSIONS:** When considering treatment choices for preventing skeletal complications associated with BM, patients and caregivers focused mainly on out-of-pocket cost to patients, avoiding renal impairment, and delaying SREs.

PCN160

CLINICAL OUTCOME ASSESSMENTS IN FDA ONCOLOGY LABELS SINCE 2010

Meyers OI[1], Foley K[2]
[1]*Truven Health Analytics, Cleveland, OH, USA,* [2]*Truven Health Analytics, Cambridge, MA, USA*

OBJECTIVES: In 2009, the FDA released Final Guidance on Patient-Reported Outcomes (PROs) and has stated that standards for PROs apply equally to Clinician and Observer Reported Outcomes (ClinROs, ObsROs; collectively, clinical outcome assessments - COAs). The objective was to survey labels for oncologic drugs approved in the three years since the "PRO Guidance" was finalized and to characterize any COAs in these labels. **METHODS:** CenterWatch maintains a list of FDA approved drugs following definitions established by the Tufts Center for the Study of Drug Development, including only drugs or NMEs newly approved by the FDA Center for Drug Evaluation and Research. From 2010 to the time of this review in 2013, 45 oncologic drugs were approved by the FDA. The FDA approved product labels of each of these drugs was reviewed and each was tabulated according to its inclusion of COAs. **RESULTS:** Few of the approved product labels reviewed included any reference to, much less data collected using PROs, ClinROs, or ObsROs. Several (e.g., carfilzomib) had clear statements to indicate that approval for the product was based on a predefined response rate rather than any "improvement in survival or symptoms." The notable exceptions are fentanyl sublingual tablets and spray and abiraterone, with PRO data on pain. **CONCLUSIONS:** There are several explanations for the low rate of COAs in oncology labels, especially that oncology trials tend to be unblinded. The FDA has stated that open label designs cannot support PRO claims. Yet there is still a heavy reliance on outcomes such as progression free and overall survival. Three labels were identified with PRO data on pain, two of which were specifically indicated for pain rather than tumor control. This review suggests there are opportunities for sponsors and the FDA to increase the degree to which the patient's voice is heard during the regulatory decision making process.

PCN161

SYSTEMATIC REVIEW OF PATIENT REPORTED OUTCOMES IN CHRONIC MYELOID LEUKEMIA

Aggarwal S, Segal J, Topaloglu H
Novel Health Strategies, Bethesda, MD, USA

OBJECTIVES: Patient reported outcomes (PRO) are becoming useful tools for collecting and generating evidence for new medical products to show improvements in health-related quality of life (HRQoL). Chronic myeloid leukemia (CML) is now a chronic disease in which HRQoL is becoming important. The objective of this study was to review, analyze, and understand trends in the PRO instruments used in patients with CML. **METHODS:** A systematic literature search for CML randomized controlled trials (RCTs) with PROs endpoints was undertaken for the databases Pubmed, Embase, Biosis, Google Scholar, and Cochrane. Data was collected for the study size, interven-

tions, year, PRO instrument, and results for PROs. Analysis was conducted to identify trends in commonly used PRO instruments and results were categorized as positive, neutral, or negative. **RESULTS:** Eight RCTs with a total of 3,342 patients were identified. In these studies, there were eight different PROs instruments identified: FACT-Leu, SF-36, FSI, PSQI, MSAS-SF, FACT-BRM, EQ-5D, and MDASI-CML. The most commonly used instruments were FACT-Leu (used in 1,336 patients) and FACT-BRM (used in 1,199 patients). Five studies reported positive results with improvement in quality of life (QoL) symptoms versus comparator treatments. Two studies reported results highlighting significant deterioration in QoL versus patients with no cancer. One study reported QoL in various types of CML and showed significant deterioration in patients with chronic phase CML versus those with acute and blast phase CML. Studies also identified two QoL domains, depression and fatigue, which matter most for patients with CML. **CONCLUSIONS:** Patients with CML have significant deterioration in their QoL. PRO instruments such as FACT-Leu and FACT-BRM can aid in generating evidence to show which therapies improve patient QoL.

PCN162

PATIENT REPORTED OUTCOMES IN METASTATIC CASTRATION-RESISTANT PROSTATE CANCER

Aggarwal S, Segal J, Kumar S
Novel Health Strategies, Bethesda, MD, USA

OBJECTIVES: Patient reported outcomes (PRO) are becoming useful tools for collecting and generating evidence for new medical products to show improvements in health-related quality of life (HRQoL). Castration-Resistant Prostate Cancer (CRPC) is a chronic disease with high importance for patient HRQoL. The objective of this study was to review, analyze, and understand trends in the PRO instruments used in patients with CRPC. **METHODS:** A systematic literature search for CRPC randomized controlled trials (RCTs) with PROs endpoints was undertaken for the databases Pubmed, Embase, Biosis, Google Scholar, and Cochrane. Data was collected for the study size, interventions, year, PRO instrument, and results for PROs. Analysis was conducted to identify trends in commonly used PRO instruments and categorize results as positive, neutral or negative. **RESULTS:** Ten RCTs with a total of 5,797 patients were identified. In these studies there were thirteen different PROs instruments were identified that were FACT-P, FACT-G, BPI-SF, EQC30, EQPR25, FLIC, SDS, SUF, PDA, IPDA, PROSQOLI, SF-36, and QOLM-P14. The most commonly used instrument were FACT-P (used in 4,297 patients) and EQC-30 (used in 1,091 patients). Six studies reported positive results with improvement in quality of life symptoms (QoL) versus comparator treatments. Fours studies reported results with deterioration in (QOL). Three studies reported improvement in pain scores. **CONCLUSIONS:** Patients with CRPC have relatively longer survival and hence QoL is an important consideration for these patients. PRO instruments such as FACT-P and EQC-30 have been commonly used to generate evidence to show which therapies improve patient QoL.

PCN163

ARE "DIZZY" AND "LIGHTHEADED" THE SAME CONCEPT OR SEPARATE CONCEPTS? CHALLENGES IN CONCEPTUAL EQUIVALENCE OF THESE TERMS IN 20 LANGUAGES

Eremenco S[1], Arnold BJ[2]
[1]*Evidera, Bethesda, MD, USA,* [2]*FACITtrans, Elmhurst, IL, USA*

OBJECTIVES: Feeling "dizzy" or "lightheaded" are common concepts in patient-reported outcome (PRO) instruments in a number of conditions. The Functional Assessment of Cancer Therapy – Anemia (FACT-An) subscale contains an item assessing "feeling dizzy (lightheaded)" as one concept while other instruments propose to assess the symptoms as two separate concepts or items. The purpose of this study was to translate and assess conceptual equivalence of this concept across 20 languages (21 countries). **METHODS:** The FACT-An was translated following the FACIT Translation methodology which is consistent with ISPOR guidelines for translation and cultural adaptation of PRO measures (Wild et al., 2005). The translation process for each language consisted of: 2 forward translations by native translators, reconciliation of the forward translations, 1 back-translation by an English-speaker fluent in the target language, 3 reviews by native translators or clinicians, final reconciliation by a native speaking linguist, and harmonization. Interviews were conducted among 456 native-speaking patients in 21 countries. Data were analyzed to assess linguistic and cultural validity of the FACT-An in each language and confirm conceptual equivalence. **RESULTS:** Mean age of the sample (N=456) was 55 years, (range 19-88) and 58% were male. During the translation phase, 12 of the 20 languages translated the concept of dizzy (lightheaded) using only one term, and the remaining 8 languages provided two terms. The rationale was that one word was used to describe this set of symptoms and it would be a complicated explanation to address the second term. The translations were well understood and considered relevant. **CONCLUSIONS:** The majority of languages in this study provided only one term for the concept of dizzy (lightheaded) indicating that it may be problematic to assess the concept as two separate symptoms in future questionnaires in other languages where this concept is not separated as it is in English.

PCN164

PRO CLAIMS IN JAPANESE ONCOLOGY PRODUCT LABELING

Crawford B
Adelphi Values, Tokyo, Japan

OBJECTIVES: There is a growing use of patient-reported outcomes (PRO) in the US and Europe but little is known about Asia. Oncology in particular is an area of growing interest. This study sought to review PRO labeling within oncology products over the last five years in Japan. **METHODS:** Oncology labels were identified by reviewing the Pharmaceutical and Medical Devices Agency (PMDA) postings of label changes for the past 5 years (2007-2012). For identified products with label changes, labels and Interview Forms (IF) were acquired and reviewed. The IF is used as a supplement to the label in Japan to provide additional data that will not fit within the package insert. Only PROs used for potential promotion were evaluated. Symptoms such as pain listed in the adverse events or safety sections were not included in this review. **RESULTS:** A total of 84 active ingredients had new indications or label changes. After removal of 25 duplicate ingredients (or updated again during this timeframe), 59 labels and IFs were identified and reviewed. No product labels contained PRO information. However, in contrast 20 (34%) IFs contained PRO information. 10 of these IFs only stated that "QOL" or "PRO" was assessed without details on the questionnaires or results. The EORTC (European Organisation for Research and Treatment of Cancer) and FACT (Functional Assessment of Cancer Therapy) were explicitly stated as measures in four and three IFs, respectively. There were also three pain assessments; two Visual Analog Scale assessments and one utilizing the Brief Pain Inventory – Short Form (BPI-SF). **CONCLUSIONS:** Although no oncology labels contained PRO information, the IFs contained PRO information. 1/3 of product information contained a mention of PROs which can be used in discussions with clinicians.

PCN165

CHANGES IN PATIENT-REPORTED OUTCOMES AMONG PEDIATRIC LEUKEMIA AND LYMPHOMA PATIENTS DURING THE FIRST 2-YEARS POST ALLOGENEIC STEM CELL TRANSPLANTATION (ALLOSCT)

Oberg JA[1], Morris E[2], Cairo M[2], Kelly KM[1]
[1]*Columbia University, New York, NY, USA,* [2]*New York Medical College, Valhalla, NY, USA*

OBJECTIVES: To explore changes in child-reported quality of life (QOL) of pediatric leukemia/lymphoma patients receiving alloSCT. **METHODS:** Hierarchical linear modeling was used to explore trends in select PedsQL 4.0 sub-scales and individual items of 43 children ≥5 years of age. QOL was assessed once pre-alloSCT and on days 100, 180, 365, and 730, post-alloSCT. **RESULTS:** Median age: 13.54 years, Range: 4.66-23.12 years; leukemia: 76.7%; lymphoma: 23.3%; reduced-toxicity conditioning (RTC)/myeloablative conditioning (MAC): 44%/56%; chronic graft-versus-host disease (cGVHD): 27.9%. Emotional and social functioning was stable pre-to-post-alloSCT and comparable to a normative pediatric sample ($p>.05$), whereas physical functioning was 19 points lower pre-alloSCT ($M=67.42$; $p<.01$; $ES=1.26$SD) with improved scores approaching norms by Day +730. 51-65% of children at baseline reported difficulties with sports/exercise, strength, pain, and fatigue. Significant improvements from baseline ($M=51.41$) were observed in sports/exercise at a rate of 1.06 points-per-month (ppm)/12.90 points-per-year (ppy) ($t=2.57$; $p=.01$) and strength ($M=47.47$; $t=2.05$; $p=.04$) at a rate of 0.84 ppm (10.21ppy). Recipients of RTC significantly improved at a rate of 14.04ppy (slope=1.16; $t=2.41$; $p=.02$) compared to children who received MAC (-4.01ppy; slope=-0.33). Similarly gains in strength were significantly better for the RTC group (12.94ppy; slope=1.06; $t=2.25$; $p=.02$) than the MAC group (-10.62ppy; slope=-0.83). Levels of pain ($M=64.82$; slope= 0.05ppm; $t=0.15$; $p=.88$) and fatigue ($M=58.01$; slope=0.39ppm; $t=1.14$; $p=.26$) remained unchanged irrespective of conditioning regimen. Emotional functioning of children ages 8-12 significantly improved from baseline ($M=70.18$; slope=1.78ppm; $t=2.89$; $p=.01$), whereas children ≥13 significantly declined post-alloSCT ($M=72.61$; slope=-1.34ppm; $t=-2.64$; $p=.01$). Presence of cGVHD did not significantly affect outcomes scores. **CONCLUSIONS:** Improvements in exercise and strength were seen with RTC regimens whereas pain and fatigue remained unchanged independent of conditioning regimen. Older children may have more emotional difficulties post-alloSCT. These results highlight the importance of including QOL to monitor patients and further define outcomes for this population.

PCN166

QUALITY OF LIFE IN PATIENTS WITH OSTOMY IN POLAND: MULTICENTRE CROSS-SECTIONAL STUDY USING WHOQOL-BREF QUESTIONNAIRE

Golicki D[1], Styczen P[2], Szczepkowski M[3]
[1]*Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland,* [2]*Gabinet Lekarski, Konopiska, Poland,* [3]*Faculty of Rehabilitation, Jozef Pilsudski University of Physical Education in Warsaw, Warsaw, Poland*

OBJECTIVES: To assess quality of life of Polish patients with a stoma using validated generic questionnaire. **METHODS:** Adult patients with colostomy, ileostomy or urostomy performed in Poland between July 2009 and December 2010 were included. Patients completed satisfaction survey at the discharge from the hospital, and The World Health Organization Quality of Life-BREF (WHOQOL-BREF) generic questionnaire at 3 months after surgery. **RESULTS:** The study involved 1519 patients (71.5%, 16.8%, 11.7% with colostomy, ileostomy and urostomy, respectively). The studied population was highly diversified in terms of: pain and discomfort, dependence on medical treatment and acceptance of physical appearance. 57% of patients with a stoma defined their quality of life as good or very good (mean 3.54 points; range: 1 to 5; SD 0.73). The subjects were characterized by low quality of life assessment in the physical health and psychological domains (53.5 and 60.0 pts.) and by high evaluation in the environment and social relationships domains (69.6 and 70.2 pts.). Respondents highly assessed: the level of social support, home environment, physical environment, personal relationships. Low assessment was related to: sexual activity, ability to work, dependence on medical treatment, financial resources, satisfaction with health. **CONCLUSIONS:** This is the first Polish study on the quality of life of patients with a stoma, based on validated generic questionnaire. The results should help improve standards of care for patients with a stoma.

PCN167

INFLUENCE OF ANXIETY AND DEPRESSION ON 1-YEAR HEALTH RELATED QUALITY OF LIFE IN COLORECTAL CANCER PATIENTS

Escobar A[1], Billbao A[1], Trancho Z[1], Quintana J[2], Sarasqueta C[3], Baré M[4]
[1]*Basurto University Hospital (Osakidetza).Red de Investigación en Servicios Sanitarios y Enfermedades Crónicas (REDISSEC)., Bilbao, Spain,* [2]*Galdakao-Usansolo Hospital (Osakidetza). Red de Investigación en Servicios Sanitarios y Enfermedades Crónicas (REDISSEC)., Galdakao-Usansolo, Spain,* [3]*Donostia Universitary Hospital. Red de Investigación en Servicios Sanitarios y Enfermedades Crónicas (REDISSEC), Donostia, Spain,* [4]*Hospital Parc Tauli. Red de Investigación en Servicios Sanitarios y Enfermedades Crónicas (REDISSEC), Sabadell, Spain*

OBJECTIVES: To assess the impact of anxiety and depression measured by Hospital Anxiety and Depression Scale (HADS) on 1-year HRQoL measured by EuroQol-3L (EQ-5D) and EORTC-QLQ-C30 on patients with colorectal cancer. This aspect of continuity

of care could be nowadays a major issue **METHODS:** This prospective study carried out in 12 Hospitals. At baseline patients fulfilled EQ-5D questionnaire (utility and VAS scale), EORTC-QLQ-C30 (physical, role, emotional, cognitive and social functioning, and global health) and HADS. One year post-surgical management they completed the EQ-5D and EORTC-QLQ-C30. We used general linear models to establish the influence of baseline anxiety (HADS-A) and depression (HADS-D) on changes in HRQoL, adjusted by baseline score and gender. We have used the recommended cut-off points of HADS ≤7 (normal); 8-10 (uncertain) and ≥11 (problem). **RESULTS:** There were 778 patients. The mean age (SD) was 67.4 (10.4). Males represented the 62.7%. At baseline, in the HADS-A there were 282 (36.4%) of patients scoring higher than 7 points (17.6% higher than 10 points). In the HADS-D 137 (17.6%) scored higher than 7 and 9.3% were higher than 10 points. Both anxiety and depression at baseline influence the changes in EQ-5D, with less gains in patients with more level of anxiety or depression ($p<0.0001$). Regarding the EORTC-QLQ-C30 domains, baseline anxiety level impacts significantly in all domains, except in physical functioning, with gains around 5 to 11 points lower in patients with anxiety problems comparing with those classified as normal (all $p<0.05$). Baseline depression level impacts significantly on changes in role and social functioning, and global health, with gains around 10 to 13 points lower in patients with depression problems (all $p<0.01$). **CONCLUSIONS:** This study supports the importance of providing psychological interventions for cancer patients before surgical management.

PCN168

A PROPOSED 6-ITEM REDUCTION FOR THE EUROPEAN ORGANIZATION FOR THE RESEARCH AND TREATMENT OF CANCER-QUALITY OF CORE QUESTIONNAIRE (EORTC QLQ-C30) - CUBAN GROUP OF TRIALISTS ON EPIDERMAL GROWTH FACTOR (CGT-EGF)

Viada C[1], Ballesteros J[2], Fors M[3], Luaces P[1], Sánchez L[1], Crombet T[1]
[1]*Center of Molecular Immunology, Havana, Cuba,* [2]*University of the Basque Country UPV/EHU, Leioa, Spain,* [3]*National Coordinating Centre of Clinical Trials, Havana, Cuba*

OBJECTIVES: To develop an unidimensional and short version of the QLQ-C30 to be used as a patient-perceived quality of life in cancer trials. **METHODS:** We analysed data of 873 patients diagnosed with non-small-cell lung cancer who participated in 4 Cuban multicenter trials of immunotherapy against the epidermal growth factor. The analysis followed a 4-step approach. First, we conducted a Mokken nonparametric item response analysis to ascertain the QLQ-C30 dimensionality and separate several scales if appropriate. Second, we conducted a parametric Samejima's graded response model (GRM) to assess the item characteristics and information. Third, we did a confirmatory factor analysis (CFA) to test the scales unidimensionality and to obtain standardised factor loadings to suggest a reduced version of the QLQ. Finally, we assessed the discriminative validity of the reduced version by using receiver-operator curve (ROC) analysis. **RESULTS:** Mokken analysis of the QLQ-C30 resulted in a unidimensional scale, with an overall scalability of 0.43 that defined a medium scale. The unconstrained GRM showed that most items presented appropriate difficulty and discrimination parameters. The CFA supported an underlying unidimensional latent structure for the whole QLQ-C30 (CFI = 0.98; RMSEA = 0.05) with modification indexes pointing to important redundancy of information. The selection of items with standardized factor loadings > 0.70 lead to a 6-item QLQ that showed good discriminative validity against independent criteria of quality of life (ROC area = 0.76; 95% CI = 0.72 to 0.80) as compared with the values for the whole scale (ROC area = 0.70; 95% CI = 0.66 to 0.74). **CONCLUSIONS:** The EORTC QLQ-C6 suggested in this study presents good psychometric properties and includes an unidimensional structure of patient-perceived quality of life.

PCN169

EVALUATING THE BURDEN OF BONE METASTASES (BM) ON PATIENTS WITH CASTRATION-RESISTANT PROSTATE CANCER (CRPC) AND THEIR TREATING PHYSICIANS: FINDINGS FROM A ROUTINE PRACTICE STUDY IN 13 MEDIUM-SIZED EUROPEAN COUNTRIES

Hechmati G[1], Vrouchou P[1], Arellano J[2], Cristino J[1], Haynes I[3], Liede A[4], Rider A[5], Worsfold A[5], Pollard R[5], Crossland V[5]
[1]*Amgen (Europe) GmbH, Zug, Switzerland,* [2]*Amgen Inc., Thousand Oaks, CA, USA,* [3]*Amgen Ltd., Uxbridge, UK,* [4]*Amgen Inc., San Francisco, CA, USA,* [5]*Adelphi Real World, Macclesfield, UK*

OBJECTIVES: To evaluate the burden of BM on patients with CRPC and their treating physicians. **METHODS:** A total of 167 physicians (100 oncologists and 67 urologists) completed a prospective 5-day workload form, interview and average of 8 patient record forms (PRFs, October 2012–March 2013) for non-metastatic and metastatic CRPC patients. Data from 142 workload forms, 167 interviews and 1,274 PRFs (including 475 CRPC patients at 'high risk' of BM, 505 CRPC patients with BM only, 102 CRPC patients with BM and VM and 192 CRPC patients with VM only) were included in these analyses. **RESULTS:** Physician interviews showed 92%, 63% and 60% of the physicians believed the greatest patient burden of BM was back pain, reduced ability to perform daily activities and fractures, respectively (from a predetermined list where 'other' was specified). PRF data confirmed that Eastern Cooperative Oncology Group (ECOG) performance status was significantly worse in patients with BM (with/without VM) when compared with patients at high-risk of developing BM ($p<0.0001$). 92% of the patients at 'high-risk' (defined by treating physician) of developing BM (n= 475) had a PSA doubling time (PSADT) ≤6 months. The biggest burden of BM on treating physicians was seeing patient deterioration (70% [n=117]; 67% of oncologists; 75% of urologists), inability to propose effective treatment (57% [n=95]; 60% of oncologists; 52% of urologists), managing complex regimens (29% [n=49]; 27% of oncologists; 33% of urologists) and transferring patients for respite/hospice care (23% [n=38]; 26% of oncologists; 18% of urologists). **CONCLUSIONS:** These data highlight the burden of BM on patients with CRPC and the perceived burden on physicians treating this population. BM are associated with a significant reduction in patients' performance status and an increased burden on the patient. There is a need for treatments to prevent or delay the onset of BM and their associated burden.

PCN170

AN EXPLORATORY ANALYSIS OF THE ASSOCIATION BETWEEN EORTC-QLQ C30 DOMAINS AND PROGRESSION FREE/OVERALL SURVIVAL IN ADVANCED MELANOMA AFTER 12 WEEKS OF TREATMENT ON IPILIMUMAB COMPARED TO GP100 IN A PHASE III CLINICAL TRIAL

Lee D[1], Harvey B[1], Gaudin AF[2], Gueron B[3], Bregman B[2], Lebbe C[4], Bonnetain F[5], Borget I[6]
[1]*BresMed, Sheffield, UK,* [2]*Bristol-Myers-Squibb, Rueil Malmaison, France,* [3]*Bristol-Myers Squibb, Rueil Malmaison, France,* [4]*Hopital Saint Louis, Paris, France,* [5]*CHU Besançon, Besançon, France,* [6]*Institut Gustave Roussy, Villejuif, France*

OBJECTIVES: This study analyses the association between health-related quality of life (HRQL) domains and progression free (PFS) and overall survival (OS) for ipilimumab, ipilimumab + gp100, and gp100 alone during the 12 week treatment induction period compared to baseline. The aim of this study was to assess whether outcomes reported in the EORTC-QLQ-C30 summary domains impact the hazard of progressing and/or dying after 12 weeks of treatment. **METHODS:** Data from the MDX010-20 trial, including 676 previously treated patients with unresectable stage III or IV melanoma, was analysed. A domain correlation plot (excluding Global domain) was constructed to determine whether the EORTC-QLQ-C30 domains showed a high level of correlation for baseline scores. It was then used to derive two components summarising fourteen domain scores, Principal Components 1, containing 10 domain scores (Pain, Appetite Loss, Nausea, Finance, Dyspnoea, Constipation, Diarrhoea, Role, Social and Physical) and 2 containing 4 domains scores (Fatigue, Sleep Disturbance, Emotional and Cognitive), based on the correlation level between domains. These two Principal Components were entered as additional covariates in the Cox model for PFS/OS and hazard ratios were determined. **RESULTS:** In the Cox regression model, Principal Component 1 showed a 30% increase in hazard of progression when comparing the upper to the lower quartile of the Principal Component score , while a lower Principal Component 1 score indicated a better HRQL at baseline. It was also showed a rate of death twice as high in the upper quartile than the lower quartile. Principal Component 2 neither affected significantly PFS nor OS. **CONCLUSIONS:** In advanced melanoma treated by ipilimumab compared to gp100, PFS and OS were associated with most of the HRQL domain scores. These findings suggest that poor baseline HRQL could be predictive of poor PFS/OS, while higher baseline HRQL could predict a better outcome.

PCN171

QUALITY OF LIFE (QOL) DURING TREATMENT OF NEWLY DIAGNOSED LOCALLY CONFINED LOW-RISK PROSTATE CANCER (LCLRPC) IN GERMANY: RESULTS OF THE HAROW STUDY

Schädlich PK[1], Baranek T[2], Häussler B[1], Weißbach L[3]
[1]*IGES Institut GmbH, Berlin, Germany,* [2]*CSG - Clinische Studien Gesellschaft mbH, Berlin, Germany,* [3]*Stiftung Männergesundheit - Foundation for Men's Health, Berlin, Germany*

OBJECTIVES: The optimal treatment choice for preserving QoL of the about 64,000 men diagnosed with prostate cancer each year in Germany still remains unclear. The objectives therefore were to generate long-term information under day-to-day conditions on QoL of men in Germany cared for newly diagnosed LCLRPC using hormonal therapy (HT), active surveillance (AS), radiotherapy (RT), operation (OP), or watchful waiting (WW) – HAROW. **METHODS:** The long-term observational multi-centre HAROW study was undertaken. The urologist provided all relevant clinical data of the patient. The patient provided inter alia data on QoL using the EQ-5D. Utilities derived from the EQ-5D based on the German value set were used to construct quality-adjusted life-years (QALYs). QALYs were discounted by 3% annually and standardised to mean QALYs per patient-year (PY) for each initial treatment strategy. Differences between strategies were tested using the Kruskal-Wallis test (Bonferroni-corrected $p=0.0018$ due to 28 tests). **RESULTS:** Between July 2008 and March 2013, 3063 patients (mean age 67.3 ± 7.5 years) with LCLRPC (T1a–T2c, N0, M0) were included from 257 urologists. Data on QoL were documented by patients as follows (% of patients/strategy): AS n=353 (78%), RT n=291 (77%), HT n=149 (71%), HT+RT n=68 (85%), combination therapy (CT) n=109 (80%), OP n=1167 (71%), other therapy (OT) n=9 (50%), WW n=93 (66%), over a mean time of between 1.6 (OT) and 2.5 years (CT). AS showed the highest undiscounted/discounted QALYs/PY (0.9297/0.9103) followed by OP (0.9289/0.9075), RT (0.9075/0.8878), CT (0.9071/0.8820), OT (0.8954/0.8818), HT+RT (0.8875/0.8699), WW (0.8646/0.8465), and HT (0.8485/0.8292). Compared to HT, QALYs/PY were significantly higher with AS ($p<0.0001$), with OP ($p<0.0001$), and with RT ($p=0.0002$). Tests with undiscounted/discounted QALYs/PY adjusted for age, tumor stage and comorbidity showed no different results. **CONCLUSIONS:** According to the HAROW study, active surveillance yielded the highest QALYs of the different LCLRPC treatment strategies in Germany evaluated.

PCN172

HR-QOL DATA IN THE AMNOG EARLY BENEFIT ASSESSMENT: INDUSTRY AND IQWIG/GBA PERSPECTIVE

Obradovic M, Radicek S, Rauland M
GfK Bridgehead, Nuremberg, Germany

OBJECTIVES: To explore how often and which types of quality of life (QOL) data are included in the dossiers submitted for the AMNOG early benefit assessment and analyze how a drug's effect in QOL is interpreted by the industry and the evaluating committee. **METHODS:** The published value dossiers up to June 15, 2013 and the corresponding benefit assessments were reviewed. Types of QOL data and the statements concerning QOL in the value dossier and the benefit assessments were collected and summarized. **RESULTS:** A total of 46 cases were analyzed. In 6 cases no dossier was submitted. Of the rest, 13 dossiers (32.5%) did not include any QOL data, 13 (32.5%) included disease-specific QOL data only, 5 (12.5%) included generic QOL data only, and 9 (22.5%) both types. The QOL instruments used were considered as valid by the assessors. However, outcomes such as pain severity, fatigue, work productivity, and health care resource use were not regarded as QOL measures. Of 27 dossiers that have included QOL data companies have claimed an added benefit in QOL, either for the whole population or a specific subgroup, in 15 (56%) cases. However, the assessors rec-

ognized the added benefit claim in 2 cases only. In an additional 2 cases no clear scoring was provided for the QOL outcome and in the remaining 11 cases no additional benefit was acknowledged. The main reasons were missing statistical significance of results or the submitted QOL data were regarded as not usable. **CONCLUSIONS:** In a majority of value dossiers companies included QOL data and also most often claimed an added benefit in QOL. However, the assessors have accepted this added value in exceptional cases only. In order to get an added value recognized showing both statistical and clinical significance of results is required.

PCN173

FEASIBILITY OF A SURVEY ON THE WILLINGNESS-TO-PAY FOR COLORECTAL CANCER SCREENING USING SOCIAL NETWORKS

Hessel FP, Fortes CS, Jantzen JH, Pion E, Andriejauskaite M, Da Costa Pina de Sousa Piscarreta M, Jarvpold A

SRH University Berlin, Berlin, Germany

OBJECTIVES: To investigate the feasibility of a online survey using social media (facebook) to estimate the willingness to pay (WTP) for a new diagnostic blood test to determine the risk of colorectal cancer. According to the approval documents of the manufacturer the new biomarker test shows a better performance, better handling and improved compliance of patients and physicians compared to standard fecal occult blood tests (FOBT). **METHODS:** A standardized questionnaire was accompanied by background information on colorectal cancer and alternative screening approaches. WTP was asked for in categories (e.g. <100 or >100 EUR) and maximum values. Other parameters such as age, sex, insurance status, income, family history of cancer and risk factors were determined in categories. The survey ran for 14 days in November 2012 and was started via 6 facebook accounts with the possibility of further distribution. **RESULTS:** Overall 123 completed questionnaires were submitted anonymously. The average age was 24,2 years and in 94% the monthly income was below 1500 EUR due to their student status. 68% of the participants had cases of cancer in the family and 36% knew about the colorectal cancer. The most important quality aspects of screening tests for were accuracy (69%), handling (14%), price (11%) and the time to result (6%). 24% stated that their WTP is lower than 100EUR and the mean WTP for S9 was 271EUR. Higher income, family history of colorectal cancer and private insurance status were positively correlated with a higher WTP. **CONCLUSIONS:** WTP and patient preference studies via social networks such as facebook are feasible, easy to perform and reveal plausible results. Advantages of online surveys in social networks are that the results are gained voluntarily and anonymously avoiding interviewer bias. Disadvantages obviously lie in a selection of young and healthy populations.

CANCER – Health Care Use & Policy Studies

PCN174

CANCER PATIENTS MAY HAVE A DIFFERENT POINT OF VIEW ON ONCOLOGY DRUG COVERAGE DECISIONS THAN NON-PATIENTS

Foley K[1], Hansen LG[2]

[1]*Truven Health Analytics, Cambridge, MA, USA,* [2]*Truven Health Analytics, Northwood, NH, USA*

OBJECTIVES: Recently a major cancer center in the United States decided not to offer treatment using a newly launched oncology drug citing comparative effectiveness and cost as reasons. This study looked at health care consumer opinions about the decision to restrict treatment options based on outcomes and price. **METHODS:** The nationally representative Truven Health PULSE Healthcare Survey gathered responses from 2,615 US households via landline telephone, cell phone or Internet. Respondents were asked their opinion regarding a decision by providers not to offer a new cancer treatment because it demonstrated the same benefit as an existing drug with the same side effects, but its cost was higher. Demographic data were gathered and respondents were asked if they are being/have been treated for cancer, and if a friend, family member or loved one is being/has been treated for cancer. **RESULTS:** Overall, 40.5% of respondents agreed with the decision; 37.5% disagreed. Agreement with the decision varied with the respondents' exposure to cancer. Those who had a family member, friend or loved one with cancer were least likely to agree (36%), while those who not only had a family member, friend or loved one with cancer, but also had cancer themselves were the most likely to agree (50.8%). Respondents who had cancer themselves with no family member, friend or loved one with cancer or had no experience with cancer were equally likely to agree with the decision (44%) (P<0.0001). **CONCLUSIONS:** Findings suggest that fear and experience may play roles in consumers' opinions regarding restrictions on cancer medications. Individuals who have experienced cancer may place more value on outcomes, side effects, and/or out-of-pocket costs than those with no personal experience or may have more realistic expectations for treatment. Additional research is warranted to better understand the drivers of consumer opinion regarding cancer treatment coverage decisions.

PCN175

ADDITIONAL INVESTMENTS, ADDED VALUE, REAL WORLD EVIDENCE AND ADDITIONAL CLINICAL BENEFIT IN THE CONTEXT OF SUBGROUPS OF SPECIAL INTEREST

Walzer S[1], Holbein B[2]

[1]*MArS Market Access & Pricing Strategy UG (h.b.), Weil am Rhein, Germany,* [2]*University of Bremen, Bremen, Germany*

OBJECTIVES: Definition of target profiles for new compounds and lifecycle planning lead to clinical studies in the context of a clinical trial program. Currently subgroups of special interest such as elderly, pediatrics or females/males are normally not separately included in these research programmes, most of the time not even stratified for. The objective of this research is to analyze the inclusion of patient-relevant endpoints in special patient subgroups during the clinical trial programme which would thereafter increase the pricing opportunity of this new compound in the German market. **METHODS:** New oncology therapies which were authorized by the European Medicine Agency (EMA) after January 1, 2011 were included and assessed with respect to their evidence for special subgroups. Regulatory guidelines were compared against the IQWIG evaluation methods with respect to the handling of subgroups and its impact on the clinical benefit assessment. Furthermore GBA decisions and potential price impact with the GKV-Spitzenverband are taken into account for the pricing impact of new evidence with special subgroups based on target profiles developed. **RESULTS:** Overall, ten new compounds were approved by the EMA in the last 2.5 years for which no subgroup trials were presented. Regulatory guidelines and IQWIG methods differ significantly with respect to subgroup handling from a statistical and health policy perspective. Most important clinical trials with a special focus on subgroups of interest could even have a negative outcome on the market access of such a compound with respect to subgroup-only reimbursement (in case of positive subgroup results) or exclusion of subgroups (in case of negative results) based on target profiles included in the analyses. **CONCLUSIONS:** Incentives from a health policy and investment decision perspective are low for the pharmaceutical industry in terms of research focus towards subgroups of special interest. Further research with respect to incentives is needed.

PCN176

DOES PERSONALISED HEALTH CARE (PHC) IN ONCOLOGY REQUIRE NEW APPROACHES TO CLINICAL DEVELOPMENT, REGULATORY ASSESSMENT, AND ECONOMIC EVALUATION?

Teale CW[1], Satherley AW[1], Maertens P[2], Kreyenberg K[3], Konieczny A[3]

[1]*GfK Bridgehead, Melton Mowbray, UK,* [2]*GfK Switzerland, Basel, Switzerland,* [3]*Daiichi Sankyo Europe GmbH, Munich, Germany*

OBJECTIVES: To identify the extent to which current approaches to clinical development, regulatory assessment, and economic evaluation of personalised health care drugs in oncology are aligned with real world clinical practice at product launch. To identify and critically evaluate alternative approaches that should be factored into future clinical development and health technology assessment (HTA) planning. **METHODS:** Structured interviews were undertaken with physicians and payers (n=50) to identify the key issues surrounding the phased development and early use of personalised health care drugs in oncology. Analogue analyses were undertaken, based on "treatment tracking", to develop a comparison between theoretical RCT (randomised control trial) evidence based, licensure aligned, utilisation and that observed in real world clinical practice Gap Analyses identified drivers of differences. The utility and limitations of retrospective and prospective observational registries in addressing these were explored. **RESULTS:** Early results indicate that the level of unmet need, the magnitude of incremental clinical benefit, the timing of biomarker testing in the treatment algorithm and, increasingly, the number and prioritisation of diagnostic tests for an increasing number of different biomarkers are drivers of real world utilisation. Differences exist between countries. The greatest differences between theoretical and real world utilisation are in markets where decisions are driven by considerations of relative clinical effectiveness rather than cost effectiveness. Comparative SWOT analyses were developed of current and alternative clinical development, regulatory and health technology assessment systems. These highlight areas where improvements in approach would be beneficial. **CONCLUSIONS:** Additional evidence sources should be used to reinforce the regulatory and health technology assessment of PHC products in oncology with the aim of bringing closer alignment between the RCT approach to drug development and assessment – and the utilisation and outcomes (economic, clinical, and humanistic) seen in real-world clinical practice.

PCN177

THE UNITED STATES PHYSICAN SURVEY TO POPULATE A DECISION-ANALYTIC MODEL FOR THE TREATMENT OF CHRONIC MYELOID LEUKEMIA

Rochau U[1], Kluibenschaedl M[2], Stenehjem D[3], Kuo KL[4], Jahn B[2], Brixner D[5], Siebert U[6]

[1]*UMIT - University for Health Sciences, Medical Informatics and Technology/ ONCOTYROL - Center for Personalized Cancer Medicine, Hall in Tyrol/ Innsbruck, Austria,* [2]*UMIT - University for Health Sciences, Medical Informatics and Technology, Hall in Tyrol, Austria,* [3]*University of Utah/ University of Utah Hospitals & Clinics, Salt Lake City, UT, USA,* [4]*University of Utah, Salt Lake City, UT, USA,* [5]*UMIT - University for Health Sciences, Medical Informatics and Technology/ ONCOTYROL - Center for Personalized Cancer Medicine/ University of Utah, Hall in Tyrol/ Salt Lake City, UT, Austria,* [6]*UMIT – University for Health Sciences, Medical Informatics and Technology / ONCOTYROL / Harvard University, Hall i. T./ Innsbruck / Boston, Austria*

OBJECTIVES: The overall goal of our project is to adapt an Austrian decision-analytic model for the treatment of chronic myeloid leukemia (CML) to the U.S. context. We conducted an electronic survey to gain expert knowledge about the state-of-the-art in CML treatment. **METHODS:** The expert survey was constructed as an online questionnaire and contained 14 questions. The questionnaire was developed in collaboration with ONCOTYROL project partners and distributed to CML experts at the Huntsman Cancer Institute in Utah. Data were generated using Qualtrics and discussed with experts in order to incorporate the findings into the model. **RESULTS:** Four out of six experts (67%) stated that effectiveness of second-line TKI depends on the response to first-line TKI therapy. NCCN and ELN guidelines are the most frequently used guidelines when treating CML patients. Furthermore, expert opinion, literature and personal characteristics influence decision making. Patients younger than 50, or between 50 and 54 years, most frequently receive stem cell transplantation after TKI failure. The recently approved TKIs bosutinib and ponatinib are used by 17% and 100% respectively. Experts stated that quality of life (QoL) on dasatinib is better (17%)/ about the same (50%)/ worse (33%) compared to imatinib. QoL on nilotinib is better (17%)/ about the same (83%) in comparison to imatinib. QoL on ponatinib is better (17%)/ about the same (67%)/ worse (17%) compared to imatinib. Although bosutinib is rarely (67%) used, experts answered that is better (17%) or about the same (17%) compared to imatinib. **CONCLUSIONS:** The results provide valuable insights into the state-of-the-art of CML treatment in the U.S. context. Due to the small sample size and the limitation to the region of Utah, results should be interpreted carefully. However, the responses for ponatinib and bosutinib are particularly valuable for the model due to lack of QoL and long-term data.

PCN178
BURDEN OF HOSPITALIZATION IN PATIENTS WITH ADVANCED LUNG CANCER IN THE UNITED STATES
Taylor-Stokes G[1], Rider A[2], Roughley A[1], Iyer S[3]
[1]Adelphi Real World, Bollington, UK, [2]Adelphi Real World, Macclesfield, UK, [3]Pfizer, New York, NY, USA
OBJECTIVES: To assess the burden of hospitalization in advanced lung cancer patients in the United States. **METHODS:** Oncologists (N=101) actively involved in management of advanced lung cancer in United States were invited to participate in a lung cancer disease specific program. Each consenting physician was asked to complete patient record forms for 12 advanced (stage IIIB/IV) lung cancer patients seen in their practice and receiving 1st, 2nd or 3rd line of therapy for advanced lung cancer. The study period extended from Oct- Dec 2011. Data on hospitalization that included reasons of hospitalization and the length of stay (LOS) over the past year was provided by physicians from patient records. **RESULTS:** Majority of the patients (N=1200) were male (56%), Caucasian (71%) and Stage IV (78%), with an average age of 65 years. Hospitalization records were obtained for 93% (n=1110) of the patients among which 22% (n=248) of the patients ≥1 hospitalization events in the previous year with an average (SD) LOS of 4 (2.4) days and a median LOS of 3 days. The reasons reported for the 293 hospitalization events were disease symptoms (61%), surgery (19%) and therapy side effects (43%). The LOS for surgery related hospitalization (n=57) ranged from 1-12 days (mean (SD): 6 (2.9) days; median: 5 days). Among disease symptoms reported as reasons for hospitalization, the most frequent were pain (51%), dyspnea (47%) and cough (47%) respectively. Among side effects reported as reasons for hospitalization anemia (25%), febrile neutropenia (21%) and fatigue (20%) were most frequently reported. **CONCLUSIONS:** Burden of hospitalization in advanced lung cancer patients is significant in the United States. Innovative therapies with favorable side effect profile that also alleviate need for surgery and are effective in improving lung cancer symptoms could help significantly in decreasing hospitalization burden in advanced lung cancer patients.

PCN179
PERCEPTION OF COUNTRY-SPECIFIC HEALTH CARE REFORM AND CONSIDERATION OF REAL WORLD EVIDENCE IN ROUTINE PRACTICE: SURVEY OF ONCOLOGISTS IN EUROPEAN UNION, UNITED STATES, CHINA AND BRAZIL
Narayanan S
Ipsos Healthcare, Gaithersburg, MD, USA
OBJECTIVES: To assess oncologist perception of their country-specific health care reforms and the consideration of 'Real World Evidence' (RWE) when prescribing medications in the EU, US, China and Brazil. **METHODS:** A multi-country cross-sectional survey was conducted in top-5 EU countries (UK, Germany, Spain, France, Italy), US, Brazil and China in February 2013 using an online physician panel in the respective geographies; oncologists were randomly selected for survey participation to be geographically representative in each country. Surveys assessed the oncologist perceptions of health care reforms in their respective countries, and their consideration of the following, when prescribing oncology medications: RWE on product effectiveness/safety, patient quality-of-life (QoL) and product cost/patient affordability. Descriptive statistics are reported. **RESULTS:** A total of 257 oncologists participated in the survey. Specialties included: medical oncology-69%, haemato-oncology-11%, radiation-oncology-9%, surgical-oncology-5%, gynecologic-oncology-3%, pediatric-oncology-2%, other-2%. Geographic distribution of oncologists was: 5EU-36%, US-33%, China-17% and Brazil-14%. Overall, 40% of oncologists indicated that they were 'not sure whether their country's health care reform is heading in the right direction' (5EU:39%, US:40%, China:44%, Brazil:36%); 38% indicated that they were 'concerned of country's health care reform's implications for them and their practice' (5EU:30%, US:50%, China:44%, Brazil:19%); 23% indicated that the health care reform 'did not have enough focus on RWE needs and cost-effectiveness of medications' ((5EU:16%, US:24%, China:37%, Brazil:19%). When prescribing oncology medications, consideration of following attributes 'all the time' differed across the countries (Overall/5EU/US/China/Brazil): RWE on product effectiveness and safety (37%/29%/38%/47%/42%), patient QoL (54%/48%/59%/42%/69%), product cost/patient affordability (23%/15%/20%/42%/28%). **CONCLUSIONS:** Across markets, a significant proportion of oncologists raised concerns regarding their country-specific health care-reforms, and between one-third and half of the oncologists reported considering RWE data while prescribing medicines. As the health care reforms evolve in the studied countries, its actual implications warrant closer scrutiny to alleviate physician concerns and improve care delivery and outcomes.

PCN180
THE EXPECTED HEALTH ECONOMIC VALUE OF USING CIRCULATING TUMOR CELLS TO PERSONALIZE CANCER TREATMENT
Schreuder K[1], Hummel JM[1], Terstappen LW[2], Ijzerman MJ[1]
[1]University of Twente, Enschede, The Netherlands, [2]Universiteit Twente, Enschede, The Netherlands
OBJECTIVES: Research has shown that circulating tumor cells (CTCs) in the blood can give valuable information about the prognosis and treatment options in oncology. A new approach, CTC therapeutic apheresis (CTCtrap) is being developed for use in breast and prostate cancer. At the moment it is not clear where in the diagnostic track CTCtrap could be of most value. The goal of this study is to estimate the health impact of using CTCtrap in 1) screening for breast cancer; 2) early staging of tumors; and 3) therapy response monitoring. **METHODS:** A systematic literature study and experts' interviews were used to document the diagnostic track in breast cancer. Headroom analysis and early health economic modelling was used to estimate the health impact of implementing CTCtrap at the three different purposes. **RESULTS:** Dependent on the assumption of sensitivity, the CTCtrap could decrease the total screening costs. Yet, it is expected that this application only has limited clinical utility. In the early staging, the CTC trap can replace the currently used FDG-PET-CT. The CTCtrap could provide additional staging information and therapy can be selected more specifically, eliminating unnecessary costs. Finally, CTCtrap as a monitoring tool enables personalising therapy by analysing discordance in hormone receptor (HR) and Human Epidermal Growth Factor Receptor 2 (HER2) expression in CTCs compared to solid tumors in metastatic breast cancer patients. It is estimated that in total 4,41% of metastatic breast cancer patients could be treated in a more efficient way, leading to increase in progression free survival of 5,59 months. Increase in clinical utility is expected to be the most important consequence of this implementation option. **CONCLUSIONS:** CTCtrap as a monitoring tool is expected to be of most value. In this stage, a more appropropiate prescription of expensive therapies can be administered to patients who are sensitive for these therapies.

PCN181
THE IMPACT OF AMNOG ON ONCOLOGY DRUGS
Walker S[1], Honoré AC[2], Ando G[1]
[1]IHS, London, UK, [2]IHS, Zurich, Switzerland
OBJECTIVES: The implementation of the 2011 German health care reform (AMNOG) introduced pricing mechanisms which oblige newly launched patented drugs to undergo an early evaluation of their additional benefit by IQWiG, with a final resolution given by the G-BA. Medicines which demonstrate an incremental therapeutic benefit versus an appropriate therapeutic comparator – with an innovation score ranging from 1 to 4 – enter the preferable pricing negotiation system; those failing to prove benefit – a score of 5 or 6 – are relegated to the reference pricing system. The study aims to discern how oncology drugs, which began the process of benefit assessment during 2012, fared under the new system, and whether survival data influenced the decisions. **METHODS:** We reviewed both IQWiG and G-BA documents relating to eight cancer drugs assessed during 2012 to determine whether each drug received a positive or negative early benefit assessment. Reasons for each specific decision were then investigated. **RESULTS:** Of the five drugs qualifying for pricing negotiations, vemurafenib (Roche, Switzerland) was the only drug to demonstrate a statistically significant improvement in overall survival (OS) at the time of assessment. It received the highest innovation score of the five qualifying drugs. For the three drugs not qualifying for pricing negotiations, the G-BA cited an incomplete dossier or issues with comparators as the reason for rejection. **CONCLUSIONS:** Although OS is considered the favoured clinical endpoint, the study results show that this endpoint is not always necessary to enter pricing negotiations. However, when OS is not proven, the G-BA often gave a positive assessment to only a small portion of eligible patients. Additionally, two of the qualifying drugs were orphan drugs, which entails exemption from the need to prove an additional benefit if annual sales are below EUR50 million.

PCN182
DEVELOPING PERSONALIZED MEDICINE DRUGS - INCENTIVES FOR PHARMACEUTICAL COMPANIES
Noweski M[1], Hessel FP[2], Walendzik A[1], Jahn R[1], Wasem J[1]
[1]University of Duisburg-Essen, Essen, Germany, [2]SRH University Berlin, Berlin, Germany
OBJECTIVES: Stratification of oncology drug therapy by genetic marker diagnostics can reveal additional patient benefit but also might influence the development process of drug manufacturers. The objective of this study is to identify and describe the most important incentives for pharmaceutical companies to develop personalized medicine drugs. **METHODS:** To describe the main factors influencing the decision-making process in the development of personalized medicine drugs. The main factors influencing the process and their priority ranking were determined by structured expert interviews with pharmaceutical companies, test manufacturers and other key stakeholders such as regulatory bodies, reimbursement decision makers and payers. **RESULTS:** In contrast to small companies big international companies constantly look for suitable companion diagnostic tests to select subgroups of high responder. The most important key factor for market success is the extent of clinical efficacy in comparison with competitors respectively the current treatment standard. Stratification of patient populations according to treatment response or frequency of adverse events using biomarker is regarded to increase clinical efficacy of the target indication. The test performance is important due to unsolved safety issues although not regarded as crucial for the success of the drug. In contrast to other stakeholders pharmaceutical companies did not consider personalized medicine to relevantly decrease development costs or marketing efforts respectively to increase the price potential for new drugs. A low prevalence of the remaining patient population after testing is not seen as a factor which might lead to a stop of the development of a new drug by pharmaceutical companies. **CONCLUSIONS:** Genetic stratification is seen as a breakthrough in cancer therapy by pharmaceutical companies and physicians. Due to the current need for improvement of approval and reimbursement processes for personalized medicine approaches in oncology especially in Europe future sales are more difficult to predict.

PCN183
ARE ICER THRESHOLD VALUES MALLEABLE? THE CASE OF LIFE-EXTENDING CANCER TREATMENTS AT THE END OF LIFE
Moïse P[1], Sweeney N[2], Lie X[2]
[1]Quintiles Consulting Europe, Levallois-Perret, France, [2]Quintiles, Hoofddorp, The Netherlands
OBJECTIVES: HTA bodies treat end of life (EOL) conditions differently than other conditions? And if so does this depend on whether they have a specific policy for EOL? **METHODS:** NICE's website was searched for single technology appraisals of cancer drugs evaluated between January 2009 to May 2013 for which NICE's supplementary advice for EOL treatments was accepted. The websites of other agencies – SMC (Scotland), TLV (Sweden), PBAC (Australia), pCODR (Canada, except Quebec) and INESSS (Quebec) – were searched for HTAs of the drugs deemed to have met NICE's EOL criteria. A literature search was performed to identify estimated willingness-to-pay ICER threshold values (WTP-ICER) for each agency and to determine if the agency has a specific EOL policy. These were compared against the final ICERs of the retained HTAs. **RESULTS:** Seventeen drugs were identified for which NICE's EOL supplementary advice was accepted. Several of these were also evaluated by other agencies, but only those with final ICERs below the WTP-ICER were retained:

11 SMC; 9 PBAC; 3 TLV; 4 pCODR; 3 INESS. The literature search revealed the following WTP-ICERs: NICE (20,000 - 30,000 GBP); SMC (30,000 GBP); PBAC (45,000 – 75,000 AUD); TLV (777,000 SEK); pCODR and INESS (50,000 – 70,000 CAD). Of the agencies with specific EOL policies, the number of drugs recommended as cost-effective despite final ICERs greater than the respective WTP-ICERs were 11 (65%) NICE; 5 (45%) SMC; 0 PBAC and 1 (33%) INESSS. The corresponding figures for the agencies with no specific EOL policy were 0 TLV and 4 (100%) pCODR. **CONCLUSIONS:** The evidence suggests some HTA bodies treat EOL conditions differently, however the example of pCODR suggests this need not depend on having a specific EOL policy. In fact, the results for PBAC and INESSS show that having a specific EOL policy is no guarantee EOL conditions are treated differently.

PCN184

TREATMENT PATTERNS OF CHRONIC LYMPHOCYTIC LEUKEMIA PATIENTS UNDER THE BRAZILIAN PUBLIC HEALTH CARE PERSPECTIVE

Vitale V[1], Asano E[2], Rego MA[2], Pereira ML[2]
[1]*Janssen Cilag Farmaceutica, São Paulo, Brazil,* [2]*Janssen-Cilag Farmaceutica, Sao Paulo, Brazil*

OBJECTIVES: To identify the chemotherapeutic treatment patterns in patients with chronic lymphocytic leukemia (CLL) treated in the Brazilian Public Healthcare System. **METHODS:** A retrospective longitudinal analysis based on Government administrative claims database (Datasus) was performed from January 2008 to December 2012. Eligibility criteria were patients with CLL (ICD code C911) diagnosed until January 2012 and starting their first chemotherapy regimen from January 2008 to January 2012. This cohort of patients was followed until December 2012, death or loss of follow-up. Patients without interruption during treatment and without change in medication were considered in the same chemotherapy regimen. Descriptive statistics (average, standard deviation and percentage) of treatment regimens, treatment free interval (TFI), age at treatment start, gender and length of treatment were performed. **RESULTS:** A total of 1,538 patients with CLL representing 15,371 APACs (Authorization for High Complexity Procedures) met eligibility criteria. The population cohort comprised 56.6% men with an average age of 67.4±12.1 years. 55.0% of the patients had only one chemotherapy regimen, whereas 44.9% had two and 19.4% had three or more chemotherapy regimens. Time between diagnosis and beginning of treatment was 4.3±7.6 months. The most widely used first chemotherapy regimen was chlorambucil (54.9%), followed by cyclophosphamide, vincristine and prednisolone (CVP) (9.1%), fludarabine and cyclophosfamide (FC) (8.1%) and chlorambucil and prednisone (7.0%). Average length of treatment was 6.3±5.7 months. For second chemotherapy scheme, the most widely used regimen was chlorambucil (45.3%), followed by FC (11.0%), CVP (7.8%), chlorambucil and prednisone (6.2%) and CHOP (3.5%). The average length of treatment was 4.9±3.6 months, with an average TFI of 3.5±5.0 months. **CONCLUSIONS:** Chlorambucil was the most used therapy as both first and second chemotherapy regimen. There was a decreasing of Chlorambucil and an increasing of FC in second scheme. The length of treatment was longer in first scheme.

PCN185

EVOLUTION OF ORAL ANTICANCER TREATMENTS USE IN FRANCE FROM 2004 – 2012: RE-ACTOR STUDY (RETROSPECTIVE ANALYSIS OF CANCER TREATMENTS GIVEN ORALLY)

Benjamin L[1], Maurel F[2], Bardoulat I[2], Ricarte C[2]
[1]*GlaxoSmithKline, Marly-le-Roi, France,* [2]*IMS Health, La Défense, France*

OBJECTIVES: Within the last decade market authorizations for oral anticancer treatments (OATs) have increased but no published data are available on their use over time. This analysis aimed at describing the evolution of OATs use in France. **METHODS:** A retrospective analysis was performed from Oncology Analyzer™ (IMS Health, France), a physician survey database covering more than 10,000 cancer patients per year treated in both public and private institutions from multiple French regions. The database includes patient demographics, diagnosis and treatment patterns. Data were extracted for all cancers patients treated by oral and intravenous (IV) anticancer drugs from October 2004 to September 2012. Analyses included active anticancer treatments (chemotherapy, targeted therapy, hormonal-therapy, immunotherapy) excluding supportive care agents. **RESULTS:** The proportion of cancer patients receiving OATs increased from 2,241/7,891 (28%) to 2,410/7,426 (32%). Data showed an increasing use of OATs over time especially among patients aged over 70 years (i.e. 40% in 2004 vs. 46% for patients in 2012). The proportion of OATs among all anticancer drugs (oral and IV) remains stable over time (45.1% in 2005 (41/91) vs. 45.4% in 2012 (54/119). The number of molecules available in oral form was stable except for targeted therapies (4 in 2004 vs. 15 in 2012). Data related to some molecules available in both forms (oral and IV) such as melphalan, fludarabine, topotecan, confirmed the preferential use for the oral route of administration over time. **CONCLUSIONS:** The Re-ACTOR study confirms the increasing uptake of OATs in oncology in France. The number of patients receiving OATs increases over time especially for targeted therapies. This trend draws the attention of the necessity to reinforce measures to accompany the development of OATs in terms of safety and health care delivery, especially for the elderly who require specific attention to provide them with patient support tools and programs.

PCN186

THREE YEARS OF THE GEFITINIB UK SINGLE PATIENT ACCESS (SPA) SCHEME: DURATION OF TREATMENT FOR PATIENTS WITH EGFR MUTATION POSITIVE NSCLC IN NHS CLINICAL PRACTICE

Vioix H[1], Franzen S[2], Selby D[1], Collomb D[1], Hauch O[3], Emmas C[1]
[1]*AstraZeneca UK Ltd., Luton, UK,* [2]*AstraZeneca R&D, Mölndal, Sweden,* [3]*AstraZeneca Pharmaceuticals LP, Wilmington, DE, USA*

OBJECTIVES: The UK National Institute for Health and Clinical Excellence (NICE) recommended gefitinib as cost-effective for use first line in locally advanced or metastatic, EGFR mutation positive NSCLC, when supplied via the SPA scheme, based on the mean duration of treatment observed in the IPASS study (8.8 months). The single fixed payment under the scheme is triggered at the order of the third 30-day pack and covers a patient for their total supply of gefitinib treatment. An initial analysis of the first 18 months of the SPA scheme indicated that the length of gefitinib therapy was at least that anticipated by NICE. This study aims to validate the length of therapy in a larger cohort with up to 3 years follow-up. **METHODS:** The SPA administrative database contained information on packs (30-days therapy/pack) dispensed to patients from September 2009 to December 2012. This retrospective study included patients registered on the database prior to the end of 2012, fulfilling NICE eligibility criteria and receiving at least 3 packs for which the NHS was invoiced. Patients were considered censored if they had ≥1 pack recorded in the last 3 months of the database. Median time to treatment cessation was estimated from a Kaplan-Meier curve of packs supplied to patients and the mean number of packs dispensed per patients from a parametric failure time model. **RESULTS:** 883/1160 registered patients met the study eligibility criteria (460/883 censored). These 883 patients, for whom the NHS was invoiced the single fixed payment, received a median of 13 packs 95%CI[12,14], equivalent to 12.8 months to treatment cessation. A mean of 19.4 95%CI[18.0, 21.0] packs were dispensed per patient. **CONCLUSIONS:** The results of this observational study confirm the average length of gefitinib therapy and mean number of packs dispensed in the SPA scheme exceed that assumed by NICE.

PCN187

TREATMENT PATTERNS OF INDOLENT NON-HODGKIN LYMPHOMA PATIENTS UNDER THE BRAZILIAN PUBLIC HEALTH CARE PERSPECTIVE

Vitale V[1], Asano E[2], Rego MA[2], Pereira ML[2]
[1]*Janssen Cilag Farmaceutica, São Paulo, Brazil,* [2]*Janssen-Cilag Farmaceutica, Sao Paulo, Brazil*

OBJECTIVES: To identify the chemotherapeutic treatment patterns in patients with indolent non-hodgkin lymphoma (NHL) treated in the Brazilian Public Healthcare System. **METHODS:** A retrospective longitudinal analysis based on the Government administrative claims database (Datasus) was performed from January 2008 to December 2012. Eligibility criteria were patients with indolent NHL diagnosed until January 2012 and starting their first chemotherapy regimen from January 2008 to January 2012. This cohort of patients was followed until December 2012, death or loss of follow-up. Patients without interruption during treatment and without change in medication were considered in the same chemotherapy regimen. Descriptive statistics (average, standard deviation and percentage) of treatment regimens, treatment free interval (TFI), age at the beginning of treatment, gender and length of treatment were performed. **RESULTS:** A total of 817 patients with indolent NHL representing 5,449 APACs (Authorization for High Complexity Procedures) met eligibility criteria. The population cohort comprised 50.7% men with an average age of 61.3±14.5years. 72.2% of the patients had only one chemotherapy regimen, whereas 18.2% had two and 9.1% had three or more chemotherapy regimens. Time between diagnose and the beginning of treatment was 3.6±6.2 months. The most widely used first chemotherapy regimen was cyclophosphamide, vincristine and prednisolone (CVP)(22.2%) followed by cyclophosphamide, doxorubicin, vincristine and prednisolone (CHOP) and rituximab(15.7%), cyclophosphamide, vincristine and prednisolone (COP) and rituximab(5.6%), chlorambucil and prednisone(4.8%). Average length of treatment was 5.0±3.7months. For second chemotherapy scheme, the most widely used regimen was CHOP and rituximab(14.1%), CVP(7.5%), interferon(9.3%), chlorambucil and prednisone(6.2%). The average length of treatment was 4.0±4.1months, with an average TFI of 3.3±4.2months. **CONCLUSIONS:** The most used chemotherapy in first regimen was CVP. Rituximab in combinations was present in most patients in the first scheme. Rituximab in second scheme in combination with CHOP was the most used therapy. The length of treatment was longer in first scheme.

PCN188

CURRENT SITUATION OF ORAL ANTICANCER TREATMENTS USE IN FRANCE: THE ACTOR STUDY (ANALYSIS OF CANCER TREATMENTS GIVEN ORALLY)

Benjamin L[1], Maurel F[2], Bardoulat I[2], Ricarte C[2]
[1]*GlaxoSmithKline, Marly-le-Roi, France,* [2]*IMS Health, La Défense, France*

OBJECTIVES: Within the last decade market authorizations for oral anticancer treatments (OATs) have increased. This analysis aimed at describing the current situation of OATs and their modalities of use. **METHODS:** An analysis was performed from Oncology Analyzer™ (IMS Health, France), a physician survey database covering more than 10,000 cancer patients per year treated in both public and private institutions from multiple French regions. The database includes patient demographics, diagnosis and treatment patterns. Data was extracted for all types of cancers and described as number of patients treated by oral and intravenous (IV) anticancer drugs. Data was collected from October 2011 to September 2012. Analyses were split into different active anticancer treatment categories and excluded supportive care agents. **RESULTS:** A total of 7426 patients treated with oral and IV anticancer treatments in France were included in the analysis. The male/female ratio was 47%/53% and 58% of patients were aged over 60 years old. Patients receiving OATs were mainly diagnosed with a solid tumor (74%) such as breast cancer (34%), non-small cell lung cancer (8%) and colorectal cancer (7%). OATs represented 45% (54/119) of all molecules available (oral and IV) of which 44% (24/54) were cytotoxic chemotherapies, 28% (15/54) were targeted therapies, 22% (12/54) were hormonal-therapies and 6% (3/54) were immunotherapies. 32% of patients (2,410/7,426) received a regimen containing at least one OATs among them 78% received OATs only versus 18% received a combination of oral and IV drug. Sixty-one percent of patients aged over 80 years received OAT's, as compared to 26% of patients aged less than 60 years. **CONCLUSIONS:** The ACTOR study is the first analysis focused on the understanding of the pattern of use of OATs. One third of cancer patients in France are treated with OATs especially among the elderly. Further research is needed to understand the OATs uptake.

PCN189

A DISEASE MODEL OF METASTATIC COLORECTAL CANCER INCLUDING MULTIPLE TREATMENT LINES

van Rooijen EM[1], Uyl-de Groot CA[1], Punt C[2], Koopman M[3], Coupe VM[4]
[1]*Institute for Medical Technology Assessment, Erasmus University, Rotterdam, The Netherlands,* [2]*Academic Medical Center, Amsterdam, The Netherlands,* [3]*University Medical Center Utrecht, Utrecht, The Netherlands,* [4]*VU University Medical Center, Amsterdam, The Netherlands*

OBJECTIVES: To develop a decision-analytic model describing the current course of disease, including the available treatments, in metastatic colorectal cancer to serve as a baseline for the analyses of new developments. **METHODS:** A disease model was constructed containing six disease states, namely 'first-line treatment', 'progression of disease after first-line',' second-line treatment', 'progression of disease after second-line', 'third-line treatment' and 'death'. Time spent in each state was predicted using log-logistic, log-normal or Weibull survival models, utilizing simulated characteristics. All survival models and simulated characteristics were based on patient-level data, provided by the CAIRO trial (n=820). The model was validated by comparing various outcome parameters with the original data. **RESULTS:** The overall survival of the simulated cohort resulted in a median survival of 498 days. The original patient level data had a median OS of 508 days (95% CI: 463- 545). For the subgroups age and treatment line data continued to match consistently with patient-level data. Patients treated with sequential therapy in the RCT had an OS of 492 days (95% CI 416-557), the model predicted an OS of 489 days. Patients in the RCT with combination therapy had an OS of 525 days (95%CI 442-591days), the model predicted 509 days OS. Similar results were achieved in other subgroups and for various other outcome measures. **CONCLUSIONS:** The model constructed during this study is a good basis on which to model the effectiveness and cost-effectiveness of numerous new treatment options, including expensive drugs. It will also allow - in future - for the evaluation of these treatment options while accounting for the heterogeneous nature of colorectal cancer As such this model offers a method to aid in determining the optimal sequence of treatments for patients with metastatic colorectal cancer, both in terms of costs and effects.

PCN190

STAGE-BASED UTILIZATION OF CHEMOTHERAPY AGENTS IN A CANADIAN BREAST CANCER POPULATION

Mittmann N[1], Seung SJ[1], Porter J[1], Rangrej J[1], Liu N[1], Trudeau M[2], DeAngelis C[1], Hoch JS[3], Leighl N[4], Earle CC[5]

[1]*Sunnybrook Health Sciences Centre, Toronto, ON, Canada,* [2]*Sunnybrook Health Science Centre, Toronto, ON, Canada,* [3]*University of Toronto, Toronto, ON, Canada,* [4]*Princess Margaret Hospital/ University Health Network, Toronto, ON, Canada,* [5]*Cancer Care Ontario / Institute for Cancer Research, Toronto, ON, Canada*

OBJECTIVES: To describe the utilization of chemotherapy agents administered to women with a diagnosis of breast cancer, by stage of disease. **METHODS:** Chemotherapy utilization was extracted from two databases with population-level coverage [New Drug Funding Program (NDFP) and Activity Level Reporting (ALR) data] for women diagnosed with breast cancer between January 1, 2005 and December 31, 2009 and resident in Ontario, Canada. NDFP included expensive antineoplastics. ALR included only intravenous antineoplastics for agents administered at cancer centres. Each entry in the database represented one exposure to an antineoplastic medication administered and funded by the province. Hormonal therapies were not included in this analysis. All duplicate entries (same patient, same drug, same date of administration, same dose) were excluded. Overall utilization and utilization by stage of disease were determined. Chemotherapy regimen utilization was not analyzed, only individual drug use was. **RESULTS:** There were 39,656 breast cancer cases (34.4% Stage I; 31.8% Stage II; 12.0% Stage III; 3.9% Stage IV; 17.9% Unstaged) with a mean age of 61.6 ± 14.0 years. Among all cases (staged and unstaged), 17,383 (43.8%) received chemotherapy. The most common drugs administered across the entire cohort were cyclophosphamide (68.4%), docetaxel (52.8%), epirubicin (47.3%), fluorouracil (36.2%), doxorubicin (31.6%) and traztuzumab (24.3%). The drug utilization for Stage I/II was cyclophosphamide (72.9%), docetaxel (52.0%), epirubicin (49.6%), fluorouracil (37.9%), doxorubicin (31.2%), paclitaxel (23.0%) and traztuzumab (22.8%). For Stage III/IV utilization was as follows: cyclosphosphamide (68.3%), docetaxel (62.4%), epirubicin (45.6%), doxorubicin (36.1%), traztuzumab (27.8%) and paclitaxel (26.0%). **CONCLUSIONS:** This frequency distribution of chemotherapeutic agents provides population level data on the management of breast cancer, by stage. Future work will involve costing of these medications from a population perspective.

PCN191

RACIAL DISPARITY IN HEALTH CARE ACCESS AND OUTCOMES ASSOCIATED WITH PROSTATE CANCER IN THE UNITED STATES

Roy D[1], Blanchette CM[2]

[1]*University of North Carolina, Charlotte, Charlotte, NC, USA,* [2]*University of North Carolina, Charlotte, NC, USA*

OBJECTIVES: Clinically significant prostate cancer is characterized by the growth of a tumor of more than 20 cc of cancerous cells within the prostate gland. Literature suggests significant disparities in prostate cancer prevalence and outcomes between Whites and African-Americans resulting in greater health services utilization. This study assessed the count of health care visits between White and African American prostate cancer patients. **METHODS:** This cross-sectional study used data from the 2010 Medical Expenditure Panel Survey. Negative binomial regression models were used to estimate the count of health services including emergency department visits, outpatient services and inpatient services associated with race in patients with prostate cancer while controlling for age and count of comorbidities. Patients who were not White or African-American were excluded due to the small numbers. **RESULTS:** The total sample consisted of 141 patients, of which 104 were White and 37 were African-Americans. Being White was associated with 43% less use of emergency services compared to being an African American while adjusting for age and comorbidities (IRR 0.57; 95% CI 0.33-0.97). Similarly, being White was associated with a 44% lower count of outpatient service use (IRR 0.56; 95% CI 0.32-0.99). No difference was found with inpatient services, most likely due to a low number of events. **CONCLUSIONS:** Being White was associated with less emergency and routine health care visits compared to being an African American, suggesting a disparity may exist among prostate cancer patients. More research should explore the sources of the disparity and whether this translates into other health care services like access to treatments.

PCN192

A FRAMEWORK FOR THE COST-EQUALITY ANALYSIS OF HEALTH CARE PROGRAMMES

Asaria M[1], Griffin S[1], Cookson R[1], Tappenden P[2], Whyte S[2]

[1]*University of York, York, UK,* [2]*University of Sheffield, Sheffield, UK*

OBJECTIVES: To describe a methodological framework for the economic evaluation of health care programmes that addresses effects on unfair health inequality as well as overall health. The framework is designed to highlight the social value judgements required to define unfair health inequality and how these impact on the estimated level of inequality, and is distinct from equity weighting or multi-criteria decision analysis. Application of the framework comprises characterisation and quantification of the distribution of health, and this is illustrated using an existing decision model evaluating a bowel cancer screening programme. **METHODS:** The decision model of bowel cancer screening is restructured using additional information on the distributions of screening uptake, baseline health levels, quality-adjusted life expectancy and health opportunity costs in order to estimate the health distribution resulting from alternative bowel cancer screening policies. Standard screening is compared to two re-design policies wherein reminders are used to increase uptake. Different sets of social value judgements are applied to explore the robustness of the results, using different approaches to measuring inequality and to adjusting health distributions for fair sources of inequality. **RESULTS:** A universal reminder to participate in bowel cancer screening results in the greatest improvement in total population health, but increases inequality compared to no reminder or targeted reminders. Targeting reminders by deprivation and ethnicity reduces health inequality. The choice between screening policies depends on the type and level of inequality aversion and on the value judgements about which sources of health inequality are unfair. **CONCLUSIONS:** The framework imposes additional data requirements and requires that decision makers consider supplementary value judgements compared to standard cost-effectiveness analysis. Differential uptake of screening results in significant, potentially avoidable, health inequalities. This framework can provide decision makers with useful information to help address such inequalities while appropriately addressing any trade off with improving overall health.

PCN194

DECISION MAKING IN HIRA FOR 5 YEARS OF POSITIVE LIST SYSTEM

MiHai P

Health Insurance Review & Assessment Service, Seoul, South Korea

OBJECTIVES: In Korea, the Positive List System was adopted in the end of 2006 and the cost-effectiveness had been important in decision making process for reimbursement. We tried to check the appraisal results. **METHODS:** Total of 5-years decision-making from 2007 to 2011 were reviewed and classified in several categories according to relative effectiveness and submission type of cost-effectiveness. **RESULTS:** Among 219 results which were made decision there were 149 recommendations(68%) for listing. Fifty submissions were cost-effectiveness(utility) analysis report but 26 submissions of those were improved relative effectiveness compared to the comparator. Twenty-four drugs were submitted CEA or CUA even though they didn't have evidence for improvement. If there was no evidence for the relative effectiveness or the new drug was inferior HIRA decided not to list. If new drug had evidence for non-inferiority it could be evaluated by cost-minimization analysis. Eleven drugs were decided to be listed among 12 submissions by CMA. There were 9 essential drugs to be appraised for 5 years. **CONCLUSIONS:** The most important factor in decision-making for reimbursement was relative effectiveness and the method of economic evaluation was determined by drug's relative effectiveness. In deciding acceptability in cost-effectiveness results the other factors are considered whether the drug used in severe disease or it was orphan drug, etc.

PCN195

HEALTH CARE RESOURCE UTILIZATION AND EXPENDITURES OF INCIDENT BREAST CANCER PATIENTS IN THE NETHERLANDS: RETROSPECTIVE ANALYSIS OF HEALTH INSURANCE DATA

Tariq L[1], Steins Bisschop CN[2], Haj Mohammad G[1], Stricker MS[2], de Wit GA[2], van Rossum-Schornagel QC[3], Hövels AM[4], Peeters PH[2], May AM[2]

[1]*GlaxoSmithKline, Zeist, The Netherlands,* [2]*Julius Center for Health Sciences and Primary Care, UMC Utrecht, Utrecht, The Netherlands,* [3]*University Medical Center Utrecht, Utrecht, The Netherlands,* [4]*Utrecht University, Utrecht, The Netherlands*

OBJECTIVES: Breast cancer generates a considerable economic burden. This study aims to quantify health care resource utilization and health care expenditures of breast cancer patients in The Netherlands. **METHODS:** A bottom-up cost-analysis was conducted using health insurance data retrieved from the AGIS Health Database in The Netherlands containing information on health care usage and –expenditures. Additionally, we estimated cost of in-hospital breast cancer medication in a top-down manner, based on Dutch National Breast Cancer treatment guidelines. Incident breast cancer cases (2008-2010) were included based on Diagnosis-Treatment-Combinations (DTC) codes containing the diagnosis of breast cancer. Health care resource utilization and expenditures were examined per phase of treatment (the year of diagnosis, second year, third year and last year of life). **RESULTS:** A total of 3494 newly diagnosed breast cancer patients were identified in the AGIS database, with an average age of 63 years at diagnosis. During the follow-up period, 220 patients died. Health care expenditures of Dutch breast cancer patients insured at AGIS were on average €17.120 per case in the year of diagnosis, €9.014 in the second year, €5.499 in the third year and €14.900 in the last year of life. The majority of the expenditures were related to health care utilized in the hospital setting. Additional costs of treatments with expensive drugs varied between €15.462 and €38.877, depending on the type of treatment. **CONCLUSIONS:** Health care usage and expenditures of Dutch breast cancer patients are substantial in the year of diagnosis, decrease in the second and third year after diagnosis, and then increase again in the last year of life. Treatment with expensive drugs adds a substantial cost burden.

PCN196
COST OF END OF LIFE PHARMACOTHERAPY IN CANCER PATIENTS: WHERE DOES THE BUDGET GO TO?
Hammerman A, Greenberg-Dotan S, Battat E, Bitterman H
Clalit Health Services Headquarters, Tel-Aviv, Israel
OBJECTIVES: Costs of cancer treatment has received increased attention in the last decade mainly because of the very high expenses on new biological drugs. Total cancer treatment costs vary by tumor type and stage, with the highest costs usually incurring in the last year of life. In this study, we characterized the drugs that have the highest budget-impact in treating cancer patients in Israel, immediately before death. **METHODS:** Clalit Health Services (CHS), Israel's largest health-care organization with over 4 million members, serves 52% of the total population. Using CHS's comprehensive databases, we identified the three leading fatal cancers in 2012. We calculated CHS's acquisition costs for all pharmaceuticals provided to patients in their last three months of life, and extracted the top budget-consuming drugs used during this period. **RESULTS:** The leading fatal cancers in 2012 were colorectal (1551 deaths), breast (1273) and lung cancer (1174). The drugs with the highest budget-impact in colorectal cancer patients were (% of total drug-expenditure, # of patients treated (% of the total number of patients)): Cetuximab (20.2%, 38 patients (2.5%)), Bevacizumab (14.6%, 56 patients (3.6%)), Panitumumab (6.6%, 21 patients (1.4%), Fentanyl (6.5%, 278 patients (17.9%)), Irinotecan (4.0%, 77 patients (5.0%)). In breast cancer: Trastuzumab (12.0%, 23 patients (1.8%)), Fulverstant (6.4%, 42 patients (3.3%), Fentanyl (5.9%, 178 patients (14.0%)), Lapatinib (5.5%, 10 patients (0.8%)), Zoledronic acid (4.1%, 59 patients (4.6%)). In lung cancer: Erlotinib (21.4%, 77 patients (6.6%)), Gefitinib (12.8%, 42 patients (3.6%)), Pemetrexed (10.5%, 57 patients (4.9%)), Crizotinib (6.0%, 8 patients (0.7%)), Fentanyl (4.5%, 298 patients (25.4%)). **CONCLUSIONS:** A significant proportion of the pharmaceutical budget was spent on a relatively small portion of patients who received expensive novel targeted therapies during their last months of life although chances for success were minimal. A much higher portion of patients received palliative treatments for a substantially smaller proportion of the pharmaceutical expenditure.

PCN197
THE GERMAN QUOTA SYSTEM AS A MODEL FOR BIOSIMILAR COST SAVINGS IN EPOETIN TREATMENT
Walsh K[1], Berger D[2], Bodenmueller W[1], Whitehouse J[3]
[1]*Sandoz Biopharmaceuticals, Holzkirchen, Germany,* [2]*Hexal, Holzkirchen, Germany,* [3]*GfK Bridgehead, Melton Mowbray, UK*
OBJECTIVES: To demonstrate real-world benefits of biosimilar quota system used in Germany. **METHODS:** Long before recent economic challenges health care costs have represented a vast and unsustainable trajectory beyond western economies real GDP. Biologics have become a driver of payer expenditure with an 83% increase in global spend expected from 2010 to 2020. The introduction of biosimilars since 2006 represents an opportunity to reduce expenditure on biologics while maintaining the quality of patient care. Uptake of biosimilars and associated cost savings has been very different across markets. One mechanism, to encourage utilization of biosimilars, is to introduce quota style systems as in Germany. Using claims data from the KV regions to determine the use of biosimilar epoetin in relation to the quotas introduced by the 17 physician based regions in Germany, and the historic spend on epoetin treatment to calculate the budget expenditure reduction. **RESULTS:** Driven by the German quota system together with consultancy via KV- and SHI-pharmacists and physicians, biosimilar epoetins in Germany have obtained 57% of the German EPO market by Q3 2012. A reduction of 51% was experienced across historic public prices from January 2007 to August 2011. The increased penetration of biosimilar epoetin resulted in cumulative savings in Germany of €551 million. German real-world research demonstrated that biosimilar epoetin treatments did not experience any significant differences in efficacy and safety when compared with the originator. **CONCLUSIONS:** The quota system has become a significant driver of biosimilar epoetin uptake in Germany, which has resulted in substantial cumulative savings to the German health care system. Additionally this has allowed for extensive clinical experience with biosimilars which resulted in confirmation of the expected efficacy and safety outcomes. The biosimilar quota system provides markets with a mechanism to reduce biologic expenditure, increase patient access to biologic medicines and increase physician experience.

PCN198
A PROSPECTIVE TIME AND MOTION ANALYSIS COMPARING INTRAVENOUS (IV) VESUS SUBCUTANEOUS (SC) BORTEZOMIB IN PATIENTS WITH MULTIPLE MYELOMA (MM)
Dranitsaris G[1], Kaura S[2]
[1]*Augmentium Pharma Consulting, Toronto, ON, Canada,* [2]*Celgene Corporation, Summit, NJ, USA*
OBJECTIVES: Bortezomib is an effective therapy for patients with MM. The recommended dosage is 1.3 mg/m^2 IV dosed on days 1, 4, 8 and 11 for eight, three week cycles. However, a recent randomized non inferiority trial demonstrated that the same dosage of bortezomib administered SC is equally effective, but with an improved safety profile. To measure the overall efficiency and cost savings of the SC route, a prospective time and motion study was undertaken in MM patients treated in a sample of U.S. community oncology clinics. **METHODS:** Time and motion and resource use data were collected from MM patients being treated with bortezomib IV (n=20) or SC (n=20) in seven U.S. community oncology clinics. Resource use and time impact on clinical staff were quantified using unit cost estimates. This included costs for drug preparation, wastage, administration, materials and supplies, premedication, patient chair time and all labor costs. **RESULTS:** The mean total time for IV and SC delivery (preparation, administration and total chair time) was 76.3 and 39.8 minutes ($p = 0.005$), with the associated (i.e. drug preparation and administration) cost being $U.S.189 and $U.S.90.84 respectively. With the inclusion of costs for drug wastage (i.e. mean of 1.2 mg for both IV and SC bortezomib, which is 34% of a 3.5 gram vial and costs approximately $U.S.500) and premedication, the cost for drug delivery was $U.S.808 (95%CI: $U.S.603 to $U.S.1011) and $U.S.596 (95%CI: $U.S.334 to $U.S.856) per dose of IV and SC bortezomib. Over a full cycle of therapy (i.e. 4 doses), the total cost for drug delivery including wastage and drug acquisition would be substantial at $U.S.7,113 and $U.S.6,327 for IV and SC bortezomib respectively. **CONCLUSIONS:** SC bortezomib resulted in a significant savings in drug delivery resources. However, drug wastage remained an important factor, regardless of the route of administration.

PCN199
RETROSPECTIVE ANALYSIS OF ONCOLOGY INDICATIONS UTILIZING DRUG EXPENDITURES FROM 2005 TO 2012 IN THE REPUBLIC OF SRPSKA
Guzvic V[1], Komjenovic D[1], Zah V[2]
[1]*Health Insurance Fund, Banja Luka, Bosnia,* [2]*ZRx Outcomes Research Inc., Mississauga, ON, Canada*
OBJECTIVES: Analyses were conducted on Republic of Srpska (RS) Health Insurance Fund (HIF) national prescription database. Analyses explored health expenditure in pharmaceutical consumption of oncology medications for the fiscal year 2005 through 2012, in order to determine impact of introduction of public tenders in 2008. RS HIF provides coverage for a population of 1.2 million. **METHODS:** RS HIF national prescription database was explored. Key cost drivers and the differences were identified across all medications covered by the RS HIF. **RESULTS:** In 2005, total expenditure for all Oncology medication was €1.2 million. In 2012, total expenditure for all Oncology medications was €8 million. This increase of 681% is a result of two critical factors: 1) a national policy shift in 2004, of patient treatment switch from being treated abroad in Republic of Serbia to being locally treated; 2) exponential increase in Oncology indications incidence. In 2008 there was an introduction of public tenders that run every two calendar years, which allowed additional medications to be purchased by the RS HIF, as well at lower costs and hence it resulted in moderate decrease in expenditures, even though there was a steady increase in quantities purchased. This resulted in balanced and average expenditure from 2008 to 2012 of €9 million. Based on 2005 through 2012 consumption of Oncology medications, it is derived that over the years to date, top three Oncology indications are: a) Metastatic breast cancer, b) Metastatic colorectal cancer, c) Colorectal cancer Stage III. **CONCLUSIONS:** Results indicate that most of the patients treated abroad, transferred back to RS HIF for treatment by 2008. Top three Oncology indications show that there is a need for higher public awareness and patient education in RS related to them. This is in line with current RS public health care policies and strategies.

PCN200
MARKET ACCESS OF CANCER DRUGS IN EUROPEAN COUNTRIES: A MATTER OF SETTING PRIORITIES FOR RESOURCE ALLOCATION
Pauwels K, Huys I, De Nys K, Casteels MR, Simoens S
KU Leuven, Leuven, Belgium
OBJECTIVES: Public health systems need to make well-founded choices in order to distribute their scarce resources in the most efficient way. Given the large number of cancer patients and their increasing life expectancy, public/private investments in oncology research, the growing launches of new anticancer agents and consequent high budget impact of cancer care, market access of cancer drugs has become delicate over the last decade. Furthermore, decision makers are challenged by ethical considerations and endeavor after fair and equal access to treatments for cancer patients. The aim of this study is to generate an overview of price setting and reimbursement procedures for cancer drugs in eight European countries. **METHODS:** Belgium, The Netherlands, France, Germany, Italy, Poland, UK and Sweden were selected as the countries of interest. Results were collected between January and March 2013 through a literature review and a qualitative questionnaire sent to authorities involved in price setting and reimbursement of drugs. The specific section of results for each country was validated by experts in the field. **RESULTS:** Diverse measures are introduced to optimize market access of cancer drugs such as adjusted cost-effectiveness thresholds and new market access agreements. Additionally, innovative cancer drugs are excluded from explicit cost control measures in some of the studied countries. Given the fact that each drug covered by the limited public health care budget might possibly exclude another one from reimbursement, results suggest preferential treatment of cancer drugs compared to drugs for other diseases. Besides societal preferences for treatments of severe diseases, there is no solid evidence that could justify prioritization of cancer. **CONCLUSIONS:** Price setting and reimbursement procedures seem to prioritize cancer above other disease areas. Further research needs to address the question if society attributes higher value to cancer drugs than to treatments for other diseases.

PCN201
A NOVEL ALGORITHM USING CLAIMS DATA TO IDENTIFY PATIENTS WITH CASTRATION-RESISTANT PROSTATE CANCER (CRPC)
Gorritz M[1], Thompson SF[2], Lee YC[1], Stern L[1], Penson DF[3]
[1]*LA-SER Analytica, New York, NY, USA,* [2]*Sanofi U.S. LLC, Bridgewater, NJ, USA,* [3]*Vanderbilt University Medical Center, Nashville, TN, USA*
OBJECTIVES: CRPC is an advanced form of prostate cancer with poor prognosis. The changing treatment landscape calls for use of real-world data to provide current information on disease epidemiology, treatment patterns, comparative effectiveness, and treatment cost. Administrative claims databases are a rich source of real-world data; however, they lack clinical values needed to identify CRPC patients. As currently there is no standard method to identify CRPC patients when clinical variables are unavailable, we developed and validated an algorithm using claims data to reliably identify CRPC patients. **METHODS:** Male patients with an ICD-9 code for PC between January 1, 2004 and November 30, 2012 were identified from IMS pharmacy and medical claims data. Metastatic PC was identified by additional tumors on or after the PC diagnosis. Surgical castration was determined using CPT and ICD-9 procedure codes for orchiectomy; medical castration was identified using codes for hormone therapies. The algorithm identified patients as having CRPC if they had any of the following: 1) switch in hormone therapy; 2) new metastases while on hormone therapy; 3) switch in treatment from any hormone therapy

to chemotherapy. The algorithm was validated against a PSA-based definition of CRPC (at least two PSA increases following castration or new metastases while on hormone therapy). **RESULTS:** A total of 269 patients met inclusion criteria and had 3 or more PSA measurements. The two methods agreed in 88% of patients; 220 (81.8%) were identified as CRPC by both methods and 17 (6.3%) were identified as not castration resistant by both methods. A statistical comparison of the two methods yielded a Cohen's kappa of 0.4491, indicating moderate agreement. **CONCLUSIONS:** The algorithm was concordant with a PSA-based definition of CRPC and serves as a new tool to identify CRPC patients using claims data. Future validation against a different data source is needed.

PCN202

INCREASED RISK OF CANCER INCIDENCE ASSOCIATED WITH REPEAT MEDICAL IMAGING: DESIGNING BETTER CLINICAL TRIAL PROTOCOLS

Zowall H, Brewer C, Deutsch A

Zowall Consulting Inc., Westmount, QC, Canada

OBJECTIVES: To assess the potential increase in lifetime attributable risk (LAR) of cancer incidence due to repeated exposure to medical imaging procedures for participants in clinical trials. **METHODS:** Medical imaging in clinical trials has grown exponentially in the last decade. We have developed an individual-based state-transition model to estimate the LAR of radiation-related cancer following a patient's exposure history, and site-specific dose according to age and gender. Monte Carlo simulations to vary effective doses, risk model coefficients, and the period for radiation-related cancer latency were performed. **RESULTS:** We examined two scenarios in a three year hypothetical clinical trial: minimal exposure describing a subject's radiation exposure as one abdominal CT scan per year; and frequent exposure consisting of five abdominal CT scans per year. For a 30 year old female the LAR of cancer incidence increased from 46 per 100,000 population in the minimal exposure scenario to 229 per 100,000 in the frequent exposure scenario. For a 30 year old male, the risk increased from 36 to 179 per 100,000. At age 30, females had a 30% higher risk than males, however, cancer incidence at ages 50, and 70 were similar for both sexes. At age 50 the LAR of cancer incidence increased from 31 to 151 per 100,000. At age 70 the risk increased from 15 to 71 per 100,000. The LAR of cancer incidence was one third lower in 70 year olds than in 30 year olds, and half the rate of 50 year olds. **CONCLUSIONS:** Although the LAR of cancer incidence of a single exposure seems to be relatively small, clinical trials that involve a comparatively large number of imaging procedures can lead to significantly higher risks. Examinations that deliver relatively high doses of radiation, such as CT, need to be clinically justified.

PCN203

TRENDS IN CHEMOTHERAPY SETTING AND COSTS FROM 2005 TO 2012: A CASE STUDY USING BEVACIZUMAB

Foley K

Truven Health Analytics, Cambridge, MA, USA

OBJECTIVES: The rising costs of cancer care are a major focus for clinicians, payers and patients. This analysis examines trends in bevacizumab chemotherapy administration and drug reimbursement. **METHODS:** Using the MarketScan© Research Databases, administrations of bevacizumab were identified from 1/1/2005 through 12/31/2012 for patients with commercial or employer-sponsored supplemental Medicare insurance. Bevacizumab claims were excluded if the claim had a diagnosis related to eye disease or the reimbursed amount was < $100. All claims were identified as occurring in an office-based setting (OBS), an outpatient hospital setting (OHS) or other setting. **RESULTS:** The percent of bevacizumab claims occurring in OHS increased from 6 to 34% among Medicare claims, and from 14 to 42% among commercial claims from 2005 to 2012. Medicare median drug reimbursement was $257 more for OHS than OBS in 2005, increasing to a difference of $3,022 in 2009 and declining to $1,722 in 2011 before narrowing to $165 in 2012. Medicare median reimbursements for chemotherapy administration in OHS were $408 more than OBS in 2005, dropping to a difference of $97 in 2008 and ending at $165 in 2012. Commercial differences in drug reimbursement for OHS and OBS settings continuously increased from $885 in 2005 to $3714 in 2011, declining slightly to $3676 in 2012. Differences in chemotherapy administration reimbursement were $176 more for OHS than OBS in 2005, the difference decreasing to $103 in 2007 and increasing to $236 in 2012. **CONCLUSIONS:** Although the difference in reimbursements to OHS and OBS has decreased over time for Medicare, the differences across settings for commercial insurance increased over time with a slight indication that cost increases are slowing. The higher reimbursements in OHS combined with the shift from OBS to OHS over the past 7 years has implications for the growth in cancer costs over the past decade.

PCN204

NOVEL MARKET ACCESS MODELS FOR CANCER DRUGS

Aggarwal S, Kumar S, Topaloglu H

Novel Health Strategies, Bethesda, MD, USA

OBJECTIVES: Cancer drugs are the world's highest selling category of therapeutic products. Due to their premium price and budget impact, several new drug reimbursement models have been implemented worldwide by public and private payers. These models have potential implications for coverage and reimbursement of all branded products. This study reviewed recent cancer drug reimbursement models and developed lessons and implications for future products. **METHODS:** Reviewed cancer drug reimbursement schemes in developed and emerging markets. Interviewed payers and KOLs to develop lessons and implications for future products. **RESULTS:** Public and private payers worldwide have implemented several new models for cancer drug reimbursement to manage budgets and control costs. In the US, private payers are piloting single source compendia and third party protocols (eg. P4 Oncology) to limit off-label use of cancer drugs. In the UK, NICE has successfully negotiated lower price and discounts for first few cycles of therapy. In Italy, AIFA has implemented registry based patient access for cancer drugs. In India, several manufacturers have implemented novel pricing strategy for first few cycles of therapy. In Germany, IQWIG has proposed to use correlations between surrogate endpoints and patient relevant outcomes to determine value of cancer drugs. Due to increased cost pressure on payers, such models are likely to inspire novel reimbursement schemes for other branded products. **CONCLUSIONS:** Cancer drug reimbursement models are setting new benchmark for payers to manage access and control costs. These models have significant implications for other expensive branded products.

PCN205

THE RELATIONSHIP BETWEEN SUBMITTED LINE OF THERAPY AND REIMBURSEMENT DECISIONS IN SOLID STATE TUMOR CANCER DRUGS

Jao R, Jaksa A, Ho YS, Daniel K

Context Matters, Inc., New York, NY, USA

OBJECTIVES: To explore the relationship between lines of therapy and submission for reimbursement across disease conditions and types of therapy. **METHODS:** This study looked at 252 Health Technology Assessments from eight agencies: CADTH, CCO, HAS, HIS, NICE, PBAC, SMC, and pCODR. The data covered 41 drugs across seven solid-state tumor cancer conditions. **RESULTS:** Of the 41 drugs, 27% (11/41) were initially submitted for first-line therapy and 73% (8/11) were recommended for reimbursement. Similarly, 32% (13/41) were initially submitted for second-line therapy and 77% (10/13) were recommended for reimbursement. Cytotoxic drugs were most likely to be reviewed initially for first-line therapy at 35% (7/20) and second-line therapy at 25% (5/20); targeted therapies were most likely to be reviewed initially for second-line therapy at 38% (8/21) and adjuvant therapy at 24% (5/21). The percentage of drugs reviewed for two or more lines of therapy varied greatly across conditions. Colorectal Cancer, SCLC, and NSCLC had the greatest percentages of drugs reviewed for 2+ lines of therapy with 100% (4/4), 100% (1/1), and 83% (5/6), respectively. Melanoma, Prostate Cancer, and Ovarian had the lowest percentages with 0% (0/2), 14% (1/7), and 40% (2/5), respectively. Additionally, there was a positive correlation (r= 0.9) between the number of drugs reviewed and number of lines of therapy covered per disease condition. **CONCLUSIONS:** There was no discernable difference in the rate of reimbursement between drugs initially submitted for first-line therapy or second-line therapy. There were, however, differences in various trends across disease conditions and between types of therapy. Future research will focus on trends across agencies and will include a larger sample size covering more conditions as well as investigational case studies on frequently reviewed drugs.

PCN206

CLINICAL AND COST-EFFECTIVENESS OF NON-PEGYLATED LIPOSOMAL DOXORUBICIN FOR NON-HODGKIN LYMPHOMA: A SYSTEMATIC REVIEW

Burda A[1], Zaremba A[1], Lubonski J[2], Matusewicz W[1]

[1]*Agency for Health Technology Assessment in Poland (AOTM), Warsaw, Poland,* [2]*General Hospital in Legnica, Legnica, Poland*

OBJECTIVES: To systematically review the currently available clinical and cost-effectiveness evidence of non-pegylated liposomal doxorubicin (NPLD) for non-Hodgkin lymphoma (nHL). The hypothesis under verification was that the administration of NPLD lowers the cardiotoxicity typical for conventional anthracyclines while being able to sustain the clinical effect of treatment. **METHODS:** A systematic literature search was conducted for clinical and cost-effectiveness data for the nHL population treated with NPLD, using the main medical databases (PubMed, EMBASE, Cochrane Library). In addition, clinical trial registries were searched, reference lists of included studies and reviews were screened for missed studies. Searches took place in September 2012. **RESULTS:** The review generated 9 one-arm clinical trials and 1 retrospective study which met the inclusion criteria. One comparative parallel trial comparing R-CHOP with R-COMP in the DLBCL population is ongoing, with no results published. Generally, available evidence is poor – studies identified are characterized by many limitations, i.e.: small and heterogeneous study populations, relatively short observation period, not always specified inclusion and exclusion criteria, diversified treatment regimens (with R-CHOP dominating), shortened or/and presented selectively safety data. The majority of studies was performed in the DLBCL population. Cumulative interpretation of data was hindered due to essential differences in between trials. Lowering of LVEF was observed with a frequency of 0% to 31,7% of cases, while symptomatic lowering of LVEF with the development of chronic ischemic heart disease occurred with the frequency of 0 to 10%. The second most frequent cardiological event observed was arrhythmia. Clinical efficacy focused on surrogate endpoints (radiological responses), defined differently in between trials. No economic evaluations studies were found. **CONCLUSIONS:** There is limited evidence on the effectiveness and safety of NPLD in patients with nHL due to the lack of well-designed and well-reported comparative studies. Further research is needed to explore the hypothesis in question.

PCN207

IMPACT OF RECOMMENDED PHARMACEUTICALS ON CANCER MORTALITY: ANALYSIS OF REAL-LIFE DATA

Wilson T, Hamerslag L

Costello Medical Consulting Ltd., Cambridge, UK

OBJECTIVES: To ascertain whether there were any trends in cancer mortality after hospital admittance and diagnosis that could be linked to recent approval of therapies by the National Institute for Health and Care Excellence (NICE). **METHODS:** Using information provided by Hospital Episode Statistics and the Office of National Statistics, yearly mortality data from both the inpatient and outpatient population between 2007 and 2010 were extracted. An analysis of 30-, 60-, and 90-day mortality following admittance to hospital was undertaken for malignancies which had seen therapies approved by NICE after 2006. **RESULTS:** Of the 37 cancer therapies assessed by NICE between 2006 and 2010 inclusive, 27 were recommended. Patients with lung cancer were found to experience one of the highest mortality rates overall. Interestingly, lung cancer also saw the largest number of therapies approved between 2006 and 2010 (7), along with a steady decline in the annual 90-day mortality over the three year period (29.6%, 28.4% and 27.1% in 2007-08, 2008-09 and 2009-

10, respectively). Similarly, patients admitted to hospital with oesophageal cancer experienced a high 90-day mortality rate, ranging from 22% to 21.9% in 2007-08 and 2009-10, respectively. However, between 2006 and 2010, no therapies were submitted for NICE appraisal for oesophageal cancer, suggesting that there may have been a lack of research interest and potentially explaining why there was no substantial decrease in mortality from 2007, as compared to indications where therapies had been approved, such as lung, colon and breast cancer. **CONCLUSIONS:** The recommendation of therapies and their uptake in the UK may at least partially explain the trends noted in this study, although other factors such as delay in therapy uptake and off-label use may also need to be taken into account.

PCN208

DO NICE EVIDENCE REVIEW GROUPS (ERG) FOCUS ON DIFFERENT ASPECTS OF MANUFACTURER SUBMISSIONS IN ONCOLOGY?

Heemstra L, Sweeney N, Van Engen A
Quintiles, Hoofddorp, The Netherlands

OBJECTIVES: Evidence Review Groups (ERGs) provide a critical appraisal of the manufacturer submission in the NICE single technology appraisal (STA) process. As the academic centres may differ in experience and methodology, the objective of this study was to evaluate whether the focus areas and key criticisms differ between ERGs. **METHODS:** The NICE website was searched for all NICE oncology STAs, published between June 2010 and June 2013. The ERG reports were retrieved, and the main critiques were categorised for the five centres that performed the most evaluations. The focus areas of the ERGs were further studied. **RESULTS:** A total of 27 STAs were identified with evaluations performed by 9 different ERGs. The most evaluations were performed by Liverpool (9), followed by Sheffield (4), and PenTAG, West Midlands and York (3 evaluations each). All ERGs would report uncertainties related to the extrapolation and gain in overall survival (OS), maturity of data, trial comparator, and the quality of life (QoL) data. In addition all critiques covered submission quality and disease specific challenges, yet variation was found in focus area between ERGs. For example a specific focus area of Liverpool was the OS modelling method. Proposed changes to survival modelling included separating the survival curves for pre- and post-progression, and removing any survival advantage post-progression where this was considered inappropriate. Comments from other agencies on OS were mainly limited to the choice of parametric survival function. Other areas that differed between ERGs were the systematic review methods (more often reported by Sheffield) and comments on the QoL data (York). **CONCLUSIONS:** Although all ERGs focus on uncertainty around the evidence and quality of the manufacturer submissions, the focus areas differed between the groups. The key difference seems to relate to research focus of the academic centre.

PCN209

REVIEW OF NICE TECHNOLOGY APPRAISALS IN ONCOLOGY: HOW DOES CLINICAL EVIDENCE CHANGE OVER TIME?

Dequen P, Cooper NJ, Abrams KR
University of Leicester, Leicester, UK

Drug licensing and reimbursement authorities worldwide are considering new ways to stimulate market access for innovative medicines such as accelerated approval and conditional coverage. Early release of pharmaceuticals calls for more responsive decision-making alongside continuous evidence generation throughout clinical development. We explore whether changing trends in clinical evidence considerations for health technology assessment (HTA) by the National Institute for Health and Care Excellence (NICE) may help inform future evidence requirements for rapid and early HTA. **OBJECTIVES:** We investigate how the submission and acceptability of clinical evidence for single, multiple and repeated assessments of cancer drugs by NICE have changed in the past decade. **METHODS:** We reviewed technology appraisals published online since February 2002 by NICE for pharmaceuticals in oncology. Information regarding the clinical evidence included and the methods used to analyse relative treatment effects across relevant comparators was extracted. Manufacturer submissions, assessment reports, and final appraisal determinations were considered for longitudinal comparison. **RESULTS:** Out of a total of 254 appraisals identified since 2002, 85 assessed cancer drugs and 76 of these were included for review based on available documentation. Only 11 products had been re-assessed to date with initial guidance superseded by a multiple technology appraisal or clinical guideline. We found a greater reliance on phase II and observational data in recent appraisals, particularly for novel therapies in areas of high unmet need. Limited data was also accompanied by an increase use of surrogate outcomes and extrapolation of observed short-term clinical benefits. Recent submissions were also marked by the uptake of network meta-analysis methodologies. **CONCLUSIONS:** NICE has previously recommended cancer drugs based on immature clinical data allowing for considerable uncertainty in 'real-world' effectiveness estimates. However, these examples remain the exception to the rule; moreover our review highlighted a need for methodological development to deal with early clinical evidence.

PCN210

G-BA ASSESSMENTS OF ONCOLOGY TRIALS: IS INCREASED OVERALL SURVIVAL A "MUST HAVE"?

Schuchardt M[1], Nijhuis T[1], Friedmann B[2]
[1]*Quintiles, Hoofddorp, The Netherlands,* [2]*Quintiles, Mannheim, Germany*

OBJECTIVES: Objective of this research was to provide an overview of Health Technology Assessments (HTAs) in oncology after introduction of AMNOG in Germany. **METHODS:** Quintiles' HTA database (HTA Watch) has been used to analyse HTAs in Germany. The timeframe chosen for analysis was 1st of January 2011 to 24th of June 2013. All reports have been analysed in detail to reveal key factors for success or failure, which are presented in the following. **RESULTS:** Since introduction of AMNOG in 2011, thirty percent (13 out of 43) of all completed assessments by the G-BA (Federal Joint Committee) evaluated cancer drugs. The products assessed were abiraterone acetate, axitinib, brentuximab vedotin, cabazitaxel, crizotinib, decitabine, eribulin, ipilimumab, pixantrone, ruxolitinib, vandetanib, vemurafenib and a combination of tegafur, gimeracil and oteracil. Across these oncology assessments a total of 19 patient subgroups have been evaluated. Eleven subgroups (58%) showed an additional benefit according to the G-BA. Eight subgroups (42%) received the rating "no additional benefit" or "less benefit than comparator". The comparators chosen by G-BA within subgroups vary widely depending on the indication. Key factors for the positive outcome of these assessments were increased overall survival, reduction of symptoms or improved quality of life. Main reasons for the G-BA to attest no additional benefit include inappropriate indirect comparison and lack of adequate patient subgroup analysis. **CONCLUSIONS:** Analysis of HTA reports in oncology shows that while overall survival is a strong end point, also increased quality of life and reduced side-effects can be sufficient to achieve a beneficial outcome (crizotinib: considerable benefit). Importantly, the provided data must be applicable to the German regulations under AMNOG, showing clinical evidence against the specified comparator. The amount of the additional benefit plays an important role in the reimbursement amount negotiations following the definition of the additional benefit by the G-BA.

PCN211

HEALTH TECHNOLOGY ASSESSMENT: IS IT THE RIGHT PIECE FOR THE JORDANIAN HEALTH CARE PUZZLE?

Al Rabayah AA, Jaddoua S
King Hussien Cancer Center, Amman, AL, Jordan

OBJECTIVES: To study the pharmaceutical reimbursement/Coverage decision making processes in Jordan to highlight the importance of conducting formalized technology assessments **METHODS:** To review publically available data regarding the reimbursement/Coverage decision making processes in Jordan through searching related organization's websites and publically available regulations. **RESULTS:** Jordan is characterized with a fragmented health care system. Pharmaceutical registration and pricing are under the responsibility of the JFDA. Furthermore, it is responsible about medication selection for the Rational Drug List (the national formulary). The medication supply chain differs between the public and the private sectors in term of process and out puts. The medication selection process is not governed by criteria and not empowered by an independent review body to support decision making by the national appraisal committee (national P&T). The rational drug list is publically available but without details of the decision or the processes of decision making process. Listing of new medication is wide without indication specification or date of listing. The role of cost-effectiveness is limited and the tender prices are not linked to any type of cost effectiveness analysis **CONCLUSIONS:** The National Agenda, the National health Policy and the National Drug Policy tackled the high health expenditure in Jordan as an essential priority. This challenged is due to the characteristics of the Jordanian health care system that is fragmented with a divided funding system between public and private sectors. A more formalized medication selection processes empowered with drug information services that provide evidence based data and analysis in the form of technology assessment would play a role in decreasing health care expenditures. All of these recommendations should move parallel with improving the level of transparency and patient engagement.

PCN214

EPIDEMIOLOGY FOR ONCOLOGICAL DRUGS REGARDING THE BENEFIT DOSSIER PREPARATION IN GERMANY

Kürschner N, Schmitter S
Pfizer Deutschland GmbH, Berlin, Germany

OBJECTIVES: An early benefit assessment of drugs after launch has been implemented since 2011 in Germany. The Institute for Quality and Efficiency in Health Care (IQWiG) assesses the benefit of the drug based on a dossier submitted by the pharmaceutical manufacturer. Based on this assessment and the statements by industry, scientific community and patient organizations the Federal Joint Committee (G-BA) reviews and decides on the extent of the additional benefit. The dossier needs also to contain information about the number of patients treated with the new drug. The objective is to investigate the sources considering the calculation of patient numbers for oncological drugs. **METHODS:** A review of oncological drugs which passed through the benefit assessment was conducted to evaluate which data sources and methods were used to calculate the potential patient number. The results were compared with IQWiG's assessment and the final decision by G-BA, to detect possible methodological difficulties. **RESULTS:** The data sources regarding German epidemiological data were mainly collected through publicly available sources such as national and local cancer registries. Difficulties occurred with small cancer entities or when specific data regarding patient subpopulations (e.g. through age, tumor stages, ECOG performance status or previous therapies) was needed. The pharmaceutical manufacturer's calculations were often challenged by IQWiG and G-BA without suggesting a precise alternative or more suited data source. **CONCLUSIONS:** The data collection and data availability within the benefit dossier process for oncological drugs is in most cases challenging and the efforts needed should not be underestimated. Authorities, industry and medical community should work on a common solution for a more valid and reliable calculation of the potential patient number in oncology.

PCN215

ECONOMICAL LOSSES DUE TO DISABLEMENTPARENTS CARRING FOR CHILDREN WITH ONCOHEMATOLOGICAL DISEASES

Ganieva D[1], Zhukovskaya E[1], Spichak I[2]
[1]*Federal Scientific Centre of Children Hematology, Oncology, Immunologyl, Moskow, Russia,* [2]*Medical Academy, Chelyabinsk, Russia*

OBJECTIVES: Socio-economic phenomena, caused by disease of children are reflected primarily in the formation of non-medical costs. Methodology for calculation of non-medical costs includes a number of parameters, including the cost of lost output by persons caring for children during the treatment period. **METHODS:** The study involved patients from Oncohematological Chelyabinsk Center for Children and Adolescents behalf of prof. V. Gerein been treated in the period from 2008 to 2013.

Patient selection was random. The basic condition for inclusion in the study was the availability of data necessary to meet the costs. The number of patients at this stage of the study was already 42 people. Age at diagnosis was 9 months to 12 years, the median age of the patients was 6,4 ± 5,6 years. All of the patients were in the hospital with their parents of working age. In the calculations have been included: - GRP Chelyabinsk region (Gross Regional Product-14 USD per day per capita) and GDP (Gross Domestic Product-44,4 USD per day per capita), which amounted on average in 2008-2012. The formula for the calculation of total costs:E $ = Nd x GRP / GDP (Nd-the number of days of disability) **RESULTS:** Comparing the various cost components of treatment revealed that the indirect costs are 66% of the total amount of all expenses for medical treatment. State losses caused by non-working period of hospitalized for care people and non-produced Gross Regional Product are 7758,5 ± 1076,1 USD per capita. Losses of GDP are 21449,6 ± 3748,8 USD per capita. **CONCLUSIONS:** The formation of regional budgets should be done with consideration of big loss connected with disability of people hospitalized for the care of the a sick child, adjusted for and with GRP/GDP taken into account of big potion non-medical costs.

PCN216

POPULATION BASED UTILIZATION OF RADIATION THERAPY BY A CANADIAN BREAST CANCER COHORT

Mittmann N[1], Seung SJ[1], Liu N[1], Porter J[1], Saskin R[1], Hoch J[2], Evans W[3], Leighl N[4], Trudeau M[5], Earle CC[6]

[1]*Sunnybrook Health Sciences Centre, Toronto, ON, Canada,* [2]*Cancer Care Ontario, Toronto, ON, Canada,* [3]*Juravinski Cancer Centre, Hamilton, ON, Canada,* [4]*Ontario Cancer Institute, Toronto, ON, Canada,* [5]*Sunnybrook Health Science Centre, Toronto, ON, Canada,* [6]*Cancer Care Ontario / Institute for Cancer Research, Toronto, ON, Canada*

OBJECTIVES: To examine the trends in radiation therapy (RT) utilization by a population based breast cancer cohort in Ontario, Canada. **METHODS:** The provincial cancer registry maintains cancer specific databases and provided a breast cancer cohort based on diagnosis dates from April 1, 2005 to March 31, 2010. Staging information was also available. The cohort was then linked, by their encrypted health card number, to linkable administrative datasets that are maintained by the Institute for Clinical Evaluative Sciences (ICES) such as RT utilization. **RESULTS:** An all female breast cancer cohort (N=39,656) was identified over a five-year timeframe and the average age was 61.6 ± 14.0 years. Approximately, two thirds (N=25,225) of patients received RT and staging information was available for 22,988 patients (stage I = 9,541; stage II = 8,516; stage III = 4,050; and stage IV = 881). Patients had an average of 1.4 ± 0.7 (stage I) number of RT courses, 1.8 ± 1.1 (stage II), 2.5 ± 1.3 (stage III), and 2.8 ± 2.4 (stage IV). The percent ratio of conventional RT to intensity modulated RT (IMRT) was 70.9%:16.6% (stage I), 71.6%:11.3% (stage II), 74.6%:4.6% (stage III), and 72.7%:12.6% (stage IV). For the non-IMRT cohort with a primary cancer (N=30,887), the average number of fractions per course was 18.1 ± 9.2. **CONCLUSIONS:** From 2005 – 2010, almost two thirds of a Canadian female breast cancer cohort received RT and the average number of courses increased with stage. A similar trend was observed with the type of RT (coventional RT utilization increased with stage) but peaked at stage III and decreased at stage IV, likely due to palliation. The next step is to apply unit costs to the number of fractions per subgroup and to also obtain RT-planning and radiation therapist times.

PCN217

DEFINING ELIGIBLE PATIENT POPULATION IN SÃO PAULO STATE BASED ON CLEOPATRA TRIAL INCLUSION CRITERIA: A RETROSPECTIVE ANALYSIS OF FUNDAÇÃO ONCOCENTRO (FOSP) CANCER PATIENT REGISTRY (REGISTRO HOSPITALAR DO CÂNCER – RHC)

Tobaruella FS, Maximo MFM, Tsuchiya CT, Buschinelli CT, Gonçalves TM

Roche Brazil, São Paulo, Brazil

OBJECTIVES: Breast cancer (BC) is the most common cancer affecting women and, despite advances in treatment, is still the leading cause of cancer death among women worldwide. Approximately 20%-25% of the women diagnosed with BC will have HER2-positive disease and those with metastatic disease (mBC) have a 5-year life expectancy of only 24%. Recently, pertuzumab (P) was approved as a new therapeutical option for first line HER2-positive mBC in Brazil. This study aims to define the proportion of BC patients that would be eligible for pertuzumab+trastuzumab+chemotherapy (P+T+C) combination therapy in São Paulo state by analyzing retrospectively (2000-March 2013) the Fundação Oncocentro (FOSP) cancer patient registry (Registro Hospitalar de Câncer – RHC). **METHODS:** Raw data of cancer cases reported from 2000-March 2013 was taken from the FOSP-RHC and mined according to the inclusion criteria of the CLEOPATRA trial. Only women with histologically/cytologically confirmed diagnosis of BC (ICD-50) and reported TNM classification at diagnosis were included in the analysis. P+T+C therapy eligible patients were those reported as stage IV at diagnosis (de novo mBC) or stages 0, I, II and III with evidence of progression at last tumour assessment (recurrent cases), excluding ones with evidence of central nervous system (CNS) metastasis. Was considered that all patients in the database would test for HER2 status and positivity rate was taken from literature (25%). **RESULTS:** During the analysis period 59,095 BC cases with TNM classification at diagnosis were reported. 4,660 cases were considered de novo mBC and 7,378 cases were considered as recurrent. According to the positivity rate 3,010 patients would be eligible for P+T therapy which accounts for approximately 5.1% of the overall cases of BC. **CONCLUSIONS:** First-line HER2-positive mBC is a targeted, clearly defined and limited patient population where pertuzumab based regimen provides significant and clinically meaningful benefits in overall survival and progression-free-survival.

PCN218

PHYSICIANS' PREFERENCES FOR BONE METASTASES TREATMENTS IN FRANCE, GERMANY AND THE UNITED KINGDOM

Qian Y[1], Hechmati G[2], Mohamed AF[3], Hauber AB[3], Arellano J[1], Gatta F[2], Haynes I[4], Bahl A[5]

[1]*Amgen Inc., Thousand Oaks, CA, USA,* [2]*Amgen (Europe) GmbH, Zug, Switzerland,* [3]*RTI Health Solutions, Research Triangle Park, NC, USA,* [4]*Amgen Ltd., Uxbridge, UK,* [5]*University Hospitals Bristol, Bristol, UK*

OBJECTIVES: To evaluate European physicians' treatment preferences for preventing skeletal-related events (SREs) in patients with bone metastases from solid tumors. **METHODS:** Physicians completed an online discrete-choice experiment survey consisting of 10 choices between pairs of hypothetical medication profiles for a putative patient. Each profile included five attributes within a pre-defined range (based on prescribing information for the available bone-targeted agents [BTA]): months until first SRE (10, 18 and 28 months); months until worsening of pain (3, 6 and 10 months); annual risk of osteonecrosis of the jaw (ONJ; 0, 1 and 5%); annual risk of renal impairment (0, 4 and 10%); and mode of administration (oral tablet, subcutaneous injection, 15-minute infusion and 120-minute infusion). Choice questions were based on an experimental design with known statistical properties. The survey was pretested with 8 physicians using open-ended interviews. A separate main-effects random parameters logit model was estimated for each country. **RESULTS:** Physicians from France (n=191), Germany (n=192) and the UK (n=197) completed the survey. Among the attributes included in the survey, months until first SRE and the risk of renal impairement were the most important attributes in France and the UK, whereas in Germany months until first SRE and a delay in worsening of pain were the most important. For all these attributes, better levels were significantly preferred to worse levels ($p<0.05$). In all three countries, a 120-minute infusion every 4 weeks was the least preferred mode of administration ($p<0.05$). The annual risk of ONJ was judged by physicians to be the least important attribute in all three countries. **CONCLUSIONS:** Physicians generally make treatment decisions regarding choice of BTA for patients with bone metastases based on intent to delay the onset of SREs, managing risk of renal impairment and preventing the worsening of pain.

PCN219

NURSES' PREFERENCES FOR BONE METASTASES TREATMENTS IN THE UNITED STATES

Mohamed AF[1], Qian Y[2], Hauber AB[1], Collins H[2], Hechmati G[3], Gatta F[3], Arellano J[2]

[1]*RTI Health Solutions, Research Triangle Park, NC, USA,* [2]*Amgen Inc., Thousand Oaks, CA, USA,* [3]*Amgen (Europe) GmbH, Zug, Switzerland*

OBJECTIVES: Several bone-targeted agents (BTAs) are approved for the prevention of skeletal related events (SREs). Nurses work closely with physicans and patients in managing the disease. Whilst influencing treatment decisions, nurses preferences for alternative treatment options have not been assessed. This study evaluated US nurses' preferences for treatment attributes in preventing SREs among patients with bone metastases from solid tumors. **METHODS:** Nurses completed a web-enabled discrete-choice experiment survey consisting of 10 choices between pairs of hypothetical medication and patient profiles. Each profile included six medication attributes within a pre-defined range (primarily based on prescribing information and real-world practice): months until first SRE (10, 18 and 28 months); months until worsening of pain (3, 6 and 10 months); annual risk of osteonecrosis of the jaw (ONJ; 0, 1 and 5%); annual risk of renal impairment (0, 4 and 10%); mode of administration (subcutaneous injection, 15-minute infusion and 120-minute infusion); and out-of-pocket cost to patients ($25, $75, $150 and $330). Choice questions were based on an experimental design with known statistical properties. The survey was pretested with 6 nurses using open-ended interviews. A main-effects random parameters logit model was estimated. **RESULTS:** A total of 196 US nurses completed the survey. Among the attribute levels included in the survey, out-of-pocket costs to patients, risk of renal impairement, and months until first SRE were the most important attributes. For all attributes, better levels were significantly preferred to worse levels ($p<0.05$) except that no difference was observed between 0% and 1% ONJ attribute. Annual risk of ONJ was perceived by nurses to be the least important attribute. **CONCLUSIONS:** When working with physicians and patients on the choice of BTAs for patients with bone metastases, out-of-pocket costs to patients, managing the risk of renal impairment and delaying time to first SRE are the primary foci for nurses.

PCN220

PHYSICIANS' PREFERENCES FOR BONE METASTASES TREATMENTS IN THE UNITED STATES

Arellano J[1], Mohamed AF[2], Hauber AB[2], Collins H[1], Hechmati G[3], Gatta F[3], Qian Y[1]

[1]*Amgen Inc., Thousand Oaks, CA, USA,* [2]*RTI Health Solutions, Research Triangle Park, NC, USA,* [3]*Amgen (Europe) GmbH, Zug, Switzerland*

OBJECTIVES: Among the bone-targeted agents (BTAs) currently approved for the prevention of skeletal-related events (SREs), several characteristics may be considered by physicians when making treatment decisions. This study evaluated US physicians' treatment preferences for preventing SREs in patients with bone metastases from solid tumors. **METHODS:** Physicians treating patients with bone metastases completed a web-enabled discrete-choice experiment survey consisting of 10 choices between pairs of hypothetical medication and patient profiles. Each profile included six medication attributes within a pre-defined range (primarily based on prescribing information and real-world practice): months until first SRE (10, 18 and 28 months); months until worsening of pain (3, 6 and 10 months); annual risk of osteonecrosis of the jaw (ONJ; 0%, 1% and 5%); annual risk of renal impairment (0%, 4% and 10%); mode of administration (subcutaneous injection, 15-minute infusion and 120-minute infusion every 4 weeks); and out-of-pocket cost to patients ($25, $75, $150 and $330). Choice questions were based on an experimental design with known statistical properties. The survey was pretested with 8 physicians using open-ended interviews. A main-effects random parameters logit model was estimated. **RESULTS:** A total of 200 US physicians completed the survey. Among the attribute levels included, out-of-pocket cost to patients, months until first SRE and the risk of renal impairment were the most important attributes. For those attributes, better levels (outcomes) were significantly preferred to worse levels ($P < 0.05$). For mode of administration, subcutaneous injection was preferred over 15-minute infusion every 4 weeks ($P < 0.05$). **CONCLUSIONS:** When making treatment decisions regarding choice of BTA for patients with bone metastases, out-of-pocket cost to patients, delaying the onset of SREs and managing the risk of renal impairment are the primary foci for physicians.

PCN221

IDENTIFICATION OF THE TREATMENT PATHWAY OF METASTATIC CASTRATE-RESISTANT PROSTATE CANCER IN SCOTLAND: A CHART REVIEW

Maman K[1], Khemiri A[2], Roïz J[1], Naidoo S[3], Baskin-Bey E[3], Holmstrom S[4]
[1]*Creativ-Ceutical, London, UK,* [2]*Creativ-Ceutical, Tunis, Tunisia,* [3]*Astellas Pharma Europe Ltd., Chertsey, UK,* [4]*Astellas Pharma Europe, Leiderdorp, The Netherlands*

OBJECTIVES: Chemotherapy with docetaxel was the first therapy approved for the treatment of metastatic Castrate-Resistant Prostate Cancer (mCRPC) while others came along rather recently. With all the treatment options available now, current treatment strategies to appropriately sequence these agents are not known. This study aims to describe mCRPC current treatment paradigms, with specific attention to docetaxel, in Scotland. **METHODS:** A retrospective chart review was conducted. A panel of Scottish physicians was contacted to identify patients diagnosed with mCRPC between 2008 and 2013. Collected data included demographics, disease history, sequencing of therapies (type, duration and time-to-event), reason for switch or discontinuation, drug-related serious adverse events and hospitalisations. Descriptive analyses were performed. Time-to-event was analysed using the Kaplan-Meier method. **RESULTS:** Twelve physicians in Scotland completed the survey and 34 patients were included in the analysis. Mean age at mCRPC diagnosis was 62 years (range 56-69 years). The mean duration between mCRPC diagnosis and the date of last contact was 1.20 years. Postcastration, most patients (19/34, 56%), received docetaxel as first-line. The second most frequent first-line was bicalutamide (14/34, 41%), alone (9/14, 64%) or in combination with LHRHa. Abiraterone was frequently prescribed as next (second or third) line of therapy after docetaxel (6/21, 29%). The median time to switch was 105 days (range 20-235 days) and did not differ between patients with docetaxel versus other as first-line ($p = 0.17$). Most patients switched after radiographic progression or PSA rise. Serious adverse events and hospitalisations were rarely reported. **CONCLUSIONS:** These findings provide insights into the treatment pathway of mCRPC patients in Scotland. Chemotherapy with docetaxel and hormonal agents appear to be the most utilised therapies. Switch from first-line treatment occurred in approximately 3.5 months and was facilitated by radiographic progression or PSA rise. A larger retrospective chart review is needed to confirm these results.

EVALUATION OF ACUTE PANCREATITIS SIGNALS WITH INCRETIN ENHANCERS: REVISITING DISPROPORTIONALITY ANALYSIS OF THE ADVERSE EVENT REPORTING SYSTEM

Ali AK
Eli Lilly and Company, Indianapolis, IN, USA

OBJECTIVES: There has been a rising concern about the association between incretin enhancers and acute pancreatitis (AP). Previous research showed conflicting findings, and this analysis of the FDA Adverse Event Reporting System (FAERS) aims at investigating signals of AP across pharmacological classes of anti-diabetes medications (ADM) and within incretin enhancers class. **METHODS:** Adverse event reports submitted to FAERS between 1997Q3-2012Q1 were analyzed. The outcome was defined by MedDRA Preferred Term (PT) "pancreatitis acute"; exposures were defined by generic names of ADM. Sensitivity analyses were conducted by creating a custom term (CT) for outcome: "autoimmune pancreatitis", "ischemic pancreatitis", "pancreatitis", "pancreatitis acute", "pancreatitis hemorrhagic", and "pancreatitis necrotizing". Reports of other pancreatic disorders were excluded. Disproportionality analysis by proportional reporting ratio (PRR) and 95% confidence interval (LL05-UL95) is applied to detect AP signals compared to all ADM. Associations with LL05≥2 are significant signals. **RESULTS:** A total of1183 AP PT and 4481 CT reports for ADM were identified (incretin enhancers, n=912 and n=3,704, respectively). Corresponding PRR and (LL05-UL95) were: metformin 0.98 (0.83-1.16) and 0.52 (0.47-0.59); sulfonylureas 0.53 (0.37-0.75) and 0.35 (0.28-0.43); thiazolidinediones 0.12 (0.09-0.16) and 0.12 (0.10-0.14); meglitinides 0.54 (0.31-0.93) and 0.39 (0.28-0.54); incretin enhancers 1.94 (1.87-2.00) and 2.09 (2.06-2.12); and combinations 0.65 (0.47-0.88) and 0.81 (0.70-0.93). Compared to all ADM, estimates for incretin enhancers were: exenatide 1.46 (1.37-1.55) and 1.54 (1.49-1.59); liraglutide 4.90 (4.37-5.48) and 4.00 (2.73-4.28); saxagliptin 4.47 (3.00-6.67) and 4.60 (3.73-5.67); and sitagliptin 2.33 (1.95-2.78) and 4.02 (3.75-4.31). There were no reports of AP PT for linagliptin, but 39 reports of CT with estimates of 6.41 (4.64-8.85) were identified. **CONCLUSIONS:** Compared to other ADM, incretin enhancers are associated with higher than expected reporting of AP. Prescribers should monitor patients with diabetes for signs and symptoms of pancreatitis while treated with incretin enhancers. Given limitations of spontaneous reporting systems, pharmacoepidemiological studies are required to test the generated hypothesis and to draw clinically rigorous conclusions.

BAYESIAN NETWORK META-ANALYSIS TO ASSESS THE RELATIVE EFFICACY AND SAFETY OF CANAGLIFLOZIN IN PATIENTS WITH TYPE 2 DIABETES MELLITUS (T2DM) INADEQUATELY CONTROLLED ON METFORMIN AND SULPHONYLUREA (MET+SU)

Pacou M[1], Taieb V[1], Abrams KR[2], Diels J[3], van Sanden S[4], Garg M[5], Schroeder M[6], Kaur V[7], Nielsen ATN[5], Nuhoho S[6], Neslusan C[8], Hemels M[5]
[1]*Amaris, London, UK,* [2]*The Institute of Cancer Research, Sutton, UK,* [3]*Janssen Pharmaceutica, Beerse, Belgium,* [4]*EMEA HEMAR Analytics, Janssen EMEA, Beerse, Belgium,* [5]*Janssen Cilag, Birkerød, Denmark,* [6]*Janssen UK, High Wycombe, UK,* [7]*Consultant, Mumbai, India,* [8]*Janssen Global Services LLC, Raritan, NJ, USA*

OBJECTIVES: To assess the relative efficacy and safety of canagliflozin (CANA), a sodium-glucose co-transporter inhibitor, as an add-on to MET+SU, versus DPP-4 inhibitors, GLP-1 agonists and insulin, using Bayesian network meta-analysis (NMA). **METHODS:** A systematic literature review was conducted according to NICE guidelines. Outcomes of interest included HbA1c, weight and hypoglycaemia. A Bayesian NMA using non-informative priors was conducted, based on linking trials with treatment and dose-specific common treatment arms. Assessment of model fit and selection of fixed versus random effects was based on the Deviance Information Criterion (DIC). Sensitivity analyses assessed the impact of individual trials and definition of priors. Consistency between direct and indirect evidence was assessed. **RESULTS:** Ten studies reporting results at 26 weeks +/- 4 weeks were identified. HbA1c-reduction (D) for CANA 100mg was comparable to DPP-4s (D between 0.05 and -0.14 versus sitagliptin and linagliptin respectively, with pairwise probabilities (P) of being more effective between 33-88%), and higher for CANA 300mg, which was comparable to GLP-1s (D=0.08;P=31% and 0.01;P=53%) versus liraglutide 1.8mg and exenatide 10µg respectively) and biphasic insulin (D=0.03;P=43%). CANA 300mg had the highest weight reduction with changes between 0.14kg;P=93% (vs. exenatide 10µg) and 5.13kg;P=100% (vs. biphasic insulin). The odds ratio for hypoglycaemia versus long-acting insulin were 0.31 and 0.39 for CANA 100mg and 300mg respectively, compared to 0.20-0.41 for other classes. **CONCLUSIONS:** NMA of add-on therapies to MET+SU suggests that glycaemic reductions for CANA at 26 weeks are at least as large for CANA 100 mg and greater for CANA 300 mg compared to DPP-4s. CANA 300mg was found to be comparable to liraglutide 1.8mg and biphasic insulin. Weight reduction was similar to GLP-1s and substantially higher compared to all other classes. All classes showed significantly lower hypoglycaemic event rates compared to insulin.

COMPARATIVE EFFECTIVENESS OF LIRAGLUTIDE VERSUS SITAGLIPTIN IN TYPE 2 DIABETES IN THE UNITED KINGDOM: A RETROSPECTIVE STUDY IN PRIMARY CARE

Nyeland ME[1], Ploug UJ[1], Skovgaard R[1], Richards A[1], Bergan EQ[1], Zammit DC[2], Evans M[3]
[1]*Novo Nordisk A/S, Søborg, Denmark,* [2]*IMS Health, Basel, Switzerland,* [3]*University Hospital Llandough, Cardiff, UK*

OBJECTIVES: Liraglutide is an incretin-based (GLP-1 analog) therapy indicated for the treatment of patients with type 2 diabetes (T2DM). This study aimed to assess whether phase 3 clinical trial data, showing significantly greater reductions in HbA1c and body weight vs. the DPP-IV inhibitor sitagliptin is translated into routine clinical practice. **METHODS:** This was a retrospective database analysis of the Clinical Practice Research Datalink (CPRD), a primary care database in the UK. Patients (≥18 years) diagnosed with T2DM and prescribed liraglutide or sitagliptin between July 2009 and July 2012, were included. Patients on insulin or fixed dose metformin combinations at therapy initiation were excluded. Outcomes included: % of patients achieving ≥1% HbA1c reduction; % of patients with HbA1c reduction ≥1% and weight reduction ≥3% (NICE criteria); % of patients achieving treatment target HbA1c <7%; absolute change in HbA1c, weight (BMI), systolic blood pressure and blood lipids. **RESULTS:** Baseline demographics: 294 liraglutide and 2790 sitagliptin patients with a mean age of 55.7 (SD 10.6) and 62 (SD 11.0) years and 36.4% and 40.5% female respectively. Patients had a baseline HbA1c of 8.9% (SD 1.9) and 8.6% (SD 1.5), a baseline BMI of 39.3 (SD 7.1) and 33.3 (SD 6.4) and had been diagnosed with diabetes 7.1 and 7.2 years prior to start of current treatment for liraglutide and sitagliptin respectively. Comparative effectiveness analysis demonstrated superior reductions for liraglutide vs. sitagliptin in HbA1c (%) (-0.89 vs. -0.57, p<.01), weight (Kg) (-3.78 vs. -1.12, p<.0001), BMI (-1.3 vs. -0.4, p<.0001) and systolic blood pressure (mmHg) (-4.1 vs. -0.37, p<.0005) after 6 months of therapy. No statistically significant differences were observed in total cholesterol and HDL reductions. **CONCLUSIONS:** The superior control and weight reduction of liraglutide vs. sitagliptin observed in clinical trials is reflected in routine primary care clinical practice.

PDB4

WEIGHT LOSS OF ≥3% IN TYPE II DIABETES PATIENTS IS ASSOCIATED WITH WEIGHT CHANGE PROPERTY OF NEWLY PRESCRIBED ANTI-DIABETIC MEDICINE IN ANTI-DEPRESSANT USERS OVER A 12-MONTH FOLLOW-UP PERIOD

Lin CC[1], Mukherjee J[2], Kawabata H[3], Colilla S[3], Wygant G[4]
[1]*University of North Carolina at Chapel Hill, Chapel Hill, NC, USA,* [2]*Bristol-Myers Squibb, Wallingford, CT, USA,* [3]*Bristol-Myers Squibb, Hopewell, NJ, USA,* [4]*Bristol-Myers Squibb, Princeton, NJ, USA*

OBJECTIVES: Anti-depressant use could complicate the weight change effect of anti-diabetes (AD) medications. This study examined if different newly prescribed AD medications were associated with weight loss in a 12-months period in type II diabetes (T2D) patients who were on anti-depressants. **METHODS:** The study included patients who were on anti-depressants (selective serotonin reuptake inhibitors, SSRI, or tricyclic antidepressants,TCA) and prescribed a new AD during 1995-2011 from the UK Clinical Practice Research Datalink (CPRD.) Patients on more than one ADs are included if ADs are within same weight-change category, categorized as weight-gain agents (WG)(sulfonylureas (SU), thiazolidinediones (TZD)) and weight- neutral/ loss agents (WN/L)(metformin(MET), DPP-4 inhibitors (DPP-4), GLP-1 agonists (GLP-1). Descriptive analyses and multivariate regression examined the association between weight loss ≥3% and newly prescribed AD medications grouped by weight change category. **RESULTS:** This study included 3,445 T2D patients, of whom 2,041 were SSRI users and 1,404 were TCA users. Mean (sd) age was 60(±13.2) years for SSRI users and 64(±12.0) years for TCA users. Baseline mean (sd) weight was 92.86(±22.24) kg for SSRI users and 89.31(±19.86) kg for TCA users. At 12 months after initiation of AD therapy, with baseline age, weight, and other characteristics controlled, the likelihood of achieving weight loss of ≥3% was higher for those prescribed a WN/L agents versus those prescribed a WG agents regardless of the anti-depressant medicine currently used: For SSRI users OR= 2.84; 95% CI [1.89, 4.32]; for TCA users OR = 1.51; 95% CI [1.03, 2.23]. **CONCLUSIONS:** T2D anti-depressant users prescribed WN/L agents had higher odds of actual weight loss of ≥3%, compared to those prescribed WG agents. This association holds regardless of the anti-depressant medicine patients are currently taking. For T2D patients on anti-depressants, considering different weight change effects when initiating anti-diabetes therapy is needed.

PDB5

ECONOMIC IMPACT OF IMPROVING THE ACCURACY OF BLOOD GLUCOSE SELF-MONITORING ON THE SPANISH HEALTH SERVICE

Sanz-Granda Á[1], Hidalgo A[2], Vieta A[3], Graefenhain de Codes R[3]
[1]Weber Economía y Salud, Majadahonda (Madrid), Spain, [2]University of Castilla La Mancha, Toledo, Spain, [3]Bayer, Barcelona, Spain

OBJECTIVES: The 15197:2003 ISO states that 95% of the glucose results shall fall within ±15 mg/dl of the concentrations ≤75 mg/dl and ±20% at those >75 mg/dl. The objective was to estimate the 1-year economic impact for the Spanish Health System of blood glucose self-monitoring by using glucose meters with different degrees of accuracy **METHODS:** A probabilistic model was designed to estimate the clinical and economic outcomes of a type 2 (T2D) or type 1 diabetes (T1D) cohort. A second-order Monte Carlo simulation was run, in order to estimate the frequency of non-detected hypoglycemia and hyperglycemia cases. The frequency of macro and microvascular events, associated with the non-detected readings, was calculated. Finally, the economic impact was assessed for better accuracy levels (±15; ±5%) **RESULTS:** We estimated a total prevalence of 96,169 type 1 and 3,115,866 type 2 treated diabetic patients in Spain. We included all the T1D patients and those insulin dependents T2D (23.4%). The average annual cost of associated events and those of monitoring blood glucose were estimated at 95,987,193 € for T2D and 11,501,292 € for T1D with a ±20% accuracy. When an accuracy of ±15% was analyzed, the annual costs for T2D were reduced to 88,349,485 € and to 9,180,317 € for T1D, showing a total saving of 9,958,682 € a year. If the accuracy rose up to ±5%, the results were 80,067,179 € in T2D and 6,084,776 € in T1D, for a total saving of 21,336.530 € a year. The total costs reduced by 9.3%, 15.4% and 19.9% with accuracy of ±15%, ±10% and ±5%, respectively, respect of the initial ±20% **CONCLUSIONS:** This study shows that if the accuracy of the glucose meters raises, several macrovascular and microvascular events and hypoglycemic episodes could be avoided. That can improve patients' quality of life and reduce significantly the associated costs

PDB6

BASELINE CHARACTERISTICS, WEIGHT AND GLYCAEMIC CHANGE AMONG PATIENTS IN THE UNITED KINGDOM WITH TYPE 2 DIABETES MELLITUS (T2DM) PRESCRIBED A NEW ANTIDIABETIC TREATMENT CLASS IN A REAL WORLD SETTING

Blak BT[1], Rigney U[1], Ycas J[2], Racketa J[2], Hammar N[3]
[1]AstraZeneca UK Ltd., Luton, UK, [2]AstraZeneca Pharmaceuticals US, Wilmington, DE, USA, [3]AstraZeneca Sweden, Mölndal, Sweden

OBJECTIVES: Patients with T2DM have an increased risk of comorbidities associated with weight gain. Depending on patients' weight, treatment guidelines give preference to treatments that have favourable weight profiles, with weight gain being an important adverse event to avoid. This study aims to characterize baseline characteristics, weight and glycaemic change in patients prescribed new antidiabetic treatment. **METHODS:** Patients with T2DM diagnosis and receiving first new antidiabetic treatment class (index) between 01/01/05-01/01/12 were identified in UK CPRD primary care records. Index class could be first-line, switch or add-on. Demographics, baseline weight and glycosylated haemoglobin (HbA1c), and change at 6 months were described by index class. **RESULTS:** Of 23,987 included (of whom 133 were lost to follow-up) 64.7% initiated metformin (MET), 15.5% sulfonylureas (SU), (14.0%) thiazolidinediones (TZD), 2.1% dipeptidyl-peptidase-4-inhibitors (DPP4), 1.9% insulin, 0.7% glucagon-like-peptide-1-agonists (GLP-1), 0.6% 'other', 0.5% acarbose. About 57% were men; baseline mean age for different index classes ranged between 56.5 (insulin) and 63.1 years (acarbose). Mean baseline weight ranged between 88.0 (SU) and 112.4 kg (GLP-1) and mean baseline HbA1c between 72.6 mmol/mol (8.8%) (acarbose) and 84.7 mmol/mol (9.9%) (insulin). Among 14,438 patients with six-month follow-up data an increase in weight was found for subjects initiating SU (2.1%;95%CI: 1.9;2.4,n=2,223), TZD (1.9%;95%CI: 1.7;2.1,n=2,034) and insulin (1.8% ;95%CI: 1.0;2.6,n=285). A reduction in weight was observed for patients on GLP-1 (-3.4%;95%CI: -4.3;-2.5,n=119), DPP4 (-0.9%;95%CI: -1.4;-0.4,n=347) and MET (-0.8%;95%CI: -0.9;-0.7,n=9,278). A mean reduction in HbA1c over the six month period was seen for all antidiabetic classes but was not statistical significant for GLP-1 and 'other'. **CONCLUSIONS:** These results indicate that initiation of antidiabetic agents such as SU, TZD and insulin frequently are associated with weight gain. This underscores the need to choose agents with favourable weight profiles for overweight or obese patients, as recommended by UK T2DM treatment guidelines.

PDB7

GLYCEMIC, LIPID, AND BLOOD PRESSURE CONTROL AMONG TYPE 2 DIABETES MELLITUS PATIENTS IN DUBAI

Szabo SM[1], Osenenko KM[1], Donato BMK[2], Korol EE[1], Qatami L[3], Al Madani A[4], Al Awadi F[4], Al Ansari J[4], Maclean R[5], Levy AR[1]
[1]Oxford Outcomes Ltd., Vancouver, BC, Canada, [2]Bristol-Myers Squibb Company, Wallingford, CT, USA, [3]Bristol-Myers Squibb Company, Dubai, United Arab Emirates, [4]Dubai Hospital, Dubai, United Arab Emirates, [5]Bristol-Myers Squibb, Plainsboro, NJ, USA

OBJECTIVES: Inadequate glycemic, blood pressure (BP), and lipid control among type 2 diabetes mellitus (T2DM) patients is associated with increased risk of T2DM-related complications. Few data on these outcomes are available from the United Arab Emirates (UAE). The objective was to estimate the proportion of T2DM patients with glycemic, lipid, and BP control at a large centre in Dubai. **METHODS:** Charts from T2DM patients aged ≥18 years that visited the Dubai Hospital from October 2009 to March 2010 (enrolment period) were systematically sampled until the target (n=250) was reached. Results of haemoglobin A1c (HbA1c), low-density lipoprotein (LDL), and BP tests conducted from enrolment to September 2011 were abstracted from patient charts. The most recent test values were compared to guideline targets. The proportion of well-controlled (target met on all tests) and never-controlled patients (target not met on any test) over the study period was calculated. All analyses were stratified by T2DM duration. **RESULTS:** Thirty-three percent of the sample was male, and at enrolment, the mean (SD) age was 58 years (12), and T2DM duration, 14 years (8). At the most recent assessment, 58 patients (23%) had HbA1c <7%, 68 (27%) had HbA1c ≥9%, and 173 (71%) had LDL <100mg/dL. Although 74 patients (29%) met BP targets (<130/80mmHg), 50% had BP ≥140/90mmHg. HbA1c, LDL and BP were well-controlled in approximately 7.2%, 41.2%, and 8.6% of patients, respectively, while 59.2%, 7.8% and 21.3% of patients were never-controlled, respectively. The proportion of patients who were never-controlled for HbA1c increased with T2DM duration. **CONCLUSIONS:** Nearly 75% of patients met targets and over 40% were well-controlled for LDL; however, rates of control for HbA1c and BP were lower. Given the increased risk of complications associated with poor control, achieving higher rates of control could reduce the burden of T2DM in the UAE.

PDB8

A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS OF SECOND-LINE ANTI-DIABETES TREATMENTS FOR THOSE WITH TYPE 2 DIABETES MELLITUS INADEQUATELY CONTROLLED BY SULFONYLUREA MONOTHERAPY

Orme ME[1], Fenici P[2], Duprat Lomon I[2], Wygant G[3], Townsend R[4], Roudaut M[2]
[1]ICERA Consulting Ltd., Swindon, UK, [2]Bristol-Myers Squibb, Rueil-Malmaison, France, [3]Bristol-Myers Squibb, Princeton, NJ, USA, [4]AstraZeneca, Brussels, Belgium

OBJECTIVES: To assess the efficacy and safety of EU-licensed anti-diabetes agents when added to sulfonylurea (SU). **METHODS:** A systematic review was conducted in MEDLINE, EMBASE and CENTRAL to identify randomised controlled trials in patients with type 2 diabetes mellitus inadequately controlled by a stable dose of SU monotherapy. Direct meta-analysis, Bucher indirect comparisons and Bayesian network meta-analysis (NMA) using WinBUGs were conducted. The effect of potentially confounding baseline factors was explored through covariate analyses. **RESULTS:** The search identified 2,976 articles of which 2,945 were excluded based on title/abstract. On reviewing remaining full-text articles, 5 studies were selected for analysis at 24 (+/- 6) weeks follow-up. All studies were comparable in terms of baseline characteristics, including: HbA1c, age and BMI. Three classes of agents had sufficient data for meta-analysis: DPP4 inhibitors ('DPP4s'), GLP1 analogues ('GLP1s') and SGLT2 inhibitors ('SGLT2s'; only dapagliflozin has an EU licence in this class). Based on the fixed-effect NMA, all three classes of treatment resulted in statistically significantly lower HbA1c at follow-up compared to placebo (based on the 95% credible interval [CrI]). SGLT2 treatment resulted in significantly lower weight at follow-up compared to placebo (–1.54 kg; 95% CrI –2.16, –0.92), which is in contrast to treatment with GLP1s (-0.65kg; 95% CrI -1.37, 0.07) and DPP4s (0.57 kg; 95% CrI 0.09, 1.06). The odds of hypoglycaemia for SGLT2 and DPP4 add-on treatment were similar to placebo, but significantly greater than placebo for GLP1 add-on treatment (10.89; 95% CrI 4.24, 38.28). Assessment of NMA model heterogeneity was hindered by the low number of studies within the network. **CONCLUSIONS:** All three classes of treatments used as add-on therapy to SU provided better short-term glycaemic control compared to SU monotherapy. However, DPP4s, GLP1s and SGLT2s may show variation in terms of impact on weight and incidence of hypoglycaemia.

OBJECTIVES: In RCTs performed in patients with T2DM liraglutide reduced HbA1c by 1.0-1.5%-point and weight up to 3.7kg. Patients had disease duration of 7.7 years on average, baseline HbA1c of 8.4%. We assessed the effectiveness of liraglutide prescribed per guidelines in the analyzed cohort. **METHODS:** Patients from an Israeli HMO (Maccabi) treated with liraglutide ≥6 months during 2010-2012 were included. Prescription rules were BMI>30; HbA1c>8.0% after use of 2 oral hypoglycemic agents. Data was extracted from electronic records included in a registry of >90,000 diabetes patients. Assessments were performed within 180 days before the date of first prescription and at 6 months +/- 90 days. **RESULTS:** A total of 462 insulin naïve patients treated with liraglutide were identified. 52% males; age was 61.0 years (SD 8.67); diabetes duration was 10.5 years (SD 3.53). HbA1c decreased by 0.93%-points (SD 1.17) (p<0.0001 95% CI 0.82-1.03), down from 8.6% (SD 1.20). Mean time between HbA1c measurements was 222 days (SD 52.39). In 170 patients with available data, weight decreased by 2.5kg (SD 5.09) (p<0.0001 95% CI 1.71-3.2) from 99.9kg (18.17). Time between measurements of weight was 202 days (SD 63.2). Diabetes duration, HbA1c levels and change of the group with weight data were similar to the main cohort. 202 patients (43.7%) achieved ≥1%-point HbA1c reduction. In 31.2% (48 of 170), the reduction was without weight gain. 26 (16.9%) achieved the NICE criteria (decrease of HbA1c≥1% and weight≥3%). Baseline HbA1c and amount of liraglutide prescribed correlated with the degree of HbA1c reduction. **CONCLUSIONS:** Real life use of liraglutide significantly reduced HbA1c and weight, showing similar outcomes as those observed in RCTs. Compared to the RCTs patients in this cohort had more severe diabetes and were more obese, yet liraglutide retained its effects.

PDB10

A BAYESIAN MULTIPLE TREATMENT COMPARISON OF DULOXETINE, PREGABALIN, GABAPENTIN, AMITRIPTYLINE, AND THEIR COMBINATIONS FOR PAINFUL PERIPHERAL NEUROPATHY BASED ON PAIN REDUCTION REPORTED IN CLINICAL TRAILS

Chinthammit C, Malone D
University of Arizona, Tucson, AZ, USA

OBJECTIVES: To compare the performance of treatment of painful diabetic peripheral neuropathy (PDPN) — duloxetine, pregabalin, gabapentin, amitriptyline, and their combinations based upon pain reduction reported in clinical trials, and inform a revised treatment algorithm. **METHODS:** Published studies of PDPN treatment through May 2012 were identified from MEDLINE(PubMed) database and extended manual search was conducted based on citations from identified studies. Inclusion criteria was restricted to randomized controlled trials lasting at least 5 weeks and at most 12 weeks and studies examining 30% pain reduction or equivalent. Direct and

indirect pairwise odds ratios (OR) were obtained. The study used Bayesian Analysis Using Gibbs Sampling in Windows (WinBUGS) version 1.4.3. and Monte Carlo Simulations to conduct a multiple treatment comparison. Results are reported in OR with 95% credible intervals (CI) and the median of ranking. **RESULTS:** There were a total of 10 studies with 23 treatment arms, representing 2,885 subjects enrolled, that were included in the analysis. The results from fix effects model indicated that duloxetine, pregabalin, gabapentin, and co-administration of duloxetine and gabapentin were significantly better than amitriptyline (OR= 3.22[95%CI, 1.54-7.17], OR = 2.53[95%CI, 1.11-5.94], OR = 4.00[95%CI, 1.33-11.69], OR = 2.86[95%CI, 1.09-7.48], respectively). The results from random effects model suggested that only duloxetine and pregabalin were significantly better than placebo (OR = 2.61[95%CI, 1.37-4.95] and OR = 1.97[95%CI, 1.01-3.62], respectively). There was no significant difference between amitriptyline and placebo in either fixed or random effects models. With regard to the median ranking, gabapentin was ranked first, followed by duloxetine, co-administration of duloxetine and gabapentin, pregabalin, placebo, and amitriptyline from the fix effects model. **CONCLUSIONS:** Treatment of PDPN with amitriptyline does not appear to be significantly different from placebo. Duloxetine and pregabalin appear to be better than both amitriptyline and placebo.

RESULTS OF GALATA STUDY: GALVUS EFFICACY AND SAFETY ASSESSMENT IN TURKISH POPULATION

Keskin L[1], Dokmetas HS[2], Akin F[3], Ayvaz G[4], Boz M[5], Canberk A[6], Tasan E[7], Guler S[8], Delibasi T[9], Sahin M[10], Uren E[11]

[1]*Malatya State Hospital, Malatya, Turkey,* [2]*Cumhuriyet University School of Medicine, Sivas, Turkey,* [3]*Pamukkale University School of Medicine, Denizli, Turkey,* [4]*Gazi University School of Medicine, Ankara, Turkmenistan,* [5]*Istanbul Training and Research Hospital, Istanbul, Turkey,* [6]*Istanbul University, Istanbul School of Medicine, Istanbul, Turkey,* [7]*Bezmialem Foundation University Hospital, Istanbul, Turkey,* [8]*Numune Training and Research Hospital, Ankara, Turkey,* [9]*Diskapi Training and Research Hospital, Ankara, Turkey,* [10]*Ankara University School of Medicine, Ankara, Turkey,* [11]*Novartis Pharma AG, Istanbul, Turkey*

OBJECTIVES: The GALATA study was the first observational study on DPP-4 inhibitors in Turkey and aimed to evaluate the efficacy, safety and tolerability of vildagliptin and metformin combination (VMc) in patients with type 2 diabetes mellitus (T2DM). **METHODS:** A total of 648 of the 682 screened T2DM outpatients (age >18 years) on VMc for at least 4 weeks prior to enrollment were included in this 24-week, multicenter, observational study. **RESULTS:** Of the 648 patients, 382 (59.0%) were female. The mean (standard deviation-SD-) age was 55.2 (10.2) years, the mean (SD) T2DM duration was 4.8 (5.2) years and 220 (34.0%) patients had T2DM for more than 5 years. Patients were followed for median (inter-quartile range-IQR-) 184.0 (74.0) days at median (IQR) 4.0 (2.0) visits. Median vildagliptin and metformin doses were 100.0 mg and 2000 mg, respectively. HbA1c decreased from 7.8% to 7.0% ($p<0.001$). A similar reduction in HbA1c from 7.6% to 7.1% was also seen in elderly patients (>65 years, 18.1% of patients) ($p<0.001$). The proportion of patients with HbA1c ≤6.5% increased from 13.3% to 42.7% ($p<0.001$) and those with HbA1c ≤7.0% increased from 26.6% to 65.3% ($p<0.001$). Mean fasting plasma glucose (FPG) decreased from 153.1 mg/dL to 136.5 mg/dL ($p<0.001$), whereas mean post-prandial plasma glucose (PPG) decreased from 217.6 mg/dL to 182.1 mg/dL ($p<0.001$). Eighty (12.3%) patients experienced 122 adverse events (AEs) including 3 serious AEs; 2 SAEs were not suspected to be related to VMc. AEs were mostly (94.3%) mild or moderate in severity and no action was taken for 44.3% of them; 76.2% of AEs resolved during follow-up. **CONCLUSIONS:** The results of the GALATA study suggested that VMc significantly decreased HbA1c, FPG and PPG, achieved glycemic control targets even in elderly patients and demonstrated good overall safety and tolerability in T2DM patients.

PDB12

EFFICACY AND SAFETY OF TREATMENTS OF TYPE 2 DIABETES MELLITUS (T2DM): A SYSTEMATIC REVIEW (SLR)

Pettré S[1], Selya-Hammer C[1], Ho S[1], Garg M[2], Schroeder M[3], Kaur V[4], Hemels M[2]

[1]*Amaris, London, UK,* [2]*Janssen Cilag, Birkerød, Denmark,* [3]*Janssen UK, High Wycombe, UK,* [4]*Consultant, Mumbai, India*

OBJECTIVES: Collect randomized clinical evidence on the efficacy and safety of antidiabetic agents used in dual or triple therapy or add-on to insulin to provide a qualitative overview of the available evidence and undertake a meta-analysis. **METHODS:** A SLR was conducted in line with NICE guidelines to identify randomised controlled trials assessing agents received in combination with metformin (MET), a sulphonylurea (SU), MET+SU, MET+pioglitazone, or insulin. Interventions of interest included SGLT-2 inhibitors (canagliflozin and dapagliflozin), sulphonylureas, pioglitazone, DDP-4 inhibitors, GLP-1 analogues and insulin. Electronic searches were undertaken using Medline, Medline-in-process, Embase, and the Cochrane Library and supplemented with hand searches. An ad hoc search was conducted to identify the most recent data at 104 weeks. **RESULTS:** A total of 159 clinical trials met inclusion criteria. The frequency of studies by background therapy was as follows: MET (38%), mixed (trials containing treatment arms with different background therapies; 25%), insulin (21%), MET+SU (9%), and SU alone (8%). One study (assessing canagliflozin) featured a background of MET+pioglitazone. Studies varied in terms of treatment duration (12 to 104 weeks), presence and duration of run-in periods (57% studies with run-in, from 0.7 to 18 weeks), HbA1c eligibility criteria (minimum from 6% to 7%), body mass index (BMI; 37 studies focused on overweight and obese patients, two studies focused on obese patients) and age for inclusion (from ≥18 to ≤ 85 years). **CONCLUSIONS:** The outcome of this SLR will serve as input-data in a meta-analysis, to assess relative efficacy of T2DM treatments in different background therapy settings.

RESULTS OF THE POST-MARKETING SURVEY OF VILDAGLIPTIN IN FRANCE

Eschwège E[1], Attali C[2], Bringer J[3], Simon D[4], Bouee S[5], Kind B[6], Quere S[7], Dejager S[7], Detournay B[5]

[1]*INSERM, Villejuif, France,* [2]*Cabinet Médical de Groupe, Epinay sous sénart, France,* [3]*CHRU Montpellier, Montpellier, France,* [4]*Hôpital de la Pitié, Paris, France,* [5]*Cemka, Bourg la Reine, France,* [6]*Novartis, Rueil-Malmaison, France,* [7]*Novartis Pharma, Rueil Malmaison, France*

OBJECTIVES: To assess the effectiveness, tolerability and maintenance of vildagliptin in type 2 diabetes (T2D) patients under real-life conditions in France, requested by the French Health Technology Agency. **METHODS:** A representative sample of T2D patients initiating a treatment with vildagliptin was enrolled in a 2 years follow-up observational cohort in 2010 by a national sample of endocrinologists and general practitioners. **RESULTS:** A total of 482 GPs and 84 endocrinologists included 1,700 patients. 60% were males, mean age=63 (±9) years, mean disease duration=7 (±6.5) years. Follow up visits were available for 96.3%, 90.7%, 86.5% and 81.8% of patients at respectively 6, 12 18 and 24 months. Mean HbA1c level decreased from 7.8% (sd=1.3) before vildagliptin prescription to 7.0% (sd=1.0) 0 to 6 months after vildagliptin initiation and remained stable thereafter: 7.0% (sd=1.0), 7.0% (sd=0.9) and 7.0% (sd=1.0) 6 to 12 months, 12 to 18 months and 18 to 24 months after vildagliptin initiation. The percentages of patients with alanine and/or aspartate aminotransferase above 120 UI were 0.5% before vildagliptin prescription and 0.3%, 0.5%, 0.1%, 0.0% at 0-6 months, 6-12 months, 12-18 months and 18-24 months after vildagliptin prescription. The mean glomerular filtration rate (MDRD formula) was 82.0 ml/minute before vildagliptin prescription and 82.4, 84.1, and 83.6 and 82.8, at 0-6 months, 6-12 months, 12-18 months and 18-24 months after vildagliptin prescription. The incidence of severe hypoglycemia (requiring third party assistance) has been estimated at 0.30/100 vildagliptin treated patients years (CI95%=[0.15,0.55]). All occurred in patients also treated with insulin and/or sulfamide The proportion of patients treated with vildagliptin remained high over the course of the study: 96.5% (CI95%[95.6,97.4]) after 6 months, 92.5% (CI95%=[91.2%,93.8%]) after one year and 88.8% (CI95%=[87.2%,90.4%]) after 2 years. **CONCLUSIONS:** Vildagliptin showed sustained effectiveness in terms of reduction in HbA1c over 24 months, with a low incidence of hypoglycemia.

PDB14

CLINICAL OUTCOMES AND HEALTH CARE COSTS EVALUATION OF SULFONAMIDES AND THIAZOLIDINEDIONES COMPARED WITH DIPEPTIDYL PEPTIDASE 4 INHIBITORS FOR THE TREATMENT OF UNCONTROLLED DIABETES

Degli Esposti L, Saragoni S, Buda S, Degli Esposti E

CliCon Srl, Ravenna, Italy

OBJECTIVES: To compare clinical outcomes and the health care costs across two cohorts of uncontrolled diabetic patients who initiated treatment with Sulfonamides or Thiazolidinediones (SU/TZD) or Dipeptidyl Peptidase 4 (DPP-4) Inhibitors in a clinical practice setting. **METHODS:** A retrospective analysis using a large administrative database and a clinical registry containing laboratory results of three Italian Local Health Units was performed. The index-period ranged from July, 2008 and June, 2010. Patients were treatment naïve to SU/TZD or to DPP-4, but already treated with other oral antidiabetic agents. Demographics, concomitant therapies, Charlson comorbidity index, glycemic and lipid control level and previous hospitalizations were assessed at baseline. Adherence was measured by *Medication Possession Ratio* (MPR). We calculated unadjusted rates and used a Poisson regression model to estimate risk ratios for diabetes-related hospitalizations occurred during the 18-months follow-up period. Total annual costs included all the pharmacological treatments and the direct costs due to hospitalizations and outpatient services. **RESULTS:** We identified 1384 patients treated with SU/TZD and 199 treated with DPP-4. DPP-4 patients were significantly younger (mean age 59.2 years and 65.0 years; $p<0.001$) and with less previous hospital discharges for diabetes-related diseases. Baseline mean HbA1c was 8.1% for SU/TZD and 8.2% for DPP-4 patients. DPP-4 naïve resulted more adherent (MPR≥80%) than SU/TZD naïve (70.9% and 55.8%; $p<0.001$). The SU/TZD group showed a significant increased risk of diabetes-related hospitalizations (unadjusted rate was 9,17 vs 3,47 per 100 person-years, $p=0.002$; adjusted incidence rate ratio 1.83; $p=0.028$). The higher hospitalization rate resulted in higher total annual direct costs per patient (€2.719 vs €2.462 of those treated with DPP-4). **CONCLUSIONS:** Results indicate that uncontrolled diabetic patients who initiated treatment with DPP-4, compared with those initiating with SU/TZD, are associated with a reduced risk of diabetes-related hospitalizations and consequently with a lower overall total annual cost per patient.

PDB15

THE PRESENCE OF METABOLIC AND OTHER RISK FACTORS IN ADRENAL INSUFFICIENCY PATIENTS COMPARED TO AN UNMATCHED BACKGROUND POPULATION FROM THE SAME REGION IN THE UNITED KINGDOM

Teneishvili M[1], Marelli C[2], Lee D[3]

[1]*ViroPharma LTD., Maidenhead, UK,* [2]*ViroPharma SPRL, Maidenhead, UK,* [3]*BresMed, Sheffield, UK*

OBJECTIVES: To describe epidemiological characteristics among adrenal insufficiency (AI) patients and describe the prevalence of risk factors in primary and secondary AI (PAI; SAI) and an unmatched, non-AI population. These analyses explore metabolic morbidity in AI, which literature suggests may be associated to a non-physiological cortisol profile. **METHODS:** Initial aggregated data from the FARSITE database were analysed. The prevalence of risk factors was evaluated, including hypertension, BMI, diabetes and depression, and compared across PAI, SAI and non-AI populations. Characteristics of non-AI patients were not matched with AI patients. **RESULTS:** A total of 261,638 patients were included; 62 PAI and 191 SAI. Prevalence of hypertension was 32% in PAI, 22% in SAI and 13% non-AI. 26% of hypertension in SAI was not on target according to QOF criteria (14% non-AI; 10% PAI). Hypercholesterolemia occurred in 13% of PAI and 6% of SAI patients (3% non-AI). Among SAI patients, 69% were overweight (BMI>25) or obese (BMI>30) (63% PAI; 39% non-AI). Diabetes (Type 1 and 2) was prevalent in 13% of PAI and 10% of SAI (5% non-AI), with HbA1c not controlled according to QOF criteria in 75% of PAI and 74% of SAI patients. Psychological risk factors were more prevalent among AI patients; 24% of PAI and 14% of SAI patients recently received anti-anxiety/depression treatment (6% non-AI). Hypnotics were recently prescribed to 6% of SAI patients (1% non-AI; PAI not reported). Bisphosphonates are used by 21% of PAI and 8% of SAI patients (2% non-AI). The hospital admission rate was 3% for SAI patients (1% non-AI; PAI not reported). **CONCLUSIONS:** The prevalence of metabolic and other risk factors is considerably higher among AI patients

than the non-AI population. Since the comparison was unmatched, results should be interpreted with caution. Ongoing analysis will include a detailed data assessment, with a stronger comparison against matched non-AI populations.

PDB16
REAL WORLD INCIDENCE OF TYPE 2 DIABETES (T2D) COMPLICATIONS LEADING TO HOSPITALIZATION IN FRANCE: THE RECODE STUDY
Bouee S[1], Cochinaire A[1], Godard C[2], Sabater FJ[2], Amelineau E[2], Emery C[3], Cotté FE[2]
[1]Cemka, Bourg la Reine, France, [2]Bristol-Myers Squibb, Rueil-Malmaison, France, [3]Cemka Eval, Bourg La Reine, France
OBJECTIVES: To estimate the cumulative incidence and cost of cardiovascular (CV) complications (stroke, acute coronary syndrome (ACS), acute heart failure (AHF) and peripheral vascular disease (PVD)) leading to hospitalization in T2D patients with a CV complication history in France. **METHODS:** We conducted an analysis of the Program for a Medicalized Information System (PMSI) databases which record all hospitalizations occurring in France including rehabilitation care. We identified all patients with a T2D diagnosis and hospitalized for any reason in 2006-2008 and selected patients with a documented CV complication history. We analyzed those patients as a retrospective cohort followed-up for 3 years from the index date (January 1st 2009) and calculated cumulative incidences of new CV complications. We considered death as a competing event. Mean hospital and rehabilitation costs were based on the National Scale of Costs. **RESULTS:** A total of 1,114,182 T2D patients were hospitalized in France in 2006-2008. Among them, 30.5% (n=339,328) had a CV complication history. Mean age was 70.6 (+/-11.1), and 61.9% were males. Hypertension, dyslipidemia, renal impairment and obesity were reported in 80.1%, 45.0%, 33.3% and 29.2% of the patients, respectively. The 3-year cumulative incidences for one or more new CV complication were: 3.6% [95%CI:3.5%;3.7%] for stroke, 5.6% [95%CI:5.5%;5.7%] for ACS, 6.8% [95%CI:6.7%;6.9%] for AHF and 15.0% [95%CI:14.9%;15.1%] for PVD with a mean cost per event of €5,724, €5 315, €4 726, €4 766, respectively. 21.8%, 10.5%, 11.4% and 9.5% of patients required rehabilitation care for stroke, ACS, AHF and PVD, at an additional mean cost of €12,000, €6 233, €6 987 and €9 219 per patient, respectively. **CONCLUSIONS:** CV complications represent an important burden for T2D patients and the health system in France. These results would be helpful for health technology assessment and for economic evaluation of upcoming interventions which reduce CV risk in T2D patients.

PDB17
STUDY AND EVALUATION OF MEDICATION ERRORS IN DIABETIC PATIENTS IN MEDICINE WARD OF A SECONDARY CARE COMMUNITY HOSPITAL AT MUMBAI, INDIA
Lokhande AK[1], Patidar D[2], Patil UK[3]
[1]Manipal College of Pharmaceutical Sciences, Manipal University, Manipal, India, [2]Indore Institute of pharmaceutical Sciences, Indore, India, [3]People's University, Bhopal, India
OBJECTIVES: While concerning to diabetic treatment, any suboptimum therapy may lead to medication error (ME). Objective of study was to report the causes, severity, increase in cost of therapy and outcomes of ME in patients undergone treatment for diabetes in medicine ward of a community hospital. **METHODS:** Prospective observational study (8 months). In-patients with type-II diabetes mellitus were chosen randomly and the details were followed till discharge. **RESULTS:** Incidences of 504 MEs were observed in 164 out of total patient pool of 230. The notable trends in MEs identified were- erroneous prescriptions 101(20.03%), inappropriate dosage-form 93(18.4%), incorrect-route 63 (12.5%), incident of drug interactions 129 on 55 patients (10.09%), failure to monitor lab levels 27(5.30%), failure to adjust doses according to lab levels 37(7.14%) and 21(4.16%) cases of incorrect-indications. On severity scale, MEs were classified as 143(28.37%) severe, 256(50.79%) moderate and 105(20.8%) mild. Predicted error outcome of 164 incidences which were reaches to patient classified as- no serious 85(51.8%), moderately serious 61(37.19%), 9(5.3%) life threatening and 9(5.35%) death (predicted). We observed fair degree of linear correlation between increasing age and occurrence of ME 0.99 ($r_{critical}$ value-0.878). Female sex was found to be at higher risk of MEs than male (X^2=6.73, P-value= 0.01). There was a linear correlation observed between the polypharmacy and ME 0.95 ($r_{critical}$value-0.44). It was observed that, out of total 129 drug interactions identified; only 35(27.13%) were moderate, while 72(55.81%) were severe and 22(17.05%) found mild. Significant increment in the length of stay in hospital and direct drug cost were observed among the severe, moderately severe and in mild cases. **CONCLUSIONS:** The observed finding of ME defines specific clinical domains and patient subgroups for which aggressive efforts needed to reduce MEs. Through information dissemination and education, managed health care professionals should play more active role in ME-reduction.

PDB18
ESTIMATING THE HEALTH OUTCOME OF TREATING TYPE 2 DIABETIC POPULATION TO TARGET IN LOCAL MUNICIPALITY LEVEL
Säävuori N[1], Tyrväinen V[2], Purmonen T[3]
[1]Oy Medfiles Ltd., Vantaa, Finland, [2]Proper Ltd., Joensuu, Finland, [3]Oy Medfiles Ltd., Kuopio, Finland
OBJECTIVES: Type 2 diabetes (T2D) and its consequences are largely studied worldwide. The number of diabetic patients is increasing and thus, a growing number of health care resources are needed to cover the treatment of this population. It is also known that in spite of the national treatment guidelines, the recommended HbA1c level (<6.5%/48 mmol/mol) is not always achieved. In order to allocate the resources effectively, local information concerning epidemiological and demographic differences across different jurisdictions must be available. **METHODS:** A national population-based study (Finriski 2007) was used to estimate the prevalence of diabetes in different geographical areas. The estimated prevalence rates and number of T2D patients were extrapolated to municipal level using demographic data from the official statistics. UKPDS risk equation was used to predict the number of cardiovascular events with and without proper treatment in each municipality. Local risk profile and different HbA1c levels (6.5% (48 mmol/mol) and 8.0% (64 mmol/mol)) were used to illustrate the importance of treating patients to target. A map-based application was built (Tableau 8) to visualize the information to be easily communicated to local authorities and clinicians. **RESULTS:** A middle-sized Finnish municipality with 74 168 inhabitants (Joensuu) was chosen as a case-example. The estimated number of diabetic patients was 2267, out of which 1678 had T2D. Within three years among patients with T2D, the predicted number of CHD events would be 73 and 57 for HbA1c levels 6.5% and 8.0%, respectively, resulting total of 16 avoidable CHD events. **CONCLUSIONS:** By bringing the understanding of epidemiology and treatment effects to local level, there is a possibility to show the positive outcomes of good diabetes care in real practice. This information may be used to help budget holders in resource allocation and to motivate authorities, clinicians (and patients) to follow the diabetes treatments guidelines.

PDB19
RESULTS FROM A TWO-STAGE DELPHI PROCESS TO IDENTIFY CARDIOMETABOLIC RISK FACTORS IN ADRENAL INSUFFICIENCY PATIENTS AND UNDERSTAND CURRENT TREATMENT IN ITALY
Elvidge J[1], Anelli M[2], Lee D[1], Marelli C[3], Teneishvili M[4]
[1]BresMed, Sheffield, UK, [2]Keypharma srl, Milan, Italy, [3]ViroPharma SPRL, Maidenhead, UK, [4]ViroPharma LTD., Maidenhead, UK
OBJECTIVES: To obtain information regarding the presence of cardiometabolic risk factors among adrenal insufficiency (AI) patients in Italy. To understand treatment patterns and goals and to gain consensus regarding how effectively existing therapies meet these goals. **METHODS:** A two-stage Delphi process was conducted with four Italian key opinion leaders (KOLs). Each KOL completed an electronic survey eliciting information regarding AI management and the prevalence and importance of risk factors. To reach a consensus on the key issues, the results were discussed at a face-to-face meeting. **RESULTS:** The KOLs agreed that avoiding adrenal crisis is the main treatment goal, and that quality of life and avoiding fatigue are most important to patients. Patients typically receive 20–30 mg cortisone acetate or hydrocortisone daily in 2-3 administrations. A consensus was reached that cardiometabolic risk factors are not hallmarks of AI, but are related to its glucocorticoid replacement treatment (GC) either due to overtreatment or non-physiological replacement of serum cortisol. In agreement with the available evidence in the literature they suggested that the increase risk may be associated with the non-physiological cortisol peaks and troughs that are characteristic of the existing GC replacement therapies. They established that 50% of AI patients are over treated, often to minimise the risk of adrenal crisis and all patients currently face non-physiological cortisol replacement, given the available treatments. GC replacement–related risks included (prevalence in AI in parentheses): hypertension (10–30%), abdominal obesity (15–35%), dyslipidaemia (33%) and metabolic syndrome (30–35%). **CONCLUSIONS:** The prevalence of cardiometabolic risk factors is associated with the treatment of AI, not AI itself. Over-treatment and non-physiological cortisol replacement may explain cardiometabolic risks. A physiological alternative to existing treatments would be welcomed in Italy.

PDB20
INCIDENCE/PREVALENCE, RISK FACTORS AND COMPLICATIONS OF TYPE 2 DIABETES MELLITUS IN INDIAN PATIENTS: A SYSTEMATIC REVIEW AND META-ANALYSIS
Likhar N, Nair SR, Rai MK, Goyal R, Shaikh S, Verma RK
Capita India Pvt. Ltd., Mumbai, India
OBJECTIVES: Type 2 Diabetes mellitus (T2DM) is becoming a major chronic disease burden worldwide. Indians are known to have an increased predisposition for diabetes which has become an important health concern. The current analysis is aimed to systematically review medical literature on T2DM, its prevalence and complications in India and also explore the differential risk factors in sub-groups. **METHODS:** Studies are being retrieved from Pubmed, Cochrane and Embase databases using relevant search strategies. Search limits are: articles in English, in human adults and published since year 2001. Pre-specified inclusion/exclusion criteria will identify study types, such as randomized controlled trials (RCTs), observational and retrospective studies reporting incidence/prevalence, risk factors and complications of T2DM patients in India. Two researchers will independently extract the data and analysis of comparable outcomes will be carried out as per appropriate statistics along with critical appraisal of the studies. Meta-analysis will be done using RevMan (v5.0) **RESULTS:** Though there have been several studies assessing incidence/prevalence, complications and risk factors for T2DM, a systematic review/meta-analysis of the evidence is lacking in the Indian scenario. This study aims to provide the much-needed evidence linking incidence/prevalence, complication and risk factors in different groups of T2DM patients. This study hopes to demonstrate association of various risk factors with disease progression and with complications of T2DM. **CONCLUSIONS:** The prevalence of T2DM has been increasing over the years. The data from published studies will hopefully answer some of the prevailing variations and trends in prevalence of T2DM between different subgroups of T2DM patients and their association with risk factors.

OBJECTIVES: To review lifestyle and genetic factors during pregnancy and early childhood in South Asian population living in Europe that may influence later risks of insulin resistance, metabolic syndrome, T2DM and CVD **METHODS:** A systematic search, using controlled and free terms (i.e.- metabolic-syndrome, glucose-intolerance, diabetes-mellitus, pregnancy, foetal development, life-style, nutrition) was conducted in Medline, Centre for Reviews and Dissemination and Cochrane Library databases. It was completed by pearling and hand-searching. Two reviewers assessed independently the results retrieved in the search, to adopt a decision on inclusion/exclusion. The quality of included papers was appraised with STROBE checklist for

observational studies and Centre for Evidence Based Medicine checklists for any other study design. The present review is part of the GIFTS project funded by Seventh Framework Programme of European Commission. **RESULTS:** A total of 349 papers were identified, after title and abstract revision 76 full text were retrieved plus 8 identified through pearling. To date 67 full texts have been assessed, 49 excluded and 18 included. 14 (78%) were conducted in the UK. South Asian pregnant women were at higher risk of developing GDM (OR ranged 2-5.6) and intrauterine growth retardation (OR ranged 2-5) than European counterparts. These factors contributed to higher rates of stillbirth, perinatal and neonatal mortality and congenital anomalies detected in South Asian origin women. As well as higher rates of babies with vitamin D deficiency, hypocalcaemia, hyperinsulinemia, dyslipidaemia, hypoglycaemia and lower birthweight. Also higher risk of rapid weight gain between 12 to 24 months and 3 to 5 years in Asian infants was reported in two different papers. **CONCLUSIONS:** There are differences between Asian women living in Europe and European women during pregnancy, and their offspring, which as early life factors might explain higher prevalence of later metabolic syndrome and type 2 diabetes in Asian migrant population.

PDB22

PREDICTING THE FREQUENCY OF SEVERE AND NON-SEVERE HYPOGLYCAEMIA IN INSULIN TREATED TYPE-2 DIABETES SUBJECTS

McEwan P[1], Foos V[2], Grant D[3], Palmer JL[4], Varol N[5], Curtis B[6], Boye KS[7]
[1]*Swansea University, Cardiff, UK,* [2]*IMS Health, Basel, Switzerland,* [3]*IMS Health, London, UK,* [4]*IMS Health, Allschwil, Basel-Landschaft, Switzerland,* [5]*Eli Lilly and Company, Windlesham, Surrey, UK,* [6]*Eli Lilly & Co., Indianapolis, IN, USA,* [7]*Eli Lilly and Company, Indianapolis, IN, USA*

OBJECTIVES: Recent studies have quantified the resource implications associated with severe hypoglycaemia episodes (SHE) and non-severe hypoglycaemia episodes (NSHE). The objective of this study was to characterize the relationship between the frequency of SHE/NSHE and patient/therapy characteristics in insulin treated type-2 diabetes mellitus (T2DM) patients. **METHODS:** We conducted a literature review of the MEDLINE database for insulin-based T2DM clinical trials where sulfonylurea usage was also reported between June 1, 2007 and June 1, 2012. Patient demographics, treatments effects and treatment type were extracted and the SHE/NSHE rate per 100 patient years (PY) was modeled via a log-linear regression model using R. **RESULTS:** Data were extracted from 82 studies for a total of 155 trial arms meeting the search criteria; treatment regimes were categorized into basal analog (30%); bolus analog (4%); basal bolus (24%); biphasic analog (25%); biphasic human (8%) and NPH (10%). Mean (standard deviation) age was 57.9 (3.8) years; 10.2 (2.4) years duration of diabetes; 8.8% (0.7)baseline and 7.5% (0.5) end-of-study HbA1c respectively. Mean reported NSHE/100 PYs was 929.8. The final regression model was NSHE/100PY=exp(14.771 - 0.088 × age - 0.667 × baseline HbA1c + 0.427 × HbA1c reduction + 0.189 × duration diabetes + 0.007 × % study allowed sulphonylurea – 0.545 × basal analog insulin) with an R^2 goodness of fit of 0.226. Mean reported SHE/100 PYs was 5.9. The final regression model was SHE/100PY=exp(10.794 - 0.101 × age - 0.723 × baseline HbA1c + 0.638 × HbA1c reduction + 0.163 × duration diabetes + 0.768 × biphasic insulin)-1 with an $R^2$of 0.219. **CONCLUSIONS:** This study provides a basis for predicting the number of SHE and NSHE in insulin treated T2DM subjects. When linked to resource and quality life, these equations may facilitate the improved estimation of the health economic burden associated with SHEs and NSHEs.

PDB23

ANTI-DIABETIC MEDICATIONS RELATED SEVERE HYPOGLYCAEMIA RISK IN DIABETES TYPE 1 AND TYPE 2 – A SYSTEMATIC REVIEW OF OBSERVATIONAL STUDIES

Paweska J[1], Jakubczyk M[2], Barszcz E[1], Czech M[3], Niewada M[4]
[1]*HealthQuest spolka z ograniczona odpowiedzialnoscia Sp. K., Warsaw, Poland,* [2]*Warsaw School of Economics, Warsaw, Poland,* [3]*Novo Nordisk Pharma Sp z.o.o., Warsaw, Poland,* [4]*Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland*

OBJECTIVES: Severe (requiring assistance from another individual) hypoglycaemic events (SHEs) are important from both clinical and economic perspectives. The aim was to assess treatment-related SHEs risk in different treatment regimens in type 1 and 2 diabetes. **METHODS:** Anti-diabetic treatments were stratified into six groups: basal-bolus (BB); basal in combination with oral therapy (BOT); insulin pumps; biphasic insulin; sulfonylureas; other than SU oral antidiabetic drugs (OADs). Insulin treatments were further split into analogues (IA) and human insulins (HI). The systematic review of Medline, EMBASE and Cochrane databases was conducted for recent (≤10 years), large (n ≥100), observational studies. Data on time horizon, participants number and SHEs occurrence were extracted. Using a random effects Poisson model within MCMC framework we estimated the SHEs rates. **RESULTS:** In the systematic review 5220 publications were found, 525 full texts evaluated and 101 articles included (55 trials). The following average SHE/year (No of studies; 95%CI) were estimated: Type 1: BB with IA as the basal component: 0.53 (7; 0.29–1.18); BB with HI: 1.10 (6; 0.58–2.71); pump treatment: 0.18 (14; 0.13–0.25); biphasic insulin: 1.10 (0.58–2.71). Type 2: BOT with IA as the basal component: 0.13 (11; 0.04–1.17); BOT with HI: 0.21 (7; 0.08–0.88); BB with IA: 0.01 (6; 0.003–0.25); BB with HI: 0.56 (3; 0.16–9.65); biphasic IA: 0.10 (12; 0.05–0.26); biphasic HI: 0.20 (6; 0.07–0.93); sulfonylureas: 0.05 (6; 0.02–0.14); OADs: 0.01 (0.001–0.008). The differences in the SHEs risk among regimens were significant at a 95% level. **CONCLUSIONS:** The SHEs risk differs in both type 1 and 2 diabetes across various treatment regimens. HI was found to increase the SHEs risk compared to IA. Limited availability of studies and heterogeneous data make it difficult to come up with precise rate estimation for typical anti-diabetic treatment regimens.

ESTIMATION OF THE COST OF COMPLICATIONS RELATED TO GLYCATED HEMOGLOBIN IN THE ITALIAN DIABETES TYPE 1 POPULATION

Nicolucci A[1], de Portu S[2], Orsini Federici M[3], D'Ostilio D[3]
[1]*Mario Negri Sud, Santa Maria Imbaro, Italy,* [2]*Medtronic International Sàrl, Tolochenaz, Switzerland,* [3]*Medtronic Italia SpA, Sesto San Giovanni, Italy*

OBJECTIVES: In Type 1 diabetic (T1D) patients high values of glycated hemoglobin (HbA1c) have been shown to be associated with higher risk of complications leading to high costs to the National Health Care System (NHS). The aim of this analysis is to evaluate the economic impact of poor glycaemic control, and the potential savings associated with better glycemic control in the Italian T1D population. **METHODS:** A probabilistic model using published risk-curves was developed to project incidence and progression of diabetes-related complications associated with different HbA1c levels over 1-year and 5-year time-horizon in T1D patients. Associated cost of retinopathy, nephropathy, neuropathy, cardiovascular disease, diabetic ketoacidosis and severe hypoglycemia in the Italian setting were used to estimate the economic impact of complications in each HbA1c interval form the NHS perspective. Subsequently the results of the simulation were translated to the entire Italian T1D population stratified by HbA1c level accordingly to published 2012 data. **RESULTS:** Estimated cost per patients of diabetes-related complications in the first year of occurrence, stratified by HbA1c intervals, ranged from 4,463€ for HbA1c ≥10% to 2,006€ for HbA1c between 7% and 8%. A 5 year follow up analysis was also conducted. A treatment strategy able to reduce HbA1c level from ≥10% to 9% could lead to potential savings of 1,342€ per patients in the first year of treatment. Considering the total T1D Italian population, improving HbA1c to <8% in the first year would results in a potential savings of about 17 million euros. **CONCLUSIONS:** The economic impact of diabetes-related complications in the Italian setting is significant. Consequently the potential savings for the NHS derived from the implementation of strategies aimed at improving HbA1c in T1 should be considered. Moreover the greater the reduction of Hba1c obtained the greater the associated savings.

PDB25

COST-COMPARISON BETWEEN DIFFERENT TREATMENT REGIMENS IN DIABETES MELLITUS IN GERMANY BASED ON LONG ACTING INSULINS

Anderten H[1], Dippel FW[2], Schneider T[2]
[1]*Ambulatory Care, Hildesheim, Germany,* [2]*Sanofi, Berlin, Germany*

OBJECTIVES: Cost comparison between different basal insulin regimens (Glargine vs. Detemir vs. NPH-insulin) in diabetic patients in Germany under real-life conditions. **METHODS:** The analysis is based on IMS LRx-database (2011). This representative patient tracking tool covers nearly 60 million insurants and includes more than 500 million drug prescriptions per year (including consumables) Patients with at least two prescriptions of basal insulin (Glargine, Detemir or NPH-insulin) in 2011 (January – December) and at least one prescription of any type in 2010 and 2012 were considered eligible. Costs included basal and bolus insulin, oral antidiabetic drugs, test strips, needles and lancets and were estimated by ex pharmacy prices (Lauer Taxe) minus legally defined rebates according to §130 a of social security code (SGB V). **RESULTS:** A total of 542.438 patients were allocated to either Glargine (207.506 patients) or Detemir (90.671 patients) or NPH (244.261 patients). The mean annual treatment costs per patient are 1.211 € (Glargine), 1.224 € (NPH insulin) and 1.572 € (Detemir). A breakdown at the level of different sick funds shows a similar pattern of annual treatment costs per patient of the three basal insulin regimens. The acquisition costs of basal insulin is considerably higher for Glargine (380 €) and Detemir (448 €) compared to NPH-Insulin (253 €). The cost of bolus insulin is lower in the Glargine group (305 €) compared to NPH-insulin (419 €) and Detemir (493 €). Costs of consumables (test strips, needles, lancets) are lowest in the in the Glargine group (395 €) due fewer insulin applications compared to Detemir (509 €) and NPH insulin (461 €.) **CONCLUSIONS:** Mean annual treatment costs are lowest with Glargine followed by NPH-insulin, whereas Detemir based regimens are 30% more expensive under real life conditions. The results are in line with previous cost analyses in diabetic patients in Germany [1-3]

A COMPARISON OF THE ECONOMIC BURDEN AND HEALTH CARE UTILIZATIONS OF VETERAN PATIENTS DIAGNOSED WITH DIABETES IN THE UNITED STATES

Xie L[1], Wang L[2], Kariburyo MF[1], Huang A[2], Baser O[3]
[1]*STATinMED Research, Ann Arbor, MI, USA,* [2]*STATinMED Research, Dallas, TX, USA,* [3]*STATinMED Research/The University of Michigan, Ann Arbor, Michigan, MI, USA*

OBJECTIVES: To assess the economic burden and health care utilizations of diabetes in the U.S. veteran population. **METHODS:** Adult (≥18 years of age) patients diagnosed with diabetes (International Classification of Disease 9th Revision Clinical Modification [ICD-9-CM] code 250.x0 or 250.x2) were identified from the dataset between October 1, 2009 through September 30, 2011. The first diagnosis date was designated as the index date. A comparator group was created consisting of patients without diabetes but of the same age, region, gender and index year, and matched by baseline Charlson Comorbidity Index. The index date for the comparator group was randomly selected to minimize selection bias. Continuous medical and pharmacy benefits 1 year pre- and 1 year post-index date were required for patients in both groups. One-to-one propensity score matching (PSM) was applied to compare health care costs and utilizations during the follow-up period between the diabetes and comparator groups, adjusted for baseline demographic and clinical characteristics. **RESULTS:** A total of 1,427,948 patients were identified for the diabetes and comparator cohorts. After applying 1:1 PSM matching, a total of 340,933 patients were matched from each group, ensuring well-balanced baseline characteristics. Patients diagnosed with diabetes were more likely to report inpatient (8.93% vs. 2.09%, p<0.01), emergency room (13.66% vs. 5.61%, p<0.01), outpatient (99.63% vs. 53.78%, p<0.01), and pharmacy visits (87.13% vs. 52.69%, p<0.01). They also incurred higher health care costs, including inpatient ($3,031 vs. $582, p<0.01), emergency room ($137 vs. $51, p<0.01), outpatient ($3,375 vs. $1,272, p<0.01), pharmacy ($708 vs. $293, p<0.01) and total costs ($7,113 vs. $2,148, p<0.01) than the comparator group. **CONCLUSIONS:** U.S. veteran patients diagnosed with diabetes reported a significantly higher economic burden compared to the matched controls over a 12-month period.

PDB27
COST OF INPATIENT MANAGEMENT OF HYPOGLYCAEMIA IN FRANCE
Torreton E[1], Vandebrouck T[2], Emiel P[3], Detournay B[4]
[1]CEMKA-EVAL, Bourg la Reine, France, [2]Novo Nordisk Pharma, Brussels, Belgium, [3]Novo Nordisk Pharma, France, La Defense, France, [4]Cemka, Bourg la Reine, France
OBJECTIVES: Severe hypoglycaemias occurring in diabetes care are associated with a major economic burden on health care systems, with a major part of the direct costs resulting from the small proportion of patients who are admitted to hospital. We assessed the inpatients costs of severe hypoglycaemic events in Type 1 and 2 diabetes (SHE) patients in France. **METHODS:** The study was done using the 2012 French National Database on hospital care (PMSI). This comprehensive database covers all hospital stays in the French population (over 20 million hospital stays per year). SHE were identified using ICD10 codes of hypoglycaemias (E160, E161, E162, T383) in combination with diabetes codes (E11, E10, E13, E14, N083) and excluding gestational diabetes. Directs costs to the health care system were estimated using the French National Costs study (2011 values). **RESULTS:** Overall, in 2012, 17,835 stays for diabetes related hypoglycaemias were identified in the database corresponding to 16,406 patients. 8.7% of patients were hospitalized twice in the year for SHE, 51% were male and aged 66.7 years on average (SD 19.7). 90% of stays occurred in public hospitals and mean length of stay was 8.1 days (median 7.0). The mean direct cost of one SHE hospital stay was €4,360. Extrapolated to the whole country the direct cost of hospitalized SHE was €77.7 million which roughly correspond to 1.2% of the overall diabetes costs for the health care system. Such value would be considered a conservative estimate due to potential underreporting of cases in the database. **CONCLUSIONS:** Our study confirmed that hypoglycaemic events lead to substantial costs for the community even it was limited to direct costs in inpatient setting. As the short-term and long term consequences of hypoglycaemia begin to be better understood, more studies have to be done to estimate the full economic burden of this disease.

PDB28
HEALTH CARE COST OF CONTROLLED VERSUS UNCONTROLLED TYPE 2 DIABETES PATIENTS IN GREECE
Hatzikou M[1], Migdalis I[2], Manes C[3], Rombopoulos G[1], Kypraios N[4], Tentolouris N[5]
[1]Novartis Hellas, Metamorfosis, Greece, [2]NIMITS Hospital, Athens, Greece, [3]Papageorgiou Hospital, Thessaloniki, Greece, [4]Polyclinic General Hospital, Athens, Greece, [5]Laiko General Hospital, Athens, Greece
OBJECTIVES: Health expenditure to treat and prevent T2DM and its complications was estimated at USD 345 million for OECD countries in 2010. These costs pose great burden to national health system's budget, which is already under pressure. In Greece there are no studies that provide information on the costs of T2DM patients including the cost of complications, hospitalizations and co-morbidities. The current study aimed to estimate the total cost of T2DM patients from a third party payer perspective. **METHODS:** A retrospective research study was performed in four major hospital diabetes centers and 211 patients with at least 10 years of T2DM from diagnosis. Patients were categorized in two groups, controlled and uncontrolled. Hospitalization and management of complications was based on DRG cost. Pharmaceutical and diagnosis cost was based on official NHS prices. Health care cost corresponds to 2012 Euros and the perspective used was of the Social Security Fund. Subgroup analysis was performed in order to evaluate the cost difference between controlled vs. uncontrolled, obese non-obese and various other subgroups. **RESULTS:** The mean age of patients was 72.9±8.1 years with mean T2DM duration 21.2±7.5 years, and mean HbA1c 7.3±1.0%. The mean average yearly cost of T2DM was €7.111 whereas only the18.8% was attributed to cost of antidiabetic drugs. Controlled patients (HbA1c $\leq$ 7) cost on average 6.366 and uncontrolled (HbA1c>7) €7.783. The mean hospitalization and complication cost was €2.456. It was found no difference of mean hospitalization and complication cost between controlled and uncontrolled patients (p=0.09). Co-morbidities cost absorbs the majority of the budget and was the differentiating factor between two groups. Few patients (21.8%) reported admission to hospital with similar hospitalization rates on number and duration between the two groups. **CONCLUSIONS:** T2DM is an expensive to treat disease with very high cost complications with economic and societal burden.

PDB29
HEALTH CARE COST OF TYPE 2 DIABETES PATIENTS IN GREECE: SUB-POPULATION ANALYSIS
Rombopoulos G[1], Manes C[2], Migdalis I[3], Hatzikou M[1], Kypraios N[4], Tentolouris N[5]
[1]Novartis Hellas, Metamorfosis, Greece, [2]Papageorgiou Hospital, Thessaloniki, Greece, [3]NIMITS Hospital, Athens, Greece, [4]Polyclinic General Hospital, Athens, Greece, [5]Laiko General Hospital, Athens, Greece
OBJECTIVES: Health expenditure to treat and prevent T2DM and its complications was estimated at USD 345 million for OECD countries in 2010. These costs pose a great burden to the national health system's budget, which is already under pressure. In Greece there are no studies that provide information on the costs of T2DM patients including the cost of complications, hospitalizations and co-morbidities. The current study aimed to estimate the total cost of T2DM patients from a third party payer perspective. **METHODS:** A retrospective research study was performed in four major hospital diabetes centers and 211 patients with at least 10 years of T2DM since diagnosis. Patients were categorized in two groups, controlled and uncontrolled. Hospitalization and management of complications was based on DRG cost. Pharmaceutical and diagnosis cost was based on official NHS prices. Health care cost corresponds to 2012 Euros and the perspective used was of the Social Security Fund. Subgroup analysis was performed in order to evaluate the cost difference between controlled vs. uncontrolled, obese non-obese and various other subgroups. **RESULTS:** The mean average yearly cost of T2DM was €7.111 whereas only 18.8% was attributed to cost of antidiabetic drugs. Diabetic men cost 2.222€ more per year in comparison to diabetic women, whereas obese diabetics cost 1.460€ more per year in comparison to overweight and normal patients. These may be explained by the higher levels of HbA1c, co-morbidities and the number of antidiabetic treatments. In addition, diabetic patients with low education level cost 2.341€ cost more on average in comparison to better educated patients. **CONCLUSIONS:** T2DM is an expensive to treat disease and in the era of limited resources and escalating costs it is critical to implement sound public health policies in order to achieve patient's good glycemic control and consequently less burden to health care budgets.

PDB30
ADRENAL INSUFFICIENCY: BURDEN OF DISEASE AND COST OF ILLNESS
Chauhan R[1], Lee D[2]
[1]Viropharma LTD., Maidenhead, UK, [2]BresMed, Sheffield, UK
OBJECTIVES: To calculate the cost of illness (COI) associated with adrenal insufficiency (AI) in the UK. AI patients do not produce cortisol and require glucocorticoid replacement therapy (RT) to survive, which is predominantly immediate-release hydrocortisone in the UK. With current therapy, AI patients have increased morbidity and premature mortality, and suffer reduced quality-of-life. **METHODS:** The COI determines the direct and indirect costs over a 1-year period. The COI includes the cost of RT, primary and secondary care costs (GP and outpatient appointments; admissions for adrenal crises; diagnosis and management of AI) and those associated with reduced productivity (absenteeism). Direct costs were estimated using national reference costs, Payment by Results tariffs and other published data. AI prevalence and adrenal crises data were taken from published literature and activity data (hospital admissions for management of AI) from Hospital Episode Statistics (HES) data. A 2012 worldwide survey of AI patients was used to determine days taken off work and clinical expert opinion was sought to determine total outpatient appointments per year. The costs associated with premature mortality, the treatment and management of co-morbidities and the burden associated with reduced quality of life were not included due to lack of data. **RESULTS:** There are ~20,000 AI patients in the UK. Based upon the burden of disease calculations, the estimated COI associated with AI is £1,922 per patient or £39.7 million over 1 year: RT, £21.7 million; GP appointments, £1.8 million; secondary care, £4.4 million; and reduced productivity, £11.8 million. **CONCLUSIONS:** The high health care and social costs associated with AI highlight the clinical and economic need to improve RT. Indeed, as some consequences of the disease were not included in the calculations, £39.7 million is likely a considerable underestimate of the true burden of disease.

PDB31
DIRECT COST OF DIABETES MELLITUS AND ITS COMPLICATIONS IN SPAIN. SECCAID STUDY: SPAIN ESTIMATED COST CIBERDEM-CABIMER IN DIABETES
Crespo C[1], Brosa M[1], Soria-Juan A[2], López-Alba A[3], López-Martínez N[1], Soria B[4]
[1]Oblikue Consulting, Barcelona, Spain, [2]Université Dauphine Paris IX, Paris, France, [3]Fundación Hospital de Jove, Gijón, Spain, [4]CABIMER, Centro Andaluz de Biología Molecular y Medicina Regenerativa, Sevilla, Spain
OBJECTIVES: To assess the direct costs associated to type I and II diabetes mellitus (DM) from a health care perspective in Spain. **METHODS:** We performed a cost of illness study considering the prevalence approach. The use of resources was estimated from the existing Spanish health care databases and bibliographic references. Costs evaluated were: hospital costs (including outpatient care), primary care costs, drugs costs, consumables costs and additional tests costs. All costs were updated to 2012 euros. **RESULTS:** The total direct annual cost of DM was 5,809 million euros representing 8.2% of the total Spanish health expenditure. The total drug cost accounted for 2,232 million euros (38%) and was mainly due to the elevated contribution of non-antidiabetic drugs (24%). Hospital costs represented 1,934 million € (33%) and were mainly driven by the acute and chronic complications (17%). Cardiovascular disease cost (521 million €) and peripheral vascular disease costs (127 million €) were the most important complications cost drivers. The contribution of monitoring strips to the total cost was only 118 million € (2%). Total complications cost represented 2,143 million € (37% of the total direct cost). **CONCLUSIONS:** DM total direct costs are strongly conditioned by DM complications cost and have a considerable economic impact on Spanish health expenditure. In order to reduce the health and economic impact generated by DM, the introduction of measures and strategies focused on improving the efficiency of the treatment of the disease are crucial.

PDB32
QUANTIFYING THE DIRECT AND INDIRECT COSTS ASSOCIATED WITH SEVERE AND NON-SEVERE HYPOGLYCAEMIA IN SUBJECTS WITH TYPE-2 DIABETES WHO ARE TREATED WITH INSULIN
Foos V[1], Grant D[2], Palmer JL[3], Varol N[4], Curtis B[5], Boye KS[6], McEwan P[7]
[1]IMS Health, Basel, Switzerland, [2]IMS Health, London, UK, [3]IMS Health, Allschwil, Basel-Landschaft, Switzerland, [4]Eli Lilly and Company, Windlesham, Surrey, UK, [5]Eli Lilly & Co., Indianapolis, IN, USA, [6]Eli Lilly and Company, Indianapolis, IN, USA, [7]Swansea University, Cardiff, UK
OBJECTIVES: There have been a number of studies quantifying the direct and indirect resource implications associated with severe hypoglycaemia episodes (SHE) and non-severe hypoglycaemia episodes (NSHE). The objective of this study was to calculate the total direct and indirect economic burden associated with SHE and NSHE in insulin treated type 2 diabetes mellitus (T2DM) subjects. **METHODS:** We conducted two literature reviews of the MEDLINE database for studies published between June 1, 2007 and June 1, 2012. The first assessed the direct (primary and secondary care and treatment related) and indirect resource implications (lost productivity) associated with SHE and NSHE; the second established the frequency of NSHE and SHE in insulin-based clinical trials where sulfonylurea usage was also reported in T2DM. An economic model written in Microsoft Excel was developed to predict the expected annual per-patient cost (using 2011 US costs) associated with the incidence of hypoglycaemia. **RESULTS:** Resource utilisation from 6 studies and data characterising hypoglycaemia frequency were extracted from 82 studies for a total of 155 trial arms where the search criteria were met. Mean annual hypoglycaemia event rates were 16.4, 8.9, 4.8 and 2.6 for NSHE and 0.083, 0.039, 0.015 and 0.003 for SHE associated with baseline HbA1c levels of 6%, 7%, 8% and 9% respectively. Total expected annual per-patient hypoglycaemia costs were $929, $471, $237 and

$117 associated with HbA1c levls of 6%, 7%, 8% and 9% respectively. **CONCLUSIONS:** In insulin treated T2DM subjects lower HbA1c is associated with higher frequency of hypoglycaemia and associated costs. Failing to account for the cost burden associated with hypoglycaemia may underestimate the value of diabetes management strategies that minimize hypoglycaemia risk.

PDB33

COMPARATIVE ANALYSIS OF THE COST AND METABOLIC CONTROL IN DIABETIC CHILDREN USING INSULIN PUMPS

Petkova V[1], Petrova G[2], Petkova E[1]
[1]*Medical University, Faculty of Pharmacy, Sofia, Bulgaria,* [2]*Medical University of Sofia, Sofia, Bulgaria*

OBJECTIVES: To assess the cost and metabolic outcomes in children with diabetes mellitus treated with CSII or with human insulin. **METHODS:** It is a cost-consequence analysis. Retrospectively were observed patients dossier and health care resources used during the period 1999 – 2012. The study sample included 34 children aged 3 to 18 years with type 1 diabetes. Seventeen of the children are using continuous subcutaneous insulin infusion (CSII) therapy and 17 using intensified dosage regime of human insulin. The duration of the disease, diabetic control, HbA1c deviation scores, height and weight were observed. Cost of pharmacotherapy, test strips were calculated and compared with the therapeutic outcomes in both studied groups. The average improvement of HbA (1c) after the CSII introduction was chosen as therapeutic outcome. **RESULTS:** Subcutaneous insulin infusion (CSII) systems are not a standard treatment for the Bulgarian children; they are of a limited usage and are not reimbursed. From the 34 children with diabetes type 1 observed 17 were on CSII (mean age 10 years, mean duration of diabetes - 7 years, average usage of CSII - 3 years). The test stripes costs 533 Euro/ year and their average cost according to the duration of the disease is 3779.45 Euro since diagnosis. The blood glucose monitoring system costs 20 Euro and for the duration of the disease - 4.96 Euro per patient per year. The CSII price is 3896 Euro and it costs 1292 euro per patient per year. The average improvement of HbA (1c) after the CSII introduction is 1.85. In the group treated while human insulin the average cost per children is 925 Euro and improvement of HbA (1c) human insulin is 0.28 for the same period. **CONCLUSIONS:** The treatment with CSII leads to significant improvement in glycemic control compared to the treatment with human insulin at the comparable costs.

PDB34

A COST ANALYSIS OF MEDICATION FOR PATIENTS WITH TYPE 2 DIABETES MELLITUS (T2DM) – HOW THIS VARIES ACCORDING TO BODY MASS INDEX (BMI) STATUS, AGE, GENDER AND CO-MORBIDITY

Queally MB
National University of Ireland Galway, Galway, Ireland

OBJECTIVES: The rising prevalence of overweight and obesity has led to an increase in related metabolic disorders; most notably t2dm. We sought to determine how the cost of medication for this condition varies within a cohort of patients attending Galway University Hospital, according to age, gender, BMI and co-morbidity status. **METHODS:** We identified a subgroup of 185 adult type 2 diabetes patients attending our university hospital-based diabetes clinic, for whom detailed information about drug therapy and comorbidities (obesity, hypertension, dyslipidaemia) was available. We modelled the lifetime costs of medications for each patient, taking account of age, gender and comorbidity. The analysis compares the lifetime cost of medication of those patients who are obese relative to those who are overweight and of those with fewer to those with more co-morbidities; specifically obesity, hypertension and dyslipidaemia. **RESULTS:** We found that obesity is associated with a higher cost of medication relative to being overweight. Those with a BMI range of 35-39.9 had the highest mean cost of medication, costing on average €615 more than those who are overweight ($p< .01$). The highest cost of medication was associated with those aged 50-65- non-significant. Among those having all three co-morbidities compared to those having only t2dm there was a significant difference in the cost of medication costing on average an extra €418 ($p< .05$). **CONCLUSIONS:** These results suggest that the health economic costs associated with t2dm are differential with respect to the BMI status of affected individuals. These findings are of use in understanding the drug related burden of illness associated with obesity, t2dm and also the burden associated with being obese when one has t2dm compared to not being obese and having it. This study generated interesting data which will need to be replicated in larger prospective multicentre cohort studies.

PDB35

COST OF MICROVASCULAR AND MACROVASCULAR COMPLICATIONS IN PEOPLES WITH DIABETES TYPE 1 AND TYPE 2 IN BULGARIA

Dimitrova M[1], Doneva M[1], Vulov V[2], Manova M[1], Savova A[1], Petrova G[3], Czech M[4]
[1]*Medical University Sofia, Faculty of Pharmacy, Sofia, Bulgaria,* [2]*NovoNordisk, Sofia, Bulgaria,* [3]*Medical University of Sofia, Sofia, Bulgaria,* [4]*Novo Nordisk Pharma Sp z.o.o., Warsaw, Poland*

OBJECTIVES: It has been shown that people with diabetes have a high prevalence of microvascular (neuropathy, nephropathy, retinopathy, diabetic angiopathy) and macrovascular (hypertension, stroke, myocardial infarction, heart failure and coronary artery disease) complications leading to hospitalizations. The objective of the present study is to evaluate the cost of hospitalizations due to micro- and macrovascular complications in an observed cohort of 433 patients with type 1 and 2 diabetes treated with insulin. **METHODS:** The evaluation is based on data from a 6 months combined retrospective and prospective observational study. People were separated in two groups depending on the type of diabetes and further into subgroups depending on the reason of hospitalization. The total costs for each subgroup of people were calculated and compared to the total costs of treatment for the observed period. **RESULTS:** In the group of people with type 2 diabetes (n=255) 128 people with complications were observed, whereas in people with type 1 diabetes it was only 70 people out of 178. The cost of hospitalizations in the type 2 diabetes group was in total 35 367 EUR for the people enrolled in the 6 months study with the following division of reported reasons: (general) diabetes- 43%, microvascular complications- 16%, and macrovascular complications- 41%. In the type 1 diabetes group the cost was equal to 15 364 EUR with the following split: 63% due to (general) diabetes, 19% due to microvascular complications, and 18% due to macrovascular complications. **CONCLUSIONS:** Type 2 diabetes is more costly than type 1 when hospitalizations occur. People with type 2 diabetes pay high cost for macrovascular complications than for microvascular probably due to high hypertension prevalence. The difference in costs between type 1 and 2 may result from different patients' characteristics.

PDB36

PHARMACOECONOMIC PECULIARITIES OF THYROID DISEASE TREATMENT IN UKRAINE

Vadziuk I
Ivan Horbachevsky Ternopil State Medical University, Ternopil, Ukraine

OBJECTIVES: Due to the preparation for the transition to health insurance in Ukraine and because of the significant increase in thyroid disease it is important to assess a range of medicines included to the Ukrainian National Formulary (UNF). **METHODS:** It was compared the range of drugs for treatment of thyroid disease which are included to the Ukrainian National Formulary with the WHO Model list of Essential Medicines. Also it was calculated the annual cost of treatment by each medication considering the usual maintenance dose. **RESULTS:** In accordance to WHO Model List of Essential Medicines it was established that Ukrainian National Formulary includes thyroid hormones and antithyroid medicines for thyroid disease treatment such as: levothyroxine sodium and potassium iodide. Also it was found that there are no propylthiouracil medications in UNF. The dosage of levothyroxine sodium tablets satisfies the norms of World Health Organization, which are: 25 micrograms, 50 micrograms and 100 micrograms. Potassium iodide tablets in dose of 100 micrograms, 200 micrograms, 1 mg does not comply the norm. According to WHO Model list of Essential Medicines dosage of potassium iodide in tablets should be 60 mg. The cheapest annual cost of treatment by levothyroxine per patient is EUR 10,95 (The EUR/UAH conversion rate: 1 EUR = 10,52 UAH (Average 2013)), the most expensive is EUR 80,30. The most expensive annual cost of treatment by potassium iodide per patient is EUR 31,32, the cheapest is EUR 2,85. **CONCLUSIONS:** Propylthiouracil should be included to Ukrainian National Formulary. The cost difference of thyroid disease treatment by essential medicines caused by presence of foreign products in the pharmaceutical market of Ukraine.

PDB37

LOWER SHORT-TERM HEALTH CARE COST WITH THE ACCU-CHEK AVIVA EXPERT SYSTEM IN MULTIPLE DAILY INSULIN INJECTION (MDI) TREATED DIABETES PATIENTS - LEARNINGS FROM THE AUTOMATED BOLUS ADVISOR CONTROL AND USABILITY STUDY (ABACUS)

Fortwaengler K[1], Parkin CG[2], Koehler W[3], Cavan DA[4], Ziegler R[5], Cranston I[6], Barnard K[7], Mast O[1], Schweitzer MA[1], Wagner RS[8]
[1]*Roche Diagnostics, Diabetes Care, Mannheim, Germany,* [2]*CGParkin Communications, Inc., Boulder City, NV, USA,* [3]*Baseline Statistics GmbH, Frankfurt, Germany,* [4]*Royal Bournemouth Hospital, Bournemouth, UK,* [5]*Diabetes Clinic for Children and Adolescents, Muenster, Germany,* [6]*Queen Alexandra Hospital, Portsmouth, UK,* [7]*University of Southampton, Southampton, UK,* [8]*Roche Diagnostics, Indianapolis, IN, USA*

OBJECTIVES: The randomized controlled ABACUS study assessed the impact of using the automated insulin bolus advisor within the Accu-Chek Aviva Expert system in combination with intensive diabetes therapy on glycemic control in patients treated with MDI therapy. This analysis assessed the potential incremental economic benefit of using this automated bolus advisor device on the short-term health care costs (SHC). **METHODS:** The study outcome parameter was "achieving the goal of an at least 0.5% reduction in HbA1c". The economic analysis was performed with a spreadsheet-model from a UK payer's direct cost perspective and based on ABACUS outcomes. Data on correlation between HbA1c change and expected cost are based on published literature. Model outputs include expected impact on SHC and sensitivity analysis. **RESULTS:** A total of 56% of patients in the intervention group (IG) achieved the goal, in the control group (CG) 34% respectively. Goal achievement led to an average HbA1c reduction of 1.2%, irrespective of group. There was no clinically relevant HbA1c effect in the remaining patients. Goal achievement correlates with an expected reduction in SHC of £189 per person / per year (PPY). The expected SHC reduction is £104 PPY in the IG and £74 PPY in the CG. The goal-achievement-rate increased by 63%, driving a comparative economic benefit of £30 PPY for an automated insulin bolus advisor supported approach. There were no significant differences in complications or in intervention cost. **CONCLUSIONS:** An MDI therapy in diabetes care that is supported by the Accu-Chek Aviva Expert systems with its automated bolus advisor leads to a 63% higher rate of goal achievement. This is expected to result in an incremental reduction in short-term health care costs of £30 PPY. Hence automated bolus calculation improved the cost-effectiveness of self-monitoring of blood glucose in this study population.

PDB38

FIRST RUSSIAN TYPE 2 DIABETES MELLITUS SIMULATION MODEL WITH DISCRETE EVENTS MODELING. HEALTH-ECONOMIC ANALYSIS

Kolbin A, Kurylev A, Balykina Y, Proskurin M
Saint Petersburg State University, Saint Petersburg, Russia

OBJECTIVES: Type 2 diabetes mellitus (DM) is widely spread in Russia, counting about 10 million. New drugs are highly effective and carry a high cost for health care. The results of clinical trials are not enough to assess long term efficacy and safety of treatment. Modeling is a tool for making long term economic and outcome prognosis and comparing treatment strategies. The main goal of the presented study was to develop a predictive model of type 2 DM outcomes validated in Russian clinical conditions and to perform pharmacoeconomic evaluation of glucose lowering therapies. **METHODS:** Existing type 2 DM models were evaluated. Risk equations for type 2 DM complications were compiled from EAGLE and UKPDS DM models. Demographic (age, sex, height, weight, DM duration, smoking), biochemical (HbA1c, lipids) and clinical (blood pressure) patient parameters were used as inputs. Glucose lowering drug effectiveness was incorporated into

the model as to its ability to modify input parameters. The model was externally validated against epidemiological data from Russia. Mortality and complications risk equations coefficients were modified in accordance with mortality rates due to complications in Russia. Cost-effectiveness analysis was performed. **RESULTS:** The developed model allows assessing the risk of more than 15 type 2 DM complications in 5 years in patients with predefined risk factors. Among comparison of 5 strategies of type 2 DM therapies (no therapy, vildagliptin, sitagliptin, liraglutide, and exenatide) liraglutide was considered the cost-effective strategy with ICER/QALY - 470120.40 RUR, which is 51% of the willingness-to-pay threshold in Russia. With the lowest complication treatment costs inside the total direct costs, liraglutide monotherapy demonstrated the most long-term sustainable blood glucose control and HbA1c goal parameters. **CONCLUSIONS:** The developed model allows increase in compliance of therapy. Possibility of individual choice of the most cost-effective treatment regimen for each patient leads to so-called "personalized" therapies.

PDB39

HEALTH CARE RESOURCE UTILIZATION AND COSTS ASSOCIATED WITH TREATMENT OF POLISH ACROMEGALIC PATIENTS WITH LANREOTIDE AUTOGEL 120 MG – A RETROSPECTIVE OBSERVATIONAL COHORT ANALYSIS

Orlewska E[1], Kos-Kudla B[2], Sowinski J[3], Sworczak K[4], Zgliczynski W[5]
[1]*Centre for Pharmacoeconomics, Warsaw, Poland,* [2]*Silesian Medical University, Katowice, Poland,* [3]*Poznan Medical University, Poznan, Poland,* [4]*Medical University Gdansk, Gdansk, Poland,* [5]*Medical Center of Postgraduate Education, Warsaw, Poland*

OBJECTIVES: To estimate the resource utilization and related costs for Polish acromegalic patients treated with lanreotide AUTOGEL 120 mg (ATG120) in routine clinical practice **METHODS:** Medical care resource (dosage regimens, diagnostic procedures, hospitalizations, out-patient visits, any treatment changes) were collected during 1-year retrospective phase of non-intreventional, observational study (Lanro-Study). The study population consisted of acromegalic patients treated for at least three injections with ATG120. The endpoints were: proportion of patients treated for acromegaly with a given pharmaceutical in a given dosing interval, resource utilization, costs per patient/month or year. Costs were calculated in PLN from the public health-care payer perspective for the year 2013 (1 EURO = 4.2 PLN). **RESULTS:** A otal of 143 patients were included in the analysis (72% women, 80% macroadenoma, 72% previous pituitary surgery). Changes in the treatment scheme were reported in 54 patients. The mean cost of treatment in patients who switched from octreotide LAR (LAR) to ATG120 (n=26) was 6060.01 PLN/patient/month with LAR and 4047.96/patient/month PLN when switched to ATG120. At the time all patients entered the prospective phase, and were receiving ATG120, the mean cost of treatment with ATG120 was estimated at 3941.84 PLN/patient/month. Most patients (n=100; 70%) received ATG120 at dosing intervals less frequent than every 4 weeks. Patients were predominantly treated in out-patient setting with 4.77 physician visits/patient/year, most common control examinations were magnetic resonance imaging of brain and brain stem (0.57/patient/year), ultrasound of neck (0.55/patient/year), and IGF-1 (1.96/patient/year), GH (1.49/patient/year), glycemia (0.91/patient/year), pituitary-thyroid axis hormones (TSH- 0.45/patient/year, T4-0.49/patient/year). Only 7.7% patients were hospitalized. The mean medical cost, excluding pharmacotherapy, was 1002 PLN/patient/year. **CONCLUSIONS:** These results represent the current use of ATG120 in the population of Polish acromegalic patients in a realistic clinical settings and indicate that this therapy may provide cost saving in comparison to octreotide LAR.

PDB40

ASSESSMENT OF REAL-WORLD USAGE OF LANREOTIDE (SOMATULINE AUTOGEL) 120 MG IN POLISH ACROMEGALIC PATIENTS – RESULTS FROM 1 YEAR PROSPECTIVE PHASE OF LANRO-STUDY

Orlewska E[1], Kos-Kudla B[2], Sowinski J[3], Sworczak K[4], Zgliczynski W[5]
[1]*Centre for Pharmacoeconomics, Warsaw, Poland,* [2]*Silesian Medical University, Katowice, Poland,* [3]*Poznan Medical University, Poznan, Poland,* [4]*Medical University Gdansk, Gdansk, Poland,* [5]*Medical Center of Postgraduate Education, Warsaw, Poland*

OBJECTIVES: To assess the treatment pattern, dosage and costs of lanreotide AUTOGEL 120 (L-ATG120) administered as part of routine acromegaly care in Poland. **METHODS:** Lanro-Study is a multicenter, non-interventional, observational study on resource utilization in the population of Polish acromegalic patients treated with L-ATG120 at 4 weeks or extended (>4 weeks) dosing interval. The study recruited adult acromegalic patients treated medically for ≥ 1 year, including at least 3 injections of L-ATG120. Data on dosing interval and aspects of administration were collected prospectively during 12-months (interim analysis). Costs were calculated in PLN from the public health care payer perspective for the year 2013 (1 EURO = 4.2 PLN). **RESULTS:** A total of 139 patients were included in the analysis. Changes in dosing regimen were reported in 14 (9.4%) patients, polytherapy was used in 11 (8%) patients. 70 patients (50%) received L-ATG120 at an extended dosing interval (> 4 weeks), the mean number of days between injections was 35.56 (SD 8.4). L-ATG120 was predominantly administered in out-patient setting (77%), by health care professionalists (94%). Mean time needed for preparation and administration was 4.33 and 1.58 min., respectively, mean product wastage – 0.13 mg. The cost of L-ATG120 was estimated at 4103.87 PLN/patient/month **CONCLUSIONS:** These results represent the current use of L-ATG120 in the population of Polish acromegalic patients in a realistic clinical settings. Findings that 50% of patients could be treated with dose intervals of longer than 28 days support the potential for L-ATG120 of reducing treatment burden.

PDB41

COST-EFFECTIVENESS OF UNIVERSAL SCREENING FOR THYROID DISEASE IN PREGNANT WOMEN IN SPAIN

Donnay S[1], Balsa JA[2], Alvarez J[3], Crespo C[4], Pérez-Alcántara F[4], Villacampa A[4], Polanco C[5]
[1]*Hospital Universitario Fundación Alcorcón, Alcorcón, Madrid, Spain,* [2]*Hospital Universitario Infanta Sofía, San Sebastián de los Reyes, Madrid, Spain,* [3]*Hospital Universitario Príncipe de Asturias, Alcalá de Henares, Madrid, Spain,* [4]*Oblikue Consulting, Barcelona, Spain,* [5]*Merck, S.L., Madrid, Spain*

OBJECTIVES: Hypothyroidism in pregnancy can lead to adverse obstetrical outcomes. Universal screening in pregnant women for thyroid disease allows diagnose and treat cases of overt and subclinical hypothyroidism that are potentially missed when screening only women at high risk. The objective of the study was to assess the cost-effectiveness of universal screening as an alternative to high risk screening and no screening for thyroid disease in pregnant women in Spain. **METHODS:** The model compared the incremental cost per quality adjusted life-year (QALY) of universal screening versus high risk screening and versus no screening. A decision analytic model was used for the pregnancy and post-partum period. Probabilities from randomized controlled trials were considered for adverse obstetrical outcomes. A Markov model was used to assess the lifetime period after the first postpartum year and accounted for the development of overt hypothyroidism. Main assumptions of the model and the use of resources were validated by local clinical experts. The analysis considered only direct health care costs (euros 2013). A 3% discount was applied to costs and QALYs for the period beyond one year. **RESULTS:** Universal screening gained 0.011 QALYs over high risk screening and 0.014 QALYS over no screening. Total direct costs per patient were €5,791 for universal screening, €5,796 for high risk screening and €5,786 for no screening. Universal screening was dominant compared to risk-based screening and highly cost-effective alternative compared to no screening with an ICER of €374 per QALY. **CONCLUSIONS:** Universal screening of pregnant women in the first trimester for thyroid disease is dominant in Spain compared to the current type of screening which is risk-based, as well as cost-effective compared to no screening.

PDB42

COST-EFFECTIVENESS OF COMBINED TREATMENT OF METFORMIN AND FENOFIBRATE ON RETINOPATHY PROGRESSION

Hren R[1], Cerovic R[2]
[1]*University of Ljubljana, Ljubljana, Slovenia,* [2]*Health Insurance Fund - Republic of Serbia, Belgrade, Serbia and Montenegro*

OBJECTIVES: To evaluate the cost-effectiveness of intensive glycemic control (metformin) combined with fenofibrate in its impact on retinopathy progression compared to the treatment with metformin only in patients with type 2 diabetes. **METHODS:** Design: Markov decision model of retinopathy progression. Population: 40-year old patient with type 2 diabetes followed for 29 years. Main outcome measures: Risk of visual impairment; incremental cost-effeciveness ratio (ICER) for the two treatment options: one combining metformin and fenofibrate, and one using solely metformin. **RESULTS:** Combined tretament of metformin and fenofibrate resulted in ICER of -133.06 GBP per QALY which means that the intervention is not only effective but is also potentially saving money to the National Health Service; tretament solely with metformin is therefore dominated. **CONCLUSIONS:** Results of our study suggest that patients suffering from type 2 diabetes will receive from additional treatment with fenofibrate substantial benefits of protection against early microvascular complications related to retinopathy, including blindness. The favorable cost-effectiveness of intensive glycemic control combined with fenofibrate will likely be further increased if other major microvascular complications (e.g., non-traumatic amputations) and macrovascular complications (e.g., total cardiovascular events) of type 2 diabetes are taken into account. Our study is one of the first to compare cost-effectiveness of combined treatment of metformin and fenofibrate with current intensive glycemic control using solely metformin in its impact on retinopathy progression. Our study also provides evidence which may be useful in shaping the current clinical practice in the UK and European Union.

PDB43

REAL WORLD OUTCOMES IN TYPE 2 DIABETES: LOWER COST OF TREATING PATIENTS TO A1C<7% WITH LIRAGLUTIDE VERSUS EXENATIDE

Dekoven M[1], Lee WC[1], Bouchard JR[2], Massoudi M[2], Langer J[2]
[1]*IMS Health, Alexandria, VA, USA,* [2]*Novo Nordisk Inc., Plainsboro, NJ, USA*

OBJECTIVES: Type 2 diabetes (T2D) is characterized by progressive β-cell failure in the presence of insulin resistance. The LEAD-6 (Liraglutide Effect and Action in Diabetes) clinical trial program compared the efficacy and safety of liraglutide once-daily (LIRA) to exenatide twice-daily (EXEN). Few studies have explored the real-world effectiveness, and associated costs, of these comparators. Glycemic goal attainment of A1C<7% and total diabetes-related pharmacy costs in clinical practice were assessed over 6 months follow-up. **METHODS:** A retrospective cohort study using integrated medical and pharmacy claims and linked A1C results from the IMS Patient-Centric Integrated Data Warehouse was conducted. T2D patients ≥18 years naïve to GLP-1, DPP-IV and insulin use during a 6 months pre-index period, with evidence of ≥1 prescription for LIRA (N=234) or EXEN (N=182) between January 2010 and December 2010 were identified. Only patients who were persistent on their index treatment during a 6 months post-index period were included in the analysis. The percentage of patients achieving A1C<7% and total diabetes-related pharmacy costs were estimated using multivariable modelling to control for confounding effects. The cost per successfully treated patient was calculated as total diabetes-related pharmacy costs divided by the percentage of patients achieving A1C<7%. **RESULTS:** The percentage of patients reaching A1C<7% was 64.4% and 53.6% for LIRA and EXEN, respectively ($p<0.05$) (baseline A1C mean: 7.8% for both LIRA and EXEN). Average total diabetes-related pharmacy costs per patient at 6 months were higher for LIRA than EXEN ($2,002 vs $1,799, $p<0.001$) but when assessed as cost per patient successfully reaching A1C<7%, LIRA was cost-effective compared to EXEN ($3,108 vs $3,354, $p<0.0001$). **CONCLUSIONS:** The average cost of treating a patient to A1C<7% at 6 months follow-up was lower with LIRA than EXEN. This suggests LIRA to be a cost-effective treatment option compared to EXEN in the management of T2D.

PDB44

HEALTH-ECONOMIC COMPARISON OF CONTINUOUS SUBCUTANEOUS INSULIN INFUSION VERSUS MULTIPLE DAILY INJECTIONS FOR THE TREATMENT OF ADULT TYPE 1 DIABETES IN KAZAKHSTAN

Roze S[1], Demessinov A[2], Zeityn M[2], Toktarova N[3], Abduakhassova G[4], Sissemaliev R[5], Karamalis M[6], Dunne N[6], Muratalina A[5], Klots M[6], Lynch P[6]
[1]*HEVA HEOR, Lyon, France,* [2]*Republican Centre for Health Development, Astana, Kazakhstan,* [3]*National Scientific Medical Centre, Astana, Kazakhstan,* [4]*National Scientific Centre of Maternity and Childhood, Astana, Kazakhstan,* [5]*Medtronic, Almaty, Kazakhstan,* [6]*Medtronic, Tolochenaz, Switzerland*

OBJECTIVES: To project the long-term costs and outcomes of continuous subcutaneous insulin infusion (CSII) compared with multiple daily injections (MDI) in adult patients with Type 1 diabetes in KAZAKHSTAN. **METHODS:** The CORE Diabetes Model is a peer-reviewed, validated model, which employs standard Markov techniques to describe the long-term incidence and progression of diabetes-related complications. It was used to simulate disease progression in a cohort of adult patients with baseline characteristics and costs taken from primary data collection in KAZAKHSTAN (mean age 39.7 years, duration of diabetes 10.1 years and mean HbA1c 8.5%). Clinical outcomes (HbA1c and hypoglycemic events) were taken from a published meta-analysis of CSII studies. Direct costs for 2013 were calculated from a third-party payer perspective. Discount rates of 5% *per annum* were applied to costs and 3% to clinical outcomes. **RESULTS:** Treatment with CSII was associated with an improvement in mean quality adjusted life expectancy (QALE) of 0.745 years compared with MDI and incidence of any diabetes related complication was delayed on average by 1 year with CSII. This produced an incremental cost-effectiveness ratio (ICER) of KZT 4'784'971 per quality-adjusted life year (QALY) gained with CSII vs. MDI. CSII related therapy costs were partially offset by the savings due to the reduction in long-term complications. CSII treatment also delayed the average onset of complications such as ESRD (1.9 years) and blindness (2.1 years). Extensive sensitivity analyses showed the robustness of the results. **CONCLUSIONS:** Improvements in glycemic control associated with CSII over MDI led to improved QALE owing to reduced incidence of diabetes-related complications. CSII was associated with ICERs representing good value for money by current standards in KAZAKHSTAN (using a WTP threshold of 6,330,000 KZT [3x GDP]) from a payer's perspective. CSII would be even more attractive from a societal perspective when including indirect costs.

PDB45

COST OF ACHIEVING RELEVANT COMPOSITE ENDPOINT OF HBA1C<7%, NO HYPOGLYCAEMIA AND WEIGHT LOSS OF ≥3% IN A 52 WEEK POST-HOC ANALYSIS OF DAPAGLIFLOZIN VERSUS GLIPIZIDE

Bergenheim K[1], Grandy S[2], Wygant GD[3]
[1]*AstraZeneca, Mölndal, Sweden,* [2]*AstraZeneca, Wilmington, DE, USA,* [3]*Bristol-Myers Squibb, Princeton, NJ, USA*

OBJECTIVES: Dapagliflozin (DAPA), a selective SGLT2 inhibitor, reduces hyperglycaemia in an insulin-independent manner by increasing urinary glucose excretion. Glipizide (sulphonylurea) reduces hyperglycemia by increasing beta cell insulin secretion. We conducted an analysis of the cost of treating patients to a clinically relevant composite endpoint of HbA1c <7%, no major or minor hypoglycaemic events and weight loss ≥3%. **METHODS:** The Cardiff Diabetes model was used to estimate the cost of treating patients to the composite endpoint of HbA1c <7%, no major or minor hypoglycaemic events and weight loss ≥3% in the UK using 52 week data from a previously published double-blind randomised clinical trial of DAPA vs glipizide (GLIP) in combination with metformin (NCT 00660907). The cost of treating one patient to the composite endpoint using DAPA or GLIP over 52 weeks was calculated as total cost per treatment arm divided by number of patients that reached the composite endpoint in that treatment arm. Calculation of costs included drug acquisition costs, cost for adverse events, and costs related to the patient's BMI level. **RESULTS:** The number needed to treat was 5 on DAPA and 54 on GLIP for one patient to achieve the composite endpoint. The overall cost of treating one patient over 52 weeks to the composite endpoint of HbA1c <7%, no major or minor hypoglycaemic events and ≥3% weight loss was £3296 on DAPA and £13620 on GLIP. **CONCLUSIONS:** The cost of treating one patient to composite endpoint of HbA1c <7%, no major/minor hypoglycaemic events and ≥3% weight loss was approximately 4 times higher with GLIP compared to DAPA. These results demonstrate that when multiple treatment goals, including weight loss and reduction of hypoglycaemic events are targeted, the cost of treating patients with DAPA is lower compared to GLIP.

PDB47

COST-EFFECTIVENESS ANALYSIS OF DAPAGLIFOZIN VERSUS OTHER T2DM TREATMENTS IN THE SPANISH CONTEXT

Abad Paniagua EJ[1], Casado Escribano P[2], Fernández Rodriguez JM[3], Morales Escobar FJ[4], Canal Fontcuberta C[5], Betegón Nicolás L[5], Capel M[6], Brosa M[7]
[1]*Centro de Salud las Águilas, Madrid, Spain,* [2]*Hospital La Princesa, Madrid, Spain,* [3]*HOSPITAL CARMEN Y SEVERO OCHOA, Asturias, Spain,* [4]*Centro de Salud de Arucas, Gran Canrias, Spain,* [5]*Bristol-Myers Squibb, Madrid, Spain,* [6]*AstraZeneca, Madrid, Spain,* [7]*Oblikue Consulting, Barcelona, Spain*

OBJECTIVES: To analyse the cost-effectiveness of dapagliflozin in combination with metformin in the treatment of type 2 diabetes (T2DM) in comparison with sulfonylureas, thiazolidinediones and DPP4 inhibitors also combined with metformin in Spain. **METHODS:** The analysis was based on the results of the available clinical trials in order to estimate the quality-adjusted life years (QALY) and economic consequences of managing the disease and its complications. An economic model was used to simulate the natural history of 10,000 T2DM patients with each treatment option. The analysis was performed from the National Health System perspective considering direct costs (pharmacological costs, adverse events, T2DM complications, hypoglycaemias and costs related to weight gain) and patient's entire life as time horizon. A discount rate of 3% was applied to costs and benefits. All costs were updated to €2013. **RESULTS:** The primary analysis compared dapagliflozin with sulfonylureas resulting in 0.525 additional QALYs and €1,835 additional cost (cost-effectiveness ratio of €3,496/QALY). The higher drug cost of dapagliflozin was partially offset by lower costs of complications, hypoglycemia and the cost associated with weight gain. In the secondary analyses, dapagliflozin was a cost-effective option compared with thiazolidinediones and DPP4, resulting in a cost per QALY gained of €20,183 and €487, respectively. The univariate and probabilistic sensitivity analyses confirmed the robustness of the results. **CONCLUSIONS:** Dapagliflozin in combination with metformin proved to be a cost-effective alternative compared to sulfonylureas, thiazolidinediones and DPP4 inhibitors in the treatment of T2DM.

PDB48

A BUDGET IMPACT AND COST-EFFECTIVENESS ANALYSIS OF BLOOD GLUCOSE MONITORING SYSTEM IN ONE ITALIAN REGION

Colombo GL[1], Cremascoli C[2], Perrone F[3], Garcia - Valero J[4], Schauf M[5]
[1]*University of Pavia, Pavia, Italy,* [2]*Johnson & Johnson, LifeScan, Milano, Italy,* [3]*Johnson & Johnson Medical, Pomezia (Roma), Italy,* [4]*Johnson & Johnson, LifeScan, Madrid, Spain,* [5]*Johnson & Johnson, LifeScan EMEA, Zug, Switzerland*

OBJECTIVES: Diabetes is a chronic disease and associated with significant health care expenditures. Increasing costs are mainly related to long-term complications. Identifying patterns of hypoglycemia by means of a blood glucose monitoring system (BGMS) can be used to support diabetes management efficiently. **METHODS:** An economic analysis was carried out to estimate the life-time cost-effectiveness (CEA) of blood glucose monitoring system (BGMS) with pattern alert technology vs. standard BGMS for the prevention of Severe Hypoglycaemia (SH) in insulin-treated type 1 (DM1) and type 2 patients (DM2). The cost-effectiveness analysis was based on a literature review and cost data (direct and indirect) from the Emilia Romagna region; a decision tree was developed to calculate the incremental cost per additional quality of life. The BIA (Budget Impact Analysis) estimated the cost of using the new pattern alert technology in the Italian Healthcare System. **RESULTS:** For the base-case scenario, the utilization of BGMS with pattern alert technology was less costly and more effective compared to standard BGMS. Life time cost savings for the prevention of SH were 300 euro for DM1 and DM2 patients using pattern alert technology. The difference in life time QALYs was 0,17. **CONCLUSIONS:** BGMS with pattern alert technology, monitoring individual blood glucose levels are cost effective in preventing SH for DM1 and insulin-treated DM2 patients, as well as in detecting blood glucose trends and patterns. Nevertheless, empirical data on the probability of reducing Severe Hypoglycemia is necessary in order to reach any firm conclusions.

INCRETIN THERAPY FOR PATIENTS WITH TYPE 2 DIABETES IN SPAIN: A COST-EFFECTIVENESS ANALYSIS OF LIRAGLUTIDE VERSUS SITAGLIPTIN

Ramirez de Arellano A[1], Hunt B[2], Mezquita Raya P[3], Briones T[1], Pérez A[4], Valentine WJ[2]
[1]*Novo Nordisk, Madrid, Spain,* [2]*Ossian Health Economics and Communications, Basel, Switzerland,* [3]*Hospital Torrecardenas, Clinica San Pedro, Almería, Spain,* [4]*Hospital de la Santa Creu I Sant Pau, Barcelona, Spain*

OBJECTIVES: Diabetes mellitus represents a significant challenge to health care providers in Spain, with a national prevalence of over 8% and approximately 20,000 diabetes-related deaths annually. Treatment with GLP-1 receptor agonists and DPP-4 inhibitors, which target the incretin axis, has the potential to improve glycemic control without the weight gain associated with traditional therapies. To evaluate the relative cost-effectiveness of incretin therapies, the present study compared the long-term clinical and cost implications associated with liraglutide and sitagliptin in type 2 diabetes patients in Spain. **METHODS:** Data were taken from a randomized, controlled trial (NCT00700817) in which adults with type 2 diabetes (mean age 55 years, HbA1c 8.4%, BMI 33kg/m^2) failing metformin monotherapy were randomly allocated to receive either 1.2mg liraglutide or 100mg sitagliptin daily in addition to metformin. Liraglutide was associated with greater improvements from baseline HbA1c (–1.24% vs. –0.9%) and BMI (–0.99kg/m^2 vs. –0.33kg/m^2). Long-term projections of clinical outcomes and direct costs (2012 EUR) were made using a published and validated model of type 2 diabetes and assumed patients switched to insulin after five years. **RESULTS:** Liraglutide was associated with improved life expectancy (14.05 years vs. 13.91 years) and quality-adjusted life expectancy (9.04 quality-adjusted life years [QALYs] vs. 8.87 QALYs) compared to sitagliptin. Improved clinical outcomes were driven by improved glycemic control, leading to a reduced incidence of diabetes-related complications, including renal disease, cardiovascular disease, ophthalmic and diabetic foot complications. Mean cost savings as a result of avoided complications were EUR 1,827 per patient. Overall, liraglutide was associated with increased direct costs of EUR 2,297, yielding an incremental cost-effectiveness ratio of EUR 13,266 per QALY gained versus sitagliptin. **CONCLUSIONS:** Liraglutide was projected to improve life expectancy, quality-adjusted life expectancy and reduce incidence of diabetes-related complication. Liraglutide is likely to be cost-effective from a health care payer perspective in Spain.

HEALTH-ECONOMIC COMPARISON OF CONTINUOUS SUBCUTANEOUS INSULIN INFUSION VERSUS MULTIPLE DAILY INJECTIONS FOR THE TREATMENT OF TYPE 1 DIABETES IN KAZAKHSTAN CHILDREN

Roze S[1], Demessinov A[2], Zeityn M[2], Toktarova N[3], Abduakhassova G[4], Sissemaliev R[5], Karamalis M[6], Dunne N[6], Muratalina A[5], Klots M[6], Lynch P[6]
[1]*HEVA HEOR, Lyon, France,* [2]*Republican Centre for Health Development, Astana, Kazakhstan,* [3]*National Scientific Medical Centre, Astana, Kazakhstan,* [4]*National Scientific Centre of Maternity and Childhood, Astana, Kazakhstan,* [5]*Medtronic, Almaty, Kazakhstan,* [6]*Medtronic, Tolochenaz, Switzerland*

OBJECTIVES: To project the long-term costs and outcomes of continuous subcutaneous insulin infusion (CSII) compared with multiple daily injections (MDI) in children with Type 1 diabetes in KAZAKHSTAN. **METHODS:** The CORE Diabetes Model is a peer-reviewed, validated model, which employs standard Markov/Monte

Carlo simulation techniques to describe the long-term incidence and progression of diabetes-related complications. It was used to simulate disease progression in a cohort of pediatric patients with baseline characteristics taken from published KAZAKHSTAN studies (mean age 10.4 years, duration of diabetes 4.1 years, mean HbA1c >7.5%). Direct costs for 2013 were calculated from a third-party payer perspective. Discount rates of 5% per annum were applied to costs and 3% to clinical outcomes. **RESULTS:** Mean undiscounted life expectancy of patients using CSII vs. MDI was increased by 3.58 years. The Incremental-Cost-Effectiveness-Ratio (ICER) for CSII was 3,935,375KZT per Quality-Adjusted-Life-Year gained based on direct costs only. CSII related therapy costs were partially offset by the savings due to the reduction in long-term complications, i.e.638,744KZT, mainly due to cardiovascular and renal diseases. Cumulative incidences of proliferative diabetic retinopathy, blindness, ESRD, and GRP were decreased by 25.3%, 5.6%, 28.3%, and 17.7%, respectively. CSII treatment also delayed the average onset of ESRD (3.9 years), blindness (3.7 years), PVD (3.5 years), CHF (3.6 years), Neuropathy (3.4 years), first ulcer (4.0 years), amputation (3.7 years), MI (3.5 years), and stroke (3.5 years). Extensive sensitivity analyses showed the robustness of the results. **CONCLUSIONS:** Using a payer's perspective, our analysis showed that CSII is cost-effective over a lifetime horizon in children with Type 1 Diabetes in Kazakhstan (using a WTP threshold of 6,330,000 KZT [3x GDP]) and can lead to an increase in life expectancy as well as delay and reduce long-term complications. When including indirect costs, CSII would be even more attractive from a societal perspective.

COST-EFFECTIVENESS OF INTRALESIONAL INJECTION OF RECOMBINANT HUMAN EPIDERMAL GROWTH FACTOR FOR THE TREATMENT OF SEVERE DIABETIC FOOT ULCERS IN RUSSIAN HEALTH CARE SETTING

Ignatyeva V[1], Avxentyeva M[1], Galstyan GR[2]
[1]*The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia,* [2]*The Endocrinological Scientific Center, Moscow, Russia*

OBJECTIVES: To assess the cost-effectiveness of using intralesional injection of recombinant human epidermal growth factor (rhEGF) for the treatment of severe non-healing diabetic foot ulcers (DFU) in highly-specialized inpatient department in Russian setting. **METHODS:** We developed a cost-effectiveness model based on hypothesis that use of intralesional injection of rhEGF in addition to standard treatment of severe DFU (Wagner grade 3-4) would reduce the rate of amputations and related increased mortality in population of amputated DFU patients. For model inputs we used published data on the rates of amputation from retrospective study of intralesional injection of rhEGF and survival rates for patients with DFU with and without major amputations. Cost data was derived from the Russian retrospective study of real practice of inpatient treatment of severe DFU and reimbursement rates in Russian compulsory medical insurance system, cost of rhEGF treatment was provided by the manufacturer. Based on the model outputs we calculated incremental cost-effectiveness ratio (ICER) as the difference in costs to the difference in years lived during the 5-year period of observation by two cohorts of patients treated with only standard methods and with addition of rhEGF. **RESULTS:** The use of rhEGF intralesional injection treatment may prevent 52 amputations and save 29.54 years of life in a cohort of 100 patients with severe DFU during subsequent 5-year period of observation. The ICER for rhEGF is estimated at EURO 27,200 per life year saved and does not exceed the acceptable threshold of three GDP per capita as recommended by WHO. The sensitivity analysis demonstrated that the results are most sensitive to the cost of rhEGF. **CONCLUSIONS:** The model has demonstrated the acceptability of adoption of intralesional injection of rhEGF in addition to standard treatment for DFU in highly specialized inpatient departments.

PHARMACOECONOMIC EVALUATION OF THE ORAL HYPOGLYCEMIC AGENTS IN THE TREATMENT OF TYPE 2 DIABETES MELLITUS PATIENTS IN THE RUSSIAN FEDERATION

Ryazhenov VV, Emchenko IV
I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: To assess the cost-effectiveness of oral hypoglycaemic agents (micronized glibenclamide, gliclazide, glimepiride and repaglinide) in the treatment of Russian patients with type 2 diabetes mellitus. **METHODS:** Based on the data from comparative studies (B. Wolffenbuttel et al., 1999; A. Holstein et al., 2001; O. Reshetko et al., 2007) the pharmacoeconomic profiles of glibenclamide and repaglinide, glibenclamide and glimepiride, glibenclamide and gliclazide were compared. It was revealed that glibenclamide and repaglinide, glibenclamide and gliclazide have equal efficacy and safety, so the cost-minimization analysis was performed. The cost-effectiveness of glibenclamide and glimepiride was measured as total costs of medicines and expenses for ambulance calls for severe hypoglycemia per one patient without hypoglycaemic events. A one-year time horizon was adopted in the models. One-way sensitivity analysis (SA) was carried out to assess the robustness of the results . **RESULTS:** Compared to repaglinide and gliclazide, treatment with glibenclamide was associated with substantial budget savings (22,699.35 RUB and 3,566.05 RUB per one patient, respectively). Costs per one patient without hypoglycaemic events were 1,137.17 RUB and 5,549.85 RUB in glibenclamide and glimepiride groups, respectively. Sensitivity analysis demonstrated that results are robust. **CONCLUSIONS:** The present study has demonstrated that administration of micronized glibenclamide is the most economically effective strategy in the treatment of Russian patients with type 2 diabetes mellitus. Treatment with micronized glibenclamide is associated with considerably lower costs as compared to repaglinide, glimepiride and gliclazide.

IMPACT OF PATIENT WEIGHT TRAJECTORY ON COST-EFFECTIVENESS OF TREATMENTS OF TYPE 2 DIABETES MELLITUS (T2DM)

Schroeder M[1], Willis M[2], Johansen P[2], Girod I[1], Neslusan C[3], Thompson G[1]
[1]*Janssen UK, High Wycombe, UK,* [2]*The Swedish Institute for Health Economics, Lund, Sweden,* [3]*Janssen Global Services LLC, Raritan, NJ, USA*

OBJECTIVES: With new classes of T2DM medications offering weight reduction in addition to better glycaemic control, HTA agencies expect fuller accounting of the impact of post-trial weight trajectory assumptions on cost-effectiveness. Four alternative scenarios were examined using the example of the novel SGLT-2 inhibitor canagliflozin (CANA) in the UK treatment setting. **METHODS:** The importance of alternative assumptions was illustrated using CANA 300mg versus glimepiride (GLIM; 1mg titrated to 6mg or 8mg) in dual therapy with metformin simulated over 40 years using the ECHO-T2DM model loaded with patient characteristics, treatment effects, and adverse event rates from the DIA3009 trial, in which CANA 300mg reduced body weight by –5.7% versus GLIM over 52 weeks. HbA1c was assumed to drift annually by 0.14% for CANA (similar to metformin in ADOPT), 0.24% for GLIM (as sulphonylurea in ADOPT), and 0.15% for rescue therapy with insulin (initiated when HbA1c >7.5%). Upon treatment discontinuation, four alternative weight-trajectory assumptions were applied: (A) weight change maintained permanently; (B) CANA weight reduction disappears fully at treatment discontinuation, GLIM weight-gain permanent; (C) GLIM weight-gain permanent, forced convergence of weight upon CANA discontinuation; (D) weight changes disappear fully at discontinuation for both treatments. A weight increase was applied when insulin was initiated and proportional weight changes were applied when insulin dose was titrated upwards. **RESULTS:** CANA 300mg generated more QALYs at modest incremental cost, resulting in ICERs of £2,766 to £4,317 in the scenarios. Maintaining the benefits permanently (A) generated the largest QALY gain (0.243); complete elimination of benefits at discontinuation (D) offered the smallest (0.198). The proportions of incremental QALYs attributable to weight differences were 34.4%, 19.5%, 18.9% and 17.4% for Scenarios A to D, respectively. **CONCLUSIONS:** CANA 300mg was cost-effective in each of four weight scenarios following discontinuation. Further work is required to define the most clinically plausible scenarios.

PDB54

THE COST-EFFECTIVENESS OF DAPAGLIFLOZIN (FORXIGA®) VERSUS A DPP-4 INHIBITOR IN THE TREATMENT OF TYPE 2 DIABETES MELLITUS (T2DM) IN ENGLAND AND WALES

Charokopou M[1], McEwan P[2], Lister S[3], Callan L[4], Bergenheim K[5], Tolley K[6], Roudaut M[7]
[1]*Pharmerit International, Rotterdam, The Netherlands,* [2]*HEOR Consulting, Monmouth, UK,* [3]*Bristol-Myers Squibb, Uxbridge, UK,* [4]*AstraZeneca UK Ltd., Luton, UK,* [5]*AstraZeneca, Mölndal, Sweden,* [6]*Tolley Health Economics, Buxton, UK,* [7]*Bristol-Myers Squibb, Rueil-Malmaison, France*

OBJECTIVES: Dapagliflozin (Forxiga®) is the first sodium-glucose co-transporter-2 inhibitor (SGLT-2) approved by the European Medicines Association, and positively assessed by the National Institute for Health and Care Excellence (NICE) for type 2 diabetes mellitus (T2DM). This study evaluates the cost-effectiveness of dapagliflozin compared with a dipeptidyl-peptidase-IV (DPP-4) inhibitor when added to metformin in patients inadequately controlled on metformin alone. **METHODS:** The published and validated CARDIFF diabetes model was used to conduct the analysis. Clinical inputs were derived from a systematic review and network meta-analysis. Based on clinical inputs and the United Kingdom Prospective Diabetes Study (UKPDS) equations, the model predicts disease progression and the number of micro- and macro-vascular complications, along with diabetes-specific and all-cause mortality. The perspective of the National Health Service in England and Wales was adopted over a lifetime horizon. Local unit costs and utility data were assigned to the appropriate model parameters to calculate total Quality-Adjusted-Life-Years (QALYs) and costs. Univariate and probabilistic sensitivity analyses (PSA) were conducted. **RESULTS:** Compared to a DPP-4 inhibitor, dapagliflozin was associated with 0.076 incremental QALYs (95%CI: –0.028; 0.146) at an additional cost of £412 (95%CI: -£212; £853); resulting in an incremental cost-effectiveness ratio (ICER) of £5,455 per QALY gained. The univariate analyses showed that no input parameter change inflated the ICER above £15,000 per QALY. The PSA estimated that dapagliflozin has a 81% chance to increase QALYs and costs, a 9% chance to increase QALYs and save costs, a 4% chance to reduce QALYs and costs and a 6% chance to reduce QALYs and increase costs. At a willingness-to-pay threshold of £20,000 per QALY gained, dapagliflozin strategy had an 86% probability to be cost-effective in this setting. **CONCLUSIONS:** Dapagliflozin in combination with metformin was shown to be a cost-effective treatment option for T2DM patients who are inadequately controlled with metformin mono-therapy.

PDB55

SOURCES OF LONG-TERM QUALITY ADJUSTED LIFE YEAR (QALY) GAINS FOR CANAGLIFLOZIN (CANA) VERSUS SITAGLIPTIN (SITA) IN THE TREATMENT OF TYPE 2 DIABETES MELLITUS (T2DM) IN THE UK SETTING

Willis M[1], Johansen P[1], Schroeder M[2], Thompson G[2], Girod I[2], Neslusan C[3]
[1]*The Swedish Institute for Health Economics, Lund, Sweden,* [2]*Janssen UK, High Wycombe, UK,* [3]*Janssen Global Services LLC, Raritan, NJ, USA*

OBJECTIVES: The NICE reference case for T2DM requires cost-utility analysis with a lifetime horizon. The denominator in cost-utility outcomes is the incremental QALY, which is driven in most T2DM economic models by several key features, including: life extension, micro- and macrovascular events, treatment and treatment-related adverse events (AEs), and excess bodyweight. The aim of this analysis is to determine which factors most impact QALY gains in an analysis of CANA 300mg versus SITA 100mg when combined with metformin and sulphonylurea in the UK treatment setting. **METHODS:** The ECHO-T2DM model was used to simulate CANA versus SITA over 40 years. ECHO-T2DM was loaded with patient characteristics, treatment effects, and AE rates from the DIA3015 trial. HbA1c was assumed to drift upwards at an annual rate of 0.14% for CANA and SITA (similar to metformin in the ADOPT trial). CANA and SITA were discontinued and insulin initiated (annual drift 0.15% as in UKPDS) when patients failed to maintain HbA1c under 58 mmol/mol (7.5%). **RESULTS:** Hypothetical patients experienced 0.039 more QALYs when treated with CANA 300mg versus SITA 100mg. Because SITA had lower initial HbA1c lowering, it was associated with greater use of rescue medication. Patients treated initially with SITA, thus, had greater insulin-mediated HbA1c lowering over time so HbA1c values converged asymptotically (limiting differences in rates of microvascular complications). There were relatively modest QALY benefits related to macro-

vascular events, but substantial benefits attributable to weight (0.020) and especially hypoglycaemic events (0.024), related to CANA's better weight-lowering and longer time to initiation of insulin. **CONCLUSIONS:** Patients treated with CANA in triple therapy experienced an additional 0.039 QALY's over 40 years versus patients treated with SITA. The primary drivers were improved weight while on agent and fewer hypoglycaemic events.

PDB56

THE COST-EFFECTIVENESS OF DAPAGLIFLOZIN (FORXIGA®) VERSUS GLIPIZIDE IN THE TREATMENT OF TYPE 2 DIABETES MELLITUS (T2DM) IN ENGLAND AND WALES

[1]*Pharmerit International, Rotterdam, The Netherlands,* [2]*HEOR Consulting, Monmouth, UK,* [3]*Bristol-Myers Squibb, Uxbridge, UK,* [4]*AstraZeneca UK Ltd., Luton, UK,* [5]*AstraZeneca, Mölndal, Sweden,* [6]*Tolley Health Economics, Buxton, UK,* [7]*Bristol-Myers Squibb, Rueil-Malmaison, France*

OBJECTIVES: Dapagliflozin (Forxiga®) is the first sodium-glucose co-transporter-2 (SGLT-2) inhibitor approved by the European Medicines Association, and positively assessed by the National Institute for Health and Care Excellence (NICE) for type 2 diabetes mellitus. This study investigates the cost-effectiveness of dapagliflozin compared with a sulphonylurea (SU) when added to metformin in patients inadequately controlled with metformin mono-therapy. **METHODS:** The published and validated CARDIFF diabetes model was used to conduct the analysis. Clinical inputs were derived from a randomized clinical trial comparing dapagliflozin and glipizide in combination with metformin. Based on these clinical inputs and the United Kingdom Prospective Diabetes Study (UKPDS) equations, the model predicts disease progression and the number of micro- and macro-vascular complications, along with diabetes-specific and all-cause mortality. The perspective of the National Health Service in England and Wales was adopted over a lifetime horizon. Local unit costs and utility data were assigned to the appropriate model parameters to calculate total Quality-Adjusted-Life-Years (QALYs) and total costs. Univariate and probabilistic sensitivity analyses (PSA) were conducted. **RESULTS:** Compared to SU added to metformin, dapagliflozin add-on to metformin was associated with an incremental benefit of 0.467 QALYs (95%CI: 0.420; 0.665) at an additional cost of £1,246 (95%CI: £613; £1,637), resulting in an ICER point estimate of £2,671 per QALY gained. The univariate analyses showed that no input parameter change inflated the ICER above £15,000 per QALY. The PSA showed that at a willingness-to-pay threshold of £20,000 per QALY gained, dapagliflozin treatment had an estimated 100% probability to be cost-effective compared to an SU treatment strategy. These findings were shown to be robust with all sensitivity analyses. **CONCLUSIONS:** Dapagliflozin in combination with metformin was shown to be a cost-effective treatment option for patients who are inadequately controlled with metformin mono-therapy within established UK cost-effectiveness thresholds.

PDB57

COST-EFFECTIVENESS OF DAPAGLIFLOZIN AS ADD-ON TO INSULIN FOR THE TREATMENT OF TYPE 2 DIABETES IN THE NETHERLANDS

van Haalen HGM[1], Pompen M[2], Bergenheim K[3], McEwan P[4], Townsend R[5], Roudaut M[6]
[1]*AstraZeneca, Zoetermeer, The Netherlands,* [2]*Bristol-Myers Squibb, Woerden, The Netherlands,* [3]*AstraZeneca, Mölndal, Sweden,* [4]*Swansea University, Cardiff, UK,* [5]*AstraZeneca, Brussels, Belgium,* [6]*Bristol-Myers Squibb, Rueil-Malmaison, France*

OBJECTIVES: Insulin, often combined with metformin, is usually the last therapy option for patients with type 2 diabetes Mellitus (T2DM) who are uncontrolled on oral anti-diabetic drugs. Dutch guidelines recommend up-titration of insulin until patients maintain an HbA1c <7%, yet in practice many patients never reach this target. Clinical evidence shows that dapagliflozin – a highly selective sodium-glucose cotransporter 2 (SGLT2) inhibitor – meets a need for these patients, i.e. by reducing HbA1c and weight. We studied the cost-effectiveness of dapagliflozin added to insulin (vs. not adding dapagliflozin) for patients with T2DM who have inadequate glycaemic control while on insulin. **METHODS:** We used the Cardiff Diabetes model to evaluate cost and effects of dapagliflozin added to insulin using direct comparative efficacy data from a randomized placebo-controlled trial (NCT00673231). In this trial up-titration of insulin was allowed in case of severe glycaemic imbalance. Risk factor progression and occurrence of future vascular events were estimated using the UKPDS 68 risk equations. Costs and utilities were derived from the literature. The analysis was conducted from a Dutch societal perspective using a lifetime horizon. **RESULTS:** The overall incidence of vascular complications was lower, and life expectancy was higher (19.43 LYs vs. 19.35 LYs) in those patients receiving dapagliflozin compared to patients not receiving dapagliflozin. Patients in the dapagliflozin arm obtained an incremental benefit of 0.42 QALYs. The lifetime incremental cost per patient in the dapagliflozin arm was € 2,293, resulting in an incremental cost-effectiveness ratio of €27,779 per LYG and an incremental cost-utility ratio of €5,502 per QALY gained. Sensitivity and scenario analyses showed that the results were robust to variation in modelling assumptions and input variables. **CONCLUSIONS:** This analysis shows that dapagliflozin increases the quality of life of T2DM patients compared to current practice (up-titration of insulin), and is cost-effective in a Dutch health care setting.

PDB58

THE COST-EFFECTIVENESS OF DAPAGLIFLOZIN (FORXIGA®) VERSUS INSULIN IN THE TREATMENT OF TYPE 2 DIABETES MELLITUS (T2DM) IN ENGLAND AND WALES

OBJECTIVES: Dapagliflozin (Forxiga®) is the first sodium-glucose co-transporter-2 (SGLT-2) inhibitor approved by the European Medicines Association, and positively assessed by the National Institute for Health and Care Excellence (NICE) for type 2 diabetes mellitus. This study assesses the costs-effectiveness of dapagliflozin in combination with insulin versus insulin alone for patients who are inadequately controlled despite high doses of insulin. **METHODS:** The published and validated CARDIFF diabetes model was used to conduct the analysis. Clinical inputs were derived from a randomized clinical trial comparing dapagliflozin add-on to insulin with insulin regimens. Based on clinical inputs and the United Kingdom Prospective Diabetes Study (UKPDS) equations, the model predicts disease progression and the number of micro- and macro-vascular complications, along with diabetes-specific and all-cause mortality. The perspective of the National Health Service in England and Wales was adopted over a lifetime horizon. Local unit costs and utility data were assigned to the appropriate model parameters to calculate total Quality-Adjusted-Life-Years (QALYs) and total costs. Univariate and probabilistic sensitivity analyses (PSA) were conducted. **RESULTS:** Compared to insulin, dapagliflozin added to insulin was associated with 0.342 incremental QALYs (95%CI: 0.288; 0.480) at an additional cost of £1,813 (95%CI: £1,165; £2,381), resulting in an incremental cost-effectiveness ratio (ICER) point estimate of £5,295 per QALY gained. The univariate analyses showed that no input parameter change inflated the ICER above £15,000 per QALY. At a willingness-to-pay threshold of £20,000 per QALY gained, the dapagliflozin treatment strategy was estimated to have a 100% probability of being cost-effective when compared to the insulin treatment strategy. These findings were shown to be robust with all sensitivity analyses. **CONCLUSIONS:** Dapagliflozin was shown to be a cost-effective treatment option in combination with insulin for patients who are inadequately controlled with insulin alone within established UK cost-effectiveness thresholds.

PDB59

ASSESSMENT OF THE KEY DRIVERS OF COST-EFFECTIVENESS IN THE ECONOMIC MODELLING OF CANAGLIFLOZIN (CANA) VERSUS GLIMEPIRIDE (GLIM) IN THE TREATMENT OF TYPE 2 DIABETES MELLITUS (T2DM) IN THE UK SETTING

Thompson G[1], Willis M[2], Johansen P[2], Neslusan C[3], Schroeder M[1], Girod I[1]
[1]*Janssen UK, High Wycombe, UK,* [2]*The Swedish Institute for Health Economics, Lund, Sweden,* [3]*Janssen Global Services LLC, Raritan, NJ, USA*

OBJECTIVES: To evaluate uncertainty, the NICE reference case requires estimation of cost-effectiveness using alternative parameter values. Because models of T2DM necessarily include many parameters, NICE requirements dictate a large number of simulations. This study assesses the relative importance of common sensitivity analyses by identifying key drivers of the incremental cost-effectiveness ratio (ICER) using the example of CANA 300mg versus GLIM (titrated from 1mg to 6mg or 8mg), in combination with metformin in dual therapy. **METHODS:** The ECHO-T2DM model was used to simulate CANA versus GLIM over 40 years. ECHO-T2DM was loaded with patient characteristics, treatment effects, and adverse event rates from the DIA3009 trial. HbA1c was assumed to drift annually by 0.14% for CANA (similar to metformin in ADOPT), 0.24% for GLIM (as sulphonylurea in ADOPT), and 0.15% for rescue therapy with insulin (initiated when HbA1c >7.5%). Twenty-four one-way sensitivity analyses assessed the impact of drug durability, macrovascular risk equations, utility weights, and HbA1c goals. **RESULTS:** In the base case, CANA 300mg was associated with 0.21 greater QALYs at an incremental cost of £828, generating an ICER of £4,050/QALY. QALY gains were driven by fewer hypoglycaemic events and a better weight profile. The low acquisition cost of GLIM was partially offset by a greater need for insulin rescue therapy earlier in treatment, more hypoglycaemic events, and more macrovascular complications. Assuming no difference in durability for CANA and GLIM had the greatest impact on the ICER (£49,717), followed by no disutility for hypoglycaemic events (£15,733). The only other scenario having a noticeable impact was an HbA1c goal of 9.0% (£9,718). Alternative macrovascular risk engines had little impact on the ICER. **CONCLUSIONS:** The ICER was robust under a large number of scenarios. Only the difference in assumed long-term GLIM durability reversed the interpretation of CANA as cost-effective versus GLIM using NICE criteria.

PDB60

SOURCES OF LONG-TERM QUALITY ADJUSTED LIFE YEAR (QALY) GAINS FOR CANAGLIFLOZIN (CANA) VERSUS GLIMEPIRIDE (GLIM) IN THE TREATMENT OF TYPE 2 DIABETES MELLITUS (T2DM) IN THE UK SETTING

Girod I[1], Willis M[2], Johansen P[2], Schroeder M[1], Thompson G[1], Neslusan C[3]
[1]*Janssen UK, High Wycombe, UK,* [2]*The Swedish Institute for Health Economics, Lund, Sweden,* [3]*Janssen Global Services LLC, Raritan, NJ, USA*

OBJECTIVES: The NICE reference case for T2DM requires cost-utility analysis with a lifetime horizon. The denominator in cost-utility outcomes is the incremental QALY, which is driven in most T2DM economic models by several key features, including: life extension, micro- and macrovascular events, treatment and treatment-related adverse events (AEs), and excess bodyweight. This analysis aims to determine which factors most impact QALY gains using the example of CANA 300mg versus GLIM (titrated from 1mg to 6mg or 8mg) when combined with metformin. **METHODS:** The ECHO-T2DM model was used to simulate CANA versus GLIM over 40 years. ECHO-T2DM was loaded with patient characteristics, treatment effects, and AE rates from the DIA3009 trial. HbA1c was assumed to drift upwards at an annual rate of 0.14% for CANA (similar to metformin in the ADOPT trial) and 0.24% for GLIM (as sulphonylurea in ADOPT). CANA and GLIM were discontinued and insulin initiated (annual drift 0.15% as in UKPDS) when patients failed to maintain HbA1c under 58 mmol/mol (7.5%). **RESULTS:** Hypothetical patients experienced 0.21 more QALYs when treated with CANA 300mg versus GLIM. Because GLIM was associated with greater use of rescue medication (and extra insulin-mediated HbA1c lowering) in the simulation, HbA1c values converged asymptotically limiting the differences in microvascular complications. However, lower blood pressure for patients on CANA versus GLIM was associated with reductions of 2.2% to 4.1% for the rates of macrovascular outcomes (although associated QALY gains were small due to discounting). Differences in weight and especially hypoglycaemic events, related both to GLIM and to earlier initiation of insulin, were associated with improvements in utility (0.04 and 0.16 QALYs, respec-

tively). **CONCLUSIONS:** Patients treated with CANA in dual therapy experienced an additional 0.21 QALYs over 40 years versus patients treated with GLIM. The primary drivers were improved weight while on agent and fewer hypoglycaemic events.

PDB61

COST-EFFECTIVENESS OF INSULIN DETEMIR IN T2DM PATIENTS POORLY CONTROLLED WITH NPH INSULIN IN POLAND

Kaczor MP[1], Pawlik D[2], Wójcik R[2], Jurkiewicz B[3]
[1]*Jagiellonian University Medical College, Kraków, Poland,* [2]*Aestimo s.c., Kraków, Poland,* [3]*Novo Nordisk Pharma, Warszawa, Poland*

OBJECTIVES: In Poland, where long acting insulin analogues (LAA) are not currently reimbursed in T2DM, it is crucial to select a group of patients for whom LAA may be particularly preferred. Based on NICE recommendation such patients are those treated with human insulin (NPH) but not achieving glycaemic control. Thus the aim of this study was to evaluate the cost-effectiveness of insulin detemir (IDet) when compared to NPH in subpopulation of poorly controlled T2DM as defined by HbA1c ≥8% and/or ≥1 episode of severe or nocturnal hypoglycemia recorded during ≥6 months of NPH treatment. **METHODS:** A validated computer simulation of diabetes model (IMS-CORE) was used to project long-term clinical and economic outcomes. Clinical effects in HbA1c improvement, BMI change and reduction in hypoglycemic episodes were modelled. Analysis was based on findings from the subgroups of the *PREDICTIVE* study – a real-world data trial – that closely reflects the defined target population. Two distinct insulin therapy regimens with IDet and NPH were evaluated: basal-supported oral therapy (BOT) and a basal-bolus (BB) regimen. Baseline cohort characteristics, disease progression and utility estimates were obtained from systematic literature review. Costs were obtained from Polish published data. The analysis was conducted from a public payer and patient perspective over a lifetime time horizon. Discount rates were 5% (costs) and 3.5% (outcomes). **RESULTS:** The mean QALY gain resulting from treatment initiation with IDet compared with NPH was 0,311 (BOT) and 0,451 (BB). Base-case incremental cost-effectiveness ratios (ICERs) were 38,136 PLN/QALY (9,113€) and 13,726 PLN/QALY (3,280€), respectively. At the current ICER threshold of 105,801 PLN/QALY (25,281€) in Poland, probability of IDet being cost-effective compared to NPH is 95% (BOT) and approaching 100% (BB). **CONCLUSIONS:** Based on generally accepted cost/QALY threshold values in the Polish settings, IDet was found to be a cost-effective option for T2DM patients with inadequately controlled diabetes.

PDB62

COST-EFFECTIVENESS ANALYSIS OF INSULIN DEGLUDEC COMPARED WITH CURRENT STANDARD OF CARE IN THE MANAGEMENT OF TYPE 1 AND TYPE 2 DIABETES MELLITUS IN THE SPANISH HEALTH SYSTEM

Ramirez de Arellano A[1], Orozco-Beltran D[2], Mezquita-Raya P[3], Pérez A[4], Galan M[5]
[1]*Novo Nordisk Pharma, Madrid, Spain,* [2]*University Miguel Hernández, Department of Clinical Medicine, Alicante, Spain,* [3]*Hospital Torrecardenas, Clinica San Pedro, Almeria, Spain,* [4]*Hospital de la Santa Creu I Sant Pau, Barcelona, Spain,* [5]*Novo Nordisk, Madrid, Spain*

OBJECTIVES: Insulin degludec (IDeg) is a basal insulin with an ultra-long duration of action for management of patients with type 1 (T1DM) and patients with type 2 (T2DM) diabetes. IDeg have demonstrated efficacious blood glucose control with less hypoglycaemic events and with an option for flexibility in dose time compared insulin glargine (IGlar). The objective was to assess the cost-effectiveness of IDeg in Spain, compared with IGlar. The analysis focused on subgroups of patients within three treatment regimens: T1DM, T2DM treated with basal insulin in combination with oral anti-diabetics (BOT) and T2DM treated with basal-bolus (BB). **METHODS:** A one-year cost-utility model driven by differences in hypoglycaemia was used. Two alternative utility approaches were used: in the first case, the utility gain was elicited from the clinical trials. In the second, published dis-utilities for hypoglycaemic events and self-monitoring blood glucose tests were used to calculate QALYs. Cost and utilities were also estimated for potential use of less blood glucose test strips. Three subgroups were analysed: those using twice daily IGlar, those with high risk of severe hypoglycaemia, and those obtaining extra utility from dosing flexibility. Unit costs pertained to public tariffs and reflected the payer perspective. Baseline incidence rates of hypoglycaemia and related resource use was derived from a Spanish observational study. **RESULTS:** IDeg was dominant for T1DM, T2DM BOT and T2DM BB switching from twice daily. T2DM BOT with high risk of hypoglycaemia was also dominant. As for patients benefiting from dosing flexibility the cost/QALY were 6,921€/QALY in T1DM, 9,244€/QALY in T2DM BOT, and 33,099€/QALY in T2DM BB. The use of the two different utility methods gave similar results. Univariate and probabilistic sensitivity analyses confirmed robust results. **CONCLUSIONS:** This analysis demonstrates that IDeg is a cost-effective option in Spain, when used in sub-groups of patients currently treated with long-acting insulin.

PDB63

EVALUATING THE COST-UTILITY OF FENOFIBRATE TREATMENT OF DIABETIC RETINOPATHY IN AUSTRALIA

Valentine WJ[1], Pollock RF[1], Carr E[2], Aubonnet P[2], Mitchell P[3], Keech A[3]
[1]*Ossian Health Economics and Communications, Basel, Switzerland,* [2]*Abbott Laboratories, Allschwil, Switzerland,* [3]*University of Sydney, Sydney, Australia*

OBJECTIVES: Evidence from the landmark trials FIELD and ACCORD demonstrated that fenofibrate significantly reduces rates of diabetic retinopathy (DR) progression in type 2 diabetes patients (T2DM). This study evaluates the long-term cost-effectiveness of fenofibrate mono- and combination therapy for DR in Australia. **METHODS:** A seven-state Markov model simulated progression of DR based on data from the Blue Mountain Eye Study. Risk reductions for retinopathy progression were derived from FIELD for fenofibrate monotherapy (vs. placebo) and ACCORD for fenofibrate+statin (vs. statin alone). No additional benefits were assumed beyond 5 years (DR progression was the same with/without fenofibrate after year 5). Quality-adjusted life expectancy, direct costs and incremental cost-effectiveness ratios (ICERs) were reported over 10 years. Unit costs (2012 Australian dollars, AUD), resource use and utilities were taken from country-specific sources/expert opinion. Future costs and clinical benefits were discounted at 5% annually. Sensitivity analyses were performed. **RESULTS:** Fenofibrate monotherapy improved mean quality-adjusted life expectancy by 0.09 QALYs versus placebo due to fenofibrate patients spending more time in mild DR states. Direct medical costs were AUD 898 higher for fenofibrate monotherapy, with additional treatment costs partially offset by reduced cost associated with advanced DR (e.g. ophthalmologist time and laser treatment), leading to an ICER of AUD 10,221 per QALY gained. Similarly, fenofibrate+statin led to an improvement of 0.05 QALYs versus statin alone with an incremental direct cost of AUD 1,707. The ICER for fenofibrate+statin was AUD 33,350 per QALY gained versus statin alone. Sensitivity analysis showed that results were relatively insensitive to changes in a range of assumptions. **CONCLUSIONS:** The reduced risk of DR progression associated with fenofibrate treatment was projected to improve quality-adjusted life expectancy, with treatment costs partially offset by reduced costs of retinopathy care. ICERs indicated that fenofibrate therapy was in the range likely to be considered cost-effective in Australia.

COST-EFFECTIVENESS OF INSULIN DEGLUDEC COMPARED WITH INSULIN GLARGINE IN A BASAL-BOLUS REGIMEN IN PATIENTS WITH TYPE 1 DIABETES MELLITUS IN THE UNITED KINGDOM

Chubb B[1], Evans M[2], Wolden M[3], Christensen T[3], Gundgaard J[3]
[1]*Novo Nordisk Ltd., Crawley, UK,* [2]*University Hospital Llandough, Cardiff, UK,* [3]*Novo Nordisk A/S, Søborg, Denmark*

OBJECTIVES: Insulin degludec (IDeg) is a basal insulin with an ultra-long duration of action for the management of patients with type 1 (T1DM) and patients with type 2 (T2DM) diabetes. IDeg has demonstrated effective blood glucose control with less hypoglycaemic events and with an option for flexibility in dose time compared to insulin glargine (IGlar). The aim of this analysis was to evaluate the cost-effectiveness of IDeg versus IGlar in adults with T1DM in the UK. **METHODS:** Meta-analysis data from two phase III clinical studies were used to populate a simple, transparent short-term model. The analysis was conducted from the UK National Health Service perspective and costs and benefits were calculated over a 12-month period. Sensitivity analyses were conducted to assess the degree of uncertainty around the results. In order to test the robustness of the results, two versions of the model were used. One applied disutilities derived from the SF-36 questionnaire used in the clinical trials, the other applied disutilities associated with the occurrence of hypoglycaemic events. In both approaches an additional utility gain was attributed to the benefit of dosing flexibility. Baseline incidence of hypoglycaemia was taken from a real-life study from the UK. Resource use associated with hypoglycaemia was documented in the clinical trials. Published tariffs were used as unit costs. **RESULTS:** The base-case ICERs were £12,637/QALY and £13,349/QALY in the two modelling approaches, which are below commonly accepted thresholds for cost-effectiveness. The results were robust and largely insensitive to changes in input parameters. **CONCLUSIONS:** This short-term modelling approach allows the economic evaluation of newer insulin analogues when advanced long-term modelling based on HbA_{1c} differences is inappropriate due to the treat-to-target nature of the clinical trials resulting in equivalent HbA1c levels. For patients in the UK with T1DM IDeg is a cost-effective treatment option compared with IGlar.

PDB65

COST-EFFECTIVENESS OF INSULIN DEGLUDEC COMPARED WITH INSULIN GLARGINE FOR PATIENTS WITH TYPE 2 DIABETES MELLITUS INITIATING INSULIN THERAPY IN THE UNITED KINGDOM

Evans M[1], Chubb B[2], Christensen T[3], Gundgaard J[3], Wolden M[3]
[1]*University Hospital Llandough, Cardiff, UK,* [2]*Novo Nordisk Ltd., Crawley, UK,* [3]*Novo Nordisk A/S, Søborg, Denmark*

OBJECTIVES: Insulin degludec (IDeg) is a basal insulin with an ultra-long duration of action for management of patients with type 1 (T1DM) and patients with type 2 (T2DM) diabetes. IDeg has demonstrated effective blood glucose control with less hypoglycaemic events and an option for flexibility in dose time compared to insulin glargine (IGlar). The aim of this analysis was to evaluate the cost-effectiveness of IDeg versus IGlar in adults with T2DM initiating insulin therapy in the UK. **METHODS:** Meta-analysis data from three clinical studies were used to populate a 1-year cost-utility model. The analysis was conducted from the UK National Health Service perspective. Sensitivity analyses were conducted to assess the robustness of results. Two versions of the model were tested, one applied disutilities derived from the SF-36 questionnaire used in the clinical trials, the other applied disutilities associated with the occurrence of hypoglycaemic events. In both approaches an additional utility gain was attributed to the benefit of dosing flexibility. Baseline incidence of hypoglycaemia was derived from a UK real-life study. Resource use associated with hypoglycaemia was documented in the clinical studies. Official tariffs were used as unit costs. **RESULTS:** Base-case ICERs were £15,705/QALY and £13,003/QALY in the two modelling approaches. Results were robust, with baseline rate of hypoglycaemia a key driver of results. Using hypoglycaemia rates from a subgroup of patients who experienced ≥1 hypoglycaemic event per year IDeg was highly cost-effective versus IGlar; with estimated ICERS of £4,706/QALY and £2,528/QALY. **CONCLUSIONS:** This short-term modelling approach allows the economic evaluation of newer insulin analogues when advanced long-term modelling based on HbA_{1c} differences is inappropriate due to treat-to-target trial design. For patients with T2DM on a basal-only insulin regimen, IDeg is cost-effective compared with IGlar and offers additional benefits to subgroups of patients, such as those suffering from recurrent hypoglycaemia.

THE COST-UTILITY OF INSULIN DEGLUDEC COMPARED WITH CURRENT STANDARD OF CARE IN THE MANAGEMENT OF TYPE ONE AND TYPE TWO DIABETES MELLITUS IN BELGIUM

Jugrin AV[1], Lamotte M[1], Malfait M[2], Vandebrouck T[3]
[1]*IMS Health HEOR, Vilvoorde, Belgium,* [2]*sa Novo Nordisk Pharma nv, Brussels, Belgium,* [3]*Novo Nordisk Pharma, Brussels, Belgium*

OBJECTIVES: Insulin degludec (IDeg) is a basal insulin with an ultra-long duration of action for management of patients with type 1 (T1DM) and patients with type 2 (T2DM) diabetes. IDeg has demonstrated efficacious blood glucose control, with less hypoglycaemic events, and with an option for flexibility in dose time, compared with insulin glargine (IGlar). The objective was to assess the cost-effectiveness of IDeg in Belgium, compared with IGlar. The analysis focused on patients in three treatment regimens: T1DM, T2DM treated with basal insulin in combination with oral anti-diabetics (BOT) and T2DM treated with basal-bolus (BB). **METHODS:** A one-year cost-utility model driven by differences in hypoglycaemia was used. Published dis-utilities for hypoglycaemic events were multiplied by the rate of hypoglycaemia to calculate quality-adjusted life years (QALYs). Costs and utilities were also calculated for potential use of less blood glucose test strips. A utility gain was attributed to the additional benefit of dosing flexibility. Unit costs pertained to public tariffs and reflected the payer perspective in Belgium. Baseline incidence rates of hypoglycaemic events and related resource utilization pertained to a Belgian patient-reported outcomes study. Hospitalization costs following severe hypoglycaemia were estimated using the IMS Hospital Disease Database. **RESULTS:** IDeg was associated with an incremental cost-effectiveness ratio of 14,677€/QALY in T1DM, 4,976€/QALY in T2DM BOT, and 12,930€/QALY in T2DM BB. Univariate and probabilistic sensitivity analyses confirmed robust results. Results were most sensitive to variations in number of IGlar doses per day, and number of glucose-monitoring tests. At a willingness to pay threshold of 30,000€/QALY, IDeg would be cost-effective in 54%, 100% and 93% of the cases in the T1DM, T2DM BOT or T2DM BB treatment regimens respectively. **CONCLUSIONS:** These analyses demonstrate that IDeg is cost-effective in Belgium, when used in patients with T1DM and T2DM currently treated with long-acting insulin analogues.

PDB67

ECONOMIC EVALUATION OF LIRAGLUTIDE FOR TREATMENT OF TYPE 2 DIABETES MELLITUS IN THE RUSSIAN FEDERATION

Yagudina R, Kulikov A, Novikov I

I.M. Sechenov First Moscow State Medical University, Moscow, Russia

OBJECTIVES: The analysis goal is to determine the cost-effectiveness of liraglutide as add-on to metformin in for patients with type 2 diabetes in condition of the Russian health care system. Total medical expenses and effectiveness in terms of QALY are compared for liraglutide, glimepiride and rosiglitazone, all in combination with metformin, and metformin monotherapy. **METHODS:** Data were sourced from a clinical trial comparing liraglutide vs. glimepiride (in combination with metformin), and a clinical trial comparing liraglutide vs. rosiglitazone (as add-on to metformin). From them data on clinical effectiveness in form of impact on HbA1(c), body mass index and blood pressure are extracted. Utility values are mostly taken from the UK Prospective Diabetes Studies supplemented with other published sources. The analysis is conducted from the perspective of the Russian health care system. Respectively the cost of the following resources is accounted: comparing of alternatives, concomitant pharmacotherapy, cost of medical manipulation, cost of ambulatory visits. Both future costs and clinical benefits are discounted at 3 percent. Sensitivity analysis is performed. Results of this analysis are shown in the incremental cost-utility rate (ICUR). **RESULTS:** The data of the analysis illustrates that liraglutide therapy for type 2 diabetes patients provides a significant health improvement from the perspective of quality adjusted life-years. Simultaneously liraglutide demonstrates better cost-effectiveness than the compared alternatives. The ICUR index of 1.2 mg liraglutide in combination with metformin equal to 1 348368 rub, 1 161874 rub and 537331 rub for QALY in comparison with metformin monotherapy, glimepiride and rosiglitazone, both in combination with metformin, respectively. **CONCLUSIONS:** Liraglutide has turned to be cost-effective therapeutic alternative for treatment of type 2 diabetes in adult patients in conditions of Russian health care system over a 10-year time horizon.

ECONOMIC EVALUATION OF SITAGLIPTIN IN DIABETES MELLITUS TREATMENT IN CHINA

Chen W, Zhu J

Fudan University, Shanghai, China

OBJECTIVES: To evaluate the long-term cost effectiveness of sitagliptin compared to glimepiride and acarbose in the treatment of type 2 diabetes mellitus in China. **METHODS:** Sitagliptin, as add-on therapy to metformin, was compared to glimepiride and acarbose, and as monotherapy was also compared to acarbose. The validated UKPDS Outcomes Model was used to estimate the direct medical costs and outcomes (life years and QALYs gained). The demographic characteristics and clinical data were taken from published literature. The quality of life data was obtained from published literature and re-confirmed through a questionnaire survey from a clinical expert panel of 20 diabetes specialists. The cost of drugs was calculated based on government guidance price or actual market price. The annual cost of complications was estimated based on expert opinions. Patients' outcomes were modeled for 40 years and incremental cost-effectiveness ratios were calculated. Both future costs and clinical benefits were discounted at 3 percent. A probabilistic sensitivity analysis was performed to understand the key drivers and general sensitivity of the model. **RESULTS:** The results showed that, compared to the treatment of glimepiride and acarbose plus metformin therapy, the add-on of sitagliptin provided a gain of 0.02 and 0.95 QALYs per patient, and the incremental cost-effectiveness ratios were USD 9,470 and USD 399, respectively. The results also showed that compared to acarbose monotherapy (100mg t.i.d and 200mg t.i.d), the sitagliptin monotherapy (100mg/d and 200mg/d) was dominant, with higher QALYs (0.58 and 0.92) and years of life (0.72 and 1.23) gained and lower cost (USD 90 and USD 185). **CONCLUSIONS:** According to the China's GDP per capita in 2011 (USD 5,674), the results demonstrate that sitagliptin is more cost-effective than glimepiride and acarbose in the treatment of diabetes mellitus in China.

PRODUCTIVITY LOSS IN POPULATION OF INFORMAL CAREGIVERS TO DIABETIC FOOT SYNDROME PATIENTS IN POLAND

Macioch T[1], Sobol E[2], Mrozikiewicz-Rakowska B[1], Krakowiecki A[1], Mienicka A[2], Mlynarczuk M[2], Kasprowicz M[1], Paweska J[1], Hermanowski TR[1], Karnafel W[1]

[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*Medical University of Warsaw Central Clinical Hospital, Warsaw, Poland*

OBJECTIVES: Foot ulceration is a major cause of disability in diabetic patients. Disability of patients with diabetic foot ulceration (DFS – Diabetic Foot Syndrome) concerns not only patients themselves, but also the informal caregivers, mainly their close relatives. The aim of this study was to estimate lost productivity in a population of family caregivers of patients with diabetic foot ulceration in Poland. **METHODS:** A survey among 189 patients with DFS (treated in ambulatory care) and their families was conducted. To assess the impact of diabetic ulceration on productivity of caregivers to DFS patients the modified questionnaire WPAI-CG was used. The PEDIS scale was used to classify severity of ulceration. **RESULTS:** A total of 116 out of 189 questionnaires were collected, and data on 93 responders (25 males) were included in the analysis (23 questionnaires were returned empty or concluded that informal care is not provided to DFS patients). Fifty-two (13 males) out of 93 caregivers were employed at the time of the survey. Mean age of the population of caregivers was 45.9±11.2 years. Most were close relatives of DFS patients (58% spouses, 27% children). Almost half caregivers were employed in private sector (46%). Most had higher (50%) or secondary (48%) education. The average weekly work time declared was 40.4±13.1 hours. Approximately 70% of caregivers were urban population. The average percentage of work time missed and the percentage of working impairment while working due to informal care of DFS patients were estimated at 11.9% and 25.0%, respectively. The percentage of overall work impairment due to informal care of DFS patients was 32.2%. This amounts to weekly average time of the absence of 13.0 hours. **CONCLUSIONS:** The lost productivity due to informal care on DFS patients is substantial and may have important implications for the economy.

PDB70

UTILISATION PATTERN OF GLP-1 AGONISTS IN COMBINATION WITH BASAL INSULIN IN PATIENTS WITH T2DM IN THE NORWEGIAN SETTING IN ONE YEAR

Levorsen A[1], Jespersen S[1], Chou E[2]

[1]*Sanofi, Lysaker, Norway,* [2]*Sanofi, Bridgewater, NJ, USA*

OBJECTIVES: GLP-1 agonists in combination with basal insulin (BI) have demonstrated additional improvement of glycemic control in uncontrolled T2DM patients in clinical trials. It is therefore important to assess the real-world utilisation of GLP-1 agonists in combination with BI in T2DM patients. **METHODS:** Retrospective cohort analysis (2010 to 2012) to assess GLP-1 agonist utilisation in T2DM patients based on the Norwegian Institute of Public Health Prescription Database (NorPD). Both ICPC=T90 and ICD-10=E11 were applied to identify T2DM patients. Patients who had ≥2 GLP-1 dispensed within 6-month in Year-2011, with 1-year pre-Baseline/post- Follow-up GLP-1 initiation were included in the analysis. Baseline antidiabetic drug use and combination use of GLP-1 and BI at Follow-up were also assessed. **RESULTS:** Of the 1,500 GLP-1 initiators identified (mean age=57; 52% male) at Baseline, 77% were on OADs, 19% on BI, 2% on prandial insulin (no BI) and 2% on other/no anti-diabetic drug. During 1-year Follow-up of GLP-1 adding on OADs patient population, 56% used GLP-1 continuously including 50% who used GLP-1 alone and 6% added BI. In total, 15% had either combined with or switched to BI, 4 months after the first GLP-1 was dispensed. Of those GLP-adding on BI patient population, 53% continuously used GLP-1 including 26% had both GLP-1 and BI dispensed throughout the Follow-up. About 52% had either BI interrupted or discontinued approximately 2 months after the first GLP-1 was dispensed. In total, 27% had insulin bolus dispensed; of which 58% either interrupted or discontinued GLP-1. **CONCLUSIONS:** About 1/3 of GLP-1 initiators were in combination with BI. In BI treated T2DM patients >25% remained on both GLP-1 and BI, while another >25% required treatment augmentation or switched to bolus. The data suggests an unmet treatment need, particularly in T2DM patients treated with BI.

PDB71

REVIEW OF COST OF DIABETES COMPLICATIONS IN FOUR EUROPEAN COUNTRIES

Beaudet A[1], Grabbi E[2], Maurel F[3], Ramos M[4], Lebioda A[5]

[1]*IMS Health, Basel, Switzerland,* [2]*IMS Health, London, UK,* [3]*IMS Health, La Défense, France,* [4]*IMS Health, Barcelona, Spain,* [5]*IMS Health, Munich, Germany*

OBJECTIVES: To provide a comprehensive and coherent reference document of published cost data for diabetic complications in France, Germany, Italy and Spain for use in economic diabetes modeling. **METHODS:** A search for published cost of diabetes complications data from a health care payer perspective was performed on government websites, in peer-reviewed journals and local cost experts. All costs were inflated to 2013 Euros (€). **RESULTS:** First year costs of myocardial infarction varied between €3,041 in France and €9,690 in Germany. Heart failure costs were similar across countries: €3,104 in France; €2,791 in Germany; €4,000 in Italy and €3,316 in Spain. Costs of non-fatal stroke were higher in Germany (€16,441) than in other countries (Spain €8,016; Italy €6,073; France €5,447). Everywhere, the cost of haemodialysis was higher than peritoneal dialysis €35,972 versus €21,255 in Spain, €21,552 versus €18,485 in Italy, €34,290 versus €34,069 in Germany €71,683 versus €48,752 in France. Renal transplant cost was estimated to €84,114 in France, €34,858 in Germany, €38,528 in Italy and €26,618 in Spain. The cost of a major hypoglycemia requiring medical care was €4,275 in Spain, €2,561 in Germany, €1,391 in Italy and €1,165 in France. Neuropathy complication costs varied widely: €3,808 (France); €16,762 (Germany); €4,290 (Italy); and €5,330 (Spain) for foot ulcers and €6,056 (Italy); €7,754 (Germany); €9,578 (France); and €12,118 (Spain) for lower-extremity amputation. **CONCLUSIONS:** This study provides a coherent set of costs for diabetes complications in four European countries. Due to the differences in health care

system structure and in cost transparency, the cost estimation methodology varied among countries. One limitation of this study is that diagnostic related group (DRG) tariffs were used to estimate several costs, which may not accurately represent the burden of a specific complication nor take into account the full burden of follow-up after an acute event.

PDB72
THE COST OF SPECIALIZED HOSPITAL CARE FOR PATIENTS WITH DIABETIC FOOT ULCERS IN RUSSIA
Ignatyeva V[1], Avxentyeva M[1], Omelyanovsky VV[1], Galstyan GR[2]
[1]The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia, [2]The Endocrinological Scientific Center, Moscow, Russia
OBJECTIVES: To assess the direct medical costs for aggressive limb preservation treatment of diabetic foot ulcer (DFU) in a highly-specialized hospital setting in Russia **METHODS:** A retrospective data analysis of 156 admissions during 1-year period was done to get direct costs (associated with hospital stay, conservative and surgical treatment and laboratory testing) for treatment of DFU in a highly-specialized inpatient department in Russian setting (Federal Endocrinology Centre). **RESULTS:** The median cost of hospital treatment was 2270 EUR and increased with severity level, defined according to Wagner classification, ranging from 1590 EUR (grades 0-2) to 3812 EUR (grade 3) and 7683 EUR (grade 4), the difference was statistically significant. The length of stay in a hospital also correlated with the severity level starting with 14 days for grade 1 and reaching 39 days for grade 4. The costs of treatment were significantly higher for patients with inadequate vascular status requiring surgery – the median was 6185 EUR for cases with only angioplastic surgery and 8622 EUR for cases with both angioplastic and foot surgery provided. **CONCLUSIONS:** Treatment of DFU aimed at limb preservation is resource consuming, costs for treating severe stage ulcer are 4,8 times higher than are those for treating low-stage ulcer. The high costs of treating severe stages of DFU in a specialized hospital setting emphasize the value of intensive outpatient interventions designed to prevent ulcer progression.

RISK FACTORS FOR DISCONTINUATION OF INSULIN PUMP THERAPY IN PEDIATRIC AND YOUNG ADULT PATIENT GROUPS
Kostev K[1], Rockel T[1], Rex J[1], Mergenthaler U[1], Rosenbauer J[2], Rathmann W[2]
[1]IMS Health, Frankfurt am Main, Germany, [2]German Diabetes Center, Duesseldorf, Germany
OBJECTIVES: Previous studies have shown that only a small number of pediatric and young adult patients discontinue pump therapy, but risk factors for discontinuation are unclear. Aim of this study was to identify characteristics of pediatric and young adult patients with pump therapy which are associated with discontinuation of treatment. **METHODS:** Retrospective cohort study using a representative nationwide database (LRx; IMS Health) in Germany covering >80% of all prescriptions to members of statutory health insurances in 2008-2011. All patients (age groups: <6, 6-<12, 12-<18, 18-<25 years) with new prescriptions of insulin pumps or related material were identified (2009-2011) and were followed for ≥12 months. **RESULTS:** Overall, 3057 new pump users were identified, of whom 177 (5.8%) switched to other forms of insulin therapy within 12 months. Discontinuation was lowest in the age group <6 years (2.1%) and was highest in adolescents (12-<18 years: 7.5%) (p<0.01). In age-adjusted logistic regression, usage of steel needles (Odds ratio, OR, 95%CI: 1.69; 1.20-2.44) and prescriptions of antiepileptics (3.14; 1.49-6.59) were related to pump discontinuation. In younger age groups only, discontinuation was significantly higher in patients with thyroid therapy as a surrogate measure for thyroid autoimmunity (<6 years: 14.3%; 6-<12 years: 25.0%) (p<0.01). **CONCLUSIONS:** About 94% of pediatric and young adult patients maintained insulin pump therapy within 12 months. Adolescence (12-18 years), usage of steel needles and prescriptions of antiepileptic drugs are independent predictors of discontinuation. In younger age groups (<12 years) also thyroid therapy (indicating autoimmunity) was related to a higher risk of discontinuation.

PDB74
PERSISTENCE PATTERNS WITH ORAL HYPOGLYCAEMIC MEDICINES (OHM) IN NEWLY TREATED IRISH PATIENTS WITH TYPE 2 DIABETES MELLITUS (T2DM)
Grimes R[1], Tilson L[2], Usher C[2], Henman M[1], Bennett K[3]
[1]Trinity College Dublin, Dublin, Ireland, [2]National Centre for Pharmacoeconomics, Dublin, Ireland, [3]Trinity Centre for Health Sciences, Dublin, Ireland
OBJECTIVES: To describe persistence patterns to OHM in newly treated Irish patients with T2DM. The study also investigated the effect of age, gender, reimbursement scheme and type of OHM on persistence. **METHODS:** A population based retrospective cohort study was conducted using national pharmacy claims databases, including two community drugs schemes; Long Term Illness, (LTI, non-means tested) and General Medical Services (GMS, means tested). Newly treated T2DM patients were identified for 2008-2009, having received no OHM in the previous year, and followed up until Nov-2012. Patients who subsequently switched or received additional OHM were excluded. Non-persistence was defined as a prescription gap of >12 weeks and within 1 year of initiating treatment. Logistic regression examined associations of age, gender, scheme and type of OHM with persistence with results presented as odds ratios (OR) and 95% confidence intervals (CI). **RESULTS:** A total of 15,174 persons were eligible for the study. Most patients were initiated on metformin (79.4%) and sulphonylureas (19.1%). Persistence at 1 year was 60.9%. The median overall time to non-persistence was 51.5 days. Men were slightly more likely to be persistent than women (OR=1.08; 95%CI=1.001 to1.15; p=0.0025). Patients aged 16-44 and 75+ were less likely to be persistent than patients aged 55-64 (OR= 0.18; 95%CI=0.16-0.21; p<0.0001 and OR=0.67; 95%CI=0.60-0.75; p<0.0001 respectively). Patients registered with the LTI Scheme were more likely to be persistent than from the GMS Scheme (OR=1.35; 95%CI=1.20-1.51; p<0.0001). Patients initiated on sulphonylureas were less likely to be persistent than those initiated on metformin (OR=0.50; 95%CI=0.45 to 0.54; p<.0001). **CONCLUSIONS:** Persistence amongst newly treated T2DM patients appears to be low. Type of OHM, age and scheme were all significantly associated with persistence. Prescribers should pay particular attention to newly treated patients covered under the GMS scheme, at the extremes of age and those initiated on sulphonylureas.

THE IMPACT OF MEMORY PROBLEMS ON DIABETES TREATMENT IN CANADA
Brod M[1], Kongso J[2], Bushnell DM[3]
[1]The Brod Group, Mill Valley, CA, USA, [2]Novo Nordisk A/S, DK-2860 Soborg, Denmark, [3]Health Research Associates, Inc., Seattle, WA, USA
OBJECTIVES: The impact of memory problems (MPs) on patient's insulin taking behavior, functioning, well-being and diabetes management is not well understood. **METHODS:** A 5 country web-based survey was conducted. MPs were defined as: unintentionally forgetting (UF) to take insulin, questioning whether or not insulin had been taken (QT), or questioning how much insulin dose was taken (QD). Data from Canadian respondents were analyzed and compared to the other countries (US, UK, Germany, and China). **RESULTS:** A total of 350 respondents in Canada completed the survey (74.0% Type 1, 52.0% male, mean age of 37.1 years, mean age of diabetes onset of 24.2). The prevalence of MPs was 60.6% (UF), 76.3% (QT) and 44.6% (QD) in the past month with only approximately 1/3 being confident they knew what to do when having an MP. Between 21.5% (QT) and 37.4%(UF) tested their blood glucose and 32.6% (QD) – 51.6% (QT) skipped their insulin dose and waited for next scheduled dose when experiencing a MP, requiring, on average, between 8.5 (QT)–19.1 (UF) hours for return to normal blood glucose ranges. Patients conducted between 1.9 (QT) –5.0 (UF) extra BG monitoring tests the week following the MP and reported moderate negative impacts on their ability to work, physical and emotional functioning. Up to 13.7% missed a work day (UF) and between 10.8% (QT) and 16.8% (UF) visited their health care provider as a result of MP Compared to respondents in the other countries (N=1404), Canadian respondents were reported significantly longer recovery times for returning to normal blood glucose levels following a MP and were significantly more likely to experience hyperglycemia following UF/QD than patients in other countries (p<.05). **CONCLUSIONS:** These findings suggest that MPs have economic implications, impact patients' functioning and well-being and may be serious obstacles to optimal diabetes control.

PDB76
THE IMPACT OF MEMORY PROBLEMS ON DIABETES TREATMENT IN THE UNITED KINGDOM
Brod M[1], Kongso J[2], Bushnell DM[3]
[1]The Brod Group, Mill Valley, CA, USA, [2]Novo Nordisk A/S, DK-2860 Soborg, Denmark, [3]Health Research Associates, Inc., Seattle, WA, USA
OBJECTIVES: The impact of memory problems (MPs) on patient functioning, well-being and diabetes management is not well understood. The purpose of this study was to examine these impacts in the UK and compare these findings to data from US, Germany, Canada, and China). **METHODS:** A 5 country web-based survey examining MPs was conducted. MPs were defined as: unintentionally forgetting (UF) to take insulin, **q**uestioning whether or not insulin had been **t**aken (QT), or **q**uestioning amount of insulin **d**ose (QD). **RESULTS:** A total of 350 UK respondents (52.0% Type 1), 49.1% male, mean age of 40.3, mean age of diabetes onset of 25.5 completed the survey. The prevalence of MPs was 66.6% (UF) forgetting, 84.9% (QT) 56.9% (QD). MPs occurred most frequently when relaxing or doing household jobs. Between 13.7% (UF) – 32.6% (QT) of respondents skipped their insulin dose due to a MP and required between 1.4 (QD)–13.1 (UF) hours, on average, to return to normal blood glucose range. As a result of a MP, patients conducted between 1.7 (QT) –6.8 (UF) extra BG monitoring tests , reported a moderate negative impact on their physical and emotional functioning, as well as their ability to go to or function optimally at work and between 8.1% (QT) and 20.0% (UF) visited/contacted their health care provider . Economic implications include cost of additional BG strips, lost work productivity and health care resource utilization. Compared to respondents in the US, Germany, China and Canada (N=1404), UK respondents conducted significantly more BG tests during the week following a missed dose of insulin were more likely to take a dose of insulin following a MP without testing their BG. **CONCLUSIONS:** These findings suggest that MPs in the UK carry financial burden, impact patients' daily functioning and well-being and may be serious obstacles to optimal diabetes control.

PDB77
DO FIXED-DOSE COMBINATIONS IMPROVE ANTIDIABETIC TREATMENT COMPLIANCE? A STUDY BASED ON FRENCH IMS LIFELINK DISEASE ANALYZER DATABASE
Grandfils N, Le Jeunne P, Maillard C, Solomiac A, Besson A
IMS Health, PARIS LA DEFENSE, France
OBJECTIVES: To compare antidiabetic treatment compliance with regards to the fixed or free treatments combination. **METHODS:** A retrospective study based on the IMS LifeLink™ Diabetes Cohort linked to IMS Disease Analyzer, a longitudinal patient database containing the electronic health records of patients followed-up by a representative panel of French general practitioners. Two cohorts of patients treated both with metformin and DPPIV were constituted, the first one treated with fixed associations ("fixed cohort"), the second one treated with free associations ("free cohort"). Study investigated patients' demographic and clinical characteristics, conditions of use, persistence rates, medication possession ratio (MPR) and proportion of days covered (PDC) of the two cohorts. **RESULTS:** Respectively 2 234 and 8220 patients have been treated with free and fixed antidiabetic associations between 2007 and 2013. Patients are significantly older (66 vs. 64 years, p<0.01) in the free cohort where the proportion of men is significantly lower (56% vs. 63%, p<0.0001). Nevertheless diabetes oldness is the same (about 10 years) in both

cohorts. Daily number of prescribed tablets whatever the therapeutic classes is significantly higher in the free cohort (4.4 per day vs. 3.1, p<0.01). At the end of the first treatment year, significantly more patients of the fixed cohort are still treated by the same association regardless daily dosages or potential add-on treatments (85% vs. 72%, p<0.0001); moreover MPR is the same in both free and fixed cohort (64% and 66% without statistical difference) while PDC is significantly higher in the fixed cohort (60% vs. 54%, P<0.0001). **CONCLUSIONS:** Patients treated by fixed antidiabetic treatments associations seem to be more persistent than these treated by free ones at the end of the first year of treatment. These results will be consolidated soon by comparing two similar sub-cohorts with the same medical profile.

PDB78

IMPACT OF DOSAGE AND SEVEN OTHER FACTORS IN THE ADHERENCE TO ORAL MEDICATION IN PEOPLE WITH DIABETES TYPE 2 IN GERMANY

Pleguezuelo Witte M
IMS Health, London, UK

OBJECTIVES: Low adherence to medications in chronic diseases is a well documented problem that diminishes drug actions. Understanding the factors that can impact adherence is a priority in order to improve it. Diabetes adherence can be influenced by the complexity of administration of some medications as well as patients' attitudes and doctor/patients interaction. This study evaluates the influence of the following variables in the adherence of people with diabetes: Dosage, patient age, gender, substance, price of drug, pack size, pack strength and doctor specialty. **METHODS:** Adherence was calculated using the medical possession ratio (MPR) = unique days of therapy/available days. A logistic regression was conducted to explore the multiple variables affecting the MPR. **RESULTS:** The analyses included 25 months (from July 2009 to July 2011) of longitudinal prescription data for Germany for the ATC class A10 (oral antidiabetic). We found significant effects on adherence for age groups 55-64 (0.0909 p<0.01), 65-74 (0.1266, p<0.0004) and > 75 (0.0868, p< 0.0155), dosage (-0.7646, p<0.0001), gender (-0.0493 p<0.001), pack size (0.0119, p <0.0001), doctor specialty (0.0251, p<0.0286) and 78% of all substances. **CONCLUSIONS:** Adherence seems to be negatively influence by dosage and younger age groups. Price does not seem to have an influence. Perhaps this is because the health care system in Germany reimbursed all oral antidiabetics. Metformin has the greater odds for poor adherence aside from the substances "glitazones". Lower adherence rate might be negatively influenced by the recent warnings for Glitazones. Gender is a weak predictor for adherence. When comparing specialists with general practitioners, the odds of adherence are not very different between them (slightly positive towards the specialist group_ coeff 0.0251, p<0.0286). This could be related to the diabetes management plan that exists in Germany since 2003, which has several aspects, from support to clinicians to training of patients.

PDB80

PSYCHOSOCIAL ADJUSTMENT IN DIABETIC PATIENTS WITH AND WITHOUT DIABETIC FOOT-ULCERS-A COMPARATIVE STUDY

Prabhu VA[1], Doddapaneni S[1], Roy RT[1], Rodrigues GS[2], Unnikrishnan MK[1], Sekhar SM[1]
[1]*Manipal College of Pharmaceutical Sciences, Manipal, India,* [2]*Kasturba Medical college and hospital, Manipal, India*

OBJECTIVES: Diabetes is a chronic illness and 15% of diabetic will develop foot ulceration at some point of their life. Poor psychosocial states have been identified as one of the major risk factors for foot ulcers. Good, regular foot care, strict metabolic control and better adjustment to illness can prevent or reduce suffering effect of the illness. The purpose of this study was to compare the psychosocial adjustment to illness between diabetic patients with and without diabetic foot ulcer (DFU). **METHODS:** A case-control study was conducted in a tertiary care teaching hospital in South India for a period of one year. Psychosocial Adjustment to Illness Scale-Self Report (PAIS-SR) were used to assess psychosocial adjustment to illness. DFU patients (Case) who admitted in the surgery units were included. Diabetic patients without foot ulcers (control) were selected from medicine units during the same period. **RESULTS:** The study participants were 84 people with diabetic foot ulceration and 84 people without diabetic foot ulceration. There were no significant differences between the two groups for gender, age and marital status. A significant difference was found between two groups for education level (p= 0.001) occupational status (p=0.045). A significant difference was found between the groups in relation to smoking (p=0.000) and drinking (p=0.000). There were a significant difference seen in PAISSR scores (lower scores means better adjustments) between the two groups (p=0.000) representing subjects without DFU had better psychosocial adjustment than subjects with DFU. **CONCLUSIONS:** The study concluded that compared to patients without DFU, patients with diabetic foot ulcer had poorer metabolic control, low educational level, bad social habits. Longer duration of diabetes, longer period of hospitalization, low level of disease knowledge and more incidence of comorbid conditions.

PDB81

DIMINISHING MARGINAL DISUTILITY OF HYPOGLYCAEMIC EVENTS

Lauridsen JT[1], Lønborg J[2], Gundgaard J[3], Jensen HH[2]
[1]*Centre of Health Economics Research (COHERE), Department of Business and Economics, University of Southern Denmark, Odense, Denmark,* [2]*Incentive Partners, Holte, Denmark,* [3]*Novo Nordisk A/S, Søborg, Denmark*

OBJECTIVES: Hypoglycaemic events are proven to have a negative impact on the health-related quality of life (HRQoL) of patients with diabetes. The negative impact of hypoglycaemia on HRQoL may be evaluated via disutility scores. The aim of this study was to assess the marginal impact of non-severe hypoglycaemic events on HRQoL and to investigate the functional form of the disutility of hypoglycaemic events. **METHODS:** Published disutility values from a large-scale, web-based time-trade-off study (TTO) conducted in UK, USA, Canada, Germany and Sweden with 8,286 respondents, were used as a basis for the analysis of non-severe daytime and nocturnal hypoglycaemia. Non-linear regression curves were fitted to the total disutility of different frequencies of hypoglycaemic events. A weighting scheme was used to allow each data point (one event quarterly, one monthly, one weekly or three weekly) to reflect the range of hypoglycaemic frequencies the data point represented. Non-parametric bootstrapping was applied to characterise the uncertainty of the marginal disutility. **RESULTS:** Power function regression curves were estimated at $U_d=0.0141x^{0.3393}$ and $U_d=0.0221x^{0.3277}$, where U_d is disutility and x is the annual hypoglycaemic event rate, for non-severe daytime and non-severe nocturnal events. An increase from 0 to 1 hypoglycaemic events per year, produced a utility decrease of 0.0141 for non-severe daytime, and 0.0221 for non-severe nocturnal, whereas an increase of one hypoglycaemic event per year for a patient who experiences 25 hypoglycaemic events per year produces a marginal impact of 0.0006 and 0.0008 for non-severe daytime and non-severe nocturnal, respectively. **CONCLUSIONS:** If patient-level data are available, non-linear functions estimated with TTO data might improve the precision of the measured impact of hypoglycaemic events. The results seen here illustrate diminishing marginal disutility with increasing numbers of hypoglycaemic events. This fits with the phenomenon of "first being worst" with regards to hypoglycaemia.

PDB82

QUALITY OF LIFE IN PATIENTS WITH TYPE 2 DIABETES IN POLAND: COMPARISON WITH GENERAL POPULATION USING EQ-5D QUESTIONNAIRE

Golicki D[1], Dudzinska M[2], Zwolak A[3], Tarach JS[2]
[1]*Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland,* [2]*Department of Endocrinology, Medical University of Lublin, Lublin, Poland,* [3]*Chair of Internal Medicine and Department of Internal Medicine in Nursing, Medical University of Lublin, Lublin, Poland*

OBJECTIVES: To compare the health related quality of life (HRQoL) in Polish patients with type 2 diabetes (T2D) and in matched sample from the general population. **METHODS:** Data on HRQoL came from two non-interventional studies: prospective study of patients with T2D and EQ-5D Polish general population norms study. Analysis of HRQoL was conducted in four separate age groups: 32–44, 45–54, 55–64 and above 65 years. We analyzed: an subjective and objective assessment of HRQoL (EQ VAS and EQ-5D index) and the presence of restrictions within five dimensions of the EQ-5D descriptive part. **RESULTS:** A total of 274 patients with T2D and 214 representatives from population norms study, were included. EQ VAS was systematically lower in diabetic patients compared to the general population, and decreased with age (68.2 vs 83.9, 62.4 vs 79.2; 54.9 vs 78.1, 50.2 vs. 69.8 in consecutive age groups). A similar relationship was observed with EQ-5D index. The largest mean differences were observed among subjects aged 55-64 years (EQ VAS: 23.2, EQ-5D index: 0.085). In three domains: self-care, usual activities and anxiety/depression, patients with diabetes above 45 years of age, reported significantly more problems than respondents from the general population. **CONCLUSIONS:** Both subjective and objective HRQoL in patients with T2D is lower than in respondents of similar age from the general population. Compared with type 2 diabetic populations from other countries, Polish patients characterize by a relatively high HRQoL objective assessment and very low subjective assessment.

PDB83

UTILITIES FOR TYPE 2 DIABETES MELLITUS AND ASSOCIATED COMPLICATIONS

Shingler SL[1], Fordham B[1], Evans M[2], Thompson G[3], Schroeder M[3], Lloyd AJ[1]
[1]*Oxford Outcomes, An ICON plc Company, Oxford, UK,* [2]*University Hospital Llandough, Cardiff, UK,* [3]*Janssen UK, High Wycombe, UK*

OBJECTIVES: The impact of Type 2 diabetes mellitus (T2DM) on health related quality of life (HRQL) is complex due to the burden of disease, lifelong treatment requirements and comorbidities. This study aimed to capture UK societal utility values for health states associated with T2DM and treatment-related adverse events (AEs) to assess the burden of the disease and common AEs. **METHODS:** Nine health state descriptions were developed (from a literature review and patient and clinician qualitative input) depicting the burden associated with T2DM and treatment related AEs. These were mild/moderate urinary tract infection (UTI); severe UTI; mycotic infection; moderate hypoglycaemic events; severe hypoglycaemic events; fear of hypoglycaemia; gastrointestinal symptoms; and hypovolaemic events. Members of the UK general public (n=100) valued these states using the time trade-off (TTO) methodology to elicit utility values (between 0= dead, 1= full health). Regression analysis was conducted to understand influence of age and gender. **RESULTS:** All treatment-related AEs were found to have a significant effect on utility. From the T2DM baseline state (0.92), the experience of AEs was associated with the following disutility: T2DM with hypovolaemic events (0.08); T2DM with mild/ moderate UTIs (0.09); T2DM with moderate hypoglycaemic events (0.11); T2DM with severe hypoglycaemic events (0.15); T2DM with fear of hypoglycaemia (0.15); T2DM with severe UTIs (0.19); T2DM with GI symptoms (0.24); andT2DM with mycotic infection (0.25); Males consistently scored the states with significantly lower utility values, but no significant age effects emerged. **CONCLUSIONS:** Findings suggest that adverse events in T2DM can be a burden for some individuals. The study indicates the potential importance of including information regarding AEs in economic evaluations. Although some states were rated severely in terms of utility, in reality, many of these only last a few days, therefore having a minimal quality adjusted life year (QALY) impact.

PDB84

HEALTH-RELATED QUALITY OF LIFE AND UTILITY IN PATIENTS WITH DIABETIC FOOT SYNDROME - AN EQ-5D SURVEY IN POLAND

Sobol E[1], Macioch T[2], Krakowiecki A[2], Mrozikiewicz-Rakowska B[2], Mienicka A[1], Mlynarczuk M[1], Kasprowicz M[2], Paweska J[2], Karnafel W[2], Hermanowski TR[2]
[1]*Medical University of Warsaw Central Clinical Hospital, Warsaw, Poland,* [2]*Medical University of Warsaw, Warsaw, Poland*

OBJECTIVES: Foot ulceration is a major cause of disability in diabetes. The aim of this study was to estimate influence of severity of diabetic foot ulceration on HRQoL. **METHODS:** A survey among DFS (Diabetic Foot Syndrome) patients with active foot ulceration treated in ambulatory care was conducted. The PEDIS scale was used to classify severity of ulceration. To assess the impact of diabetic ulceration on HRQoL in DFS patients the EQ-5D-3L questionnaire was used. Utility scores were calculated based on Polish EQ-5D value set (Golicki et al.) **RESULTS:** Between April 2012 and May 2013 185 patients were questioned directly. 179 of them (131 males) completed the EQ-5D questionnaire and had full record on ulceration severity (the PEDIS scale). The mean age of patients was 61.9±10.6 years. Diabetes type 2 was diagnosed in 150 (83.8%) patients while diabetes type 1 in 26 (14.5%). Other type of diabetes was diagnosed in 2 persons and data on one were missing. Mean time from the diagnosis of diabetes was 18.0±11.1 years. 99 (55%) and 69 (39%) patients had grade 1 and 2 perfusion, respectively. The mean ulceration size was 6.2±13.4 cm^2. 74 (41.3%), 65 (36.3%) and 40 (22.3%) patients had grade 1, 2 and 3 depth/tissue loss respectively. 84 (46.9%), 55 (30.7%) and 36 (20.1%) patients had grade 1, 2 and 3 infection, respectively. Most patients (89.4%) had loss of protective sensation (grade 2 sensation). Mean utility value in overall population was estimated at 0.618±0.320. Very week negative correlation was found between ulceration size and utility value. Despite some differences in utility value in patients with different perfusion grade no strict correlations between severity of ulceration and utility values were found. **CONCLUSIONS:** There is little or no strict correlation between severity of ulceration measured with the PEDIS scale and HRQoL measured with the EQ-5D.

PDB85

DIABETIC PATIENTS IN PRIMARY CARE: SELF-PERCEPTION AND SATISFACTION. COMPARATIVE STUDY SPAIN VERSUS EUROPE

Sánchez-Piedra C, García-Pérez S, Sarría Santamera A
Agencia de Evaluación de Tecnologías Sanitarias (AETS), Madrid, Spain

OBJECTIVES: EUprimecare is an European Union project aimed at analyzing the costs and quality of the different models of primary care (PC) in Europe. The aim of this study is to analyze the management of diabetic patients in PC services in Spain compared to other European countries, the satisfaction of these patients with PC services and their self-perceived health status. **METHODS:** We conducted a population survey by telephone among PC users in each of the consortium countries (Germany, Spain, Estonia, Finland, Hungary, Italy and Lithuania). The questionnaire included information on sociodemographic characteristics, health status, satisfaction, utilization of PC services, and frequency of some interventions carried out by PC professionals. The survey was conducted to 431-432 PC users in each country (Ntotal = 3020). **RESULTS:** The percentage of diabetic patients in Spain was 6.7% (N = 29), lower than the overall average (9.1%). Eighty three percent of patients living in Spain were diagnosed by their PC physicians compared with 73% of the European average. Eighty six percent of patients in Spain said that they were being treated for diabetes (EU average = 84%) and in 88% of these cases the treatment was prescribed by their PC doctor (EU average = 70%). Only 6.9% of patients said their health was poor or very poor, the lowest proportion of all countries assessed. The overall satisfaction with PC services among diabetic patients was 4.10 points on a scale of 1 to 5. Satisfaction in Spain was below the global average for all the items measured. **CONCLUSIONS:** Diabetic patients in Spain are more frequently controlled by PC professionals than in other European countries. These patients have a better self-perceived health status and the results of this study suggest a lower level of dissatisfaction with the services provided by PC.

PATIENTS PREFERENCES REGARDING THE TREATMENT OF TYPE II DIABETES MELLITUS: COMPARISON OF BEST-WORST SCALING AND ANALYTIC HIERARCHY PROCESS

Mühlbacher AC, Bethge S, Kaczynski A, Juhnke C
Hochschule Neubrandenburg, Neubrandenburg, Germany

OBJECTIVES: There is limited evidence available regarding patient preferences for treatment alternatives, including those treatment characteristics that have greatest influence on the perceived value, and how this knowledge can be used in health care decision-making. The objective of this study was to identify and elicit patient preferences for treatments in Type-II-Diabetes in different patient groups. **METHODS:** In order to elicit patient preferences this study used an explorative qualitative approach in combination with quantitative survey techniques. Literature research and semi-structured interviews (N=15) were the basis of quantitative elicitations (N=388) using Analytic-Hierarchy-Process (AHP) and Best-Worst-Scaling (BWS). The study aimed at the determination of the relative importance of patient-relevant decision criteria as well as to compare two methods of measuring preference. In total, seven therapy-related attributes (three levels each) were tested. The sample contained patients receiving oral anti-diabetics (OAD) (N=200) or insulin (N=188). **RESULTS:** The qualitative study identified 22 patient-relevant treatment-characteristics. Out of these the seven most important were included in AHP and BWS. The AHP- as well as BWS-surveys resulted in a dominance of the attribute "HbA1c-Level", for both OAD- and Insulin-patients. In the OAD-group AHP and BWS independently showed the same ranking of the three attributes: "Delay of Insulin-Therapy" (Rank 2), "Occurrence of hypoglycemia" (Rank 3) and "Weight changes" (Rank 4). In the Insulin-group "Occurrence of hypoglycemia" was ranked second using AHP and third within BWS. "Weight changes" were ranked equally in both methods. However their relevance among different patient groups changed. **CONCLUSIONS:** In both patient-groups AHP and BWS show similar results. Nonetheless both groups have different horizons of experience and differ in the ranking of decision criteria. For the first time the methods of AHP and BWS were used to assess patients' preferences for different characteristics of treatment in Type-II-Diabetes, as well as the influence of those criteria on the patient benefit.

PDB87

THE DIABETIC PERIPHERAL NEUROPATHIC PAIN IMPACT (DPNPI) MEASURE – PSYCHOMETRIC VALIDATION OF A NEW PATIENT REPORTED OUTCOME MEASURE

Brod M[1], Ramasamy A[2], Bushnell DM[3], Blum SI[2]
[1]*The Brod Group, Mill Valley, CA, USA,* [2]*Forest Research Institute, Jersey City, NJ, USA,* [3]*Health Research Associates, Inc., Seattle, WA, USA*

OBJECTIVES: The Diabetic Peripheral Neuropathic Pain Impact (DPNPI) Measure is a patient-reported outcome (PRO) measure developed in accordance with the FDA PRO guidance for assessing the impacts of living with Diabetic Peripheral Neuropathic Pain (DPNP). A validation study was conducted to evaluate the measurement model and properties of the 27-item draft version of the DPNPI. **METHODS:** A non-interventional, observational, survey-based validation study enrolled outpatients from clinical sites in the United States. Recruitment included diagnosed DPNP patients (aged 18-80) both treated and untreated with prescription agents. Subjects completed a retest survey via mail two weeks after their in-clinic assessment. Analyses included assessment of the measurement model (factor analysis), reliability (internal consistency, test-retest) and validity (content, known-groups) of the DPNPI. IRT was utilized to evaluate item fit and function. **RESULTS:** Out of 124 subjects (56% male, mean age 62.8),105 completed the retest survey. Nine items from the draft version were deleted due to conceptual issues and/or redundancy. Factor analysis confirmed the three hypothesized domains: *Physical/Mobility Function*; *Daily Life*; *Sleep*. All domains and the total score were internally consistent (0.91 to 0.96) and reproducible (0.84 to 0.91). All *a priori* convergent validity hypotheses were confirmed ($p<.001$) with moderate-strong association between the total and/or subscale scores on the DPNPI measure and other logically related measures (range 0.43 to 0.79). Additionally, all *a priori* hypothesized associations for content and known-group validity of domains and total score were confirmed ($p<.001$) and IRT fit statistics were within acceptable range. **CONCLUSIONS:** The final 18-item version of the DPNPI can be considered a well-designed, valid and reliable measure of the impact of DPNP on patients' daily lives and physical functioning. This measure can be used as an endpoint in clinical trials to assess impacts related to DPNP. Further study is needed to understand the responsiveness of the DPNPI.

PDB88

HOW HYPOGLYCEMIA IMPACTS QUALITY OF LIFE AND TREATMENT SATISFACTION IN TYPE 2 DIABETES MELLITUS PATIENTS ON BASAL-BOLUS INSULIN THERAPY?

Ionova TI[1], Odin VI[2], Nikitina TP[1], Kurbatova KA[1], Shablovskaya NE[1]
[1]*Multinational Center for Quality of Life Research, Saint-Petersburg, Russia,* [2]*Military Medical Academy, Saint-Petersburg, Russia*

OBJECTIVES: Hypoglycemia burden is the most common problem in patients with type 2 diabetes mellitus (T2DM) receiving insulin treatment. However, how hypoglycemia affects quality of life (QoL) and treatment satisfaction in this patient population is less clear. We aimed to study the QoL and treatment satisfaction in T2DM patients on basal-bolus insulin therapy with the absence and presence of different types of hypoglycemia. **METHODS:** A total of 500 T2DM patients receiving basal-bolus insulin therapy for at least 6 months were enrolled in the survey: male/female 122/378; mean (SD) age 61.8 (8.4) yrs; mean (SD) time from T2DM diagnosis 12.8 (6.9) yrs. Mean HbA1c level was 8.3%. Patients were classified as with no, non-severe, severe and nocturnal hypoglycemia events during the last month. Patients filled out SF-36 and Patient Treatment Satisfaction Questionnaire. The impact of hypoglycemia on QoL and treatment satisfaction was examined through multivariate regression, adjusting for sociodemographics and disease status. QoL and treatment satisfaction scores were analyzed using t-test, ANOVA, Chi-square test. **RESULTS:** After adjustment, QoL and treatment satisfaction decreased with the increase of hypoglycemia events ($p<0.05$). Patients with hypoglycemia had significantly lower QoL scores for 6 out of 8 SF-36 scales as compared to those without hypoglycemia ($p<0.05$). Treatment satisfaction was higher in patients without hypoglycemia than in those with hypoglycemia (mean score 7.25 vs 8.0; $p=0.01$). Patients with nocturnal and severe hypoglycemia had significant reduction of role-physical, social functioning, vitality and pain as compared to patients with non-severe hypoglycemia ($p<0.05$). The percentage of patients who were completely dissatisfied or poorly satisfied with treatment was higher in the group with severe or/and nocturnal hypoglycemia than in those with non-severe hypoglycemia (20% vs 8%; $p=0.002$). **CONCLUSIONS:** Hypoglycemia has negative impact on QoL and treatment satisfaction in T2DM patients. Severe and nocturnal hypoglycemia significantly decreases QoL and reduces treatment satisfaction.

PDB89

ASSESSING QUALITY OF LIFE IN ADULT GROWTH HORMONE DEFICIENCY: FURTHER DEVELOPMENT OF THE QOL-AGHDA

Graham JE, McKenna S, Wilburn J, Twiss J
Galen Research Ltd., Manchester, UK

OBJECTIVES: The QoL-AGHDA assesses quality of life (QoL) specific to adults with Growth Hormone Deficiency (GHD). Questionnaire content was derived from qualitative interviews conducted with individuals who had the condition. Since its development a number of new language adaptations have been made for Europe (9), Eastern Europe (4), and Central and South America (2). New language versions of the measure were required for use in two major new multinational clinical trials. These were for Greece, Hungary, Israel, Romania, Russia, Slovakia, Ukraine and the US (Spanish). **METHODS:** The dual-panel methodology was employed to translate each of these measures. This approach has been used in the adaptation of all needs-based QoL measures. Two panels are held. The first employs local people who are also proficient in English who agree the most appropriate translation for the instructions and items. The second panel involves lay people who ensure that the level of language is appropriate and will be understood by future respondents. Following translation, cognitive debriefing interviews were conducted with adults with GHD in each country. **RESULTS:** No major difficulties were experienced in producing

the translations. Ten to fifteen cognitive debriefing interviews were conducted in each country. Interviewees reported the measure to be easy to understand and complete and that the content was relevant without missing important issues. **CONCLUSIONS:** The standards set by the existing UK version of the QoL-AGHDA are high with internal consistency and test-retest reliability above 0.90. Construct validity was also demonstrated by the measure's ability to distinguish between patients according to self-perceived general health and by correlating scores with those on the General Well Being Index (> 0.70). Completed validations have obtained a similar psychometric quality. Similar studies are underway to evaluate the formal construct validity and reproducibility of these new language versions.

PDB90

USEFULNESS OF THE HYPOGLYCEMIA PERSPECTIVES QUESTIONNAIRE (HPQ) IN MANAGEMENT OF PATIENTS WITH TYPE 2 DIABETES

Ionova TI, Nikitina TP, Kurbatova KA, Shablovskaya NE
Multinational Center for Quality of Life Research, Saint-Petersburg, Russia

OBJECTIVES: Assessment of patient's perspectives of hypoglycemia burden may be of value to provide adequate management of type 2 diabetes (T2D) patients. The Hypoglycemia Perspectives Questionnaire (HPQ) is a new multidimensional instrument assessing patient's experience of hypoglycemia. The goal of this study was to test the practicability and utility of HPQ-Russian version (HPQ-R) by means of its psychometric performance. **METHODS:** A total of 200 T2D patients receiving oral hypoglycemic therapy (59% – metformin; 41% – metformin plus vildagliptin or sulphonylureas, SU) were enrolled in the study: male/female 71/129; mean age – 58.7 yrs; mean disease duration – 4.1 yrs. Mean HbA1c level was 7%. All the patients completed HPQ-R at baseline and after 2-3 months of treatment. Patients and physicians were interviewed to test practicability of the instrument. Construct validity, reliability and sensitivity of the HPQ-R were assessed to provide its utility. **RESULTS:** Both patients and physicians acknowledged the comprehensiveness of the tool for revealing hypoglycemia-related problems; physicians used information from it for their decision-making. It was easily understood by, and administered to patients: 2.8% of missing values. An exploratory factor analysis revealed a strongly dimensional instrument (explained 70% of total pooled variance), with Chronbach alphas $\geq$0.9 for 6 out of 7 scales. Reproducibility of the tool was shown by comparing HPQ-R scores at two time-points for patients with effective HbA1c control receiving metformin plus vildagliptin: r=0.53–0.87 for 5 scales ($p<0.05$). HPQ-R scores were lower in patients with hypoglycemia events than in patients without hypoglycemia as well as in patients with severe hypoglycemia than in patients with non-severe hypoglycemia ($p<0.05$). Increased occurrence of hypoglycemia events and worsening of scores for 4 HPQ scales was shown after switch from monotherapy to therapy metformin plus SU ($p<0.05$). **CONCLUSIONS:** Thus, the HPQ-R is a practical and useful tool for comprehensive assessment of hypoglycemia experience in T2D patients.

PDB91

BENEFITS OF VILDAGLIPTIN PLUS METFORMIN COMBINATION THERAPY IN TYPE 2 DIABETES MELLITUS (T2DM) FROM PATIENT'S PERSPECTIVE: QUALITY OF LIFE (QOL) AND HYPOGLYCEMIA BURDEN ANALYSIS

Ionova TI[1], Odin VI[2], Nikitina TP[1], Kurbatova KA[1], Shablovskaya NE[1]
[1]*Multinational Center for Quality of Life Research, Saint-Petersburg, Russia,* [2]*Military Medical Academy, Saint-Petersburg, Russia*

OBJECTIVES: Patients' preferences and evaluation of treatment benefits/risks from patient's perspective are increasingly being considered in decision-making regarding treatment option. The goal of this prospective, open, observational study was to evaluate QoL and hypoglycemia burden in T2DM patients treated with vildagliptin and metformin as compared to those treated with sulphonylureas (SU) and metformin. **METHODS:** A total of 194 T2DM patients previously on oral monotherapy were enrolled in the study. 111 patients were selected by their treating physician to receive vildagliptin and metformin (cohort 1 – mean age 58 yrs; male/female 43/68) and 83 patients – SU and metformin (cohort 2– mean age 58.6 yrs; male/female 27/56). Patient-reported outcomes were assessed at base-line and after approximately 3 mo using the SF-36 and the Hypoglycemia Perspectives Questionnaire (HPQ). For comparisons adjustment for age, sex, disease duration, complications and comorbidities was made. **RESULTS:** QoL parameters for all SF-36 scales were significantly higher in cohort 1 as compared to cohort 2 after 3 mo of therapy ($p<0.01$). Switch to vildagliptin plus metformin therapy was accompanied with remarkable increase of Integral QoL Index ($p<0.0001$) whereas no changes of Integral QoL Index were observed after switch to SU plus metformin. After 3 mo of combination therapy the number of self-reported symptomatic hypoglycemic events was 16% in cohort 1 versus 70% in cohort 2; 12% of pts had severe hypoglycemic events in cohort 2. SU plus metformin therapy was accompanied with significant hypoglycemia burden – after switching worries, awareness and symptom concern increased ($p<0.001$). No changes were observed in cohort 1. The changes in glycemic control were the same in both cohorts: DHbA1c=0.8%. **CONCLUSIONS:** Benefits of vildagliptin plus metformin combination therapy in terms of improved QoL and reduced hypoglycemia burden in T2DM patients were shown. This therapy is an effective and preferable treatment in daily medical practice from patient's perspective.

PRELIMINARY TESTING OF THE SAGIT TOOL: A TOOL TO HELP ENDOCRINOLOGISTS IN THEIR MANAGEMENT OF PATIENTS WITH ACROMEGALY IN CLINICAL PRACTICE

Giustina A[1], Bevan J[2], Bronstein M[3], Casanueva F[4], Chanson P[5], Petersenn S[6], Truong Thanh XM[7], Massien C[7], Dias Barbosa C[8], Guillemin I[8], Arnould B[8], Melmed S[9]
[1]*Piazzale Spedali Civili, Brescia, Italy,* [2]*Aberdeen Royal Infirmary, Aberdeen, UK,* [3]*Hospital das Clinicas, Sao Paulo, Brazil,* [4]*Universidad de Santiago de Compostela, Santiago de Compostela, Spain,* [5]*Hôpital Bicêtre, Kremlin-Bicêtre, France,* [6]*ENDOC Center for Endocrine Tumors, Hamburg, Germany,* [7]*Ipsen Pharma, Boulogne Billancourt Cedex, France,* [8]*Mapi, Lyon, France,* [9]*Cedars Sinai Medical Center, Los Angeles, CA, USA*

OBJECTIVES: Acromegaly is a rare, chronic, hormonal disorder caused by excessive growth hormone (GH) and insulin-like growth factor 1 (IGF-1) production resulting predominantly from pituitary adenoma. The objective was to test endocrinologist acceptability of the newly developed SAGIT tool in clinical practice. **METHODS:** SAGIT (**S**igns and symptoms - **A**ssociated comorbidities - **G**H concentration level – IGF-1 – **T**umour) is a Clinician-Reported Outcomes (ClinROs) tool developed with international experts in acromegaly; it allows patient classification and description in a standardised manner. The tool was pre-tested for acceptability, understanding and ease of use with practicing endocrinologists in France, Germany, UK, Spain, Italy and Brazil (n=2 per country) using the PRAgmatic Content and face validity Test (PRAC-Test). The endocrinologists completed the SAGIT tool prior to and following an intervention (therapeutics or surgery) for three patients each (n=36). Once completed, a one-hour phone interview was conducted with each endocrinologist to collect their feedback on the tool. **RESULTS:** The tool was well accepted and deemed concise (n=11) and informative (n=10) by the endocrinologists. Several points were raised that illustrate its usefulness in clinical practice, including the removal of the subjectivity when assessing the disease severity, the possibility of rapid evaluation of the control/progression of acromegaly or of a treatment response, and the possibility for standardisation across countries. Key recommendations for improvements were the need to include: 1) instructions to facilitate the understanding and the use of the tool; 2) definitions of rules and recommendations for patient management; and 3) addition of other signs and symptoms and further details about tumour size to better reflect their clinical cases. **CONCLUSIONS:** SAGIT is a useful tool for endocrinologists to accurately stage and classify acromegaly patients in clinical practice. It is currently being piloted in a cross-sectional study. Validation of scoring rules will confirm the utility of the tool to improve patient management.

PDB93

A DISCRETE CHOICE EXPERIMENT TO EVALUATE BLOOD GLUCOSE METER PREFERENCES IN PEOPLE WITH TYPE 1 AND TYPE 2 DIABETES IN THE UNITED KINGDOM

Perard R[1], Orme ME[2]
[1]*Montpellier University, Montpellier, France,* [2]*ICERA Consulting Ltd., Swindon, UK*

OBJECTIVES: Regular self-monitoring of using a blood glucose meter helps diabetic patients to adjust their management strategies proactively, thus avoiding diabetic complications which place a burden on health care resources. The aim of this study was to elicit diabetic patients' preferences for different blood glucose meter attributes. **METHODS:** A cross-sectional, web-based survey of UK patients with Type 1 and type 2 diabetes was conducted in January 2013 and preferences for five key attributes associated with blood glucose meters were estimated using a discrete choice experiment (DCE) framework. A foldover design and optimised orthogonal differences were considered, but the final choice experiment was a Bayesian d-efficient design. Responses were analysed using a conditional logit model in STATA 12.1. **RESULTS:** Out of 447 responses, 406 (90.83%) patients were suitable for inclusion in the DCE analysis. Statistically significant differences ($p<0.05$) were found between the Type 1 and Type 2 sub-groups when comparing responder characteristics (years diagnosed, age, tests per day, number of comorbidities). Regarding glucose meter attributes, Type 1 respondents considered the 'time to test' to be the most critical factor and were willing to trade a compact device (2.61 units), or convenience (1.37 units) for a device that could produce test results in under 30 seconds. Type 2 respondents preferred the low maintenance attribute and were most willing to trade a compact device (2.72 units) or convenience (1.37 units) for this attribute. **CONCLUSIONS:** This is the first DCE to examine the impact of blood glucose meter attributes on blood glucose meter choice and adherence. Devices that provide value added features such as offline storage of data and additional data analysis will be valued by both Type 1 and Type 2 patients whereas a compact device is less valued.

PDB94

GROWTH MIXTURE MODELING (GMM) TO DETERMINE TREATMENT EFFECTS OF CANAGLIFLOZIN VERSUS SITAGLIPTIN ON WEIGHT-RELATED QUALITY OF LIFE (WRQOL) IN SUBJECTS WITH TYPE 2 DIABETES MELLITUS (T2DM)

Stull DE[1], Houghton K[1], Traina SB[2]
[1]*RTI Health Solutions, Didsbury, Manchester, UK,* [2]*Janssen Global Services, LLC, Raritan, NJ, USA*

OBJECTIVES: Canagliflozin is a sodium glucose co-transporter 2 inhibitor developed for T2DM. GMM was used to evaluate the effects of canagliflozin versus sitagliptin on WRQoL in subjects with T2DM. **METHODS:** Data were from 2 multinational, randomised, double-blind, Phase 3 trials: 1) subjects inadequately controlled with metformin (N=1,284) receiving canagliflozin 100 or 300 mg, sitagliptin 100 mg, or placebo for 26 weeks with a 26-week extension (placebo switched to sitagliptin; dual therapy); and 2) subjects inadequately controlled with metformin plus a sulphonylurea (N=755) receiving canagliflozin 300 mg or SITA 100 mg for 52 weeks (triple therapy). WRQoL was assessed using the Impact of Weight on Quality of Life-Lite (IWQOL-Lite) questionnaire. GMM was used to assess heterogeneity within samples to identify data-driven subgroups with differential changes in IWQOL-Lite total scores. **RESULTS:** In both trials, GMM identified 2 subgroups per treatment arm: "subgroup 1" (81% and 87% of total trial samples) started with high scores (~85 points), while "subgroup 2" (19% and 13% of total trial samples) started with low scores (44-53 points). Subgroup 1 scores remained high throughout both trials for all treatments. For the dual-therapy trial, subgroup 2 subjects treated with canagliflozin 100 or 300 mg had improvement (2.1 and 5.4 points, respectively), while those treated with sitagliptin 100 mg had declining scores (–4.0 points) over the course of the trial ($P<0.05$). For the triple therapy trial, all subgroup 2 subjects improved; improvement was significantly greater with canagliflozin 300 mg versus sitagliptin 100 mg (19.6 vs 4.8 points; $P<0.05$). In both trials, there were significant differences between the subgroups based upon baseline demographic, clinical, and patient-reported characteristics. **CONCLUSIONS:** GMM applied to these trial data enabled identification of treatment effects that were masked by standard statistical techniques. Heterogeneity should be considered when analysing WRQoL data.

PDB95
WEIGHT- AND HEALTH-RELATED QUALITY OF LIFE (WRQOL AND HRQOL) WITH CANAGLIFLOZIN (CANA) VERSUS SITAGLIPTIN (SITA) IN SUBJECTS WITH TYPE 2 DIABETES MELLITUS (T2DM) ON BACKGROUND METFORMIN
Traina SB[1], Ho KF[2]
[1]Janssen Global Services, LLC, Raritan, NJ, USA, [2]STAT-TU Inc., Toronto, ON, Canada
OBJECTIVES: CANA is a sodium glucose co-transporter 2 inhibitor developed for the treatment of T2DM. In a Phase 3 multi-national, randomised, double-blind, placebo- and active-controlled study, CANA improved glycaemia and reduced body weight and systolic blood pressure compared with placebo and SITA in subjects with T2DM on background metformin. Herein we report post-hoc analyses of the HRQoL and WRQoL data. **METHODS:** WRQoL and HRQoL were measured using the Impact of Weight on Quality of Life-Lite (IWQOL-Lite) and the 36-item Short Form (SF-36) at baseline, Week 26, and Week 52; with both instruments, higher scores indicate better quality of life. Data were analysed for CANA 100 (n=368) and 300 mg (n=367), and SITA 100 mg (n=366). Least-squares mean changes were evaluated using ANCOVA models; gender, anti-hyperglycaemic adjustment, baseline score, and treatment as covariates. **RESULTS:** Improvements from baseline to Weeks 26 and 52 were detected for WRQoL total, physical function, and self-esteem scores in the CANA (both doses) and SITA groups (95% CI excludes zero), and for the other WRQoL domains, there was either improvement or no difference. A comparison of CANA 300 mg versus SITA at Week 26 suggests a difference in physical function (p=0.0374). Improvements from baseline to Weeks 26 and 52 were also detected for HRQoL general health scores in the CANA (both doses) and SITA groups (95% CI excludes zero), and for other domains, there was either improvement or no difference. Other HRQoL results suggest possible differences in bodily pain (Week 26, CANA 100 mg vs. SITA, p=0.0518) and the mental component summary score (Week 52, CANA 300 mg vs. SITA, p=0.0908). **CONCLUSIONS:** CANA and SITA were associated with improvements in WRQoL and HRQoL over 1 year in dual therapy. Results suggest that CANA is associated with a greater positive impact on patients versus SITA.

PDB96
ASSESSING THE RELATIONSHIP BETWEEN THE DIABETES HEALTH PROFILE AND DIABETES SPECIFIC CLINICAL INDICATORS: CASE FOR TAILORED THERAPEUTICS
Mulhern B[1], Meadows K[2], Churchman D[3]
[1]University of Sheffield, Sheffield, UK, [2]DHP Research & Consultancy Ltd., Banbury, UK, [3]University of Oxford, Oxford, UK
OBJECTIVES: With the increasing use of patient reported outcome measures in diabetes, it is important to understand which dimensions are most relevant to clinical indicators, and are the most predictive when assessing clinical change over time. This is important as the PROM scores can help inform the development of tailored therapeutics by highlighting the psychosocial functioning and quality of life impacts of different treatments. The aim of this study is to assess the relationship between the Diabetes Health Profile (DHP-18) and diabetes specific clinical variables to investigate how the measure can be used in the assessment of the impacts of different related complications and treatments. **METHODS:** The relationship between the DHP-18 and a number of variables, including diabetes specific and co-morbid health complications and length of time diagnosed were assessed. This was done cross-sectionally and longitudinally using a large dataset of Type 1 and Type 2 people with diabetes (n=1,802) collected in one United Kingdom health authority area. The analysis was carried out using Ordinary Least Squares and Logit regression. **RESULTS:** The Psychological distress domain is significantly associated with eye and foot related complications, and a number of co-morbid conditions including depression. The Barriers to activity domain is significantly associated with eye and foot related complications, duration of diabetes and a range of co-morbid conditions. The Disinhibited eating domain is related to duration of diabetes and co morbid conditions such as bone and lung disease. The number of associated problems was also a key predictive variable. **CONCLUSIONS:** The findings indicate that there is relationship between psychosocial functioning as measured by the DHP-18 and a range of clinical indicators. Tailored therapeutics can be used to change or reduce clinical concerns while also impacting on a patient's psychosocial functioning and quality of life, and the DHP can be used to efficiently measure this.

PDB97
A RELATIONSHIP BETWEEN BODY MASS INDEX AND HEALTH-RELATED QUALITY OF LIFE AMONG KOREANS WITH DIABETES: THE KOREA NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY
Lee JY, Lee EK
Sungkyunkwan University, Suwon-si, Gyeonggi-do, South Korea
OBJECTIVES: Little is known about the impact of body mass index (BMI) on health-related quality of life (HRQoL) for diabetics in the Korean population. The aim of this study was to estimate the association between BMI and HRQoL of type 2 diabetic patients in Korea. **METHODS:** This study is a cross-sectional analysis of adults who participated in 4th (2007-2009) and 5th (2010-2011) Korean National Health and Nutritional Examination Survey(total, 42,347 participants). HRQoL was measured by EuroQoL five-dimension (EQ-5D) and its association with BMI was investigated in Korean diabetic patients, especially those who did not have adequate control of blood glucose (HbA1c ≥6.5). Multivariate linear regression was performed at p-value of 0.05 with the use of SAS software, version 9.2. **RESULTS:** Out of 42,347 participants, 9.04% had diagnosed of diabetes. Among 2,726 diabetic patients in Korea, we assessed the association in 1,838 patients (median age 63) whose diabetes was not adequately controlled. We found that BMI was significantly negative associated with HRQoL(-0.0038, p-value <0.001), after adjusting for age, sex, education, income, marital status, smoking status, alcohol, HbA1c, insulin treatment status, oral anti-diabetic drug therapy, history of hypertension/high cholesterol/high triglyceride prevalence, stress level, and depression for more than two weeks. EQ-5D index decreased with rising BMI in Korean diabetic patients with HbA1c ≥6.5(-0.0038, p-value <0.001) **CONCLUSIONS:** BMI was negatively associated with HRQoL based on the multivariate regression analysis among Korean diabetic patients with HbA1c ≥6.5, after adjusting for confounding factors. This finding alerts diabetic patients to the danger of the weight gain as it is related to the lower quality of life.

PDB98
HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH TYPE 1 DIABETES AND IMPAIRED HYPOGLYCAEMIA AWARENESS: THE ROLE OF SENSOR-AUGMENTED INSULIN PUMP THERAPY WITH AUTOMATED INSULIN SUSPENSION
McBride M[1], Eggleston AS[2], Jones T[3], Ly T[3]
[1]Medtronic Australasia Ltd., North Ryde, NSW, Australia, [2*]Medtronic International Ltd., North Ryde, Australia, [3]Princess Margaret Hospital for Children, Perth, WA, Australia
INTRODUCTION: Compared with multiple daily injections, insulin pump therapy (continuous subcutaneous insulin infusion - CSII) improves glucose control in patients with type 1 diabetes mellitus (T1DM). When CSII is combined with continuous glucose monitoring (CGM) with automated low glucose insulin suspension (LGS), exposure to hypoglycaemia is significantly reduced. Patients with impaired hypoglycaemia awareness (IHA) are at increased risk of severe hypoglycaemia, so the benefits of this technology should be evident in patient reported health-related quality of life (HRQoL). **OBJECTIVES:** To compare HRQoL in T1DM patients with IHA treated with CSII alone or CSII with CGM + LGS in this 6 month, prospective, single centre RCT. **METHODS:** T1DM patients with IHA and CSII experience were randomised to either CSII alone (control, n=49) or CSII with CGM + LGS (treatment, n=46). Patients >12 years were included in this analysis (n=64, male 50%, age 23.2 ± 11.9 years, diabetes duration 13.8 ± 9.5 years, CSII duration 4.9 ± 3.6 years, Hypoglycaemia Awareness score 6.2 ± 1.4). Hypoglycaemia Fear survey (HFS) and HRQoL (EQ5D) were analysed using ANCOVA least-squares mean change from baseline to 6 months post-randomisation. **RESULTS:** Enrolled patients were not appreciably impaired at baseline (EQ5D Utility mean +SD 0.96+0.07), but overall gains in treatment group (+0.038) and decrements in control (-0.035) over 6 months produced a significant comparative utility gain for the intervention (LS mean difference 0.073, 95% CI: 0.008-0.139, p=0.028). Although not statistically significant, supporting trends were noted in EQ5D VAS and HFS (Worry subscale). **CONCLUSIONS:** Success of T1DM treatment relies upon effective and compliant self-management, so the patient perspective is relevant when evaluating treatment options and determining the impact on aspects of daily life. This analysis further supports the important role of insulin pump therapy plus CGM with automated LGS in the effective management of T1DM patients with IHA.

PDB100
QUALITY OF LIFE (QOL) AND RESOURCES CONSUMPTION IN INSULIN-DEPENDENT DIABETIC PATIENTS WITH A1CNOW+ AND CONTOUR USB. COMET STUDY
Graefenhain R, Vieta A
Bayer, Barcelona, Spain
OBJECTIVES: To analyse the quality of life in insulin-dependent patients and resource consumption due to poor metabolic control after the standarization of glycated hemoglobin measure with A1CNOW+ and the glycemia measure with CONTOUR USB. **METHODS:** An observational, prospective, multicentre study in patients with diabetes, insulin-dependent, with poor metabolic control has been conducted. Distribution of the ESDQOL questionnaire which contains the domains satisfaction, impact, social /vocational, concern regarding diabetes and degree of perception of QoL at baseline, at 3 and 6 months. The score of the domains and the full questionnaire is measured on a scale 0-100; where lower scores indicate a higher QoL. Also, Visual Analogic Scale was used to assess the patient's own perception of their quality of life. The resource consumption is analysed for urgent attention due to poor metabolic control, the use of resources included are visits to emergency department, income, length of hospital stay and additional consultations. **RESULTS:** The evolution of the domains in satisfaction goes from 35.9 at baseline to 31.5 at 6 months. The impact improves from 27.9 at baseline to 26.0 at 6 months, social/vocational concern 25, 8 to 22.4 as well as concerns related to diabetes from 37.7 to 33, 1. Also the degree of perceived improvement in VAS was 2.1 points. All analysed results were statistically significant. At baseline there were 26 patients (7.9%) who required urgent attention due to poor metabolic control in the previous 3 months versus 9 patients (2.8) who requested urgent attention on data collected at 6 months. **CONCLUSIONS:** CONTOUR USB device to measure glycemia and A1CNow device to measure HbA1C improve the quality of life of patients and reduce the use of resources due to poor control.

PDB101
IMPACT OF NOCTURNAL AND DAYTIME NON-SEVERE HYPOGLYCAEMIC EVENTS ON PEOPLE WITH DIABETES IN SOUTH AFRICA
Snyman J[1], Todorova L[2]
[1]Agility Global Health Solutions, Centurion, South Africa, [2]Novo Nordisk International Operations, Zurich, Switzerland
OBJECTIVES: Two surveys aimed to understand the impact of nocturnal and daytime non-severe hypoglycaemic events on health care system utilisation and patient quality of life. **METHODS:** People with diabetes from six countries who had experienced a non-severe hypoglycaemic event in the 4 weeks prior to the survey were eligible (n=300/survey). In South Africa, surveys were conducted online. **RESULTS:** In the South African nocturnal (N)/daytime (D) hypoglycaemia cohorts (n=50/survey), 80% and 80% (N/D) had type 2 diabetes; 30%/24% (N/D) were male; mean age 45/43 years (N/D); mean diabetes duration 11.1/9.4 years (N/D); 93/93% (N/D) insulin users. 34/40% (N/D) experienced ≥1 non-severe hypoglycaemia events/week. Most respondents (70/76% [N/D]) were unemployed, which could skew the observed impact of hypoglycaemia on productivity. Both surveys revealed that, following an event, it took 20 min (median) for acute symptoms to disappear and 60 min (median) for the respondent to function at their normal level. After an event, 11/11% (N/D) decreased insulin dose, 14/12% (N/D) modified insulin administration time

and 14/12% (N/D) contacted a health care professional. In the week after an event, respondents added an average of 2.8/3.6 (N/D) blood glucose tests to an average of 18.8/17.4 (N/D) tests in a normal week. Nocturnal events had a high impact on sleep quality (46% of respondents) and social life (24%), and 84% of respondents felt tired and/or fatigued the next day. In the daytime survey, about 26% reported the event highly impacted daily activities (outside of work). Also, 40/18% (N/D) of respondents indicated that the event had a high impact on their fear of hypoglycaemia. The majority ascribed hypoglycaemia to stress (50%/58% [N/D]) or irregular/insufficient food intake (50%/40% [N/D]). **CONCLUSIONS:** Both nocturnal and daytime hypoglycaemic events had an impact on patients' use of health care system, quality of life and daily productivity.

CLINICAL SIGNIFICANCE OF CHANGE IN THE QUALITY OF LIFE-ASSESSMENT OF GROWTH HORMONE DEFICIENCY IN ADULTS (QOL-AGHDA) SCORE IN ADULT GROWTH HORMONE DEFICIENCY (AGHD)

Wiid Z[1], Pleil A[2], Ho K[3], Holdaway I[4], Cutfield W[5], Bullinger M[6], Koltowska-Häggström M[7], Mardekian J[8]

[1]*Pfizer Australia, West Ryde, Australia,* [2]*Pfizer, Inc., San Diego, CA, USA,* [3]*Centres for Health Research, Brisbane, Australia,* [4]*Greenlane and Auckland Hospitals, Auckland, New Zealand,* [5]*Director Liggins Institute, Auckland, New Zealand,* [6]*Hamburg University, Hamburg, Germany,* [7]*Pfizer Inc., Sollentuna, Sweden,* [8]*Pfizer, Inc., New York, NY, USA*

OBJECTIVES: To investigate the clinical significance of change in QoL-AGHDA score after 1 year of growth hormone (GH) replacement. **METHODS:** Observational data were obtained from KIMS (Pfizer International Metabolic Database). Minimal important differences (MID) for the QoL-AGHDA score and its five domains (memory and concentration, tenseness, tiredness, self-confidence, and social isolation) were calculated using an anchor-based approach with a rating of patient-perceived treatment benefit and patient-reported change in need for assistance. Perception of treatment benefit was measured using the KIMS Patient Life Situation Form (PLSF), a 5-point ordinal assessment of change (much improved, a little improved, no change, a little worse, much worse). The effect of baseline (BL) scores on MID was analysed using the QoL-AGHDA thresholds included in the New Zealand (≥16) and England (≥11) reimbursement criteria. **RESULTS:** Data from 1404 patients (52% female, 96% Caucasian, mean age [SD] of 45 [14] years) were included in the analysis. Mean GH dose [SD]was 0.20 [0.14] mg/day at BL and 0.32 [0.16] mg/day during Year 1. The Spearman correlation between change in QoL-AGHDA score and perception of treatment benefit was moderately positive (0.45; $p < 0.01$). The correlation was stronger for females and for patients with more impaired (higher) BL QoL-AGHDA scores. Using the anchor-based approach with patient-perceived treatment benefit, the MID for the QoL-AGHDA score was -4.61 at Year 1. Self-confidence was most sensitive and tenseness least sensitive of the domains in predicting patient-perceived treatment benefit. Patients requiring assistance at BL and not at Year 1 experienced the largest mean improvement in QoL-AGHDA score. **CONCLUSIONS:** Several national reimbursement authorities currently include the QoL-AGHDA score in eligibility criteria for access to reimbursed GH replacement. This is the first study to calculate the MID for the QoL-AGHDA score. Findings indicate that change in QoL-AGHDA score is positively correlated with patient-perceived treatment benefit.

PDB103

THE IMPACT OF DAYTIME AND NOCTURNAL NON-SEVERE HYPOGLYCAEMIC EVENTS ON PEOPLE WITH DIABETES IN BRAZIL

Fraige Filho F[1], Todorova L[2]

[1]*ABC Faculdade de Medicina SP Brasil, Sao Paulo, Brazil,* [2]*Novo Nordisk International Operations, Zurich, Switzerland*

OBJECTIVES: This study examined the effects of nocturnal and daytime non-severe hypoglycaemic events on utilisation of health care services and patient quality of life in Brazil. **METHODS:** People with diabetes from six different countries who had experienced a non-severe hypoglycaemic event in the past 4 weeks were asked to take part in a nocturnal and/or daytime hypoglycaemia survey. In the Brazilian subgroup, 86 people responded (50 respondents per survey). The surveys were conducted either face to face or online; hypoglycaemic events were self-reported. **RESULTS:** In the Brazilian cohort (nocturnal [N]/daytime [D] survey, respectively), 80% (N)/76% (D) had type 2 diabetes, 46%/38% (N/D) were male, mean age was 41(N)/40(D) years and mean weight was 82.4 kg(N)/81.8 kg (D). Participants received treatment with insulin (53%/70% [N/D]), oral medication (61%/60% [N/D]), GLP-1 (0%/8% [N/D]) and/or diet and exercise (32%/45% [N/D]). Approximately a quarter of respondents (26%/22% [N/D]) reported that they generally experienced a hypoglycaemic episode at least once a week. After the non-severe nocturnal (N)/daytime (D) hypoglycaemic event, 29% and 53% (N/D) decreased their insulin dose and 38% and 50%, respectively, contacted a health care professional. Participants used on average 13.0 or 11.5 (N/D) extra blood glucose tests the following week and 56%/32% (N/D) of the surveyed reported a high level of fear of a hypoglycaemic event. Among the 44/43 (N/D) respondents who worked for pay, 48%/35% (N/D) went to work late or left early; 23%/9% (N/D) missed ≥1 full days due to the non-severe event and 55%/26% (N/D) said that the event highly impacted upon their productivity at work. **CONCLUSIONS:** In Brazil, nocturnal and daytime non-severe hypoglycaemic events severely impact upon patients' quality of life and work productivity, with half of patients surveyed decreasing their insulin dose and/or contacting their health care provider after a non-severe event.

DIABETES/ENDOCRINE DISORDERS – Health Care Use & Policy Studies

HEALTH ECONOMICS ASSESSMENT OF THE CNAMTS SOPHIA DIABETIC PATIENT SUPPORT PROGRAMME: RESULTS OF THE FIRST 4 YEARS

Aguadé AS, Martin C, Saugnac C, Gastaldi-Menager C, Prieur JP, Gomez E

CNAMTS (National Health Insurance), Paris Cedex 20, France

OBJECTIVES: Since 2008, the *Caisse Nationale d'Assurance Maladie des Travailleurs Salariés*has set up a diabetic patient support programme in ten pilot departments in France. In addition to written advice, programme members also have access to telephone support from health education nurses. In 2010, the sophia programme was extended to another nine departments and, at the beginning of 2013, it was generalized to all French departments. The present study evaluated the health economics impact of the programme after a follow-up of 3 years. This analysis follows a preliminary assessment that demonstrated positive results after 1 year. **METHODS:** The variation of various health care use indicators as well as outpatient and inpatient costs was compared between three cohorts: members of pilot departments, non-members, and a control group of diabetic patients living in departments in which sophia was not available. Results are adjusted for between-group differences observed at the beginning of the programme. **RESULTS:** Adjusted analysis showed that, after matching for all other characteristics, compliance with recommended examinations improved to a much greater extent among programme members than among control subjects and non-members. Although all health care costs continued to increase in each cohort, outpatient and inpatient expenditure was €226 lower for programme members than for controls for the period 2009-2011: -€54 for outpatient care and -€172 for inpatient care. Although the outpatient expenditure of programme members was higher (+€40) for outpatient visits and medical procedures, their paramedical expenditure was lower (-€89). Hospitalization rates for diabetes were significantly lower among members than among controls. **CONCLUSIONS:** These results confirm the significant impact of the sophia programme on compliance with clinical practice guidelines in diabetology, hospitalization rates, and the 3-year growth of outpatient and inpatient costs. An assessment of the impact of the sophia programme on clinical parameters will be conducted in the near future.

PDB106

CONSISTENCY OF CURRENT TYPE 2 DIABETES (T2DM) TREATMENT PATTERNS IN GENERAL PRACTICE VERSUS THE 2013 FRENCH HAS T2DM GUIDELINES: A TRANSVERSAL STUDY BASED ON THE FRENCH IMS LIFELINKTM PROSPECTIVE DIABETES COHORT

Larger E[1], Ansolabehere X[2], Le Jeunne P[2], Grandfils N[2], Briand Y[3], Gibelin B[3]

[1]*Hotel Dieu Paris, PARIS, France,* [2]*IMS Health, PARIS LA DEFENSE, France,* [3]*Boehringer Ingelheim France, PARIS, France*

OBJECTIVES: To evaluate the consistency of T2DM management by French GPs in 2012 versus 2013 HAS guidelines that recommend modulating glycaemic objectives depending on patient's profile. To assess current treatment need for T2DM patients. **METHODS:** A transversal study, based on the IMS LifeLink™ prospective Diabetes Cohort linked to Electronic Medical Records database (Disease Analyzer) was used to investigate patients' profiles (age, disease history and complications, renal impairment, cardiovascular events, co-morbidities), HbA1c, hypoglycaemic risk, self monitoring of blood glucose (SMBG), and BMI evolution, linked to the current treatment. **RESULTS:** A total of 6680 T2DM patients (56% men) were included in the 2012 study cohort. The mean age was 66.6 years (25% of patients above 75 years); 19% had moderate to severe renal impairment and 56% had cardiovascular history. The new HAS guidelines split patients into several categories with associated HbA1c objectives varying from 6.5% to 9% based on age, frailty, diabetes history, and co-morbidities. 4%, 35%, 43%, and 18% of diabetic patients were eligible for the 6.5%, 7%, 8%, and 9% HbA1c objectives respectively. It appears that 55% of the diabetic population were at risk of hypoglycaemia, age and long diabetes history being the major risk factors. Given the modulation of glycaemic objectives more patients reached the new HbA1c objectives (74% of patients) vs. previous guidelines (about 55%). In this representative cohort, SU were prescribed with no dosage adjustment to all patients and even more frequently to patients at risk of hypoglycaemia (60.6%) while DDP4i were prescribed to "healthy patients" mostly not at risk of hypoglycaemia (51.5%). **CONCLUSIONS:** A minority of T2DM patients (39%) are eligible for an HbA1c objective of 7% or below, highlighting their frailty. This survey also shows that more patients are reaching their HbA1c target. However many of them are receiving treatments they should not due to high risk of hypoglycaemia.

PDB107

THE IMPACT OF MEMORY PROBLEMS ON DIABETES TREATMENT IN GERMANY

Brod M[1], Kongso J[2], Bushnell DM[3]

[1]*The Brod Group, Mill Valley, CA, USA,* [2]*Novo Nordisk A/S, DK-2860 Soborg, Denmark,* [3]*Health Research Associates, Inc., Seattle, WA, USA*

OBJECTIVES: The impact of memory problems (MPs) on patient functioning, well-being and diabetes management is not well understood. This study examines these impacts in Germany and compares findings to data from US, UK, Canada and China. **METHODS:** A 5 country web-based survey was conducted. MPs were defined as: **u**nintentionally **f**orgetting to take insulin (UF), **q**uestioning if insulin had been **t**aken (QT), or **q**uestioning amount of **d**ose (QD). **RESULTS:** A total of 350 German respondents (60.0% Type 1) completed the survey, 61.1% male, mean age of 39.5 (±13.3) and mean age of diabetes onset 30.2 (±12.6). The prevalence of MPs in the past month was: 74.0% UF, 82.0% QT and 68.3% QD. MPs occurred most frequently when waking in the morning or when relaxing. Between 27.9% (UF) – 48.3% (QD) of respondents skipped their insulin dose and waited for next scheduled dose when experiencing a MP. Patients experiencing MPs required between 2.0 (QT)–8.7 (UF) hours, on average, to return to normal blood glucose range, conducted between 1.2 (QT) –4.4 (UF) extra BG monitoring tests, reported a moderate negative impact on their physical and emotional functioning, work absenteeism or reduced ability to function optimally when at work and between 3.6% (QT) and 13.8% (QD) visited/contacted their health care provider due to MPs. Compared to the total sample (N=1404), German respondents were more likely to report that their diabetes was very well/well controlled and that they were very/extremely confident in knowing what to do when they had an MP compared to respondents and were less likely than patients in other countries to have contact with a physician or other health care professional following a MP. **CONCLUSIONS:** These findings suggest that MPs

carry financial burden, impact patients' daily functioning and well-being and may be serious obstacles to optimal diabetes control. This burden may be some lower in Germany than other countries.

PDB108

TREATMENT PATTERNS AND HEALTH CARE RESOURCE UTILIZATION OF PATIENTS WITH ACROMEGALY IN THE UNITED STATES

Chuang CC[1], Dinet J[2], Bhurke S[1], Chen SY[1], Brulais S[2], Gabriel S[2]
[1]*Evidera, Lexington, MA, USA,* [2]*IPSEN Pharma, Boulogne Billancourt, France*

OBJECTIVES: To examine patient characteristics, treatment patterns, and health care resource utilization of patients with acromegaly in the US. **METHODS:** Using a large US claims database, adult individuals with commercial insurance newly diagnosed with acromegaly (ICD-9-CM: 253.0) between 07/01/2007 and 12/31/2010 were identified (the first observed diagnosis was the index date). Patients were required to have 6-month pre-index and 12-month post-index continuous enrollment. Descriptive analysis was performed to describe demographic and clinical characteristics, treatment patterns of acromegaly, and health care resource utilization during the post-index period. Similar analysis was conducted for Medicare-eligible patients with supplemental private insurance. **RESULTS:** This study included 930 commercially-insured patients (mean age: 47.2 years; 52.0% female) and 104 Medicare-eligible patients (mean age: 72.8 years; 36.5% female) with acromegaly. For the commercial population, of the comorbidities evaluated, hypertension (38.2%), diabetes (25.9%), and anthropathy/arthralgia/synovitis (23.7%) had the highest prevalence. More than half of the patients (57.3%) received no treatment; 21.7% received tumor resection surgery and 21.0% received medical therapy as the first-line treatment. During the 12-month post-index period, one-third had inpatient hospitalization and 23.2% had emergency room visit; the mean physician office visit was 17.1. For the Medicare population, hypertension (67.3%), diabetes (36.5%), and anthropathy/arthralgia/synovitis (29.8%) were most prevalent comorbidities. About two-thirds (63.5%) received no treatment; 8.7% received tumor resection surgery and 27.9% received medical therapy as the first-line treatment. More than one-third (34.6%) had inpatient hospitalization and 26.9% had emergency room visit during the 12-month post-index period; the mean physician office visit was 21.1. **CONCLUSIONS:** Our findings suggest high unmet needs in the population with more than half of patients with acromegaly being untreated. Efforts should be made to understand this untreated population to provide better care. Future research should investigate different treatment options as well as their impact on health care costs and health care resource utilization.

PDB109

UK QUALITY OUTCOMES FRAMEWORK (QOF) THRESHOLDS AND ELEVATED HBA1C LEVELS AMONG PATIENTS WITH TYPE II DIABETES - A LONGITUDINAL STUDY USING THE CLINICAL PRACTICE RESEARCH DATALINK (CPRD)

Jameson K[1], D'Oca K[1], Murray-Thomas T[2], O'Regan C[1], Leigh P[1]
[1]*MSD Ltd., Hoddesdon, UK,* [2]*Medicines and Healthcare Products Regulatory Agency, London, UK*

OBJECTIVES: HbA1c concentrations predict the risk of complications in patients with type 2 diabetes mellitus (T2DM). This study assessed temporal trends in elevated HbA1c levels in the UK primary care setting. **METHODS:** T2DM was identified by medical diagnosis, prescribing, elevated blood glucose and/or prescribing of monitoring devices. Patients had ≥12 months of CPRD history, with data available for the entire year of observation. T2DM patients prescribed insulin were excluded. Mean HbA1c levels and proportion of patients with elevated HbA1c were assessed across six years (01/04/2006–31/03/2012). Elevated HbA1c was defined according to the UK Quality and Outcomes Framework (QOF) threshold: >7.5% for all years except 2009/2010 (>7.0%). Estimates were stratified by age-band, gender, T2DM-status and treatment categories. **RESULTS:** Mean HbA1c levels among 176,428 patients were relatively stable and below threshold across the study period (2006/2007: 7.05%; 2011/2012: 7.16%), with the exception of 2009/2010 (7.09%). Nonetheless, >20% of patients had a record of elevated HbA1c in each year (36.7% in 2009/2010). Elevations were more common among males than females (20%-25.0% vs. 18%-20%) and among patients 40-59 years (27.2%-33.7 %) vs. those ≥60 years (15.9%-23.3%). Although elevations were similar among prevalent (20%-23%) and incident-T2DM (22%-23%), prevalent-T2DM showed an increasing trend in the proportions with an elevation over time, whilst incident-T2DM showed a decreasing trend. The proportion with elevated HbA1c varied by treatment: diet and exercise 4.8%-6.1%; monotherapy 24%; dual therapy 32.7%-38.0%, and; triple therapy 42%-50%. Over 80% of patients with elevated HbA1c were overweight or obese, >20% had a 10-year Framingham Risk score >20% (patients without existing CVD) and 17%-21% of patients had history of chronic renal failure. **CONCLUSIONS:** Although mean HbA1c concentrations were below target (apart from 2009/2010), elevated HbA1c was present in >20% patients across all years. Further efforts are needed to help patients to achieve adequate glycaemic control.

PDB110

SELF-MONITORING OF BLOOD GLUCOSE WITH INSULIN ANALOGUES: NICE TO HAVE OR NEED TO HAVE? ANALYSIS OF PHASE III REGISTRATION TRIALS AND EUROPEAN PUBLIC ASSESSMENT REPORTS OF INSULIN ANALOGUES

Caruso A, Hilsdorf HL, Mast O
Roche Diagnostics GmbH, Mannheim, Germany

OBJECTIVES: Registration trials' purpose is to show safety and efficacy of insulin therapy. They are the basis of subsequent insulin reimbursement decisions. Insulin dosing is typically individualized: a safe and efficacious insulin therapy requires upfront dose finding and regular dose adjustments. These adjustments are based on data from Self-Monitoring of Blood Glucose (SMBG). However, some countries reimburse insulin analogues, but not blood glucose test strips. This analysis investigates the use of SMBG in Phase III registration trials of selected insulin analogues and if consequently the European Public Assessment Reports (EPARs) recommend the use of SMBG as part of the insulin therapy. **METHODS:** Systematic search and analysis of phase III registration trials (full-publication if available, and Clinical Trial report/study Synopsis) and EPARs of commonly used short-acting (Insulin Aspart and Insulin Glulisine) and pre-mix (Biphasic Insulin Aspart) insulin analogues. **RESULTS:** Therapy adjustments based on SMBG data were documented in 5/24 Insulin Aspart-, 3/18 Insulin Glulisine- and 4/15 Biphasic Insulin Aspart phase III registration trials. The EPARs of all three insulin analogues recommend the use of SMBG to adjust the insulin doses, repeatedly and throughout all sections in EPAR. **CONCLUSIONS:** Overall, in 12/57 phase III registration trials the dose of insulin analogues was regularly adjusted based on SMBG data, and the EPARs of all insulin analogues explicitly recommend the use of SMBG to adjust the insulin doses. Therefore, the demonstrated safety and efficacy of these insulin analogues are the result of a complex intervention including insulin analogues, their dose adjustments based on SMBG data as well as training rather than the insulin analogues alone. This is not consequently reflected in reimbursement schemes, in particular in emerging countries. Full study reports were not available for further analysis. These potentially would have provided deeper insights on how SMBG was used in the remaining 45/57 trials.

PDB111

DIFFERENT INJECTION FREQUENCIES OF BASAL INSULINS IN TYPE 2 DIABETES PATIENTS UNDER REAL-LIFE CONDITIONS: A RETROSPECTIVE DATABASE ANALYSIS

Kostev K[1], Dippel FW[2], Rathmann W[3]
[1]*IMS Health, Frankfurt am Main, Germany,* [2]*Sanofi, Berlin, Germany,* [3]*German Diabetes Center, Duesseldorf, Germany*

OBJECTIVES: Little is known about routine use of basal insulins (Glargine, Detemir, NPH) in primary care patients with type 2 diabetes. The aim was to compare injection frequencies of basal insulins in type 2 diabetes (T2D) in primary care practices, both for basal-supported oral (BOT) and basal-bolus (ICT) treatment regimens. **METHODS:** Primary care data from 4,503 Glargine (BOT/ICT: 2,247/1,964), 1,373 Detemir (490/800), and 4,072 NPH-insulin (1,331/2,425) users were retrospectively analysed (05/2009-04/2012). The Disease Analyzer database (IMS HEALTH) assembles drug prescriptions, diagnoses, basic medical and demographic data obtained from the practice computer system of general practitioners and specialists throughout Germany. The Charlson Comorbidity Index was used as generic marker of comorbidity. Logistic regression (>1 daily injection) and propensitiy scores were used to adjust for various confounders (age, sex, type of physician, dosage, BMI, HbA1c). **RESULTS:** Overall, more than one daily injections were observed in 7.5% of Glargine users (BOT: 6.2%, ICT: 9.0%), which was lower than for Detemir (overall: 25.4%; BOT: 22.0%, ICT: 27.4%) and NPH-insulin (25.4%; BOT: 23.9%, ICT: 27.2%) (all $p<0.001$). The adjusted odds of having more than one injection was lower for Glargine compared to Detemir (OR; 95% CI: 0.26; 0.22-0.32) and NPH-insulin (0.20; 0.17-0.23). Similar results were found for BOT (Glargine vs. Detemir: 0.23; 0.17-0.32; Glargine vs. NPH-insulin: 0.16; 0.13-0.21) and for ICT (Glargine vs. Detemir: 0.27; 0.21-0.35; Glargine vs. NPH-insulin: 0.22; 0.18-0.27). Finally, after matching the groups for the propensity score, the odds for more than one daily injection was also significantly reduced in the Glargine group both compared to Detemir (OR; 95%CI: 0.30; 0.24-0.37) and NPH insulin (0.25; 0.22-0.29). **CONCLUSIONS:** Glargine is associated with significant lower injection frequencies than other basal insulins. These findings might impact treatment satisfaction and as a consequence quality of life, persistence and economic aspects of diabetes treatment.

PDB112

ORAL HYPOGLYCAEMIC MEDICINE (OHM) INITIATION IN NEWLY TREATED TYPE 2 DIABETES MELLITUS (T2DM) IN IRELAND: AN ANALYSIS OF TREATMENT INTENSIFICATION AND SWITCHING PATTERNS

Grimes R[1], Tilson L[2], Usher C[2], Henman M[1], Bennett K[3]
[1]*Trinity College Dublin, Dublin, Ireland,* [2]*National Centre for Pharmacoeconomics, Dublin, Ireland,* [3]*Trinity Centre for Health Sciences, Dublin, Ireland*

OBJECTIVES: To examine treatment intensification and switching patterns of individuals with T2DM initiating OHM. The results are compared to international guidelines issued in 2009. **METHODS:** Data were analysed using a population-based pharmacy claims database from January 2008 to November 2012. Incident users of OHM were identified for 2008-2009 as not having received OHM in the previous 12 months. Patients dispensed insulin, >one OHM, or <16 years were excluded from the study. Patients were followed until Nov-2012. Treatment intensification was defined as receiving an additional one, or two hypoglycaemic medicines (double or triple-therapy respectively). Treatment switching was defined as OHM monotherapy discontinuation with initiation on alternative monotherapy. **RESULTS:** A total of 24,869 patients were included in the study. Most were initiated on metformin (76.4%) or sulphonylureas (21.6%). Treatment intensification: 25.8% of patients initiated on metformin progressed to double-therapy. Sulphonylureas (61.5%), DPP-4 inhibitors (23.9%) and GLP-1 agonists (6.2%) were the most frequently prescribed add-on treatment (median time to add-on OHM=424days). Of those initiated on sulphonylureas 32.4% progressed to double-therapy; metformin (78.4%), DPP-4 inhibitors (9.3%) and long-acting insulin (5%) were the most frequently prescribed (median time to add-on=295days). 14.3% of patients on double-therapy progressed to triple-therapy (median time to add-on=434days). 26.6% of patients did not receive the recommended double-therapy and 64.3% received agents in their triple-therapy that were not recommended. Treatment Switching: Overall 7.1% switched medication. The most frequent switches were metformin to sulphonylureas (46.5%, median time to switch=226days), sulphonylureas to metformin (22.5%, median time to switch=330days) and metformin to DPP-4 inhibitors (6.9%, median time to switch=577days). Initial OHM was significantly associated with time to switch ($p<.0001$). **CONCLUSIONS:** Initial drug treatment followed guidelines. However, evidence-based practice was not closely followed for treatment intensification suggesting prescribers may be unaware of treatment guidelines. This data may be useful for assessing the potential place in therapy, and cost-effectiveness of new hypoglycaemic medicines.

PDB113

THREE-YEAR HEALTH CARE EXPENDITURES IN DIABETIC PATIENTS RECEIVING RAPID-ACTING INSULIN ANALOGUES VERSUS THOSE ON HUMAN REGULAR INSULIN

Cammarota S[1], Bruzzese D[2], Catapano AL[3], Citarella A[4], De Luca L[1], Manzoli L[5], Masulli M[6], Menditto E[1], Mezzetti A[7], Riegler S[8], Riccardi G[6]

[1]*CIRFF- Center of Pharmacoeconomics, Naples, Italy,* [2]*Federico II University Hospital School of Medicine, Naples, Italy,* [3]*University of Milan, Milan, Italy,* [4]*Karolinska Institutet, Stockholm, Sweden,* [5]*"G. D'Annunzio" University Foundation, Chieti, Italy,* [6]*University of Naples, Naples, Italy,* [7]*University , Chieti, Italy,* [8]*CIRFF, Federico II University, Naples, Italy*

OBJECTIVES: To compare health care expenditures following rapid-acting insulin analogues or human regular insulin utilization in a cohort of diabetic patients through the analysis of administrative databases. **METHODS:** A population-based cohort study was conducted using administrative data from four local health authorities in the Abruzzo Region (900,000 inhabitants). Diabetic patients free of macrovascular disease at baseline and treated either with human regular insulin or rapid-acting insulin analogues were followed for a maximum of 3 years. Propensity score matching was used to adjust for significant differences in the baseline characteristics between the two treatment groups. The direct cost was calculated as the sum of drug use, financial compensation by hospital DRG and outpatient activities (laboratory tests, services use and specialistic consultations), all regulated by government contracts. Generalised linear mixed models under gamma distribution were used to evaluate the costs. In case of cost variables with a large proportion of zeros, a two part model (logistic regression and glm with gamma distribution) was employed. **RESULTS:** After PS approach, 566 patients treated with human regular insulin were matched with an equal number of patients receiving rapid-acting insulin analogues. During the 3-year follow-up, the average number of hospitalizations was higher (0.54 vs. 0.47; P=0.028), and the average length of stay was 4,7 days longer (P < 0.004), among patients receiving human regular insulin in comparison with those receiving rapid-acting insulin analogues. The annualized total health care costs were significantly lower in the rapid-acting insulin analogues group than human regular insulin group with an estimated difference between the two groups of 1336.7 € per patient per year (P=0.001) . **CONCLUSIONS:** This analysis from real-world clinical practice suggests that rapid-acting insulin analogue is associated with lower rates of hospitalizations and lower overall health care costs in diabetic patients.

PDB114

HEALTH CARE COST AVOIDANCE DUE TO INSULIN GLARGINE FOR TYPE 2 DIABETIC PATIENTS IN HONG KONG AS COMPARED TO NPH INSULIN

Lee KK[1], Wu DBC[2]

[1]*Monash University Sunway Campus, Selangor, Malaysia,* [2]*Monash University Sunway Campus, Kuala Lumpur, Malaysia*

OBJECTIVES: Many studies have shown that insulin glargine (IG) is associated with a better glycemic control and less incidents of hypoglycemia. The objective of this study is to examine the potential cost avoidance arising from reduced hypoglycemic episodes by IG vs NPH insulin in T2DM patients receiving insulin in Hong Kong. The findings will fill a knowledge gap as no data is available before. **METHODS:** A decision analytic model was developed using local and international data to evaluate the potential health and economic impact of routine use of IG over a 1-year horizon. The study was conducted from a payer perspective. Probability of IG and NPH causing severe hypoglycemia was derived from the LEAD (LANTUS Evaluation in Asian Diabetics) study. Disease epidemiology and costs were all Hong Kong-specific. One-way sensitivity analysis was performed to test the robustness of model assumptions. **RESULTS:** The use of IG over a 1-year period is estimated to result in a substantial 81.9% reduction of hospitalization cost (HKD313,572,521) and a 29% reduction of emergency room cost (HKD1,184,312) which together accounts for about 0.7% of the overall annual public hospital budget of HK. In addition, IG is expected to prevent 23,755 cases of severe hypoglycemia events and to avert 95,022 hospitalization-days over 1 year. The overall incremental cost using IG vs. NPH is HKD126,843,257. **CONCLUSIONS:** The use of IG in T2DM patients receiving insulin in Hong Kong is likely to substantially reduce health care costs in hospitalization and emergency room visits due to severe hypoglycemia compared with NPH. The results of this study are considered as conservative because if improvement in clinical outcomes of IG over NPH is included, the additional clinical benefit will translate into larger long term health savings.

PDB115

HEALTH CARE UTILIZATION FOLLOWING NEWLY-DIAGNOSED TYPE-2 DIABETES IN SWEDEN: A FOLLOW-UP OF 38,956 PATIENTS IN A REAL CLINICAL SETTING

Sabale U[1], Bodegård J[1], Sundström J[2], Svennblad B[3], Östgren CJ[4], Nilsson P[5], Johansson G[3], Henriksson M[1]

[1]*AstraZeneca Nordic-Baltic, Södertälje, Sweden,* [2]*George Institute for Global Health, Sydney, Australia,* [3]*Uppsala University, Uppsala, Sweden,* [4]*Linköping University, Linköping, Sweden,* [5]*Lund University, Malmö, Sweden*

OBJECTIVES: The growing prevalence of diabetes leads to increased pressure on national health care budgets. Despite the high prevalence the long-term health care costs of diabetes patients are not widely studied in a clinical practice setting. The study objective was to quantify and describe health care resource utilization following newly-diagnosed type-2 diabetes mellitus (T2DM) patients over time. **METHODS:** Newly diagnosed T2DM patients were identified from 84 primary care centers in Sweden between 1999 and 2009, and followed for a maximum of 9 years. Resource use data were extracted from electronic patient records (primary care contacts and laboratory tests) and a national patient register (hospitalizations). Data were linked using unique social security numbers. Resource use patterns are reported for the full study period and by partitioned time periods to investigate trends in resource use over time. The relationship between weight and resource use was also investigated. **RESULTS:** The study included 38,956 T2DM patients (women, 45%; mean age, 64 years; HbA1c, 5.7%; mean BMI, 29.8) with a total number of 183,614 observation years. Over a mean follow-up of 4.7 years there were 2,134,870 (per patient mean 55) primary care contacts; 1,200,142 (31) laboratory tests and 24,656 (0.63) hospitalizations. Mean annual resource use almost doubled the first year after diagnosis and remained on a higher level than before diagnosis throughout the study period. This pattern was seen in primary care as well as for hospitalizations. Furthermore, obesity at baseline appeared to be correlated with a higher level of resource use. The relationship between resource use, baseline weight and weight changes appears complex. **CONCLUSIONS:** Data from 183,614 patient years of follow-up show that T2DM diagnosis is associated with increased long-term resource use. Quantifying resource utilization using data from clinical practice setting may provide an important input to diabetes cost-effectiveness modeling and resource allocation decisions.

THE IMPACT OF THE POLISH HUMAN INSULIN (GENSULIN) ON PUBLIC PAYER'S EXPENDITURE IN 2001-2013

Orlewski J[1], Orlewski PM[2], Orlewska E[3]

[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*Warsaw University of Technology, Warsaw, Poland,* [3]*Centre for Pharmacoeconomics, Warsaw, Poland*

OBJECTIVES: Reference pricing (RP) – an approach where a payer sets payment for a group of similar drugs using benchmark based on a lower-priced option is a strategy commonly used to control drug expenditures. The aim of this study was to determine the impact of Polish human insulin (Gensulin, BIOTON) on public payer's expenditure in 2001-2013. **METHODS:** We analyse published data on insulin consumption and changes in reimbursement limits between October 2001 and February 2013. An Excel-based model was developed to compare scenario with (1) and without (2) Gensulin on the Polish pharmaceutical market. The reimbursement limit for insulin in (1) was determined by Gensulin (the lowest priced product within a group of human insulins), in (2) was fixed at 151 PLN/1500 i.u (A) or decreased to 134.99 from April 2002 (B). In the calculation all products containing 1500 i.u.insulin/pack or only pen were considered. Cost was adjusted for inflation and reported in PLN at 2013 prices (1 Euro=4.2 PLN). Results were presented as total and incremental cost in subsequent years and over the entire period. **RESULTS:** Between 2002-2012 the consumption of human insulins in Poland increased from 3.8 mln to 5.6 mln pack a 1500 i.u. The reimbursement limit in PLN/pack decreased gradually from 151 in 2001 to 98.57 in 2013 (scenario 1). Overall for the 12.5-year period the total public payer savings resulting from setting the reimbursement limit by Gensulin were 3 157 114 474 and 2 039 163 591 PLN in A and B, respectively. If only pens were considered RP policy led to a saving of 2 719 053 565 PLN in (A) and 1 777 711 973 PLN in (B) over 12.5 years. **CONCLUSIONS:** The launch of Gensulin and RP resulted in considerable reduction of public resources spent on human insulin in Poland

WHO KNOWS BETTER? A KNOWLEDGE, ATTITUDE AND PRACTICE SURVEY OF OSTEOPOROSIS PRESCREENING TOOLS AMONG PHARMACISTS AND PHYSICIANS

Khan Y, Sharriff A, Khan AH

Universiti Sains Malaysia, Minden, Malaysia

OBJECTIVES: Although osteoporosis is preventable, still its prevalence is escalating to endemic proportions. The reason for this massive incidence of osteoporosis is lack of identification of high risk individuals. In order to overcome this scenario and to cut cost associated with bone scanning; various prescreening tools were developed in 1990's. The purpose of such tools is to select high risk individuals for bone densitometry. The objective of current study is to analyze knowledge, attitude and practices of both physicians and pharmacist towards prescreening tool and to evaluate possible reasons for non-implementation of existing prescreening tools. **METHODS:** Using convenience sampling method, an explorative cross sectional survey was conducted in Penang, Malaysia. A pre-validated self- administered questionnaire was used to carry out the study among community pharmacists (n=83) and physicians (n=87). **RESULTS:** There was a statistically significant difference between mean rank score of pharmacist (137.55) and physicians (78.05). Although, pharmacists scored higher than physicians in all three domains of questionnaire but still both showed poor knowledge and practices regarding prescreening tools. Pharmacists considered low awareness regarding availability of such tools as the main factor that pose hindrance in implementation of such tools while physician suggested lack of time ,on their part, as the main reason. **CONCLUSIONS:** Participants showed general lack of awareness regarding osteoporosis pre-screening tools but in order to save cost associated with bone densitometry majority showed willingness to utilize such tools in future.

PDB118

REAL LIFE APPLICATIONS OF SOCIAL SECURITY INSTITUTION (SSI) REGULATIONS; A CASE STUDY OF DPP4 INHIBITORS IN TREATMENT OF DIABETES IN TURKISH HEALTH CARE SYSTEM

Kececioglu S[1], Ulus P[2], Cukadar F[3], Ozkan M[3], Urganci B[3]

[1]*Boehringer Ingelheim Turkey, Istanbul, Turkey,* [2]*Boehringer Ingelheim Turkey, ISTANBUL, TURKEY, Turkey,* [3]*Boehringer Ingelheim Turkey, ISTANBUL, Turkey*

OBJECTIVES: Analyze real life applications of SSI regulations via a case study: patient access to DPP4 inhibitors (ProductA*&Product B**) for Diabetes treatment, in Turkish health care system (2010-2012). **METHODS:** Regulation analysis is completed to define access conditions to DPP4 inhibitors. IMS Medical Index is used for prescription data analysis (patient age, sex, diagnosis, localization, medications, etc.). Calculations and process modelling are completed by Microsoft Excel-2007. **RESULTS:** Patient access to DPP4 inhibitors is possible if glycemic control cannot be sustained after use of maximum tolerable doses of metformin and/or sulphonylurea. This new requirement is being applied since April 2011. This study evaluates two comparable timeframes T1 and T2 (before and after regulation update); T1: 2010 (Q1/Q2/Q3/Q4) & 2011 (Q1) and T2: 2011 (Q2/Q3/Q4) & 2012 (Q1/Q2). From T1 to T2, Product A percentages of monotherapy, w-biguanides and w-sulphonylurea prescriptions changed from 32% to 35% (+3%), 51% to 42% (-9%) and 17% to 23% (+6%), whereas for Product B presciptions changed from 10% to 37% (+27%), 68% to

47% (-21%) and 22% to 16% (-6%), respectively. **CONCLUSIONS:** For Product A, after the regulation update, prescription rate for w-biguanides is decreased, while that for w-sulphonylurea and monotherapy options are increased. However, for Product B, prescription rate for w-sulphonylurea is decreased, while those for w-biguanides and monotherapy options are increased. For both products, prescription rate for monotherapy is increased. Limitation of this study is level of comprehensiveness for the system variables (market dynamics, patient profiles, etc.) This study concludes that, regardless regulation updates, there is an unmet need, which results in physicians' preference of innovative treatment options in clinical practice for treatment of Diabetes. *ProductA=Sitagliptin, **ProductB=Vildagliptin

THE POTENTIAL IMPACT OF AMNOG-TRIGGERED INTERNATIONAL REFERENC PRICING: A SCENARIO FROM DPP-IV INHIBITORS
Ando G[1], Van Mol C[2], Reinaud F[3], Honoré AC[4]
[1]*IHS, London, UK,* [2]*Alliance Concepts, Schilde, UK,* [3]*IHS, Paris, France,* [4]*IHS, Zurich, Switzerland*
OBJECTIVES: 1) International reference pricing (IRP) is a complex cost containment policy which has an often unclearly defined ripple effect across countries; 2) The aim of this study was to quantify by simulation what the ripple effect through IRP would be if prices of DPP-IV inhibitors in Germany dropped post-AMNOG benefit assessment because of either internal referencing or subject to the specific AMNOG provisions under which the IRP process can be deployed; and 3) A secondary objective was to draw initial conclusions over the evolution of IRP. **METHODS:** 1) The IRP landscape was studied using primary and secondary payer research on the basket of countries formally or informally employed in 40 countries, specifying a) those which reference Germany directly and b) identifying a cascading "indirect wave" of those which reference the countries that reference Germany, and 2) We examined current pharmaceutical pricing data and employed an industry validated proprietary simulation model for assessing the impact of selected AMNOG-triggered price decline scenarios. **RESULTS:** 1) In the universe of 32 countries where the 2 DPP-IV inhibitors studied are on the market, 25 countries are potentially affected by a price decrease in Germany: 16 countries that reference Germany directly and 9 via a secondary phase of IRP, and 2) The resulting interdependent price impact - solely from IRP - in the diverse afflicted countries is quantified for each model scenario. **CONCLUSIONS:** 1) As more countries explore the possibility or already deploy IRP as a pricing policies, it will become increasingly crucial for pharmaceutical companies to gauge the full impact of evolving international referencing and cross-referencing – and integrate this early on in their pricing strategy; 2) The results demonstrate that he composition itself of the basket of reference countries is driving the pricing impact; and 3) IRP and value-based or market pricing could be complementary and need not necessarily be diametrically opposed.

PDB120
TREATMENT PATTERNS AND BURDEN OF ILLNESS OF ACROMEGALY IN THE UNITED KINGDOM: REAL WORLD (RW) DATA FROM CLINICAL PRACTICE RESEARCH DATALINK (CPRD)
Murray RD[1], Forsythe A[2], Roset M[3], Siva V[4], Oliver N[4], Rojas-Farreras S[3], Ayuk J[5]
[1]*Leeds Teaching Hospitals NHS Trust, West Yorkshire, UK,* [2]*Novartis Oncology, Florham Park, NJ, USA,* [3]*IMS Health, Barcelona, Spain,* [4]*Novartis Pharmaceuticals UK Limited, GB- Frimley/Camberley, Surrey, UK,* [5]*University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK*
OBJECTIVES: Acromegaly is a rare slowly progressing endocrine disorder characterized by abnormally elevated levels of growth hormone (GH) and insulin-like growth factor-1 (IGF-1). Acromegaly has a significant impact on patients' health, as well as on their physical, cognitive, emotional, and social well-being. Treatment of acromegaly is complex involving surgery, radiotherapy and medication; however, there are limited published real world data on treatment patterns. **METHODS:** A retrospective database analysis study using CPRD linked with Hospital Episode Statistics (HES) was conducted. Patient population included patients enrolled between January 1956 and March 2012 with Acromegaly diagnosis at two timepoints or Acromegaly diagnosis and either GH or IGF-1 test. Data was collected from 500 general practitioners (GPs). Patients' characteristics, treatment history, comorbidities and disease control were analysed. Biochemical control was defined as an age/gender adjusted IGF-1≤ULN and GH≤2.5mg/l. Standardized Mortality Ratio (SMR) was calculated and compared to general age/gender matched UK population. **RESULTS:** A total of 822 patients with Acromegaly were identified (580 alive and 242 dead at March 2012). Among alive patients, mean age (SD) was 63(15) years old, 52% male, mean age at diagnosis was 48(14). Comorbidities included: hypertension (46%), osteoporosis (31%), arthralgia/synovitis (21%), diabetes (18%), carpal tunnel (13%) and sleep apnea (11%); 31% of patients had no treatment records. Among treated patients: 38% received TSS, 29% radiotherapy, 45% somatostatin analogs (SSAs), and 45% dopamine agonists (DAs). A total of 45% of TSS 1st line and 52% of radiotherapy 1st line patients received further treatment; 22% of SSAs patients and 34% of DAs patients switched to/added 2nd line medical therapy. 64% of patients with GH+IGF-1 data (n=109) were not controlled. SMR was 4.6, 3.4 and 2.5 at 5, 10 and 15 years after diagnosis respectively. **CONCLUSIONS:** This study demonstrated significant mortality and morbidity burden of Acromegaly in the UK GP practice.

PDB121
HOW DOES HOSPITALIZATION IMPACT INSULIN TREATMENT IN DIABETES MELLITUS? RESULTS OF A RETROSPECTIVE GERMAN DATABASE ANALYSIS
Schmidt J[1], Dippel FW[2], Steinmeier T[3]
[1]*Technical University, Garching, Germany,* [2]*University, Leipzig, Germany,* [3]*Sanofi, Berlin, Germany*
OBJECTIVES: One important aspect for patients suffering from diabetes is an appropriate metabolic control to avoid micro- and macrovascular complications. There is a lack of information about adjustment of antidiabetic treatment during hospitalization. **METHODS:** To identify a change in medication in patients suffering from diabetes, treatment regimens before and after hospitalization were investigated retrospectively. Information was taken from 2006 to 2010 German claims data. Data of about 25,000 hospitalizations from 180,000 diabetic patients were analyzed over a five year period. **RESULTS:** Study population of statutorily insured diabetic patients is representative as it is comparable to the overall German population by age, gender, mortality and morbidity. Treatment of most diabetic patients on oral anti-diabetic drugs remained unchanged before and after a hospital stay (55.8%). A smaller part of diabetic patients (37.6%) is admitted and discharged with the same insulin regimen. In 15% of the cases where patients are discharged with insulin, insulin treatment was initiated or changed during hospitalization. 53% of these patients received a first prescription of insulin. Basal supported oral therapy (BOT) and conventional insulin treatment (CT) regimens made up the largest fraction of all insulin initiations (62%). If a BOT was initiated, insulin glargine was favored (60%) compared to all other long acting insulin formulations such as human insulin (30%) and insulin detemir (10%). In 21% of the cases initiation results in a basal-bolus regimen (ICT) and in 17% in a prandial insulin therapy (SIT). **CONCLUSIONS:** Insulin treatment was first prescribed or switched during hospitalization in 15% of the cases where patients are discharged with insulin. Initiation of BOT and CT regimens turned out to be the overall preferred therapies in the underlying analysis. Given the fact that 26.7% of the German diabetic population has suboptimal HbA1c-values more of them should receive an adequate adjustment of antidiabetic therapy during hospitalization.

PDB122
TREATMENT PATTERNS AND BURDEN OF ILLNESS OF CUSHING'S DISEASE IN THE UNITED KINGDOM: REAL WORLD (RW) DATA FROM CLINICAL PRACTICE RESEARCH DATALINK (CPRD)
Murray RD[1], Forsythe A[2], Siva V[3], Oliver N[3], Rojas-Farreras S[4], Roset M[4]
[1]*Leeds Teaching Hospitals NHS Trust, West Yorkshire, UK,* [2]*Novartis Oncology, Florham Park, NJ, USA,* [3]*Novartis Pharmaceuticals UK Limited, GB- Frimley/Camberley, Surrey, UK,* [4]*IMS Health, Barcelona, Spain*
OBJECTIVES: Cushing's disease (CD) is an extremely debilitating endocrine condition caused by an adrenocorticotropic hormone (ACTH)-secreting pituitary adenoma. CD has a significant impact on patients' health, as well as on their physical, cognitive, emotional, and social well-being. Treatment of CD is complex involving surgery, radiotherapy and medication; however, there are limited published real world data on treatment patterns. **METHODS:** A retrospective database analysis study using CPRD linked with Hospital Episode Statistics (HES) was conducted. Patient population included patients enrolled after January 1956 up to March 2012 with at least two CD diagnosis or Cushing's Syndrome diagnosis and one of the following: transsphenoidal surgery, benign pituitary neoplasm or pituitary disorder. Data was collected from 510 general practitioners (GPs). Patients' characteristics, treatment history, and comorbidities were analysed. Cortisol values (urinary free or serum) were expressed as ULN-fold based on patient specific lab norms. Standardized Mortality Ratio (SMR) was calculated and compared to general age/gender matched UK population. **RESULTS:** A total of 258 patients with CD were identified (227 alive and 31 dead)). Among alive patients, mean age (SD) was 54(15) years old, 76% female, mean age at diagnosis was 38(15). Comorbidities were: infections (63%), hypertension (47%), fractures (30%), depression (25%), diabetes mellitus (22%), osteoporosis (22%) and obesity (18%); 65% of patients had treatment records. Among those: 48% received TSS, 41% adrenalectomy, 24% radiotherapy and 42% oral medications. A total of 32% of 1st line TSS and 34% of 1st line radiotherapy patients received further treatment; 26% of adrenalectomy patients were treated with radiotherapy and/or surgery for Nelson's syndrome. Among patients on oral medications, majority received metyrapone (79%) or ketoconazole (32%). 69% of patients with cortisol measurements (n=92) were not controlled. SMR was 7.4, 5.1 and 3.1 at 5, 10 and 15 years respectively. **CONCLUSIONS:** This study demonstrated significant mortality and morbidity burden of CD in the UK primary practice.

PDB123
SYSTEMATIC REVIEW ON THE COST-EFFECTIVENESS OF THERAPEUTIC EDUCATION TO PREVENT THE DEVELOPMENT AND PROGRESSION OF TYPE 2 DIABETES
Odnoletkova I[1], Goderis G[1], Pil L[2], Nobels F[3], Aertgeerts B[1], Annemans L[4], Ramaekers D[1]
[1]*University of Leuven, Leuven, Belgium,* [2]*Ghent University, Gent, Belgium,* [3]*Aalst Hospital, Aalst, Belgium,* [4]*Ghent University & Brussels University, Ghent, Belgium*
OBJECTIVES: To critically appraise current evidence on the cost-effectiveness (CE) of therapeutic education for people with type 2 diabetes (T2D) and prediabetes compared to usual care. **METHODS:** We conducted a systematic review of economic evaluations of educational programs for people with T2D or prediabetes which were based on randomized controlled trials and published between 2002 and 2012. The quality of the clinical and the health economic evidence was ranked high, moderate, low or very low after critical appraisal by means of the Cochrane Collaboration's tool for assessing risk of bias and the Consensus Health Economic Criteria List. Interventions were classified based on the reported incremental cost-effectiveness ratios (ICERs). **RESULTS:** The search yielded 1.886 publications. Fourteen met the inclusion criteria. In prediabetes, patient education was found to be cost-saving in two out of five studies. The reported ICERs were €850; €24.400; €110.850 per quality adjusted life-year (QALY) gained from the payer's perspective and €6.800; €40.000; €48.500 per QALY gained from the societal perspective. In T2D, the CE of patient education varied from cost-saving to not cost-effective and had a mean ICER of €44.500 (range: €6.380; €83.000) per QALY gained from the payer's perspective. The quality of the health economic evidence was mainly moderate or low in studies on prediabetes, and very low in studies on T2D. The uncertainty analysis were not exhaustive in most studies. In the modeling studies (n = 10), the models' structural assumptions and validation methods were in general not properly reported. **CONCLUSIONS:** Current evidence on CE of therapeutic education of people with prediabetes and T2D is limited in volume and quality but consistently suggests that investing in patient education may offer good value for money. Studies of better quality are needed to reconfirm these findings. Commonly accepted methodologies for performance and assessment of health economic evaluations should guide further research.

PDB124

IMPACT OF VALUE COMMUNICATION IN DECISION MAKING: AN APPROACH TO THE TREATMENT OF TYPE 2 DIABETES IN PORTUGAL

Viriato D[1], Antunes M[2]
[1]*Novartis, Sintra, Portugal,* [2]*Faculdade de Ciências da Universidade de Lisboa, 1749-016, Portugal*

The increasing budgetary constraints faced by health care payers have made the access decision increasingly complex and decentralized processes a growing trend. Thus, demonstration of new health technologies value has become critical to ensure patients' access to innovation.**OBJECTIVES:** To identify the most important value messages within decision making process in the treatment of Type 2 Diabetes *Mellitus* (T2DM) among General Practitioners (GP) coordinating Primary Care Centers. **METHODS:** Regional meetings based on Health Economics training held (during 2013) with GPs, including the presentation of a cost-effectiveness analysis of vildagliptin vs sulphonilureas (SU) and a budget impact tool that enables the estimation of meaningful impacts of T2DM. Two surveys were developed to be applied at beginning and end of training to characterize the learning insights and identify the factors considered in the decision process. **RESULTS:** Partial results based on a 51 GPs sample are presented. The positive impact of the training in HE concepts was statistically significant (p=0.000) with an 89.4% average rate of correct answers. More than 50% of GPs considered the increasing prevalence of T2DM, cost of macrovascular and microvascular complications and the impact of hipoglycaemias in patients' quality of life (QoL) and costs, as the most important factors in the decision process. The key decision factor to use vildagliptin is the improvement of patients' QoL. The use of SU is explained due to its fast response, mainly in patients with Hb1Ac level above 7.5%. Majority of GPs (87.5%) chose vildagliptin as the preferred therapeutic for T2DM patients not controlled with metformin. **CONCLUSIONS:** This analysis demonstrated that both epidemiological and economic factors are important at local decision process. Clinically, patients' QoL is the most relevant achievement. Most GPs prefer vildagliptin to control T2DM, considering QoL improvements its greatest benefit.

PDB125

QUALITY OF CARE FOR TYPE 2 DIABETES MELLITUS PATIENTS IN DUBAI

Donato BMK[1], Osenenko KM[2], Korol EE[2], Szabo SM[2], Qatami L[3], Al Madani A[4], Al Awadi F[4], Al Ansari J[4], Maclean R[5], Levy AR[2]
[1]*Bristol-Myers Squibb Company, Wallingford, CT, USA,* [2]*Oxford Outcomes Ltd., Vancouver, BC, Canada,* [3]*Bristol-Myers Squibb Company, Dubai, United Arab Emirates,* [4]*Dubai Hospital, Dubai, United Arab Emirates,* [5]*Bristol-Myers Squibb, Plainsboro, NJ, USA*

OBJECTIVES: Despite the high prevalence (25%) of type 2 diabetes mellitus (T2DM) in the United Arab Emirates (UAE), few data are available on the types and quality of care administered. Quality of care is an important determinant of whether clinical targets can be met, and serious complications avoided. The objective was to estimate the proportion of T2DM patients receiving recommended monitoring of clinical measures in Dubai, over one year. **METHODS:** Charts from T2DM patients aged ≥18 years that visited the Dubai Hospital between October 2009 and March 2010 (enrolment period) were systematically sampled until the target (n=250) was reached. Quality of care was assessed from April 2010 to March 2011, adapted from the United States (US) Healthcare Effectiveness Data and Information Set (HEDIS) Comprehensive Diabetes Care measures. Measures included: glycosylated haemoglobin (HbA1c) screening, control (<8%) and poor control (>9%); low-density lipoprotein (LDL) screening and control (<100mg/dL); blood pressure (BP) control (<140/90mmHg); retinopathy screening; and medical attention for nephropathy. Patients were classified as having control based on their latest test in the period. **RESULTS:** Mean age at enrolment was 58 years (standard deviation (SD): 12 years), 33% were male, and mean T2DM duration was 14 years (SD: 8 years). Over the 12-month period, 98% underwent HbA1c screening (54% had control and 26% displayed poor control); 90% underwent LDL screening (64% had control); 43% had BP control; 32% had retinopathy screening; and 16% attention for nephropathy. Two-hundred and eleven patients (84%) were screened for BP, LDL and HbA1c measures over the period. **CONCLUSIONS:** Guideline monitoring was conducted for most patients; rates of compliance were comparable to or higher than US benchmarks for HbA1c and LDL monitoring. Greater understanding of the factors leading to high adherence to the guidelines would be useful for other areas of preventive care, and other hospitals and jurisdictions.

PDB126

USING A "STANDARDS OF CARE ECONOMIC MODEL" TO QUANTIFY BARRIERS AND POTENTIAL SOLUTIONS TO PROVIDING OPTIMAL GUIDELINE-DRIVEN CARE TO PATIENTS WITH DIABETES MELLITUS IN THE UNITED STATES

Hughes KE
Avalere Health LLC, Washington, DC, USA

OBJECTIVES: 1) Build economic model to estimate resources to deliver current standards of care to US diabetes patients, and 2) Evaluate provider costs to meet standards, assess patient outcomes specified in guidelines relative to reimbursement. **METHODS:** Build model: 1) Integrate 3 national standard sets (ADA, AACE, and TES) into 28 consolidated standards of optimal care; 2) Develop provider matrix for rendering care; 3) Draft 6 clinical vignettes: 3 each T1DM and T2DM; 4) Convene 3 multidisciplinary panels of 4-7 care professionals; with facilitator, estimate minimum/maximum time to achieve care standards/patient type – baseline/best cases; 5) Convene separate panel estimating time to start/follow patients using CSII or CGM; 6) Multiply provider time by average wage and overhead amounts to determine visit cost; 7) Map activities to CPT and HCPCS billing codes and payment rates; 8) Compute reimbursement per expected payer mix; and 9) Note gaps in reimbursement compared to costs on unit and total basis. Populate model; perform analytics: Repeat Steps 4-9 with data from national provider survey and national database. **RESULTS:** 1) Baseline scenarios show provider costs exceed reimbursements for all type patients; best case indicates same in 5 of 6 scenarios; 2) In different scenarios costs of treating adults exceed reimbursement by >$750,000 per year; practices would require 19%-64% increase to breakeven; 3) In pediatric practice, costs exceed reimbursement by >$471,000 per year; 4) Gaps are increased for patients using CSII and CGM; and 5)Results are more sensitive to reimbursement for routine physician care and lifestyle modification services. **CONCLUSIONS:** 1) Seven American professional societies comprising the Diabetes Working Group (DWG) concur delivering high-quality, guideline-based diabetes care unrealistic given current care and payment paradigms; 2) DWG recommends alternative approaches in 3 areas: care management, payment reform, and workforce supply, to mitigate increasing medical and financial impact of this epidemic chronic illness; 3) Model can be used internationally to support public policy efforts.

PDB127

GLP1 AND INSULIN GLARGINE TREATMENT PATTERNS AMONG TYPE 2 DIABETES PATIENTS IN MAJOR EU MARKETS

Divino V[1], Hallinan S[1], Dekoven M[1], Varol N[2], Lee WC[1], Reaney MD[2]
[1]*IMS Health, Alexandria, VA, USA,* [2]*Eli Lilly and Company, Windlesham, Surrey, UK*

OBJECTIVES: Evaluate treatment patterns of Type 2 diabetes (T2D) patients initiating glucagon-like peptide-1 receptor agonists (GLP1) or insulin glargine in Germany (GE) and UK. **METHODS:** Adult T2D patients initiating exenatide twice-daily (exBID), liraglutide (LIRA) or glargine (1/10-12/11), or exenatide once-weekly (exQW) (1/10-6/12), were identified using the IMS LifeLink™ EMR-EU databases (exQW in GE only). Therapy initiation date was termed '*index date*'. Eligible patients were naïve to index therapy class and had ≥180 days pre- and ≥360 days post-index data (180 post-index exQW only). Treatment modification was evaluated over 180-day and total post-index period. Patients were required to have non-missing prescription data. **RESULTS:** 6,171 GE (300 exBID/174 exQW/906 LIRA/4,791 glargine) and 1,042 UK (249 exBID/306 LIRA/487 glargine) patients were included. Approximately half were male (GE/UK% 53.9/51.9). At index, mean age in GE/UK was 57.6/57.6 among GLP1 initiators; 67.4/63.1 among glargine initiators. Incidence of treatment modification (discontinuation, switch or augmentation) over 180-day post-index varied by treatment and country (GE/UK,%): exBID (58.0/41.4), LIRA (54.1/39.2), exQW (40.8/NA), glargine (13.7/29.2). Augmentation as first modification was rare among exBID and LIRA patients (GE/UK,% of those with modification); 11.5/6.8 and 10.0/7.5, respectively, compared to exQW (26.8/NA) and glargine (66.1/45.1). Discontinuation rates (i.e., stopping index therapy without switch to a new therapy) were higher than switching rates throughout the 180-day period for GLP1 and glargine users (GE/UK,% of those with modification): GLP1 74.4/75.3 discontinuation & 13.6/17.5 switch; glargine 32.9/52.8 discontinuation and 1.1/2.1 switch. Using all available post-index data, mean follow-up was (GE/UK, months): exBID 24.5/25.6, LIRA 24.0/21.8, exQW 10.6/NA, and glargine 24.4/25.4; proportions with treatment modification were (GE/UK,%): exBID 91.0/81.5, LIRA 80.1/71.6, exQW 57.5/NA, glargine 69.8/72.1. **CONCLUSIONS:** Treatment patterns varied among GLP1 and glargine patients. Longer-term data would be useful to further elucidate practice patterns associated with these medicines, particularly exQW.

PDB128

TREATMENT PATTERNS AMONG TYPE 2 DIABETES MELLITUS PATIENTS IN DUBAI

Osenenko KM[1], Szabo SM[1], Donato BMK[2], Korol EE[1], Qatami L[3], Al Madani A[4], Al Awadi F[4], Al Ansari J[4], Maclean R[5], Levy AR[1]
[1]*Oxford Outcomes Ltd., Vancouver, BC, Canada,* [2]*Bristol-Myers Squibb Company, Wallingford, CT, USA,* [3]*Bristol-Myers Squibb Company, Dubai, United Arab Emirates,* [4]*Dubai Hospital, Dubai, United Arab Emirates,* [5]*Bristol-Myers Squibb, Plainsboro, NJ, USA*

OBJECTIVES: The United Arab Emirates (UAE) has among the highest prevalence (25%) of type 2 diabetes mellitus (T2DM) globally; however, few data are available on how patients are managed in clinical practice. The objective was to characterize recent treatment patterns among T2DM patients in Dubai. **METHODS:** Charts from T2DM patients aged ≥18 years that visited the Dubai Hospital between October 2009 and March 2010 (enrolment period) were systematically sampled until the target (n=250) was reached. Treatment data from enrolment to September 2011 were abstracted from patient charts, as well as treatments received before enrolment. Treatment regimens, their frequency of use, and the number of switches (drug replacement/removal/addition) over the study period were calculated. Analyses were stratified by T2DM duration, and data for those recently-diagnosed (<5 years; n=29) and with longstanding disease (≥20 years; n=67) are presented. **RESULTS:** Mean age at enrolment was 58 years (SD: 12 years), 33% were male, and mean T2DM duration was 14 years (SD: 8 years). At enrolment, 74% of patients had received prior insulin treatment (recently-diagnosed: 55%; longstanding disease: 84%). During the study period, the most common regimens were insulin+oral combination therapy (55%) and oral combination therapy (39%). Overall, 67% received any insulin therapy during the study period (recently-diagnosed: 45%; longstanding disease: 87%). By study end, 78% had received insulin therapy at any time (recently-diagnosed: 62%; longstanding disease: 88%). On average, T2DM patients had two treatment switches; little variation was seen by T2DM duration. **CONCLUSIONS:** Most patients had longstanding T2DM and received treatment with insulin. Patients had an average of two treatment switches over the relatively short study period, indicating modification was attempted to improve T2DM control. Novel therapies may improve clinical outcomes among T2DM patients and this study provides valuable baseline data with which to compare the effectiveness of new T2DM treatments in Dubai.

HOW CO-PAYMENT MECHANISM HAS CHANGED PATIENTS' PERCEPTION TOWARDS OTC-TYPE PRODUCTS?

Deger CC, Tuna E, Ozdemir Z, Ozel MO, Parali E, Sumer F, Yilmaz ZS
Bayer Turk Kimya San. Ltd. Sti., Istanbul, Turkey

OBJECTIVES: Turkish health care system has developed in terms of quality, access, equity and efficiency with the introduction of a number of reforms under "Health Transformation Program" since 2003. However, these have created significant financial burden to the government. In order to contain expenditures, avoid overuse, misuse and abuse; government has implemented certain cost sharing tools. Our objective is to define how co-payment mechanism has affected patients' purchasing behavior regarding OTC-type products. **METHODS:** Regulations and reports published by Ministry of Health and Social Security Institution, "Health Systems in Transition Turkey 2011" and "IMS Market Prognosis 2012-2016" reports are examined. **RESULTS:** In Turkey, family physicians do not act like gatekeepers since a formal referral system does not exist. Therefore, patients could directly apply to secondary/tertiary health care services without co-pay. At secondary/tertiary health care levels, co-payment rate is 5 TL and 12 TL for outpatient care in public and private hospitals respectively, 3 TL for prescription fee and extra 1 TL for each product exceeding 3 products per prescription. All active workers pay 20% while retirees pay 10% of total amount of the prescriptions as co-pay. Patients with chronic conditions requiring medical report are exempt from co-pay. Considering different co-payment rates and number of visits/prescriptions recorded in hospitals, it is calculated that patients paid approximately 3 billion TL in total outpatient care as co-payment in 2012. **CONCLUSIONS:** Minimum 9 TL in total is required as a co-payment for outpatient care and prescription, if patient visits a public hospital. Therefore, for products with a lower price than 10 TL, patients rather go directly to pharmacies. This behavioral change of out-of-pocket payments might be explained by improved purchasing power and increased co-pay rates.

METHODOLOGICAL CHALLENGES IN MULTI-CRITERIA DECISION ANALYSIS (MCDA) FOR HEALTH POLICY DECISION-MAKING: A SYSTEMATIC REVIEW

Wahlster P[1], Goetghebeur MM[2], Kriza C[1], Niederländer CS[1], Kolominsky-Rabas PL[1]
[1]*Centre for Health Technology Assessment (HTA) and Public Health (IZPH), University of Erlangen-Nuremberg, Erlangen, Germany,* [2]*LASER Analytica, Dorval, QC, Canada*

OBJECTIVES: Decision making about health technologies from research and development to reimbursement is affected by heterogeneous opinion and criteria of participating stakeholders. There is a lack of systematic consideration of stakeholders' preferences in current health policy. Multi-criteria decision analysis (MCDA) offers a solution to take preferences into account. This study gives an overview about the applications of MCDA methods in health economic decision-making. **METHODS:** A systematic review of the health care literature was performed to identify original research articles. Using predefined categories, data was systematically extracted for the type of policy applications, MCDA methodology, criteria used and how they were defined. **RESULTS:** Twenty-one studies were included in the analysis. 12 studies (67%) used indirect approaches and nine studies (43%) used direct MCDA approaches. Four studies (19%) focused on technologies in the early innovation process. The majority of 17 studies (81%) examined a technology on the level of reimbursement decision. Eight studies (38%) resulted into implementation, which means that an official committee considered the MCDA results. Other studies were conducted in an explorative manner. MCDA decision criteria used were obtained from literature research and context-specific studies, expert opinions, and group discussions. The number of criteria ranged from three up to 15. The most prominent criteria described health outcomes (71%), disease impact (62%), and implementation of the intervention (38%). **CONCLUSIONS:** MCDA is used at different levels of medical innovation and can increase transparency for involved stakeholders by explicitly structuring decision criteria. Further research is needed to understand existing variability of the number of criteria used and ensure that models are robust regarding potential criteria overlaps, performance scales and operationalizability aligned with evidence needs.

SUPPLEMENTARY HEALTH INSURANCE IN TURKEY

Deger CC, Tuna E, Ozdemir Z, Ozel MO, Parali E, Sumer F, Yilmaz ZS
Bayer Turk Kimya San. Ltd. Sti., Istanbul, Turkey

OBJECTIVES: In Turkey, almost everyone is covered by General Health Insurance Scheme (GHIS) under Social Security Institution (SSI). GHIS provides a Basic Benefit Package (BBP) for patients to benefit from both public and private health care providers contracted with SSI. Patients are obliged to pay certain level co-pays for extra services as defined in the regulation. Besides GHIS, patients could benefit from private health insurances(PHI) by paying relatively high level of premiums for different types of PHI packages. Supplementary Health Insurance(SHI) law has been enacted in June 2012 and patients started to benefit from SHI by paying relatively lower premiums for health care services that are not covered or partially covered by BBP. The objective is to evaluate the significance and potential of SHI in Turkey. **METHODS:** Regulations of SSI, OECD publications, International Investors Association's Turkey Report and database of Insurance Association of Turkey are examined. **RESULTS:** Number of private hospitals has increased by 50% over 5 years and reached out 500 by 2012. Parallel with this growth, PHI sector market share has also increased. By 2012, number of people covered by PHI has reached out more than 2 million and the PHI market is expected to reach nearly USD 2 billion in 2015. Meanwhile, approximately 20 thousand people has covered by SHI since November 2012 and SHI is expected to reach 5 million people next 5 years. **CONCLUSIONS:** Public health care expenditure is continuously rising due to increased health demand, increased coverage and demographic changes. In order to assure a financially sustainable health care system, PHI could be an option and create source of funding for the health care expenditure. In this context, SHI will reduce the pressure on public health budget, create an area of growth for the private health insurance sector, allowing health care providers supplying both public and private health care to become more effective.

THE ROLE OF COMMUNICATION AND HEALTH LITERACY ON PATIENT SAFETY IN PUBLIC PHARMACIES IN THE REPUBLIC OF SRPSKA

Janjic Z[1], Tasic L[2], Rados L[3], Krajnovic D[2], Medic G[4]
[1]*Pharmacies "Zdravlje Pharm", Bijeljina, Republic of Srpska, Bosnia,* [2]*University of Belgrade – Faculty of Pharmacy, Belgrade, Serbia and Montenegro,* [3]*Pharmacy Zrenjanin, Zrenjanin, Serbia and Montenegro,* [4]*Mapi - HEOR & Strategic Market Access, 3995 AX Houten, The Netherlands*

Health literacy is the skill (social and cognitive) that determines the motivation and ability of the person to receive, understand and use information in order to improve and maintain good health. Communication between patients and pharmacist is essential for optimal patient safety.**OBJECTIVES:** To highlight the importance and present the results of conducted research and to give recommendations for improving the health literacy among patients and pharmacists' communication skills. **METHODS:** The study was conducted in June 2013 in 5 selected branches of pharmacy-chain "Zdravlje Pharm" in Bijeljina, Republic of Srpska, Bosnia and Herzegovina. The sample consisted of 219 patients selected randomly, of whom 195 accepted the survey, and 24 rejected to participate. The instrument was previously validated and adjusted questionnaire of Pharmacy Zrenjanin, Serbia, related to patient satisfaction with pharmacy services, but also conceived needs of the thesis, with 32 close-type questions, except one. Health literacy of patients and communication with pharmacists were followed. The analysis was done in Excel, and the results are given in tables and graphs. **RESULTS:** About 90% of patients reported that pharmacists give clear information during consultations and the advices helped them. A total of 65% reported to easily remember the information from the pharmacists, which shows a good level of patient health literacy; but the rest can have uncertain outcomes of the therapy and be exposed to greater safety risks. **CONCLUSIONS:** There is a place for improvement of aspects which can contribute to better patient safety. That can be achieved by applying certification standards throughout the health care system in the Republic of Srpska.

PHP5

ARE THE BIOTECHNOLOGY AND PHARMACEUTICAL SECTORS DEFENSIVE RELATIVE TO THE S&P 500?

Furnback W, Wang B, Magyar AF
Alliance Life Sciences, Somerset, NJ, USA

OBJECTIVES: The health care sector is widely regarded as a defensive play in the stock market. We analyzed the performance of a pharmaceutical and a biotechnology index from March 2000 through April 2013 alongside the S&P 500. **METHODS:** We categorized the S&P 500 from March 2000 through April 2013 into bull and bear markets. During this time there were three bull markets and three bear markets. Bull and bear markets were defined as changes in the S&P 500 of more than 20%. We followed the AMEX Pharmaceutical (^DRG) and Biotechnology (^BTK) Indices to represent their sectors. We compared the returns of the sectors with the overall market and also calculated their correlated volatility (beta) with the S&P 500. **RESULTS:** For the entire analysis period, the S&P 500 returned 4.59% while ^DRG and ^BTK returned 25.43% and 252.83%, respectively. During the bear markets, the S&P 500 lost at an average annual rate of 27.17%, while ^DRG and ^BTK lost at annual rates of 12.16% and 21.99%, respectively. Though ^DRG performed best during the bear markets, it was a laggard in the bull market gaining 8.15% annually, while the S&P 500 and ^BTK had 22.04% and 31.97% annual returns, respectively. The overall beta during our analysis period was 0.63 for ^DRG and 1.07 for ^BTK. **CONCLUSIONS:** Both the AMEX Pharmaceutical and Biotechnology Indices fell at a lesser rate than the S&P 500 during bear markets. The Pharmaceutical Index may be the more defensive play as it lost at an average annual rate of more than two times less than the S&P 500. However, the Biotechnology Index gained almost four times more than the Pharmaceutical Index in bull markets and also outperformed the S&P 500 by almost 10 percentage points during bull markets.

COMPARISON OF DEVELOPMENT DIAGNOSIS RELATED GROUPS BASE RATE IN HUNGARY AND GERMANY

Ágoston I[1], Bordi K[2], Sebestyén A[3], Szarka E[1], Schaefer J[4], Boncz I[1]
[1]*University of Pécs, Pécs, Hungary,* [2]*AGAPLESION gAG, Frankfurt am Main, Germany,* [3]*National Health Insurance Fund Administration, Pécs, Hungary,* [4]*AGAPLESION FRANKFURTER DIAKONIE KLINIKEN gGmbH, Frankfurt am Main, Germany*

OBJECTIVES: Diagnosis Related Groups (DRG) based methods was introduced for acute hospital care reimbursement in 1993 in Hungary (H-DRG) and in 2003 in Germany (G-DRG). The aim of our study is to compare the development of DRG base rate in Germany and Hungary. **METHODS:** The Hungarian data derive from the financial database of the Hungarian National Health Insurance Fund Administration (NHIFA), the only health care financing agency in Hungary. German data derive from German DRG Institute. We analyzed how the uniform, nationwide DRG base rate has been introduced in both countries. **RESULTS:** The German DRG system consists of 1200 disease groups, while the Hungarian contains ca. 736 groups. The German DRG base rate was hospital specific between 2003-2004. From 2005 to 2009 hospital-specific base rates converged to a state-wide base rate. From 2010 to 2014, the state-wide base rates should converge to a nationwide base rate. The German hospital specific base rate varied between EUR2200-3200. In Hungary, a hospital groups specific base rate was applied for 16 groups of hospitals between 1993-1998 with a gradual converge of base rates. Middle level (county or regional) base rate was not introduced in Hungary. The nationwide uniform DRG base rate was set up in 1998 in Hungary. The Hungarian uniform DRG base rate was EUR518 in 2012. **CONCLUSIONS:** Both Hungary and Germany applied a gradual implementation of uniform DRG base rate. Germany took three steps (hospital, Lander and nationwide), while Hungary took two steps (hospital group, nationwide) in reaching the nationwide uniform DRG base rate.

THE ASSOCIATION BETWEEN EUROPEAN MEDICINES AGENCY APPROVAL AND HEALTH TECHNOLOGY ASSESSMENT RECOMMENDATION

Lipska I[1], Hövels AM[2], McAuslane N[1]

[1]*Centre for Innovation in Regulatory Science, London, UK,* [2]*Utrecht University, Utrecht, The Netherlands*

OBJECTIVES: To find the association between duration of the process of marketing authorization (MA) approval at European Medicines Agency (EMA) and health technology assessment (HTA) recommendations in European Union (EU) countries. **METHODS:** EMA MA timing for new active substances (NASs) during 2007-2009 were analyzed based on publicly available information. HTA recommendations (positive, positive with restrictions, negative, not assessed) issued for the same medications in 6 EU countries (SMC, Scotland; AOTM Poland; CVZ, The Netherlands; HAS, France; NICE, UK; INFARMED, Portugal) were also analyzed based on public information. Hypothesizing that EMA approval process timing might be an indicator of complexity and potential issues in the dossier, the potential for longer EMA approval times being associated with less beneficial HTA recommendation was investigated. Analyses were performed per country as EMA decisions are centralized but HTA recommendations are taken independently by member states. **RESULTS:** A total of 86 NAS were approved by EMA in 2007-2009; mean time of approval was 460 days (median 423 days). In total, we expected 516 HTA recommendations (86 drugs assessed by 6 organizations). We found in total 138 positive, 77 positive with restrictions, 67 negative recommendations. 234 expected recommendations for 6 HTA included in this study were not assessed (45,3% of all expected recommendations). The association between HTA recommendation and approval time (in days) was analyzed using Spearman's rho rank correlation. There was statistically significant negative correlation between approval time and HTA recommendation in The Netherlands. More time needed for EMA approval was associated with less beneficial HTA recommendations. Correlations in other countries were not statistically significant. **CONCLUSIONS:** Our research indicates that a longer EMA approval process is associated with a less beneficial HTA recommendation in The Netherlands. Further research is required whether this indicates that the same issues that cause delays at EMA are reconsidered at HTA authorities.

PHP9

THE IMPACT OF INDICATION EXTENSIONS ON PHARMACEUTICAL PRICES

Genane C[1], Marinoni G[2], Ando G[2], Reinaud F[1]

[1]*IHS, Paris, France,* [2]*IHS, London, UK*

OBJECTIVES: To assess the impact of an indication extension on pharmaceutical prices in 9 markets: Australia, Brazil, France, Germany, Italy, Japan, Spain, Turkey, and the UK. **METHODS:** Websites of the EMA and national regulatory agencies were surveyed to indentify medicines granted an indication extension between 2007 and 2013. Eight case studies (bevacizumab, trastuzumab, sunitinib, ivabradine, telmisartan, aripiprazole, paliperidone, and omalizumab) were selected based on market share and availability across the geographies of interest. The list prices, at ex-manufacturer levels, of these eight drugs and those of the medicines belonging to their therapeutic class (at ATC level 3) were collected for the period 2007-13. Price movements for these eight medicines were compared to the price evolution within their therapeutic class over the period. **RESULTS:** Based on the selected case studies, there is ambivalent synchrony between indication extensions and pharmaceutical list price movements in the countries analysed. The data show that list prices tend to remain stable following an indication extension. When list prices changed subsequent to an indication extension, the movements could not directly be linked to the indication extension, as external factors such as a class trend or a wider pricing and reimbursement process (e.g. blanket price cuts) could also play a role. **CONCLUSIONS:** There is inconclusive evidence that indication extensions lead to list price changes in the countries analysed. Moreover, the impact of commercial agreements and discounts should be taken into account as secondary indications may be subject to separate pricing arrangements (e.g., patient access schemes). As such, the selection of the indication for the first marketing-authorisation filing (such as a high medical need, niche indication, commanding a premium price) is pivotal for the commercial success of a medicine, as its launch price seems unlikely to be reviewed following subsequent approvals in broader patient populations.

PHP10

ECONOMIC ANALYSIS OF THE PREVENTION OF MEDICAL SHARPS INJURIES WITH SAFETY-ENGINEERED DEVICES: A SYSTEMATIC REVIEW

Barnett GS[1], Maclaine GDH[2]

[1]*Gillian Barnett & Associates Ltd., Dunfanaghy, County Donegal, Ireland,* [2]*Becton, Dickinson UK Ltd., Oxford, UK*

OBJECTIVES: To protect health care workers from risk of needlestick injury, preventive safety measures are increasingly mandated in the health care environment, which may include the use of safety-engineered medical sharp devices (SEDs) specifically designed to prevent sharps injuries. We undertook a systematic review of the literature to understand the economic impact of replacing conventional sharps devices with SEDs. **METHODS:** We conducted searches of electronic databases including Embase/MEDLINE, PubMed, CINAHL Plus, HEED, NHS EED, the Cochrane Library, ProQuest Nursing and Allied Health Source, and the Tufts CEA Registry. Databases of the WHO and HTA agencies, reference lists of identified studies, conference abstract books and the internet were also searched. The time horizon covered January 1990 to March 2013. Two reviewers independently screened titles and abstracts, applied inclusion criteria to full text papers and extracted data from identified studies according to an a priori defined data set. Differences were resolved by consensus. Study quality was assessed using a published 10-point checklist. **RESULTS:** From 19621 records, 21 studies met the review criteria and were selected. Most studies (16) were budget impact analyses (BIAs). Reductions in sharps injuries with SEDs ranging from 12% to 100% were reported. Just 4 studies were assessed as providing the best quality evidence: a cost benefit analysis and 3 BIAs. Key assessment criteria that the other studies did not meet were consideration of all relevant costs and execution of a sensitivity analysis. Of the best quality studies, 3 reported net economic benefits from implementing SEDs, at least in the base case analysis. **CONCLUSIONS:** Investment in SEDs generates economic benefits from savings in managing medical sharps injuries and their sequelae. Future economic evaluations need to carefully assess all important and pertinent costs to enable well-informed decision making about the implementation of SEDs in the health care workplace.

PHP12

A PRICE COMPARISON STUDY OF RECENT DRUGS IN EU5, 2008-2012

Le Pen C[1], Vigier D[2], Grandfils N[2]

[1]*Université Paris Dauphine, PARIS, France,* [2]*IMS Health, PARIS LA DEFENSE, France*

OBJECTIVES: To compare prices of new drugs between France and the other EU4. **METHODS:** Study used IMS MIDAS database for economic data such as prices and sales volume and LEEM database (French association of the pharmaceutical manufacturers) for the ASMR scale (HAS assessment of the drug's added value/innovation). All the products applying for the first time for reimbursement by the French Public health insurance between January 2008 and June 2012 were included in the study (except those restricted to hospital use in France) and having an ASMR rating and an official price in June 2012. Paasche and Laspeyres price-index were calculated for drugs with: a) high ASMR, b) ASMR IV, c) ASMR V and d) all drugs. A sensitivity analysis was conducted to measure the effect of different weighting options. **RESULTS:** A total of 107 products (245 dosages) were included in this study. Fifty-one (48%) have been found available in the community pharmacies of all the 5 countries. The availability analysis by pair of countries (France + another) is higher: 94 for Germany, 79 for UK, 71 for Spain and 69 for Italy (Italy often restricts drug's access to hospitals only). French prices are generally equal to or lower than prices in the four other markets, which shows a relative price index decrease for France since 2008 studies. The only significant exception are UK prices for products ranked in France ASMR 1-2-3 (20% less expensive). Prices are regularly and significantly higher in Germany than in all other countries. Interestingly, the highest disparities in prices occur for the ones ranked as most innovative in France – while ASMR IV have surprisingly consistent prices across EU5. **CONCLUSIONS:** European patients don't have consistent access to the same drugs in retail market, and the drugs considered innovative in France show a large price index disparity across EU5, with UK prices being 20% lower.

PHP13

TO WHAT EXTENT CAN BIOSIMILARS COMPETE WITH BRAND NAME BIOLOGICS? A EU-5 GRANULOCYTE-COLONY STIMULATING FACTORS MARKETS ANALYSIS

Bocquet F[1], Paubel P[2], Fusier I[3], Cordonnier AL[3], Le Pen C[1], Sinègre M[3]

[1]*Dauphine University, Paris, France,* [2]*Paris Descartes University, Paris, France,* [3]*General Agency of Equipment and Health Products (AGEPS), AP-HP, Paris, France*

OBJECTIVES: To determine the ability of biosimilars (copies of branded biologics) to compete with brand name biologics within the same therapeutic class by analyzing EU-5 G-CSF (Granulocyte-Colony Stimulating Factors) markets and the factors affecting the G-CSF biosimilar uptakes, particularly that of biosimilar prices relative to reference G-CSFs. **METHODS:** Data on medicine volumes, values and ex-manufacturer prices for all G-CSF categories were provided by IMS Health. Volumes were calculated in DDD (Defined Daily Doses) and prices in euros per DDD. In the EU-5 countries biosimilar G-CSFs benefit from a 5-year experience. Data were available from 2007 until 2011. **RESULTS:** There are two G-CSF market profiles: i) countries with a high retail market distribution which are the largest G-CSF markets with low global G-CSF biosimilar uptakes (5.4% in France and 8.5% in Germany in 2011); ii) countries with a dominant hospital channel which are the smallest markets with higher G-CSF biosimilar uptakes (12.4% in Spain and 20.4% in the UK). The G-CSF biosimilar uptakes depend critically on their market access at a local/regional level. The more the decisions are decentralized (hospitals, local purchasing structures) the more their uptakes are high (28.3% of the hospital market in France in 2011 and 20.4% in the UK). The price difference between G-CSF biosimilars and their reference plays a marginal role at a global level (+13.3% in the UK and -20.4% in France). **CONCLUSIONS:** The competition with G-CSF biosimilars varies significantly between EU-5 countries due to distribution channel differences. Currently, this competition is not mainly based on prices, but on local political options to stimulate tendering between them and other most recently branded products. In countries with dominant retail markets, a prerequisite for the success of biosimilar G-CSFs is that governments approve their substitution in the same way generics are authorized by introducing them case-by-case.

PHP14

CHARACTERISING PRELIMINARY PROFILE PARAMATERS FOR FDA BREAKTHROUGH THERAPY CANDIDATES

Labban M, Izmirlieva M, Ando G

IHS, London, UK

OBJECTIVES: Since the new Breakthrough Therapy (BT) designation was introduced with the new Food and Drug Administration Safety and Innovation Act (FDASIA) on 9 July 2012, the FDA has received over 50 requests, and has issued over 20 such designations to various candidates in various indications based on preliminary evidence that the investigational drugs fulfill a highly unmet medical need where no alternatives exist, or demonstrate a significant improvement over existing therapies. We have set out to examine the key parameters that characterise a "Breakthrough" candidate, and to determine the likelihood of an investigational therapy being granted the status. **METHODS:** Using the FDA listing of BT designation statistics, publicly available information, as well as IHS Global Insight data, we identified a list of currently approved BT candidates between 9 July 2012 and 14 June 2013 and determined their preliminary profile characteristics. **RESULTS:** To date, nearly 75% of the designations have been publicly announced by the pharmaceuticals firms

developing the candidates, with investigational oncology drugs representing the largest proportion (53%). Orphan diseases make up the second largest group with over a third of publicly disclosed BT therapies. In therapeutic areas with already available treatment options, such as Hepatitis C Virus infections and advanced melanoma, there is still potential for drug candidates to gain BT designation if they can be shown to provide an alternative to effectively treat patients that fail to respond to the current standard of care. **CONCLUSIONS:** Our investigation has highlighted the FDA's focus on finding breakthrough candidates within oncology as well as rare genetic or orphan diseases that do not currently have adequate treatment options. Additionally, candidates offering alternative options to non-responders have also secured a place on the list, which is likely to grow as increased interest and awareness is generated.

PHP16

MEDICO-ECONOMIC EVALUATION IN FRANCE: METHODOLOGY AND IMPACT ON THE PRICING AND REIMBURSEMENT SYSTEM

Furet J[1], Marinoni G[2], Ando G[2]
[1]*IHS Global, Paris, France,* [2]*IHS, London, UK*

OBJECTIVES: From October 2013, some pharmaceutical products will be required to undergo a medico-economic evaluation in France. The aim of this study was to interview key stakeholders involved in this conceptual change in order to understand how this reform will be implemented and how it will affect market access in France. **METHODS:** Primary research was conducted between April and June 2013 with stakeholders from the French National Authority for Health (HAS), the Economic and Public Health Evaluation Commission (CEESP), the Transparency Commission (TC) and relevant French ministries. Interviews lasted between 45 and 75 minutes and focused on the methodology for medico-economic assessment and its implications on the French pharmaceutical pricing and reimbursement (P&R) process. **RESULTS:** Medico-economic evaluation in France will be based on cost-utility or cost-effectiveness analyses, depending on whether or not quality of life is an important outcome. Cost-utility analyses will rely on QALYs (quality-adjusted life years), whereas cost-effectiveness analyses will rely on survival. The medico-economic assessments will inform pricing negotiations, on the one hand, and potentially the development of prescribing guidelines, on the other. Medicines will be subjected to a medico-economic assessment based on their level of innovation and/or on their financial impact on the health care budget. **CONCLUSIONS:** France is formally introducing the QALY into its P&R system; however, this reform will come with a twist on the Anglo-Saxon approach, as there will be no associated ICER (incremental cost-effectiveness ratio) above which the medicine will not be reimbursed. While there is still some level of uncertainty with regards to the medicines that will be subjected to this assessment (as stakeholders have yet to put a quantitative value on a "significant impact" on the health care budget), the direction of travel is toward greater pressure on pharmaceutical prices.

PHP17

OVERCOMING THE HTA HURDLE IN GERMANY: KEY CONSIDERATIONS FOR A MANUFACTURER'S PRICING AND MARKET ACCESS STRATEGY

Ratcliffe M, Ralston S, Chetty M
PHMR Associates, London, UK

OBJECTIVES: In 2011, we saw the introduction of an evidence-based pricing approach to new branded pharmaceuticals in Germany. The process arose from the Act of the Reform of the Market for Medicinal Products (AMNOG) and all new drugs must undergo clinical benefit assessment by the Federal Joint Committee (GBA) followed by price negotiation with the German sick fund (GKV-SV) heads depending on whether additional benefit has been demonstrated. A review of the final GBA assessments published to date was undertaken and the aim was to evaluate the implications for manufacturers considering Germany as a launch country. **METHODS:** The GBA and IQWIG websites were searched for AMNOG evaluations performed between January 2011 to May 2013. Where appropriate the approach taken in the GBA assessment was compared with that of other HTA groups in Europe. **RESULTS:** The most important consideration for a manufacturer is choosing the right comparator in their submission, the core evidence document in this process. A number of drugs have been compared to the wrong treatment and subsequently were found to have no additional benefit. Some submissions chose the appropriate comparator but only for certain subgroups, leading to a reduced overall benefit for the new drug. Like most HTA groups, the preference is for mortality, morbidity and side effects evidence from head-to-head trials, however GBA appear to give little consideration to quality of life evidence. The review also revealed that GBA make decisions that are independent of other HTA bodies and sometimes reject recommendations of its own evidence review group, IQWIG. **CONCLUSIONS:** Early engagement with GBA to agree an appropriate comparator, patient population and clinical outcome measures is very important to improve chances of a positive assessment. However, the requirements of the GBA process should be balanced with those of other key markets as part of the drug's global PRA strategy.

PHP18

TROIKA IN PORTUGAL: PHARMACEUTICAL SECTOR FROM PAPER TO REALITY

Teixeira I, Mendes Z, Guerreiro JP, Costa S
Centre of Health Research & Evaluation (CEFAR), National Association of Pharmacies (ANF), Lisbon, Portugal

OBJECTIVES: The Memorandum of Understanding signed in May 2011, between the Portuguese Government and the International Authorities, increased requirements to reduce the public expenditure with medicines. These measures included the major change in margins distribution system. This study aims to: 1) describe the MoU measures related to medicines; 2) analyze public expenditure and impact of distribution margins reductions on medicines public expenditure, due to MoU and legislative changes in Portugal. **METHODS:** Descriptive study with updates to the MoU and published legislation. Market analysis and simulations were computed based on the Pharmacy Sales Information System (a nationwide database with representative drug dispensing data from ambulatory care). The statistical analysis was performed using SAS Enterprise Guide 4.1. **RESULTS:** The average price of medicines in the NHS market reduced significantly. Until March 2013, the average price of generics reduced 59.0% and brands 12.9%. The margins of pharmacies and wholesalers decreased in 2012. As a consequence, the outpatient pharmaceutical market decreased € 752 million and the NHS expenditure € 468.1 million, between 2010 and 2012. However, hospital market in 2012 remains at the same level observed in 2010. In the first quarter of 2013, outpatient market reduced another 90.3 million € and NHS expenditure € 49.7 M, of which 21% is due to the reduction of distribution margins. **CONCLUSIONS:** Even before the MoU, several changes led to a great reduction of the public expenditure in 2011. This impact worsened after the MoU, with direct effects on the reduction of the remuneration of pharmacies and wholesalers. Urgent strategies that ensure the access of patients to medicines while preserving the sustainability of both the NHS and the network of pharmacies are required, as well as policies to monitor the prescribing, dispensing and utilization of medicines and concrete changes in the inpatient NHS expenditure.

PHP19

UTILIZING STORYTELLING TO PROMOTE RATIONAL ANTIBIOTIC USE IN 9-11 YEARS OLD SCHOOL CHILDREN IN IRAN

Soleymani F[1], Mohammadhosseini N[2], Mohammadzadeh S[2], Kazemi M[2]
[1]*Tehran University of Medical Sciences and Ministry of Health, Tehran, Iran,* [2]*National Committee on Rational Drug use, Tehran, Iran*

OBJECTIVES: Antimicrobial resistance is still a growing health problem which increases morbidity, mortality, and health costs and has been associated with inappropriate antibiotic use. In Iran antibiotic prescription rates are high in children and antibiotics are the most common medication prescribed. Teaching children about the different types of microbes and the increasing problems of antibiotic resistance with unnecessary and inappropriate use of antibiotics should not only raise awareness in our future generation of antibiotic users but also in the family environment. This study aimed to evaluate the effectiveness of the story telling in improving children's knowledge about rational antibiotic use. **METHODS:** Junior (9–11 years) school classes were divided into either control or intervention groups for evaluation of the story telling. Students were required to complete identical knowledge questionnaires at three time points (before, immediately after and 4 weeks after teaching), to assess knowledge change and retention. Teaching, using story books which provided by National Committee on Rational Drug Use (NCRUD), was given by junior school teachers. **RESULTS:** A total of 164 junior students, 95 were intervention and 69 control groups, were studied. The junior story telling demonstrated a significant improvement in student's knowledge (34.5% of change) and there was no significant decrease in student knowledge observed after a 4 week period. **CONCLUSIONS:** Availability of information on the effectiveness of intervention for improving and promoting appropriate antibiotics use can facilitate implementation of strategies in this field. Regarding the effectiveness of storytelling, it is therefore recommended that decison-maker place greater emphasis on the use of such interventions.

PHP20

RELEVANT DECISION-MAKING CRITERIA IN GERMAN HOSPITAL FORMULARIES

Rübesam T[1], Jain M[2], Pioch E[1]
[1]*University of Gloucestershire, Cheltenham, UK,* [2]*BioMarin Europe Limited, London, UK*

OBJECTIVES: Hospital formularies are usually the gatekeepers for pharmaceutical drugs. Typical majority members of hospital formularies are physicians, although most of the time the formulary is chaired by a pharmacist. As German hospitals are struggling with a difficult economic environment the question arises: what kind of decision-making criteria are applied when pharmaceutical drugs should be added to the formulary list? Information regarding this topic is scarce due to the sensitive topic of decision-making. Only one study (Thürmann et al., 1997) is looking into this for Germany. **METHODS:** a total of 588 public, private and ecclesiastic hospitals in Germany have been contacted to participate in an online-survey regarding the structure of their hospital formulary, roles of members and applied decision-making criteria. **RESULTS:** Thirty-five of 588 hospitals (6%) have finally participated and filled out the complete questionnaire. Out of the 35 participants, 29 were pharmacists (82.9%) and 6 were physicians (17.1%). 34.3% of the hospitals have no guidelines for their decision-making and 65.7% of the hospitals with guidelines have written (48.6%) or verbal (17.1%) guidelines. Out of these, 78.3% discuss decision-making criteria, but only 47.8% talk about the relative importance of the discussed decision-making criteria. Budget impact (82.6%), clinical studies (69.6%) and price (65.2%) are the most often mentioned decision-making criteria in the guidelines. **CONCLUSIONS:** A third of the participating hospitals do not have guidelines for their decision-making process and only half of the guidelines discussing decision-making criteria also talk about the relative importance. Hospital formularies in Germany do not seem to be transparent in their decision-making process. In addition the top 3 decision criteria in the existing guidelines include 2 economical criteria which lead to the question of dominance of economical versus medical or other criteria. Further research needs to look at the real applied decision-making criteria and how much impact economical criteria have on decision-making in German hospital formularies.

PHP21

2.5 YEARS OF AMNOG IN GERMANY – AN ANALYSIS OF BENEFIT ASSESSMENT AND NET PRICE NEGOTIATION TRENDS

Dehnen J, Schmoeller M
IMS Consulting Group, Muenchen, Germany

OBJECTIVES: In 2011, the AMNOG law changed the price-setting procedure for drugs in Germany. Manufacturers are now required to submit a dossier to the Federal Joint Committee (GBA) for newly launched or, upon specific request, already market products. The GBA decides on the level of additional benefit which impacts the reimbursement price negotiations with German sick funds. The objectives of this study were thus to: 1) identify ways in which manufacturers can optimize the benefit

assessment outcomes, 2) analyze correlations between additional benefit, budget impact and negotiated rebate. **METHODS:** To achieve objective 1, assessments by the GBA and the IQWiG (Institute for Quality and Efficiency in Healthcare) (source: GBA website) were scanned for key trends. To achieve objective 2, list and post-negotiation prices were extracted from the Lauer-Taxe (German price database). For the 10 agents that had so far completed price negotiations, these were mapped against additional benefit and the budget impact (annual therapy costs as stated in GBA assessment). **RESULTS:** The results linked to objective 1, which were more qualitative in nature, allowed for the extraction of 5 key learnings for manufacturers to keep in mind. The results associated with objective 2 showed no link between additional benefits granted and negotiated rebate but did reveal price impacting parameters apart from budget impact. **CONCLUSIONS:** Concerning objective 1, the ways in which manufacturers can attempt to optimize benefit outcomes include: 1. Focus on comparator choice, 2. Focus on hard endpoints, 3. Make patient segmentation more solid, 4. Expect independent action of GBA and IQWiG and 5. Accept that there is no methodological standard for the definition of an additional benefit. Regarding objective 2, we concluded that budget impact, influenced primarily by target population size, annual therapy costs and drug price, is an – if not the most important driver in the negotiation.

PHP22

IS DRUG INNOVATION STILL REWARDED IN THE TOP 5 EUROPEAN PHARMACEUTIAL MARKETS?

Reinaud F[1], Ando G[2]

[1]*IHS, Paris, France,* [2]*IHS, London, UK*

OBJECTIVES: To assess how drug innovation is rewarded and how it is impacted by cost-containment policies. **METHODS:** Manufacturer prices per unit of package and strengths were compared and assessed in a basket of 97 innovative drugs approved by the European Medicines Agency (EMA) since 2000. The products were still patent protected, and available in each of the top 5 European pharmaceutical markets. **RESULTS:** Prices of innovative drugs in Germany were still the highest and had a benchmark price index of 100. In France, when drugs were deemed innovative, premium prices were granted – resulting in a price index of 94 – but significantly decreased over time. While prices at launch in Italy, Spain and the UK were commonly lower – with price indexes of 89, 88 and 86 respectively - they tended to remain constant over time. **CONCLUSIONS:** Despite the fact that governments in developed markets are attempting to lower prices, differences still exist across the largest markets, enabling pharmaceutical companies to implement differential and protective pricing strategies. In Germany, time to market is comparatively fast and premium prices at launch have been granted. In future, the AMNOG reform will complicate this picture, although pricing premiums have still been achieved for drugs deemed innovative that have gone through the full AMNOG process. In France, although prices are relatively high at launch, they drop at time of renewal and innovation is granted to a limited number of drugs. Prices have been comparatively low at launch but remain constant in Italy and Spain, reflecting the fact that price cuts in those countries have often been directed towards generics, although these are still considered high-risk markets. In the UK, it remains to be seen how the value-based pricing reform will impact prices.

PHP23

ACCESSIBILITY OF ORPHAN DRUGS IN FRANCE, UNITED KINGDOM AND GERMANY: DIFFERENT APPROACHES WITH REGARD TO HTA AND PRICES

Grandfils N, Hounkanlin H, Troubat A

IMS Health, PARIS LA DEFENSE, France

OBJECTIVES: To describe availability of orphan drugs in France, UK and Germany and to compare agencies' assessments and prices. **METHODS:** All the products designated as orphan drugs by the European Commission and commercialized at least in one of the three countries were included in the study. Comparison of prices is made per dosage and is based on prices per standard unit, using IMS MIDAS database. Comparison of assessments is based on Transparency Committee opinions, NICE guidances and IQWIG benefit assessments. **RESULTS:** Sixty-two products (103 dosages/forms) were included in this study; 47 (76%; 84 dosages/forms) are commercialized in the 3 countries, 8 (13%) products in only 2 countries (6 both in Germany and UK and 2 both in Germany and France) and 7 (11%) only in 1 country (6 in Germany only and 1 in France only). Among the 84 products/dosage/forms available in the three countries, most of them are available at hospital (respectively 68, 70 and 77 in Germany, France and UK) but those available through retail pharmacists are much numerous in Germany (72 of them) than in France (29) or UK (30). German and UK manufacturer March 2013 retail prices more often higher than French one, despite the fact that among the 49 orphan drugs commercialized in France, 31 are innovative products (ASMR rate I to III). For instance, French assessment of pirfenidone was less favorable than the Germans'one, and German price is thus +65.2% higher than French price. French and UK HTA assessments for azacitidine were both positive and led to similar prices. **CONCLUSIONS:** Most orphan drugs are available in the three studied countries but accessibility to them seems to be different and depends on HTA results.

PHP24

COMPARISON RETAIL PRICES OF DRUG PRICES BETWEEN TURKEY AND EUROPEAN COUNTRIES

Kockaya G[1], Atikeler K[2], Esen A[3], Tuna E[2]

[1]*Health Economics and Policy Association, Ankara, Turkey,* [2]*Hacettepe University, Ankara, Turkey,* [3]*Yeditepe University, Istanbul, Turkey*

OBJECTIVES: The reference pricing system is used for setting drug prices in Turkey since 2006. There are 5 reference countries following; Spain, Italy, Germany, France and Greece. Except those countries, manufactured or imported countries may be used as reference countries. Reference prices are reviewed time by time and may be subject to certain alterations, but evaluation of box prices may be different if evaluation made based on milligram. The aim of this study is to evaluate differences of average milligram sales prices of some generic medicines between Turkey and European countries. **METHODS:** Comparison of miligram based prices analysis between European countries done by Intelligent Health System(IHS) was used. The analysis of IHS included Germany, France, United Kingdom(UK), Spain and Italy(EU5). Comparison was done with taken row data of analysis EU5 and Turkey average milligram retail prices of Ceftriaxone, Clopidogrel, Esomeprazole, Fentanyl, Lamotrigine, Levofloxacin, Metformin, Venlafaxine, Letrozole and Olanzapine molecules. **RESULTS:** It has been reported that compared 10 molecules highest average miligram based prices of Esomeprazole(0,043 €), Levofloxacin(0,058 €) and Clopidogrel(0,0083 €) molecules belong to Turkey, Lamotrigine(0,01 €) belongs to Germany. The highest average miligram based prices of other 6 molecules belong to UK with following; Ceftriaxone(0,0196 €), Fentanyl(0,186 €), Letrozole(1,24 €), Metformine(0,00013 €), Venlafaxine(0,0074 €), Olanzapine(0,261 €). **CONCLUSIONS:** It has known that because of UK used free pricing mechanism on drugs, prices of drugs are higher than other compared countries. This sitiuation established on the anaylsis. But despite of Turkish Government policy decisions; it is important indiciation that 3 drugs represents highest prices out 10 drugs. Reference pricing system applied based on box price. Better control mechanism may achievable if miligram based pricing apply in Turkey. On the other hand because of the study only consist retail sales prices the evaluation should be done from point of reimbursement prices on future studies.

PHP25

CONSUMPTION OF BIOSIMILAR DRUGS IN CAMPANIA REGION IN THE YEARS 2009-2012

Menditto E[1], Cammarota S[1], Putignano D[1], Orlando V[1], Fiorentino F[2]

[1]*CIRFF-Center of Pharmacoeconomics, Naples, Italy,* [2]*Regional Health Authority of Campania region, Naples, Italy*

OBJECTIVES: The expiration of biotech drugs patent has led to the creation of drugs copies of originator products, defined 'biosimilars'. No European country allows automatic substitution between the originator and the biosimilar. In Italy, due to the lack of a national legislation, some Regions have issued directives to encourage the use of biosimilars, recognizing a potential saving of resources. Campania Region was the first region to legislate on the matter, (decree no. 15 of 11.30.2009) supporting the prescription of biosimilars to the naive patient. The aim of our study is to describe trends in biosimilars consumption in Campania region and evaluate how biosimilar products are replacing the originators in the respective markets. **METHODS:** IMS Health regional database was used to analyze biosimilar drugs consumption patterns (erythropoietins, G-CSF, somatropin) in the years 2009- 2012. Information was retrieved about different distribution channels (retail, direct distribution, hospital). Consumptions are expressed in Counting Units (CU) and trends have been calculated using Compound Average Grow Rate (CAGR). The study especially focused on consumption trends of erythropoietin (ATC B03XA) in the years 2009-2012. **RESULTS:** In 2012 the penetration rate of biosimilars was 40.1% (evaluated as the biosimilars share of the total erythropoietins, G-CSF, somatropin market). These values are double than those at national level, that are estimated to be 19.7% of consumption. Focus on erythropoietin trends showed a strong increase in biosimilars consumption (451 CU in 2009 vs 140,327 CU in 2012) after the introduction of regional measures to promote the prescription of biosimilars to the naive patient. In 2012, biosimilar erythropoietins and reference drugs show similar market shares (37.0% and 33.7% of the total erythropietins market respectively) showing a high substitution effect. **CONCLUSIONS:** Our analysis outlines the significant effects of regional measures on market penetration rates of biosimilars.

PHP26

INDIRECT AND DIRECT SAVINGS RESULTED FROM PARALLEL TRADE OF PHARMACEUTICALS IN POLAND – RESULTS OF VALUATION SALES DATA FROM PUBLIC PHARMACIES

Baran-Lewandowska I, Hermanowski T

Department of Pharmacoeconomics, Medical University of Warsaw, Warsaw, Poland

OBJECTIVES: Estimation of the direct and indirect savings generated by parallel importing (PI) of pharmaceutical products in public pharmacies in Poland, and estimation of the savings for the payer in the case of reimbursed drugs. **METHODS:** IMS Health Poland National Sales Data (2005-2012) and data from respective reimbursement lists were used for all calculations. Direct savings were estimated considering all PI products sold in public pharmacies(433 products, 1550 SKUs). To avoid overestimation, only 18 products that passed restrictive criteria were used for calculations of indirect savings. Twenty-seven reimbursed products were used for the payer savings calculations. Direct savings were calculated as a difference between PI and reference product prices multiplied by the number of packs of PI product. Indirect savings were calculated as a difference between the reference product price and the theoretical reference product price (i.e. prices in a hypothetical situation where there is no price pressure caused by PI – calculated using linear regression). Indirect savings considered only those products which met the criteria of the reference product's price decrease of at least 5% within 3 months prior to, or after, the appearance of the PI product. **RESULTS:** Study revealed that the savings generated by the PI of pharmaceuticals in Poland between 2005-2012 may be estimated at the level of EUR 146m (direct savings EUR 46m and indirect savings EUR 100m). Savings for the payer calculated for reimbursed products between 2008-2012 reached the level of EUR 0.06m. **CONCLUSIONS:** This is the first study estimating direct and indirect savings coming from PI phenomena covering all years since PI was reinforced by Poland's accession to the EU. It has been found very interesting that indirect savings tend to be substantially higher that direct ones. This indicates that high price pressure is created by PI, and affects the prices of reference products.

PHP27

PRICING OF "FOLLOW-ON" DRUGS AND COMPETITION WITHIN PHARMACEUTICAL CLASSES: EVIDENCE FROM GERMANY 1993-2008

Mueller MT[1], Frenzel A[2]

[1]*Universität Witten/Herdecke, Witten, Germany,* [2]*IMS Health, Frankfurt/Main, Germany*

OBJECTIVES: Competition within therapeutic drug classes from "follow-on" drugs has been a highly controversial issue. Manufacturers launching new molecules in existing drug classes have often been criticized for inflating health systems' expenses, but it has been argued that such drugs increase therapeutic options. Economic theory suggests that follow-on drugs induce price competition. We contribute to this discussion by addressing the topic of pricing at market entry and price development in the German market with the distinct focus on competition within already existing drug classes. **METHODS:** We measure determinants of price strategies of follow-on drugs using regression analyses, considering all new molecules launched in the German market in the period from 1993-2008. Prices of products are standardized on Defined Daily Dosages controlling for sales volumes based on data from the IMS Health DPM database, a census audit of pharmaceutical sales in Germany, and for the therapeutic quality of a new product using ratings by Fricke/Klaus as a proxy for innovation. **RESULTS:** We identify prices correlating with therapeutic value at market entry. While the first two molecules engage in quality competition by offering more therapeutic options, price discounts below the market price can be observed from the third entrant on. Price discounts are even more distinct in development races with several drugs entering the market within two years and in classes with a low degree of therapeutic differentiation. Prices remain relatively constant over time. **CONCLUSIONS:** This study contributes to assessments of competition in pharmaceutical markets focusing on price strategies of new market entrants. After an initial phase of market building, further follow-on products induce price competition. Largely unchanged prices after 4 years may be interpreted as quality competition and can be attributed to prices in Germany being anchor point for international price referencing.

PHP28

THE IMPACT OF GENERIC SUBSTITUTION ON HEALTH OUTCOMES AND COSTS: A SYSTEMATIC REVIEW

Schall I[1], Saverno K[2], Luzak A[1], Mitrovic M[1], Gothe H[3], Brixner D[4], Siebert U[5]
[1]*UMIT – University for Health Sciences, Medical Informatics and Technology, Hall i.T., Austria,* [2]*Department of Pharmacotherapy, University of Utah / UMIT – University for Health Sciences, Medical Informatics and Technology, Salt Lake City, UT, USA / Hall i.T., Austria,* [3]*UMIT - University for Health Sciences, Medical Informatics and Technology / ONCOTYROL - Center for Personalized Cancer Medicine, Hall i. T. / Innsbruck, Austria,* [4]*UMIT, Salt Lake City, UT, USA / Hall i.T., Austria,* [5]*UMIT – University for Health Sciences, Medical Informatics and Technology / ONCOTYROL / Harvard University, Hall i. T./ Innsbruck / Boston, Austria*

OBJECTIVES: Although generic drugs are considered to be therapeutically equivalent to their off-patent (branded) counterparts, the overall impact of generic substitution on clinical and economic outcomes has not been comprehensively evaluated. The goal of this study was to test whether 1) generics and branded products yield the same health outcomes; and 2) generic therapies save economic resources versus branded therapies for de-novo patients and patients on maintenance therapy. **METHODS:** We performed a systematic literature review in Medline, Cochrane Database of Systematic Reviews and Embase (2000-2012) to identify original research studies on clinical or economic outcomes with either independent or pre-post comparator groups. Data were aggregated using a standardized extraction form. For each included study, outcomes were categorized as favoring or opposing generic drug substitution. As we compared different outcomes, one publication could contribute to multiple outcome comparisons. **RESULTS:** We included 40 studies that led to 121 outcome comparisons. Similar clinical effects were found in 74% of all studies in which patients were initiating therapy (de novo) and 64% of all studies involving maintenance therapy comparisons. 100% of the economic analyses of de novo patients and 56% of comparisons of maintenance therapy patients showed lower costs associated with the use of original brand. Overall, 66% of the outcome comparisons reported similar clinical outcomes and 64% suggested that brand products lower costs compared to generic substitution. **CONCLUSIONS:** Our analyses suggested that clinical effects were mainly similar, whereas economic savings of brand to generic drug substitution may be overstated, particularly in sensitive therapeutic areas such as anti-epileptic drugs or immunosuppressives. More systematic research comparing clinical and cost outcomes with or without generic substitution is needed to inform policy on the use of generic substitution. **ACKNOWLEDGEMENTS:** We would like to thank Anke-Peggy Holtorf and Zoltán Kaló for their scientific input.

PRICING AND REIMBURSEMENT ANALYSIS OF LIFESTYLE MEDICINES IN SERBIA

Baltezarevic D[1], Petrova GI[2], Medic G[3], Samardzic J[4]
[1]*Pharmacoeconomics Section of the Pharmaceutical Association of Serbia, Belgrade, Serbia and Montenegro,* [2]*Medical University, Faculty of Pharmacy, Sofia, Bulgaria,* [3]*Mapi - HEOR & Strategic Market Access, 3995 AX Houten, The Netherlands,* [4]*University of Belgrade, Medical Faculty, Belgrade, Serbia and Montenegro*

OBJECTIVES: To determine whether there was a difference between wholesale prices, utilization and market share, as well as to explain Rx-OTC switches and reimbursement possibilities of "lifestyle-medicines", in 2009 and 2010, before and after the adoption of new Medicines Law, in Serbia. **METHODS:** We investigated how many potential "lifestyle-medicines", satisfying the previously determined criteria, were authorised for sale. Utilization, price changes and reimbursement status were monitored. Price index and margin index were calculated using the formula: I=QxP (index(I),quantity(Q),price(P)). To compare the differences in prices and utilization, non-parametric Mann-Whitney test was used. To test difference in market shares, T-test of proportion was used. **RESULTS:** There were 21 registered "lifestyle-medicines". Five medicines (oral contraceptives) were listed. In 2009, there were 1,763,030 units dispensed worth 16,074,922€. In 2010, 1,814,405 units were dispensed while total value was 14,129,792€. The average sales(€) were higher in 2009, which is not in line with the expected growth trend, but observed difference was not statistically significant. The wholesale price-index 2009/2010 was -13%. This means that prices were 13% lower in 2010. In fact, during 2010, prices remained the same in national currency, which weakened against euro. The margin index was 21% in 2009 and 20% in 2010. Since all drugs were Rx (margin was set up to 12%, VAT was fixed to 8%), this was completely expected. At the end of 2010, two medicines: levonorgestrel (1,5mg) and orlistat (60mg), were authorised as OTC medicines (free pricing, margin:25%, VAT:18%). **CONCLUSIONS:** "Lifestyle-medicines" are difficult to define. Market success depends on product characteristics, effectiveness, tolerability, convenient drug-delivery format, simple dosing regimen, good safety profile, first-to-market position, premium prices, sustained media attention, Rx-OTC switch potential and reimbursement potential. Although more new "lifestyle-medicines" will be authorised in Serbia, market share is expected to decrease because of low purchasing power and low reimbursement potential.

PHP30

IS EXTERNAL PRICE REFERENCING AN APPROPRIATE DRUG POLICY FROM AN EFFICIENCY, EQUITY, AND QUALITY PERSPECTIVE?

Wouters OJ, Kanavos P
London School of Economics and Political Science, London, UK

OBJECTIVES: Different external price referencing (EPR) configurations are applied by countries worldwide. Depending on how EPR schemes are implemented, they may have varying effects on short- and long-run prices, market dynamics, key stakeholders, and other relevant endpoints. This research evaluated the merits and demerits of EPR from an efficiency, equity, and quality perspective. **METHODS:** A theoretical and empirical analysis of the effectiveness of EPR was conducted, based on a systematic review of the literature and stakeholder interviews. As EPR has been most common in Europe, the study focused on this region. **RESULTS:** The systematic review identified 100 relevant articles. The articles were categorised according to study characteristics and four major themes were identified; these findings were confirmed by the interviewees. The evidence suggests that EPR schemes often generate disproportionate price levels in relation to national abilities to pay; this is likely due to the reliance on foreign list prices which do not reflect negotiated discounts. If manufacturers apply launch strategies to exert upward pressure on prices (e.g. launch delays or product withdrawals), it may also limit patient access to life-saving medicines. In addition, the bureaucratic complexity of many EPR schemes may undermine the objectives of EPR use (i.e. cost containment and macroeconomic efficiency). Finally, widespread EPR application may stifle pharmaceutical and biomedical innovation. **CONCLUSIONS:** A national pricing policy should provide an effective, predictable, transparent, and stable pricing environment for pharmaceutical products. It should internalise national priorities for health and industrial policy, including cost containment, employment, innovation, and trade promotion. EPR is associated with important short- and long-term issues. If EPR is going to continue to be applied by EU Member States and other countries, then it is necessary to establish guiding principles to govern EPR use across jurisdictions. Still, differential pricing and risk-sharing agreements may represent more sustainable policy options.

PHP31

DOES EUROPE REWARD REFORMULATIONS? A DATA DRIVEN ANALYSIS OF VALUE PRESERVATION THROUGH REFORMULATION

Hughes ALH[1], Luft D[1], Lions I[2], Flostrand SJA[3]
[1]*IMS Consulting Group, London, UK,* [2]*IMS Consulting Group, Basel, Switzerland,* [3]*IMS Consulting Group, La Défense Cedex, France*

OBJECTIVES: Reformulating existing drugs can improve patient convenience, compliance and create new uses for the product. However, reformulations cost millions of Euros - a risky investment without guaranteed exclusivity or returns. This study assessed whether markets reward incremental value creation through reformulation by comparing sales performance close to patent expiry for reformulated and non-reformulated products. **METHODS:** IMS MIDAS data was interrogated to identify 829 small molecule, non-generic products which had peak sales above €5M and lost patent protection between 2001 and 2010 in EU-5 (France, Germany, Italy, Spain and UK). Ex-manufacturer sales value (€) 2 years after patent expiry was compared with sales value 4 years earlier to calculate percentage value erosion for each of the 829 products. A subset of 133 products which launched at least 1 reformulation close to patent protection expiry (launch between 3 years before and 1 year after patent protection expiry) were analysed to assess whether value erosion varied across countries or therapy areas. **RESULTS:** Mean ex-manufacturer sales value erosion of reformulated products (24%) was significantly less than non-reformulated products (37%, $P<0.01$). Reformulated product value erosion varied with country and therapy area. Germany saw highest number of reformulations launched yet only reformulations launched in Italy showed significantly less value erosion than non-reformulated products ($P<0.01$). Across therapy areas, reformulations were most common in nervous system, metabolism and anti-infective categories. However, reformulated anti-infective product value erosion was pronounced while musculoskeletal and nervous system products experienced significantly less value erosion than for non-reformulated products (both $P<0.05$). **CONCLUSIONS:** Overall, reformulated products do maintain more value than non-reformulated products following loss of patent protection. Chronic disorders e.g. nervous and musculoskeletal system disorders appear to be the most promising areas for reformulating. Future reformulation potential is tightly linked to country-specific pricing and market access policy decisions to recognise incremental value products.

PHP32

CONSTRUCTING AN INDEX OF INTERNATIONAL PHARMACEUTICAL PRICES. A COMPARISON OF PHARMACEUTICAL PRICES IN 56 COUNTRIES

Davey P
Macquarie University, Sydney, Australia

OBJECTIVES: To construct a number of pharmaceutical price indices for a broad set of countries, covering a range of regions, including countries with different levels

of economic development and a representative sample of medicines. **METHODS:** The indices were developed using the Fisher EKS method. In order to construct an index the products needed to be defined as like. The definition of like in this study was based on molecules which are deemed to deliver equivalent health outcomes. This is a very broad definition and allows a large number of countries and molecules to be included in the indices. Two price indices have been constructed. The first compares prices of mostly off-patent medicines across 56 countries over the period from 2005 to 2011 and included 42 molecules which were sold in each country for the period. The second examined on-patent medicines across 17 countries and 9 molecules. **RESULTS:** The results showed prices varied significantly between regions and that prices of genericised medicines both fell and converged over time. For the mostly generic drugs index the regions from lowest to highest price were - Region of the Americas A; South-East Asian Region D; South-East Asian Region B; European Region B; Western Pacific Region A; European Region A; African Region E; European Region C; Western Pacific Region B; Eastern Mediterranean Region D; Region of the Americas D; Region of the Americas B and Eastern Mediterranean Region B. Prices tended to be similar within each region. These results will be presented in detail. **CONCLUSIONS:** This research makes a unique contribution to our understanding of drug prices. It is the largest international comparison of pharmaceutical prices ever undertaken; employs new method to pharmaceutical pricing indices through the Fisher EKS method and outcomes based definitions of equivalence and examines genericised and on-patent markets separately.

PHP33

TRANSPARENCY OF THE MEDICINES REIMBURSEMENT SYSTEM IN IRELAND: A QUANTATIVE ANALYSIS OF THE INFLUENCES ON REIMBURSEMENT DECISIONS [2006-2013]

Mahon S, Redmond S, Carney P
GlaxoSmithKline, Dublin, Ireland

OBJECTIVES: To identify what process and technology related characteristics influence reimbursement decisions in Ireland. **METHODS:** Using publically available data compiled from the NCPE and HSE websites from 2006 to 2013, we examined several variables (disease area; transparency; and, assessment and judgement of effect and CE), as defined in Fischer (2013), to identify what influences reimbursement decisions made through the community drugs schemes (i.e. GMS, and High Tech schemes). Analyses included, Spearman's Rank Correlation (SRC), Kruskal-Wallis and Fishers exact tests in the univariate analyses, and a step-wise multivariate regression. **RESULTS:** For technology features most disease areas were found not to have a significant influence on reimbursement decisions (SRC: max 0.30, Fishers Exact: $p>0.10$; and, regression analysis $p>0.10$). However, treatments for endocrine conditions were significant ($p<0.10$). For process features the availability, quantity, and type of assessment information were strongly correlated with reimbursement decision (SRC: ≥ 0.73). Judgement of effect and cost-effectiveness were significant ($p<0.05$), and the multivariate regression showed "transparency", "judgement of effect" and "judgement of CE" to be statistically significant (odds ratios: 0.095, 2.752, and 3.657 respectively; $p<0.10$). **CONCLUSIONS:** Overall, increased transparency (i.e. publically available documentation of the decision rationale) has a negative influence on the likelihood of reimbursement. This can be explained by the Rapid Review process, whereby products are initially screened and selected for further HTA analysis. As expected, those not selected for HTA are more likely to be reimbursed, but have less documentation supporting the decision, introducing less transparency overall. Where a HTA has been conducted, judgement of effectiveness and cost-effectiveness has strong positive influence on reimbursement, with cost-effectiveness being the strongest positive influence. Fisher (2013) found stakeholder involvement to be an important influence; this could not be tested in the Irish context as the numbers of stakeholders known to be involved are constant across all observations.

PHP34

RELEVANCE OF A NATIONAL FORECAST GROWTH RATE, AS A REGULATION TOOL OF THE EXPENSIVE HOSPITAL DRUG SPENDING, IN FRANCE

Monnier R, Degrassat-Théas A, Parent de Curzon O, Sinègre M
General Agency of Equipment and Health Products (AGEPS), PUBLIC WELFARE HOSPITAL OF PARIS (AP-HP), PARIS, France

OBJECTIVES: In France, a forecast growth rate in spending related to the list of expensive hospital drugs, funded in addition to DRG-based payment, is determined annually (2% in 2012). If hospitals exceed the rate, they will be controlled, based on the proper use of drugs. The objective is to question the relevance of this national growth rate as a regulation tool. **METHODS:** This study used 2011/2012 data from "medicalized information system program". Expensive drug expenditures are aggregated by each type of French hospitals (without private sector): cancer centers (CC=19), university hospitals (UH=32), hospitals centers (HC=415) and private non-profit hospitals (PNPH=104). In order to identify their specificities, we analyzed the expenditures of the first therapeutic class in value by hospital type and how much the top 3 drugs, that drive the overall growth, contribute to their respective growth. **RESULTS:** Overall spending grew by 4.95% in 2012. Antineoplastic drugs (1% of decrease) represent 48% of overall expenditures. Their market share varies from 34% in UH expenditures to 95% in CC, the only hospital type that meet the forecast rate. The top 3 drugs (2 immunosuppressant drugs and 1 replacement enzyme; 17% of overall expenditures) contribute to 3.93 points of the total growth. Their contribution to the growth of each hospital types is uneven: from -0.02 point out of -6% in CC to 5.35 points out of 9.03% in UH. **CONCLUSIONS:** There is a divergence in the growth of spending for the different hospital types because of their specific characteristics leading to different consumption profiles. Therefore, some hospitals are more impacted by changes in the spending structure, as CC for antineoplastic drugs. A regulation by an annual growth rate is useful because of its flexibility. But relevance of a single national rate does not reflect the care's offer heterogeneity and needs local analyses.

PHP35

INTRODUCTION OF INNOVATIONS INTO THE GERMAN STATUTATORY REIMBRUSMENT SYSTEM – FACTORS FOR SUCCESS

Krensel M
University Medical Center Hamburg-Eppendorf, Hamburg, Germany

OBJECTIVES: Innovations are fundamental for progress and improvement in health care and medicine. In German hospitals provision of all kind of services is allowed, since it is not forbidden explicitly. But it is paid only if it is represented in the reimbursement system. For integration of innovations into this system applications must be addressed by each hospital which wants to provide a special innovative service in each year separately to the German institute for reimbursement in hospitals which decides about (additional) payments. The objective is to determine which factors influence the chance for innovations being incorporated. Results can be used by hospitals to assess if certain innovations have good chances to be afforded. **METHODS:** Data about applications, their approval and assessment, number of hospitals and years in which approvals were made were obtained from the German institute for reimbursement systems in hospitals from 2005 to 2011. Innovations have been classified into types of methods. Applications made by medical associations and for orphan drugs were identified. Associations between each variable and success of application were calculated. In all analyses Bonferroni correction was conducted. Finally intercorrelation of variables was assessed. **RESULTS:** Chance of integration was best for innovations with the following characteristics: Applications were made by medical associations, innovations were applied over a period of 6 years and by more than 100 hospitals, subjects were drugs (especially orphan drugs) and they belong to gynecology, oncology or cardiology and vascular medicine. Intercorrelation between these independent variables is also a predictor of success in some constellations. **CONCLUSIONS:** The success of integration of a new method depends on all analyzed variables. Therefor all of them have to be taken into account when decision is made about what innovation should be applied.

PHP36

THE IMPACT OF AMNOG ON DRUG REIMBURSEMENT IN GERMANY

Heeg B[1], Schoeman O[2], Mueller S[3], Wilke T[3]
[1]*Pharmerit International, Rotterdam, The Netherlands,* [2]*Pharmerit International, Berlin, Germany,* [3]*IPAM - Institut für Pharmakooekonomie und Arzneimittellogistik, Wismar, Germany*

OBJECTIVES: There are three main governmental stakeholders in the German AMNOG process: The IQWiG assesses the AMNOG drug manufacturer's submission and provides advice on any additional benefit to the GBA who makes the final decision. Following confirmation of additional benefit, manufacturers start price negotiations with the GKV-Spitzenverband (association of German sickness funds). The aim of this research is to assess the AMNOG-decisions so far. **METHODS:** All AMNOG decisions up to December 2012 were analyzed in terms of additional benefit decision, reason for additional benefit decision, reimbursed price versus manufacturer set price, and consistency in IQWiG-recommendation and GBA-decision. **RESULTS:** In total AMNOG decisions of 41 drugs (60 subgroups) were identified. IQWiG recommendations were as follows: 22 cases demonstrated no additional benefit, 2 unquantifiable benefit, 3 slight benefit, 7 significant benefit, and 7 additional benefit due to orphan-drug status. In 6 cases, the GBA upgraded IQWIG's recommendations. In 3 cases it downgraded it. The following reasons were identified for GBA "additional benefit decisions" (multiple reasons apply for some decisions): No or non-quantifiable additional benefit (18 cases); no reliable clinical data (14 cases; 3 cases no submission), wrong comparator (5 cases); additional benefit in any form (23 cases): mortality advantages (7 cases), orphan drug status (7 cases), morbidity advantages (8 cases), and QoL advantages (3 cases). The negotiated price rebates varied from 4.7% to 70.7% based on manufacturer set price; the rebates show limited correlation to the degree of additional benefit so far. **CONCLUSIONS:** Key factors for positive AMNOG decisions are conducting superiority trials on mortality or at least morbidity/QoL against active comparators. If benefits are based on soft end-points, it is crucial to demonstrate these on high quality, preferably German data. Indirect comparisons seem to be challenged as proof of additional benefits.

PHP37

EU PAYER AND DECISION MAKER USE OF OBSERVATIONAL STUDIES FOR HEALTH CARE REIMBURSEMENT DECISIONS

Hogue S[1], Hollis K[2], McLeod L[2], Brogan A[1], Heyes AE[3]
[1]*RTI-Health Solutions, Research Triangle Park, NC, USA,* [2]*RTI Health Solutions, Research Triangle Park, NC, USA,* [3]*RTI Health Solutions, Manchester, UK*

OBJECTIVES: As cost-containment pressures across Europe intensify, evidentiary hurdles to justify new drugs will continue to grow. Data from clinical trials alone are no longer adequate to meet the needs of all health care decision makers (e.g., payers and health technology assessment [HTA] agencies, physicians and patients), driving a need for robust, complementary data. However, perceived need to collect real-world clinical, patient-centered, and/or economic outcomes through observational studies varies across countries, stakeholders and organizations. The objective was to better understand how decision makers use observational studies to inform reimbursement and/or market access decisions for new products. **METHODS:** Desktop research identified the types of observational studies most valuable for reimbursement decision making. This project extends a United States (US) payer study by conducting qualitative one-on-one interviews with decision makers across Europe to review the need for real-world evidence. Participants represented national and regional decision makers from several European countries, to identify specific evidence requirements and design attributes most accepted by payers/ HTA advisors and to understand how real-world evidence contributes to the value of a new drug from the decison-makers' perspectives. **RESULTS:** Data from observational studies are used to describe patient segments, understand treatment patterns, resource utilization, and provide effectiveness data that supplement clinical trial data as well as inform risk sharing schemes. Observational studies help inform payer decision making but the validity and robustness of the results is often scrutinized. Publication of observational data in a Tier 1, peer-reviewed journal lends critical credibility to real-world study

results. **CONCLUSIONS:** The current study extends the evaluation into Europe to confirm that as reimbursement decision makers continue to rigorously review new drug therapies, accurate, robust, peer-reviewed published and generalisable real-world data will become particularly important for outcomes- or performance-based access schemes and health care budget management both in the US and Europe.

PHP38

THE SURVEY OF THE JAPAN-STYLE PREMIUM SCHEME IN PHARMACEUTICAL PRICING DECISIONS

Kamae I[1], Murata T[2], Suman D[3], Yamabe K[4], Sugimoto T[3], Kobayashi M[5]
[1]*The University of Tokyo, Graduate School of Public Policy, Tokyo, Japan,* [2]*Crecon Research & Consulting Inc., Tokyo, Japan,* [3]*The University of Tokyo, Tokyo, Japan,* [4]*MSD.K.K. & HTA and Public Policy, Graduate School of Public Policy, The University of Tokyo, Tokyo, Japan,* [5]*CRECON Research & Consulting Inc, Tokyo, Japan*

OBJECTIVES: To review the new drugs which were listed in the past on the Medical Fee Schedule of Japan, and to clarify the profile of the quasi value-based pricing in the Japan-style premium scheme. **METHODS:** The information on pricing decisions with premium was searched, extracted, and analyzed from the government documents open to public on the website of the Ministry of Health, Labour and Welfare in Japan. The four drug categories were focused due to data availability: 1) antihypertensive; 2) antidiabetic; 3) antibiotic; and 4) psychotropic, listed from April 1998 through April 2013. The information relevant to the premium decision included listing dates, drug prices, premium categories, premium rates, and also clinical evidence that could be associated with the premium decision. **RESULTS:** Among total 106 of new drugs, 27 have been identified with premium, whilst 79 with no premium. For each category, there existed 12 antihypertensive (single agent), 25 antidiabetic, 52 antibiotic, 17 psychotropic. That is, the acquisition rate of premium for each category was 17%, 20%, 31% and 24%, respectively. The high proportion, 85%,of the rewarded premium categories was recognized in the category of "Usefulness II", i.e., the 3rd ranked premium, while only one drug obtained the premium of innovativeness, the highest ranked premium. Regarding the benefit associated with the premium, both of clinical and humanistic outcomes seemed to be accepted for decision-making although the criteria for the decisions were not clearly indicated. **CONCLUSIONS:** The profile of the Japan-style premium scheme was clarified based on the survey over the new drugs listed in 1998 to 2013. The information extracted in our study will be useful for further investigations to improve the Japanese quasi value-based pricing methods.

PHP39

THE STRUCTURE AND PROCESS OF WORK OF SPANISH REGIONAL COMITTEES ASSESSING MEDICINES: PRELIMINARY RESULTS

Sarría-Santamera A, Polo M, Gacía S
Institute of Health Carlos III (ISCIII), MADRID, Spain

OBJECTIVES: Spain has a decentralized health care systems with several levels of decision-making. After a drug is approved by the Spanish Agencia del Medicamento, regional committees (RC) conduct evaluate and assess those drugs for their use in ambulatory settings making recommendations to health professionals within its territory. The objective of this study is to analyze the structure and process of work of those RC. **METHODS:** RC were contacted by phone and informed about this study. A web based questionnaire was ellabored including questions on: 1) General information of the RC; 2) Procedure of work of RC; and 3) Criteria used for the selection of medicines to asess and the procedures followed to. A link was sent by email to contact persons of the RC of the Spanish 17 Autonomous Comunities (AC). **RESULTS:** To this date 10 RC (59%) have submitted their answers and 3 regions (18%) have responded indicating the absence of this type of structure or process in their region. These 3 regions, though, make recommendations usually conducting their own assessments or using assessments conducted by other regions. 7 RC have a normalized process of work (5 is open to the public). 8 RC have more than 8 members. All RC evaluate medicines prescribed for outpatients purchased through pharmacies (5 of them exclusively), and 5 conduct also assessments of drugs used in hospitals. 9 RC use as comparator the standard treatment for a given indication. Economic evaluation is performed through budget impact (6 RC), cost-effectiveness (5 RC); and cost-minimization (2 RC). 6 RC make public their assessments through public web pages and 2 using electronic bullletins. **CONCLUSIONS:** Preliminary data indicate that the majority of Spanish regions conduct their own drug assessments, and most of them have established RC, whose structure and process of work show some variability and indicate certain degree of duplication.

CROATIA'S EU ACCESSION IN THE CONTEXT OF INTERNATIONAL REFERENCE PRICING: WHAT WILL BE THE WIDER IMPACT FOR PRICING AND REIMBURSEMENT?

Melck B, Izmirlieva M, Ando G
IHS, London, UK

OBJECTIVES: To assess the implications of Croatia's accession to the European Union for the pricing and reimbursement landscape both in Croatia and other EU member states, focusing on international reference pricing. **METHODS:** Changes to Croatia's laws governing drug pricing and reimbursement were examined in detail, in relation to their likely effects on drug prices in Croatia and in other EU member states through international reference pricing. The IHS International Reference Pricing Matrix was used to determine impact of Croatian prices on other markets likely to include Croatia in their reference pricing basket. Interviews were conducted with representatives of the pharmaceutical industry in Croatia, and regulators in Croatia and other EU member states, to gauge their views. **RESULTS:** The existence of comparatively low prices of medicines in Croatia is likely to result in some downward pressure on pricing in countries which include all EU countries in the IRP basket of countries. However, this impact is not likely to be felt immediately, and only for the few therapeutic areas where Croatia's prices are among the lowest in Europe. Changes to Croatia's international reference pricing basket are unlikely to result in any great changes, although in certain areas, price reductions can be expected. **CONCLUSIONS:** Some downward pressure on prices in other EU markets is likely as Croatia becomes a reference market for IRP, although this is likely to be limited in scope in the short term, with only particular products and therapeutic groups affected. Over the longer term, as more markets add Croatia to their reference-pricing baskets, this pressure is likely to intensify.

PHP41

GENERIC SUBSTITUTION IN IRELAND – THE VIEWS OF KEY STAKEHOLDERS

O'Leary A[1], Usher C[2], Lynch M[1], Interns and tutors[1]
[1]*Royal College of Surgeons in Ireland, Dublin, Ireland,* [2]*National Centre for Pharmacoeconomics, Dublin, Ireland*

OBJECTIVES: The Health (Pricing and Supply of Medical Goods) Act 2013 passed in June 2013 provides for generic substitution in Ireland. The aim of the study was to ascertain the views of the stakeholders i.e. patients, pharmacists and prescribers on generic substitution,prior to the Act's introduction. **METHODS:** Three stakeholder specific surveys were developed to assess knowledge of and attitudes to generic substitution. Convenience samples of health care professionals and patients were gathered until data saturation was achieved. Descriptive quantitative and qualitative analysis was undertaken. **RESULTS:** A total of 742 health care professionals and 330 patients responded. The study highlighted 4 areas where prescribers and pharmacists differed; (1) Prescribers ranked cost-savings as the most important information to impart to patients while pharmacists advocated therapeutic equivalence as highest. (2) Pharmacists considered that more patients would be agreeable to generic substitution (52%) as compared to 41% of prescribers. (3) Prescribers considered that generic substitution would have a greater effect (25%) on patient care than pharmacists (14%). (4) 19% of prescribers supported generic substitution in all cases and 76% with some exceptions, compared to 16% and 84% for pharmacists respectively. More than 80% of patients were on between 1 and 8 medicines daily, and of these >50% reported that they were on generic medicines. More than 80% would be happy with generic substitution, while more 75% of those interviewed considered generic drugs to contain the same drug, to be as effective and as safe as branded medicines. **CONCLUSIONS:** To prevent possible confusion and concern among patients it is important that health care professionals acquire the necessary tools and knowledge to manage transition into and rollout of this new system, so that they can work together to ensure the obvious benefits of the new system are maximised.

PHP42

AN ANALYSIS OF PRISCRIPTION AND REIMBURSEMENT OF POTENTIALLY INAPPROPRIATE MEDICATION (PIM) IN A GERMAN PRACTICE NETWORK

Pohl-Dernick K[1], Meier F[1], Maryschok M[1], Wambach V[2], Lindenthal J[2], Wunder S[3], Schöffski O[1], Emmert M[1]
[1]*Friedrich-Alexander-University Erlangen-Nuremberg, Nuremberg, Germany,* [2]*Practice network "Qualität und Effizienz eG", Nuremberg, Germany,* [3]*AOK Bavaria, German Statutory Health Insurance, Nuremberg, Germany*

OBJECTIVES: Potentially inappropriate medication (PIM) in the elderly increases the risk of adverse drug reactions (ADR) and consequently has an impact on both patients' quality of life and health care costs. In 2010, the PRISCUS list was published in Germany to identify PIM and to propose adequate substitution medication. The objective of the study was to assess both the prevalence and reimbursement of PIM in a German practice network applying the PRISCUS list. Moreover, costs for proposed surrogates were evaluated. **METHODS:** Patients fulfilling the following criteria were included: (1) insured at the local health fund AOK Bavaria, (2) treated by physicians of the practice network, and (3) aged ≥65. Data was provided from AOK Bavaria and contained 214,177 anonymized prescriptions between Q1/2009 and Q4/2011. Information included age, gender, date of prescription and ATC-Code. Since no information on dosage or package size was given, medication and its application duration were differentiated in acute and long-term medication by expert opinion. Costs were calculated by applying the concept of DDD. **RESULTS:** On average, 16.0% of the patients received at least one PIM prescription each quarter. 13,736 prescriptions were classified as PIM (6.4%; 68.7% to women). Out of these, psycholeptics such as Zopiclon (11.8%) and calcium antagonists such as Nifedipin (7.9%) were prescribed most frequently. Total costs of PIM-prescriptions were calculated to be 446,430€ (mean 40,585€ per quarter; min. 32,869€; max. 50,024€). When assuming prescription of surrogates, costs varied between 267,990€ and 935,826€. **CONCLUSIONS:** PIM represents both a medical and economic burden to the German health care system. From an economic perspective, substitution of PIM may result in cost disadvantages. Thus, there is little economic incentive for health insurances to further promote the substitution of PIM. Future research should take a broader perspective and include costs of PIM-related ADR to fully evaluate the economic impact of PIM in the elderly.

PHP44

HOW DOES PRESCRIPTION OF GENERIC DRUGS SPREAD OUT?: DATA MINING AND VISUALIZATION BY USING PRESCRIPTION DATA FORM ACUTE CARE HOSPITALS NATIONWIDE

Shimizu S[1], Ishikawa KB[2], Ikeda S[3], Fushimi K[4]
[1]*Institue for Health Economics and Policy, minato-ku, Japan,* [2]*National Cancer Center, Tokyo, Japan,* [3]*International University of Health and Welfare, Ohtawara-City, Japan,* [4]*Tokyo Medical and Dental University Graduate School of Medicine, bunkyo-ku, Tokyo, Japan*

OBJECTIVES: To clarify the spread with prescription of generic drugs and the shift from brand drug market by using nationwide administrative data. **METHODS:** For the sample, out of 30 drugs seen as the parameter for generic drugs in France, 27 have been selected after considering their availability in Japan. For those drugs unapproved in Japan, they were replaced by other drugs with the same effects, and anticancer agents as well as radio contrast agents were added. New drugs listed to National Health Insurance list around the same time were also included for comparison. Database was created by extracting the data of patients who were

prescribed those drugs from DPC/PDPS data collected between 1st April 2010 and 31st March 2012 at 1139 of acute care hospitals in Japan. Hospitals were classified into five categories (university, private, publi, social insurance group, and others). SQL Server 2008 R2 was used for data handling, R for data analysis, and ArcGIS for statistical analysis of geography. **RESULTS:** Generic drugs were least used amongst almost all types of drugs in university hospital and social insurance group. For prescription of generic drugs, private hospital was the most proactive, followed by public hospital. It was revealed, thorough comparison between 20% of medical care institutions that are the most proactive towards introduction of generic drugs and 20% of the least proactive, that the shifting progress was slower in bigger size medical care institutions. **CONCLUSIONS:** This study indicated that for effective promotion of generic drugs, it is important to establish plans for changing the policy of medical care institutes, which are amongst the bottom 20% of introduction rate, where a policy maker does not shift to generic drugs even in the area of expensive drugs such as anti anticancer agents and radio contrast agents.

PHP45

HEALTH TRANSFORMATION PROGRAM IMPACT ON IMPORT AND LOCAL PHARMACEUTICAL CONSUMPTION IN TURKEY

Ufuktepe B[1], Kockaya G[2]
[1]*Istanbul University, Istanbul, Turkey,* [2]*Health Economics and Policy Association, Ankara, Turkey*

OBJECTIVES: Health Transformation Program(HTP) started in year 2003 by MoH of Turkey. All health system changed dramatically. It had impact on all health consumptions and expenditures. The aim of this study is to show the impact of HTP on the imported pharmaceuticals(IP) and local manufactured pharmaceutical(LMS) sales in Turkey. **METHODS:** Pharmaceutical retail sales data in units and volume(US$) from year 1998 to 2012 were retrieved from IMS Dataview. Local and import consumption trends were reviewed. The data was analyzed with Microsoft Excel 2010. **RESULTS:** Total unit sales were 689M in 1998, 698M in 2002 and 1768 M in 2012; after 10 years of HTP. Total sales were 1937M, 2526M and 8000 M USD for the same years, respectively. Between 1998 and 2012, CAGR(Cumulative Annual Growth Rate) of unit sales was 7%, while the majority of this growth came from HTP(9,7% after HTP vs 0,3% before HTP). There was no significant change in unit sales between 1998 and 2002; total CAGR was 0,3%. Sales between 1998 and 2012 in USD had an average growth rate of 10,7%. Comparing CAGR for before and after HTP; LMP was 1,5% before and 7% after while IP showed an inverse ratio with the total and LMP values and was 23,5% and 13,1% before and after. In the beginning of the 15 years period market share for local manufacturing 92,6% in units and 80,8% in USD; in 2002 dropped down to 88,8% in units and 65,7% in USD, and finally in 2012 to 75,2% in units and 49,8% in USD. **CONCLUSIONS:** The percentage of IP both in units and volume increased in years. This increase may be caused by different reasons, particularly new oncology and biotechnology molecules. It was observed that the volume increase in IP or decrease in LMP was limited by the HTP.

PHP46

UNDERSTANDING PATTERNS OF MONITORING OF APPROPRIATE PRESCRIBING IN EUROPE

Schroeder C[1], Keja J[2], Hughes B[2], Toussi M[3]
[1]*IMS Health, Munich, Germany,* [2]*IMS Health, London, UK,* [3]*IMS Health, Paris La Défense, France*

OBJECTIVES: To analyse the current requirements and patterns for drug use monitoring in Europe and highlight new ways for pharmaceutical companies to meet these requirements **METHODS:** We combined three methods of data collection to characterise current requirements and patterns for drug use monitoring: 1) review of official reports by European agencies; 2) analysis of data elements on the European Medicines Agency (EMA) website; and 3) interviews with experts from pharmaceutical companies, facing requirements for conducting drug utilisation studies (DUS). **RESULTS:** The recent Good Vigilance Practice (GVP) established a clear regulatory framework for drug safety monitoring and calls for the assessment of the effectiveness of risk minimisation measures (RMMs). This should include the evaluation of their implementation and outcome. DUS provide simple metrics for monitoring of appropriate drug use, and thus the implementation of RMMs. We identified 28 drugs with DUS in their risk management plan and an additional 23 DUS requested by EMA. We observed a top total number of requests for DUS in the fields of contraception (n=10), infectious diseases (mainly HIV and hepatitis) (n=8) and diseases of the metabolism (mainly diabetes) (n=6) and less for other therapeutic areas. The main reasons for DUS requests were monitoring of off-label use (n=30) and new safety concerns (n=27). Experts confirmed an increasing demand for DUS. In order to optimise the RMMs, repetitive DUS in different points in time are necessary. This study analyses DUS' critical data elements allowing for the automation of such measurements. **CONCLUSIONS:** Current and future EMA practice for DUS seems to focus on new active substances, particularly in diseases of high public health relevance and infectious diseases. To meet this demand, pharmaceutical companies are required to propose more repetitive measurements of the drug use. This study identifies data elements allowing for the automation of such measurements.

PHP47

CATCHING THE LOW-HANGING FRUIT IN MEDICINES OPTIMISATION

Faria R, Sculpher MJ
Centre for Health Economics, York, UK

OBJECTIVES: The medicines bill in high income countries accounts for approximately 17% of total health care expenditure. However, around $500 million could be saved a year worldwide by optimising medicines use. This study aims to scope the evidence on the effectiveness and cost-effectiveness of interventions to address suboptimal use of medicines and pinpoint the evidence gaps to prioritise future research. **METHODS:** Systematic searches (up to February 2013) of the NHS Economic Evaluation Database, the Cochrane Database of Systematic Reviews and the Database of Abstracts of Reviews of Effects for systematic reviews on effectiveness or cost-effectiveness and for primary research on cost-effectiveness of interventions. Studies in English set in any country were included. **RESULTS:** Of the 646 records found, 108 studies met the inclusion criteria (29 cost-effectiveness studies (CES) and 81 systematic reviews on effectiveness (SRE)). The majority of CES addressed adherence (55%), followed by inappropriate prescribing (31%) and prescribing errors (28%). No studies addressed the full medicines pathway. A similar picture emerged for SRE at 67%, 15 and 11 respectively. Among the 15 types of outcomes used in CES, the top three were clinical (31%) measures of adherence (21%) and quality-adjusted life years (17%). In SRE, hospitalisations (43%), measures of adherence (23%) and mortality (21%) were the most frequent. **CONCLUSIONS:** Interventions to improve suboptimal use of medicines tend to be specific to a particular aspect of the pathway and/or to a particular disease area. Little consideration is made on how to improve medicines use in patients with co-morbidities and poly-medication. The medicines pathway is rarely examined holistically but in a fragmented manner, making it difficult to draw conclusions on which aspect of suboptimal use of medicines should be prioritised for investment.

PHP48

THE EFFECT OF REDUCED OR REMOVED COPAYMENTS FOR PRESCRIPTION MEDICINES ON ADHERENCE – A SYSTEMATIC REVIEW

Sinnott SJ, Sinnott CM, Whelton H
University College Cork, Cork, Ireland

OBJECTIVES: To examine the effect of removal or reduction in prescription copayments, in the absence of disease management plans, on adherence to prescription medications. **METHODS:** Six electronic databases were systematically searched for relevant articles, along with hand searches of references in review articles and the included studies. Studies were included if they involved an intervention which reduced or removed copayments and if the outcome was objectively measured adherence. Study designs permitted were randomised controlled trials, time series analyses, controlled before/after studies and cohort studies. Studies were excluded if the intervention was part of a disease management plan. Study exclusion, data extraction and quality appraisal were carried out by two independent reviewers. Data were qualitatively synthesised. **RESULTS:** Nine out of 40 studies were included. One study was an RCT; the remainder were all controlled before/after studies. There were 144,991 cases and 125,057 controls in this review. The mean age was 54.39yrs and 55.21yrs for the cases and controls respectively. 44.79% of the cases were female, whereas 49.54% of the controls were female. Four studies analysed the effect of reduced copayment, 4 studies analysed the effect of a removed copayment and 1 study analysed both. Only one study received a strong quality assessment, one study was rated as moderate, and the remainder were rated as weak. Seven studies showed a significant improvement in adherence. Two studies did not show an improvement in adherence. **CONCLUSIONS:** This review concludes that there is some evidence of small increases in adherence on the removal or reduction of copayments. However, confounders and biases between the included studies were variable. Future studies should concentrate on establishing associations between reduced cost-sharing and clinical and economic outcomes.

PHP49

PREVALENCE OF PHYSICIANS CAUSING POTENTIAL DRUG INTERACTIONS IN AMBULATORY CARE IN SWITZERLAND: A REPRESENTATIVE NATIONAL SURVEY

Bucher HC
Basel Institute for Clinical Epidemiology & Biostatistics, Basel, Switzerland

OBJECTIVES: No representative data on the quality of drug prescription exist in Switzerland. We analysed potential drug interactions (PDI) in primary care based on prescription data from 2010 from three large health insurers. **METHODS:** In our study population we identified based on the national drug formulary 494 drug-drug interactions (DDI) classes. Of those, 41 were from drug interaction severity classes I (contraindicated) and II (potentially contraindicated) and classified as PDI. PDI were calculated for two indicators with different denominators, 1) the total number of DDI and 2) the total number of patients potentially exposed to a PDI. For each physician we calculated the probability that the number of caused PDI was unlikely (p-value between 0.05 and 0.01; 'problematic prescription behaviour') and very unlikely (p-value <0.01; 'likely problematic prescription behaviour') to be explained by chance. **RESULTS:** Of 3.13 million individuals 1.34% were exposed to at least one PDI; figures increased to 3.78% and 4.40% in females and males aged ≥70 years. Of 20,710 physicians 42% caused at least one PDI. With DDI being the denominator 6.2% und 3.4% of general practitioners and 0.9% und 0.5% of specialists were classified with a 'problematic' and 'likely problematic prescription behaviour'. With the patient population being the denominator between 0.96% and 6.22% of physicians from all specialty groups had caused a PDI that was classified as 'likely problematic' (p-value <0.01). When combining both indicators 457 of 20'720 physicians (2.2%) had a prescription behaviour causing a PDI that in comparison to peers was highly unlikely to be explained by chance (p-value <0.01). **CONCLUSIONS:** A total of 2.2% of physicians in primary care prescribe during one year at least one drug combination that is classified as PDI. A linkage to other data sources would be needed to further classify PDI that put patients at serious risk for adverse drug reactions.

PHP50

A SYSTEMATIC EVALUATION OF DRUG-DRUG INTERACTIONS IN PRESCRIPTIONS; FACTS AND COMPARISONS

Ahmad M, Arshad W, Usman Minhas M
The Islamia University of Bahawalpur, Bahawalpur, Pakistan

OBJECTIVES: The study focus was to evaluate and compare the prescriptions for the encountered potential drug-drug interactions (pDDIs) and their different levels on the basis of onset, severity and documentation status, in a tertiary care hospital and community pharmacies in Bahawalpur, Pakistan. **METHODS:** Total 800 prescriptions, 400 from a tertiary care teaching hospital and 400 from community pharmacies, fulfilling inclusion criteria were collected thrice a week during a period of three months and were analyzed for potential drug-drug interactions using dug digest database, drug interaction checker of www.drugs.com and reference text

Drug Interaction Facts. **RESULTS:** A highly significant difference was observed between the prevalence of pDDIs in prescriptions from hospital (45%; 180 out of 400 prescriptions with at least 1 pDDI) and community pharmacies (29.25%; 117 out of 400 prescriptions with atleast 1 pDDI). On the whole, out of total 543 pDDIs (hospital = 337; community = 206) majority of them were of delayed onset (hospital = 50.44%, community = 44.66%), moderate severity (hospital = 57.87%, community = 42.72%), suspected type (hospital = 27.6%) and possible documentation (community = 14.08%). Most of the prescriptions (hospital = 80%; community = 83%) contained 2-4 medicines. The interacting combinations such as aspirin-clopidogrel omeprazole-clopidogrel and digoxin-furosemide (in hospital); isoniazid-rifampin and tramadol-escitalopram were found to be frequently involved in major interactions. The findings showed that cardiovascular drugs were involved in most of the rapid pDDIs (in hospital = 32.46%; in community = 33.33%) and respiratory system drugs were associated with majority of established documented pDDIs (in hospital = 16.67%; in community = 42.86%). **CONCLUSIONS:** Drug-drug interactions in prescription medicines were observed in high percentage both in hospitals and community pharmacies. Clinical practices must be standardized as rational prescribing practices.

HEALTH CARE USE & POLICY STUDIES – Equity and Access

PHP51
UNMET HEALTH NEEDS OF IMMIGRANTS LIVING IN GREECE DURING THE ECONOMIC CRISIS: THE LONG-TERM IMPACT FOR THE HEALTH CARE SYSTEM

Kaitelidou D[1], Galanis P[1], Zikos D[2], Lemonidou C[1], Chrysopoulou E[1], Bellali T[3], Vafeiadis J[4], Siskou O[2], Velonakis E[1]

[1]*National and Kapodistrian University of Athens, Athens, Greece,* [2]*Center for Health Services Management and Evaluation, National and Kapodistrian University of Athens, Athens, Greece,* [3]*Alexander Technological Educational Institute of Thessaloniki, Thessaloniki, Greece,* [4]*National Organization for the Provision of Health Services (EOPYY), Marousi, Greece*

OBJECTIVES: To examine access of migrants in health care services, their unmet health needs, and the factors associated with these. **METHODS:** A cross-sectional pilot study was conducted from January to May 2013. The study population consisted of 231 recent immigrants living in Greece. A questionnaire was developed including information about demographics, health status, difficulties in health services access etc. Statistical analysis included Pearson's x^2 test, x^2test for trend, student's t-test, analysis of variance and Pearson's correlation coefficient. **RESULTS:** Almost half of the participants (n=115, 49.7%) used public health services in the last 12 months in Greece. Among them, 56.8% (n=131) used emergency department services. A considerable proportion of the participants (n=144,62.3%), during the last year, needed at least one time to use health services but they could not afford it. The most important reasons for that were high cost of health care (n=80, 34.5%) and the long waiting lists (n=29, 12.6%). More than half of the participants (n=122, 52.9%) reported that they had major difficulties in accessing health services. Increased family monthly income was associated with decreased difficulties in access in health services (x2 test for trend=32.1, p<0.001). The use of preventive services has been limited since more than 60% of the women 40+ reported not having conducted a pap test or a mammography, while more than 30% of the respondents were not subjected to a blood test or a cholesterol examination. **CONCLUSIONS:** Barriers to health services access for migrants may lead to decreased use of health services, especially primary, and thus lead to increased hospitalizations and higher cost in the longer-run. Formulation of policies to improve access and use of health care services are necessary.

PHP52
IMPORTANCE OF SUBGROUP ANALYSES FOR HEALTH TECHNOLOGY ASSESSMENTS

Aggarwal S, Topaloglu H, Kumar S

Novel Health Strategies, Bethesda, MD, USA

OBJECTIVES: Cost effectiveness analyses play a critical role in determining coverage of novel drugs and devices. Increasingly, payers are demanding subgroup analyses to determine indications which would be covered by the national health system or insurance agency. **METHODS:** To understand and review trends in the use of subgroup cost effectiveness analysis, we analyzed NICE HTAs for products approved between 2011-2012. Manufacturer submissions for CEA were compared to final review and decision by HTA agency. Analogs were identified and case studies were developed to further understand the use of subgroup analyses and cost effectiveness models. **RESULTS:** Decisions made by NICE in 2011-2012 show increasing trends towards the use of subgroup analysis for determining indications for coverage by national payer bodies. Between 2011-2012, 80% of the assessments included subgroup analyses. Approximately half of them included cost effectiveness analyses for various subgroups. Interestingly, the ICER values estimated by NICE for the same subgroups showed a large variation (1X-3X fold difference) compared to ICER values estimated by manufacturers. Selected case studies highlighted that for several products, NICE is recommending treatments only for subgroups whose ICER values are within the cost effectiveness threshold. **CONCLUSIONS:** New products need robust broader population and subgroup analyses for insurance coverage.

PHP53
CHRONIC PATIENTS' ACCESS TO PHYSICIANS SERVICES IN TIMES OF ECONOMIC CRISIS

Kyriopoulos II[1], Skroumpelos A[1], Mylona K[1], Anastasiou L[2], Pavi E[1]

[1]*National School of Public Health, Athens, Greece,* [2]*Novartis Hellas, Metamorfosi, Greece*

OBJECTIVES: To explore the magnitude of certain access barriers to physician services that chronic patients are in front of as well as which patients are more vulnerable to such restrictions. **METHODS:** A cross-sectional study was conducted in 1600 chronic patients suffering from diabetes, hypertension, COPD and Alzheimer. Logistic regression analysis was carried out in order to explore the factors related to economic and geographical barriers in access, as well as the determinants of barriers imposed by waiting lists. **RESULTS:** A total of 25% of chronic patients face geographical barriers while 63.5% and 58.5 % of them are in front of economic and waiting list barriers, respectively. More likely to face economic barriers in access are unemployed patients [coef.0.55; 95% CI (0.1, 1)] and patients with low income [-0.2; 95% CI (-0.26,-0.13)] and lower educational level [-0.04; 95% CI (-0.08, 0)]. Women [0.22; 95% CI(0.02,0.42)], low-income patients [-0.13 ; 95% CI(-0.2, -0.06)], and patients with lower health status [-0.02 ; 95% CI(-0.02,-0.01)] are more likely to be in front of geographical barriers in access. Moreover, all occupational categories examined, demonstrate a statistically significant positive relationship with the probability of geographical barriers occurrence. In addition, unemployed patients [0.51; 95% CI (0.06, 1)], public or private sector employees [0.45; 95% CI (0.09, 0.81)] and low income patients [-0.086; 95% CI (-0.15, 0.02)] are more likely to deal with barriers attributed to waiting lists. **CONCLUSIONS:** Chronic patients face extensive barriers in access, which can mainly be explained by the fall of income, the rise of unemployment and the policy of decreasing the supply of certain health services in order to reduce health expenditure. If such barriers won't be minimized inequalities will be enlarged and chronic patients' health status will be worsened which might lead to increased future costs and adverse effects on health expenditures.

PHP54
QUALITY ASSURANCE OF FOURTH HURDLE CONCERNING TO DRUGS AND MEDICAL DEVICES

Tesar T[1], Babela R[2]

[1]*Union Health Insurance Fund, Bratislava, Slovak Republic,* [2]*St. Elizabeth University of Health and Social Sciences, Bratislava, Slovak Republic*

OBJECTIVES: From 2011, there are basic thresholds (λ1=24 x average monthly salary € / QALY and λ2 = 35 x average monthly salary € / QALY) defined directly in the Slovak legislation reflecting the benefits displaced elsewhere in the Slovak health care system when funds are allocated to new medicines and medical devices. The objective of this study was to analyse the quality of submitted economic studies, related critical appraisals process and impacts of the new legislation on the access to medicines and medical devices. **METHODS:** We created a working group to review previously submitted economic evaluations and related critical appraisals in order to identify potential technical and methodological problems. The working group scrutinized previous submissions and critical appraisals, concerning to chosen ATC groups of drugs and groups of medical devices, published between June 2012 and June 2013 at the webside of MoH. **RESULTS:** Pharmacoeconomic evaluations of drugs and medical devices within decision making process concerning to reimbursement are mandatory but the quality of studies are very often rather poor. The concept "the QALY is a tool not a rule" was slightly modified in Slovakia. Our analysis shows that implicit thresholds included into the Slovak legislation have influenced decision-making process concerning to drugs and medical devices. In the defined time period 4 drugs exceeded the basic thresholds described in the Slovak legislation, however 108 drugs and medical devices were refused to include into the reimbursement list, because of the poor quality of provided pharmacoeconomic studies from the side of applicants. **CONCLUSIONS:** The transparent method of HTA can improve the consistency of reimbursement decisions making related to drugs and medical devices in Slovakia. However significant improvements in the quality of submitted pharmacoeconomic dossiers have to be the first step towards the better access to drugs and medical devices for the Slovak patients.

PHP55
THE HYBRID PURCHASER-PROVIDER SPLIT IN ENGLAND: SHOULD EUROPE FOLLOW SUIT?

Sewak NPS, Devienne E, Karia R

Double Helix Consulting, London, UK

OBJECTIVES: Developed countries have embraced the purchaser-provider split as a mechanism to improve health resource allocation and outcomes. With the emergence of Clinical Commissioning Groups (CCGs) as both buyers and providers of health services a hybrid purchaser-provider model is being explored. This research explored the opportunities and challenges of this model and analysed the implications for NHS England and Europe. **METHODS:** Eighty influential regional and national payers involved in the NHS England reforms took part in 1-hour tele-depth interviews to better understand the changes and uncertainties before the reforms were implemented. This research was re-visited three months post implementation in an advisory board setting to externally validate our findings and identify case studies for further analysis. **RESULTS:** NHS payers stated that they were still 'broadly optimistic' about the re-allocation of purchaser responsibilities to CCGs. One case study illustrated that greater clinician involvement provided opportunities to redesign services like respiratory care and allocate funding more efficiently between acute and primary care. Initial success stories include the creation of primary care diabetes clinics and Pharma-NHS local partnerships to help reduce hospital activity. Within the advisory board, payers voiced concerns with this hybrid model. Questions raised from the meeting included: 1) How do we equip GP commissioners with the right skill set to draft and negotiate hospital contracts? 2) How can we help GP commissioners and GP providers to help minimise potential conflicts of interest? **CONCLUSIONS:** The purchaser-provider model implemented in England presents a new way to tackle reduced financial budgets and need to improve health outcomes. The results of this research suggest that the purchaser-provider model has the potential to make a difference for patient care. A number of challenges appear to still be present and it will be important to address these in order for the UK and other countries to further explore its benefits.

PHP56
CURRENT STATUS AND EVIDENCE OF EFFECTS OF E-PRESCRIBING IMPLEMENTATION IN UNITED KINGDOM, ITALY, GERMANY, DENMARK, POLAND AND UNITED STATES

Hermanowski TR[1], Kowalczyk M[1], Szafraniec-Burylo SI[2], Krancberg AN[1], Pashos CL[3]

[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*National Institute of Public Health – National Institute of Hygiene, Warsaw, Poland,* [3]*Evidera, Lexington, MA, USA*

OBJECTIVES: Electronic-prescribing (E-prescribing) in comparison to manual ("by hand") generation, transmission and filling of prescriptions is thought to substantially lower the risks of inaccuracy and therefore reduce associated health care resource use and costs. The purpose of this work is to describe the current state of e-prescribing systems implementation in Denmark, Germany, Italy, Poland, United Kingdom (UK) and United States (USA), and to assess present evidence of its influence on health care. **METHODS:** A systematic review supplemented by additional hand-search was conducted to find relevant articles. Medline, Embase, The Cochrane Library and Scopus were searched. Quality was assessed on the basis of PRISMA, MOOSE and STROBE checklists and West 2002 recommendations. **RESULTS:** Thirty-one relevant full texts were identified during systematic review, and then as a result of hand-search, 5 publications were added. E-prescribing varies considerably across these countries. It is currently voluntary in Germany, Italy and United States. In United Kingdom the system is implemented except for electronic signature. In Denmark e-prescribing is mandatory for primary care providers. Model implementation in Poland is expected to take place in 2014. Of these 36 sources, 4 articles assessing e-prescribing were of the highest quality, as judged using the assessment methods. Positive influence on medical visits frequency, quality of care, patient satisfaction, prescription errors frequency, and prescriber-pharmacy-patient communication was described in literature; most studies were conducted in the UK and USA. No data about effects of implementation for Germany, Italy, Denmark and Poland were found. **CONCLUSIONS:** Implementation of e-prescribing is in process in the majority of described countries. Although few studies exist that definitely demonstrate positive impact of e-prescribing on health care, gathered papers do indicate positive effects. More comprehensive assessments would be valuable in showing the attributes of e-prescribing that are most valuable, and those that may be strengthened.

PHP57

MODELS OF DRUG SAFETY MONITORING IN ENGLAND, POLAND, ITALY, GERMANY, DENMARK AND UNITED STATES

Hermanowski TR[1], Krancberg AN[1], Szafraniec-Burylo SI[2]
[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*National Institute of Public Health – National Institute of Hygiene, Warsaw, Poland*

OBJECTIVES: To review, describe and assess models of drug safety monitoring in England, Poland, Italy, Germany, Denmark and in the United States and prepare recommendations useful in health authorities decision-making process. **METHODS:** A review of documents, materials and information published on national medicines agencies as well as WHO's statements was conducted, supplemented by hand-search of literature. **RESULTS:** The advantages and disadvantages of described pharmacovigilance schemes in selected countries has been discussed. The gathered data, related i.a. to the level of adverse drug reaction reporting in different countries, was used to assess the efficacy of national reporting process. Moreover our research allowed us to value the formula of pharmacovigilance schemes as well as the attitudes of health care professionals and patients towards it. **CONCLUSIONS:** Although the majority of compared countries are European Union members bound to respect the same acts of European law, there are still many significant differences met in Pharmacovigilance practice reflecting in the level of adverse reaction reporting. These differences may be found as the treatment of newly registered medicines, data availability and transparency of procedures within the agencies or the relationship between health authorities and potential reporters. A set of recommendations has been prepared related to special treatment of new medicines, creating awareness of importance of pharmacovigilance in health care (hospitals, pharmacies), changing the attitude to risk aspects, transparency of safety monitoring practice and patients' enrollment. The implication of our proposals could help to amend the pharmacovigilance systems in all discussed countries.

PHP58

SPECIFIC ATTRIBUTES OF PHARMACEUTICAL CARE IN ENGLAND, POLAND, GERMANY, DENMARK, ITALY AND UNITED STATES

Hermanowski TR[1], Duleba D[1], Krancberg AN[1], Szafraniec-Burylo SI[2], Pashos CL[3]
[1]*Medical University of Warsaw, Warsaw, Poland,* [2]*National Institute of Public Health – National Institute of Hygiene, Warsaw, Poland,* [3]*Evidera, Lexington, MA, USA*

OBJECTIVES: To describe existing models of pharmaceutical care (PC) in England, Poland, Germany, Denmark, Italy and United States and to indicate similarities and specific attributes meant as differences (from the whole system point of view), identifying possibly promising solutions (promising means having preliminary or probably positive results described in found literature). **METHODS:** A systematic and non-systematic literature review in Medline, Embase, Scopus and the Cochrane Library was performed. Quality of publications was critically appraised. **RESULTS:** The review identified 48 full texts. The majority of papers were of moderate quality (PRISMA, MOOSE or STROBE checklists) and intermediate consistency, coherence and strength (West 2002). In chosen countries differences in the definition of PC have been noticed and therefore often it is difficult to find similarities. Although in some countries like England and the US, PC is firmly established and comparable with one another, in other it is very heterogeneous. Mainly in Central and Eastern Europe (CEE), especially in Poland, it is offered to a very limited extent or only pilot implementations exist. Four types of PC models have been distinguished: Anglo-Saxon, Scandinavian, German and Italian. Specific attribute of English PC is division into essential, advanced and enhanced services. American pharmacists providing this service must be highly specialized. Danish system focuses on identifying, solving and prevention of drug-related problems. In Germany family pharmacy concept emerged. Pivotal point of Italian system is hospital PC. Identified promising solutions found in some countries were i.a. Drug Utilization Review, disease management programs or medicines use review. **CONCLUSIONS:** Identical PC concept may be difficult to introduce in all EU Member States, due to differences in health systems. However, some identified, promising actions should be considered by decision makers and providers, as well as implementing PC to a sufficient extent in CEE countries.

PHP59

WHICH ARE THE ATTITUDES OF PRIMARY HEALTH SERVICES USERS CONCERNING COST SHARING MEASURES IN A PERIOD OF ECONOMIC CRISIS IN GREECE?

Siskou O[1], Galanis P[1], Kouli E[1], Tsavalias K[1], Kaitelidou D[1], Theodorou M[2], Prezerakos P[3], Spinthouri M[1], Vafeiadis J[4], Kalogeropoulou M[1]
[1]*National and Kapodistrian University of Athens, Athens, Greece,* [2]*Open University of Cyprus, Latsia, Cyprus,* [3]*University of Peloponnese, Sparta, Greece,* [4]*National Organization for the Provision of Health Services (EOPYY), Marousi, Greece*

OBJECTIVES: To identify the extent to which patients accept the measure of cost sharing fee (5€) in public primary health care units (health centers and hospitals' outpatient departments) as well as to investigate whether patients perceive the potential benefits of the measure for the quality improvement of provided health care. **METHODS:** The study population consisted of 1260 people, who used public primary health care units. A structured questionnaire was used, including questions for patients' demographic characteristics, their attitude regarding the cost sharing mechanism (compliance, perception of the benefits for health services upgrade etc), and their level of satisfaction with the provided services. **RESULTS:** The implementation of cost sharing mechanism was positively accepted by 30% of respondents. Approximately 90% of the respondents, who expressed positive opinion for the implementation of the mechanism, considered that it would provide financial support to health units. Among the respondents who expressed negative opinion for the measure, 95% believed that health services should be public and free for everyone, 83% expressed lack of confidence that the measure aims at upgrading the provided services, 78% believed that the insurance contributions they already pay are high and 67% stated no financial comfort. The negative opinions were more frequent among people with lower socio-economic profile and those who have used health centers ($p<0.06$). Respondents with higher socio-economic profile, coming from urban areas and respondents who were very satisfied with health services had statistically significantly greater possibility to express positive opinion for the measure. **CONCLUSIONS:** Low socio-economic profile is negatively associated with the acceptance of the implementation of cost sharing mechanism, while high satisfaction with services is positively associated with the acceptance of the mechanism. The majority of those, who expressed positive opinion for the measure, consider it as a contribution to the enhancement of health services.

PHP60

FINANCIAL INCENTIVES IN HEALTH CARE: EVIDENCE OF UNINTENDED CONSEQUENCES

Jensen SO[1], Amelung VE[1], Hermanowski TR[2], Krauth C[1]
[1]*Hannover Medical School, Hannover, Germany,* [2]*Medical University of Warsaw, Warsaw, Poland*

OBJECTIVES: Financial incentives or Pay-for-Performance (P4P) have become a common approach to improve the quality in health care. Although the effectiveness is mixed, more and more P4P initiatives are implemented. Besides the desired effects of quality improvement, a growing number of evaluations show that financial incentives lead to unintended consequences. Therefore this study analyses negative effects of P4P. **METHODS:** On the basis of a systematic review of systematic reviews regarding P4P in health care (nine systematic reviews included that evaluate 75 different primary studies; Methodological quality assessment using the AMSTAR checklist) an additional hand search was conducted to identify evidence of unintended consequences of P4P. **RESULTS:** Both theory and evidence of financial incentives demonstrate the potential of negative effects. Risk selection is identified in six reviews: Patients could get selected due to their severity of illness in order to achieve quality targets with minimum effort (cherry picking); Physicians will focus on indicators or aspects of care that are linked to payments (teaching to the test). Focussing on incentivized indicators could lead to quality decrease in non-incentivized indicators (negative spillover effects), assessed in four reviews. Five reviews show that physicians could game the P4P program by reporting incorrect results and therefore increase their payments (gaming). Furthermore, improvements can be the result of better documentation and not actual quality improvements (four reviews). Finally one review identified crowding out of intrinsic motivation due to financial incentives. **CONCLUSIONS:** The available evidence shows that P4P can result in unintended consequences. Evaluations of P4P should include these effects in order to assess an overall effect and thereby determine the effectiveness of P4P. To avoid negative effects it is important to consider the potential of unintended consequences and develop appropriate solutions.

PHP61

GEOGRAPHICAL INEQUALITIES IN THE ACCESS TO AND UTILIZATION OF HOME CARE (NURSING) SERVICES IN HUNGARY

Cs Horváth Z[1], Molics B[2], Ágoston I[2], Sebestyén A[3], Boncz I[2]
[1]*National Institute for Quality- and Organizational Development in Healthcare and Medicines, Pécs, Hungary,* [2]*University of Pécs, Pécs, Hungary,* [3]*National Health Insurance Fund Administration, Pécs, Hungary*

OBJECTIVES: Home care (nursing) was introduced into the Hungarian basic health insurance package in 1996. The aim of our study is to analyze the geographical inequalities in the access to and utilization of that services in Hungary. **METHODS:** Data were derived from the nationwide administrative dataset of the National Health Insurance Fund Administration (OEP), the only health care financing agency in Hungary. The geographical inequalities in home care (nursing) services were measured by the number patients, visits and reimbursement according to 20 Hungarian counties. We analyzed the year 2011. **RESULTS:** The national average number of patients was 51 patients / 10000 population. We found the highest patient number in county Zala (67), Jász-Nagykun-Szolnok (63) and Baranya (62), while the lowest number in county Békés (43), Somogy (43) and Szabolcs-Szatmár-Bereg (28). The national average number of home visits was 1193 visits / 10000 population. We found the highest number of visits in county Nógrád (1494), Tolna (1385) and Fejér (1377), while the lowest number in county Somogy (1138), Csongrád (1106) and Szabolcs-Szatmár-Bereg (678). The national average of reimbursement per patient was 65345

Hungarian Forint (HUF) or 234 Euro (EUR) / patient. We found the highest reimbursement per patient in county Nógrád (87879 HUF, 315 EUR), Fejér (80851 HUF, 290 EUR) and Békés (77643 HUF, 278 EUR), while the lowest reimbursement county Budapest (58859 HUF, 211 EUR), Jász-Nagykun-Szolnok (55757 HUF, 200 EUR) and Zala (54924 HUF, 197 EUR). **CONCLUSIONS:** We found significant differences measured by all the three indicators in home care (nursing) services in Hungary. Our results revealed that there are important inequalities both in the access to and utilization of home care services.

SELF-REPORTED POPULATION HEALTH: AN INTERNATIONAL PERSPECTIVE BASED ON EQ-5D

Szende A[1], Janssen MB[2], Cabasés JM[3], Ramos Goñi JM[2]
[1]*Covance, Leeds, UK,* [2]*EuroQol Group, Rotterdam, The Netherlands,* [3]*Public University of Navarra, Pamplona, Spain*

OBJECTIVES: General population EQ-5D health surveys have been accumulated in the EuroQol Group's archive over the past two decades. Using the database as a source of standardized measure of self-reported health, the objective was to estimate the level of health (EQ-5D population norms) and the distribution of health within populations along socio-demographic characteristics. **METHODS:** Analyses captured EQ-5D data on 163,838 individuals from 18 countries with nationally representative population surveys. Descriptive statistics were used to provide EQ-5D-3L population norms by age and gender categories for EQ VAS, EQ-5D index values, and for the 5 dimensions for each country. Odds ratios and the health concentration index methodology were used in the socio-demographic analysis of EQ-5D data. **RESULTS:** The mean EQ-VAS rating varied from 71.1 to 83.7 and from 70.4 to 83.3 across countries without and with age standardization, respectively. Statistically significant inequalities existed in all samples ($p<0.01$) with the EQ-VAS based health concentration index varying from 0.090 to 0.157 across countries. Among the socio-demographic factors, age had generally the largest contributing share, while education also had a consistent role in explaining lower levels of self-reported health. Among the 5 dimensions, usual activities and pain/discomfort were the highest contributors to overall inequalities in most countries. **CONCLUSIONS:** EQ-5D norms can be used as reference data to compare patients with specific conditions and to assess the burden of the disease in question. Inequalities in self-assessed health exist in all countries with different social and cultural backgrounds, deserving the attention of policy makers within each country.

ANALYSIS OF ADVERSE REACTIONS OF MEDICINE IN UKRAINE

Zalis'ka O, Maksymovych N, Zaliskyy O
Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

OBJECTIVES: In Ukraine the pharmacovigilance system for adverse reactions is working. In 2008 was received 7,115, 2009 – 8291, 2010 – 8673, 2012- 11674 card-reports of adverse reactions (AR) drugs. MoH conducted a detailed analysis of these reports found that 13% of them experienced serious adverse events, and 0.7% of the cards with the unexpected AR. **METHODS:** We analyzed the side effects depending on the ATC-group drugs. **RESULTS:** We found that antimicrobial agents for systemic use the largest number of reports received on AR (75.4%), which in most cases manifested anaphylactic AR. Further analysis showed that AR often were drugs (by INN): ceftriaxone (12.6%), amoxicillin in combination with clavulanic acid (8.0%), levofloxacin (6.3%). Among the cardiovascular drugs, reports AR often came on enalapril (10.0%), pentoxifylline (9.7%) and amlodipine (8.1%).Among the drugs affecting the nervous system, haloperidol (7.4%), metamizol sodium (7.4%) and paracetamol (7.0%). The analysis showed that the ratio of serious not serious AR under anti-neoplastic drugs and antiretroviral drugs is 1:2, anti-TB drugs - 1:3, and those affecting the cardiovascular system, gastrointestinal tract, respiratory system - under 1:9, 1 : 6, 1:6. Thus, the frequency of serious AR is much higher in the application of anti-neoplastic, anti-HIV and anti-TB drugs.The greatest risk AR was for children aged 28 days - 11 years, especially boys, and adults, especially women aged 46-60 years. **CONCLUSIONS:** Results of the analysis of AR indicate that needed pharmaceutical care when dispensing antiretrovirals, anti-tuberculosis, anti-neoplastic drugs that meet the requirements of Good pharmacy practice in Ukraine. Implementation of training courses and programs for pharmacists on the subject of safe use of drugs to treat infectious diseases, tuberculosis and HIV / AIDS is essential. As well as acquiring skills pharmaceutical care and prevent AR in dispensing drugs to children and women 45-60 years.

PHP64

A 10-YEAR REVIEW OF THE CANADIAN COMMON DRUG REVIEW: PHARMACEUTICAL MANUFACTURERS' SUCCESS RATE

Shum D[1], Wyatt G[2], Siu E[2], Mills F[2]
[1]*Hoffmann-La Roche Limited, Mississauga, ON, Canada,* [2]*Wyatt Health Management, Oakville, ON, Canada*

OBJECTIVES: The Canadian Common Drug Review (CDR) is a national HTA agency that has been in existence for 10 years. During this, the CDR has reviewed the clinical and cost-effectiveness of 188 drugs and provided 269 recommendations to the publically funded drug plans. Of all the drugs reviewed over the past 10 years, 50.4% have received a positive recommendation and 49.6% have received a negative recommendation. The objective of this analysis was to describe the success rate of each pharmaceutical manufacturer in terms of type of recommendation, time to recommendation, and time to listing in the provincial formularies. **METHODS:** The CDR Tracker database was used to analyze all CDR drug reviews from 2003 to the end of 2012. There were a total of 189 reviews during this 10 year period. All manufacturers that had three or more submissions with CDR were included in the analysis; 29 companies met this criterion. **RESULTS:** Of the 189 reviews and 29 companies analyzed, the positive recommendation rates ranged from 100% to 17%. The top 5 most successful manufactures in terms of positive recommendations were Roche (100%), Abbott (100%), Bayer (83%), Gilead (80%), and Boehringer-Ingelheim (80%). The average time to receive a CDR recommendation varied from 170 days to 248 days. The manufacturers with the fastest time to recommendation are GSK, Abbott, Roche, Boehringer-Ingelheim, and Watson. Time to reimbursement / formulary listings in all provinces ranged from 123 days to 593 days. **CONCLUSIONS:** This is the first analysis to describe the success rate of pharmaceutical manufacturers through the CDR. There appears to high variability in all the metrics that were measured and further research into the determinants of variability is warranted.

IMPACT OF MEDICARE PART D ON PRESCRIPTION USE, HEALTH CARE EXPENDITURES, AND HEALTH SERVICES UTILIZATION: NATIONAL ESTIMATES FOR MEDICARE BENEFICIARIES, 2002 TO 2009

Cheng LI[1], Rascati KL[2]
[1]*Amgen, Thousand Oaks, CA, USA,* [2]*The University of Texas at Austin, Austin, TX, USA*

OBJECTIVES: To investigate the impact of Medicare Part D on prescription utilization, health services utilization, and health care expenditures in the general Medicare population. **METHODS:** A retrospective analysis of Medicare beneficiaries (N=32,228) was conducted using the Medical Expenditure Panel Survey 2002 to 2009 data. Multivariable quantile regression was used to estimate the following outcomes at the 25th, 50th, 75th, and 90th percentiles, adjusting for socio-demographic characteristics: 1) number of prescription fills; 2) out-of-pocket (OOP) drug expenditures; 3) total drug expenditures; 4) OOP health care expenditures; 5) total health care expenditures; 6) number of hospitalizations; and 7) number of emergency department (ED) visits between the pre-Part D (2002-2005) and post-Part D (2006-2009) periods. All expenditures were inflation-adjusted to 2009 dollars. **RESULTS:** In the general Medicare population, Part D was associated with decreases in OOP drug expenditures (-25.7% to -33.6%; $p<0.0001$) and OOP health care expenditures (-22.1% to -24.3%; $p<0.0001$) across all percentiles. Part D was associated with increases in the number of prescription fills across all percentiles (5.8% to 8.4%; $p<0.0001$) but only at the 75th and 90th percentiles for increases in total drug expenditures (75th percentile: 5.5%; 90th percentile: 10.2%; $p<0.0001$). Part D was not associated with changes in total health care expenditures, hospitalizations, or ED visits in the general Medicare population. **CONCLUSIONS:** Part D resulted in increases in medication utilization and reductions in OOP drug and OOP health care expenditures among Medicare beneficiaries, but was not associated with differences in total health care spending, hospitalizations, or ED visits.

PHP66

THE IMPLICATIONS OF DEMOGRAPHIC CHANGES FOR GMS COSTS IN IRELAND THROUGH TO 2026

Conway A[1], Kenneally M[1], Thummel A[2], Woods N[1], Ryan M[1]
[1]*University College Cork, Cork, Ireland,* [2]*Darmstadt University, Darmstadt, Germany*

OBJECTIVES: The General Medical Services (GMS) scheme presently covers around 40% of the Irish population and entitles them, inter alia, to free prescription drugs and appliances. This paper projects the effects of future changes in population, coverage, claims rates and average claims cost on GMS costs in Ireland. **METHODS:** Data on GMS coverage, claims rates and average cost per claim are drawn from the Primary Care Reimbursement Service (PCRS) and combined with Central Statistics Office (CSO) (Regional and National Population Projections through to 2026). A Monte Carlo Model is used to simulate the effects demographic change (by region, age, gender, coverage, claims rates and average claims cost) will have on GMS prescribing costs in 2016, 2021 and 2026 under different scenarios. **RESULTS:** A total of 100,000 Monte Carlo simulations indicate that GMS medicines costs could rise to €1.9bn by 2026 and will likely fall in the €1.7bn to €2.3bn region. Population is projected to grow by 32% by 2026 and by 96% for the over 70s. The Eastern region is estimated to grow by 3% over the lifetime of the projections at the expense of most other regions. The Monte Carlo simulations project that females will be a bigger driver of GMS costs than males. Those aged 70 and over and children under 12 will be significant drivers of GMS costs with the impending demographic changes. **CONCLUSIONS:** GMS coverage is increasing in tandem with falling public health budgets and poses a threat going forward to the sustainability and funding of the GMS scheme. Our projections and simulations map the likely evolution of GMS cost, given existing policies and demographic trends.

PHP68

VARIABILITY IN PUBLICALLY-PRESCRIBED DRUG COSTS: THE ROLE OF REGION, AGE AND GENDER

O Céilleachair AJ, Woods N, O'Sullivan K, Kenneally M
University College Cork, Cork, Ireland

OBJECTIVES: Ireland currently has one of the highest levels of public drug spending per capita in Europe. As budget retrenchment efforts continue, publically-funded drug schemes such as the General Medical Scheme have been the subject of several initiatives to reduce costs in recent years. However, little is known about the regional and socio-demographic factors that may influence variations in prescribing across the state. The objective of this study was to identify these factors. **METHODS:** Using a 192,000-strong sample of PCRS data drawn from monthly GMS returns for 2007, we constructed an ANOVA model that included the main effects of age, gender and region together with their second order and third order interactive terms in an interactive effects regression model examining the role of gender, age category and region of residence in explaining variation in prescribing costs for Ireland. **RESULTS:** Mean cost per person per month was €102. Men were on average more expensive than women (€109 vs. €94) and cost increased with age group (€34 for those 0-12yrs and €169 for those over 75). The most expensive region was the Midlands HSE region (€103) while the North West (€90) was the least costly. Most of the variation in prescribing costs was explained by age, though the relationship between prescribing cost and age category was not constant. A significant three-way interaction was found between age category, gender and region. **CONCLUSIONS:** The regional and

demographic factors underlying the cost of GMS prescribing in Ireland are complex and inter-related. Alternative solutions to the question GMS coverage in the elderly may need to be found soon that prove fiscally and economically sustainable. The large gap in GMS prescribing costs between men and women in early adulthood requires further investigation.

PHP69

THE TRANSPARENCY OF NATIONAL HEALTH CARE COSTS IN THE 'EUROPEAN UNION FIVE (EU-5)'

Firth ZA, Smith TA
Mapi, London, UK

OBJECTIVES: Cost-effectiveness analyses play a key role in the reimbursement of health care technologies and require health care resource use (HRU) cost inputs. Inaccuracies in inputs can lead to potentially significant differences in results. Thus, the availability of HRU costs is vital for decision-making. This study's objective is to assess the transparency and ease of access to HRU costs in France, Germany, Italy, Spain and the UK. **METHODS:** A targeted search and contact with country-specific representatives highlighted existing national documentation. A cross-sectional selection of costs were searched for including GP and nurse costs; hospital bed and overhead costs; drug prices; follow-up/out-patient visit costs; and the availability of Diagnosis-Related Group (DRG) codes and tariffs. The transparency and availability of costs were assessed using the following criteria: the date, access restrictions and the need for assumptions to generate cost estimates. **RESULTS:** DRG tariffs were identified for all countries, but the availability of other data varied. Drug prices were obtainable online (such as the website MedicPrix, France), but others required paid registration (Giofil, Italy). The UK had the most accessible primary and secondary care HRU cost data through PSSRU. Italy was the least transparent however AIFA informed us a website reform will increase access to data in 2014. Where not explicit, HRU costs can be indirectly derived from total procedure codes (for example through ATIH, France). Spain and Italy's regional structure made sourcing national cost data challenging, resulting in wide ranges in input costs in published cost-effectiveness analyses. **CONCLUSIONS:** Whilst some nations provided transparent HRU cost data, others did not, causing inconsistent inputs across cost-effectiveness analyses. To minimise inconsistency we propose a hierarchy of evidence for use when sourcing costs: 1) Govt/health service official sources; 2) Official international websites (OECD/WHO); 3) Published economic studies; 4) Published non-economic studies; 5) National expert opinion; and 6) Unofficial websites/sources.

PHP70

A RETROSPECTIVE ANALYSIS OF DRUG REIMBURSEMENT DECISIONS IN IRELAND: A MULTI CRITERIA DECISION ANALYSIS APPROACH

Schmitz S[1], McCullagh L[2], Adams R[2], Barry M[2], Walsh C[1]
[1]*Trinity College Dublin, Dublin, Ireland,* [2]*National Centre for Pharmacoeconomics, Dublin, Ireland*

OBJECTIVES: Standard approaches to economic evaluations based on cost utility analysis are increasingly considered inadequate. While simple and intuitive, it is acknowledged that the QALY alone does not capture all aspects of health benefit. Multi Criteria Decision Analysis (MCDA) has been proposed as a way of incorporating multiple factors influencing the value of a health technology. The objective of this study was to analyse past reimbursement recommendations by the National Centre for Pharmacoeconomics (NCPE) in Ireland in order to identify factors which have influenced decisions in the past. **METHODS:** Based on published literature, national guidelines and experience, a list of potentially influencing criteria was identified. Information on each criterion was extracted for each full pharmacoeconomic assessment conducted by the NCPE. Logistic regression was used to estimate the impact each of these criteria has had on past recommendations. Model fit was assessed using the Deviance Information Criterion and the best fit model was chosen using backwards stepwise regression. **RESULTS:** Between 2006 and May 2013 the NCPE conducted 54 full pharmacoeconomic assessments. Each of these was scored against 14 criteria, which can be grouped into clinical utility, consumer demand, economic incentives, societal perspective and efficiency/affordability. The model of choice identified criteria of each group which impact on reimbursement recommendations. **CONCLUSIONS:** This analysis shows that factors other than cost per QALY have impacted on past valuations of health technologies in Ireland. Since the analysis was carried out retrospectively, these factors have influenced decisions in an informal manner and do not necessary represent the factors which should influence future reimbursement decisions. This approach contrasts with methods used elsewhere to estimate weights for the criteria. The results of this analysis provide a basis for the development of a MCDA approach to HTA in Ireland, which has the potential to improve consistent and transparent decision making.

PHP71

MEDICAL CARDS DURING RECESSION: HOW MANY, FOR WHOM AND HOW MUCH?

Kenneally M
University College Cork, Cork, Ireland

OBJECTIVES: To model the age, gender and regional pattern of GMS coverage rates as they are key determinants of public spending on GMS medicines. **METHODS:** We used PCRS (Primary Care Reimbursement Service) and CSO (Central Statistics Office) databases to estimate GMS coverage rates by age, gender and region in 2010 and 2011. Assuming log-normally distributed incomes we used CSO SILC data to estimate GMS coverage semi-elasticities in 2010. We estimated how much GMS male and female coverage rates in 7 adult age categories and 8 Irish regions in 2010 responded to changing average income levels, income inequality and income thresholds. We tracked how well our predicted GMS coverage rates fitted actual rates in 2011. We simulated the 2011 GMS medicines cost burden of a ceteris paribus repeat of the 2010 changes in income and income-inequality. **RESULTS:** Our modelled coverage rates have high goodness of fit compared to conventional econometric estimates. Coverage income-semi-elasticity ranges from .7 to 2.3, is highest for elderly age cohorts and in the South-East and South-West regions and is similar for males and females. Growing inequality generally increases GMS coverage but pushes some persons aged over 70 above the qualifying income threshold. Repeating 2010 average income in 2011 would increase the 2011 GMS medicines cost by around €110m; repeating the 2010 inequality changes would increase it by a further €105m, ceteris paribus. **CONCLUSIONS:** Fiscal cutbacks during recession induce countervailing increases in the medical card population and the public cost of its medicines. These are the first systematic and detailed estimates – by age, gender and region – of whose medical access is affected and how much the offsetting public cost will increase.

PHP72

THE BURDEN OF DISEASE ATTRIBUTABLE TO PHYSICAL INACTIVITY IN THE AUSTRIAN REGION OF BURGENLAND

Walter E[1], Dragosits A[1], Gollner E[2], Szabo B[2], Schnabl F[2]
[1]*Institute for Pharmaeconomic Research, Vienna, Austria,* [2]*University of applied science Burgenland, Pinkafeld, Austria*

OBJECTIVES: About 52.6% or 125,434 people of the population in Burgenland is physical inactive. As a risk factor for several chronic diseases like cardiovascular diseases, type 2 diabetes, osteoporosis, depression, back-pain, hypertension, breast cancer and colorectal carcinoma physical inactivity can potentially be a substantial public health burden. Furthermore, it is one of the greatest risk factors for global mortality. Hence, the aim of the analysis was to estimate the direct health-care costs saved, the number of diseases and premature death saved each year attributable to a health promotion program focusing on walking ("3,000 steps" more). **METHODS:** The evaluation of the health-economic impact was performed using a cost-of-illness analysis. We have used relative risk (RR) estimates from the literature to evaluate the effects of physical inactivity on the above mentioned diseases. Afterwards, the population-attributable fraction (PAF) for each illness to estimate the risk factor on the given disease was computed. Direct medical costs were considered from the health care system perspective. Costs were calculated bottom-up for the year 2012. We have calculated effects of a reduction in inactivity level by 10,000 physical inactive people in Burgenland. **RESULTS:** Results show that physical inactivity causes 27,542 cases of illness as well as 50 premature deaths in population of Burgenland, leading to a total cost-of-illness of 58.9 million Euro (6.3% of total health expenditure). Reducing the inactive group by 10,000 people, 2,221 cases of illness and cases of death will be reduced by four. Moreover the cost of illness could be reduced by 6.40 million Euro each year of which 5.03 million Euro are directly related to diminish physical inactivity. **CONCLUSIONS:** Physical inactivity represents an important public health burden in Austria. Even modest reductions in inactivity levels could result in substantial cost savings.

PHP73

THE IMPACT OF THE BLIND BID PROCEDURE IN HUNGARY

Komáromi T, Gyáni G, Andriska P
Healthware Consulting Ltd., Budapest, Hungary

OBJECTIVES: The modified reference price procedure, which was introduced in October 2011, caused significant savings in the Health Insurance Fund's Pharmaceutical budget. In our analysis we aim to give an insight into the effects of this measure on the drug consumption and on the sales of the pharmaceutical companies as well as measure the generated savings and losses on the side of the industry. In the course of the analysis we examine the change in the demand of the related drugs and in their composition, from the aspect of industry, financer and patients. We explore which are the price strategies of the companies and are they managed to increase the sales or decrease the losses with them. The proper knowledge of the effects of blind bid will support the decision making of the concerned market actors as well as the further rulemaking. **METHODS:** A retrospective data analysis was conducted on the official NHIFA (national Health Insurance Fund) monthly data-base between October 2011 and March 2013. **RESULTS:** In the blind bid procedure 90 companies, 169 active substances and more than 2100 product were involved. The relevant products market share is almost 30% of the total Hungarian Pharmaceutical budget, which is almost 1 billion € annually. As we found, the blind bid process has a significant saving effect for the financer. The cumulative savings on the 18 months period reached 113 millions € for the financer. It means 24% reduction on the average reimbursement level, whilst the average manufacturer price decreased 16% and a minimal 3% savings was realized on the co-payment side. **CONCLUSIONS:** Huge savings were realized with this new reference pricing method, where the financer realized the most of the savings.

PHP74

COST-EFFECTIVENESS OF AN INTERFACE GERIATRIC INTERVENTION: ACUTE MEDICAL UNIT COMPREHENSIVE GERIATRIC ASSESSMENT INTERVENTION STUDY (AMIGOS)

Tanajewski L[1], Franklin M[1], Gkountouras G[1], Berdunov V[1], Edmans J[1], Conroy S[2], Bradshaw L[1], Gladman J[1], Elliott RA[1]
[1]*University of Nottingham, Nottingham, UK,* [2]*University of Leicester, Leicester, UK*

OBJECTIVES: Older people (>70) with high risk of future health problems discharged from acute medical units (AMU) within 72 hours, in Nottingham and Leicester, England, were included in an RCT of an interface geriatric intervention (IGI) comprising geriatrician assessment and further specialist management. The objective was to assess cost-effectiveness of IGI compared to standard care. **METHODS:** In the trial-based economic evaluation, 417 participants (IGI: 205) were analysed at 90-day follow-up. Health (inpatient, day-case, outpatient), social care and IGI resource-use data were collected and combined with unit costs to estimate total cost. Quality-adjusted life years (QALY), based on EQ-5D valuations at baseline and follow-up, were obtained for 254 (60.9%) participants. Multiple imputation by chained equations was applied to deal with missing QALY values. Cost and QALYs were adjusted by baseline characteristics using regression methods, and probabilistic incremental cost-effectiveness ratios (ICER) were constructed. Sub-group analysis was carried

out for patients who had not been hospitalized within six months prior to index AMU admission. **RESULTS:** In the whole group, total cost for IGI was higher (£207.4, 95%CI: £94.8-£331.2) with no QALY gain (-0.001, 95%CI: -0.009-0.007); IGI was dominated by standard care (3%-probability of ICER<£30,000/QALY). In the sub-group of 209 patients (IGI: 106) without a hospital stay in the previous six months, total cost for IGI was lower (-£274.2, 95%CI: -£480.4--£46.3) with non-significant QALY gain (0.001, 95%CI: -0.011-0.013), and 49%-probability of IGI being dominant (90%-probability of ICER≤£30,000/QALY). In the whole group (sub-group), inpatient cost was lower by £212 (£778), and social care cost was higher (lower) by £220 (£141), comparing IGI to standard care. **CONCLUSIONS:** The IGI for high-risk older people discharged from AMU was not cost-effective for all patients, but was cost-effective in patients without a hospital stay in the previous six months. This suggests targeting the intervention is required.

PHP75

ANALYSIS OF TOTAL TREATMENT COSTS OF ORGANOPHOSPHOROUS POISONING IN A TERTIARY CARE HOSPITAL

Pariti B[1], Thunga G[2], MK U[2], Nikhil B[2]
[1]*Manipal University, Manipal, India,* [2]*Manipal College of Pharmaceutical Sciences, Manipal University, Manipal, India*

OBJECTIVES: . To establish the correlation of log mean cost with respect to APACHE II score, pre-hospitalization and length of hospital stay, and to determine the intra-group variance of log mean treatment costs in different parameters. **METHODS:** Categorical data was presented as frequencies with percentages and was analyzed by Chi-square test, log regression and Pearson correlation. A logarithmic transformation was used for total cost to convert into normal distribution. Geometric mean and Geometric SD was used to summarize total cost. One way ANOVA was used to compare the mean of log (total cost) across various categorical variables. Multiple linear regression was used to find the factors associated with total cost of hospitalization of OPP. Correlations was used for measuring the strength of linear relationship between total cost and APACHE II score. **RESULTS:** A significant variance in log mean treatment costs was observed in different parameters like pseudocholinesterase levels, type of poison consumed, anticholinergics administered and incidence of intermediate syndrome. A high mean cost was observed in patients with a pseudocholinesterase level of less than 2000 and those who consumed WHO class Ib pesticide. A cost difference of INR 25,000 was noted in patients who developed intermediate syndrome. The APACHE II Score, pre-hospitalization period and length of hospital stay had significant correlation with log cost. Among the variables, length of hospitalization had strong correlation with log cost ($r=0.673$, $p<0.001$). For every one-unit increase in pre-hospitalization period, APACHE II score and length of hospital stay, the log cost increases by INR 1.01, 1.27 and 1.5 respectively. **CONCLUSIONS:** High costs of treatment coupled with a proportionately great loss of man-days, make OPP an extremely important area for pharmacoeconomic evaluation and for framing appropriate policies for remedial measures. Hence studies evaluating treatment regimens with respect to costs and outcome are highly desirable.

PHP76

COST OF INTENSIVE CARE STAY IN TURKEY: IN THE VIEW OF PAYER AND HEALTH CARE PROVIDER

Daylan Kockaya P[1], Kavuncubasi S[2], Kockaya G[3]
[1]*Zirve University, Gaziantep, Turkey,* [2]*Baskent University, Ankara, Turkey,* [3]*Health Economics and Policy Association, Ankara, Turkey*

OBJECTIVES: The demand for intensive care units has risen in the recent years as the increasing aged population in all countries and in Turkey. The aim of the study is to calculate the average cost of intensive care stay(ICS) and to compare the cost with the reimbursement amount depending on a public hospital data in Turkey. **METHODS:** The records of ICSed patients from a public hospital in Ankara were evaluated retrospectively between November 2011 and January 2012. The hospital cost and reimbursement amount were calculated depending on the data. **RESULTS:** A total of 104 patients stayed in the given time line. Four patients excluded due to the missing data in files. The average cost of pharmaceuticals, medical devices, laboratory, health care and total cost per patient were calculated as 1209.16 TL± 492.46, 137.48 TL± 41.08, 422.35 TL± 108.70, 873.10 TL± 247.82 and 2992.43 TL± 994.06, respectively. The average reimbursement amount per patient was calculated as 2846.59 TL± 842.60. The average profit or deficit of the hospital were calculated for the 1st,2nd,3rd,4th, 5th,6th, 7th,8th,9-15th,16-29th and 30-51st days as 34.90 TL± 49.69, -75.48 TL± 671.39, -23.25 TL± 315.41, 382.80 TL± 368.58, 283.09 TL± 628.57, -266.13 TL± 612.81, 312.45 TL± 416.11, 118.99 TL± 729.00, -916.58 TL± 1430.94, -1500.57 TL± 3217.87 and -2054.55 TL± 3204.79, respectively. The profit and deficit trend line was calculated with the number of ICS days as "y = -51,889x2 + 446,98x - 631,73" (y=profit or deficit, x=hospital stay days). **CONCLUSIONS:** It was concluded that the average daily cost of ICS increased depending on the length of stay. The patients in critical state who needed more ICS days may have caused this. On the other hand, it was observed that the fixed daily reimbursement amount is inadequate for prolonged ICS. As a result this leads to the deficits of the hospitals in the prolonged ICS.

PHP77

REVIEW OF THE USE OF RESOURCE USE INSTRUMENTS BASED ON PATIENT RECALL IN RELATION TO OTHER METHODS OF COST ESTIMATION

Ridyard C, Linck P, Hughes DA
Bangor University, Bangor, UK

OBJECTIVES: Instruments for resource use measurement based on patient-recall (e.g. questionnaires, logs and diaries) are used extensively in trial-based economic evaluations; sometimes on their own and sometimes alongside other methods for estimating costs. The aims were to assess: 1) how resource use instruments are used in practice; 2) which items of resource use are based most frequently on patient-recall; and 3) how estimates compare if more than one method of data collection is used for the same resource items. **METHODS:** Articles citing 38 trial-based resource use instruments catalogued in the MRC-funded Database of Instruments for Resource Use Measurement (www.DIRUM.org) were identified using Google Scholar, ISI Web of Science and Scopus, and screened according to resource use measure usage. Data were extracted on: the method of administration, resources measured, rates of return and the nature of the other methods of resource use measurement. **RESULTS:** A total of 146/1503 citations met the screening criteria. Nearly all (143/146) used resource use instruments derived from Beecham and Knapp's Client Service Receipt Inventory. Most instruments relied on patient- or proxy-recall (126/146) generally administered during researcher interviews. Primary and secondary care usage were the most widely asked items (136/146) with 75 using no supplementary supporting data such as from hospital notes. Twelve studies compared one or more method of data collection for the same resource items with 8 indicating good agreement between medical records and patient/carer recall, 1 indicating the greater reliability of case notes and 3 were not evaluable. **CONCLUSIONS:** Resource use instruments based on patient recall are valuable complements to other methods and essential for certain items (e.g. out of pocket costs, non-medical costs). However, there remains inappropriate use in circumstances where more objective measures are available.

PHP78

BEYOND PATENT EXPIRY: DEVELOPMENT OF A MODEL FOR PRICING GENERIC DRUGS IN SOUTH AFRICA

Keele MG[1], Butkow N[1], Venter D[2]
[1]*University of the Witwatersrand, Johannesburg, South Africa,* [2]*Nelson Mandela Metropolitan University, Port Elizabeth, South Africa*

OBJECTIVES: Generic drugs provide a safe, effective and affordable alternative to medicines whose patent protection has expired. Generics have to meet the same quality standards as the innovator drugs; the only substantive difference is the price. Generic manufacturers compete 'on a knife-edge' of narrow margins of profitability. The generic pharmaceutical industry is risky and complex, success depends on the number of other generic drug manufacturers on the market, which affects the profit margins and volumes that each company could realize. The objective of the current study was to develop a model that explains the effect of generic drug entry on price competition after patent expiration in the pharmaceutical industry. **METHODS:** Innovators and their generics selected from all the chemical entities whose patents expired from 1999 through 2009. Data were obtained from IMS Health (Market Segmentation Report) and National Department of Health (Database of Medicine Prices) for the patents' expiration dates, prices, sales volume, therapeutic group, schedule, and dosage forms of drugs in the sample. **RESULTS:** A year after patent expiration, the innovators' products retained an average of 59% of the market share; the generic-to-innovator price ratio was at an average of 65%. By the end of the first year after patent expiration, an average of 2 generics was registered per innovators' product. **CONCLUSIONS:** Generic entry is commercially driven; it is influenced by the market size of the innovator product prior to the expiry of the patent protection. Generic penetration is slow, only intensifies after 5 years since the loss of patent protection. The price erosion of the innovator product is strongly influenced by generic penetration. The cost of drugs in South Africa is not coming down fast enough.

PHP79

HOSPITAL RESOURCE USE IN CHRONIC DISEASE COMBINATIONS: IS IT ENOUGH TO JUST ADD THEM UP?

Seah JZ, Harris A, Lorgelly PK
Monash University, Victoria, Australia

OBJECTIVES: Economic evaluations often ignore the possibility of non-linear health care costs when chronic diseases occur in combination. This paper aims to quantify the comparative effect of single and multiple chronic diseases on hospital resource use. **METHODS:** Using records of all admissions to public hospitals in the state of Victoria, Australia in 2010-2011 we estimate multiple regression models of hospital length of stay (and total annual discharges) for combinations of 11 chronic diseases. For length of stay we run separate models for same-day and overnight stays, adjusting for observed and unobserved characteristics of patients. **RESULTS:** A higher chronic disease count decreases the odds of a same-day hospitalization (day-case) exponentially while some disease combinations increased these odds. Having ischemic heart disease (IHD) & dementia doubled the odds of a day-case compared to a patient with dementia only. Among overnight stays, having a mental disease had the highest single disease effect on length of stay (LOS) – increasing LOS by 3-4 days. Some disease combinations had non-additive effects (i.e. their combined effect was greater/less than the sum of their single disease effects) on LOS while others were additive. The interaction effect in a depression-renal failure combination added 3 days to its single disease effects, while in cancer-osteoporosis it was -2 days. Disease combinations that produced a positive interaction effect were usually unrelated diseases. We found disease count to be positively correlated with number of admissions. Having a combination of diseases was generally found to have a less-than-additive effect on the number of admissions. **CONCLUSIONS:** Patients with chronic diseases have a resource use pattern that includes longer lengths of stays and more admissions. Combinations of unrelated diseases are particularly correlated with longer lengths of stay therefore it is the disease and combination type that is associated with higher lengths of stay and admitted episodes.

PHP80

PHARMACEUTICAL EXPENDITURE, CLINICAL OUTCOMES AND EXPENDITURES ON OTHER HEALTH SERVICES

Siskou O[1], Galanis P[1], Tsavalias K[1], Kalogeropoulou M[1], Kaitelidou D[1], Pasaloglou S[2], Schneider M[3], Liaropoulos L[1]
[1]*National and Kapodistrian University of Athens, Athens, Greece,* [2]*Novartis Hellas, Metamorfosi, Greece,* [3]BASYS, *Augsburg, Germany*

OBJECTIVES: The study examined: a) the relationship between pharma care and health outcomes, b) the influence of expenditure on drugs to the level of expenditure on other forms of care c) the impact of providers on the level of pharma expenditure. **METHODS:** We conducted linear multiple regression analysis with pharma expenditure as independent variable, and dependent variables such as clinical indicators and expenditure of other categories. Also, we conducted analyses with number of physicians and pharmacists as independent variables and pharma expenditure as dependent. Analyses were conducted for all Eurozone countries (2003-2011). All tests of statistical significance were two-tailed, and p-values of less than 0.05 were considered significant. **RESULTS:** Increased total per capita outpatient pharma expenditure (in US $ PPP's) by 10% was related to increase in life expectancy: a) at birth for men by 0.41% (p=0.07), b) for men 65+ by 2.35% (p=0.004), and c) at birth for women by 0.37% (p=0.03). Moreover, increased public pharma expenditure as a % of total current public expenditure by 10% was related to a reduction of public current health expenditure (as a % of GDP) by 2.8% (p<0.001). A 10% increase of total pharma expenditure as a % of total current health expenditure as a % of GDP, was related to a reduction of total current health expenditure as a % of GDP by 3.3% (p=0.045). Finally, an increase in the number of pharmacists/100,000 population by 10% was related to an increase of total per capita pharmaceutical expenditure by 0.93% (p=0.07). **CONCLUSIONS:** Overall drug expenditure is positively related to population health and negatively connected with the level of total health expenditure, a finding that should influence political decisions on public insurance coverage. The accuracy of our results will be further enhanced by similar research in the future, when longer time series data are available.

PHP81

BIOSIMILAR AND ORIGINATOR BIOLOGIC PRICING DYNAMICS IN EMERGING MARKETS

Lockwood C[1], Reinaud F[2], Marinoni G[1], Ando G[1]
[1]*IHS, London, UK,* [2]*IHS, Paris, France*

OBJECTIVES: To characterise pricing dynamics between originator biologics and biosimilar products in a number of emerging markets, namely Brazil, China, India, Mexico, Russia, South Korea and Turkey. **METHODS:** Prices for the products concerned were based on calculations of ex-manufacturing prices. Prices at time of biosimilar launch and from the most recent time point available were selected for the respective biosimilar and originator products, and converted to a price-per-unit basis. Average prices were then calculated per brand name, where more than one strength or formulation of a product existed. In addition, primary and secondary research were utilised to obtain further manufacturer and/or retail-level price data where possible. **RESULTS:** At the time of launch, biosimilar products in emerging markets exhibit a manufacturer-level price representing an approximately 30% discount, on average, over that of the originator biologic. There are a number of exceptions, with evidence that some biosimilar products are priced at a mere 40% of the originator at time of launch. The more typical 30% differential appears to narrow significantly with time, as evidenced across a number of markets that have seen activity in the first generation of biosimilar products (e.g., erythropoietins, granulocyte colony-stimulating factor, etc). **CONCLUSIONS:** At time of launch, the pricing dynamic between originator biologics and their respective biosimilars in emerging markets appears to mimic the scenario which has thus far been observed in Europe. However, there are exceptions, with some products associated with significantly larger discounts at time of launch in certain emerging markets. Over time, there tends to be dramatic price erosion for both originators and biosimilars as a function of the original originator price. This erosion is driven by competitive entry into the market of subsequent biosimilars, coupled with widespread use of tendering in the public markets.

PHP82

EVALUATION OF THE POLICIES IMPLEMENTED TO MONITOR PRESCRIPTION AND REDUCE PHARMACEUTICAL EXPENDITURE AT THE UNIVERSITY GENERAL HOSPITAL OF PATRAS, GREECE

Tsiata K[1], Letsios A[1], Kousoulakou H[2], Geitona M[2]
[1]*University General Hospital of Patra, Patra, Greece,* [2]*University of Peloponnese, Corinth, Greece*

OBJECTIVES: The University Hospital of Patras (GPNP) has implemented a series of prescription monitoring measures that aim at reducing the hospital's pharmaceutical expenditure. The objective of this study was to evaluate the results of those policies. **METHODS:** Analysis of the 2011 and 2012 economic data of the GPNP on purchase and consumption (in terms of quantity and value) of pharmaceutical products, both in the inpatient and outpatient settings, was conducted. Data on the total number of outpatient prescriptions and high-cost drugs were also analyzed. The subgroup of high-cost drugs was further investigated, by performing a breakdown analysis of the expenditure of high-cost drugs by disease area. **RESULTS:** The cost containment measures implemented by the GPNP (which include, among others, the development of guidelines on rationalizing the use of pharmaceutical products, and a hospital formulary, which took into consideration both clinical and cost data), have resulted in a reduction of the total pharmaceutical consumption by 11.5% in 2012 (€29.4 million) compared to 2011(€33.2 million). Although total outpatient prescriptions and the related quantity of pharmaceutical products prescribed were increased by 8.1% and 10.5%, respectively, the pharmaceutical cost of outpatient care was reduced by almost 28%, indicating a significant increase in the prescription of lower cost pharmaceuticals. Indeed, the high-cost hospital medicines prescribed to outpatients was reduced by almost 21% in 2012. In the inpatient setting, the total expenditure on high-cost hospital medicines was reduced by 12.9%. The expenditure on cytostatic drugs, which accounts for more than 70% of the total expenditure for high-cost drugs in the inpatient setting, was reduced by almost 10%, while the number of patients hospitalized was reduced by only 1.6%. **CONCLUSIONS:** The policies implemented by the GPNP were successful in reallocating pharmaceutical budget towards more innovative medicines in order to ensure patients' access to new therapies.

PHP83

COST-OUTCOME DESCRIPTION OF CLINICAL PHARMACIST INTERVENTIONS IN A UNIVERSITY TEACHING HOSPITAL

Gallagher J[1], Mc Carthy S[1], Lynch D[2], Woods N[1], Byrne S[1]
[1]*University College Cork, Cork, Ireland,* [2]*Cork University Hospital, Cork, Ireland*

OBJECTIVES: Clinical pharmacist interventions are actions which aim to improve a patient's pharmaceutical care. The primary objective of this study is to estimate the cost savings achieved by clinical pharmacists through the prevention of adverse drug events (ADE) in a hospital setting. Previous studies have estimated the benefit of these interventions over shorter periods of time and in specific hospital areas. This study will encompass a longer time period and a complete hospital system. **METHODS:** This study was a retrospective analysis of a database detailing pharmacist interventions on patient therapies at Cork University Hospital. Period examined was from January 2012 to December 2012 inclusive. Cost savings were calculated based on the probability that an ADE would have occurred in the absence of the proposed pharmacist intervention (Average cost of ADE = €970). Input costs were calculated based on the time required for pharmacists (n = 17) to enact interventions. One way sensitivity analysis incorporated published ranges for intervention time, pharmacist salary and probability an ADE would have occurred. Alternative costs for an ADE were also included in analysis. Cost savings are from the perspective of the health care institution. Costs are presented in 2012 € values. **RESULTS:** A total of 4,247 interventions were documented. Base case analysis resulted in net cost benefit of €590,000 per annum and a cost benefit ratio of 10.4:1. Cost savings of €650,000 were generated and the cost of providing the service was estimated at €60,000. Sensitivity analysis resulted in cost benefit ratio varying from 5.2 – 64.8 (minimum – maximum). The most prevalent pharmacist intervention was the identification of drug omissions (n=1820, 42.9%). **CONCLUSIONS:** Cost benefit ratio remained positive in all situations examined. This study has added to the body of evidence that clinical pharmacist interventions are cost effective over extended time periods and entire hospital settings.

PHP84

DIFFERENTIAL DISCOUTING: CAPTURING THE VALUE OF LIVING LONGER AND BETTER

Ralston S, Floyd D, Ratcliffe M
PHMR Associates, London, UK

OBJECTIVES: Discounting future cost and health benefits is standard in pharmacoeconomic evaluations. Using different discount rates for costs and benefits remains controversial, although there is a case for lowering the health effect discount rate as the general population benefits from better health over a longer period of time. The implications of differential discounting on the likely duration of health benefits was assessed. **METHODS:** An extensive literature review sourced current discount rates for European countries, including the justification for those rates where available. Using a specific example (mifamurtide [Mepact, Takeda] for the treatment of osteosarcoma) the time to loss of health benefits for equal and differential discount rates using a UK reference case was assessed. **RESULTS:** Like most of Europe, the UK National Institute for Clinical Excellence (NICE) has been using a discount rate of 3.5% for both costs and health effects. However, it has recently adopted a differential reference case where health effects are sustained over a period of 30 years or more: 1.5% for health effects and 3.5% for costs. Taking the example of mifamurtide and using the original rate of 3.5% for health effects, all benefit would be discounted away after just 22 years. By adopting the lower rate, the effects will not be discounted away until 49 years after treatment. In this case, the discount rates used to for mifamurtide are particularly sensitive because all costs are borne in the first year, yet benefits of treatment can be over a patient's lifetime. **CONCLUSIONS:** Adopting differential discounting rates reflects the potential long-term benefits of new health care technologies. However, most European countries, with the exceptions of Belgium, The Netherlands and now the UK in specific circumstances, continue to use the same discount rate for costs and health effects, thereby potentially undervaluing the long-term benefits current and new treatments.

PHP85

ADVANCED BUDGET NOTIFICATION (ABN): IS THERE A WIN:WIN FOR MANUFACTURERS AND PAYERS GIVEN THE CURRENT AUSTERITY MEASURES ACROSS THE EU

Mallinson M
Access Partnership, London, UK

OBJECTIVES: The mature health economies across the EU are severely fiscally challenged, and yet manufacturers of innovative medicines are where the legislation permits expected to give a notifiable 'warning' of expected budget impact. A survey was undertaken amongst payers to ascertain their real world expectations in terms of advanced warning and how realistically a collaborative approach to access could be achieved. **METHODS:** Manufacturers of innovative technologies are where legislation permits advised to supply payers and budget holders with information that will assist the aforesaid bodies with sufficient information to decide on the managed entry of that technology; historically manufacturers are in two minds about the value of this process. A study was undertaken with payers as to their perceived interest and interaction with manufacturers who willingly entered into ABN. Payers at a regional and national level were interviewed to gauge their opinions. **RESULTS:** There appears to be a dichotomy of opinion amongst payers as to the value of the legislation; 'damned if you do, damned if you don't', however it clearly is in the interest of both parties to work together. Payers value the contact and information provision from Manufacturers, Manufactures seek to garner the approval of payers. **CONCLUSIONS:** The EU is in the worst economic depression since the 1930's, affordability is the key watchword. New technologies need to continue to be presented to payers in a manner which allows them to plan for fiscal pressure and service redesign.

PHP87

PHARMACOECONOMIC ANALYSIS OF IOVERSOL VERSUS IOHEXOL FOR DIAGNOSTIC PROCEDURES

Ivakhnenko O[1], Khachatryan G[1], Avxentyeva M[2], Rebrova O[3], Müller-York A[4]
[1]*Autonomous non-profit organization "National Centre for Health Technology Assessment", Moscow, Russia,* [2]*The Russian Presidential Academy of National Economy and Public Administration, Moscow, Russia,* [3]*Pirogov Russian National Research Medical University, Moscow, Russia,* [4]*Mallinckrodt Deutschland GmbH, Neustadt an der Donau, Germany*

Contrast-induced nephropathy (CIN) is a clinically significant and costly complication related to the use of iodine-based contrast media (CM). The hypothesis regarding the advantages of isoosmolar CM compared to low-osmolar CM was not confirmed in recent meta-analyses; still, there may be safety differences between individual CM. **OBJECTIVES:** To perform a pharmacoeconomic comparison of the CM ioversol and iohexol used for x-ray procedures in Russia. **METHODS:** We calculated the costs for using ioversol and iohexol taking into account the risk of the occurrence of CIN and CIN-associated complications. Data for the model were extracted from published clinical trials and reviews. We performed an indirect comparison of both CM to calculate the relative risk (RR) of CIN (via the CM iodixanol as a mutual control). This RR value was used in the model to simulate the impact of potential safety differences between both CM on the costs. Direct medical costs were calculated based on the Russian health care system setting. Related costs for CM and for CIN-associated complications (e.g. cardiovascular complications, respiratory distress syndrome and hemodialysis for acute kidney injury) were also taken into account. Cost calculations were performed separately for patients with low, medium and high risk for CIN. One-way sensitivity analysis was performed. **RESULTS:** RR of CIN was 0.26 (95% confidence interval 0.12-0.58) for ioversol vs iohexol in the indirect comparison. Direct medical costs were higher for iohexol than for ioversol due to the slightly higher rate of CIN, thus, CIN-associated complications: net benefits were 469.16; 752.88 and 3313.13 rubles (~11.03; 17.70; 77.91 Euros) per patient with low, medium and high risk of CIN correspondingly. Still, results were sensitive to the price of both CM. **CONCLUSIONS:** In the Russian health care setting, the use of ioversol seems to be more cost efficient than iohexol due to slightly favorable renal safety.

PHP88

ECONOMIC EVALUATION OF INTRAVENOUS IODINATED CONTRAST MEDIA IN ITALY

Iannazzo S[1], Vandekerckhove S[2], De Francesco M[1], Nayak A[3], Morana G[4], Valentino M[5], Ronco C[3]
[1]*IMS Health, Milan, Italy,* [2]*IMS Health HEOR, Vilvoorde, Belgium,* [3]*San Bortolo Hospital, Vicenza, Italy,* [4]*Ca' Foncello Hospital, Treviso, Italy,* [5]*S. Antonio Abate Hospital, Tolmezzo, Italy*

OBJECTIVES: Contrast-induced acute kidney injury (CI-AKI) is defined as a deterioration in renal function after administration of radiologic iodinated contrast media (CM). Iodixanol, showed a lower CI-AKI incidence than low-osmolar contract media (LOCM). A cost-effectiveness analysis was performed comparing iodixanol and LOCM in intravenous (IV) setting in Italy. **METHODS:** A Markov model was developed. Patients moved across four health states, CI-AKI free, CI-AKI, myocardial infarction and death. The simulation horizon was lifetime with one-month cycles. Costs and outcomes were discounted at 3.5% rate. CI-AKI incidence was considered from published literature across different definitions. Cost-effectiveness of iodixanol was assessed in terms of incremental cost per life year gained. Net monetary benefit (NMB) was also calculated. Both deterministic and probabilistic sensitivity analysis were performed. **RESULTS:** Base-case results showed an average survival increase of 0.51 LYs and a saving of €7.25 for iodixanol vs. LOCM. The cost-effectiveness of iodixanol was confirmed when other scenarios were explored, such as varying CI-AKI definition, sub-populations with specified risk factors, CM hospital bids prices and inclusion of adverse drug reactions of allergic nature. A NMB ranging between €6,007.25 and €30,007.25 was calculated. **CONCLUSIONS:** base-case results are showing that IV iodixanol is cost-effective compared to LOCM in the Italian clinical setting of hospital CT radiology practice. However, some caution is due, mainly linked to inherent limitations of the modelling technique and to the lack of agreement on CI-AKI incidence data in the clinical literature.

PHP89

A DETERMINISTIC MODEL TO EVALUATE THE COSTS FOR SURGICAL PROCEDURES: THE WIN-WIN MODEL

Velleca M[1], Mauro E[1], Belarbi S[2], Perrone F[1]
[1]*Johnson & Johnson Medical, Pomezia (RM), Italy,* [2]*Ethicon Surgical Care, a Johnson & Johnson company, Issy les Moulineaux, France*

OBJECTIVES: The Italian National Health Service (*Servizio Sanitario Nazionale-SSN*)is financed at hospital level by DRG (Diagnosis Related Group): the classification is defined at national level and the tariffs at regional level. Each region could define different tariffs for different types of hospital, choosing different criteria to identify them. The aim of this study is to analyze the incidence of the different types of costs for different surgical procedures and to evaluate the impact of the case mix on the total hospital costs. **METHODS:** We developed an excel model, the Win-Win, in order to analyze the incidence of different types of costs using the hospital perspective: length of stay, operating room time, personnel, materials. We identified 8 surgical procedures, based on the International Classification of Disease 9-Clinical Modification, and for each one, we collected all the data from a survey based on different clinical practices in different types of hospitals. The model has been set up with the possibility to customize each type of data, consumptions and unit costs. **RESULTS:** We calculated the average (AVG) and the confidence interval (IC) for the incidence of each type of cost among the different surgical procedures. For the length of stay we observed the highest average incidence (35,1%; IC95% 24,4-39,9), followed by the cost of materials with an average of 34,9% (IC95% 30,1-43,1), the operating room cost (avg 20,6%; IC95% 18,8-22,8), and the personnel (avg 9,4%; IC95% 7,2-11,1). **CONCLUSIONS:** Through the Win-Win Model it is possible to analyze the costs of each type of surgical procedure and evaluate the economic impact of the case mix of the hospital activity. As a consequence, it could be a useful model to increase the awareness of the economic impact and to allow a more informed management at hospital and regional level.

PHP90

COST ANALYSIS OF AN INTENSIVE CARE UNIT

Putignano D[1], Di Maio FF[1], Orlando V[1], Cammarota S[1], De Nicola A[2], Menditto E[1]
[1]*CIRFF-Center of Pharmacoeconomics, Naples, Italy,* [2]*Presidio Ospedaliero San Leonardo - Castellammare di Stabia, Castellammare di Stabia, Italy*

OBJECTIVES: The aim of our study is to analyze the costs incurred by hospitalized patients in 2010, in the intensive care unit (ICU) of San Leonardo Hospital (Southern-Italy). **METHODS:** A retrospective cost analysis was performed on patients with a length of stay longer than 24 hours. Direct medical costs were estimated (hospitalization, surgical procedures, devices). The costs of hospitalizations and surgical procedures were calculated based on the 24.0 version of the tariff system DRG (Diagnosis Related Group). The data on the costs of the devices were provided by the management of the hospital pharmacy. To evaluate the burden of the diagnostic groups two indicators were used: cost per surviving patient (total resources used / total survivors) and money loss per patient (total resources used for dead patients / total patients) [Rossi et al. Intensive Care Med. 2006]. **RESULTS:** A total of 201 patients hospitalized in the ICU in 2010 were selected and analyzed depending on their diagnostic group. Hospitalized patients who had a hospital stay longer than or equal to 24 hours, were 95% of the sample. Most frequent diagnostic groups have been: edema (16.4%), left heart failure (13.9%) and COPD (9.0%). There is a wide variation between the average costs per patient probably due to the difference in the duration of hospitalization (from a minimum of € 2,777 in stroke, to a maximum of 7,227 euros in nephro-urological disease). Intracranial bleeding is the disease causing the highest costs per dead or survived patient. The nephro-urological and neurological diseases are characterized by the lowest costs, for dead and survived patients, indicating a better efficiency. **CONCLUSIONS:** The results are a starting point for further investigations aimed at the exploitation of resources absorbed by ICU opposed to the need to provide patients with the best possible health care.

PHP91

HEALTH ECONOMIC EVIDENCE FOR MEDICAL NUTRITIONS: ARE THESE INTERVENTIONS VALUE FOR MONEY?

Walzer S[1], Droeschel D[2], Nuijten MJC[3], Chevrou-Severac H[4]
[1]*State University Baden-Wuerttemberg, Loerrach, Germany,* [2]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [3]*Ars Accessus Medica, Jisp, The Netherlands,* [4]*Nestlé Health Science, Vevey, Switzerland*

OBJECTIVES: Medical nutrition (MN) targets patients with malnutrition or with specific disease such as Crohn's disease (CD) to support their recovery. Efficacy of MN has been demonstrated in malnutrition, as well as in paediatric CD or gastrointestinal (GI) cancer surgery. However, its health economic evidence is less known. This article summarizes the findings of a systematic literature search on health economics evidence of MN in order to understand what the value for money of MN interventions is. **METHODS:** A systematic literature search was performed to identify publications related to health economics evidence of MN. The result of it was communicated elsewhere. For selected articles, the clinical background, basis of the analysis, health economic design and results were extracted and summarized by relevant disease areas. **RESULTS:** Among the 32 articles found, 11 covered malnutrition, 9 related to GI surgery, 6 studied cow milk allergies (CMA), whereas the remaining focused on various diseases. When targeting malnutrition, MN was accepted as being cost-effective and/or cost-savings from budget impact analyses. In GI surgery, when taking into account the full episode of care, oral and enteral nutrition was assessed as good value-for-money. In CMA, there was a significant health care budget impact of using MN to treat symptoms of this allergy. In the remaining indications, the use of enteral tube feeding was demonstrated as being cost-saving compared to parenteral nutrition. **CONCLUSIONS:** Based on a systematic literature search, MN interventions showed value for money in different health care settings. Although few studies calculated an incremental cost-effectiveness ratio (ICER), those calculated were all below thresholds applied in medical settings. In addition, most of the times MN was more effective and cost saving, thus a dominant option. However, more research is needed to strengthen economic modelling for medical nutrition interventions.

PHP92

IMPACT OF PHARMACOECONOMICS MODELLING ON REIMBURSEMENT OF MEDICINES IN SERBIA

Medic G[1], Baltezarevic D[2], Novakovic T[2]
[1]*Mapi - HEOR & Strategic Market Access, Houten, The Netherlands,* [2]*Pharmacoeconomics Section of the Pharmaceutical Association of Serbia, Belgrade, Serbia and Montenegro*

OBJECTIVES: To assess the impact of recently published (2011) Guidelines for Pharmacoeconomic Evaluations for Serbia and ISPOR Guidelines (2013) on the methods and the conduct of budget impact analysis (BIA) during reimbursement submission. **METHODS:** We investigated how many reimbursement submissions were made with an accompanying BIA to the Health Insurance Fund in Serbia from 2012 till June 2013. **RESULTS:** There were 306 submissions in 2012 and 2013 and none of those had a thorough and complete BIA submitted. There were 65 new drugs (international non-proprietary names (INNs)) added to the Reimbursement list in 2012 and 5 new drugs (INNs) in April 2013. Possible reason for a non-complete BIAs was that it is not an obligatory part of the submission dossier. It is recommended at this moment, but the plan is to make it an obligatory part. BIA simply quantifies the financial consequences of using health-care services, comparing reference with anticipated scenario. Currently there is no template for the BIA, just recommendations how to address time horizon, target population, costing, scenarios and discounting. This could be one of the reasons why most of the submissions had almost complete pharmacoeconomics evaluation. **CONCLUSIONS:** The availability of a template for BIA would increase transparency, the quality of submissions and pro-

mote its use. The audience includes those who develop, submit or use budget impact models and committees who evaluate reimbursement submissions. With a use of Guidelines for Pharmacoeconomic Evaluations, ISPOR Guidelines and proposed BIA template (which will be published in the updated version of the Guidelines for Pharmacoeconomic Evaluations) the quality of submissions to the HIF in Serbia would be raised and the decision time could be reduced.

PHP93

THE SUSTAINABILITY OF IRISH PHARMACEUTICAL EXPENDITURE

Walshe V[1], Kenneally M[2]
[1]*Health Service Executive, Cork, Ireland,* [2]*University College Cork, Cork, Ireland*

OBJECTIVES: The recent economic crisis has threatened the sustainability of many international economies as well as their health care systems. The objective of this paper was to quantify recent cost containment measures used to reduce Irish public pharmaceutical expenditure in light of the ongoing fiscal restrain. **METHODS:** Pharmaceutical expenditure across the EU was briefly examined using the most current OECD data. The main pharmaceutical cost containment measures recently adopted in Ireland were identified under the headings of drug prices, fees/mark-ups and coverage/co-payments with full year 2011 public savings estimated. **RESULTS:** EU pharmaceutical expenditure was estimated at €190 billion in 2010, almost one fifth of all health expenditure. At €528, Ireland spent more on pharmaceuticals than any other European country on a per capita basis and 50% more than the average across EU member states. Governments under pressure to maintain a sustainable national health system and reduce deficits, while still preserving acute care levels, are cutting pharmaceutical expenditure. Many European countries, including Ireland, have increased the use of cost containment measures including a mix of price and volume controls. Collectively, these measures were estimated to have reduced Irish public pharmaceutical expenditure by €380m in 2011. The main cost containment measures used involved addressing; 1) the ex-factory price of drugs including price cuts of up to 40% on off-patent and generic drugs leading to an estimated €200m saving, 2) pharmacy dispensing fees and mark-ups via a new dispensing fee structure and reducing both retail and wholesale mark-ups with a €100m saving, and 3) scheme coverage and patient co-payments including restricting scheme coverage for persons over 70 years and increasing the level of co-payments with savings of €80m. **CONCLUSIONS:** There use of pharmaceutical cost containment measures to decrease health expenditure is a trend that is likely to continue for some time yet.

PHP94

BASIC ATTITUDE TOWARDS HEALTH CARE RESOURCE ALLOCATION DECISION MAKING IN JAPANESE PEOPLE -UTILITARIANISM OR EGALITARIANISM?

Saito S[1], Shiroiwa T[2], Shimozuma K[3], Kodama S[4], Noto S[5], Fukuda T[2]
[1]*Okayama University, Okayama, Japan,* [2]*National Institute of Public Health, Saitama, Japan,* [3]*Ritsumeikan University, Kusatsu, Japan,* [4]*Kyoto University, Kyoto, Japan,* [5]*Niigata University of Health and Welfare, Niigata, Japan*

OBJECTIVES: Japan is now confronting budget constraints and trying to introduce economic evaluation into health care resource allocation. To clarify the basic attitude towards health care resource allocation in Japanese people, a national survey was conducted. **METHODS:** A survey was carried out in a face-to-face manner with random sampling on the 50 municipalities in Japan, adjusting for age and sex, between March and April 2013. The questionnaire consisted of two scenarios; question 1:"Imagine that there are two clinical examinations (A: less expensive with low power; B: more expensive with high power) and choose from the following two options: option 1: all subjects receive examination A and subsequently the death of 1,000 people is prevented; option 2: a half of the subjects is selected by lottery and receives examination B, preventing the death of 1,100 people as a consequence." ; question 2:" Imagine that two types of diseases differing the treatment cost(A: 10 million per patient; B: 2 million per patient), and allocate 100 million yens to these diseases." **RESULTS:** Out of 1143 respondents, 601 chose the option 1 in question 1. In question 2, 217 chose the least utilitarian combination(A;8, B;10), 139 chose 2nd combination(A;6, B;20), 289 chose 3rd one(A;4, B;30), 67 chose 4th one(A;2, B;40), and 379 chose the most utilitarian option(A;0, B;50). The weak correlation was observed in the utilitarian trend and age ($r=0.29$, $p<0.01$). Utilitarian tendency to maximize the health benefit varied among respondents with different educational backgrounds. **CONCLUSIONS:** We investigated the basic attitude towards health care resource allocation in Japanese people by answering to specific scenarios, which revealed fairly extreme utilitarian selection was the most popular. This utilitarian tendency correlated with age and education. It seems that the discussion on the priority setting in health care resource allocation in Japan based on this kind of empirical data become important.

PHP95

RESOURCES SAVED BY THE INTRODUCTION OF DAY SURGERY IN THE GREEK NATIONAL HEALTH SYSTEM

Skroumpelos A[1], Mylona K[1], Naoum P[1], Kyriopoulos D[1], Oikonomidou R[2], Thireos E[3], Pavi E[1]
[1]*National School of Public Health, Athens, Greece,* [2]*Health Center Kallikrateia, Thessaloniki, Greece,* [3]*Greek NHS, Athens, Greece*

OBJECTIVES: Day surgery has been introduced in numerous heath care systems and has been proved able to save resources and promote efficiency and effectiveness. The aim of this study is to estimate the savings that can be realized by the adoption of day surgery by the Greek National Health System. **METHODS:** Surgery procedures were classified according to the type of anesthesia and the post-operative care they require. The procedures identified as suitable for day surgery, according to the above criteria, were matched to the Greek Diagnostics Related Groups (DRGs). The possible savings were calculated on the basis of the marginal cost these procedures impose to hospitals when treating them as inpatient surgeries. Savings were estimated for both the social insurance(SI) and for the government budget due to the fact that SI reimburses the capital production factor of each DRG while the labor cost is funded by the government budget. **RESULTS:** Sixty-two DRGs were identified as suitable for day cases. The majority of these were procedures of the eye (16%), the ear, nose and throat (11.3%), the myoskeletal system (9.7%), the kidney and the urinary tract (9.7%) and the female reproductive system (9.7%). The hospital marginal cost of an increase in the length of stay by one day was estimated at 563.32 euros (95%CI: 541.6–585.1). The annual savings were estimated at 93.7 million euros for the SI and when labor opportunity cost is included the amount saved exceeds 225 million. **CONCLUSIONS:** In light of the economic crisis and the continuously reduced health care budget, the health system should adopt cost-effective intervention in order to preserve a satisfactory level of health services output. As this study concludes, day surgery can save a great amount of resources and according to the international literature can also guarantee patients' safety and satisfaction.

PHP96

CHRONIC PATIENTS' PERCEPTIONS ABOUT GENERIC MEDICINES IN GREECE: FINDINGS FROM A CROSS SECTIONAL SURVEY

Mylona K[1], Skroumpelos A[1], Zavras D[1], Pasaloglou S[2], Pavi E[1], Kyriopoulos J[1]
[1]*National School of Public Health, Athens, Greece,* [2]*Novartis Hellas, Metamorfosi, Greece*

OBJECTIVES: The Greek authorities implemented mandatory generic substitution trying to expand the use of generics, due to reasons of cost-containment. However, Greece lacks a strong, established generics culture. This study aims to investigate chronic patients' perceptions on generics in Greece. **METHODS:** We carried out a cross-sectional study among 1600 patients from four chronic illness groups (HTN, Diabetes, COPD and Alzheimer mild to moderate stage). Logistic regression analysis was used to determine the factors associated with chronic patients' perceptions. **RESULTS:** Of 1600 patients, 1594 responded to the survey (99.6%). Only 67% has used generics in the past. 39.3% considers them safe, 34.3% thinks that the generics have the same quality standards as the originals and 37.3% believes that they have the same treatment outcomes. 63% expressed concern on potential adverse effects from generics. 58% argues that the drug's country of origin affects its safety. Statistical analysis revealed that generics quality has a statistical significant relationship with patient's income (OR 1.24; 95% CI 1.00-1.19), age (OR 0.99; 95% CI 0.98-1.00), gender (OR 0.73; 95% CI 0.57-0.94) and health status (OR 1.00; 95% CI 1.00-1.02) while generics effectiveness was positively related with the patient's income (OR 1.10; 95% CI 1.02-1.20), gender (OR 0.70, 95% CI 0.55-0.90) and health (OR 1.00, 95% CI 1.00-1.01). Women and the elderly are less likely to consider that the generics have the same standards as the originals. **CONCLUSIONS:** Our findings reveal that chronic patients express reservations towards generic medicines which in an extent can probably explain the low generic market share in Greece. Perceptions about generics were found significant related mostly with patients' demographic characteristic. The latter can be considered as useful information as it assists stakeholders to identify on which chronic patients groups should direct campaigns in order to encourage generic drug use as a means to control expenditures and to save resources for innovative drugs.

PHP97

ANALYSIS OF SPANISH GENERIC MEDICINES MARKET: RECOMMENDATIONS TO ENHANCE LONG-TERM SUSTAINABILITY

Dylst P[1], Simoens S[1], Vulto A[2]
[1]*KU Leuven, Leuven, Belgium,* [2]*Erasmus University Medical Center, Hospital Pharmacy, Rotterdam, The Netherlands*

OBJECTIVES: To provide an overview of the Spanish generic medicines retail market and to identify policy measures which impede its development. Finally, recommendations to increase both the efficiency of health care with regards to pharmaceuticals in general and the sustainability of the Spanish generic medicines retail market are put forwards. **METHODS:** A literature review has been carried out to explore the current situation of the Spanish generic medicines market. In addition, a survey has been developed and interviews have been conducted to validate the information obtained from the literature review. **RESULTS:** The Spanish government's focus on the price level of generic medicines in the past has decreased prices of generic medicines drastically. The current reference pricing system (since 2011) has eroded price differentials between originator and generic medicines in more than 90% of the reference groups. Differing policies at the demand-side have resulted in differing generic market shares between the autonomous communities. Policies are needed to increase both the efficiency of the health care system with regards to pharmaceuticals (e.g. electronic prescribing, prescribing by international non-proprietary name, etc.) and the sustainability of the Spanish generic medicines retail market (e.g. creating price difference between originator and generic medicines, accelerating market entrance, building and improving trust for generic medicines in patients and physicians, etc.). **CONCLUSIONS:** The low volume of generic medicines used in Spain combined with the continuous pressure on the price level of generic medicines threatens the sustainability of the generic medicines industry. The reduced price difference between originator and generic medicines tends to be an important barrier for the development of a generic medicines market. The unique experience in the Spanish market shows the importance of demand-side policies on the use of generic medicines.

PHP98

ACCEPTABILITY OF INDIRECT EVIDENCE TO SUPPORT DRUG REIMBURSEMENT IN AUSTRALIA

O'Leary BA, McKenna SJ, Cheng YY, McElroy HJ
Covance Pty Ltd., North Ryde, Australia

OBJECTIVES: When there are no direct head-to-head trials versus an appropriate comparator, indirect comparisons are commonly performed to support a clinical claim and relative pricing. In Australia, Public Summary Documents (PSDs), reporting on the Pharmaceutical Benefits Advisory Committee's (PBAC) decision-making process relating to government reimbursement of medicines, have been published since July 2005. A review of PSDs specific to drugs where the primary claim was based on indirect evidence was undertaken to assess the success of the approach and

identify the PBAC's main concerns relating to the methodology. **METHODS:** All PSDs published between July 2005 and November 2012 where the primary evidence was based on an indirect comparison, either as simple or a mixed treatment comparison, were reviewed. Data relating to comparator, clinical claim, economic analysis, and PBAC concerns were extracted and analysed. **RESULTS:** PSDs relating to 105 products using an indirect comparison as the primary analysis were reviewed. A total of 70 (67%) submissions were recommended; the remaining submissions were rejected (32, 30%) or deferred (3, 3%). An indirect comparison was used to support a non-inferiority claim in 84 (80%) submissions and superiority claim in 21 (20%) submissions. Of those claiming non-inferiority, 60 (71%) submissions were recommended by the PBAC. Of those claiming superiority, the PBAC accepted the clinical claim for 10 (48%) submissions; 6 (29%) received a price premium. The PBAC expressed concerns relating to the indirect comparisons in 56 (53%) PSDs. The key issues related to the exchangeability of the trials as a consequence of different patient populations (25%), quality of trials (24%), and dosing (18%). **CONCLUSIONS:** Clinical comparisons based on indirect evidence are associated with increased uncertainty related to the exchangeability of the trials. The PBAC usually accepts evidence to support a claim of non–inferiority, but rarely the same in regards to superiority.

PHP99

INVESTIGATING THE ECONOMIC IMPACTS OF NEW PUBLIC PHARMACEUTICAL POLICIES IN GREECE

Siskou O[1], Litsa P[2], Georgiadou G[3], Paterakis P[2], Alexopoulou E[2], Argyri S[3], Kaitelidou D[1], Liaropoulos L[1]

[1]*National and Kapodistrian University of Athens, Athens, Greece,* [2]*National Organization for the Provision of Health Care Services, Athens, Greece,* [3]*Ministry of Labour and Social Security, Athens, Greece*

OBJECTIVES: Since 2010, cost contaiment efforts in Greece focused on the reduction of public pharmaceutical expenditure. Changes in cost sharing levels (dementia/alzheimer & epilepsy 0%-10%, osteoporosis & copd: 10-25% etc.), reductions in prices and generics substitution are some of the measures implemented after the second quarter of 2012. The aim of the study is to investigate the economic impact of the above measures for public funds and households. **METHODS:** Data on volume and values for prescribed drugs for each therapeutic category and cost sharing level were derived from EOPYY, the main reimbursement agency (95% of population). The periods compared were January to February 2012 vs. January to February 2013. **RESULTS:** During 2009-2011, public pharmaceutical expenditure in Greece declined by 23%, while for 2009-2014 the decline is projected at 61%.During 2013, 2014 targets are €2.44billion or 1.3% of GDP and 1.935 billion or 1% of GDP. In 2013, only 8.2% of prescribed drugs boxes were provided free of charge, vs 13.6% in 2012 A 25% cost sharing level was imposed to 76.4% of prescribed medicines in 2013 compared to 51.4% in 2012. Consequently, the mean cost-sharing burden for pharmaceuticals in 2013 was estimated at 18% vs 13.1% in 2012. Monthly savings in public expenditures from changes of cost–sharing patterns was estimated at €18-€20 mil. Average price per package declined in 2013 by 23%, from €18 in 2012 to €14 in 2013. Public funds savings, because of consumption of cheaper drugs, were estimated at €55-€60 mil.per month. Major savings for public funds were achieved through cardiovascular diseases drugs **CONCLUSIONS:** The economic results of the measures for third party payers are positive. However, the measures should be reconsidered and examined more closely also taking in mind social effects, in terms of accessibility of users and especially for vulnerable groups who in need of essential pharmaceutical care.

PHP100

CHRONIC PATIENTS RESPONSE TO THE IMPLEMENTATION OF INTERNATIONAL NON-PROPRIETARY NAME (INN) PRESCRIBING IN GREECE

Mylona K[1], Skroumpelos A[1], Zavras D[1], Pasaloglou S[2], Pavi E[1], Kyriopoulos J[1]

[1]*National School of Public Health, Athens, Greece,* [2]*Novartis Hellas, Metamorfosi, Greece*

OBJECTIVES: Under the pressure of fiscal consolidation and pharmaceutical spending decrease in Greece, mandatory generic substitution and compulsory prescription by international non-proprietary name (INN)were recently introduced as reimbursement drivers in Greece. This study aims to investigate the implications of INN implementation regarding chronic patients' choices and their willingness to switch to an alternative pharmaceutical treatment. **METHODS:** A cross-sectional study was carried out among 1600 patients from four chronic disease groups(HTN, Diabetes,COPD and Alzheimer). Logistic regression analysis was used to investigate the factors associated with chronic patients' choices. **RESULTS:** Out of 1600 patients approached, 1594responded to the survey(99.6%). 69% of them stated that they were aware of the new reimbursement system. After the implementation of INN prescribing, only few(11%) have changed their usual drug. 43% were totally certain that an original drug is more effective than a generic, while 67% have never used generics in the past. Most patients(82%) preferred to be prescribed their usual medicine, despite of the extra cost they had to bear. This choice was a co-decision with their physician as 58% of them stated. The average additional amount that they would be willing to spend in order not to switch to another medicine was estimated at €17.8. These results showed a significant statistical correlation with patients' income, educational level and occupation category. **CONCLUSIONS:** According to this study chronic patients are not willing to change their usual drug and switch to a generic, despite the cost this choice imposes. Consequently INN prescribing may decrease public expenditures on pharmaceuticals but it will lead to higher private expenditure. Given that due to economic crisis incomes are continuously decreasing and unemployment rate is rising, the measure might eventually result in lower adherence to medication and consequently in adverse effects on patients health status and future public expenditure for treating possible complications.

PHP101

MARKET ACCESS RISK SCORING: A UNIFIED FRAMEWORK FOR CROSS COUNTRY COMPARISON OF DIVERSE MARKET ACCESS SYSTEMS AND PROCESSES

Mehta P, Ando G

IHS, London, UK

OBJECTIVES: To define and develop risk - and more specifically market access risk– as a framework towards understanding and evaluating stability in market access systems at an individual country level. **METHODS:** We created a combination model of rating quantitative and qualitative variables which affect a country's ability and willingness to pay for new drugs. The criterion for selection of variables is based on relevance, availability and uniformity in our model. We included a total of 42 variables categorised under three verticals - quantitative, qualitative and measures of stability. In order to derive a non-recursive model of ratings, we fit the regression equation for quantitative and qualitative variables as: $Y(1) = \alpha_i + \sum\beta_i{}^*X_i + \varepsilon$ (Equation 1.1) $Y(2) = \alpha_j + \sum\beta_j{}^*X_j + \varepsilon$ (Equation 1.2) where Y(1) and Y(2) are the market access risk ratings for quantitative and qualitative variables, X_i and X_j are vectors of independent quantitative and qualitative variables, and ε is the error term. The final score was derived by taking the geometric mean of the two ratings together with ratings for the measures of stability and is described as below: Total Risk Score = √Y(1)^2* Weight of Y(1) + Y(2)^2*Weight of Y(2) + Risk Rating (Measures of Stability)^2*Weight of (Measures of Stability). **RESULTS:** We decided to aggregate risk scores from different countries into defined clusters – such as BRICS (Brazil, Russia, India, China and South Africa), BRICS-MT (Brazil, Russia, India, China, South Africa, Mexico and Turkey), and Emerging Europe (Czech Republic, Hungary and Poland) - for easier comparison. Their respective risk scores were 4.17, 4.96 and 3.30. **CONCLUSIONS:** Market Access Risk ratings could serve as a starting point for crafting tailored strategies to fully capitalise new opportunities. These ratings could also serve as a benchmark for a country to improve its overall access to pharmaceutical products and improve quality of care.

PHP103

CAN VARIATION IN HOSPITAL PROCEDURE RATES IDENTIFY CANDIDATES FOR HEALTH TECHNOLOGY REASSESSMENT AND DISINVESTMENT?

Hollingworth W, Busby J, Jones H, Sterne J

University of Bristol, Bristol, UK

OBJECTIVES: The process of disinvestment from inefficient health care involves identification and prioritisation of candidates, a health technology reassessment (HTR)of evidence, implementation and monitoring of discontinuance. We evaluate whether variation in procedure rates is a useful tool for identifying potential candidates for HTR and disinvestment. **METHODS:** We used English Hospital Episode Statistics (HES) data to identify inpatient procedures. We selected the 181 most frequent interventional procedures for analysis. For each procedure we used Poisson regression to estimate the variance in procedure rates, adjusting for age, gender and other proxies of clinical need, between Primary Care Trusts in England. We conducted multivariate regression analyses to examine factors that might be associated with high variation in procedure rates (e.g. coding uncertainty, evolving evidence). **RESULTS:** The degree of inter-PCT variation in procedure rates differed vastly from procedure to procedure. Among the five procedures with the highest inter-PCT variance, the procedure rate was more than thirty times higher in the PCT at the ninetieth percentile than the PCT at the tenth percentile. The multivariable analysis provided strong evidence that large increases in procedure use, large decreases in procedure use, the presence of a substitute procedure, and shorter length of stay were all associated with higher inter-PCT variation in procedure rates. **CONCLUSIONS:** The widespread geographic variation in hospital procedure rates in England are not solely due to variance in clinical need and are likely to reflect clinical uncertainty about appropriate procedure use which might be reduced by HTR. The relevant HTR questions often concern the appropriate procedure setting and patient subgroups or the relative value of two alternative procedures rather than the value of a single procedure per se. In some circumstances knowledge of geographic variation might lead to NHS savings and disinvestment or discontinuation of inefficiently used procedures.

PHP104

INFERENCE ON INCREMENTAL COST EFFECTIVENESS THRESHOLDS INFLUENCING NICE DECISIONS: A BAYESIAN ANALYSIS

Cao X[1], Yin DD[2], Mavros P[2]

[1]*Temple University, Philadelphia, NJ, USA,* [2]*Merck & Co., Inc., Whitehouse Station, NJ, USA*

OBJECTIVES: NICE has been issuing health technology guidance based on cost-effectiveness evidence alongside other factors since 2000. Previous studies have shown that technologies with higher incremental cost-effectiveness ratio (ICER) were more likely to be rejected; however none drew direct inference on the ICER threshold(s). Our aim is to directly estimate the ICER threshold(s) as well as the possible range. **METHODS:** Data were abstracted from the technology appraisals (TA) published from 03/2000 to 12/2012. For each decision to 'recommend' or 'reject' a technology we collected: ICER, publish date, disease area, technology type, comparator, reason for rejection if rejected, population and end of life (EOL) criteria (applies only to TAs after January 2009). Cancer related technologies which had been evaluated for EOL criteria were classified as satisfying or not satisfying the criteria. A Bayesian hierarchical model was implemented to estimate the overall threshold as well as the thresholds in different technology categories. **RESULTS:** A total of 270 TA's were evaluated. After excluding those updated or terminated, a total of 187 appraisals with 323 decisions entered the final analysis. Non-informative priors were given to all the model parameters. The unadjusted estimate of the ICER threshold was £46,850 (95% CI: £40,420-£55,570). After adjusting for disease area, cancer related technologies had an estimated threshold of £48,550, (95% CI: £36,550-£63,200) compared to non-cancer related technologies' estimated threshold of £43,430, (95% CI: £35,440-£52,300). Among the 37 technologies evaluated for end of life criteria, the estimated ICER threshold was £56,160, (95% CI: £39,020-£79,970) and £33,100, (95% CI: £19,180-£49,620) for those satisfying and not satisfying the criteria respectively. **CONCLUSIONS:** Preliminary assessment of NICE appraisals and associated ICER indicates that a likely ICER threshold exceeds the £20K-£30K quoted in the NICE Methods Guide. Additional analyses are needed to assess the impact of other factors on the likely variability of ICER thresholds.

PHP105

DRIVERS OF CLINICIAN PRESCRIBING DECISIONS AND THE ECONOMICS OF INFORMATION

Parkinson B, Viney R, Goodall S, Haas M
University of Technology, Sydney, Ultimo, Australia

OBJECTIVES: Policy decision makers require accurate forecasts of the financial implications of funding a new drug. They may also wish to influence adoption to ensure the most cost-effective pattern of care. The seminal theory regarding the adoption of innovations was published by Rogers in 1962; but there are several reasons why health care may be a special case. This paper assesses the applicability of Rogers's theory to the adoption of new drugs, and identifies how it could be extended using economic theories of information. **METHODS:** The empirical literature on drug adoption was reviewed to determine the consistency of findings with Rogers's theory and the economic theories of information. **RESULTS:** Overall 74 empirical studies were reviewed. Clinicians consider a broad range of attributes when adopting a new drug, with their relative importance dependent on the patient and therapeutic area. Consistent with Rogers's theory, interpersonal communication channels are the most important information source, with clinicians, especially GPs, more likely to rely on advice from specialists or pharmaceutical representatives than peer-reviewed publications. Moreover, clinicians are influenced by 'norm' prescribing behaviour. These findings can be further explained using economic theories of information. Obtaining information via peer-reviewed publications requires more effort compared to specialists and pharmaceutical representatives. As patients cannot observe the effort expended, there is a potential for moral hazard in terms of reduced effort and thus an increased reliance on pharmaceutical representatives. Clinical evidence is often uncertain and not always directly applicable to current practice, which can lead to following 'norm' prescribing behaviour and persistent prescribing when combined with risk-aversion. **CONCLUSIONS:** Rogers's theory only partially explains drug adoption. An expanded framework regarding drug adoption is proposed, incorporating agency relationships, moral hazard, uncertainty and risk-aversion.

PHP106

HEALTH ECONOMIC ANALYSES IN MEDICAL NUTRITION: A SYSTEMATIC LITERATURE REVIEW

Walzer S[1], Droeschel D[2], Nuijten MJC[3], Chevrou-Severac H[4]
[1]*State University Baden-Wuerttemberg, Loerrach, Germany,* [2]*Swiss Tropical and Public Health Institute, Basel, Switzerland,* [3]*Ars Accessus Medica, Jisp, The Netherlands,* [4]*Nestlé Health Science, Vevey, Switzerland*

OBJECTIVES: Medical nutrition is dedicated to patients with some nutritional deficiencies or inability to eat normally. When used on top of normal diet in patients or in Crohn's disease, medical nutrition can improve patient's recovery or have a therapeutic effect. Although efficacy studies of medical nutrition exist, it is unclear regarding health economic analysis. This research assessed the current health economic evidence published on medical nutrition. **METHODS:** A systematic literature search was performed using PubMed, the Health Technology Assessment Database, and the NHS Economic Evaluation Database. For selected articles, the clinical background and basis of the analysis, health economic design and results were extracted. Finally for health economic modeling studies, the Drummond checklist was applied to validate their quality; whereas for systematic reviews the AMSTAR checklist was used. **RESULTS:** Fifty-three articles were identified and obtained via PubMed. Among them, 32 articles have been included in a thorough data extraction procedure. Among these articles, only few health economic models have been found: Most of the articles were modelling analyses and economic trials. Overall only 8 health economic models were validated applying the Drummond checklist. Anyhow, most included models have been carried out with a quite high quality standard even though some areas were identified for further improvement. Within the two identified reviews of health economic studies one review achieved the highest quality scores applying the AMSTAR checklist. **CONCLUSIONS:** Reasons for finding only few modeling studies but quite a large number of clinical trials with health economic endpoints might have different reasons. Until recently, health economics wasn't required in reimbursement or coverage decisions for medical nutrition interventions; and there might be specificities of medical nutrition which might not allow easy modeling. Further research is warranted to understand the specifics of medical nutrition and its applicability for health economic modelling.

PHP107

PREFERENCE STRUCTURE OF CLINICIANS IN THE USE OF ELECTRONIC MEDICAL RECORDS; QUANTIFYING THE RELATIVE IMPORTANCE OF BARRIERS AND FACILITATORS OF AN INNOVATION

Struik MHL[1], Koster K[2], Veldwijk J[3], Schuit AJ[4], Lambooij MS[5]
[1]*VU University Amsterdam, Amsterdam, The Netherlands,* [2]*Erasmus University Rotterdam, Rotterdam, The Netherlands,* [3]*National institute for public health and the environment, Bilthoven, The Netherlands,* [4]*National Institute for Public Health and the Environment, Bilthoven, The Netherlands,* [5]*National Institute of Public Health and the Environment, Bilthoven, The Netherlands*

OBJECTIVES: Electronic medical records (EMRs) in hospitals are potentially beneficial for quality and safety of care, but diffuse slowly. Many of the barriers and facilitators of the adoption of EMRs are identified, but the relative importance of these factors is still undetermined. This paper quantifies the relative importance of known barriers and facilitators of EMR, experienced by the users (i.e., nurses and physicians in hospitals). **METHODS:** A d-efficiently designed discrete choice experiment (DCE) was conducted among physicians and nurses. Participants answered ten choice sets containing two scenarios. Each scenario included attributes that were based on previously identified barriers in the literature and the model of the Unified Theory of Acceptance and Use of Technology (UTAUT), namely : data entry hardware, technical support, supervisor attitude, performance feedback, flexibility of interface and decision support. Panel Mixed Multinomial Logit analysis was used to determine the relative importance of the attributes. **RESULTS:** Data on 148 nurses and 150 physicians showed that high flexibility of the interface was the most important factor for the intention to use the EMR. For nurses this attribute was followed by support from supervisor, presence of performance feedback from the EMR and presence o f decisions support. While for physicians this ordering differed since presence of decision support was relatively more important than performance feedback and support from the supervisor. **CONCLUSIONS:** Considering the prominent wish of all the intended users for a flexible interface, currently used EMRs only partially comply with the needs of the users, indicating the need for closer incorporation of user needs during development stages of EMRs. The differences in priorities amongst nurses and physicians show that different users have different needs during the implementation of innovations. Hospital management may use this information to design implementation trajectories to fit the needs of various user groups.

PHP108

EVALUATE THE STATUS OF PHARMACOECONOMIC RESEARCH DEVELOPMENT IN CHINA FROM 2002 TO 2013

Chen CI[1], Huang Y[2]
[1]*Pfizer China, Beijing, China,* [2]*University of Florida, Gainesville, FL, USA*

OBJECTIVES: To describe the current status of Pharmacoeconomic (PE) research in China from Jan 2002 through June 2013. **METHODS:** We conducted a review of pharmacoeconomic studies performed in China during Jan 2002 to June 2013. Using the Wanfang Chinese Database, we identified a total of 1338 articles. Keywords used are 'Pharmacoeconomics' or 'Cost-Effectiveness Analysis' or 'Cost-Benefit Analysis' or 'Cost-Utility Analysis' or 'Cost' or 'Cost Study' or 'Economics Analysis' all following by '(Healthcare and Medical Care)' to exclude animal and other studies. Through a manual review, we excluded another 52 articles that did not align with study objectives. Article types selected are Journals, Academic Essays and Conference Essays. Descriptive analyses were performed to identify current trends, including number of articles by year, type of studies, and type of studies by year. **RESULTS:** A total of 1286 articles were conducted in China from 2002 to 2013. In general, the number of articles per year has been on the rise since 2002and appears to approach a steady state after 2007. Numbers of articles by year are 91 in 2002, 84 in 2003, 107 in 2004, 110 in 2005, 136 in 2006, 132 in 2007, 121 in 2008, 120 in 2009, 130 in 2010, 116 in 2011, 112 in 2012 and 27 during first half of 2013. The most common type of studies found were economic analyses (n=908/1286), of which cost-benefit analyses (n=395) were most commonly conducted. Two other common research types included treatment use (n=48) and application of PE (n=146), namely the role of PE to help determine price and inform health care management decisions. **CONCLUSIONS:** The development of Pharmacoeconomic research in China has been on a steady rise since 2002 with most output focused on economic modeling, followed by application of PE and treatment use.

PHP110

LONG-TERM SURVIVAL AFTER INTENSIVE CARE UNIT DISCHARGE IN THAILAND: A RETROSPECTIVE STUDY

Luangasanatip N[1], Hongsuwan M[1], Lubell Y[1], Limmathurotsakul D[1], Teparrukkul P[2], Chaowarat S[2], Day NP[1], Graves N[3], Cooper BS[1]
[1]*Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand,* [2]*Sappasithiprasong Hospital, Ubon Ratchatani, Thailand,* [3]*Queensland University of Technology, Brisbane, Australia*

OBJECTIVES: Economic evaluations of interventions in the hospital setting often rely on the estimated long-term impact on patient survival. Estimates of mortality rates and long-term outcomes among patients discharged alive from the intensive care unit (ICU) are lacking from lower and middle-income countries. This study aimed to assess the long-term survival, life expectancy (LE) and the quality-adjusted life expectancy (QALE) amongst post-ICU patients in a middle-income country. **METHODS:** In this retrospective cohort study, data from a regional tertiary hospital in northeast Thailand and the regional death registry were linked and used to assess patient survival time after ICU discharge. Adult ICU patients aged at least 15 years who had been discharged alive from an ICU between 1anuary 1, 2004 and December 31, 2005 were included in the study, and the death registry was used to determine deaths occurring in this cohort up to December 31, 2010. These data were used in conjunction with standard mortality life tables to estimate annual mortality and LE. **RESULTS:** A total of 10,321 ICU patients were included in this analysis; 3,251 patients (31.5%) died during ICU admission. Of 7,070 patients discharged alive, 2,527 (35.7%) were known to have died within the five-year follow-up period, a mortality rate 2.5 times higher than that in the Thai general population (age- and sex-matched). The mean LE was estimated as 18.3 years compared with 25.2 years in the general population. Given the range of the Health Related Quality of Life (HRQOL) from the published literature, the mean QALE of post-ICU patients would range from 10.2 to 16.1. **CONCLUSIONS:** Post-ICU patients experienced much higher rates of mortality than members of the general population over the five-year follow-up period, particularly in the first year after discharge. Further work assessing HRQOL in both post-ICU patients and in the general population in developing countries is needed.

PHP111

INVESTIGATING SAFETY-APPRAOCH IN SAUDI ARABIA MINISTRY OF HEALTH HOSPITALS

Alkelya MA[1], Haleem RM[2]
[1]*King Abdullah International Medical Research Center (KAIMRC); King Saud Bin Abdulaziz University for Health Sciences (KSAU-HS), Riyadh, Saudi Arabia,* [2]*King Abdullah international medical research center, Riyadh, Saudi Arabia*

Joint commission (JCI) International Patient centered standards-2011 promotes improvements in patient safety(ISPG) & Medication Management Use (MMU). **OBJECTIVES:** To investigate historical changes of patient-safety approach in Saudi Arabia, create comparison baseline for future studies. **METHODS:** Cross-sectional 2003 survey sent to pharmacy managers of 127 hospitals of Ministry of Health(MOH); 67.7% responded; data of 63.7% hospitals were valid for analysis. 19 hospitals were chosen deliberately according to their level of development, their data was tested against selected criteria. Due to limitations of data; only 2 criteria were selected:

IPSG.1; identify patients correctly (criteria 1) and MMU.1& MMU.7; identify medication use & monitoring (criteria 2) Average for conforming to both criteria was calculated for each hospital. Correlation was tested between compliance to both criteria and hospital characteristics which were hospital type; general/tertiary & hospital geographical location; urban/rural. For each criterion; several measurables were selected from literature; and their average was calculated accordingly. Criteria 1; 1 measurable, composed of 2 components of which there average was calculated. Criteria 2; 2 measurables; measurable for MMU.1 composed of 3 components, while measurable for MMU.7 composed of 2 components. Average of averages was calculated. **RESULTS:** A total of 89.47% were complying to criteria 1 &10.53% non-complying with 10 hospitals 100% conforming. 52.63% were complying to criteria 2& 47.37% non-complying. Average compliance percentage with criteria 1 was 97.75, 85.91& 98.25 for general rural, general urban and tertiary urban hospitals respectively. In case of criteria 2, it was 28.75, 27.18& 20.5 for general rural, general urban and tertiary urban hospitals respectively. Correlations could not be established, no significant difference in means of compliance between or within criteria for different geographical locations or different hospital types; this can be contributed to the small sample size. **CONCLUSIONS:** A baseline for comparison of compliance to safety-related approach in Saudi Arabia was established which can be used for comparison in future studies.

PHP112

PHARMACISTS' SATISFACTION WITH DIFFERENT PHARMACEUTICAL DISTRIBUTION MODELS IN FIVE EUROPEAN COUNTRIES

Dragosits A, Said M, Walter E
Institute for Pharmaeconomic Research, Vienna, Austria

OBJECTIVES: Serving 172,709 dispensing points, the pharmaceutical wholesale-industry is a vital branch. One of the major business-objectives is total-customer-satisfaction. Thus, a questionnaire aimed to draw a comprehensive picture of the level of satisfaction (including delivery-times and country-specific-issues) of pharmacists with pharmaceutical-full-line and short-line wholesalers, Direct-sales from manufacturers, Direct-to-Pharmacies (DTP) and Reduced-Wholesale-Arrangements (RWA) in Europe, focusing on Germany, UK., France, Spain and The Netherlands. **METHODS:** The necessary data was obtained from an online-questionnaire (March 2011-October 2011) which was directed to pharmacies (n=473). **RESULTS:** The majority of the observed countries (99% in Spain to 72% in the UK) of the respondent pharmacists were satisfied with the distribution through pharmaceutical-full-line-wholesalers. With regard to the delivery-time offered by pharmaceutical-full-line wholesalers the satisfaction ranged from 97% in Spain to 76% in the UK. With regard to the distribution through short-line-wholesalers 62.50% of the German pharmacists were satisfied. With their delivery-time 56.30% of the pharmacists were satisfied, whereas 50.00% (distribution) and 38.90% (delivery-time) of the Dutch-participants showed satisfaction. Less than half of the respondents (58% in Spain to 12% in the UK) in four out of the five countries observed showed satisfaction with the distribution through Direct-sales from manufactures. 80% of the pharmacists in the UK were unsatisfied with this kind of distribution-system. Concerning the delivery-time pharmacists in the majority of the observed countries answered with neutral. Pharmacists in the UK (76%) were unsatisfied with Direct-sales from manufacturer. Pharmacists in the UK were unsatisfied with Direct-to-Pharmacy and the Reduced-Wholesale-Arrangements (DTP: 89.70% distribution vs. 75.90% delivery-time; RWA: 90.80% distribution vs. 58.50% delivery-time). Country-specific-issues mentioned were lack-of-availability of medicinal-products, stock-problems (UK), out-of-stocks problems (NL), shortages, supply-problems (ES) and decrease in discount-rates (DE). **CONCLUSIONS:** The satisfaction of pharmacists varies greatly between different distribution-models. Responding pharmacists in the countries observed receiving their medicinal-products through pharmaceutical full-line-wholesalers showed overall-satisfaction with this kind of distribution-system.

PHP113

THE FUTURE OF INDIVIDUAL FUNDING REQUESTS IN CLINICAL COMMISSIONING GROUPS ERA

Chaudhari SD
PAREXEL International, Uxbridge, Middlesex, UK

OBJECTIVES: Until March 2013,decisions on Individual funding requests (IFRs) had been the job of the primary care trusts to decide upon such requests. It has been widely acknowledged that IFRs to fund particular treatments have caused PCTs some thorny problems (with the rate of acceptance of IFRs having fallen from 59% in 2008/09 to 46% in 2010/11). However, with the Clinical Commissioning Groups (CCGs) formally assuming commissioning responsibilities for their local populations since April 2013, it is expected that health services and care pathways will become more patient focussed. The objective of this study was to assess whether IFRs will enjoy better success under the so-called 'patient centred' CCG leadership. **METHODS:** This research was based on a combination of secondary and primary research to assess the CCGs attitudes and expertise to cope with IFRs. Secondary research of published data such as current IFR policies and overall CCG health care priorities contributed towards a framework to understand the key factors affecting successful management of IFRs, which was then validated through a telephone survey of health care stakeholders. **RESULTS:** CCGs understand the importance and the value of having a clear and robust IFR policy. Learning from PCTs, CCGs also realise that having a clear IFR standard operating procedures and clear timeframes would mean spending significantly less time considering and defending decisions on IFRs. Some CCGs also believe that public conversation may be required IFRs are to be managed effectively. **CONCLUSIONS:** While CCGs realise that IFRs would be one of complicated bit of commissioning responsibilities, their real challenge is avoid making the same mistakes as PCTs. Early engagement with local populations about commissioning priorities is perceived to be crucial. Also the success of IFRs depends on organisations such as NHS Clinical Commissioners due to their dual role as CCG supporter and a body accountable to government.

PRE-FINANCING FUNCTION OF THE PHARMACEUTICAL FULL-LINE WHOLESALE SECTOR IN THE EUROPEAN UNION

Said M, Dragosits A, Walter E
Institute for Pharmaeconomic Research, Vienna, Austria

OBJECTIVES: Pharmaceutical full-line wholesalers carry out a variety of main functions. One of these is the financing function. Pharmaceutical full-line wholesalers stock and distribute the complete assortment of products in range and depth. Moreover, they acquire ownership over the medicinal products when purchasing them from the manufacturers and pass on ownership to pharmacies when they are delivered. Thus, the analysis aims to draw a comprehensive picture of the pre-financing function, expressed in terms of working capital, of the pharmaceutical wholesale sector in Europe. **METHODS:** The necessary data was provided by the European Association of Pharmaceutical Full-line Wholesalers (GIRP). The study analysed core indicators representative for all countries of the European Union plus Croatia, Norway and Switzerland (EU-25 + 3), with the exception of Malta and Cyprus as no full-line wholesalers are operating in the latter. **RESULTS:** In the analysed countries, 935 pharmaceutical full-line wholesalers operate 1,220 warehouses, serving 171,767 retail and hospital pharmacies and dispensing doctors and supply 520 million people. In 2012, pharmaceutical full-line wholesalers generated a total turnover of €130 billion in the EU-25 + 3. Pharmaceutical full-line wholesalers assume a pre-financing function towards manufacturers and pharmacies that is not offered by other distribution models. In the EU-25 + 3 alone they pre-financed on average €12.2 billion over a period of 35 days. In total, this sum is pre-financed approximately ten times per year. **CONCLUSIONS:** Pharmaceutical full-line wholesalers pre-finance the entire retail market of medicinal products, guarantee the continuous supply of all medicinal products and secure the cash flow of social insurers. The funding and holding of buffer stocks, the resulting working capital and ownership that goes with wholesaling services are vital for an effective and efficient functioning of the health care industry in Europe.

PHP115

ESTIMATING MARKET POTENTIAL FOR BIOSIMILAR INTRODUCTION

Paglia R[1], Bache G[2], Rossi C[3]
[1]*PAREXEL Consulting, East Brunswick, NJ, USA,* [2]*PAREXEL Consulting, Uxbridge, UK,* [3]*PAREXEL INTERNATIONAL, Uxbridge, UK*

OBJECTIVES: The global biopharmaceutical industry is facing a biologics "patent cliff" between 2013 and 2020, which will leave approximately $54 billion in drug revenue, without patent protection. In order to achieve success with these biosimilar agents, it is critical that manufacturers/marketers target the highest potential global markets. The objective of this research is to provide a framework for identifying the markets with the highest potential for biosimilar adoption and utilization. **METHODS:** A review of literature, research reports, and review articles was conducted, along with a panel discussion of industry thought leaders in biosimilars. Key indicators of biosimilar market potential were identified, evaluated, and prioritized. A systematic approach was developed to score each key indicator, and a mathematical approach adopted to aggregate the market scores. A series of 20 country markets were evaluated and ranked in order of biosimilar market potential. **RESULTS:** Key indicators of biosimilar market potential were separated into three categories: 1.) Originator-drug indicators including originator sales, reimbursement level, and reimbursement status. 2.) Market indicators including rate of uptake of currently available biosimilars, payer cost-containment mechanisms, and future biosimilar outlook. 3.) Regulatory indicators including barriers to marketing authorization based on the complexity of required data packages, and the risks associated with the development of clinical programs. Secondary research of public domain information was conducted on each of 20 countries, in order to obtain the data to populate the key indicators for market potential. Each country achieved a score based on the data, and was ranked based on biosimilar market potential. **CONCLUSIONS:** The process demonstrates a rational approach to identifying and sequencing of biosimilar market potential, which can be used to inform clinical-development and market-access plans. Also, in practical application for a manufacturer/marketer, "resource indicators" of market-specific assets should be included.

PHP116

CONFIDENTIAL PATIENT ACCESS SCHEMES IN THE UNITED KINGDOM – DO THEY AFFECT PRICES IN OTHER MARKETS?

Nijhuis T[1], Haigh J[2], Van Engen A[1]
[1]*Quintiles, Hoofddorp, The Netherlands,* [2]*Quintiles, Reading, UK*

OBJECTIVES: To investigate whether trends exist in drug prices of products approved by the UK NICE with a Patient Access Scheme in other key EU countries in the last 2 years. **METHODS:** Expensive new pharmaceuticals that are not deemed cost-effective by NICE in the first instance, can often still become recommended with a Patient Access Scheme. It is a trend that the type of scheme offered is becoming purely financial-based, with the last 17 schemes approved offering a simple discount. Although these discounts are 'commercial in confidence', the company's willingness to negotiate is obvious. To investigate if NICE recommended drugs with simple discount schemes affect pricing elsewhere in Europe, we compared their list prices in France, Germany, Italy and the UK. The analysis focused on pharmaceuticals recommended after 1 January 2011. **RESULTS:** Since 2011, 20 therapies were recommended by NICE with a PAS based on a simple discount. In all except one case, the UK list price was the lowest among available list prices in all countries analysed. Where an Italian list price was available it was usually the highest. When comparing the prices on an ex-manufactory level, the UK prices remain the lowest, but the German prices are generally the most expensive in this scenario. Of the countries analysed, only Italy has a risk sharing framework in place besides the UK. Out of the 20 therapies analysed here, only 3 were under an Italian scheme. **CONCLUSIONS:** The analysis shows that even before a PAS discount is applied, the UK price is already low, usually the lowest in the 4 EU countries analysed. There were no clear

signs that a potential discount had lowered a list price in one of the other countries, but is it clear that despite the external reference price systems in Europe prices of high-priced therapies vary considerably.

PHP118

PUBLIC PREFERENCE ELICITATION IN DRUG REIMBURSEMENT USING MULTI-CRITERIA DECISION ANALYSIS (MCDA) FOR UNIVERSAL HEALTH INSURANCE SYSTEM IN SOUTH KOREA

Cho HY, Lee EK
Sungkyunkwan University, Suwon, South Korea

OBJECTIVES: To elicit public preference for drug reimbursement criteria in Korea's universal health insurance system using three commonly used weighting methods in Multi-Criteria Decision-Analysis (MCDA). **METHODS:** Based on literature review, we established five criteria in drugs reimbursement decision-making: disease impacts, context of reimbursement, improvement of health outcomes, economics and quality of evidence. We evaluated the relative importance of five criteria using three weighting methods of direct rating (DR), SWING and analytic hierarchy process (AHP). 283 people were selected across the country by quota sampling and asked to assess the weights of five criteria with all three weighting methods repeatedly. The survey was self-administered by the participants with help of the trained interviewers. **RESULTS:** It was revealed that improvement of health outcomes and disease impacts have relatively higher weights than other three criteria in all weighting methods. Survey participants considered improvement of health outcomes the most important with DR (Mean [SD]: 0.210 [0.033]) and AHP (0.271 [0.127]), whereas disease impacts with SWING (0.231 [0.050]). Meanwhile, no coherence was shown in the low-ranked three criteria (context of reimbursement, economics, and quality of evidence) over three weighting methods. Quality of evidence ranked the third with DR (0.200 [0.035]), the fifth with SWING (0.165 [0.041]) and the fourth with AHP (0.160 [0.121]). Economics ranked the fourth with DR (0.197 [0.035]) and the third with SWING (0.192 [0.045]) and AHP (0.207 [0.118]). Lastly, context of reimbursement ranked the fifth with DR (0.188 [0.035]) and AHP (0.112 [0.090]) and the fourth with SWING (0.189 [0.045]). **CONCLUSIONS:** In this study, it was discovered that the survey participants considered improvement of health outcomes and disease impacts relatively more important than economics, context of reimbursement and quality of evidence in drug reimbursement decision making.

PHP120

DIFFUSION OF THE EFFICIENCY FRONTIER APPROACH WITHIN HEALTH ECONOMIC EVALUATION: CURRENT AND FUTURE APPLICATIONS

Sandmann FG, Lhachimi SK, Gerber A
Institute for Quality and Efficiency in Health Care (IQWiG), Cologne, Germany

OBJECTIVES: This study explores current applications (and potential future use) of the Efficiency Frontier (EF) in health economic evaluation. **METHODS:** We performed desk research on pharmacoeconomic guidelines for current usage of the EF and investigated possibilities for future use. **RESULTS:** Currently, the EF is officially used in 3 European countries. In Germany, since the enforcement of the 'Act on the Reform of the Market for Medicinal Products' (AMNOG) in January 2011, IQWiG applies the EF to determine non-arbitrary flexible thresholds across disease areas to ultimately determine an appropriate reimbursement price of new drugs (including interquartile-range to display uncertainty) in negotiations on request of the decision maker or manufacturer. In Belgium, the updated KCE guidelines dated July 2012 request the EF to identify the appropriate comparator among all relevant alternatives. In France, the updated HAS guidelines dated October 2012 require health interventions to be plotted on the EF to inform decision-making. In the future, the EF-approach could also be used to check on prices of national reference pricing clusters. Furthermore, the EF could help with priority setting (as suggested by the World Health Organization guide to cost-effectiveness analysis in 2003) and guiding or informing potential future (dis)investment decisions. The EF may also be combined with other approaches (e.g. making reimbursement decisions up to an ex ante fixed cost/outcome-threshold but setting prices beyond that level with the flexible EF). Lastly, it should not be overlooked that the EF can be applied for multiple purposes simultaneously. **CONCLUSIONS:** Since its first use to measure hospital efficiency, the EF is a valuable tool in health economics. Currently, its use diffuses within health economic evaluation and reimbursement decision-making. Yet, the full potential of the approach has not been exploited so far and the EF-approach remains under-researched by the scientific community.

PHP122

IMPACT OF THE GERMAN AMNOG EVALUATION ON DRUG PRICES: CORRELATION OF REBATE?

Neeser K, Loeffler D, Schmidt E, Muller E
LASER Analytica, Loerrach, Germany

OBJECTIVES: In January 2011 the new German law on the reorganization of the pharmaceutical market (AMNOG) came into force with the intention to reduce drug prices in Germany. Up to June 2013 44 dossiers completely evaluated and for 16 drugs (excluding orphan drugs) a price has been negotiated between the manufacturer and the National Association of Statutory Health Insurance Funds (GKV-SV). Since previous analyses have shown no correlation of negotiated price and the extent of clinical benefit, the underlying analysis aims to identify further parameters potentially influencing the reimbursed price of a new drug. **METHODS:** Evaluated drugs with completed price negotiation between manufacturers and the GKV-SV were selected from the website of the Federal Joint Committee (G-BA). The manufacturer free price was analyzed for potential interactions with following parameters extracted from module 3 of the AMNOG dossier: number of eligible patients, annual drug cost of the evaluated intervention and appropriate comparator, and the final price as listed in the Lauer-Taxe (official German drug price index). **RESULTS:** The 16 drugs, for which a negotiated reimbursement price was available, showed a minor (n=8), considerable (n=5), not quantifiable (n=2) or no additional clinical benefit (n=1).The investigated drug price was between 0,73 and 71 times the price of its appropriate comparator before entering negotiations. The negotiated price was between 0% and 56% lower compared to the price listed in the AMNOG dossier, regardless of the level of additional benefit. The number of eligible patients for each drug (141 - 214,000) tends to correlate with the negotiated rebate. **CONCLUSIONS:** An additional benefit is necessary for a reimbursement beyond the reference group price. Despite the small number of observations it might be concluded, that the reimbursed price inversely correlates with disease incidence. The highest rebate on reimbursement price resulted from the decision of the arbitration board.

PHP123

INFORMING THE AFFORDABILITY OF VACCINES WITH DIFFERENT HEALTH CARE FINANCING MECHANISMS

Varghese L, Li X, Sauboin C, Standaert B
GlaxoSmithKline Vaccines, Wavre, Belgium

OBJECTIVES: Budget impact analysis is the traditional approach of assessing the affordability of new interventions. While vaccination has been shown to be one of the most cost-effective means to improve health, budget requirements can be a barrier. This study aims at comparing an affordability indicator of a new vaccine in countries with similar Gross Domestic Product (GDP) per capita, but different health care financing mechanisms. **METHODS:** Based on National Health Accounts data, analyses of Total Health Expenditures (THE) and share of Public Health Expenditures (PHE) of various middle income countries were performed. Brazil and Turkey were selected for in-depth analysis as they had comparable GDPs and health care expenditures per capita. Health care access and financing data were also obtained from various government sources for a quantitative analysis. The budget requirements for a new vaccine costing $40 Purchasing Power Parity (PPP) per immunized child covering 80% of the birth cohort were calculated and expressed as a share of PHE. **RESULTS:** THE per capita doubled over 10 years in both countries since 2001, reaching $1,037 (PPP) for Brazil and $1,160 for Turkey in 2011. However, the share of PHE is vastly different; 46% in Brazil compared to 75% in Turkey. Implementing the new vaccine would require an additional budget of $97Million and $42Million. While large in absolute values they represent only 0.11% of the PHE in Brazil and 0.07% in Turkey. The higher affordability in Turkey can be explained by a different financing mechanism. **CONCLUSIONS:** While the implementation of a new vaccine in comparable countries in terms of wealth and THE per capita would require significant additional national spending in absolute terms, it represents only a small fraction of the PHE. The underlying health care financing mechanisms is an important factor affecting the affordability of a new vaccination program.

PHP124

IQWIG'S EFFICIENCY FRONTIER APPROACH: FIT FOR PURPOSE!

Sandmann FG, Gerber A, Lhachimi SK
Institute for Quality and Efficiency in Health Care (IQWiG), Cologne, Germany

OBJECTIVES: Since its adoption by the Institute for Quality and Efficiency in Health Care (IQWiG) in 2009, the Efficiency Frontier (EF) approach is criticized by the pharmaceutical industry, key opinion leaders and national organizations. In a German context, we aim to verify the accuracy of those concerns. **METHODS:** Review of the most commonly stated arguments against the EF-approach published within the scientific community and given as stakeholders' response on IQWiG's first cost-effectiveness analysis of antidepressants. **RESULTS:** Often stated objections against the EF include: 1) no international health economic standard, 2) merely disease specific without prioritization across disease areas, 3) no fixed threshold, and 4) avoiding the quality-adjusted life year (QALY). Ad 1): IQWiG adopted the EF-approach to inform setting appropriate reimbursement caps (since 2011 to inform negotiations for appropriate reimbursement caps with an interquartile-range as basis). In other jurisdictions, an appropriate price need not be determined; decisions (or recommendations) are made regarding whether or not the cost-effectiveness of a drug supports (restricted) reimbursement. Ad 2+3): Although prioritizing funds is no primary aim in Germany, the EF can still be applied equally across indications. Within indications, the reimbursement cap may not distort competition by disadvantaging a manufacturer unfairly and needs to be appropriate when compared with other available interventions. Contrary to the EF-approach, determining prices based on arbitrary fixed thresholds may not stand up in court. Ad 4): Despite methodological doubts concerning QALYs, they are not antecedently excluded as possible patient-relevant outcome measure when using the EF in Germany. Only a fixed cost/QALY-threshold was rejected. **CONCLUSIONS:** The EF fits the purpose of decision-making in Germany. Most objections are flawed or originate from a profound misunderstanding of the concept or the German (legal) context, where the EF is necessary and viable. The EF's prime distinction remains: Deriving flexible, non-arbitrary thresholds for disease areas.

PHP125

A SYSTEMATIC COMPARISON OF MARKET ACCESS AND REIMBURSEMENT PATHWAYS FOR DIAGNOSTIC TESTS IN GERMANY, UNITED KINGDOM AND THE UNITED STATES

Walzer S[1], Gartemann J[2]
[1]*MArS Market Access & Pricing Strategy UG (h.b.), Weil am Rhein, Germany,* [2]*Roche Diagnostics International Ltd., Rotkreuz, Switzerland*

OBJECTIVES: A diagnostic test is any kind of medical test performed to aid in the diagnosis or detection of disease and is becoming a key component of Personalized Health Care (PHC). The market access and reimbursement pathways for pharmaceuticals are well described however such pathways are missing for diagnostics in many countries and similarities between countries are not well understood. **METHODS:** A targeted literature review has been executed on top of reviews from market access and reimbursement authorities in Germany, the UK and the US. Existing pathways were plotted and key decision criteria have been evaluated in terms of comparability and health care decison-maker impact. **RESULTS:** In Germany inpatient reimbursement is being differentiated from outpatient with inpatient access being easier to be achieved (DRG, OPS coding). The outpatient pathway includes a full evidence pack-

age including clinical and health economic data and takes on average more than two years. In the UK the process is largely based on three different PCT payment and the various NHS value for money mechanisms combined with procurement systems. The value-based pricing system might change the current situation. Finally, in the US CPT codes are similarly being applied as DRG codes in Germany with a different pathway of application. In comparison the health economic evidence plays a larger role in the UK, even though (still) not in a systematic manner as for pharmaceuticals. The clinical evidence plays an important role in all countries, however it was identified that for diagnostic tests the access routes and especially the coding process is more dependent on consistency on applicability of existing codes and technology argumentation. **CONCLUSIONS:** In the different countries the evidence base for market access and reimbursement pathways for diagnostics differs significantly. Instead, having a unified approach might ease a value based market access argumentation for diagnostics.

A COMPARATIVE STUDY OF THE ROLE OF DISEASE SEVERITY IN DRUG REIMBURSEMENT DECISION MAKING IN BELGIUM, FRANCE, THE NETHERLANDS AND SWEDEN

Franken M, Koopmanschap M
Erasmus University, Rotterdam, The Netherlands

OBJECTIVES: Considerations beyond (cost-) effectiveness are increasingly important in reimbursement decision-making. We investigated the importance of disease severity relatively to other decision criteria in drug reimbursement decision-making in four European countries. **METHODS:** The importance of disease severity and its operationalization was assessed in Belgium, France, The Netherlands and Sweden. We investigated scientific literature, policy documents, reimbursement reports, and conducted three interviews in each country (four in The Netherlands) with policymakers involved in drug reimbursement. **RESULTS:** All interviewees acknowledged that disease severity is, especially in case of high severity, an important criterion while considering a drug's (cost-) effectiveness. However, its relative importance compared to other decision criteria remains implicit in the decision-making process. Although rarity of the disease is not a criterion as such, interviewees indicated difficulties in separating rarity from severity and the availability of alternative treatments. Only Belgium and France explicitly show societal willingness to pay by using reimbursement levels depending on the severity of the disease. In Sweden, 'need and solidarity' is one of the three prioritizing principles. The Netherlands is the only country that quantitatively operationalized disease severity using the proportional shortfall method and suggesting a cost-effectiveness threshold range depending on disease severity (which was never formalised by the minister). Although interviewees acknowledged that quantitative information, besides a qualitative description of the disease, may provide additional decision information, none of them considered such information to be of decisive importance. **CONCLUSIONS:** Disease severity is, especially in case of high severity, an important decision criterion in all four countries. However, all countries seem to struggle in making its actual role explicit. The operationalization differs across countries. While Belgium and France are most explicit by using the severity of the disease in setting reimbursement levels, all countries could improve transparency of its actual importance relatively to other decision criteria.

CLINICAL AND HEALTH ECONOMIC EVIDENCE REQUIREMENTS FOR OBTAINING HEALTH INSURANCE COVERAGE FOR INNOVATIVE MEDICAL DEVICES IN GERMANY

Schwander B[1], Krone FA[2], Walzer S[3]
[1]*AHEAD GmbH, Loerrach, Germany,* [2]*Baden-Wuerttemberg Cooperative State University, Lörrach, Germany,* [3]*MArS Market Access & Pricing Strategy UG (h.b.), Weil am Rhein, Germany*

OBJECTIVES: To evaluate the clinical and health economic evidence requirements for obtaining statutory health insurance coverage for innovative medical devices (MDs) in Germany. **METHODS:** We have assessed the requirements for innovative MDs in Germany according to the available reimbursement pathways and grouped them by the application setting as this had a significant impact on the research question. **RESULTS:** According to the German statutory rules in the inpatient care setting (reservation of prohibition; 'Verbotsvorbehalt') all innovative MDs can be applied once they have received marketing approval for Germany (CE mark) whereas a positive voting from the federal joint committee is required before MDs can be applied in the outpatient setting (reservation of authorization; ‚Erlaubnisvorbehalt'). The reimbursement coverage in the inpatient setting depends on the available coding and grouping mechanisms that define specific diagnoses related groups and their reimbursement value. If this value is not adequate or an adequate coding/grouping is not possible specific applications can be made, that require no specific clinical and health economic evidence; only a detailed (additional) cost estimation of the new procedure and a rationale of the innovative character are required. In contrast the outpatient reimbursement of the statutory health insurance shows very strict requirements as a detailed clinical evidence reporting (e.g. randomized-controlled trials) and a full health economic evaluation (e.g. cost-effectiveness and budget impact assessment) need to be provided for obtaining reimbursement coverage. There are recent political streams that claim that the regulatory and reimbursement process of MDs should be adapted comparable to the more restrictive regulations for pharmaceuticals which might have a major impact on the evidence requirements for the inpatient sector. **CONCLUSIONS:** Currently MDs applied in the inpatient setting require no specific evidence whereas strong clinical and health economic evidence is required for MDs applied in the outpatient setting.

PHP128

IMPACT OF REIMBURSEMENT OF MEDICINES ON ECONOMIC ACCESSIBILITY LEVEL FOR WORKING POPULATION IN REPUBLIC OF MOLDOVA

Chitan E[1], Brumarel M[2]
[1]*State University of Medicine and Pharmacy "Nicolae Testemitanu", Chisinau, Moldova,* [2]*State University of Medicine and Pharmacy, Chisinau, Moldova*

OBJECTIVES: Moldova is a country where expenditure on pharmaceuticals is already very high and exceeds several times the prices in the region. Drugs expenditure represents 70% of direct health expenditure of a household and is the main factor that reduces the financial protection of health care services. The objective of the study was to assess affordability of reimbursement medicines and to evaluate the National Health Insurance Company (NHIC) impact on ensuring economic accessibility. **METHODS:** To determine the affordability of medicines was used the methodology recommended by the World Health Organization. Have been analyzed data concerning price of drugs, the amounts paid by patients and the amounts paid by the NHIC for partially reimbursed drugs for 5 years (2008-2012). Was calculated: the median price for each drug international common name dependent's on strength; duration of treatment and number of units needed for treatment (for chronic disease); number of working days required for a treatment cure depending on minimum wage and average wage in economy. Available treatment is considered, the cost of which is 1 or less than the cost of one working day. Based on these results has been also determined the impact of the NHIC. **RESULTS:** Number of economically accessible reimbursed drugs depending on minimum wage was: 2008-24 (42%), 2009-34 (60%), 2010-43 (53%), 2011-48 (58%), and 2012-71 (86%); depending on average wage in economy: 2008-50 (87%), 2009-50 (87%), 2010-66 (81%), 2011-73 (88%), and 2012-77(94%). The average number of working days compensated by NHIC based on the minimum wage: 2008-6.23, 2009-3.5, 2010-3.7, 2011-2.92, and 2012-1.03; based on average wage in economy: 2008-0.98, 2009-0.76, 2010-0.75, 2011-0.55, and 2012-0.38. **CONCLUSIONS:** Compensation of drugs by NHIC, doesn't significantly affect the affordability of reimbursement medicines. Patients feels no real benefit from NHIC, drugs expenditure within the households practically remain unchanged even if it get reimbursed medicines.

PHP129

ASSESSMENT OF METHODOLOGICAL QUALITY OF ECONOMIC EVALUATIONS IN BELGIAN DRUG REIMBURSEMENT APPLICATIONS

Simoens S
KU Leuven, Leuven, Belgium

OBJECTIVES: To assess the methodological quality of economic evaluations included in Belgian reimbursement applications for Class 1 drugs. **METHODS:** For 19 reimbursement applications submitted during 2011 and Spring 2012, a descriptive analysis assessed the methodological quality of the economic evaluation, evaluated the assessment of that economic evaluation by the Drug Reimbursement Committee and the response to that assessment by the company. Compliance with methodological guidelines issued by the Belgian Healthcare Knowledge Centre was assessed using a detailed checklist of 23 methodological items. The rate of compliance was calculated based on the number of economic evaluations for which the item was applicable. **RESULTS:** Economic evaluations tended to comply with guidelines regarding perspective, target population, subgroup analyses, comparator, use of comparative clinical data and final outcome measures, calculation of costs, incremental analysis, discounting and time horizon. However, more attention needs to be paid to the description of limitations of indirect comparisons, the choice of an appropriate analytic technique, the expression of unit costs in values for the current year, the estimation and valuation of outcomes, the presentation of results of sensitivity analyses, and testing the face validity of model inputs and outputs. Also, a large variation was observed in the scope and depth of the quality assessment by the Drug Reimbursement Committee. **CONCLUSIONS:** Although general guidelines exist, pharmaceutical companies and the Drug Reimbursement Committee would benefit from the existence of a more detailed checklist of methodological items that need to be reported in an economic evaluation.

PHP130

PRICING AND REIMBURSEMENT SYSTEM OF ORPHAN DRUGS IN THE CZECH REPUBLIC

Prochazkova M[1], Kubickova P[1], Mazelova J[2], Hambalek J[2], Heislerova M[2]
[1]*Ministry of Health, Prague, Czech Republic,* [2]*State Institute for Drug Control, Prague, Czech Republic*

OBJECTIVES: In the CZ, orphan drugs so-called highly innovative drugs first enter a temporary reimbursement period of three years. Having proven their cost-effectiveness they later become permanently reimbursed. The objective of the study was to determine how successfully orphan drugs enter the database of reimbursed drugs. **METHODS:** The EMA list of orphan drugs was compared to the Czech database of reimbursed drugs to the date of 1-Jul-2013. For each detected drug the date of entering the database was found. In drugs reimbursed after 2008, submissions of cost effectiveness analyses were recorded. Although CZ has no willingness to pay threshold, interpretation of cost effectiveness analyses results could improve the process of HTA of drugs. **RESULTS:** To the date of 1-Apr-2013 the EMA has registered 65 orphan drugs. Out of these, 28 have been assigned a maximum and reimbursement price in the CZ. To this date, 27 drugs have not applied for reimbursement price. Starting from 2008, 30 drugs have applied: in 20 products the decision is legally effective, in 2 cases only hospital use has been approved, in 7 cases (3 appeals, 4 unfinished proceedings) the proceedings are still in process and in one case the application was withdrawn. In about a third of cases a cost effectiveness analysis was submitted and accepted by SUKL. The upper limit of the ICER of the submitted analyses exceeds by far the cost-effectiveness level recommended by the WHO. **CONCLUSIONS:** The results imply that in almost in all cases the submitted applications for maximum and reimbursement price are approved by SUKL. In some cases, however, the health insurance companies hinder reimbursement of drugs by filing an appeal. However, the assessment of cost effectiveness of drugs should be performed at an earlier level – during the administrative proceedings. This calls for necessary emphasis on health technology assessment.

PHP131

PRICING AND REIMBURSMENT OF PHARMACEUTICALS IN IRAN

Moradi M
Corvinus University of Budapest, Budapest, Hungary

OBJECTIVES: To investigate the problem of pricing and reimbursement of pharmaceuticals in Iran. A large amount of country's Health care expenditures, including insurance organizations' expenses, are spent for pharmaceutical products. However, the high amount of capital spent by the users for purchasing pharmaceuticals indicates a serious flaw in the system. As will be shown, this flaw is due to the structures, policies, and regulations of Iranian medical insurance system. **METHODS:** This is a descriptive study and, therefore, ethnographic site and fieldwork were used as the main source of information. Furthermore, information on the Internet and several Iranian online databases has been used for comparison purposes. **RESULTS:** Ministry of Health and Medical Education (MOHME) is the main responsible body for pharmaceuticals in Iran. However, different government organizations such as Ministry of Commerce, the Central Bank of Iran, and National Industries Organizations are involved in policy-making in this sector. MOHME decides how to allocate governmental supports and foreign currency quotas, to various related industries. This is done due to the fact that MOHME decides which pharmaceuticals should be covered and distributed in the country. However, prices are set by insurance organizations due to their bargaining power over MOHME. Insurance companies pay approximately 70-90% of the final price of a product. However, for purchasing expensive products, confirmation from insurance companies is needed. The reimbursed price is set at the level of the lowest priced equivalent on the market. **CONCLUSIONS:** These flaws and loopholes arise because of system's negligence on research and development methods and, therefore, lack of standard regulations on reimbursement decisions and priority settings. Inflexible profit margins for different products with different unit costs, incomplete support for vulnerable groups and patients with chronic diseases, and absence of rational pharmaceutical usage campaigns can be named as other major problems.

PHP132

PERSONALIZED HEALTH CARE IN FRANCE, GERMANY AND THE UNITED KINGDOM: ARE HEALTH TECHNOLOGY ASSESSMENT AGENCIES READY?

Walzer S[1], Gartemann J[2], Zoellner YF[3], Towse A[4], Garrison L[5]
[1]*MArS Market Access & Pricing Strategy UG (h.b.), Weil am Rhein, Germany,* [2]*Roche Diagnostics International Ltd., Rotkreuz, Switzerland,* [3]*Hamburg University of Applied Sciences, Hamburg, Germany,* [4]*Office of Health Economics, London, UK,* [5]*University of Washington School of Pharmacy, Seattle, WA, USA*

OBJECTIVES: Personalized health care (PHC) is a treatment model that customizes health care based on biomarker-based prediction of likely response. It is increasingly being prioritized by politicians and payers—one recent example is the published strategy plan by the German Federal Ministry of Education and Research. A key policy question remains whether health care systems and health technology assessment (HTA) bodies are adequately prepared evaluating these new treatment options. **METHODS:** Existing HTA evaluation methods for therapies in France, Germany, and the UK were reviewed with respect to the applicability to PHC products based on information provided by decision-making bodies and the literature. **RESULTS:** Current HTA evaluation methods being applied to medical therapies, in general, need to be modified when applied to PHC. For example, traditional benefit evaluations that require randomized clinical trials are standard but cannot always be fulfilled in PHC. Furthermore, combined benefit assessments for typical PHC treatment—e.g., a pharmaceutical combined with a diagnostic test—lack experience about appropriate evaluation methods to use. Today, decison makers and manufacturers rarely make use of the opportunity to re-assess or for joint evidence generation. Finally, reimbursement for PHC is inflexible and does not fully reflect the value of targeting, including the reduction in uncertainty and greater appropriate use. Among these three, the UK seems the most open to PHC funding. HTA in France and Germany does not recognize the special economic and evidence features of PHC, though the French system is more open to innovative market access. **CONCLUSIONS:** If the largest EU health care systems are to secure the full benefits of PHC, they will need to provide for full and flexible reimbursement for innovative technologies and services based on value. Currently, the importance of PHC by health care politicians is not being reflected in the evaluation tools or reimbursement methods being applied.

PHP133

TRENDS IN REIMBURSEMENT DECISIONS IN IRELAND: AN ANALYSIS OF THE NCPE DATABASE FROM AN INDUSTRY PERSPECTIVE

Redmond S, Mahon S, Carney P
GlaxoSmithKline, Dublin, Ireland

OBJECTIVES: To analyse trends in reimbursement in Ireland to help in the planning of HTAs from an industry perspective. **METHODS:** A database of all NCPE decisions and reimbursement for drugs from 2006 to April 2013 was developed from publically available NCPE reports and HSE websites. A descriptive analysis of the database was undertaken. **RESULTS:** From 2006 to April 2013 37% of drugs were reimbursed without a HTA and 63% were recommended for HTA (N=126). There were three HTAs undertaken in 2006 compared to 26 in 2012. High Tech (HT) drugs were more likely to attract a HTA compared to General Medical Services (GMS) drugs (83% vs. 51%). Of the HTAs completed, 57% resulted in a positive reimbursement recommendation within a median time from HTA submission to reimbursement of 7.9 months (min 3.9, max 16.3). The median time was 7.1 and 9.8 months for GMS and HT drugs respectively. Dominance almost perfectly predicted reimbursement; 83% reimbursed. Of the ICERs in the north-east quadrant, 54% resulted in a positive reimbursement recommendation (average ICER around €60,000/QALY). The cost per QALY for those not reimbursed in this quadrant was almost twice this at around €110,000. Finally, the average probability of cost effectiveness for reimbursed and non-reimbursed drugs were 60% and 30% respectively. **CONCLUSIONS:** Companies can expect more requests for HTAs especially for HT drugs. When HTAs are requested the probability of success is around 60% with an expected timeline of 8 months from submission to launch. Budget impact does have an important role to play as dominance is a strong predictor of reimbursement. The average cost per QALY for reimbursed drugs is above the €45,000/QALY threshold but does not take into account confidential discounts under patient access schemes. Finally, the threshold probability of cost effectiveness seems to lie between 30% and 60%.

PHP134

PARAMETER UNCERTAINTY IN VALUE BASED MULTI CRITERIA DECISION ANALYSIS: A SYSTEMATIC REVIEW OF METHODS

Groothuis-Oudshoorn CGM[1], Broekhuizen H[1], Hummel J[2], van Til J[1], Ijzerman M[1]
[1]*University of Twente, Enschede, The Netherlands,* [2]*University Twente, Enschede, The Netherlands*

OBJECTIVES: Multi criteria decision analysis (MCDA) aims to support decision-making where decisions are based on multiple criteria. In disciplines like engineering and environmental policy, MCDA is widely accepted and routinely used. The use of MCDA in HTA priority setting and reimbursement decisions is growing, but mostly limited to research projects. A factor that might influence acceptance is a perceived difficulty to value an MCDA's outcome when its inputs and outputs contain uncertainties. When this is the case, decision makers might not feel confident in accepting or rejecting its outcome. The objective of this study is to systematically review how parameter uncertainty is taken into account in value-based MCDA methods in general, and to discuss which of the approaches is appropriate for the setting of reimbursement decision making in health care. **METHODS:** A systematic literature review was conducted using the Scopus database. Found abstracts were categorized by MCDA method used. Then, themes and families of methods were identified by two independent reviewers. Selected full text articles were read to identify methodological details. **RESULTS:** The search strategy identified 635 abstracts, mostly from engineering and environmental journals and only 1.6% in health journals. Identified themes were fuzzy set theory (n=223), probabilistic framework (n=68), deterministic sensitivity analysis (n=140), Dempster-Shafer theory (n=14), Bayesian framework (n=7) and Grey theory (n=8). A large number of papers considered the Analytic Hierarchy Process in combination with fuzzy set theory (n=155). **CONCLUSIONS:** In the health literature there is little attention for parameter uncertainty. Methods to deal with parameter uncertainty in MCDA must strike a balance between comprehensibility and understandability. Several complex methods are developed for parameter uncertainty, but there seems to be a gap between the theory and the implementation of those methods. For simple applications, methods like deterministic sensitivity analysis are likely to be sufficient.

PHP135

AMNOG BENEFIT ASSESSMENT: TIME DELAY OF MARKET ACCESS FOR PHARMACEUTICALS IN GERMANY?

Neubauer AS, Voss P, Gmeiner A, Neubauer G
IfG Institute for Health Economics (www.ifg-muenchen.com), München, Germany

OBJECTIVES: To investigate quantitatively, if and to which extent the German Arzneimittelmarkt-Neuordnungs-Gesetz (AMNOG) delays market access of pharmaceuticals. Secondary objective was to potentially identify predictors for access delay. **METHODS:** All AMNOG assessment procedures that were completed at the level of the joint federal committee (G-BA) by May 15 2013 were included (website www.g-ba.de). Time delay to dossier submission was calculated between the approval date of the European Medicines Agency (EMA) and the mandatory AMNOG dossier submission date. Submission date usually occurs when pharmaceuticals are made available and is decided upon by the manufacturer. We also included in the analysis the ordinal level classification and evidence certainty level for each product as assessed by Institute for Quality and Efficiency in Health Care (IQWiG) and G-BA as well as the ATC code. **RESULTS:** In n=17 (49%) of N=35 investigated pharmaceuticals a small time delay greater than 1.1 months (which is usually feasible) after EMA approval was observed, but only 20% had a delay >2 months. A negative correlation existed between the amount of time delay to dossier submission and the benefit level outcome as assessed by IQWIG (r=-0.258, n.s.) and the final result by G-BA (r=-0.484, p=0.003). Benefit assessment outcomes between IQWiG and G-BA were correlated moderately with r=0.442 (p<0.008). For both, IQWiG (r=0.841) and G-BA (r=0.773) certainty of evidence correlated highly with the benefit level outcome. **CONCLUSIONS:** This analysis highlights the impact of AMNOG on the market access of pharmaceuticals in Germany. Overall, only small time delays existed for most products. Time delay in market access correlated significantly with a negative assessment of additional benefit by G-BA. Evidence certainty clearly correlated with benefit outcomes.

PHP136

A COMPARISON OF COVERAGE AND REIMBURSEMENT DECISIONS IN GERMANY (AMNOG) AND SCOTLAND (SMC)

Charokopou M[1], Heeg B[1], Schoeman O[2], Mueller S[3], Tempest MJ[4], Schlagmüller SC[1], Wilke T[3]
[1]*Pharmerit International, Rotterdam, The Netherlands,* [2]*Pharmerit International, Berlin, Germany,* [3]*IPAM - Institut für Pharmakooekonomie und Arzneimittellogistik, Wismar, Germany,* [4]*Pharmerit Ltd., York, UK*

OBJECTIVES: In Scotland, drug reimbursement is predominantly based on cost-effectiveness in contrast to the corresponding German AMNOG process. The study compares the reimbursement and pricing process in Germany (AMNOG), as reformed in 2011, and Scotland (SMC) based on reimbursement assessments. **METHODS:** All AMNOG and SMC appraisal decisions made in 2011-2012 were identified. Matching AMNOG-SMC cases were found and compared in terms of final appraisal decision and rationale. **RESULTS:** For 2011-2012, forty-one AMNOG cases over 60 subgroups and 193 SMC cases were identified; twenty five matching cases were compared as these were assessed by both organizations. Regarding these 25 cases, AMNOG deemed ten cases demonstrated no additional benefit, in two cases the additional benefit was unquantifiable, slight benefit was acknowledged in seven cases and in six there were significant benefits. Based on the benefit assessment the negotiated price rebates ranged from 4.7% to 70.7% based on manufacturer set price. No restrictions to subgroups were opposed to any reimbursement decision. The SMC reimbursed 18 products (72%), of which four were restricted to a certain population due to cost-effectiveness. SMC rejected 7 cases (28%) based on weak economic evi-

dence. Both organizations reached the same assessment regarding clinical benefit in only 13 cases (52%). **CONCLUSIONS:** AMNOG implements a more rigorous process with respect to clinical evidence assessment compared to SMC. All AMNOG decisions are positive; however final prices may resemble generic prices for products that demonstrate low additional benefit ("Festbetragsgruppen"). In comparison, a negative decision by SMC warrants re-submission and re-assessment of the set price for successful drug reimbursement. Orphan drugs are assessed as normal products in Scotland and may be rejected on the grounds of economic evidence, while in Germany the additional benefit is presumed and price negotiation starts automatically. Furthermore, the SMC assessment process starts later than the AMNOG process.

PHP137

ACCESSING THE PHARMACEUTICAL MARKETS OF BRAZIL, RUSSIA, INDIA AND CHINA

Faria-Billinton EC[1], Murray GC[1], Raza SA[2], Grubert N[3], Pickering L[4]
[1]*Abacus International, Manchester, UK,* [2]*Abacus International, East Delhi, India,* [3]*Decision Resources, London, UK,* [4]*Decision Resources, Burlington, MA, USA*

While pharmaceutical sales in mature economies are declining, in emerging markets they have been expanding rapidly, with growth rates in double figures. Here we focus on market access in BRIC (Brazil, Russia, India and China) which together represent just over 40% of the world population.**OBJECTIVES:** To identify the processes and key stakeholders involved in gaining market access in BRIC; to assess the importance of health technology assessment (HTA) in gaining reimbursement in these countries; to identify opportunities and challenges to market access. **METHODS:** A review was conducted to identify the current processes and key stakeholders in market access in the BRIC countries and to identify favourable and unfavourable factors to market access. **RESULTS:** The licensing and reimbursement processes vary in the BRIC countries. Brazil follows processes similar to those in Western Europe, including HTA and public consultation as part of the reimbursement application. In China, the licensing process can take 4-6 years, though fast-tracking for innovative drugs has recently been introduced. Russia, China and India do not yet rely on HTA for reimbursement decisions. In India plans to use "pharmacoeconomic principles" in setting prices of new molecules have been announced. Opportunities in all these countries result from increasing affluence and life expectancy and the diseases associated with these. Some challenges to market access are: poor IP protection; protectionist measures; compulsory licensing; drive to use generics or biosimilars, often produced locally; price controls; variable health insurance/NHS coverage; and limited budgets for prescription drugs. **CONCLUSIONS:** HTA is now common practice in Brazil, but not yet in Russia, India or China. Although demand for new drugs is increasing in these markets, protectionism measures, competition from generics and budget constraints due to the increased burden and requirement for new high priced drugs present a challenge when accessing the pharmaceutical market in BRIC countries.

PHP138

PLACEBO-CONTROLLED TRIALS: ARE THEY ACCEPTABLE TO HEALTH TECHNOLOGY ASSESSMENT BODIES?

Casamayor M, Ivanescu C, Van Engen A
Quintiles, Hoofddorp, The Netherlands

OBJECTIVES: The gold-standard pivotal trial design has three arms with experimental medicine, placebo and active control however, often marketing authorisation is granted on placebo controlled (PLAc) trial(s). While PLAc trials are often still acceptable to the European Clinical Trials Directive and European Medicines Agency (EMA), they are less acceptable to Health Technology Assessment (HTA) bodies. The latter request an (in)direct comparison vs. the relevant active comparator(s) (AC) to demonstrate the added value of existing standard of care. We have investigated the hurdles encountered during HTA assessments for those drugs with marketing authorization based solely on PLAc studies. **METHODS:** We identified those drugs approved since 2010 by EMA based only on PLAc trials. We then reviewed the HTA assessments for these drugs in France (HAS), Germany (G-BA) and the UK (NICE and SMC) and compared these HTA assessments to others where the trial included an AC. **RESULTS:** Applications for 41 (45 indications) of the 220 drugs approved by EMA between 2010 and end of 2012 were based exclusively on PLAc trials. The number of indications already assessed and recommended (percentage) by HTA bodies are 19 and 11 (58%) for NICE, 33 and 18 (55%) for SMC, 24 and 20 (83%) for HAS, and 18 and 12 (67%) for G-BA. When compared to all HTAs irrespective of comparator being placebo or AC assessed since 2010, lack of an AC seemed to have no impact in HAS (83% vs 75% favorable opinion among all assessments) and G-BA (67% vs 58%) assessments but had a negative impact on SMC (55% vs 85%) and NICE (58% vs 64%) recommendations. **CONCLUSIONS:** The impact of no direct comparison with an AC varies across countries. The analysis seems to indicate that in absence of head-to-head data HTA agencies will accept indirect evidence against the right AC.

PHP139

THE IMPACT OF THE ECONOMIC RECESSION AND PHARMACEUTICAL-HEALTH SERVICE AGREEMENT ON THE PROBABILITY AND TIME OF REIMBURSEMENT OF NEW MEDICINES IN IRELAND

Carney P, Redmond S, Mahon S, Barry C
GlaxoSmithKline, Dublin, Ireland

OBJECTIVES: To assess the impact of the Irish economic recession (September, 2008) and the Irish Pharmaceutical Healthcare Association agreement (IPHA; November, 2012) on the probability of reimbursement decided by the National Centre for Pharmacoeconomic Evaluation (NCPE). We also aim to test whether the new IPHA agreement reduced the time-to-reimbursement for new medicines in the General Medical Services (GMS) and High Tech Drug Scheme (HTDS). **METHODS:** A database of all NCPE decisions since 2006 to present was compiled from publically available NCPE decision reports and a logistic model was used to test the occurrence of the recession and the IPHA agreement on the rate of positive reimbursement made by the NCPE. We also tested whether the new agreement had an impact on the time-to-reimbursement using a linear regression model. **RESULTS:** The results of the logit model suggest that neither the economic recession nor the agreement had any statistically significant impact on the probability of reimbursement. However, there was some evidence that the time-to-reimbursement was reduced after the agreement ($p<0.10$). **CONCLUSIONS:** Although the analysis suggests that these two events had no impact on the rate of reimbursement it is possible that the reimbursement price of new drugs may have decreased over this period which could have facilitated reimbursement. Unfortunately, details of the final price of medicines are not always known in the Irish system and it is therefore not possible to test this hypothesis using currently available data. Our analysis of time-to-reimbursement suggests that the new agreement may have satisfied one of its main objectives in getting new medicines onto the market sooner.

PHP140

MODELLING THE HEALTH TECHNOLOGY ASSESSMENT (HTA) PROCESS FOR INNOVATIVE DRUG TECHNOLOGIES (IDTS) IN THE TURKISH HEALTH CARE SYSTEM

Kececioglu S[1], Ulus P[2], Cukadar F[3], Ozkan M[3], Urganci B[3]
[1]*Boehringer Ingelheim Turkey, Istanbul, Turkey,* [2]*Boehringer Ingelheim Turkey, ISTANBUL, TURKEY, Turkey,* [3]*Boehringer Ingelheim Turkey, ISTANBUL, Turkey*

OBJECTIVES: Offering a standardized HTA process model through economic evaluation of IDTs in the Turkish health care system. **METHODS:** Current regulations on evaluation of innovative drug technologies through the reimbursement process are defined via a process flow scheme. A stepwise model is proposed to cover a standardized HTA system within the economic evaluation through an independent HTA body (Model HTA Authority). **RESULTS:** In the current system, economic evaluation content of a reimbursement application dossier is evaluated by Social Security Institution (SSI) through Technical and Main Commissions respectively. However this evaluation process is not standardized with respect to main variables such as scientific methodologies, timelines and responsibilities. This study offers a model, which initiates a re-defined application step for economic evaluation content of a IDT reimbursement dossier; parallel application to SSI and an independent HTA body (Model HTA Authority). Therefore, the Main Commission in SSI will be able to combine a general evaluation from the Technical Commission and an HTA report of the IDT by an independent HTA body. These reports will be available to owners of reimbursement applications until announcement of a final decision of SSI, and will become publicly available afterwards. **CONCLUSIONS:** IDTs are not involved in a standardized HTA process in the current Turkish health care system. However, pharmacoeconomic analysis reports are requested by SSI for reimbursement applications of IDTs. This study offers a model, which includes a standardized HTA process for IDT in the Turkish health care system. Applicability of this model may be tested through pilot projects and further steps may be defined for further excellence.

PHP141

CANADIAN PRIVATE PAYERS' PERCEPTIONS AND EXPECTATIONS OF SUBMISSION REQUESTS FOR DRUG REIMBURSEMENT SUBMITTED BY THE PHARMACEUTICAL INDUSTRY

Charaan M
University of Montreal, Montreal, QC, Canada

OBJECTIVES: To identify, from a private payer's perspective, the required elements to include in a pharmacoeconomic model and a budget impact analysis and compare them to that of the public payers' requirements. The secondary objective was to determine the preferred components to present in a submission regarding private payers. **METHODS:** A survey was sent to 21 submission reviewers from 14 private insurance companies offering drug reimbursement, using an online survey builder, *KwikSurveys*. The survey included 15 questions divided in 5 sections: General information, Clinical information, Pharmacoeconomic evaluation, Budget impact analysis and General appreciations. **RESULTS:** Nine reviewers from eight different companies, which represent 80% of the Canadian private payer market shares, responded to the survey. Results showed that 67% of participants follow the Canadian Agency for Drugs and Technologies in Health (CADTH) guidelines for economic evaluations. 88% of participants prefer a cost-effectiveness evaluation, while 75% prefer a cost-benefit evaluation. 100% of the participants would like direct drug costs and the indirect costs related to loss of productivity due to reduced working capacity to be included in the pharmacoeconomic model. 75% would like the costs to employer to hire and train replacement worker, the costs of premiums paid to, as well as benefits received from, private insurers to also be included in the model. 63% of the participants would like to see a population data-based model for their budget impact analysis. Similarly, 63% of the participants prefer a time horizon of 3 years for the budget impact analysis. **CONCLUSIONS:** The parameters to be considered in a submission sent to private payers are different from public payers' requirements. The perspective of the pharmacoeconomic model should be that of a private payer and the budget impact analysis should only consider a population covered by private payers.

POINT OF CARE TESTS: THE LONG AND WINDING ROAD TO REIMBURSEMENT

Hogue S[1], Brogan A[1], Heyes A[2]
[1]*RTI-Health Solutions, Research Triangle Park, NC, USA,* [2]*RTI Health Solutions, Manchester, UK*

OBJECTIVES: Market access for innovative new technologies can be complex and time consuming. As cost-containment pressures in the European Union (EU) intensify, evidentiary hurdles to justify new point-of-care (POC) tests continue to grow. Decentralized health care decision making can also be a significant hurdle. This study aimed to characterize the process and identify challenges for Health Technology Assessment (HTA), pricing, reimbursement, and market access for a new POC test in the EU-5 countries. **METHODS:** We conducted desktop research of

published literature, HTA reports, and third-party websites, to identify the critical path and data most valuable to reimbursement decision making. We conducted 26 qualitative one-on-one interviews with payer decision makers in the EU-5: 12 key opinion leaders, 4 laboratory directors, and 10 academic health economists and HTA advisors. **RESULTS:** Reimbursement is critical to rapid adoption of new technologies. There are multiple appropriate access pathways for various theatres of care (e.g., outpatient office/clinic, inpatient, emergency), all with varying requirements and value drivers. Payment for new diagnostic tests typically is handled regionally or locally; treating physicians and medical societies can influence these budget decisions. Shared financial agreements or risk-sharing scenarios may speed introduction of a new POC test. Test reimbursement processes may differ for inpatient versus outpatient use. Currently, the evidence hurdle for a POC test is not as high as for prescription medicines. **CONCLUSIONS:** Market access for a POC test varies across and within countries; adequate data to meet decision makers' needs is not well understood. No roadmap exists for navigation of the critical path for POC tests, and evidence requirements in the EU are not well established. Access for a POC test will be complex; regardless of pathway, decisions regarding reimbursement and adoption of new technology are diverse and dispersed across and within countries with varying levels of required evidence.

VALUE OF LIFE: AS PERCEIVED BY PHYSICIANS AND THE GENERAL PUBLIC

Tichopad A, Zigmond J
CEEOR s.r.o., Prague, Czech Republic

OBJECTIVES: With the advancing process of HTA in the Czech Republic question emerged such as what is the willingness to pay (WTP) for health and life as well as what is the general awareness of the national health care policy and health economics. So far all estimations of WTP were largely based on academic deductions, thus we adopted a previously published approach to estimate the empirical WTP. **METHODS:** A total of 381 doctors of 15 specializations and 500 respondents from general population, both matching the CZ demography, were interviewed online. Doctors were asked directly to suggest reasonable WTP per equivalent of QALY. The general public was interview using the dichotomous double bounded choice method. The value of WTP, including 95% confidence interval, was determined using proc lifereg of the SAS system that allowed estimating averages for interval data. Optimal parametric extrapolation of the data was chosen based on the minimum value of Akaike's information criterion (AIC). **RESULTS:** Economics is the last criterion considered as important by doctors following the quality of life, clinical parameters and ethical/social aspects. Doctors not rejecting the concept of paying for health (28%) produced median of CZK 700,000 (EUR 27,129) to be an adequate payment for an extra year in full health, representing one QALY. General population suggested CZK 18.4 million (EUR 731,110) as an adequate WTP to be paid by the national health insurance fund, largely in contrast to only CZK 177,000 (EUR 6859) as suggested for the pay-of-pocket WTP. **CONCLUSIONS:** The awareness about health economics and its methodology is rather low among doctors and general public. While those medical doctors who expressed understanding for the concept of WTP and QALY suggested a value similar with the implicit WTP of CZK 1,000,000 (EUR 38,756) general public suggested extreme WTP from public budget, reflecting distant position of the public.

TOWARDS EVIDENCE-BASED EUROPEAN POLICY IN CLINICAL TRIALS THE SURVEY OF ATTITUDES TOWARDS TRIAL SITES IN EUROPE - THE SAT-EU STUDY™

Gehring M[1], Taylor R[2], Casteels B[3], Piazzi A[4], Mellody M[4], Gensini GF[5], Ambrosio G[6]
[1]*sbg Healthcare Consulting, Pully, Switzerland,* [2]*Peninsula Medical School, Exeter, UK,* [3]*BC Consulting & Solutions Sàrl, Lausanne, Switzerland,* [4]*Virtuoso Sàrl, Grand Saconnex, Switzerland,* [5]*University of Florence, Florence, Italy,* [6]*University of Perugia, Perugia, Italy*

OBJECTIVES: Applications to run clinical trials in Europe have been falling since 2007. Costs, speed of approvals, and shortcomings of European Clinical Trial Directive (CTD) are commonly held responsible. However, there is no hard evidence on the actual weight of these factors, nor are policy recommendations typically founded on a research-based understanding of factors impacting trial site selection. Indeed, borrowing from the rigour of its own discipline, medical policy decisions ought to be "evidence-based". **METHODS:** The SAT-EU Study™ was an anonymous, cross-sectional Web-based survey designed to systematically assess factors impacting European clinical trial site selection. It explored 19 factors across investigator-, hospital-, and environment-driven criteria, and costs. It also surveyed perceptions of the European trial environment. Clinical Research Organizations (CROs), academic Clinical Trial Units (CTUs), and Industry were invited to respond. OUTCOME MEASURES: Primary: Weight assigned to each factor hypothesized to impact trial site selection and trial incidence; Secondary: Desirability of twelve European countries to run clinical trials **RESULTS:** Responses were obtained from 485 professionals in 34 countries: 49% from BioPharma, 40% from CTUs or CROs. Investigator-, environment-, and hospital-dependent factors were rated highly important, costs being less important ($P<0.0001$). Within environment-driven criteria, pool of eligible patients, speed of approvals, and presence of disease-management networks were significantly more important than costs or government financial incentives ($P<0.0001$). Germany, UK, and The Netherlands were rated the best trial markets ($P<0.0001$). **CONCLUSIONS:** Fostering European clinical research does not require additional government spending or a revamping of the clinical trial cost structure. Rather, it requires greater visibility of centres of excellence and the harmonised national adoption of recently approved revisions to the CTD. Carefully crafted harmonization of approvals, including aligned hospital contracting, speedier trial authorization and greater visibility of disease networks may bring significantly more clinical research to Europe and stimulate growth.

JAPANESE REPRESENTATION IN LEADING GENERAL MEDICINE AND BASIC SCIENCE JOURNALS: A COMPARISON OF TWO DECADES

Takahashi O
St.Luke's International Hospital, Tokyo, Japan

OBJECTIVES: During 1991-2000, Japan contribution to the top basic and clinical science journals was less than 1% and 3%, respectively. The objective of this study was to compare the Japanese representation in 7 major general medicine journals and 6 basic science journals between the years 1991-2000 and 2001-2010. **METHODS:** Retrospective observational study. We measured the frequency of journal article publications in PubMed from Japan in both seven high-impact general medical and internal medicine journals and six high-impact basic science journals using Boolean operators to connect name of the journal, year of publication and corresponding authors' affiliation with different universities, cities and places in Japan. **RESULTS:** Japan represented 0.66% (260/39,255) and 0.74% (265/36,038) of journal articles in 7 of the top general medicine journals during 1991-2000 and 2001-2010, respectively. In contrast, the respective representation in 6 of the top basic science journals was 2.51% (849/33,779) and 3.60% (1364/37,908), respectively. Overall, we observed that the proportion of Japan-originated articles published in the top general medicine journals during 2001-2010 remained unchanged compared to 1991-2000 ($P=0.255$). However, the Japanese representation in basic science journals during 2001-2010 increased significantly compared to 1991-2000 ($P<0.001$). Japanese representation in basic science journals had an upward trend during the 1991-2000 period ($P<0.001$) but remained flat during 2001-2010 ($P=0.177$). In contrast, the trend of Japanese representation in general medicine journals remained flat during the period of 1991-2000 ($P=0.273$) but exhibited a marginally downward trend during 2001-2010 ($P=0.073$). **CONCLUSIONS:** Overall, the Japanese representation in top general medicine journals has remained negligible and unchanged over the last two decades. Representation in basic science journals remained unchanged during the time period of 2001-2010, although it had shown an upward trend during the years 1991-2000. Interventional measures are needed to address these trends.
