APPENDIX TO AAU TECHNICAL REPORT ON BREAKWATER SAFETY LEVELS

13.3.16

Appendix A1 Background note containing assumptions and formulae applied in optimizations analyses of rock and cube armoured rubble mound breakwaters

1. Objective

To identify the optimum cost safety levels for rubble mound breakwater armored by rock and Cubes in shallow, moderate and deep water.

The study comprises the influence of the following parameters on the minimum cost safety level:

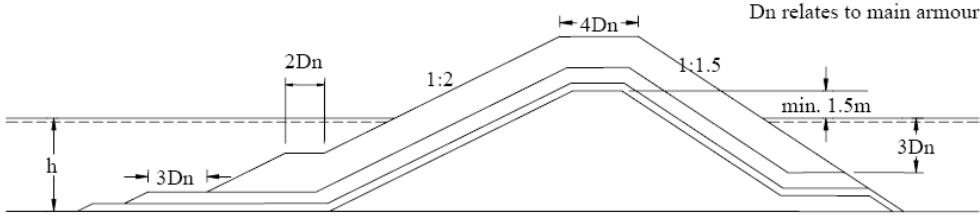

- Real interest rate
- Service lifetime of the breakwater
- Downtime costs due to malfunction of the breakwaters
- Repair policy
- Damage accumulation

2. Procedure in numerical simulations for identification of minimum cost safety levels

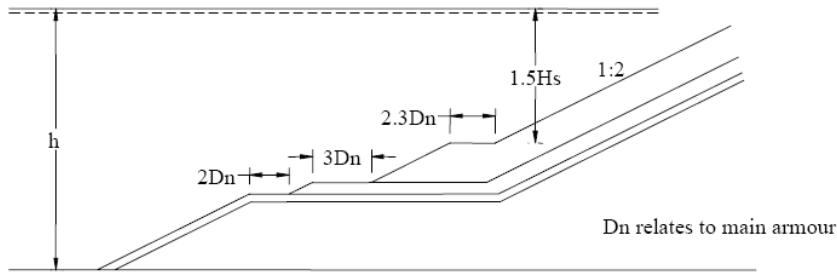

- 1) Select type of breakwater
- 2) Design geometries of the structure corresponding to the chosen H_s^T value (deterministic design is sufficient)
- 3) For each structure geometry calculate construction costs
- 4) Define repair policy and related cost of repair
- 5) Define down-time costs related to damage levels
- 6) Define a model for accumulation of damage
- 7) For each structure geometry use stochastic models for wave climate and structure response (damage) in Monte Carlo simulation of occurrence of damages within service life time (uncertainties included)
- 8) Calculate for each structure geometry the total capitalized costs for each simulation. Calculate the mean value and the related safety levels corresponding to defined design limit states
- 9) Identify the structure safety level corresponding to the minimum total costs

3. General assumptions

Cross sections

$$\text{Shallow water cross section: } h < 1.5H_s + 2.7D_n$$

$$\text{Deep water cross section: } h \geq 1.5H_s + 2.7D_n$$

Fig. 1. Shallow and deep water cross sections

Volume per meter for shallow water conditions

$$V_{\text{armour}} = a D_n [0.5 a D_n + 2D_n + \beta \sqrt{1+n_1^2} + 4D_n] + 1/2 n_2 [(R_c + 3D_n)^2 - (R_c + 3D_n - aD_n)^2]$$

$$V_{\text{filter1}} = b D_n [(0.5b + 3 + a + 2)D_n + \beta \sqrt{1+n_1^2} + 4D_n + (R_c + 3D_n - aD_n) \sqrt{1+n_2^2} + 3D_n n_2]$$

$$V_{\text{filter2}} = \frac{c}{b} V_{\text{filter1}} + 2c D_n^2 + c D_n \sqrt{(h - (3+b)D_n)^2 (1+n_2^2)}$$

$$V_{\text{core}} = 0.5(n_1 + n_2) \beta^2 + 4D_n \beta + (h - (3+b+c)D_n)(a+b) \sqrt{1+n_2^2} D_n$$

where $\beta = R_c + D - (a+b+c)D_n$, front slop $1:n_1$, back slop $1:n_2$, armour, first filter, and second filter layers heights are aD_n, bD_n, cD_n , respectively. When $D_n < 1.75m$ then filter 2 is omitted, i.e. filter 2 is substituted by core material. The total volume of the core is then, $V_{\text{filter2}} + V_{\text{core}}$

Volume per meter for deep water conditions

$$V_{\text{armour}} = a D_n [0.5 a D_n + 2 D_n + \beta \sqrt{1+n_1^2} + 4 D_n] + 1/2 n_2 [(R_c + 3 D_n)^2 - (R_c + 3 D_n - a D_n)^2]$$

$$V_{\text{filter1}} = b D_n [(0.5 b + 3 + a + 2) D_n + \beta \sqrt{1+n_1^2} + 4 D_n + (R_c + 3 D_n - a D_n) \sqrt{1+n_2^2} + 3 D_n n_2]$$

$$V_{\text{filter2}} = V_{\text{filter2}}^{\text{shallow}} + 1.5[h - 1.5 H_s - (1.7 + b + c) D_n] c D_n$$

$$V_{\text{core}} = V_{\text{core}}^{\text{shallow}} + [(12.4 + b) D_n + (1 - n_1) 0.5 l] l$$

where $\beta = R_c + 1.5 H_s$, $l = h - 1.5 H_s - (1.7 + b + c) D_n$ and $\beta = h + R_c - (a + b + c) D_n$ in calculation of $V_{\text{core}}^{\text{shallow}}$

Filter 1 (Quarry rock)

$$\text{Mass } M_{F1} = \frac{M_A}{15} \sim \frac{M_A}{7} \cong 0.1 M_A \quad \text{Mass density, } \rho_s = 2.65 t/m^3$$

$$D_{n50} = \left(\frac{M_{F1}}{\rho_s} \right)^{1/3}$$

Filter 2 (Quarry rock)

$$\text{Mass } M_{F2} = 0.1 M_{F1} \cong 0.01 M_A \quad \text{Mass density, } \rho_s = 2.65 t/m^3$$

$$D_{n50} = \left(\frac{M_{F2}}{\rho_s} \right)^{1/3}$$

Free board R_C

R_C is determined such that the transmitted wave height due to overtopping in a sea with return period equal to structure life time T_L is 0.50 m.

Minimum R_C is $1.50m + t_A + t_{F1} + t_{F2} = 1.50m + 1.963H$ due to construction road on top of core.

Case 1, rock armour: $D_{n50} = 0.312 H_s$, $s_{\text{om}} = 0.03$, $s_{\text{op}} = 0.02$

Wave transmission formula by van der Meer and d'Angremond (1991) for Rock armoured Low-crested, submerged, and reef breakwaters

$$C_t = \frac{H_{s,t}}{H_s} = (0.031 \frac{H_s}{D_{n50}} - 0.24) \frac{R_c}{D_{n50}} + b \quad (0.075 \leq C_t \leq 0.75 \text{ for conventional structures})$$

where $b = -5.42 s_{op} + 0.0323 \frac{H_s}{D_{n50}} - 0.0017 \left(\frac{B}{D_{n50}} \right)^{1.84} + 0.51$

$$R_C = \max \begin{cases} 1.071 H_s^{T_L} - 2.217 H_{s,t} (m), \min R_C & \text{for } s_{op} = 0.02 \\ 0.831 H_s^{T_L} - 2.217 H_{s,t} (m), \min R_C & \text{for } s_{op} = 0.04 \end{cases}$$

Case 2 and 3, cube armour: $D_{n50} = 0.28 H_s$, $s_{om} = 0.025$, $s_{op} = 0.02 (\sim 0.016)$

d'Angremond et al.(1996) suggested this formula for $B / H_{s,i} < 8$

$$C_t = -0.40 \frac{R_c}{H_{s,i}} + 0.64 \left(\frac{B}{H_{s,i}} \right)^{-0.31} (1 - e^{-0.50 \xi_{op}}) \quad (0.075 \leq C_t \leq 0.8)$$

where

$$\xi = \tan \alpha / \sqrt{s_{op}}, \tan \alpha = 0.5$$

$$C_t = \frac{H_{s,t}}{H_{s,i}} = -0.40 \frac{R_c}{H_{s,i}} + \begin{cases} 0.502, \text{ for } s_{op} = 0.02 \\ 0.432, \text{ for } s_{op} = 0.04 \end{cases}$$

Therefore,

$$R_C = \max \begin{cases} 1.26 H_s^{T_L} - 2.50 H_{s,t} (m), \min R_C & \text{for } s_{op} = 0.02 \\ 1.08 H_s^{T_L} - 2.50 H_{s,t} (m), \min R_C & \text{for } s_{op} = 0.04 \end{cases}$$

Note that the freeboards R_c in all Cases are determined by the set minimum level of +1.5 m for the top of the core material to be used as construction road.

Limit state and repair policy

Repairs are assumed to take place immediately after the damage limit for repair is exceed.

Table 1. Repair policy as function of damage levels

| Damage levels | S (rock) | N_{od} (cubes) | Estimated D | Repair policy |
|--|------------|------------------|---------------|----------------------------------|
| Initial | 2 | 0 | 2 % | No repair |
| Serviceability (minor damage, only to armor) | 5 | 0.8 | 5 % | Repair armor |
| Repairable (major damage, armor + filter 1) | 8 | 2.0 | 15 % | Repair armor + filter 1 |
| Ultimate (failure) | 13 | 3.0 | 30 % | Repair armor + filter 1 and 2 |

* D is the relative number of displaced units (US Army, 2006)

Linear regression is applied to evaluate the damage levels between serviceability damage level and ultimate damage level. These equations are the relationship between S or N_{od} and D .

$$D = 0.0311S - 0.1031 \quad (R = 0.999)$$

$$D = 0.1126N_{od} - 0.0511 \quad (R = 0.99)$$

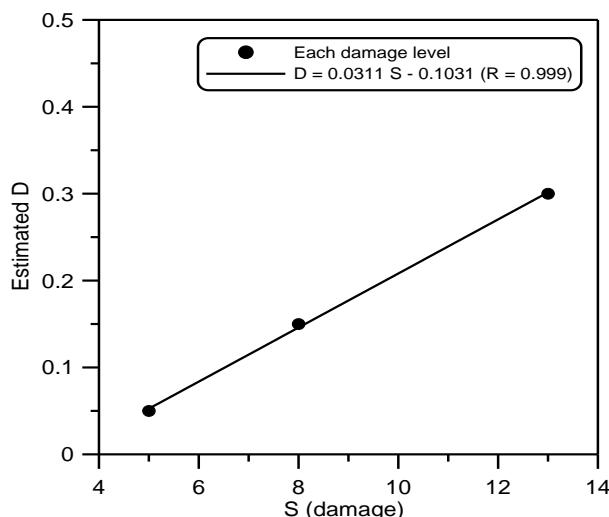

Fig. 2. The relationship between D and S for rock

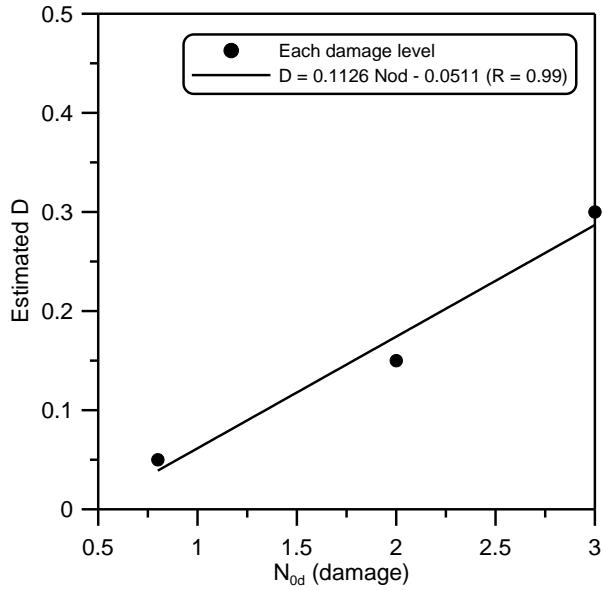

Fig. 3. The relationship between D and N_{od} for cubes

Costs of repair

D = 5 %

Cost of repair of minor damage, $C_{R1} = (1+K)DC_{I,armor}R$,

in which $C_{I,armor}$ is the initial construction cost of the main armor layer, $R=3.0$ is a factor signifying high cost of repair, and $K=0.3$ is a factor signifying mobilization costs. The chosen values of R and K are estimates, but can vary considerably from case to case.

D = 15 %

Cost of repair of major damage, $C_{R2} = (C_{I,armor} + C_{I,filter1} + KC_{I,armor})DR$, where $C_{I,filter1}$ is the initial construction cost of filter 1.

D = 30 %

Cost of repair after a failure, $C_{R3} = (C_{I,armor} + C_{I,filter1} + C_{I,filter2} + KC_{I,armor})DR$, where $C_{I,filter2}$ is the initial construction cost of filter 2.

Downtime costs

When $D \geq 15\%$ is added downtime costs given as 200,000 EUR/day in 3 months. The relative short duration of 3 months is justified only for outer breakwaters with no berths

along the harbour side of the structure. The downtime costs are related to 1 km length of breakwater.

Structure length

Calculations performed for a structure length of 1 km and damage is assumed to take place over the whole length of the breakwater.

Stability formulae

Rock armour (plunging wave, $\xi_m < \xi_{mc}$, $P=0.4$, $N_z = 1000$, $\tan \alpha = 0.5$)

$$N_s = \frac{H_s}{\Delta D_n} = 6.2 S^{0.2} P^{0.18} N_z^{-0.1} s_{om}^{0.25} \tan \alpha^{-0.5} \quad \text{Van der Meer (1988a)}$$

Cube armour

$$N_s = \frac{H_s}{\Delta D_n} = \left(6.7 \frac{N_{od}^{0.4}}{N_z^{0.3}} + 1.0 \right) s_{om}^{-0.1} \quad \text{Van der Meer (1988b)}$$

This formula is valid for the slope of structure 1:1.5 so the formula has been modified by Hudson equation analogy to cover the slope of structure 1:2.

$$N_s = \frac{H_s}{\Delta D_n} = \left(\frac{2}{1.5} \right)^{1/3} \left(6.7 \frac{N_{od}^{0.4}}{N_z^{0.3}} + 1.0 \right) s_{om}^{-0.1}$$

Damage accumulation model

The damage was accumulated until to be damaged the serviceability, repair, or ultimate limit state. If the damage was occurred, the structures were repaired immediately. We performed the two cases which are with and without considering damage accumulation model. Regardless of the damage accumulation, the number of waves in one storm was generated in 1000 waves. The damage that is less than a damage of serviceability limit state is neglected in case of no damage accumulation. After that, we can only explain the damage accumulation model. There are several damage accumulation models. Now, the modified Melby and Kobayashi's (1998) model was decided in this calculation.

$$S = \left(\frac{H_s}{6.2 P^{0.18} s_{om}^{0.25} \tan \alpha^{-0.5} \Delta D_{n50}} \right)^5 N_z^{0.5}$$

This equation can be used to calculate the damage level S due to the incident waves with constant H_s starting from $S=0$ at $t=0$ ($N_z=0$). To calculate the cumulative damage level in real situations of H_s and N_z , the damage level S_i was expressed as

$$S_i = S_{i-1} + \left(\frac{H_{s,i}}{6.2 P^{0.18} s_{om}^{0.25} \tan \alpha^{-0.5} \Delta D_{n50}} \right)^5 (N_{z,i}^{0.5} - N_{z,i-1}^{0.5})$$

where S_{i-1} = known damage level at $N_z = N_{z,i-1}$. We assumed that each storm was generated in the $N_z = 1000$.

For the Cubes, the relative damage level $N_{od,i}$ can expressed as

$$N_{od,i} = N_{od,i-1} + \left(\frac{\left(\frac{1.5}{2} \right)^{1/3} \frac{H_{s,i}}{\Delta D_n} s_{0m}^{0.1} - 1.0}{6.7} \right)^{2.5} (N_{z,i}^{0.75} - N_{z,i-1}^{0.75})$$

4. Formulation of total cost functions

The optimum design is determined using the optimization problem formulated assuming no rebuilding in case of failure. No benefits, costs related to loss of life and cost of decommissioning at the end of service lifetime are included.

$$\min_T C(T) = C_I(T) + \sum_{t=1}^{T_L} \{C_{R_1}(T)P_{R_1}(t) + C_{R_2}(T)P_{R_2}(t) + C_F(T)P_F(t)\} \frac{1}{(1+r)^t}$$

where

T return period used for deterministic design

T_L design life time

$C_I(T)$ initial costs (building costs)

$C_{R_1}(T)$ cost of repair for minor damage

$P_{R_1}(T)$ probability of minor damage in year t

$C_{R_2}(T)$ cost of repair for major damage

$P_{R_2}(T)$ probability of major damage in year t

$C_F(T)$ cost of failure including downtime costs

$P_F(T)$ probability of failure in year t

r real rate of interest

5. Characteristics of design variables in stochastic model

Rock armour, slope 1:2

The Van der Meer formula (1988a) is used. The limit state equation is written:

$$g = S - \left(\frac{X_{H_s} H_s}{Z 6.2 P^{0.18} s_{om}^{0.25} \tan \alpha^{-0.5} \Delta D_{n50}} \right)^5 N_z^{0.5}$$

where the parameters are describes in Table 2.

Cubes, slope 1:2

The van der Meer formula is used, but modified to slope 1:2. The limit state equation is written:

$$g = N_{0d} - \left(\frac{\frac{1}{Z} \left(\frac{1.5}{2} \right)^{1/3} \frac{X_{H_s} H_s}{\Delta D_n} s_{0m}^{0.1} - 1.0}{6.7} \right)^{2.5} N_z^{0.75}$$

where the parameters are describes in Table 3.

Table 2. Parameters of design variables for rock armour, slope 1:2

| Variables | Description | Distribution | Expected value | Standard deviation |
|-----------|--|------------------------|----------------|--------------------|
| S | critical damage level | see Table 1 | | |
| H_s | annual maximum significant wave height | Weibull | Various | |
| X_{H_s} | model uncertainty wave height | Normal | 1 | 0.1 |
| Z | model uncertainty | Normal | 1 | 0.0645 |
| Δ | model parameter | Normal | 1.57 | 0.06 |
| N_z | Number of waves in one storm | 1000 | | |
| s_{om} | wave steepness | Normal | 0.030 | 0.006 |
| D_n | armor size | Normal | $0.35H_s^T$ | COV=0.05 |
| H_s^T | design wave height with return period T years | | | |
| ρ | armor density | 2.65 ton/m^3 | | |

Table 3. Parameters of design variables for cubes, slope 1:2

| Variables | Description | Distribution | Expected value | Standard deviation |
|-----------|--|------------------------|----------------|--------------------|
| N_{od} | critical damage level | See Table 1 | | |
| H_s | annual maximum significant wave height | Weibull | Various | |
| X_{H_s} | model uncertainty wave height | Normal | 1 | 0.1 |
| Z | model uncertainty | Normal | 1 | 0.1 |
| Δ | model parameter | Normal | 1.33 | 0.03 |
| N_z | Number of waves in one storm | 1000 | | |
| s_{om} | wave steepness | Normal | 0.025 | 0.005 |
| D_n | armor size | Normal | $0.28H_s^T$ | COV=0.01 |
| H_s^T | design wave height with return period T years | | | |
| ρ | armor density | 2.40 ton/m^3 | | |

6. Case studies

Table 4. Case study data

| Case | Water depth | Armor density | Wave climate | Stability formula | Built-in unit prices core/filter 2/filter 1/armor in EURO/ m ³ |
|------|-------------|-----------------------|--------------|----------------------|---|
| 1 | 10 m | 2.65 t/m ³ | Follonica | van der Meer (1988a) | 10/ 16/ 20/ 40 |
| 2 | 15 m | 2.40 t/m ³ | Follonica | van der Meer (1988b) | 10/ 16/ 20/ 40 |
| 3 | 30 m | 2.40 t/m ³ | Sines | van der Meer (1988b) | 5/ 10/ 25/ 35 |

There is limitation of wave height in the Case 1 due to limited water depth. We assumed that the bottom slope is 1: 50 – 1:100 so that the maximum significant wave height will be $0.55h$.

Table 5. Distribution parameters for H_s - data samples (PIANC, 1992)

| Site | Total number | Average number per year | Weibull | | Exp. |
|-----------|--------------|-------------------------|----------|---------|--------|
| | N | λ | α | β | H_s' |
| Follonica | 46 | 5.94 | 1.14 | 0.58 | 2.69 |
| Sines | 15 | 1.25 | 1.78 | 2.53 | 7.10 |

Weibull distributed annual maximum wave height

$$F(H_s) = \left[1 - \exp \left(- \left(\frac{H_s - H_s'}{\beta} \right)^\alpha \right) \right]^\lambda$$

T -year maximum wave height

$$[F(H_s)]^T = F(H_s)^T = \left[1 - \exp \left(- \left(\frac{H_s - H_s'}{\beta} \right)^\alpha \right) \right]^{\lambda T}$$

Deterministic design

Rock armour

$$P=0.4, N_z=1000, \cot \alpha=2, \Delta=1.57,$$

$$S = \left(\frac{H_s}{5.84 D_{n50} s_{om}^{0.25}} \right)^5 = 4 \quad (\xi_m < \xi_{mc})$$

$$\frac{H_s}{D_{n50}} = 4^{0.2} 5.84 s_{om}^{0.25} = 7.706 s_{om}^{0.25}$$

$$D_{n50} = 0.312 H_s \quad (s_{om} = 0.03)$$

The stochastic parameters are that wave steepness is $\bar{s}_{om} = 0.030$ and the standard deviation is **0.006**. Therefore, the mean value is used in the calculation of cost optimization. But, the relationship between the significant wave height and diameter of rock armour is not changed due to the conservative deterministic design.

$$D_n = 0.312 H_s^T \quad (\bar{s}_{om} = 0.030)$$

where T is the return period of wave height. The return period is used from 5 years to 1000 years (i.e. 5, 10, 25, 50, 100, 200, 400, 500, 1000) in the cost optimization.

Cube armour

$$N_z = 1000, \cot \alpha = 2, \Delta = 1.33,$$

$$N_{0d} = \left(\frac{\left(\frac{1.5}{2} \right)^{1/3} \frac{H_s}{\Delta D_n} s_{0m}^{0.1} - 1.0}{6.7} \right)^{2.5} N_z^{0.75} = 0.8$$

$$\frac{H_s}{D_n} = 1.33 \cdot 1.1 \left(6.7 \frac{0.8^{0.4}}{1000^{0.3}} + 1 \right) s_{om}^{-0.1} = 2.592 s_{om}^{-0.1}$$

$$D_n = 0.27 H_s \quad (\bar{s}_{om} = 0.025)$$

Mass density of sea water and concrete armour units ranges from 1.03 to 1.025 and from 2.3 to 2.4 respectively. Therefore, in this calculation of cost optimization for cubes armour unit, the relationship between the significant wave height and diameter of cubes is expressed as

$$D_n = 0.28 H_s^T \quad (\bar{s}_{om} = 0.025)$$

where T is the return period of wave height. The return period is used from 5 years to 1000 years (i.e. 5, 10, 25, 50, 100, 200, 400, 500, 1000) in the cost optimization.

Appendix B1 Background note containing assumptions and formulae applied in optimizations analyses of berm breakwaters

1. Objective

To identify the safety levels corresponding to minimum lifetime costs of berm breakwaters. The analyses are performed solely for the Icelandic type berm breakwater.

2. Procedure in numerical simulations

The procedure is the same as given for rock and cube armoured breakwaters, cf. Annex A1.

3. General assumptions

Failure modes and cross section

The berm of the reshaping type is initially unstable but will reshape during normal and more severe wave conditions into more stable gentle s-curved slopes which change/adjust to the various sea states. Oblique waves over a certain threshold cause transport of stones along the structure which can cause problems in terms of lack of stones in some sections, Van der Meer and Veldman (1992) and Tomasicchio et al. (2013). The structures are designed for a maximum reshaping/recession of the berm in the design storm.

The non-reshaping type is designed for practically no erosion of the berm under more severe wave actions. Only for design storm conditions is some limited recession of the berm allowed. Before recession of the berm takes place, erosion of the front slope might take place if the berm level is

more than approximately half a significant wave height over SWL, see Sigurdarson and Van der Meer (2011) and Burcharth (2013).

The two failure modes recession R_{ec} and front slope erosion area A_e are illustrated in Fig. 1.

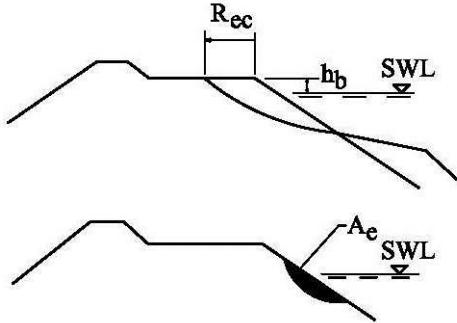

Fig. 1. Definition of the failure modes recession and front erosion

The recession R_{ec} of the berm shoulder shown in Fig. 1 is the only damage parameter used in the analyses. The parameterized cross section applied in the analyses is shown in Fig. 2. Three classes of stones are considered although more classes are used in some berm breakwaters. This however has no importance because the damage calculated in the present analyses is related only to the recession of the berm and therefore only affecting the Class 1 berm stones. This on the other hand necessitates that the berm of Class 1 stone must be so deep that the eroded surface does not extend to the under-laying Class 2 stones. The nominal diameter D_{n50} of the three stone classes is for simplicity denoted D_1 , D_2 and D_3 .

If the recession exceeds the berm width the crest will be eroded and eventually large overtopping will erode the rear slope.

$$\text{Slopes 1:1.5 , } R_c = 0.35 H_s S_{op}^{-1/3}, \quad h' = \min[2.5 H_s, h - 0.3D_1], \quad D_2 = 0.8 D_1$$

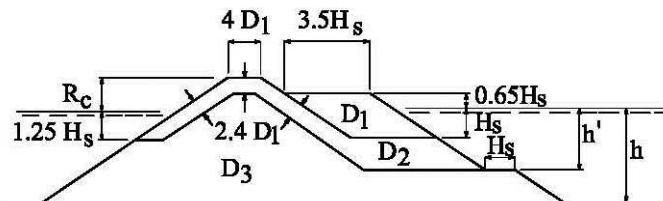

Fig.2. Parameterized Icelandic type berm breakwater. All slopes are 1:1.5

Volumes

Cross sectional volumes (m^3/m) V_1 , V_2 , and V_3 refer to stone classes D_1 , D_2 and D_3 . D_2 is set to 0.8 D_1 .

$$V_1 = 11.69 * H_s * D_1 - 7.21 * D_1^2 + 5.775 * H_s^2 - 11.69 * H_s * D_1 + 7.21 * D_1^2$$

$$V_2 = (2.75 * H_s + 0.35 H_s * S_{op}^{-1/3}) * 2.16 * D_1$$

$$\begin{aligned}
& + (0.525 * H_s * s_{op}^{-1/3} + 3.68 * D_1 - 0.375 * H_s) * (0.175 * H_s * s_{op}^{-1/3} - 0.125 * H_s) \\
& + (0.35 * H_s * s_{op}^{-1/3})^2 * 0.75 - 0.0625 * H_s^2 \\
& + (3.5 * H_s - 3.6 * D_1) * (0.65 H_s - 2 * D_1) \\
& + [H_s * (0.525 * s_{op}^{-1/3} + 3) - 0.25 h'] * h' - 2.34 * H_s * D_1 - (5.775 * H_s^2 - 11.69 * H_s * D_1 + \\
& 7.21 * D_1^2)
\end{aligned}$$

$$\begin{aligned}
V_3 = & (4.5 * H_s + 4 * D_1 + 1.5 * h' + 1.5 * h + 1.05 * H_s * s_{op}^{-1/3}) * (h - h') + 4.32 D_1 * (h' - 1.25 H_s) \\
& + (1.75 * h' + 0.0625 * H_s + 0.525 * H_s * s_{op}^{-1/3} - 0.33 D_1) * (h' + 0.25 * H_s) - 0.25 * (h' + 0.25 * H_s)
\end{aligned}$$

Limit states and repair policy

Table 1 explains the applied limit state damage definitions and the related repair strategy.

Table 1. Limit state performance and related repair strategy

| Limit state | Damage definition | Repair strategy |
|-------------|--|--|
| SLS | Recession reaches half of the berm width | Eroded volume replaced |
| RLS | Some erosion of crest and rear side | Eroded volume replaced plus extra volume |
| ULS | Recession exceeds the width of the berm | Eroded volume replaced |

The repair strategy is in the cost optimization analyses related to recession as well as to the damage to the rear slope. As to the rear side damage Van der Meer and Veldman (1992) suggested on the basis of model tests with two different breakwater designs the following limits for rear side damage, also given in the PIANC WG 40 report (2003):

$$s_{op} R_{ec} / H_s = 0.25 \quad \text{Start of damage}$$

$$s_{op} R_{ec} / H_s = 0.21 \quad \text{Moderate damage}$$

$$s_{op} R_{ec} / H_s = 0.17 \quad \text{Severe damage}$$

Inserting $R_{ec} = 0.35 H_s s_{op}^{-1/3}$ the criteria simplifies to ratios of H_s^y / H_s in which H_s^y is the y-years design return period H_s -value. This ratio is used in the criteria for repairs and failure given below.

Front slope erosion is not included as repairs are generally not necessary.

R_{ec} is calculated for each storm.

If in storm n+1 $R_{ec}^{n+1} > R_{ec}^n$ take R_{ec}^{n+1} , otherwise disregard R_{ec}^{n+1} .

R_{ec} is calculated for each storm. If in storm n+1 $R_{ec}^{n+1} > R_{ec}^n$ then R_{ec}^{n+1} is used, otherwise R_{ec}^{n+1} is disregarded

Repair takes place:

SLS R1. When total recession in storm n is larger than half of the initial berm width, i.e.

$$R_{ec} \geq 1.75 H_s^y$$

then the eroded volume of berm is taken as $V_r^b = R_{ec} \cdot H_s^y$, and the related costs

$$C_r^b = 1.5 U_{cl} \cdot V_r^b$$

RLS R2. If rear side and crest are eroded in a storm, i.e. when for unchanged S_{op} ,

$$1.44 H_s^y \leq H_s \leq 2.12 H_s^y$$

then the eroded + extra added volume is taken as $V_r^c = 8 H_s^y \cdot D_l$, and the related costs

$$C_r^c = 1.5 U_{cl} \cdot V_r^c$$

ULS Failure FL occurs if

$$R_{ec}^{n+1} \geq 3.5 H_s^y$$

or $H_s > 2.12 H_s^y$ (for unchanged S_{op})

In both cases is the volume to replace taken as $V_f = V_1 + 0.8 V_2$, and the related costs are taken as $C_f = 2.5 C_{cl} \cdot V_f$. V_1 and V_2 are the volumes of the Class 1 and the Class 2 stones, respectively.

Downtime costs occur only in case of failure.

More relevant criteria for R2 and FL (based on overtopping discharge and rock size) than those given by the ratios of H_s^y/H_s have been investigated, but no convergence could be found in the scattered readily available information. More systematic model test results are needed in order to improve the criteria.

Costs

The quarry rock built-in unit prices are based on bids for the construction of the Sirevåg berm breakwater in Norway, regulated to the 2007 cost level, Sigurdarson et al. (2007). In the optimization analyses only the relative costs between the stone classes are important, not the actual

costs which vary from year to year. Table 2 gives the built-in unit prices for the various sizes of stones in EURO per m³ bulk volume, i.e. stones plus voids.

Table 2. Bulk volume built-in unit prices for stones

| Mean mass (t) | Unit price (EUR/m ³) |
|---------------|----------------------------------|
| 0.1 | 10.1 |
| 0.6 | 14.7 |
| 2 | 15.0 |
| 6 | 18.9 |
| 13.3 | 23.5 |
| 23.3 | 27.0 |

To be applied in the optimization simulations are fitted the cost function shown in Fig. 3.

Stone mass (t)

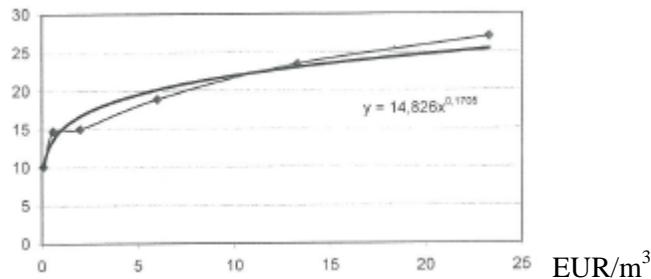

Fig.3. Built-in unit price cost function for stones

The built-in unit prices for stone Classes I and II are determined from the equation given in Fig. 3. The applied bulk volume built-in unit price for stone Class III (core material) is set to 10.1 EUR/m³.

For SLS and RLS repairs the unit prices are increased by 50%. For ULS repair the unit price is increased by 150%.

Downtime costs are set to 18.000 EURO/m breakwater for 1 km breakwater. Downtime costs are included only in case of failure

Construction costs (initial costs) of structure is given as $C_i = U_{c1} V_1 + U_{c2} V_2 + U_{c3} V_3$, where U are unit prices for the stone classes.

Recession formulae

Several formulae for estimation of the berm recession R_{ec} have been applied in the analyses.

Sigurdarson et al. (2007)

$$R_{ec} / D_1 = 0.037 (H_o T_o - S_c)^{1.34}, \quad R_{ec} / D_1 = 0 \text{ for } H_o T_o < S_c$$

(1)

with $\mu(S_c) = 20$ and $\sigma(S_c) = 20$, both assumed Normally distributed

$$H_o = \frac{H_s}{\Delta D_1}$$

$$T_o = T_m \left(\frac{g}{D_1} \right)^{0.5} = 0.8 T_p \left(\frac{g}{D_1} \right)^{0.5} = 0.8 \left(\frac{2\pi H_s}{g s_{op}} \right)^{0.5} \left(\frac{g}{D_1} \right)^{0.5} = 0.8 \left(\frac{2\pi H_s}{s_{op} D_1} \right)^{0.5}$$

The only input parameters are wave height H_s , wave period T_m , rock and water mass densities, ρ_s and ρ_w , and D_1 . The cross section geometrical parameters such as berm width, berm height, water depth and front slope are not included. D_1 is the only geometrical parameter.

The formula is fitted to model tests with berm breakwaters with the berm crest level some metres above SWL. The data set contains values of R_{ec}/D_{n50} up to 33 and $H_o T_o$ up to 170. The scatter of the data is very large as can be seen from the standard deviation of S_c .

Sigurdarson et al. (2008)

$$R_{ec} / D_1 = 0.032 (H_o T_{op} - S_c)^{1.5} \quad R_{ec} / D_1 = 0 \text{ for } H_o T_o < S_c \quad H_o T_{op} < 70$$

(2)

$\mu(S_c) = 35$ and $\sigma(S_c) = 5$, both assumed Normally distributed

The formula is calibrated to be valid for the Icelandic type of berm breakwaters with front slope 1:1.5 and

$R_{ec} / D_1 < 5$. In the data set maximum H_o is 2.8 and maximum $H_o T_{op}$ is 65.

Sigurdarson and Van der Meer (2013)

$$Rec_{av}/D1 = 1.6 (H_o - 1)^{2.5} \quad Rec_{av}/D1 = 0 \text{ for } H_o < 1$$

(3)

The formula is fitted to data with maximum $H_o = 3$ and $R_{ec}/D_{n50} < 14$. The formula is a simplification of the formula (2). No scatter is given, but in the simulations an estimated standard deviation of $\sigma = 0.3$ is used. This might be on the unsafe side as the scatter is large, partly because the formula is fitted to model tests in which the front slope in the initial profiles vary between 1: 1.3 and 1:1.5. A steeper front slope gives a larger Rec although the S-profile remains the same.

A more precise formula for the estimation of R_{ec} is given by Lykke Andersen and Burcharth (2010), updated in Lykke Andersen et al. (2014). The formula is fitted to all available data for mass berm breakwaters and Icelandic type berm breakwaters. Besides D_1 it contains the following important geometrical parameters: Water depth h , height of berm h_b above SWL, front slope angle α , angle of

incidence β of the waves. The other parameters are significant wave height H_s , wave period and wave steepness, number of waves N , and mass density of rock and water.

Applied to the berm breakwater geometry, shown in Fig. 2, the formula simplifies for perpendicular waves to

$$\frac{Rec}{D_{n50}} = A \left[\frac{2.2 \cdot h^* - 1.2 \cdot h_s}{h^* - h_b} \cdot f_{H_0} \cdot f_N - \frac{0.225(h^* - h_b)}{D1} \right] + B \quad (4)$$

$$\mu(A) = 1 \quad , \quad \sigma(A) = 0.15 \quad \mu(B) = 0 \quad , \quad \sigma(B) = 1.4, \quad \text{Normally distributed}$$

$$H_0 = \frac{H_{m0}}{\Delta \cdot D1}$$

$$T_0 = \sqrt{\frac{g}{D_{n50}}} \cdot T_{0,1}$$

$$f_{H_0} = \begin{cases} \min \left\{ -4.7 \cdot 10^{-5} (H_0 \sqrt{T_0})^4 + 1.6 \cdot 10^{-3} (H_0 \sqrt{T_0})^3 + 2.2 \cdot 10^{-2} (H_0 \sqrt{T_0})^2 + 3.8 \cdot 10^{-2} H_0 \sqrt{T_0} \right. \\ \left. 0.429 \cdot H_0 \sqrt{T_0} + 12.0 \right\} \end{cases}$$

$$h^* = \min \left(h ; \sqrt{4.44 f_{H_0} \cdot f_N \cdot D1 \cdot [1.2h_s - 2.2h_b] + h_b^2} \right)$$

$$h_b = -0.65 \cdot H_{m0}$$

$$h_s = \begin{cases} \min \left\{ 0.65 \cdot H_{m0} \cdot s_{0m}^{-0.3} \cdot f_N \right\} \\ h \end{cases}$$

$$f_N = \left(\frac{N}{3000} \right)^{\varphi} \quad \varphi = \begin{cases} 0.30 & \text{for } H_0 \sqrt{T_0} \leq 24 \\ 0.64 - 0.0143 H_0 \sqrt{T_0} & \text{for } 24 > H_0 \sqrt{T_0} > 40 \\ 0.07 & \text{for } H_0 \sqrt{T_0} \geq 40 \end{cases}$$

The formulae (1), (2), (3) and (4) predict quite different recession especially for high values of H_o . However, because the formulae 2 and 3 are valid only for $H_o <$ app. 2.8, a comparison should be restricted to the lower H_o values.

Moreover, formula (4) predicts much less recession than the other formulae. As a result, formula (4) gives economical optimum designs with smaller rock sizes than the other formulae, cf. the tables with optimization results given in Appendix B2.

A significant difference between the formulae is that as opposed to formula (4), the formulae (1), (2) and (3) do not contain any parameter signifying the water depth. The validity of the formulae in shallow water is therefore unknown. However, an indication of the importance of the water depth is

seen from the simulations in that for shallow water conditions the formulae (1), (2) and (3) predict almost the same optimum design conditions in terms of H_o and D1 whereas formula (4), which includes water depth, predicts larger optimum H_o values and smaller D1 values and also lower lifetime costs. In deep water conditions all formulae predict almost identical optimum design conditions but formula (4) predicts lower lifetime costs.

4. Formulation of total cost functions

See Appendix A1, Chapter 4.

5. Characteristics of design variables in stochastic modelling

As to wave modelling see Appendix A1. Data for the other variables are given in Chapter 3 section on recession formulae.

Case studies

Cost optimization analyses are made for structures in 11 m and 20 m water depths. Table 3 gives an overview of the case study simulations. In each case study are identified the service lifetime costs of the berm breakwaters cross sections designed deterministically for H_s values corresponding to return periods $T = 5, 25, 50, 100, 200$, and 400 years, and $H_o = N_s$ - values of 1.8, 2.0, 2.4, 2.8 and 3.2.

The deep water wave steepness is set to $s_{op} = 0.035$ ($s_{om} = 0.0484$) and the mass density of the stones to 2.70 t/m³. Interest rate including inflation is 5% p.a. Structure service lifetime is 50 years. Downtime costs are set to 18.000 EURO/m breakwater for 1 km breakwater.

The raw data sheets for the simulations are given in Appendix B2.

Table 3. Case studies

| Case study | Water depth (m) | Waves (see Table 11.1) | Formula |
|------------|--------------------|---------------------------|------------------------------|

Appendix B2 Raw data sheets for the optimizations analyses of berm breakwaters

In the tables the following notation is used:

$HSY = H_s^{T(\text{years})}$, $HOD = H_o$, $D1 = D1$, $CR1 = \text{costs of R1}$, $CR2 = \text{costs of R2}$, $CFL = \text{costs of FL}$, $CTOT = \text{total lifetime costs}$. $PR1$, $PR2$ and $PFL = \text{Probability of R1, R2 and FL within 50 years lifetime of the structure, respectively}$. The lines correspond to wave return periods $T = 5, 25, 50, 100, 200, 400$ and 1000 years.

Appendix C1 Background note containing assumptions and formulae applied in optimizations analyses of Accropode armoured breakwaters

1. Objective

To identify the minimum cost safety levels for rubble mound breakwaters in shallow, moderate and deep water armoured with Accropodes, and to investigate the partial safety factors corresponding to the minimum costs.

The study comprises the influence of the following parameters on the minimum cost safety level:

- Real interest rate
- Service lifetime of the breakwater
- Downtime costs due to malfunction of the breakwaters
- Repair policy
- Damage accumulation

2. Procedure in numerical simulations for identification of minimum cost safety levels

As given in Appendix A1 for conventional rubble mound breakwaters.

3. General assumptions

Cross section

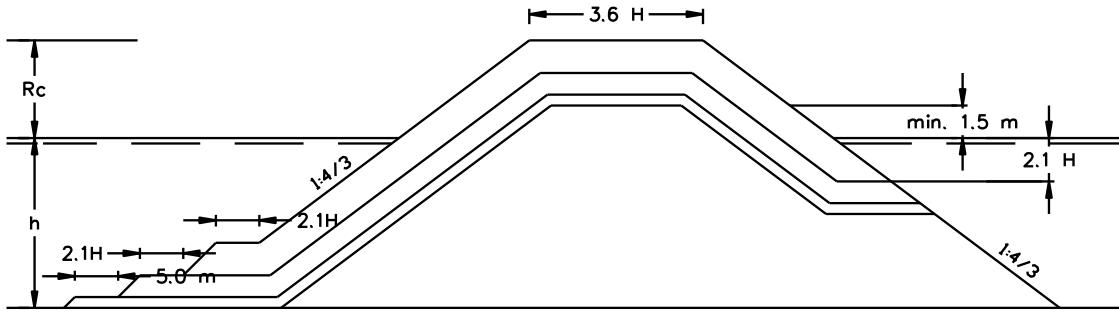

Fig. 1. Typical cross-section without superstructure for Accropode-armoured breakwater

Accropode data:

$$\text{Block height } H, \quad \text{Volume } V_A = 0.34H^3, \quad D_{nA} = V_A^{1/3} = 0.6980H$$

$$\text{Mass } M_A = \rho_A 0.34H^3, \quad \rho_A = 2.40t/m^3$$

Filter 1 (quarry rock)

$$\text{Mass } M_{F1} = \frac{M_A}{15} \sim \frac{M_A}{7} \cong 0.1M_A, \quad \text{Mass density, } \rho_s = 2.65t/m^3$$

$$D_{n50} = \left(\frac{M_{F1}}{\rho_s} \right)^{1/3} = \left(\frac{0.1 \cdot 0.34H^3 \cdot 2.40}{2.65} \right)^{1/3} = 0.314H, \quad t_{F1} = 2D_{n50} = 0.627H$$

Filter 2 (quarry rock)

$$\text{Mass } M_{F2} = 0.1M_{F1} \cong 0.01M_A, \quad \text{Mass density, } \rho_s = 2.65t/m^3$$

$$D_{n50} = \left(\frac{M_{F1}}{\rho_s} \right)^{1/3} = \left(\frac{0.01 \cdot 0.34H^3 \cdot 2.40}{2.65} \right)^{1/3} = 0.146H, \quad t_{F2} = 3D_{n50} = 0.437H$$

Bulk volumes per meter

$$\text{Accropode layer} \quad BV_A = 0.9H \left(5.762H + \frac{10}{3}R_c + \frac{5}{3}h \right)$$

$$\text{Filter 1} \quad BV_{F1} = 0.6269H(9.547H + \frac{10}{3}R_c + \frac{5}{3}h)$$

$$\text{Filter 2} \quad BV_{F2} = 0.4365H(5.00(m) + 9.487H + \frac{10}{3}R_c + \frac{5}{3}h)$$

$$\text{Core} \quad BV_c = \frac{4}{3}(R_c^2 + h^2) - 9.689H^2 - 2.945R_cH + \frac{8}{3}R_ch + 0.3273Hh$$

Free board R_c

R_c is determined such that the transmitted wave height due to overtopping in a sea with return period equal to structure life time T_L is 0.50 m

Minimum R_c is $1.50m + t_A + t_{F1} + t_{F2} = 1.50m + 1.963H$ due to construction road on top of core.

$$R_c = \max \begin{cases} 1.090 H_s^{T_L} - 1.155(m), \min R_c & \text{for } s_{op} = 0.02 \\ 0.840 H_s^{T_L} - 1.155(m), \min R_c & \text{for } s_{op} = 0.04 \end{cases}$$

Note that the freeboards R_c in all cases are determined by the set minimum level of +1.5 m for the top of the core material to be used as construction road.

Wave steepness $s_{op} = 0.035$ is used in all simulations. This assure that with armour front slope 1:1.33 the validity range of the applied armour stability formula, $3.5 < \xi_m < 4.5$ will be respected. If $s_{op} = 0.02$ ($s_{om} = 0.02 \cdot 1.5625 = 0.031$), then, $\xi_m = 4.92 > 4.5$, i.e. a little outside the validity range of the formula..

JONSWAP spectra with peak enhancement factor $\gamma = 3.3$ are applied.

$$T_m/T_p = 0.8, s_{om}/s_{op} = (T_p/T_m)^2 = (1/0.8)^2, s_{om} = 1.5625s_{op}.$$

Limit state and repair policy

Repairs are assumed to take place immediately after the damage limit for repair is exceeded.

Table 1. Repair policy as function of damage levels and limit states

| Damage levels/limit state | Estimated D | Repair policy |
|---------------------------|---------------|---------------|
|---------------------------|---------------|---------------|

| Initial | 2 % | No repair |
|---|------|----------------------------------|
| Serviceability / SLS (minor damage, only to armor) | 5 % | Repair armor |
| Repairable / RLS (major damage, armor + filter 1) | 15 % | Repair armor + filter 1 |
| Ultimate / ULS (failure) | 30 % | Repair armor + filter 1 and 2 |

* D is the relative number of displaced units (CEM, 2006)

Costs of repair

$D = 5\%$, SLS

$$\text{Cost of repair of minor damage, } C_{R1} = (1+K) D C_{I,armor} R, \quad (1)$$

in which $C_{I,armor}$ is the initial construction cost of the main armor layer, $R=3.0$ is a factor signifying high cost of repair, and $K=0.3$ is a factor signifying mobilization costs. The chosen values of R and K are estimates, but can vary considerably from case to case.

$D = 15\%$, RLS

$$\text{Cost of repair of major damage, } C_{R2} = (C_{I,armor} + C_{I,filter1} + K C_{I,armor}) D R, \quad (2)$$

where $C_{I,filter1}$ is the initial construction cost of filter 1.

$D = 30\%$, ULS

$$\text{Cost of repair after a failure, } C_{R3} = (C_{I,armor} + C_{I,filter1} + C_{I,filter2} + K C_{I,armor}) D R, \quad (3)$$

where $C_{I,filter2}$ is the initial construction cost of filter 2.

Downtime costs

When $D \geq 15\%$ is added downtime costs given as 200,000 EUR/day in 3 months. The relative short duration of 3 months is justified only for outer breakwaters with no berths along the harbour side of the structure. The downtime costs are related to 1 km length of breakwater.

Structure length

Calculations performed for a structure length of 1 km and damage is assumed to take place over the whole length of the breakwater.

Stability formula

The stability formula of Burcharth et al. (1998) is applied

$$N_s = \frac{H_s}{\Delta D_n} = A(D^{0.2} + 7.70) \quad (4)$$

where the mean of A is 0.46 and the coefficient of variation is $0.02+0.05(1-D)^6$. D is the relative number of units displaced more than distance D_n .

Valid for:

- Irregular, head-on waves
- Breaking and nonbreaking wave conditions
- One layer of Accropodes on slope 1:1.33 placed in accordance with SOGREAH recommendations on filter layer and conventional quarry rock run
- $3.5 < \xi_m < 4.5$ (minimum stability range)
- No influence of number of waves were found except after start of failure

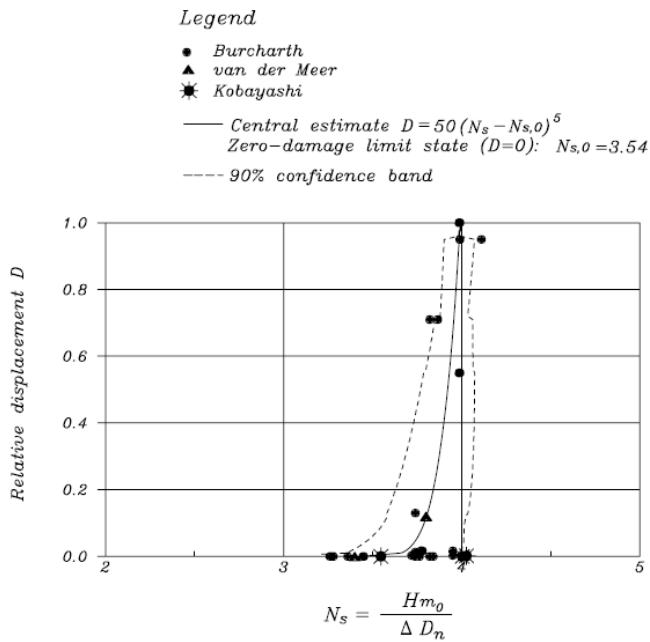

Fig. 2. Stability of Accropode armour on slope 1:1.33. Range for minimum stability, $\xi_p = 3.5 - 4.5$ corresponding to wave steepness, $s_{op} = 0.03 - 0.05$. Burcharth et al. (1998)

Damage accumulation and calculation

Simulations are performed with and without damage accumulation.

$$D = \left(\frac{N_s}{A} - 7.70 \right)^5 \quad \text{Range of damage, } 0 \leq D \leq 1.0 \quad (5)$$

As the mean value of damage level, D is greater than 0.0, N_s should be more 3.542 as shown in Fig. 2. Stability results with and without application of damage accumulation are almost identical.

4. Formulation of total cost functions

The optimum design is determined using the optimization problem formulated assuming no rebuilding in case of failure. No benefits, costs related to loss of life and cost of decommissioning at the end of service lifetime are included.

$$\min_T C(T) = C_I(T) + \sum_{t=1}^{T_L} \{C_{R_1}(T)P_{R_1}(t) + C_{R_2}(T)P_{R_2}(t) + C_F(T)P_F(t)\} \frac{1}{(1+r)^t} \quad (6)$$

where

T return period used for deterministic design

T_L design life time

$C_I(T)$ initial costs (building costs)

$C_{R_1}(T)$ cost of repair for minor damage

$P_{R_1}(T)$ probability of minor damage in year t

$C_{R_2}(T)$ cost of repair for major damage

$P_{R_2}(T)$ probability of major damage in year t

$C_F(T)$ cost of failure including downtime costs

$P_F(T)$ probability of failure in year t

r real rate of interest

5. Characteristics of design variables in stochastic model

Limit state function for stability of Accropode armor, slope 1:1.33

$$g = D - \left(\frac{X_{H_s} H_s}{A \Delta D_n} - 7.70 \right)^5 \quad (7)$$

where the parameters are described in Table 2.

Table 2. Parameters of design variables

| Variables | Description | Distribution | Expected value | Standard deviation |
|------------------|---|--------------|-------------------------|---|
| D | critical damage level | see Table 1 | | |
| H_s | annual maximum significant wave height | Weibull | Various | |
| X_{H_s} | model uncertainty wave height | Normal | 1 | 0.1 |
| Δ | model parameter | Normal | 1.341 | 0.03 |
| D_n | armor size | Noraml | various | COV=0.01 |
| A | Empirical coefficient | Normal | 0.46 | COV= 0.02 + 0.05(1 - D) ⁶ |
| H_s^T | design wave height with return period T years | | | |
| $W = \rho D_n^3$ | Weight of armor | | | |
| ρ | armor density | | 2.40 ton/m ³ | |

- Random variables: H_s , A , X_{H_s} , Δ , D_n

6. Case studies

Table 3. Case study data

| Case | Water depth | Armor density | Wave (see Table 4) | Stability formula | Built-in unit prices core/filter 1/filter 2/armor in EURO/ m ³ |
|------|-------------|------------------------------------|--------------------|---------------------|---|
| 1 | 10 m | Accropode 2.4 t/ m ³ | Follonica | Burcharth (1998) | 15/20/30/ 80 or 160* |
| 2 | 20 m | | North sea | | |
| 3 | 20 m | | Bilbao | | |

* It was used in the costs of repair doubled (i.e. 160) corresponding to the fact that almost twice the number of Accropodes must be replaced due to the interlocking

Table 4. Distribution parameters for H_s - data samples (PIANC, 1992)

| Site | Total number | Average number per year | Weibull | | Exp. |
|-----------|--------------|-------------------------|-----------|----------|-------|
| | | | λ | α | H_s |
| Follonica | 46 | 5.94 | 1.14 | 0.58 | 2.69 |
| North sea | 30 | 1.88 | 1.28 | 1.48 | 5.70 |
| Bilbao | 50 | 4.17 | 1.39 | 1.06 | 4.90 |

Weibull distribution

Annual maximum wave height

$$F(H_s) = \left[1 - \exp \left(- \left(\frac{H_s - H_s^*}{\beta} \right)^\alpha \right) \right]^\lambda \quad (8a)$$

T -year maximum wave height $[F(H_s)]^T = F(H_s)^T = \left[1 - \exp \left(- \left(\frac{H_s - H_s^*}{\beta} \right)^\alpha \right) \right]^{\lambda T} \quad (8b)$

Deterministic design

Determination of D_n by formula

$$N_s = \frac{H_s}{\Delta D_n} = A(D^{0.2} + 7.70) \quad (9)$$

For each N_s – value of 2.2, 2.5, 2.7 and 2.9, H_s – values corresponding to return periods $R = 5, 25, 50, 100, 200$ and 400 years are calculated the D_n – value, in total 24 values.

$$D_n = \frac{H_s^R}{\Delta N_s} \quad (10)$$

Cost optimization

Fig. 3 shows the flow chart of cost optimization of an Accropode-armored breakwater.

First, using the extremal wave height distribution function given by Eq. (8a) a preliminary return period and a stability number are picked up and the corresponding significant wave height and armour diameter are calculated. Then the breakwater is designed according to the conventional deterministic design method and the initial construction cost is calculated. The values of A , Δ , and D_n are randomly selected based on their statistical characteristics given in Table 2. These values are assumed to be constant during the lifetime of the breakwater. The designed breakwater is subjected to simulated storm waves over T_L years. A Poisson distribution with the occurrence rate λ is used to determine the number of storms in each year. For each simulated storm, the damage and corresponding repair and downtime costs are calculated. The costs are accumulated to find the total lifetime cost. The process of T_L -year cycles is repeated 100,000 times, and the total lifetime costs are added up to yield the expected total cost. This process is repeated for 24 combinations of different return periods and stability numbers. Finally, the significant wave height and armour diameter that yield the minimum total cost are searched.

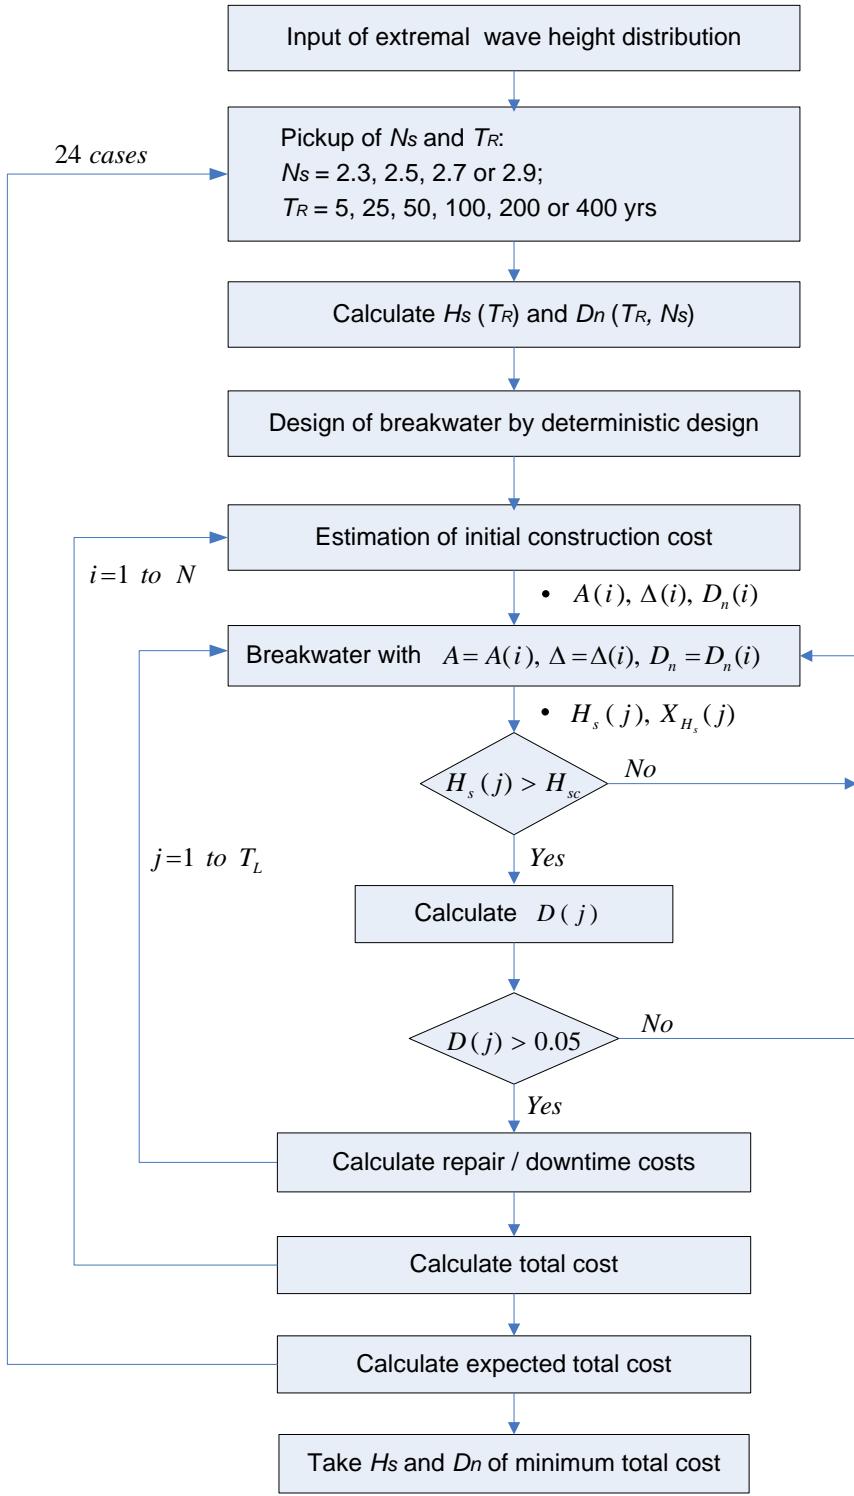

Fig. 3. Flow chart of cost optimization of Accropode armoured breakwater (• denotes random number generation)

Appendix D1 Background note containing assumptions and formulae applied in optimizations analyses of caisson breakwaters

1. Objective

The present note explains the basis for the optimization calculations performed with the objective of identifying the most economical safety levels for conventional caisson breakwaters, evaluated over the service lifetime of the structures. Caissons on bedding layer and high rock foundation are analyzed.

2. Procedure in numerical simulations

Reference is given to Appendix A1.

3. General assumptions

Cross sections

Fig. 1 shows the cross sections dealt with in the simulations. In accordance with Japanese recommendations given by OCDI (2002) for outer breakwaters is chosen a freeboard of $h_c = 0.6 \cdot H_s^{T_L}$, where T_L is the design life time of the structure.

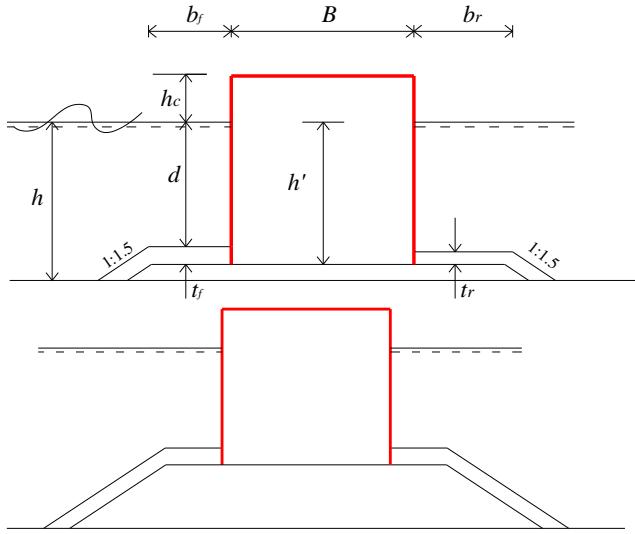

Fig. 1. Cross sections of outer caisson breakwaters on bedding layer (top) and on high mound foundation (bottom).

The ratio between the caisson draft h' and the water depth h has been varied in all the simulations in order to identify the most economical ratios.

Volumes

U is bulk unit prise, V is volume

$$\text{Caisson : } U_c, \quad V_c = (h' + h_c)B$$

$$\text{Armour layer front : } U_{af}, \quad V_{af} = (h' - d)(b_f + 1.80(h - 0.5d - 0.5h'))$$

$$\text{Armour layer rear : } U_{ar}, \quad V_{ar} = t_r(b_r + 1.80(h - h' + 0.5t_r))$$

$$\text{Foundation core : } U_{co}, \quad V_{co} = (h - h')(B + b_f + b_r + 1.5(h - h'))$$

Conditions both with sea bed materials strong enough to resist slip failures (hard bottom) and sandy sea beds have been analysed. The studied failure modes are shown in Fig. 2. For the slip failure the angle θ giving the lowest resistance has been identified.

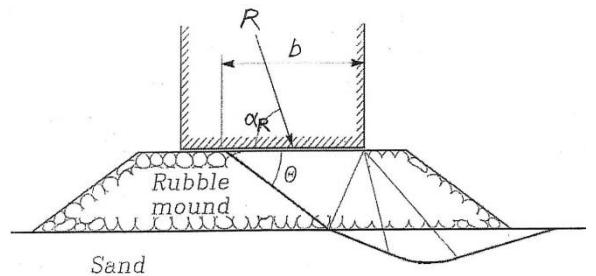

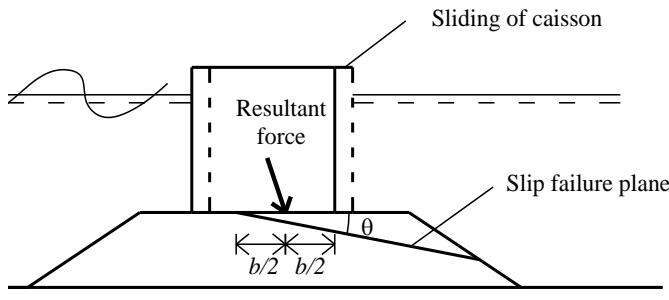

Fig. 2. Failure modes included in the optimization

Toe berm stability has not been included because the extra cost of making the berm armour very safe is too small to have significant influence on the cost optimization.

Repair strategy, limit state performances, costs of construction and repairs

Two methods of repair/stabilization as shown in Fig.3 are considered; armour blocks in front and/or a rubble mound behind the caisson.

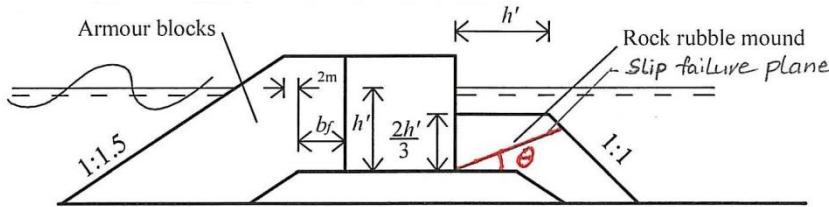

Fig.3. Armour blocks in front of caisson and rubble mound behind caisson as means of repair.

Volume of armour blocks in front for repair (dissipation blocks)

$$V_{diss} = 0.75 (h + h_c)^2 + (b_f + 2)(h + h_c) - 0.75 (h - d)^2 - b_f(h - d)$$

Volume of mound behind for repair

$$V_m = (h - h'/3)h' + 0.5 (h - h'/3)^2 - V_{ar} - (h - h')b_r - 0.75 (h - h')^2$$

The used limit state performances and related methods of repair are given in Table 1.

Table 1. Limit state performances and repair.

| Limit states | Failures | Repair |
|--------------|--|--|
| SLS | Sliding distance 0.2 m | No |
| RLS | Sliding distance 0.5 m | Armour blocks in front or mound behind |
| ULS | Sliding distance 2.0 m Slip failure | Both Both , double unit costs |

The chosen sliding distances are assumed reasonable values for outer breakwaters with no berths arranged on the harbour side of the caissons.

Table 2 provides the average built-in bulk unit prices collected by the PIANC MarCom Working Group 47 members. The Japanese prices are used in the present analyses. For the identification of

the optimum safety level only the ratio between the costs of the various parts of the structure including repairs are of importance.

The unit price for the caissons is kept constant although the price will increase if the height of the caissons demands special production plants. The consequence of this simplification is that the optimization calculations will show that it is more economical even in very deep water to have the caissons placed on a thin bedding layer rather than on a high rubble foundation. In order to avoid such bias the maximum draught of the caissons is set to 24 m in the simulations.

Table 2. Average built-in bulk unit prices in Euro/m³ (app. 2007).

| Structure part | Europe | Japan |
|---|--------|-------|
| Caisson, U_c | 90 | 150 |
| Armour layers, U_{af} and U_{ar} | 150 | 235 |
| Foundation core, U_{co} | 25 | 37 |
| Armour blocks in front for repair, U_{diss} | 150 | 200 |
| Mound behind for repair, U_m | 30 | 50 |

The ratio of unit prices in Japan and Europe is approximately 1.6.

Construction costs

$$C = U_c \cdot V_c + U_{af} \cdot V_{af} + U_{ar} \cdot V_{ar} + U_c \cdot V_c$$

Downtime costs

No downtime costs are included as increase in wave transmission in case of failures will be very limited because the reduction in caisson crest level will be small.

4. Wave induced loads

The formula of Goda (1974) with inclusions of Tanimoto et al. (1976) is used. It is assumed that large impulsive forces are avoided by imposing the conditions that the sea bed is more gentle than 1:50 and $d/h \geq 0.6$.

Fig. 4. Definition sketch related to the Goda wave loads on caisson

Waves perpendicular to caisson front.

$$\eta^* = 1.50 \cdot H_{\max} \quad (1)$$

$$p_1 = (\alpha_1 \lambda_1 + \alpha_2 \lambda_2) \rho_w \cdot g \cdot H_{\max}$$

$$p_2 = \frac{\eta^* - h_c}{\eta^*} \cdot p_1, \quad p_2 \equiv 0 \text{ for } h_c \geq \eta^*$$

$$p_3 = \alpha_3 \cdot p_1$$

$$p_u = \lambda_3 \alpha_1 \cdot \alpha_3 \rho_w \cdot g \cdot H_{\max}$$

where

$$\alpha_1 = 0.6 + 0.5 \left[\frac{4\pi \cdot h / L}{\sin h (4\pi h / L)} \right]^2$$

$$\alpha_2 = \min \left[\frac{h-d}{3h} \left(\frac{H_{\max}}{d} \right)^2, \frac{2 \cdot d}{H_{\max}} \right]$$

$$\alpha_3 = 1 - \frac{h'}{h} \left[1 - \frac{1}{\cos h (2\pi h / L)} \right]$$

$\lambda_1 = \lambda_2 = \lambda_3 = 1$ for impermeable wall without blocks in front

In accordance with OCDI (2002), the following factors in the Goda formula for the reduction of the wave loads in case of repair with armour blocks in front of the caisson is used:

$$\lambda_1 = \lambda_3 = \begin{cases} 1.0 & \text{for } H_{\max} / h < 0.3 \\ 1.2 - 0.67 H_{\max} / h & \text{for } 0.3 \leq H_{\max} / h < 0.6 \\ 0.8 & \text{for } H_{\max} / h \geq 0.6 \end{cases} \quad \lambda_2 = 0$$

L = wave length corresponding to the significant wave height H_s at water depth at distance five times H_s from the front of the caisson.

$$H_{\max} = 1.8 \cdot H_{so}^{T_L} \text{ (non - depth limited conditions)}$$

$$\text{Deep water wave steepness } s_o = \frac{H_{so}^{T_L}}{L_{so}^{T_L}}$$

$$L_{so}^{T_L} = \frac{H_{so}^{T_L}}{s_o} = \frac{g}{2\pi} T_s^2$$

$$L = L_{so}^{T_L} \tan h\left(\frac{2\pi}{L} h\right) = \frac{H_{so}^{T_L}}{s_o} \tan h\left(\frac{2\pi}{L} h\right)$$

Resultant wave induced forces

(No crown wall. Japanese case for outer breakwater)

Fig. 5. Definition sketch for resultant wave induced forces on caisson

Horizontal force

$$F_H = 0.5(p_1 + p_2) \cdot h_c + 0.5(p_1 + p_3)h' \quad (2)$$

$$a_{F_H} = \frac{1}{F_H} \left[\frac{1}{2} p_2 h_c h' + \frac{1}{3} p_2 h_c^2 + \frac{1}{6} p_1 h_c^2 + \frac{1}{3} p_1 h'^2 + \frac{1}{2} p_1 \cdot h_c h' + \frac{1}{6} p_3 h'^2 \right]$$

(control: for $p_1 = p_2 = p_3 \Rightarrow F_H = p_1(h_c + h')$ and $a_{F_H} = \frac{1}{2}(h_c + h')$)

Vertical forces

$$G_c = [\rho_c \cdot B(h' + h_c) - \rho_w \cdot B \cdot h']g \quad (3)$$

$$a_{G_c} = \frac{1}{2}B$$

$$F_u = \frac{1}{2} \cdot p_u \cdot B$$

$$a_{F_u} = \frac{2}{3}B$$

Resultant vertical force

$$R_v = G_c - F_u = B[(\rho_c - \rho_w)h' + \rho_c h_c]g - \frac{1}{2}p_u B$$

(4)

Fig. 6. Definition sketch for resultant caisson force on foundation

$$R = F_u \frac{\cos \alpha_1}{\sin \alpha_2} \quad (5)$$

where

$$\alpha_1 = \tan^{-1}\left(\frac{G_c}{F_H}\right)$$

$$\alpha_2 = \tan^{-1}\left(\frac{F_u \cos \alpha_1}{(G_c^2 + F_H^2)^{0.5} - F_u \sin \alpha_1}\right)$$

$$\alpha_R = \alpha_1 - \alpha_2$$

$$a_R = \frac{1}{R}(G_c \cdot a_{G_c} - F_H \cdot a_{F_H} - F_u \cdot a_{F_u}), \text{ must be positive in order to keep the intersection}$$

between R and the base plate inside the caisson.

$$b = \frac{2 a_R}{\sin \alpha_R}$$

5. Stability calculations

Wave loads on caissons are determined by the formula by Goda (2000). It is assumed that large impulsive forces are avoided by imposing the conditions that the sea bed slope is milder than 1:50, and $d/h \geq 0.6$, see Fig.1.

Deterministic design

The caisson width B in the deterministic design is determined by applying the design wave height $H_{design} = 1.8 \cdot H_{so}^{T_L}$ for non-depth limited conditions. $H_{so}^{T_L}$ is the deep water significant wave height corresponding to return period T_L , i.e. the service life time of the structure. Wave lengths corresponding to local water depths h given a deep water wave steepness of $s_o = 0.04$ are applied. For depth limited conditions is used a maximum $H_{design} = 0.8 h$.

The design equation for B reads

$$B = \frac{S \cdot F_H}{f \left[(\rho_c - \rho_w) h' g + \rho_c h_c \cdot g - \frac{1}{2} p_u \right]} \quad (6)$$

where F_H is the horizontal wave load corresponding to H_{design} , calculated by the Goda formula for wave loads on caissons, see Goda (2000).

$S = 1.2$ is a safety factor

$f = 0.6$ is the friction coefficient of the base plate

$\rho_c = 2150 \text{ kg/m}^3$, bulk mass density of caisson

$\rho_w = 1025 \text{ kg/m}^3$, mass density of water

p_u = wave induced uplift pressure at base plate front edge calculated by the Goda formula.

Tilting of the caisson around the heel applying a safety factor of $S = 2.5$ is included in the deterministic determination of B , but was never critical.

The average normal stress σ over the effective foundation width b shown in Fig. 2 is calculated in order to get a simple measure for the foundation loading.

Reliability calculations

In the probabilistic calculation of the performances of the deterministic designs are used the actual time series of Rayleigh distributed wave heights obtained from sample simulations in accordance with predefined long-term statistics, see PIANC (1992), including uncertainties on the distribution parameters. In order to avoid unrealistic wave height double truncated Weibull distributions are used (Tae-Min Kim, 2004). The number of waves in each storm is set to 1,000.

A limit for the maximum wave height of 0.8 times the local water depth h is used.

Wave loads were determined from the Goda formula without safety factor, corrected for bias and including uncertainty by introducing double truncated Normal-distributed factors X_{FH} and X_{FU} on

F_H and F_U as follows:

Horizontal force factor, $0.5 < X_{FH} < 1.4$, $\mu_{X_{FH}} = 0.90$,

$$\frac{\sigma_{X_{FH}}}{\mu_{X_{FH}}} = 0.20$$

Uplift force factor, $0.5 < X_{FU} < 1.4$, $\mu_{X_{FU}} = 0.80$,

$$\frac{\sigma_{X_{FU}}}{\mu_{X_{FU}}} = 0.30$$

F_U is the wave induced uplift force on the caisson bottom slab.

For limits related to the double truncated normal distributions see Tae-Min Kim (2004) p. 55-62, Table 3.11.

The Goda formula is a conservative design formula for which reason a positive bias is inherent in the formula. The bias was not included in the calculations by Tae- Min Kim (2004).

The friction factor f is modelled by a double truncated normal distribution with mean value $\mu_f = 0.6$, $\sigma_f / \mu_f = 0.1$, and cut-off limits $0.7 < f < 1.4$.

Resistance to sliding from mound behind caisson

The resistance to sliding R_m provided by the mound behind the caisson is calculated in accordance with OCDI (2002), see Figs. 3 and 7 for dimensions of the mound.

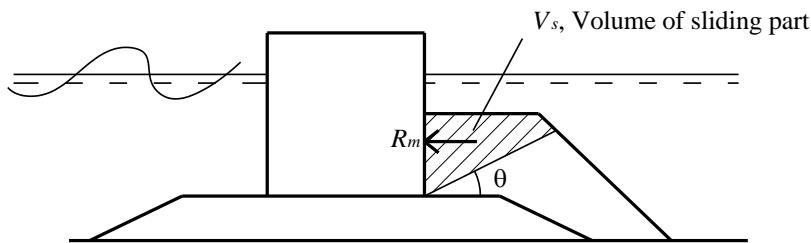

Fig. 7. Illustration of resistance of mound to sliding.

$$R_m = V_s \cdot \gamma' \tan(\theta + \varphi)$$

where V_s is the volume of the sliding part of the mound

$$\gamma' = 9810 \text{ N/m}^3 \text{ submerged unit weight of mound}$$

$$\varphi = 38^\circ, \text{ friction angle of mound material}$$

θ is the slip plane angle with horizontal to be identified related to min. R_m .

$$V_s = 2/9 h^2 \tan(90^\circ - \theta) \quad \text{for } \theta \geq 33.7^\circ$$

$$V_s = (0.333 + 0.708 \sin(33.7^\circ - \theta) / \sin(45^\circ + \theta)) h^2 \quad \text{for } \theta < 33.7^\circ$$

Geotechnical slip failure resistance

The equations related to slip failures are given in Sorensen and Burcharth (2000).

For the strength of the quarry rock rubble foundation are used friction angles of 37° , 40° and 45° are used . For the sand seabed are used the friction angles 30° and 35° .

These friction angles are the effective friction angles, i.e. they include the effect of the dilation angles of the materials. The uncertainty on the friction angles is modelled as a Normal distribution with a coefficient of variation of 10%.

Determination of caisson sliding distance

The sliding distance SD of the caisson should preferably be determined from the dynamic equation of motion assuming a model for the time history of the loading by each wave. In order to save computation time the diagrams shown in Fig. 8 are used. The ordinate is the ratio of the actual horizontal wave force F_H of a single wave to the wave force $F_{H,\text{limit}}$ which is the force just causing the caisson to slide, calculated from eq. (6) with $S = 1$.

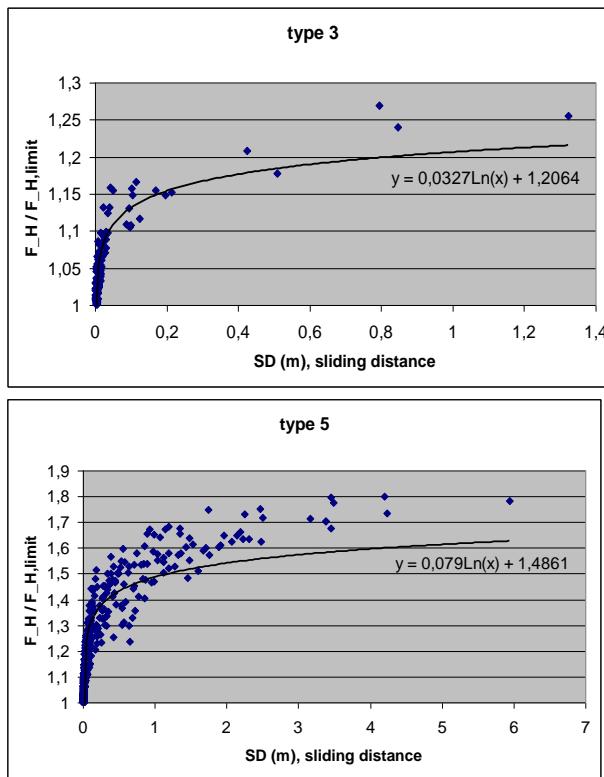

Fig. 8. Diagrams for the estimation of caisson sliding distance.

The data points in Fig. 8 was provided by Tae-Min Kim (2005), based on his earlier calculations for a caisson (type 3) in water depth $h = 16$ m, of dimensions

$h' \times h_c \times B \times d = 13 \times 5 \times 25.3 \times 11.5$ m, and a caisson (type 5) in water depth $h = 24$ m, of dimensions
 $h' \times h_c \times B \times d = 14 \times 5 \times 26.8 \times 12.5$ m

The graphs fitted to the data points are deliberately chosen to be on the safe side for larger values of $F_H/F_{H,\text{limit}}$ because the dimensions of the caissons and the wave conditions applied in the simulations deviate somewhat from those studied by Tae-Min Kim. A sensitivity analyses has shown that if a graph following more closely the larger data points for Type 5 caisson is used in the simulations then the probability of occurrence of the limit state sliding distances will be approximately halved. However, the slip failure probabilities and the minimum lifetime costs are not significantly changed.

6. Formulation of total cost functions

See Appendix A1.

7. Characteristics of design variables in stochastic model

As to wave modelling see Appendix A1. Data for other variables are given in Chapter 5.

8. Case studies

The performance of caisson structures deterministically designed for significant wave height return periods of 25, 50, 100, 200, 400, 1000, 1600 and 3200 years are analysed by probabilistic Monte Carlo simulations. The related lifetime costs are determined and the safety levels and the structure dimensions corresponding to the minimum lifetime costs are identified.

Caissons on rubble foundation on hard bottom seabed

A deep water wave steepness of 0.04 and an interest rate of 5% p.a. are used in all cases. No downtime costs are included. Service lifetime is 100 years. Rubble friction angles of $\varphi = 37^\circ$, 40° and 45° are applied.

Table 3 gives an overview of the studied cases.

Table 3. Case studies. Caissons on hard bottom. Structure lifetime $T_L = 100$ years

| Case | Water depth, h (m) | Wave climate | | Rubble friction angle φ (degrees) | Dimensions of berms and armour (Fig.1), (m) | | | | Sliding eq. No. cf. Fig. 14.4 | RLS repair |

Caissons on rubble foundation on sand seabed

The simulations are performed with sand friction angles $\varphi = 30^\circ$ and 35° . The friction angles of the rubble foundation are $\varphi = 37^\circ$, 40° and 45° . A deep water wave steepness of 0.04 and an interest rate of 5% p.a. are used in all cases. No downtime costs are included. Service lifetime is 100 years.

Table 4 gives an overview of the studied cases.

Table 4. Case studies. Caissons on sand sea beds. Structure lifetime $T_L = 100$ years

| Case | Water depth , h (m) | Wave climate | | Friction angle φ (degrees) | | Dimensions of berms and armour (Fig.1), (m) | | | | Sliding eq. No. cf. Fig. 14.4 | RLS repair |
|------------|------------------------|--------------|----------------------|---------------------------------------|------|---|-------|-------|-------|-------------------------------------|--------------|

Appendix D2 Raw data sheets for the optimizations analyses of caisson breakwaters.

In the data sheets the following notation is used:

D = toe level below SWL (m)

TDES = return period of design waves (years)

B = width of caisson (m)

bz = effective width of caisson in terms of width over which the foundation load is distributed (m)

sigma = average foundation normal stress in kN/m²

EH1 = ratio of maximum wave height to H_s in a storm

EH2 = mean value of H_s in simulations

PFS = probability of SLS within structure service lifetime

PRS = probability of RLS within structure service lifetime

PFU = probability of ULS within structure service lifetime

PFF = probability of foundation slip failure within structure lifetime

CIN = construction costs (EURO/m)

ERR = costs of RLS repair (EURO/m)

EUU = costs of ULS repair (EURO/m)

EFF = costs of foundation failure repair (EURO/m)

CTOT = total lifetime costs (EURO/m)

PFrubble = probability of slip failure in rubble foundation within structure lifetime

PFsand = probability of slip failure in sand seabed within structure lifetime

D2.1. Caissons on rubble foundation on hard seabed
