**Aims & Methods:** Reflect is a multicenter, prospective, observational study conducted in France which aims to describe characteristics of pts' receiving CT-P13 and to assess safety and effectiveness in real-life conditions. Pts (age ≥ 6 years) with Crohn's disease (CD), ulcerative colitis (UC) and rheumatic diseases treated with CT-P13 were eligible for enrolment, including IFX naïve pts (IFXn) or those having switched from IFX originator to CT-P13 (IFXs). Complementary data after a two-year follow-up period in pts suffering from CD and UC using descriptive statistical analyses are presented here.

**Results:** From 3<sup>rd</sup> October 2018 to 31<sup>st</sup> January 2019, of the 1321 included pts, 680 pts with inflammatory bowel disease were analyzed in the present sub analysis [480 CD pts (48.3% males; mean age: 37.1 ± 14.1 years; median disease duration: 6.9 years) and 200 UC pts (54.5%; 41.2 ± 17.5 years; 5.4 years)]. Previous biologics other than IFX were taken by 40.3% of CD and 41.8% of UC pts. At baseline, a minority of pts (21.8% of CD and 18.5% of UC) have been switched from the IFX originator to CT-P13; more pts have an active disease in IFXn 79.5% for UC and 52.2% of CD comparing to IFXs pts 37.5% and 15.4% respectively (p=0.002 and p< 0.001). In UC pts, median Mayo score were 7.5 and 1.5 in IFXn and IFXs pts at baseline and, it decreased by 3 and 5 points at 12 and 24 months in IFXn pts. In CD pts, median Harvey-Bradshaw Index (HBI) were 4 and 1 in IFXn and IFXs pts respectively and, it decreased by 2 and 1 points in at 12 and 24 months IFXn pts. In IFXs pts, there was no change in both UC and CD median disease activity scores at 12 and 24 months except for the HBI which increased slightly at 24 months by 1 point. The treatment with CT-P13 has been withdrawn due to treatment failure or safety reason in 5,6 % of CD pts and 12,7 % UC pts in IFXn pts and in 2,1% and 2,9% of IFXs pts.

**Conclusion:** The two years follow-up data suggest that CT-P13 was effective in inducing and maintaining remission in CD and UC in both naïve and switched patients. This real-life study did not identify new safety concerns.

**Introduction:** Anti-TNFs represent a key treatment strategy for the management of IBD. However, it would be important to have more data about their use with the aim of facilitating the right choice in clinical practice. One of the aims of this study was to learn about the patterns of use of two anti-TNFs, adalimumab and infliximab, when used in biologic-naïve patients for the treatment of Crohn's disease (CD).

**Aims & Methods:** This was a retrospective, observational study, conducted in 24 hospitals in Spain. IBD patients who started first anti-TNF treatment between June 2011 and June 2013 were included consecutively in the participating centres. Data about anti-TNF management were collected. Kaplan Meier analyses were used to evaluate time to treatment intensification and time to discontinuation in CD with adalimumab and infliximab. Data are presented descriptively

**Results:** One hundred and ninety-four CD patients were included (n=85 treated with infliximab and n=109 treated with adalimumab). Median age was 43.0 years (range: 20.0-74.0) and most patients presented ileum and colon (L3=44.6%) or terminal ileum location (L1=37.3%). The most common disease behaviour was inflammatory (B1=44.6%). Median follow up time (from treatment initiation until informed consent signed) was 59.7 (range: 43.5 - 76.2) and 60.2 (range: 45.3 - 74.9) months for adalimumab and infliximab respectively.

Dose intensification was recorded in 29.4% of patients treated with adalimumab and 28.2% of patients treated with infliximab. Median time to first dose intensification was similar with adalimumab, 15.1 months (range 1.3-61.8) and infliximab, 14.1 months (range 0.2-59.5).

Regarding treatment discontinuation, it occurred in 56.0% of patients treated with adalimumab, and in 63.5% with infliximab. Median time to treatment discontinuation was 27.4 months (range 0.9-66.9) with adalimumab, and 23.0 months with infliximab (range 0.0-58.9).

Concomitant use of corticosteroids at any time during maintenance was similar with adalimumab (31.2%) compared with infliximab (28.2%) being the mean number of cycles needed was similar (adalimumab 1.5, SD 0.8 vs infliximab 1.2, SD 0.5). The use of immunosuppressants at any time during maintenance was similar among the two products (adalimumab: 60.5% vs infliximab: 76.5%) being the mean number of required cycles was also comparable (adalimumab 1.3, SD 0.9 vs infliximab 2.2, SD 8.4).

**Conclusion:** Similar proportions of patients with CD received dose intensification with infliximab and adalimumab, and the discontinuation rates with both anti-TNFs were also similar.

Dose intensification with both anti-TNFs was required in around one in every three patients, and after a similar median time (slightly longer than 1 year).

More than half of patients treated with adalimumab and infliximab discontinued treatment during the follow-up, and this occurred after a comparable median time (slightly longer than 2 years).

Although a significant proportion of patients required concomitant use of corticosteroids and/or immunosuppressants, the average number of required cycles was low.

Despite the common use of anti-TNFs as the first biologic in CD, we have not found any major difference between adalimumab and infliximab that could lead to a preferred treatment option.

**Disclosure:** VERNE Study has been sponsored by Takeda Farmacéutica Española

## P1796 TOFACITINIB INDUCTION EFFICIENCY AND INTRACELLULAR CYTOKINE DYNAMICS IN ULCERATIVE COLITIS: RESULTS FROM CLINICAL PRACTICE

**Introduction:** Tofacitinib is an oral JAK inhibitor with intracellular mechanism of action, approved for the treatment of ulcerative colitis (UC). Its efficiency was proven in registration trials, however data from clinical practice are insufficient. Our aim was to evaluate response to tofacitinib after 8 weeks in UC patients, and to assess potential predictors of response including early cytokine production shifts.

**Aims & Methods:** Data from consecutive UC patients who started tofacitinib 10 mg b.i.d. between January and April 2019 were evaluated. Disease activity was assessed by Mayo score including endoscopic Mayo at baseline and week 8 together with C-reactive protein (CRP) and fecal calprotectin (FC). Production of IL-4, IL-10, IL-17, TNF $\alpha$  and IFN $\gamma$  in T-helper cells was determined at baseline and week 4 by flow cytometry after lymphocyte activation.

At week 8, patients with total Mayo 0-5 with endoscopic subscore 0-1 (corresponding to mucosal healing) were considered responders. Adverse events were registered at every visit (weeks 2, 4 and 8).

**Results:** 24 patients (41.7% males, 58.3% females), mean age 35.3 $\pm$ 11.8 years were included. Mean disease duration was 8.3 $\pm$ 5.2 years. In median, the patients were previously treated with 2 biologic agents, however, 25% of the patients were naive to any biologic therapy. Systemic corticosteroids were present in 41.7% patients at baseline and no patient had concomitant biologic or other immunosuppressive therapy. At week 8, 52.9% of patients responded to therapy. Total Mayo decreased in responders from mean 5.9 $\pm$ 3.5 to 1.1 $\pm$ 1.3 (p=0.01), while in nonresponders it changed from 8.0 $\pm$ 2.5 to 8.9 $\pm$ 2.1 (p=0.86). Endoscopic subscore decreased from 2.0 $\pm$ 1.0 to 0.6 $\pm$ 0.7 (p=0.02) in responders, however remained stationary in nonresponders (2.9). CRP and FC dropped significantly in responders (6.7 $\pm$ 6.2 vs. 2.0 $\pm$ 2.2 mg/L, p=0.04; 1195 $\pm$ 1189 vs. 578 $\pm$ 654  $\mu$ g/g, p=0.05), but not in nonresponders. The responding and nonresponding groups differed significantly in baseline triglycerides, which were higher in nonresponders. Other baseline parameters were comparable including corticotherapy, previous biologic therapy, disease duration and laboratory values, however, nonresponders tended to have more active disease at baseline and there were more females in the responding group (62.5% vs. 18.2%, p=0.07). Significant difference was observed in shifts of production of cytokines IL-4 and IL-10 in T-helper cells. In responders, there was a significant decrease in IL-4 and no change in IL-10, while in nonresponders, there was no change in IL-4 and significant decrease in IL-10. Interestingly, there was also a significant increase of intracellular TNF $\alpha$  in all patients. Tofacitinib was stopped in 23.5% of patients at week 8 due to insufficient response. Two patients reported headaches after treatment initiation and single events of CMV colitis, *C. diff.* colitis and oral candidiasis occurred.

**Conclusion:** Tofacitinib was efficient in inducing clinical response with mucosal healing in about 50% of UC patients after 8 weeks of therapy in clinical practice. There was no clear baseline predictor of response, however, considering limited sample, there was also no indication of even multiple biologics failure negatively affecting response. Tofacitinib might thus be an option in respective patients. Preliminary results of cytokine dynamics suggest early IL-4 decrease as a potential biomarker of response, warranting further investigation.

**Contact E-Mail Address:** zuzana.zelinkova@nsmas.sk

**Introduction:** Approximately one third of inflammatory bowel disease (IBD) patients are primary non-responders to vedolizumab, a monoclonal antibody against  $\alpha 4\beta 7$  integrin receptor. Activated lymphocytes are homing to the gut mucosa through binding to mucosal vascular addressin cell adhesion molecule 1 (MAdCAM1) localised on the intestinal endothelial cells. MAdCAM1 expression is subject to great interindividual variability which may impact the efficacy of vedolizumab. If stable overtime decreased or absent MAdCAM1 expression might be one of the determinants of primary non-response to vedolizumab.

**Aims & Methods:** The aim of this study was thus to determine the stability of MAdCAM1 expression on intestinal endothelial cells of IBD patients overtime and the influence of immune suppressive therapy on this expression.

From all IBD patients who underwent bowel resection in one referral center between January 2016 and March 2019 the resection specimens were randomly selected for assessment of MAdCAM1 expression in lamina propria endothelial vessels. The expression was determined by immunohistochemistry and was arbitrarily assigned into three categories: negative, low and high (0%, up to 30% and above 30% of MAdCAM1 positive lamina propria vessels, respectively). For patients with serial specimens, resection or biopsies, the changes in MAdCAM1 expression overtime were assessed. The medication used in the last 30 days before resection was noted and the differences between the respective groups according to MAdCAM1 expression were analyzed.

**Results:** There were in total 112 resections performed, out of which 52 resection specimens (38, 73% with Crohn's disease, 14, 27% with ulcerative colitis; 48% of males) were randomly selected for MAdCAM1 expression

assessment. There were 6 pts (12%) with negative MAdCAM1 expression, 10 (19%) had low and 36 (69%) had high MAdCAM1 expression. There were no differences in rates of respective immune suppressive therapies used preceding the surgery; the systemic steroids, azathioprine and biologics were equally distributed among all three groups.

For fifteen patients, serial specimens were available. Among these patients, there were 11 patients with high MAdCAM1 expression and 4 with low expression. All patients with high MAdCAM1 expression had concordant levels of expression overtime. From four patients with low MAdCAM1 expression, one patient had negative expression in one and low expression in a second specimen, other three had low MAdCAM1 expression in all serial specimens.

**Conclusion:** One fifth of IBD patients do not express or have low expression of MAdCAM1. The expression of MAdCAM1 is stable overtime and is not influenced by immune suppressive medication. Further studies are needed to determine whether this low MAdCAM1 expression might underlie the primary non-response to vedolizumab.

**Disclosure:** ZZ received lecture fees from Takeda.

## P1798 MANAGEMENT OF ANTI-TNF ANTIBODY THERAPY FOR LONG-TERM REMISSION OF CROHN'S DISEASE

Kitamura K., Okafuji H., Matsukawa H., Seishima J., Miyazawa M., Asahina Y., Hayashi T., Iida N., Takatori H., Kaneko S.  
Kanazawa University, Dept of Gastroenterology, Kanazawa, Japan

**Contact E-Mail Address:** kazuyak2010@gmail.com

**Introduction:** To maintain the long-term remission of Crohn's disease, it is important to sustain the effects of anti-tumor necrosis factor (TNF) antibody therapy. Here we examined risk factors related to primary or secondary failure of anti-TNF therapy.

**Aims & Methods:** We analyzed 127 patients with Crohn's disease who treated with anti-TNF antibody as maintenance therapy at our hospital, and the frequency of primary as well as secondary failure of anti-TNF antibody therapy was determined. In addition, factors related to primary or secondary failure during the treatment were examined retrospectively.

**Results:** Among subjects, 100 patients were treated with infliximab (IFX) and 27 patients were treated with adalimumab (ADA) as first biologics. Primary failure was observed in 6 patients (6%) treated with IFX and 3 patients (11%) treated with ADA, with no differences among the drugs. We further examined 118 patients excluding primary failure, secondary failure was observed in 53 patients (56%) treated with IFX and 3 patients (13%) treated with ADA. Thiopurines were administered in 62 patients (66%) treated with IFX and 15 patients (63%) treated with ADA. The cumulative rate of secondary failure was 5% for 1 year, 28% for 3 years, and 47% for 5 years. We next examined risk factors related to secondary failure by Kaplan-Meier method and log-rank test. Thiopurine administration prior to anti-TNF antibody ( $p = 0.01$ ) and C-reactive protein (CRP) less than 0.3 mg/dl at the start of treatment ( $p = 0.02$ ) showed significantly longer prognosis of primary therapy. In multivariate analysis by proportional hazards model, the time to secondary failure was significantly longer in the cases with prior administration of thiopurine ( $p = 0.03$ ), whose hazard ratio was 3.3. Finally, 55 cases were examined whether the single nucleotide polymorphism of Fcγ receptor could be a predictor of primary or secondary failure of anti-TNF therapy. The frequency of primary failure of IFX was significantly higher in the cases with single nucleotide polymorphisms of FCGR2A and FCGR3A ( $p = 0.006$ ).

**Conclusion:** Continuation of primary treatment is important for maintaining long-term remission of Crohn's disease, and prior administration of thiopurine was considered to be useful to avoid secondary failure of anti-TNF therapy. In addition, it has been suggested that single nucleotide polymorphism of Fcγ receptor may be a predictor to IFX primary failure.

**Disclosure:** Nothing to disclose

## P1799 THE METHODOLOGY, FEASIBILITY AND SAFETY OF COLONIC TRANSENDOSCOPIC ENTERAL TUBING: A MULTICENTER, RANDOMIZED CONTROLLED TRIAL

Wen Q.<sup>1</sup>, Cui B.<sup>1</sup>, Li P.<sup>1</sup>, Zhang J.<sup>1</sup>, Wu X.<sup>1</sup>, Tu H.<sup>2</sup>, Yuan Y.<sup>3</sup>, Zhang F.<sup>1</sup>  
<sup>1</sup>The Second Affiliated Hospital of Nanjing Medical University, Medical Center for Digestive Diseases, Nanjing, China, <sup>2</sup>Hubei Provincial Hospital of TCM, Department of Spleen and Stomach Diseases, Wuhan, China, <sup>3</sup>The First Affiliated Hospital of Guangdong Pharmaceutical University, Department of Gastroenterology, Guangzhou, China

**Contact E-Mail Address:** wenquan@njmu.edu.cn

**Introduction:** Colonic transendoscopic enteral tubing (TET) is a novel, safe and quick technology for microbiota transplantation (MT) and whole colon administration. During the TET procedure, this technique needs insert colonoscope twice, the first time is for inserting the TET tube, the second time is for affixing the TET tube to the intestinal wall using titanium clips. However, it is difficult to find the cavity during the second time after inserted tube for some patients because of the gather of colonic folds and acute angle of colonic cavity caused by the TET tube pulling. It is well known that cap assisted colonoscopy is easier to flatten the haustral folds and improve mucosal exposure. Here we establish the hypothesis that using cap assisted colonoscopy can decrease the second cecal intubation time which not only improve work efficiency, but also save procedure time.

**Aims & Methods:** We designed a prospective multicenter, randomized controlled trial to compare the effect of with or without cap assisted colonoscopy for the second insertion on colonic TET procedure in order to perform the colonic TET faster and more convenient. All subjects who underwent colonic TET were included at three centers in China from August 2018 to March 2019. Subjects were randomly assigned to cap assisted group ( $n=105$ ) and non-cap assisted group ( $n=106$ ). The primary outcome was the second cecal intubation time. Secondary outcomes included TET procedure time, success rate, single titanium clip fixation time, retaining time of TET tube, maximum insertion pain score and all related adverse events (AEs).

**Results:** Baseline characteristics were comparable between the two groups ( $P>0.05$ ). The TET tubes were used in 50 patients for MT and whole colon administration, 127 patients for MT, and 6 healthy volunteers for sampling. The success rate of TET procedure was 100% in two groups. The median second cecal intubation time in the cap assisted group was shorter in comparison with non-cap assisted group (2.6 (IQR: 1.7-3.4) min vs 3.0 (IQR: 2.0-4.1) min,  $P=0.019$ ). The difference of mean second cecal intubation time was more obvious in two groups among patients with constipation (cap vs non-cap:  $2.9\pm1.2$  min vs  $4.0\pm2.0$  min,  $P=0.017$ ). The mean second cecal intubation time in cap assisted group was shorter than that of non-cap assisted group among patients with ulcerative colitis, however, there was no statistical difference ( $2.5\pm1.2$  min vs  $3.2\pm2.1$  min,  $P=0.137$ ). The median TET procedure time was shorter in cap assisted group, but there was no significant difference between the groups (8.9 (IQR 7.5-11.9) min vs 9.1 (IQR 7.0-10.9) min,  $P=0.352$ ). The median single titanium clip fixation time was also no significant difference between the groups (1.2 (IQR 0.9-1.5) min vs 1.2 (IQR 1.0-1.4) min,  $P=0.777$ ). Their maximum insertion pain scores were lower in cap assisted group, but there was no significant difference ( $4.6\pm2.6$  vs  $5.2\pm1.9$ ,  $P=0.573$ ). 3 subjects had anal discomfort and 1 subject had anal pain in cap assisted group, and 1 subject had anal pain in non-cap assisted group after TET. AEs were no significant difference between the groups (4.5% vs 1.0%,  $P=0.201$ ). No severe AEs was observed during and after TET.

**Conclusion:** This study confirms that cap assisted colonoscopy for TET procedure can shorten the second cecal intubation time, and is a safe and effective method. Therefore, it is recommended to insert colonoscope in the second time with cap assisted in TET procedure to improve work efficiency and reduce procedure time, especially for patients with constipation.

## P1800 PATIENT SATISFACTION AND ADHERENCE TO FECAL MICROBIOTA TRANSPLANT ON LONG-TERM CLINICAL OUTCOME OF ULCERATIVE COLITIS

Li Q., Zhang T., Ding X.

*the Second Affiliated Hospital of Nanjing Medical University, Medical Center for Digestive Disease, Nanjing, China*

**Contact E-Mail Address:** xding@njmu.edu.cn

**Introduction:** Ulcerative colitis (UC), a phenol type of inflammatory bowel disease (IBD), is a chronic relapsing and remitting inflammatory disorder of the gastrointestinal tract. Although the pathophysiology of UC remains unknown, growing evidence suggests that the changes in gut microbiota composition may be a key element in gut inflammatory processes<sup>1</sup>. Fecal microbiota transplantation (FMT), which involves the infusion of fecal microbiota from a healthy donor into a patient's intestine for reconstructing gut microbiota, has become an option for the treatment of UC. The way to improve the long-term efficacy of FMT remains unclear.

**Aims & Methods:** This study aimed to evaluate the UC patients' satisfaction with FMT and the role of adherence to scheduled FMT for long-term clinical outcomes. Patients with UC who underwent FMT at our center from November 2012 to September 2018 were evaluated. We assessed patient satisfaction with post-FMT outcomes, adherence to the second course of FMT, and attitude towards delivering ways of FMT.

**Results:** 176 patients were included into the final analysis. At one week, one month, three months, and six months after FMT, the clinical response rate was 48.9%, 69.3%, 49.4%, and 32.7%, respectively. Patients' quality of life was significantly higher one year after FMT than that before FMT ( $P < 0.001$ ). Partial Mayo score at one month post-FMT ( $P < 0.001$ ) was an independent factor of patients' satisfaction. The laboratory preparation process was related to the incidence of adverse events ( $P < 0.05$ ). 76.2% (93/122) of patients exhibited poor adherence to the treatment of sequential FMTs while 23.8% (29/122) of patients followed our recommendation for the second course of FMT. Patients achieved longer clinical response in the good adherence group as compared with the poor adherence group ( $P < 0.001$ ). Patients preferred to choose colonic transendoscopic enteral tubing (TET) as the FMT delivery route.

**Conclusion:** Patients' good adherence to scheduled FMT is an important factor to maintain long-term clinical benefits achieved from FMT.

**Disclosure:** Dr. Faming Zhang invented the concept of GenFMTer and transendoscopic enteral tubing and devices related to it.

## P1801 A PROPENSITY SCORE-WEIGHTED COMPARISON OF VEDOLIZUMAB, ADALIMUMAB, AND GOLIMUMAB IN PATIENTS WITH ULCERATIVE COLITIS: REAL-LIFE DATA FROM THE SICILIAN NETWORK FOR INFLAMMATORY BOWEL DISEASE (SN-IBD)

**Contact E-Mail Address:** fsmacaluso@gmail.com

**Introduction:** The recent VARSITY trial showed that Vedolizumab (VDZ) was superior to Adalimumab (ADA) in achieving clinical remission and mucosal healing in patients with ulcerative colitis (UC). Conversely, no real-life data on the comparative effectiveness of VDZ, ADA, and Golimumab (GOL) in UC have been published yet.

**Aims & Methods:** Data of consecutive patients with UC treated with VDZ, ADA, and GOL from June 2015 to December 2018 were extracted from the cohort of the Sicilian Network for Inflammatory Bowel Disease (SN-IBD). A three-arms propensity score-adjusted analysis was performed to reduce

bias caused by imbalanced covariates at baseline, including the proportion of TNF- $\alpha$  inhibitor naïve and non-naïve patients, using the Inverse Probability of Treatment Weighting (IPTW) approach. The effectiveness was evaluated at 8 weeks, 52 weeks, and as treatment persistence at the end of follow up. The clinical endpoints were steroid-free clinical remission (partial Mayo score  $< 2$  without steroid use) and clinical response (reduction of the partial Mayo Score  $\geq 2$  points with a concomitant decrease of steroid dosage compared with baseline). The sum of the two outcomes was defined as clinical benefit. The achievement of mucosal healing (endoscopic Mayo score 0-1) was assessed after at least 6 months of biological treatment.

**Results:** A total of 463 treatments (187 VDZ; 168 ADA; 108 GOL) were included, with a median follow-up of 47.6 weeks (IQR 20.0-85.9). At 8 weeks, a clinical benefit was achieved in 70.6% patients treated with VDZ, in 68.5% patients treated with ADA, and in 67.6% patients treated with GOL ( $p = n.s.$  for all comparisons); at 52 weeks, VDZ showed better rates of clinical benefit compared with both ADA (71.6% vs. 47.5%; OR: 2.79, 95% CI 1.63-4.79,  $p < 0.001$ ) and GOL (71.6% vs. 40.2%; OR: 3.77, 95% CI 2.08-6.80,  $p < 0.001$ ), while the difference between ADA and GOL was not significant. Cox survival analysis demonstrated that patients treated with VDZ had a reduced probability of treatment discontinuation compared to those treated with ADA (HR: 0.42, 95% CI 0.28-0.64,  $p < 0.001$ ) and GOL (HR: 0.30, 95% CI 0.19-0.46,  $p < 0.001$ ), while patients treated with ADA had a significantly reduced risk of treatment discontinuation compared to those treated with GOL (HR: 0.71, 95% CI 0.50-1.00,  $p = 0.048$ ). Post-treatment mucosal healing rates showed a numerical but non-significant difference in favour of VDZ (48.1%) compared with ADA and GOL (38.0% and 34.6%, respectively).

**Conclusion:** In the first study comparing at the same time the clinical effectiveness of VDZ, ADA, and GOL in UC patients via propensity score-adjusted analysis, VDZ was superior to both subcutaneous agents at 52 weeks and as treatment persistence, while ADA showed a superior treatment persistence compared to GOL.

## P1802 THE FREQUENCY OF FECAL MICROBIOTA TRANSPLANTATION FOR MAINTENANCE OF LONG-TERM EFFICACY IN PATIENTS WITH ULCERATIVE COLITIS: A PILOT STUDY

Li Q., Zhang T., Ding X.

<sup>1</sup>The Second Affiliated Hospital of Nanjing Medical University, Medical Center for Digestive Disease, Nanjing, China, <sup>2</sup>the Second Affiliated Hospital of Nanjing Medical University, Medical Center for Digestive Disease, Nanjing, China

**Contact E-Mail Address:** xding@njmu.edu.cn

**Introduction:** Ulcerative colitis (UC), a phenol type of inflammatory bowel disease (IBD), is a chronic relapsing and remitting inflammatory disorder of the gastrointestinal tract. Although the pathophysiology of UC remains unknown, growing evidence suggests that the changes in gut microbiota composition may be a key element in gut inflammatory processes<sup>1</sup>. Fecal microbiota transplantation (FMT), which involves the infusion of fecal microbiota from a healthy donor into a patient's intestine for reconstructing gut microbiota, has become an option for the treatment of UC. Increasing evidence has shown that fecal microbiota transplantation (FMT) is emerging as a novel therapy for ulcerative colitis (UC).

**Aims & Methods:** To study the frequency of fecal microbiota transplantation for maintenance of long-term efficacy in patients with ulcerative colitis. Patients were recruited from November 2012 to September 2018. 122 patients who achieved clinical response at one month after first course of FMT were included into the final analysis. The risk factors of the efficacy maintenance time and readmission for FMT were assessed by Chi-square test or non-parametric test.

**Results:** The median time of maintaining clinical response to the first course of FMT in total 77 patients was 90 days (IQR, 30-150). The time of maintaining clinical response to the second course of FMT in 25 of 77 patients was 180 days (IQR, 97.5-297.5). Compared with the time of maintaining clinical response to the first course FMT, the second course of FMT achieved prominently longer maintenance time in the 25 patients ( $p < 0.05$ ). No severe adverse event related to the FMT was observed during and after the FMT procedure, as well as during the long-term follow-up. The volume of fecal microbiota did not affect the clinical response maintenance time ( $p = 0.562$ ). The patients with readmission attained remarkably longer time of maintaining efficacy than those without readmission ( $p < 0.0001$ ) and they had significantly better efficacy at 3 months after the first course of FMT comparing with the patients who were not readmission ( $p < 0.0001$ ).

**Conclusion:** This study demonstrated that patients with UC could be administered the second course of FMT less than 3 months after the first FMT and they were advised to get the third course of FMT less than 6 months after the second one for maintaining the long-term clinical benefits from the FMT. Readmission for next course of FMT was valuable to maintain long-term efficacy.

**Disclosure:** Dr. Faming Zhang invented the concept of GenFMTer and transendoscopic enteral tubing and devices related to it.

## P1803 ASSOCIATION OF USTEKINUMAB SERUM CONCENTRATIONS AND PERIANAL FISTULA RESOLUTION IN THE CROHN'S DISEASE UNITI PROGRAM

**Introduction:** Previous studies have demonstrated the efficacy and safety of ustekinumab (UST) IV induction and SC maintenance in Crohn's disease. Analysis from the Phase 2 and 3 UST trials also demonstrated possible benefit in fistula resolution at week 8 [14.1% (10/71) PBO vs 24.7% (37/150) all UST doses combined] despite a small proportion (10.8 to 15.5% across the studies) of patients with active perianal fistulas at baseline (Sands et al DDW 2017). Here we examine the relationship between perianal fistula resolution at induction week 8 (maintenance week 0) and maintenance week 44 based on serum UST levels at maintenance weeks 0 and 24 in patients receiving IV UST induction and SC UST maintenance.

**Aims & Methods:** Patients in UNITI-1 and 2 induction studies were randomized to IV PBO or UST (130mg or ~6mg/kg). Patients with open, draining perianal fistulas at baseline had their fistulas assessed by physical exam (including gentle compression). Patients were analyzed for complete fistula resolution (100% reduction) at subsequent study visits. Fistula resolution at induction week 8 was also analyzed based on week 8 UST serum concentration quartiles, while fistula resolution at maintenance week 44 was analyzed based on maintenance week 24 UST serum concentration quartiles (incorporating non-randomized and randomized groups). Patients who started a prohibited medication (e.g. another biologic) were considered not to be in fistula resolution.

**Results:** In observed data, among randomized patients with open, draining perianal fistulas at baseline of UNITI-1/2 27.5% (11/40) receiving 130mg, 23.7% (9/38) receiving ~6mg/kg UST and 25.6% (20/78) combined UST had fistula resolution induction week 8 compared to 9.3% (4/43) in the PBO group ( $p=0.03$ , 0.08, and 0.03, respectively). At week 44, 85.7% (6/7) and 71.4% (5/7) patients randomized to UST maintenance (90mg Q8W or Q12W) had perianal fistula resolution, compared to 44.4% (4/9) of patients randomized to PBO ( $p=0.15$  and 0.36, respectively). Incorporating all patients (randomized and non-randomized) treated with UST maintenance, perianal fistula resolution occurred in 42% (21/50) of patients. In the induction week 8 quartile analysis, perianal fistula resolution was 38.9% (7/18) in Q1, 11.8% (2/17) in Q2, 27.8% (5/18) in Q3, and 29.4% (5/17) in Q4 for all UST treated patients (Table 1). Fistula resolution at maintenance week 44 based on week 24 concentration quartiles also did not show any exposure response relationship (Table 1).

### Fistula Resolution at Week 8 Post Induction (Week 0 Maintenance) by Serum Concentrations at Week 8 Post Induction (Week 0 Maintenance)

UST Concentration Quartiles WK 0 <sub>a</sub>	130mg UST <sub>b</sub>	~6mg/kg <sub>c</sub>	Combined
Q1	33.3% (3/9)	44.4% (4/9)	38.9% (7/18)
Q2	11.1% (1/9)	12.5% (1/8)	11.8% (2/17)
Q3	44.4% (4/9)	11.1% (1/9)	27.8% (5/18)
Q4	33.3% (3/9)	25.0% (2/8)	29.4% (5/17)

### Fistula Resolution at Week 44 Post Maintenance by UST Serum concentrations at Week 24 Post Maintenance

UST Concentration Quartiles WK 24 <sub>a</sub>	90 mg Q8W <sub>b</sub>	90mg Q8W or Q12W <sub>c</sub>	-
Q1	85.7% (6/7)	75% (9/12)	-
Q2	57.1% (4/7)	50% (6/12)	-
Q3	28.6 (2/7)	25% (3/12)	-
Q4	14.3% (1/7)	27.3% (3/11)	-

a Patients in fistula resolution with missing PK data were excluded from this analysis

b Q1: <1.18 µg/ml; Q2 >1.18 µg/ml <1.62 µg/ml; Q3: >1.62 µg/ml <2.84 µg/ml; Q4 >2.84 µg/ml

c Q1 <3.40 µg/ml; Q2 >3.40 µg/ml <5.04 µg/ml; Q3 >5.04 µg/ml <9.30 µg/ml; Q4 >9.30 µg/ml

d Q1: <1.34 µg/ml; Q2: >1.34 µg <1.99 µg/ml; Q3: >1.99 µg/ml < 3.01 µg/ml; Q4 > 3.01 µg/ml

e Q1: <1.25 µg/ml; Q2: >1.25 µg <2.31 µg/ml; Q3: >2.31 µg/ml < 3.47 µg/ml; Q4 > 3.47 µg/ml

[Table 1: Fistulation Resolution at Induction Week 8 and Maintenance Week 44]

**Conclusion:** Some evidence of efficacy in perianal fistula resolution is present with UST in both induction and maintenance, despite a relatively small number of patients with perianal fistulas. However, perianal fistula resolution did not appear to be associated with higher UST serum concentrations.

## P1804 LOWER TNF-A INHIBITOR DRUG SURVIVAL IN FEMALE PATIENTS WITH INFLAMMATORY BOWEL DISEASE IS RELATED TO A GREATER RISK OF SIDE EFFECTS

Schultheiss J.P.D., Brand E.C., Lamers E., van der Berg W.C.M., Van Schaik F., Oldenburg B., Fidder H.H.  
UMC Utrecht, Gastroenterology, Utrecht, Netherlands

**Contact E-Mail Address:** j.p.d.schultheiss-7@umcutrecht.nl

**Introduction:** Approximately 11% of patients fail to respond to induction therapy with anti-tumour necrosis factor-α (TNF-α) (primary non-responders) and 25-40% of primary responders discontinue treatment because of loss of response or side effects over time. Identification of patient-specific factors related to drug discontinuation is therefore important to aid physicians in clinical decision making. In rheumatoid arthritis and psoriasis female sex has been shown to be associated with discontinuation of anti-tumour necrosis factor-α (TNF-α) therapy. We assessed the association between sex and TNF-α drug survival in patients with inflammatory bowel disease (IBD).

**Aims & Methods:** All IBD patients treated with infliximab (IFX), adalimumab (ADA) or golimumab (GOL) between January 2011 and December 2017 were retrospectively identified in the hospital's pharmacy's record. Patients with a follow-up time of less than 12 months at our hospital were excluded. Patient and treatment characteristics and reasons for anti-TNF-α discontinuation (primary non-response, secondary loss of response, side effects and 'other' discontinuation reasons) were recorded.

The primary analyses were done by multilevel Cox proportional hazards regression models with random intercepts per patient. Univariable hazard ratios for overall discontinuation were estimated. Subsequently the association between sex and overall anti-TNF-α discontinuation was multivariable assessed. Competing risks Cox proportional hazards models were fitted to assess uni- and multivariable hazard ratios for the discontinuation reasons separately.

**Results:** In total 529 patients were included (50.1% female, 631 treatment episodes - 357 IFX, 240 ADA, 34 GOL - and 2280 TNF-α inhibitor treatment years). Female sex (adjusted hazard ratio [aHR] 1.42, 95% CI 1.16 - 1.74), higher age at start of therapy per decade (aHR 1.15, 95% CI 1.04

Current smoker	0.94 (0.61-1.44)	0.93 (0.62-1.40)	0.92 (0.55-1.55)	0.87 (0.52-1.47)	1.20 (0.60-2.41)	0.94 (0.45-1.95)	0.94 (0.38-2.33)	Removed from model
Dose escalation	3.54 (2.64-4.76)	3.74 (2.78-5.02)	6.88 (4.77-9.92)	7.71 (5.28-11.26)	1.22 (0.61-2.44)	1.39 (0.67-2.87)	0.60 (0.27-1.35)	Removed from model
Concomitant immunomodulator use	0.95 (0.72-1.27)	0.94 (0.71-1.24)	0.98 (0.69-1.41)	0.89 (0.62-1.28)	0.72 (0.42-1.22)	0.76 (0.44-1.34)	1.14 (0.61-2.12)	Removed from model

[P1804 Table. Total cohort & total cohort cause-specific analysis]

- 1.27) and dose escalation (aHR 3.74, 95% CI 2.78 - 5.02) were associated with anti-TNF- $\alpha$  therapy discontinuation in both primary and sensitivity analyses. Total cohort cause-specific analysis identified female sex to be associated with side-effects but not with other reasons for discontinuation (aHR 4.05, 95% CI 2.36 - 6.98). Adalimumab (aHR 1.70, 95% CI 1.11 - 2.60) and golimumab (aHR 4.97, 95% CI 2.30 - 10.74) use and dose-escalation (aHR 7.71, 95% CI 5.28 - 11.26) were associated with secondary loss of response.

**Conclusion:** Drug survival of anti-TNF- $\alpha$  therapy is lower in females as compared to males, mainly because of higher rates of discontinuation for side effects in females. Understanding the sex-specific differences in effectiveness and safety of anti-TNF- $\alpha$  compounds can aid physicians in clinical decision-making.

**Contact E-Mail Address:** danipug@libero.it

**Introduction:** The role of Therapeutic Drug Monitoring widely validated for anti TNF- $\alpha$  drugs, especially in case of loss of response, remains debated with Vedolizumab.

**Aims & Methods:** We investigated the utility of early serum Vedolizumab trough levels for predicting the first-year Vedolizumab therapy outcome and identifying patients at higher risk of therapy failure. We included consecutive patients affected by Crohn's disease and Ulcerative Colitis, who started Vedolizumab therapy at two hospitals in Italy. Vedolizumab trough levels and anti-Vedolizumab antibodies were assayed by ELISA at week 6

and 14. Clinical remission (according to Harvey Bradshaw Index and Partial Mayo Score, as appropriate) was assessed at week 6, 14, 22 and 54. The primary endpoint was to explore the correlation between early Vedolizumab trough levels and Vedolizumab persistence over the first year of treatment, defined as the maintenance of therapy because of sustained clinical benefit.

**Results:** 101 patients (82% exposed to anti TNF- $\alpha$  drugs) were included. Median VTL were 28.3  $\mu$ g/mL (IQR 16.9-39.8) at week 6 and 18.4  $\mu$ g/mL (IQR 11.8-25) at week 14 after the first infusion of vedolizumab. A cut-off TL of 16.55  $\mu$ g/ml at week 14 predicted Vedolizumab persistence within the first year of therapy with a sensitivity of 73.3 % and a specificity of 59.4% (p = 0.0009, AUROC 0.686, 95% CI 0.581-0.779).

Week 14 Vedolizumab trough levels were significantly higher in patients with clinical remission at week 14, 22, 54, as well as in those patients achieving mucosal healing within 54 weeks. Early Vedolizumab trough levels were significantly correlated with serum albumin levels (Spearman's rho=0.204, p=0.0107).

**Conclusion:** High VTL at week 14 were associated with a higher probability of maintaining Vedolizumab therapy over the first year because of a sustained clinical benefit.

**Disclosure:** Nothing to disclose

## P1806 IMPACT OF THE SWITCH FROM ORIGINAL ADALIMUMAB TO BIOSIMILAR ADALIMUMAB SB5 ON SERUM DRUG TROUGH LEVELS, CLINICAL AND BIOLOGICAL DISEASE ACTIVITY IN PATIENTS WITH IBD

**Contact E-Mail Address:** milan.lukas@email.cz

**Introduction:** Biosimilar adalimumab SB5 is a biosimilar monoclonal antibody for the treatment of patients with autoimmune diseases such as inflammatory bowel disease (IBD). Generally, biosimilars are biological products showing high resemblance to the reference biological products, and they exhibit no clinically meaningful differences in terms of safety and effectiveness.

Since monitoring of adalimumab serum trough levels hold an important significance in treatment modalities, insufficient data about monitoring of drug serum trough levels in IBD patients treated with SB5 are present to date.

**Aims & Methods:** In this study, we applied original adalimumab-validated ELISA based on TNF $\alpha$  as a target antigen to determine drug serum levels of SB5. The primary objective of current study was to compare serum trough levels of original adalimumab and SB5 before and after switching from the original to the biosimilar drug. Secondary aims were to assess clinical effectiveness of biological treatment after the switching from original adalimumab to SB5 by symptom activity indexes (Harvey-Bradshaw index (HBI) in Crohn's disease, and partial Mayo score (pMayo) in ulcerative colitis and response as assessed by systemic and local inflammatory markers (C-reactive protein, CRP; and fecal calprotectin, FC).

Eighty-seven IBD patients, responders in maintenance adalimumab treatment period, after the switching from original adalimumab to SB5, with known previous three measurements of the original adalimumab trough levels, were included. Sera from IBD Blood Bank established according to the Ethics Committee of ISCARÉ (Nr 2015/1a) were used, and patient data were anonymously processed according to the latest version of the Helsinki Declaration of Human Research Ethics.

Biosimilar adalimumab trough levels at W10 after the switching were measured by enzyme immunoassay (ADALIMUMAB ELISA ImmunoGuide, REF: IG-AA103). CRP serum concentrations measured by immunonephelometry and fecal calprotectin levels measured by fluoroimmunoassay on switching day were compared with W10 values after the switching.

**Results:** Of 87 patients, 47 were women and 40 were men; 77 with Crohn's disease and 10 with ulcerative colitis; median age 39.5 (23 to 70) years. No differences in CRP and FC values before and after the switching were observed (Spearman's rank correlation coefficients  $r = 0.320$  ( $p = 0.0048$ ) and  $r = 0.833$  ( $p < 0.0001$ ), respectively). Similarly, no significant differences were found in HBI and pMayo values: Kruskal-Wallis H-test have shown  $p = 0.824$  for HBI and  $p = 0.855$  for pMayo indexes. Moreover, excellent quantitative agreement was observed between mean adalimumab trough levels before and after the switching from the original drug to SB5: Spearman's rank coefficient values were  $r = 0.756$  and  $p < 0.0001$ .

**Conclusion:** TNF $\alpha$ -based ELISA kit for measuring adalimumab trough levels showed similar overall performance in the detection of original and biosimilar adalimumab-containing sera. Clinical effectiveness of adalimumab treatment after the switching from the original to the biosimilar adalimumab SB5 assessed by symptom activity indexes and by systemic and local inflammatory markers remained identical after the switching.

**Disclosure:** Supported by the IBD-Comfort Endowment Fund.

## P1807 CLINICAL DECISION SUPPORT TOOL PREDICTS RISK OF INFECTION IN PATIENTS WITH INFLAMMATORY BOWEL DISEASE TREATED WITH VEDOLIZUMAB

Dulai P.<sup>1</sup>, Feng D.<sup>2</sup>, Lasch K.<sup>2</sup>

<sup>1</sup>University of California San Diego, La Jolla, United States, <sup>2</sup>Takeda Pharmaceuticals USA Inc, Deerfield, United States

**Contact E-Mail Address:** pdulai@ucsd.edu

**Introduction:** Disease activity is an independent predictor of infections while patients are receiving biologic therapy; however, prior studies have not taken into consideration the persistence of disease activity due to ineffectiveness of therapy when attempting to identify predictors of infectious complication. We hypothesized that a clinical decision support tool (CDST) that predicts treatment effectiveness would also predict the risk of developing an infection while on therapy.

**Aims & Methods:** Two previously built and externally validated CDSTs that predict the treatment effectiveness of vedolizumab in ulcerative colitis (UC) and Crohn's disease (CD) were used in combination with the phase 3 clinical trial data sets (GEMINI). UC and CD patients were stratified by baseline variables using the CDSTs into low, intermediate, or high probability of response to vedolizumab. Time-to-event with Cox proportional hazard models was used to compare the risk of infection across groups and to identify independent predictors of infections among subgroups.

**Results:** A total of 618 UC and 1,023 CD patients were included. Among both UC and CD patients, those categorized as having a low-intermediate probability of response ( $n=479$  UC,  $n=814$  CD) to vedolizumab were more likely to develop infectious complications while on therapy than those categorized as having a high probability ( $n=139$  UC,  $n=209$  CD) of response to vedolizumab (UC: hazard ratio [HR] 1.383, 95% confidence interval [CI] 1.024-1.868; CD: HR 1.458, 95% CI 1.124-1.893). The proportion of patients developing a serious infection was 1% of UC and 3% of CD patients in the high-probability groups versus 2% of UC and 5% of CD patients in the low-

intermediate probability of response groups. Among the low-intermediate probability of response UC group, independent predictors of developing an infection were baseline extraintestinal manifestation (no versus yes; HR 0.755, 95% CI 0.569-1.001), previous tumour necrosis factor (TNF) antagonist exposure (no versus yes; HR 0.671, 95% CI 0.497-0.906), and baseline faecal calprotectin (log transformed; HR 1.135, 95% CI 1.016-1.268). Among the low-intermediate probability of response CD group, an independent predictor of developing an infection was previous TNF antagonist exposure (no versus yes; HR 0.727, 95% CI 0.553-0.957).

**Conclusion:** Vedolizumab is an overall safe and well-tolerated biologic therapy in both UC and CD. We observed that patients with a low-intermediate probability of response to vedolizumab have an increased risk for developing infectious complications. These data suggest that persistence of disease activity due to lack of efficacy may be a primary determinant of safety, as opposed to drug-related mechanisms.

## P1808 SORBICILLIN FRACTION OF *PENICILLIUM FLAVIGENUM* FOR THE TREATMENT OF INFLAMMATORY BOWEL DISEASE: IN VITRO AND IN VIVO STUDIES

Dovbynchuk T.<sup>1</sup>, Ivashchenko O.<sup>1</sup>, Dikmen M.<sup>2</sup>, Zholos A.<sup>1</sup>, Öztürk Y.<sup>2</sup>, Canturk Z.<sup>2</sup>, Tolstanova G.<sup>1,3</sup>

<sup>1</sup>Taras Shevchenko National University of Kyiv, ESC Institute of Biology and Medicine, Kyiv, Ukraine, <sup>2</sup>Anadolu University, Pharmacy Faculty, Eskisehir, Turkey, <sup>3</sup>Taras Shevchenko National University of Kyiv, Institute of High Technology, Kyiv, Ukraine

**Contact E-Mail Address:** mtaisa80@gmail.com

**Introduction:** Inflammatory bowel diseases (IBD) are chronic relapsing intestinal inflammation that often require to treat patients over years and to adapt the therapy repeatedly with respect to side effects or loss of previous medication effect. By so, we constantly need to search for a new non-toxic compound to better optimize the current IBD treatment.

**Aims & Methods:** The aim of the present study is to test the effects of secondary metabolite sorbicillin of *Penicillium flavigenum* *in vitro* and *in vivo* model of IBD.

1) Aqueous fraction of sorbicillin was extracted from *Penicillium flavigenum* isolated from Lake Salt (Konya, Turkey) and analysed on LC-MS.

2) The cytotoxicity, cell proliferation and apoptotic effects of sorbicillin and mesalazine (positive control) (500, 250, 125, 62.5 and 31.25  $\mu$ g/mL) were investigated on Caco2 colorectal adenocarcinoma cells after 24 h incubation by WST-1 assay, xCELLigence RTCA-DP Real Time Cell Analyzer and AnnexinV-PI assay, respectively. IL-1 $\beta$  production by LPS (1  $\mu$ g/mL)-stimulated THP-1 human monocyte cells was analysed by flow cytometry.

3) Ulcerative colitis (UC) was induced in unfasted Wistar rats by 6% iodoacetamide (IA) in 1% methylcellulose or vehicle - control (0.1 ml/rat, given intracolonically).

Sorbicillin (50, 100 and 200 mg/kg) dissolved in H<sub>2</sub>O or placebo (sterile H<sub>2</sub>O) were gavaged daily for 5 days after IA enema, followed by autopsy on the 7th day. Body weight, lethargy and diarrhea were recorded daily. Damage score of colonic lesions; MPO activity by H<sub>2</sub>O<sub>2</sub>-dependent oxidation of o-dianisidine hydrochloride; colonic vascular permeability by the extravasation of Evans blue injected intravenously 15 min prior euthanasia; glycoproteins levels in colonic mucus by PAS staining on PVDF membrane; and cecum weight were recorded.

**Results:** Sorbicillin and mesalazine did not show cytotoxic and apoptotic effects at all studied concentrations on Caco2 cells. Whereas treatment of LPS-stimulated THP-1 cells with 500  $\mu$ g/mL of Sorbicillin or mesalazine for 24 h reduced the levels of IL-1 $\beta$  from 28.4% in control to 6.6 and 6.7 %, respectively. Sorbicillin in dose 50 and 100 mg/kg did not induce significant effect on clinical and morphological signs of IA-UC. While, rats treated with sorbicillin 200 mg/kg had the same pattern of body weight gain as the control rats (15% IA+sorbicillin vs 4% in IA+placebo). Sorbicillin in dose 200 mg/kg significantly ( $p < 0.05$ ) reduced lesioned area, loss of rugae, dilatation, weight of colon/100 g, cecum weight/100 g and colonic MPO activity vs. IA+placebo group. Moreover, sorbicillin (200 mg/kg) reduced 2-fold ( $p < 0.05$ ) the colonic vascular permeability and increased 1.5-fold ( $p < 0.05$ ) glycoproteins levels in colonic mucus in rats with IA-UC vs. IA+placebo group.

**Conclusion:** Sorbicillin-containing aqueous fraction of *Penicillium flavigenum* does not have cytotoxic and apoptotic effects on Caco-2 cell, but has anti-inflammatory effect by reducing IL-1 $\beta$  levels in LPS-stimulated THP1 cells. Sorbicillin ameliorates iodoacetamide-induced UC in rats. The restoration of mucosal barrier and resolving inflammation are the potential mechanism of sorbicillin beneficial effect. **Acknowledgement:** This study was supported by Mevlana Project Based International Exchange Programme (Project number: D26-MEVLANA-01).

## P1809 REVERSE SWITCHING TO ORIGINATOR INFlixIMAB MAY BE CONSIDERED IN PATIENTS WITH INFLAMMATORY BOWEL DISEASES EXPERIENCING NEW SIDE EFFECTS OR LOSS OF RESPONSE AFTER SWITCHING TO A CT-P13 BIOSIMILAR

Mahmmod S.<sup>1</sup>, Schultheiss J.P.D.<sup>1</sup>, Mahmmod N.<sup>2</sup>, Tan A.C.<sup>3</sup>, Dijkstra G.<sup>4</sup>, Fidler H.H.<sup>1</sup>

<sup>1</sup>UMC Utrecht, Gastroenterology, Utrecht, Netherlands, <sup>2</sup>Antonius Ziekenhuis Gastroenterology, Zeist, Netherlands, <sup>3</sup>Canisius Wilhelmina Hospital Dept. of Hepatogastroenterology, Nijmegen, Netherlands, <sup>4</sup>UMC Groningen Gastroenterology and Hepatology, Groningen, Netherlands

**Contact E-Mail Address:** j.p.d.schultheiss-7@umcutrecht.nl

**Introduction:** In current clinical practice, patients with inflammatory bowel disease (IBD) treated with originator infliximab (IFX) have been or are being switched to biosimilar infliximab because of lower costs and seemingly similar effectiveness of biosimilars. Over a one-year follow-up 7%-26% of the patients discontinued biosimilar IFX treatment, which is comparable to originator IFX. Common reasons for discontinuation of biosimilar IFX treatment are (subjective) loss of response or side effects. As a result of newly experienced side effects or loss of response while using biosimilar infliximab, patients are occasionally switched back to treatment with originator IFX. However, not much is currently known regarding reverse switching to originator IFX.

**Aims & Methods:** Our aim was to assess the prevalence of and the specific reasons for reverse switching to originator infliximab within 52-weeks after an initial conversion from originator infliximab to a CT-P13 biosimilar in patients with IBD. Additionally, we evaluated whether reinitiating originator infliximab led to the desired favorable effect.

In this retrospective, observational, multi-centre cohort study, data of IBD patients from two tertiary care centres and two large general hospitals in the Netherlands were collected. Adult patients with IBD were eligible for inclusion if they had been switched from infliximab originator to the CT-P13 biosimilar and had a follow up time of at least 52 weeks after initial conversion. Reasons for re-switching were categorised into side effects or loss of response to the biosimilar.

**Results:** A total of 254 patients with IBD were switched (165 Crohn's disease, 52 Ulcerative colitis and 2 IBD-Unclassified). Reverse switching occurred in 35/254 (13.8%) of the patients after a mean of 23.6 weeks. Reverse switchers were more often female (48.9% versus 68.6%,  $p = 0.02$ ) than those who stayed on biosimilar treatment.

Thirty-two patients (91.4%) switched back to the originator because of newly experienced side effects and only three (8.6%) because of loss of response on biosimilar IFX. Most frequently reported side effects were skin reactions in 37.1% of patients (13/35), an increase in IBD related symptoms 37.1% (13/35) of patients and fatigue in 25.7% (9/35) of patients. Three patients had by calprotectin (>250 mg/L) objectified loss of response on infliximab biosimilar. In 75% (24/32) of the patients experiencing side effects and 100% (3/3) of the patients with loss of response, reverse switching to originator IFX led to the desired effect of improvement of the side effect or regaining of response to IFX therapy.

**Conclusion:** Switching back to originator infliximab seems effective in patients with IBD, who experience side effects or loss of response after switching from originator to biosimilar infliximab. Switching patients back to originator infliximab may therefore be justified in case patients experience new side effects or loss of response after switching to a biosimilar IFX.

**Introduction:** Vedolizumab (VDZ) therapy as alternative option in the management of moderate and severe IBD has been registered since 2016 in Hungary, however all newly initiated VDZ therapy was individualized, it should be approved by the steering committee of five Hungarian IBD-specialist up to 2019. This situation resulted that only those patients could be received VDZ treatment whose longstanding disease showed inadequate response to the conventional anti-TNF-alpha and/or immunosuppressant therapy. The aim of our observational study was to assess the efficacy of short- and long-term VDZ therapy on clinical and endoscopic activity in moderate and severe active IBD in real-life setting.

**Aims & Methods:** Our non-interventional multicenter cohort study enrolled all adult IBD patients with moderate and severe activity who received VDZ therapy between July 2016 and December 2018 in our entire country. The therapeutic response was assessed based on the changes of clinical (Crohn's Disease Activity Index [CDAI], Mayo score) and endoscopic (Simple Endoscopic Score for Crohn Disease [SES-CD], endoscopic Mayo score) scores. Clinical response was defined as >3 points decrease in the total Mayo score or >100 decrease in CDAI score from baseline. Remission was defined as Mayo score ≤2, with no individual subscores >1, or as CDAI score ≤150. Mucosal healing was defined as Mayo endoscopic subscore ≤1 or as SES CD score ≤4.

**Results:** 83 Crohn's disease (CD) and 121 ulcerative colitis (UC) patients completed VDZ induction therapy. The mean age was 39.9 years (range 18-78; median 36) and the average disease duration was 9.6 years (range 1-36; median 8). Extraintestinal manifestations occurred in 57 patients (27.9%), and in 11 cases (5.4%) IBD was associated with primary sclerosing cholangitis (PSC). The mean value of activity scores significantly decreased by the end of short-term treatment period both in CD (SES-CD: 20.93 vs. 13.55;  $p < 0.00001$ ; CDAI: 303.58 vs. 167.66;  $p < 0.00001$ ) and UC (Mayo: 9.74 vs. 4.33;  $p < 0.00001$ ; eMayo: 2.80 vs. 1.41;  $p < 0.00001$ ) subgroups. The rate of clinical response during the short-term VDZ therapy was substantially higher in the UC group compared with CD group (84.3% vs. 61.5%;  $p < 0.0001$ ). No significant difference in terms of the proportion of clinical remission and steroid-free remission was observed between the UC and CD subgroups (49.6% vs. 51.8%,  $p = 0.777$ ; and 27.3% vs. 37.4%,  $p = 0.169$ ). In 124 cases (72 UC and 52 CD) the first-year VDZ treatment could have been completed during the study period, however in 32 cases (25.8%) primary non-response for induction therapy was observed. 92 patients (60 UC and 32 CD) received maintenance VDZ therapy. The rate of response, clinical remission and steroid-free remission were substantially higher in UC (65.3%, 47.2% and 44.4%) compared with CD (42.3%, 32.7% and 30.8%) by the end of first-year therapy ( $p < 0.001$ ). Significant difference was observed between UC and CD subgroups in terms of mucosal healing both by the end of induction and by the end of first-year therapy (52.9% and 21.7%,  $p < 0.0001$  vs. 51.4% and 21.2%,  $p = 0.015$ ).

**Conclusion:** Our results suggest that both the short-term and the one-year long maintenance VDZ therapy is effective and safe therapeutic option in anti-TNF-alpha failure or intolerant IBD patients with moderate or severe disease activity, however significant difference was observed between the UC and CD subgroups. Mucosal healing was achievable in every second UC and in only every fifth CD patients both by the end of the induction and by the end of first-year treatment in this difficult-to-treat population.

**Introduction:** Thioguanine (TG) is an alternative thiopurine therapy which has been used for patients with inflammatory bowel disease (IBD) who have failed azathioprine or 6-mercaptopurine due to side effects or sub-optimal response. Its widespread use has been hampered from concerns about safety of TG due to reports of liver toxicity, especially nodular regenerative hyperplasia (NRH), when TG was used in higher doses.

**Aims & Methods:** The aim of this study was to investigate the long-term efficacy and safety of low-dose TG in IBD after failure of prior conventional therapy in an English cohort.

A retrospective multicentre chart study was performed on IBD patients who were treated with TG from 2006 to 2019 in three hospitals in the United Kingdom. Both patients' characteristics and drug history as well as the efficacy and safety profile of TG therapy were reviewed in the patients' medical records. Clinical, radiological and laboratory parameters were collected; to assess NRH liver biopsies and MRI results were assessed. Clinical remission was defined as: no (re)initiation of corticosteroids, no initiation of biological therapy and no surgical intervention.

**Results:** In total 193 patients (57% female and Crohn's disease in 64%) were included, with a median daily TG dose of 20 mg (range: 20-40 mg), a median treatment duration of 23 months (range: 0-155 months) and a

median follow-up of 36 months (range: 1-155 months). 71% of the patients showed clinical remission to TG within 6 months and 54% of the patients were still using TG at final follow-up. Forty-three patients (22%) stopped TG due to intolerance(s) and 15 patients (8%) stopped due to resistance. Intolerances to TG occurred in 28% of the patients ( $n = 54$ ), primarily consisting of elevated liver enzymes ( $n = 9$ , 5%), myelotoxicity ( $n = 9$ , 5%) and rash ( $n = 9$ , 5%). Pancreatitis only occurred in one patient with a history of thiopurine-induced pancreatitis. NRH was diagnosed in two patients (1%).

**Conclusion:** Long-term follow-up shows that thioguanine was effective and well-tolerated in 54% patients who had failed conventional therapy. The occurrence of pancreatitis and NRH was very little in this study.

**Disclosure:** Nothing to disclose

### P1812 THE OUTCOME OF RESECTED CROHN'S DISEASE PATIENTS WITH NO POSTOPERATIVE TREATMENT BUT UNDER CLOSE ENDOSCOPIC FOLLOW UP AND ACCELERATED STEP UP TREATMENT IN CASE OF ENDOSCOPIC RELAPSE: A TERTIARY REFERRAL CENTER PILOT STUDY

**Introduction:** According to POCER study, postop. endoscopic follow up at 6 mo. and relevant treatment (tx) escalation of resected CD patients might decrease endoscopic relapse rates at 18 mo. compared to those getting the best postop. tx according to their risk stratification without endoscopic follow up. However after minimizing the inflammatory load in the postop. setting there might be still a group of unnecessarily overtreated patients. So our aim was to determine the outcome of resected CD patients with no initial postop. tx independent of risk status.

**Aims & Methods:** Starting in 2012 we closely followed up each CD patient after their first ileocecal resection with colonoscopy at 3-6-12-18-24 mo. and then annually. Active smoking, resection for penetrating disease were accepted as risk factors for relapse but both high or low risk groups were followed up without any initial tx. If relapse was detected at any colonoscopy an accelerated step up tx. was applied starting with 5-ASA+ budesonide, continuing with AZA and ending up with biologics in an add on fashion.

All patients' demographic features like age, age at onset, operation, sex, disease duration, location, behaviour, reason for resection, smoking status, Rutgeerts score at each colonoscopy were noted. Patients with active perianal disease and upper GI involvement were excluded.

**Results:** A total of 45 patients [mean age 40.40±10.66 yr, 24 being female, 29 (65%) with high risk] were enrolled into the study. Mean follow up time was 54.46±18.83 mo. The overall endoscopic relapse rate during whole follow up was 36/45 (80%), median time to relapse being 3 mo. Relapse rate showed no relation with parameters like age, age at onset, and operation, sex, disease location, and established risk factors for postop. relapse (active smoking, penetrating disease). After starting the step up tx the percentage of relapsers decreased to 23 out of 36 at the very last visit. Nine out of 45 (20%) never had a relapse although six of them actually having risk factors.

**Conclusion:** In light of previous POCER study the relapse rate at 18 mo. was 50% when the best tx immediately was started and managed according to postop. colonoscopy at 6 mo. In the present study the endoscopic relapse rate was the same despite a longer follow up time of 54 mo., although none of them had an immediate postop. tx. but received the appropriate tx. in an accelerated step up manner. These results make us question the defined postop. risk factors and we think that our approach could help tailoring individual tx. and avoiding unnecessary tx. at least in a subgroup of patients.

**Introduction:** Previous studies have demonstrated that early bowel resection (EBR) in ileocolonic Crohn's disease (CD) can result in an improved clinical course compared to initial medical treatment (IMT), including escalation to biologic therapy

**Aims & Methods:** We sought to compare the safety and efficacy of EBR versus IMT for the management of patients with ileocolonic CD. A systematic search was performed to identify studies that compared EBR (performed < 1yr from initial diagnosis) or IMT for the management of ileocolonic CD. Log hazard ratios (lnHR) for recurrence free survival (RFS) and their standard errors were calculated from Kaplan-Meier plots and pooled using the inverse variance method. Dichotomous variables were pooled as odds ratios (OR). Quality assessment of the included studies was performed using the Newcastle-Ottawa (NOS) and Jadad scales

**Results:** 7 studies of 1863 CD patients (EBR n= 581, 31.2%; IMT n= 1282, 68.8%) were eligible for inclusion. The studies had a moderate to high risk of bias. The median NOS was 8 (range 7-9). There was a reduced likelihood of overall (OR 0.53 95% Confidence interval [95% CI]: 0.34, 0.83, p=0.005) and surgical (OR 0.47, 95% CI 0.24, 0.91, p=0.03) recurrence with EBR than with IMT. There was also a less requirement for maintenance biologic therapy (OR 0.24, 95% CI 0.14, 0.42, p< 0.0001).

Patients who underwent EBR had a significantly improved RFS than those who underwent IMT (HR, 0.62 95% CI 0.52, 0.73, p< 0.001). There was no difference in morbidity (OR 1.67, 95% CI 0.44, 6.36, p=0.45) between the groups.

**Conclusion:** Surgery is associated with reduced recurrence and need for maintenance biologic therapy in CD. It is critical that both a surgeon and a gastroenterologist review patients early, at the time of diagnosis, to facilitate informed management decisions.

## P1814 HOME-DELIVERED INFLIXIMAB INFUSION: SAFETY DATA FROM 373 HOME INFUSIONS OVER 4 YEARS

Shaikh F.A.<sup>1</sup>, Goodoory V.<sup>2</sup>, Shenderey R.<sup>2</sup>, McConnell J.<sup>3</sup>

<sup>1</sup>Airedale General Hospital Keighley, Gastroenterology, Keighley, United Kingdom, <sup>2</sup>Airedale Hospital NHS Foundation Trust, Gastroenterology, Keighley, United Kingdom, <sup>3</sup>Airedale Hospital NHS Foundation Trust, Keighley, United Kingdom

**Contact E-Mail Address:** f\_shaikh88@hotmail.com

**Introduction:** Treatment with infliximab for patients with Inflammatory Bowel Disease (IBD) in the UK consists of intravenous infusions usually delivered in hospital via a nurse-led service. Several studies have proven the safety of infliximab infusions at home which also eases the capacity for hospital infusions. However, the uptake in clinical practice has been slow in the UK. We aim to evaluate the safety and patient satisfaction of home infliximab infusions in a district general hospital 4 years after its introduction.

**Aims & Methods:** This is a retrospective audit of all IBD patients enrolled in a home infliximab infusion programme from July 2014 to July 2018. Data were collected from the electronic database and case notes. Data collected included serious adverse reactions requiring hospital admission and number of times home infusions were put on hold/stopped because of safety concerns. Patients currently on the home infliximab infusion programmed were interviewed by telephone by 2 Gastroenterology specialist trainees. Satisfaction rate (out of 10) were collected for adequate communication, delivery times, customer service, driver assistance/attitude, nurse support service, clinical waste collection and overall satisfaction.

**Results:** A total of 41 patients were included in the analysis (3 excluded due to insufficient follow up data): median age was 42 years, 19 (46.3%) were women, 9 (22%) had ulcerative colitis and 32 (78%) had Crohn's disease. Three hundred and seventy three (373) infliximab infusions were given at home: there were no deaths and no adverse reactions requiring hospital admission. There were 3 (0.8%) instances where home infliximab infusions were put on hold or stopped as shown in table 1. Patients were given a median number of 7 doses of infliximab in hospital before moving to the home infliximab infusion. The median follow up time on home infliximab was 14 months and the median number of doses given at home was 7. Eighteen (69.2%) out of 26 patients on home infliximab in July 2018 responded to a telephone interview. Mean and median satisfaction rates were 9.7 and 10 (out of 10).

**Conclusion:** A home infliximab infusion programme for patients with IBD is safe with all adverse reactions being minor and managed in the community. Patient satisfaction rate is high.

**Disclosure:** Nothing to disclose

## P1815 THE DUBLIN INFLAMMATORY BURDEN SCORE PREDICTS EARLY CLINICAL AND BIOCHEMICAL RESPONSE TO GOLIMUMAB TREATMENT IN UC; EARLY RESULTS OF THE GOAL-ARC STUDY

**Contact E-Mail Address:** ciaraegan@rcsi.ie

**Introduction:** Golimumab (GLM) is an anti-TNF monoclonal antibody licensed for the treatment of Ulcerative Colitis. Higher trough levels are associated with enhanced response to therapy. (GOAL-ARC) is a randomized multi-centered trial of the impact of personalized dosing of Golimumab based on inflammatory burden (assessed by FCP - faecal calprotectin) and therapeutic drug monitoring versus standard of care (with dosing according to label). We aimed to evaluate the impact of inflammatory burden in UC on drug levels and early response to GLM treatment.

**Aims & Methods:** All study participants had a diagnosis of UC, with moderate to severe disease activity (Mayo 6-12), with an endoscopic sub-score of ≥2. Clinical response was defined as a decrease in baseline modified partial Mayo score of 2 points or a decrease of ≥30% from baseline. GLM was administered at 200mg at week 0, 100mg at week 2 in all patients in advance of week 6 assessment.

Induction data was analyzed to week 6 including baseline inflammatory burden (DUBLIN Score - Rowan et al, JCC 2019), FCP and modified partial Mayo scores and week 6 trough GLM levels.

**Results:** 70 patients have been recruited to GOAL-ARC. 90% have completed the induction phase to week 6. Moderate disease activity was present in 79% with a Mayo endoscopic sub-score of 2 at screening. 56% had a weight < 80Kg.

Pre and post induction data was available on 51 patients. Clinical response was achieved in 57% at week 6. The median modified partial Mayo score decreased from 4 (IQR 3-5) at baseline to 2 (IQR 1-3) at week 6 (p< 0.001). Median FCP reduced from 1380 (IQR 685-3000) at baseline to 180 (IQR 15-1122) at week 6 (p=0.001). A lower baseline DUBLIN score was associated with clinical response at week 6 (p=0.048).

Median GLM level at week 6 was 3.97 (IQR 2.3-5.8). Higher week 6 drug levels were associated with clinical response. (p=0.012). Week 6 GLM level was inversely proportional to week 6 FCP (p=0.001). Baseline DUBLIN score was inversely proportional to week 6 drug levels (p=0.021).

**Conclusion:** Early results of GOAL-ARC demonstrate the majority (57%) of UC patients treated with GLM show early clinical response (by week 6). Significant improvements are observed in modified partial Mayo scores and FCP by week 6, with higher drug levels being significantly associated with achieving clinical response and reductions in faecal calprotectin. Lower baseline DUBLIN (inflammatory burden) scores are associated with higher trough drug levels and clinical response at week 6 indicating that a higher inflammatory burden is associated with poorer outcomes.

	Baseline	Week 6	p value
Faecal Calprotectin µg/g Median (IQR)	1380 (685-3000)	179.5 (15-1122)	0.001
Modified Partial Mayo score median (IQR)	4 (3-5)	2 (1-3)	<0.001

[Table 1. Comparison of baseline and week 6 median faecal calprotectin and modified partial mayo scores following induction with Golimumab]

## P1816 EARLY 'REAL WORLD' EXPERIENCE WITH TOFACITINIB FOR MODERATE TO SEVERE ULCERATIVE COLITIS

Honap S., Sharma E., Ray S., Begum Y., Tamilarasan A.G., Cunningham G., Lubner R., Mawdsley J., Anderson S., Sanderson J., Irving P.M.  
IBD Centre, St. Thomas' Hospital, London, United Kingdom

**Contact E-Mail Address:** honap@hotmail.co.uk

**Introduction:** Tofacitinib is an oral, small molecule Janus kinase inhibitor, which received NICE approval for the treatment of moderate to severe treatment-refractory ulcerative colitis in late 2018. We present early clinical and biomarker outcome data for a cohort of new starters in a tertiary IBD referral centre.

**Aims & Methods:** A retrospective cohort analysis of patients was undertaken using prospectively maintained records. Patients commenced on tofacitinib between October 2018 to April 2019 were included. Clinical disease activity was measured at baseline and at four and eight weeks using the Simple Clinical Colitis Activity Index (SCCAI). Faecal calprotectin (FCAL) and C-reactive protein (CRP) were measured at baseline and eight weeks. Descriptive statistics and Wilcoxon signed rank test were calculated using GraphPad Prism version 8.0.

**Results:** Twenty five patients commenced tofacitinib, median age 32 (range 19-74) and median disease duration of 7 years (range 0.4-20). All patients had previously failed biologic therapy (24 anti-TNF, 1 vedolizumab and 13 both). Paired outcome data was available for n=20 at week 4 and n=15 at week 8. Median baseline SCCAI fell from 8 (range 2-14) to 3 (1-7) after four weeks (n=20), further decreasing to 2 (0-6) at week 8 (n=15) (p<0.0001). Median baseline FCAL (n=15) fell from 451(63-6020) to 95(5-1420) (p<0.0001). There was no significant change in CRP following induction therapy. One patient discontinued due to non-response. Tofacitinib was well tolerated in our cohort with only one patient ceasing therapy after two weeks due to headaches. No significant haematological or biochemical abnormalities were noted.

**Conclusion:** Our early experience with tofacitinib for those with disease refractory to one or more biologic agents, is encouraging. Real life effectiveness appears to be at least as good as the efficacy demonstrated in the trial programme and tolerance is also reassuring, albeit in a small cohort with limited follow up.

## P1817 PREDICTIVE FACTORS FOR THE RESPONSE TO INTRAVENOUS CORTICOSTEROID THERAPY IN SEVERE ACUTE COLITIS

Tamzaourte M., Berrag S., Jamal S., Mourabit S., Aourarh A.  
Mohammed V Teaching Military Hospital, Gastroenterology 1 Departement, Rabat, Morocco

**Contact E-Mail Address:** mouna.tamzaourte@gmail.com

**Introduction:** Acute severe colitis can be a revelation or occur in the course of a known chronic inflammatory bowel disease, especially ulcerative colitis. Intravenous corticosteroid therapy (IVC) is the first-line medical treatment of acute severe colitis. The aim of our work is to evaluate the predictors of the response to intravenous corticosteroid therapy in severe acute colitis

**Aims & Methods:** This is a two-year observational study of 27 cases of acute colitis collected in our department. acute severe colitis was defined by a Lichtiger score greater than 10. Clinical, biological, endoscopic and radiological data were collected and analyzed by SPSS20 software.

**Results:** The average age of our patients is 37.9 ± 17.1 years with a clear female predominance (21/27). 6 patients (22.2%) had known IBD. The average Lichtiger score was 13 ± 1.45. 9 patients (33.3%) were naive steroids. 9 patients (33.3%) had endoscopic severity criteria. 19/20 of the patients in failure with the CO received the IFX, a patient was operated for colectomie. In univariate analysis, the factors significantly associated with the failure of CO IV were: CRP elevated on D3 (>45mg / l), presence of blood on D3, pancreatic involvement, non-naive status with corticosteroids. In multivariate analysis and adjusting to the above factors, only CRP >45mg / l to J3 is significantly associated with CO IV failure (OR = 1.3, p = 0.02).

**Conclusion:** Our study confirms the data in the literature on the importance of the CRP assay at D3 to evaluate the response or failure to intravenous corticosteroid therapy in the initial management of severe acute colitis.

**Disclosure:** Nothing to disclose

## P1818 THE EFFICACY AND THE SAFETY OF VEDOLIZUMAB IN A GROUP OF ANTI-TNF EXPERIENCED PATIENTS WITH IBD; A REAL-LIFE DATA FROM TURKEY

**Introduction:** Vedolizumab is a new agent acting as an anti-Integrin which has been started to be use in treatment of Crohn's disease (CD) and Ulcerative Colitis (UC). In this retrospective study we aimed to examine the safety and effectiveness of vedolizumab treatment in anti-TNF experienced patients with CD and UC. In addition we aimed to show whether there is a role for thiopurines in vedolizumab treatment.

**Aims & Methods:** : Chart review was performed retrospectively in patients with UC and CD in Cerrahpasa University, Ankara University and Acibadem University IBD outpatient clinics. Clinical response and clinical remission rates were calculated by using Harvey-Bradshaw Index and Partial Mayo score.

**Results:** Total of 101 patients [mean age 39.4±12.7 yr, 51 Male, 57 CD (56%)] were enrolled into the study. The clinical response rates were 66%, 62% and 44% in 3, 6 and 12 months of vedolizumab treatment in CD patients. The Clinical remission rates were 22%,34% and 36% in the same intervals in CD patients. The clinical response rates were 59%, 62% and 36% in 3, 6 and 12 months of vedolizumab treatment in UC patients. The Clinical remission rates were 25%,39% and 33% in the same intervals in UC patients. There was no correlation found between thiopurin use, disease duration, clinical response and clinical remission rates in either diseases. No serious side effects were recorded during vedolizumab treatment.

**Conclusion:** Vedolizumab treatment is effective and safe in patients who were previously treated with anti-TNF agents. Thiopurins did not show any beneficiary effect over Vedolizumab treatment.

**Introduction:** 5-aminosalicylates(5-ASA) are the key drugs in induction and maintenance therapy in ulcerative colitis (UC). Some UC patients are involved in 5-ASA intolerance after induction of oral 5-ASA compounds. There are no evidence of the prognosis including the risk of colectomy in 5-ASA intolerant UC patients.

**Aims & Methods:** The aim of this study is to establish the prognosis of 5-ASA intolerant UC patients in multicenter cohort study. A retrospective review of a prospective multicenter database (2014-2018) of 1,208 UC patients was carried out and a total of 1,064 patients treated with oral 5-ASA compounds were enrolled. We compared the risk of colectomy and biologics induction between patients (i) tolerant to first 5-ASA compound (880), (ii) intolerant to first 5-ASA compound but tolerant to other 5-ASA compound (96) and (iii) intolerant to 5-ASA compound and withdrawal of 5-ASA (88).

**Results:** We identified 1,064 patients with UC, of which 32 patients (3%) resulted in colectomy and 211 patients (20%) treated with biologics. Colectomy rate in patients (iii)intolerant to 5-ASA and withdrawal of 5-ASA were higher than (i) tolerant to first 5-ASA and (ii) intolerant to first 5-ASA but tolerant to other 5-ASA (6.1%, 3.1%, 2.1%, respectively). (iii) Patients withdrawal of 5-ASA showed higher risk of colectomy compared with (i) tolerant to first 5-ASA (Hazard ratio (HR) 3.02, 95% Confidence interval (CI): 1.08-8.45). The risk of colectomy among (ii) patients intolerant to first 5-ASA but tolerant to other 5-ASA showed no significant difference compared with (i) tolerant to first 5-ASA (HR 0.72, 95% CI: 0.16-3.10). The biologics induction rate in (iii) patients withdrawal of 5-ASA was significantly higher than (i) tolerant to first 5-ASA and (ii) intolerant to first 5-ASA but tolerant to other 5-ASA (39%, 21%, 17%, respectively). Also (iii) patients withdrawal of 5-ASA showed higher risk of induction with biologics compared with (i) tolerant to first 5-ASA (HR 2.10, 95% CI: 1.28-3.45). Those risk among (ii) patients intolerant to first 5-ASA but tolerant to other 5-ASA showed no significant difference compared with (i) tolerant to first 5-ASA (HR 0.72, 95% CI: 0.40-3.45).

**Conclusion:** Patients with UC who had 5-ASA intolerance and withdrew from 5-ASA showed poor prognosis. We should consider trying other 5-ASA compounds even if the patients had intolerance to one 5-ASA compound.

## P1820 AUDIT OF STEROID EXCESS IN INFLAMMATORY BOWEL DISEASE IN THE ERA OF BIOLOGICS

Parry R.<sup>1</sup>, Durai D.<sup>2</sup>, Hawthorne B.<sup>2</sup>, Siddique N.<sup>2</sup>, Evans R.<sup>2</sup>, Datta K.<sup>2</sup>

<sup>1</sup>Cardiff University, Department of Gastroenterology, Cardiff, United Kingdom, <sup>2</sup>University Hospital Wales, Gastroenterology, Cardiff, United Kingdom

**Contact E-Mail Address:** parryrj2@cardiff.ac.uk

**Introduction:** Currently systemic corticosteroids are key treatments in the induction of remission of inflammatory bowel disease (IBD). Steroid excess can cause significant adverse side effects. Steroid dependency, excess and appropriateness have each been defined within ECCO guidelines, but currently there is no agreed benchmark on what is an acceptable rate of steroid use in IBD(1-2). A large study from the United Kingdom (UK) found a steroid use of 30% and excess in 14.9% in patients seen in IBD clinics(3). The aim of this study is to evaluate the rates of steroid use/excess in patients attending a large tertiary IBD clinic in the era of increasing biologics usage.

**Aims & Methods:** Data was collected over 16 weeks from unselected patients seen in our IBD clinic in Wales, UK, where over 4000 patients attend. A steroid assessment tool was used to determine patients' steroid use. Oral

steroid (Prednisolone/Budesonide) data was collected from the patients at clinic and cross referenced with the hospital patient records, hospital pharmacy database and primary care records. Each set of results were evaluated against ECCO guidelines, steroid excess or dependency was defined as a patient requiring >2 courses of steroids in the past 12 months or a disease flare with tapering of a steroid course or a relapse within 3 months of stopping steroids. Prescriptions were evaluated to determine their appropriateness. Current and prior drug usage including all immunosuppressants (IS) were collected.

**Results:** 258 patients were analysed in total, 60.9% of these had Crohn's disease(CD), 33.7% Ulcerative Colitis(UC) and 5.4% Inflammatory bowel disease unclassified (IBDU). Mean age 45 years, Male 50% Female 50%. Disease severity was assessed and 58.9% of patients had inactive disease, 26.0% mild, 14.0% moderate and 1.1% severe. Drug usage:

5ASA Thiopurine Other IS Anti-TNF Anti-integrin Anit-IL23

Current Past Current Past Current Past Current Past Current Past

UC 21.3% 9.7% 7.0% 7.4% 0.8% 1.2% 3.1% 2.3% 0.8% 0.8% 0% 0%

Crohn's 5.0% 19.4% 13.1% 29.5% 2.7% 10.8% 13.6% 10.9% 1.2% 2.7% 4.3% 0.4%

IBD-U 2.3% 2.7% 0.4% 1.6% 0.4% 0.4% 0.4% 1.2% 0% 0.8% 0% 0%

Total 28.6% 31.8% 20.5% 38.5% 3.9% 12.4% 17.1% 14.4% 2.0% 4.3% 4.3% 0.4%

In the preceding 12 months 34.1% of patients had received at least 1 course of oral corticosteroids, 16.7% patients were in steroid excess/dependency. The dependency/excess occurred more frequently in Crohn's patients (CD 17.8%, UC 14.9%). Of the people in steroid excess the percentage on each drug were 5ASA 14.0%, Thiopurine 14.0%, Other IS 4.7%, Anti-TNF 14.0%, Anti -integrin 2.3%, Anti -IL23 9.3%

**Conclusion:** High proportion of IBD patients seen in clinic were exposed to steroids in the preceding year. In comparison to previous study(3) the use of steroids seems higher despite increasing use of biologics. When evaluating steroid excess it is essential to include primary care and hospital pharmacy records. Future studies should evaluate steroid use in all IBD service set up including patient directed self management service.

## P1821 VEDOLIZUMAB IN THE TREATMENT OF CHRONIC REFRACTORY POUCHITIS - A SYSTEMATIC REVIEW

Lim W.-C., Lin H.

Tan Tock Seng Hospital, Gastroenterology and Hepatology, Singapore, Singapore

**Contact E-Mail Address:** huiyu\_lin@ttsh.com.sg

**Introduction:** Approximately 50% of patients with ileal pouch anal anastomosis (IPAA) develop pouchitis, with 10-15% of acute pouchitis developing chronic pouchitis(CP). Whilst the majority responds to antibiotic therapy, treatment options for chronic antibiotic refractory pouchitis(CARP) include combination antibiotic therapy, budesonide, immunomodulators(IM) or anti-tumour necrosis factor (TNF) antibodies. There is limited data on the role of vedolizumab(VZB), an a4b7 integrin antagonist, in the treatment of CP. We performed a systematic review of the literature to explore the efficacy of VZB in CP

**Aims & Methods:** A systematic literature search in MEDLINE (1966-November 2018), Cochrane Central Register of Clinical Trials, and abstracts from recent major gastroenterology meetings (Digestive Disease Week, United European Gastroenterology Week and Congress of European Crohn's and Colitis Organisation) was performed using the following terms: "integrin", "vedolizumab", "pouchitis". Only English language publications and abstracts on the efficacy of VZB for CP in ulcerative colitis patients with

IPAA were included; Crohn's disease of the pouch was excluded. Additional trials were identified through review of reference list of included articles

**Results:** 6 case reports (n=6)<sup>1-6</sup> and 3 retrospective case series<sup>8-10</sup> (2 in abstract form, n=51) were included; 1 case series (Philpott J 2017)<sup>7</sup> was excluded (duplicate). Only 1 ongoing randomised-controlled phase IV study (NCT02790138) was found whose data has yet to be reported.

All patients (n=57) had chronic antibiotic refractory/ dependent pouchitis and received VZB after failing prior therapy, including IM and anti-TNF. In the case reports, 6 patients (mean age 36yrs, M:F 1:1) with CARP received induction/maintenance VZB; symptom improvement was seen as early as 6 wks and pouchoscopy at 14-33 wks reported near/complete resolution of pouchitis.

In the 3 retrospective case series, 64-75% achieved improvement/clinical remission (CR) at 12-14 wks, with 58.3% still in CR at 46 wks: (a) 14 of 19 (73.7%) with CARP who received at least 1 dose of VZB had improvement of modified Pouchitis Disease Activity Index (mPDAI) at 12 wks (median decrease 2 units, p=0.031); (b) 9 of 12 (75%) who received induction/maintenance VZB achieved CR (mPDAI < 5 + decrease of ≥2) at 14 wks, with 7 (58.3%) still in CR at median 46(14-105) wks; (c) after 3-4 doses of VZB, 64% with CARP/antibiotic dependent pouchitis achieved CR (PDAI < 7) at 14 wks. Minor adverse events were reported in 10-16%

**Conclusion:** From uncontrolled studies and case reports, VZB appears to be efficacious and safe for the treatment of CP refractory to antibiotics and other therapy including anti-TNF. Controlled data is needed to confirm its efficacy in this group of patients.

## P1822 SYSTEMATIC REVIEW OF CALCINEURIN INHIBITORS (CNI) AND VEDOLIZUMAB (VDZ) COMBINATION THERAPY IN ACUTE SEVERE ULCERATIVE COLITIS (ASUC)

Lin H., Lim W.-C.

Tan Tock Seng Hospital, Gastroenterology and Hepatology, Singapore, Singapore

**Contact E-Mail Address:** huiyu\_lin@ttsh.com.sg

**Introduction:** Patients with acute severe ulcerative colitis (ASUC) may be refractory to treatment with steroids and anti-tumour necrosis factor agents (anti-TNF). Cyclosporin inhibitors (CNI) have been used effectively as a fast-acting bridge to slower-onset immunomodulators in thiopurine-naïve patients; however concerns over toxicity limit prolonged use of CNI as maintenance therapy. Patients who are azathioprine-exposed or anti-TNF-refractory have limited medical treatment options, often resulting in colectomy.

Combination of CNI as induction therapy, together with slower-acting but potentially safer vedolizumab (VDZ) has recently been used in patients with severe inflammatory bowel disease (IBD). We aim to review the utility of this combination treatment in ASUC.

**Aims & Methods:** A systematic bibliographic review was conducted on PubMed using the keywords "vedolizumab", "calcineurin inhibitors", "inflammatory bowel disease", and "severe ulcerative colitis". Additional studies were identified by manual search of reference lists.

6 articles were identified within the period 2013 to March 2019. Only English language publications and abstracts on use of combination CNI+VDZ in adult ASUC patients were included. 1 paediatric study<sup>(1)</sup>, 1 case report<sup>(6)</sup> and 1 abstract<sup>(2)</sup> (ASUC data not reported) were excluded.

**Results:** There were 2 prospective observational studies<sup>(3,4)</sup> [N= 30] and 1 retrospective study<sup>(5)</sup> [N=39]. Patients were refractory to conventional treatment with steroids [1 study, N=17] and/or anti-TNF therapy [N=48]. CNI (cyclosporin or tacrolimus) was used for induction of remission in majority of cases, or as rescue agent in those failing induction with Vedolizumab [subgroup of 1 study, N=7].

In 2 studies, IV cyclosporine 2 mg/kg titrated to goal trough level 300-400 or Tacrolimus 0.05mg-0.1mg/kg/d with target levels 10-14ng/mL was started; a week later, CNI-responsive patients were given vedolizumab (IV 300mg at week 0,2,6 then maintenance 8-weekly) and CNIs were stopped after 8-12 weeks per protocol. In another study, VDZ was initiated on average 30days after CNI, with average combination CNI+VDZ of 64 days.

Combination CNI+VDZ showed good short-term efficacy (1 study: 14/15 in remission). At 1 year, there was a respectable colectomy-free rate of 75% (2 studies, N=39/52), comparable to other studies with infliximab/cyclosporin combined with azathioprine. In those receiving steroids at baseline, Steroid-free remission was achieved in 18/36 = 50% at week 14. Serious adverse events (N=7) were attributed to CNIs; there were no deaths.

**Conclusion:** Preliminary studies of combination CNI and VDZ in patients with ASUC appear promising. However, the methodology in these limited studies was heterogeneous. Further prospective trials are needed for the confirmation of the utility and efficacy of this treatment strategy in the management of ASUC.

**Introduction:** Postoperative recurrence is a major concern in patients with Crohn's disease (CD). Curcumin exhibited antiinflammatory and antioxidative properties in cellular and rodent models. Recently, a randomized controlled trial demonstrated that oral curcumin was more effective than placebo to induce clinical and endoscopic remission in patients with ulcerative colitis failing to mesalamine [1].

**Aims & Methods:** We aimed to assess the efficacy of oral curcumin compared to placebo to prevent endoscopic POR in patients with CD receiving concomitant thiopurines therapy. We conducted a double-blind, randomized, placebo-controlled trial in eight IBD centers. All patients with CD (> 18 years-old) undergoing bowel resection were consecutively enrolled within

15 days after the surgery or the closure of diverting stoma. All macroscopic lesions had to be removed and the anastomosis had to be reached by colonoscopy. The patients were randomized to be treated with azathioprine 2.5mg/kg, and either placebo (placebo group) or oral curcumin (3g/day) (curcumin group).

The primary endpoint was endoscopic POR at 6 months (M6), defined as Rutgeerts' index  $\geq 2a$ .

Secondary endpoints were severe endoscopic POR ( $\geq 3$ ), clinical POR (CDAI  $> 150$ ), quality of life (IBDQ) and safety. An intermediary analysis was planned after the enrollment of 50% of the patients (n=62 patients).

**Results:** Overall, 62 patients were enrolled (mean age  $36.3 \pm 12.0$  years, mean CD duration  $8.1 \pm 8.0$  years, 67.2 % female genders, 37.8% smokers, 8.2 % with perianal lesions, 45.9 % with structuring CD, 36.1 % with fistulizing CD, 45.9 % with prior bowel resection, 18.0 % of anti-TNF naïve patients). In intermediary analysis (intent-to-treat), curcumin was not more effective than placebo to prevent endoscopic POR at M6: 67.7 % (21/31) vs 58.1 % (18/31) (p=0.60), in curcumin and placebo groups, respectively (Figure 1). The rate of severe endoscopic POR was significantly higher in patients treated with curcumin (17/31, 54.8%) compared to placebo (8/31, 25.8 %) (p= 0.02). The rate of clinical POR was not different between the two groups: 38.7 % (12/31) in curcumin group vs 45.2 % (14/31) in placebo group (p = 0.80). IBDQ was similar between the two groups (178.5 in the curcumin group vs 181.5 in the placebo group; p=0.63). The rate of adverse events was not different between the two groups.

**Conclusion:** Oral curcumin was not more effective than placebo to prevent endoscopic postoperative recurrence (POR) in patients with CD receiving concomitant thiopurines therapy.

## P1824 IMPACT OF PATIENT EDUCATION ON SWITCH ACCEPTANCE IN IBD PATIENTS IN REMISSION, WITH INFLIXIMAB ORIGINATOR SWITCHED FOR AN INFLIXIMAB BIOSIMILAR: A PROSPECTIVE STUDY

Hastier-De Chelle A.<sup>1</sup>, Cluzeau V.<sup>1</sup>, Condat J.<sup>1</sup>, Arab N.<sup>1</sup>, Hebuterne X.<sup>2</sup>, Filippi J.<sup>3</sup>

<sup>1</sup>CHU of Nice, Gastroenterology and Clinical Nutrition, Nice, France, <sup>2</sup>Hospital Archet 2, Nice, Department of Gastroenterology and Clinical Nutrition, Nice, France, <sup>3</sup>Hopital de l'Achet, Dept. de Gastroenterologie Dept. de Nutrition Oncologie, Nice Cedex 3, France

**Contact E-Mail Address:** hastier-dechelle.a@chu-nice.fr

**Introduction:** CT-P13, the first biosimilar to infliximab (IFX), has an efficacy and tolerance profile comparable to IFX originator, at a lower cost. Physicians are thus strongly encouraged to propose a biosimilar. However, for patients, the switch from IFX originator to a biosimilar is not always accepted.

**Aims & Methods:** The aim of this study was to evaluate the impact of patient education (PE) on the acceptance of a switch from IFX originator to biosimilar in IBD patients treated with IFX originator. In a monocentric prospective study, all IBD adult patients treated with IFX originator between June 2017 and June 2018, in clinical remission for at least 6 months, were asked to complete a questionnaire specifically designed for this study, to assess their knowledge on biosimilars and their acceptance of a switching strategy. Patients had the choice whether or not to accept the switch, with or without PE. The primary endpoint was the percentage of patients who accepted the switch, after receiving a PE session due to an initial refusal. Secondary endpoints were the evaluation of patient knowledge and feeling regarding biosimilar treatment; clinical remission, based on the Harvey-Bradshaw Index (score  $< 4$ ) for CD and the partial Mayo score ( $< 2$ ) for UC; biological remission: C reactive protein ( $< 5$  mg/l) and faecal calprotectin ( $< 150$  µg/g stool) and immunogenicity after the switch, trough levels of IFX (TLI) and anti- IFX antibodies (ATI).

**Results:** 86 patients (median age: 44 years [19-79]) were included (36% UC and 64% CD). The switch was initially refused by 47% of patients. In this subgroup, 78% agreed to participate in an educational interview with the PE nurse; 68% finally accepted the switch.

At Week 16, the persistence on biosimilar was 91%. At weeks 0, 8 and 16, respectively, Mayo score was  $0.68 \pm 0.69$ ,  $0.81 \pm 0.95$  and  $0.57 \pm 0.76$  (p = 0.733) and Harvey-Bradshaw score was  $0.88 \pm 1.70$ ,  $1.95 \pm 2.27$  and  $2.14 \pm 2.36$  (p = 0.134); CRP was  $2.92 \pm 4.52$ ,  $3.48 \pm 5.99$  and  $4.33 \pm 10.82$  (p = 0.724); faecal calprotectin was  $291 \pm 402$ ,  $418 \pm 596$  and  $427 \pm 459$  (p = 0.745); TLI was  $5.00 \pm 3.98$ ,  $4.81 \pm 3.97$  and  $4.44 \pm 3.34$  (p = 0.642); no

patients had immunisation after the switch; IBDQ was  $182.61 \pm 28$  at W0 and  $175 \pm 34$  for at W16 (p = 0.494). The evaluation on the knowledge of biosimilars at W0 showed that 77% of patients had never heard about it, 85% were in favour of the switch and 61% expressed fears about their use. At Week 16, the same evaluation showed that 84% of patients said they knew about biosimilars, 93% were in favour of the switch and 39% were still concerned about their use.

**Conclusion:** This study confirms the safety of switching infliximab by CT-P13 and demonstrates for the first time that PE plays a key role in switch acceptance by patients.

**Disclosure:** The study was funded by Pfizer, France

## P1825 PERSISTENT OBESITY AFTER TREATMENT WITH WEIGHT LOSS MEDICATIONS OR BARIATRIC SURGERY IS A RISK FACTOR FOR DEVELOPMENT OF INFLAMMATORY BOWEL DISEASE

Kochhar G.<sup>1</sup>, Syed A.<sup>2</sup>, El-hachem S.<sup>1</sup>, Abdal-Baki H.<sup>1</sup>, Chintamaneni P.<sup>1</sup>, Singh S.<sup>3</sup>, Loftus E.<sup>4</sup>, Thakkar S.<sup>1</sup>, Shen B.<sup>5</sup>, Dulai P.<sup>3</sup>

**Contact E-Mail Address:** drkochhar@gmail.com

**Introduction:** An association between bariatric surgery and risk of new-onset inflammatory bowel disease (IBD) has been suggested, however, the epidemiology of this association is not well characterized.

**Aims & Methods:** Using IBD Explorix, a HIPAA-enabled web platform that includes clinical data from over 62 million unique individuals with accompanying lab data, we aimed to quantify the risk for new-onset IBD among patients undergoing bariatric surgery (roux-en-y gastrojejunostomy, sleeve gastrectomy or resection, stomach stapling, gastric banding), versus patients being treated with weight loss medications (orlistat, phentermine + topiramate, lorcaserin, naltrexone + bupropion, liraglutide), and the general population (without prior bariatric surgery, weight loss medication exposure, or IBD diagnosis upon entry into Explorix). We further explored the association between persistence of obesity, defined as a BMI  $> 30$  up to 6 months after exposure to bariatric surgery or weight loss medication, and the risk of new-onset IBD. IBD was diagnosed based on a combination of ICD-9 codes + at least 1 prescription for an IBD specific medication (5-ASA, immunomodulator, biologic). Relative risks (RR) with 95% Confidence Intervals (CI) are reported.

**Results:** A total of 59,630 and 198,270 patients were exposed to bariatric surgery and weight loss medications respectively, with 640 and 2,240 developing new-onset IBD after exposure. The prevalence of new-onset IBD after exposure to bariatric surgery (1,073/100,000 persons) was comparable with exposure to weight loss medications (1,130/100,000 persons, p=0.222), and both were significantly higher than the prevalence of new-onset IBD in the general population (512/100,000, {RR 2.14, [95% CI 1.98, 2.31] p<0.001} and weight loss medication {RR 2.40, [95% CI 2.30, 2.49] p<0.001}). Among patients who developed new-onset IBD after exposure to bariatric surgery or weight loss medications, >80% of them had a BMI  $> 30$  up to 6 months after treatment of obesity (p<0.001). None of the new-onset IBD post bariatric surgery had zinc or selenium deficiency.

Characteristic	All IBD [N = 319,610]	Post-BS IBD [N = 640]	Relative Risk	p
Age, n(%) 18-65 years	203,920 (64)	520(81)	2.67 [2.45, 2.91]	< 0.0001
Race: Caucasian	263,140 [82]	560(88)	2.23 [1.05, 2.42]	< 0.0001
African american	2,660 [10]	80(13)	2.56 [2.06, 3.19]	
Hispanic	4,610 [1]			
Subtypes, n(%)	135,080 [42]	300 [47]	2.32 [2.08, 2.60]	< 0.0001
CD US	110,850 [35]	220 [34]	2.08 [1.82, 2.37]	
IBD associated surgery: Colectomy	39,000 [12]	100 [16]	2.68 [2.21, 3.26]	< 0.0001
Proctocolectomy	2,890 [1]	50 [8]	3.07 [2.33, 4.05]	
Ileostomy	17,030 [5]			
All cause mortality	16,780 [5]	30 [5]	1.87 [1.31, 2.68]	0.0006

[Demographics and surgical outcomes]

**Conclusion:** Exposure to bariatric surgery and weight loss medications is associated with an increased risk for new-onset IBD compared to the general population, and this is predominately seen among those who fail to normalize their BMI up to 6 months after treatment.

**Disclosure:** Nothing to disclose

## P1826 SURGERY AND BIOLOGIC PRESCRIPTION RATES FOR CROHN'S DISEASE IN LOTHIAN, SCOTLAND 2000-2017; A POPULATION BASED COHORT

Jenkinson P.<sup>1</sup>, Jones G.R.<sup>1</sup>, Plevris N.<sup>1</sup>, Lyons M.<sup>2</sup>, Burgess C.<sup>3</sup>, Wilson D.C.<sup>4</sup>, Arnot I.D.<sup>1</sup>, Lees C.W.<sup>1</sup>

**Contact E-Mail Address:** philipjenkinson@nhs.net

**Introduction:** Recent years have seen a shift in Crohn's disease (CD) management to earlier initiation of biologic therapy using a treat to target strategy. However, the effect on long-term outcomes, in particular surgical resection, remains unclear.

**Aims & Methods:** The aim of this study was to describe trends in rates of surgery and biologic prescription in CD over time in a population-based cohort. All incident CD cases (adult and paediatric) diagnosed between 01/01/00 and 31/12/17 were identified from the Lothian IBD registry (Jones G, ECCO 2019). Abdominal surgeries were identified from Scottish coding data. All data were manually validated using the EHR and pathology records. Kaplan-Meier methods were used to generate incidence curves for first IBD surgery, repeat surgery, permanent stoma formation and first biologic prescription. To compare surgical resection rates over time the cohort was divided into quartiles by date of diagnosis: 00-04, 05-08, 09-13 and 14-17; analysis was performed using the log rank test.

**Results:** 532/1753 (30.3%) incident CD cases underwent surgery during the study period. 170/532 (32.0%) patients had surgery at diagnosis and were excluded from survival analysis. The overall cumulative incidence rates of first surgery at 1, 5, and 10 years were 7.6% (95% CI, 4.5%-11.7%), 16.9% (13.3%-20.9%), and 25.7% (21.7%-29.9%) respectively. When comparing temporal trends there was a significant reduction in surgical rates by date of diagnosis (logrank  $p < 0.001$ ; see table).

A total of 601/1753 patients (34.3%) were prescribed biologics. The rates of first biologic prescription at 1, 5, and 10 years were 8.8% (CI, 5.9%-12.3%), 20.3% (17.2%-23.7%), and 29.5% (26.4%-32.8%), respectively. When comparing temporal trends there was a significant increase in biologic prescription rates by date of diagnosis (logrank  $p < 0.001$ ; see table). Biologic prescription in the first year after diagnosis rose significantly over time from 1.0% in the first cohort to 19.0% in the latest.

Date of Diagnosis	Cumulative incidence of surgery			Cumulative incidence of biologic prescription		
	1 year	5 years	10 years	1 year	5 years	10 years
2000-2004	10.0%	22.0%	32.7%	1.0%	5.7%	14.9%
2005-2008	6.4%	18.3%	27.2%	2.8%	12.2%	25.8%
2009-2013	7.7%	15.5%	21.1%	6.1%	22.0%	43.0%
2014-2017	5.2%	13.7%*	-	19.0%	44.9%*	-

[Table 1. Cumulative incidence of first surgery and first biologic prescription (Kaplan Meier analysis, \*censored).]

**Conclusion:** In our population based cohort the earlier use of biologics in CD has been paralleled by a significant reduction in surgical rate and time to first operation.

**Contact E-Mail Address:** meadesc@yahoo.co.uk

**Introduction:** Temporary stomas are commonly used during surgery for Crohn's disease to reduce the risk of anastomotic leaks. There is limited data on pre-operative evaluation prior to reversal and whether this predicts adverse outcomes.

**Aims & Methods:** We performed a retrospective review of patients with Crohn's disease being considered for stoma reversal between January 2012 and July 2018 in a tertiary inflammatory bowel disease centre. Investigations and results prior to stoma reversal were evaluated. Notes review clarified whether investigations altered management. We also collected data on pre- and post-operative medical management and time to first flare.

**Results:** 48 patients (age range 15-78y, 21 females:27 males) were evaluated. Montreal classification was; 19% L1 (n=9, 89% B2, 11% B3), 4% L2 disease (n=2 B3), 77% L3 (n=37, 27% B2, 73% B3). 23% also had perianal disease. Investigations performed prior to stoma reversal included faecal calprotectin (2%, n=1), rigid sigmoidoscopy (2%, n=1), endoscopy (27%, n=13), cross-sectional imaging 33% (23%, n=10 MR Enterography, and 10%, n=5 CT enterography), contrast studies 83% (54%, n=26 loopogram, and 30%, n=14 water soluble enema) and examination under anaesthesia (5%, n=2). 19% (n=9) investigation findings changed management; expedited closure n=3, delayed closure n=1, intraoperative endoscopy n=2, reversal indefinitely postponed due to active disease n=3. Time with stoma ranged from 32-1806 (median 192) days. Time with stoma was similar for elective and emergency stoma-forming operations.

Of the patients whose stomas were reversed (n=45), 9 patients had flares within a year of reversal and 28 did not. Contrast studies were requested in 78% (flare) and 79% (no flare) of cases whereas disease activity was assessed in 33% and 54% of cases respectively. The characteristics of each group (those that flared under a year and those that did not flare) differed in terms of disease phenotype (67% vs 36% B2 and 33% vs 64% B3 respectively). There was no significant differences between historical treatments and post-reversal therapy (33% vs 29% no therapy, 56% vs 40% thiopurine monotherapy and 11% vs 32% biologic therapy). Three patients were not reversed; one had obvious symptoms of active disease and supporting investigations, two had abnormal investigation findings (in the absence of obvious symptoms of active disease) resulting in a decision against surgery.

**Conclusion:** There are no current guidelines to advise how patients with Crohn's disease should be assessed prior to stoma reversal. Practice is variable and investigations focus on anatomical abnormalities (exclusion of strictures) rather than objective measures of disease activity. As clinical symptoms do not always mirror disease activity, failure to assess disease activity may have an association with adverse outcomes post-operatively and deserves further research.

**Disclosure:** Nothing to disclose

## P1828 OPTIMAL TIMING OF ILEOCECAL RESECTION IN CROHN'S DISEASE: NO DIFFERENCE IN CLINICAL OUTCOME AFTER EARLY AND LATE SURGERY

**Introduction:** Early ileocecal resection (ICR) in Crohn's disease (CD) may prolong clinical remission and reduce the risk of complications. Optimal timing of ICR is yet unknown as long-term data comparing the clinical outcome after ICR at different CD stages are lacking. In this study, we aim to compare the disease course in CD patients following acute, early and late ICR.

**Aims & Methods:** CD patients aged 16 years and older who underwent primary ICR between 2000 and 2018 in 4 academic and 2 teaching hospitals were included. Patients were identified in a local pathology database and demographic, clinical and surgical data were collected from medical charts. The study population was divided in 3 groups according to the timing of resection: ICR at first CD manifestation or within 1 month after diagnosis (surgery at diagnosis), within 1 year after diagnosis (early surgery) or more than 1 year after diagnosis (late surgery). The primary outcome was clinical recurrence, defined as the start or switch of CD medication for symptomatic disease. Secondary outcomes were endoscopic recurrence (Rutgeerts score  $\geq 2b$ ) and/or radiologic recurrence (echo, CT and MRI), surgical recurrence (re-resection) and hospitalization. Early surgery and late surgery cohorts were matched using propensity score matching (1:1) accounting for sex, disease localization, disease behaviour, peri-anal fistulas, smoking, calendar year of ICR, and the use of prophylactic postoperative biologicals or thiopurines. Kaplan Meier survival analysis and Cox proportional hazard analysis were performed.

**Results:** A total of 513 CD patients (320 females (62%), median age 30.8 (IQR 23.5 - 42.3)) were included. ICR was performed at first CD manifestation or within 1 month after CD diagnosis in 48 patients (9%), early surgery was performed in 103 patients (20%, after median 5.1 months, range 1.1 - 11.9) and late surgery in 361 patients (70%, after median 62.3 months, range 12.5 - 562.6). The cumulative probability of clinical recurrence after surgery at diagnosis was 18.8%, 33.4% and 47.7% after 1, 5 and 10 years respectively, which was significantly lower as compared to 25.6%, 57.1% and 77.6% after early surgery ( $p = 0.005$ ) and 28.4%, 63.6% and 80.6% after late surgery ( $p = 0.001$ ). Endoscopic and/or radiologic recurrence rates were also significantly lower in patients with an acute resection at diagnosis as compared to early and late surgery ( $p = 0.023$ ). No significant differences were observed between groups regarding hospitalization ( $p = 0.578$ ) and re-resection ( $p = 0.327$ ).

After propensity score matching, clinical recurrence rates for the matched early surgery group ( $n = 99$ ) were 25.5%, 56.9% and 77.6% after 1, 5 and 10 years and 24.0%, 63.1% and 74.8% after 1, 5 and 10 years ( $p = 0.849$ ) in the late surgery group ( $n = 99$ ). No significant differences were found in endoscopic and/or radiologic recurrence, hospitalization or re-resection.

**Conclusion:** The long-term outcome of acute ICR at CD diagnosis is characterized by lower rates of clinical recurrence as compared to early and late surgery. When accounting for known risk factors for postoperative recurrence and prophylactic postoperative medication use, no differences were observed in clinical, endoscopic or surgical recurrence rates in early versus late ICR in CD.

**Introduction:** Crohn's disease (CD) is a relapsing and remitting disorder with an annual incidence of 3 to 20 per 100,000. Ileocecal involvement is the commonest disease pattern in Crohn's disease (CD) and is seen in over half of the patients [1]. Surgery is required when medical management fails or when secondary complications develop. The probability of requiring surgery for CD is 78% and 90% after 20 and 30 years of disease, respectively [2].

**Aims & Methods:** The primary aim of this study was to identify factors associated with laparoscopic procedures requiring conversion to open surgery in patients undergoing minimally invasive ileocolic resection (MIICR) for Crohn's disease (CD).

We analysed data of consecutive patients who underwent MIICR between January 2005 and May 2018 for CD at 2 European tertiary care centres.

A Logistic regression analysis was performed to identify statistically significant factors associated with conversion to an open approach.

**Results:** Three hundred and ninety-two patients (M:F 185:207) underwent MIICR. Their mean age at surgery was 48.3 (SD-14.5) years. Seventy-two (18.4%) patients required conversion to an open approach.

The regression model was statistically significant ( $p < 0.0001$ ) and classified 84.5% of the cases accurately. The multivariate analysis identified age at surgery (odds ratio 1.03), males (OR 2.8), prior resection (OR 2.9), diversion of stool (OR 4.3) and simultaneous colon resection (OR 2.5) to be associated with a higher risk of conversion to open surgery.

Ethnicity, ASA grade, smoking, diabetes, use of biologics, albumin level, perianal disease, stricturoplasty, or duration of disease did not affect conversion.

**Conclusion:** Males, older patients, prior resection and stool diversion were associated with a higher chance of conversion to open approach. This finding should be considered during the preoperative informed consent process.

**Contact E-Mail Address:** marmaduke007@hotmail.com

**Introduction:** Crohn's disease (CD) is a relapsing and remitting disorder with an annual incidence of 3 to 20 per 100,000. Ileocecal involvement is the commonest disease pattern in Crohn's disease (CD) and is seen in over half of the patients [1]. Surgery is required when medical management fails or when secondary complications develop. The probability of requiring surgery for CD is 78% and 90% after 20 and 30 years of disease, respectively [2]. A prolonged hospital stay after surgery has health, economical and social implications. Enhanced recovery pathways aim to optimise the hospital stay.

**Aims & Methods:** The primary aim of this study was to identify pre- and perioperative factors associated with a prolonged length of stay (LOS) after ileocolic resection in CD.

We analysed data of consecutive patients who underwent surgery for CD between January 2005 and May 2018 at 2 European tertiary care centres. A logistic regression analysis was performed to identify statistically significant factors associated with a prolonged hospital stay.

**Results:** A total of 628 patients (M: F 326:302) were included in the analysis. Their mean age at surgery was 44.1(SD-15.0) years. The median length of stay was 6-days (interquartile range 5-9).

The regression model was statistically significant ( $p < 0.0001$ ) and classified 66.3% of the cases accurately. The multivariate analysis identified open surgery (Odds ratio 2.2), strictureplasty (OR 2.5), longer disease duration (OR 1.03) and Asian ethnicity (OR 3.1) to be significantly associated with a hospital stay of  $\geq 7$  days.

Age at surgery, sex, ASA grade, smoking, diabetes, use of biologics, albumin level, perianal disease, prior bowel resections, simultaneous bowel resection or laparoscopic conversion did not increase the LOS.

**Conclusion:** Patients undergoing open surgery, strictureplasty and longer disease duration were more likely to require a hospital stay greater than seven days. Such factors should be taken into consideration in any enhanced recovery pathway in order to tailor the patient journey.

**Introduction:** Crohn's disease (CD) is a relapsing and remitting disorder with an annual incidence of 3 to 20 per 100,000. Ileocecal involvement is the commonest disease pattern in Crohn's disease (CD) and is seen in over half of the patients [1]. Surgery is required when medical management fails or when secondary complications develop. The probability of requiring surgery for CD is 78% and 90% after 20 and 30 years of disease, respectively [2]. Although most patients do not require a stoma at the primary operation, there is no way to predict the likelihood of a stoma. This ambiguity affects pre-operative informed consent. Injudicious avoidance of a stoma can increase the risk of anastomotic complications and need for additional interventions.

**Aims & Methods:** The primary aim of this study was to identify factors leading to primary stoma formation after ileocolic resection for Crohn's disease (CD).

We analysed data of consecutive patients who underwent surgery for CD between January 2005 and May 2018 in 2 European tertiary care centres. A Logistic regression analysis was performed to identify statistically significant factors associated with stoma formation in patients undergoing ileocolic resection for CD.

**Results:** A total of 628 patients (M: F 326:302) underwent surgery. Their mean age at surgery was 44.1(SD-15.0) years. Eighty-one patients (12.8%) had stomas created at the primary operation. Forty-three(53.1%) were end-ileostomies the rest were defunctioning stomas.

The regression model was statistically significant ( $p < 0.0001$ ) and classified 86.3% of the cases accurately. The multivariate analysis identified lower pre-op albumin (odds ratio 0.89), males (OR 2), simultaneous colonic (OR 7.3) resection and prior resection (OR 2.8 per previous surgery) to be significantly associated with stoma formation.

Age at surgery, ethnicity, use of biologics, smoking, perianal disease, emergency surgery or simultaneous strictureplasty or small bowel resection were not associated with a higher chance of stoma formation.

Of the patients who did not have a stoma at the primary operation, 11 (2%) needed subsequent surgery for anastomotic leaks in the post-operative course. Fifty-five (67.9%) had their stomas reversed.

**Conclusion:** Low albumin, previous resections, males and simultaneous colonic resection were associated with a higher chance of primary stoma formation. Preoperative strategy planning including the approach to primary-stoma might reduce the need for reintervention.

**Introduction:** Perianal fistulizing Crohn's disease (PCD) remains a challenge to treat, despite the use of TNF antagonists. Several guidelines agreed to recommend a medico-surgical management but half of patients with PCD would still suffer from persistent disease. The aim of the study was to assess the best medico-surgical strategy for treating PCD.

**Aims & Methods:** The medical records of all patients with fistulizing perianal Crohn's disease treated with TNF antagonists in two referral centers between 1998 and 2018 were reviewed. The therapeutic persistence was performed to compare infliximab and adalimumab treatment using a Kaplan-Meier method. The cumulative incidences of complete fistula closure were estimated using the Kaplan-Meier method. Medical and surgical predictors of long-term outcomes were identified using a Cox proportional hazards model and used to propose the optimal medico-surgical management.

**Results:** A total of 200 patients were included. At PCD diagnosis, 19% of patients were B3 and 44.5% were L3 according to the Montreal classification. A total of 41% of patients had associated proctitis. The overall cumulative probabilities of fistula closure were 26.8% and 69.8% at 1 and 5 years, respectively. Infliximab were more likely to be used compared to adalimumab (73.5% vs 26.5%, respectively). The therapeutic persistence of TNF antagonist was of 138.73 weeks without difference between adalimumab and infliximab. Of note patients treated with ADA were more likely to experience treatment optimization (60.4% vs 30.6% in IFX group). Regarding the medical treatment, the combination of TNF antagonist with an immunosuppressant (HR=1.55, p=0.03) and the presence of a proctitis (HR=1.74, p=0.0086) were independently associated with fistula closure. B1 phenotype was associated with lower rate of fistula closure. When considering the perianal surgery, the initial drainage of the fistula with a seton and an additional surgery during the follow-up were also associated with an increase of fistulas closure. No difference was observed between the type of additional surgery (seton insertion, fistulotomy, rectal advancement flap and others). However, this effect was only observed when the complementary surgery was performed within the first year of TNF antagonist treatment.

Finally, the best management of the PCD was the association of a combination therapy following a first drainage with a seton and then a complementary surgery within the first year. The cumulative probabilities of fistula closure in this setting were 44% and 98% at 1 and 5 years, respectively.

**Conclusion:** The combination of medical and surgical treatment is required for the management of patients with PCD. Both part of the treatment should be early and proactively optimized to increase the rate of fistula closure.

**Introduction:** In light of the global growth in the spread of antibiotic-resistance in microorganisms, commensal bacteria require serious attention, particularly the key representatives of the human intestinal microbiota in view of their genome plasticity, reservoirs of antibiotic resistance, resistance mechanisms *in vivo* and *in vitro*, as well as the ability to transfer resistance modules. Bacteria of the genus *Lactobacillus*, including *L. plantarum*, are important residents of human gut, oral cavity, and urogenital tract, and are widely used for correction of the intestinal microbiota composition. However, the information of the antibiotics effects on genomic profile and drug sensitivity of these microorganisms is rare and contradictory.

**Aims & Methods:** The aim of our research was to elucidate the effects of clarithromycin (Clr) and amoxicillin (Amx) used for the eradication therapy of *Helicobacter pylori* on the *L. plantarum* genomic profile and sensitivity to these antibiotics. The object of the study was the strain *L. plantarum* 8P-A3, isolated from the probiotic supplement "Lactobacterin dry" (Biomed Perm Research and Manufacturing Association, Russia), and the clinical strain *L. plantarum* HP227-5, isolated from the intestinal microbiota of a patient who underwent *H. pylori* eradication treatment according to the Maastricht Protocol (amoxicillin 1000 mg bid, clarithromycin 500 mg bid, proton pump inhibitor and bismuthate tripotassium dicitrate 240 mg bid for 14 days). Both strains were cultivated at 37°C on Man-Rogosa-Sharpe (MRS) medium. In order to obtain the resistant strain, sequential cultivation of the initial *L. plantarum* 8P-A3 with an increasing antibiotics concentration to clinically significant levels was performed. Total DNA extracted from strains was sequenced on the MiSeq platform (Illumina). The reads were assembled using SPAdes v.3.11.1, the SNP calling was performed using SNPEff v.3.6.

**Results:** As a result of selection of the initial laboratory strain *L. plantarum* 8P-A3 (MIC of Clr and Amx was 0.04 µg/ml and 0.01 µg/ml, respectively) the strain *L. plantarum* 8P-A3<sup>Clr+Amx</sup> with high resistance to both clarithromycin and amoxicillin (Clr concentration of 5.5 µg/ml and Amx concentration of 14.5 µg/ml) was obtained. Ten mutations were found in the genome of *L. plantarum* 8P-A3<sup>Clr+Amx</sup>, including 4 mutations in antibiotics target genes (rplD, rplV, penA, pbpB) and 6 novel mutations in genes which were not mentioned earlier as determinants of clarithromycin and amoxicillin resistance in bacteria: transcriptional termination factor Rho (rho), PhoH-like protein, teichoic acid ribitol-phosphate polymerase (tarL), GDP-mannose 4,6-dehydratase (gdpP), transcriptional regulatory protein (walR) and one hypothetical protein. However, mutations identified in *L. plantarum* 8P-A3<sup>Clr+Amx</sup> were not detected in the genome of *L. plantarum* HP227-5, and no resistance to clarithromycin and amoxicillin was revealed in the clinical isolate.

**Conclusion:** Our data suggests that the antibiotic therapy used in the Maastricht Protocol for *H. pylori* eradication does not cause the development of antibiotic resistance in clinical isolate *L. plantarum*, and the mechanisms for adapting to antimicrobials *in vitro* and *in vivo* may vary significantly in these bacteria. To confirm this assumption, it is necessary to conduct a study with a large cohort of patients. The ability of *L. plantarum* str. 8P-A3<sup>Clr+Amx</sup> to transfer clarithromycin and amoxicillin resistance genes to other bacteria also requires further research.

**Introduction:** *Fusobacterium nucleatum* has long been found to cause opportunistic infections and has recently been implicated in colorectal cancer (CRC), which brings great attentions widely. However, the mechanism is still largely unknown. We found that the relative abundance of *F. nucleatum* in fecal microbiota was significantly increased in colorectal cancer patients in our previous study. To explore the causative role it may have in CRC development, we inoculated C57BL/6 mice with one clinical *F. nucleatum* strain isolated from a CRC patient's fecal sample, and then evaluated the structure of colon microbiota, colon pathology and gut barrier function after *F. nucleatum* infection.

**Aims & Methods:** We isolated one clinical strain (FN16) enriched in relative abundance 3% of the CRC patient's gut mucosa bacteria, and identified it as *F. nucleatum* by biochemical tests and 16S ribosomal RNA gene sequencing. Four groups of mice were then compared to reveal difference, i.e., control group, *F. nucleatum* infection group (FUSO), Azoxymethane-induced CRC group (AOM) and AOM+FUSO infection group. To establish infection, we infused 10<sup>8</sup> cells of FN16 every day for two weeks into C57BL/6J mice by gastric gavage. Body weight, length of colon, colorectal tumor formation ratio, colorectal barrier function and gut microbiota structure were assessed to explore the potential role of FN16 in the development of CRC.

**Results:** The body weight, colon length and colorectal tumor formation ratio profiles exhibited significant differences among the four groups. FUSO group showed significantly reduced body weight and shorter colon length compared with the control group. And AOM+FUSO showed the highest tumor formation ratio and the worst body weight among the four groups. What's more, colon pathology was the most serious in the AOM+FUSO group, which was confirmed by hematoxylin-eosin staining. The colon mucosa of FUSO mice developed obvious inflammation phenotype with the higher level of IL-6 ( $P < 0.01$ ) and TNF- $\alpha$  ( $P < 0.01$ ) by the RT-PCR results. The AOM+FUSO group showed the same pattern compared with the AOM group, and the mRNA expression of IL-6 ( $P < 0.05$ ) and TNF- $\alpha$  ( $P < 0.01$ ) in colon tissue of AOM+FUSO group were significantly higher. In addition, the mRNA expression of ZO-1 ( $P < 0.05$ ) and Claudin-1 ( $P < 0.01$ ) in colon mucosa of FUSO group were reduced, indicating the dysfunction of gut barrier. To explore the reason of *F. nucleatum*-caused colon inflammation and gut barrier damage, we profiled the structure of mucosa microbiota of the four groups. We found that the structure of colon microbiota changed a lot after *F. nucleatum* infection; striking differences in fecal microbial population patterns were observed between FUSO and control group, AOM+FUSO and AOM group. Inflammation-inducing genus *Bacteroides* was enriched in the mucosa microbiota of FUSO and AOM+FUSO group, whereas the genera *Lactobacillus* and *Ruminococcus* were significantly less abundant. The dysbiosis of colon mucosa microbiota, characterized by the enrichment of inflammation-inducing pathogens and the decreased in probiotics members, therefore represent a specific microbial signature of *F. nucleatum* infection, which may provide new sights into the role of this bacteria in promoting colorectal cancer.

**Conclusion:** The CRC mice with infection of *F. nucleatum* FN16 isolated from the CRC patient shows aggravated intestinal inflammatory conditions and dysbiosis of colon microbiota, suggesting that the *F. nucleatum* may be a contributing factor to CRC, rather than a bystander.

**Introduction:** Obviously *H. pylori* eradication therapy can lead to changes of gut microbiota composition. However, there is limited data concerning the influence of eradication therapy on functional potential of the human gut microbiota that is probably more important in maintaining human health.

**Aims & Methods:** The aim of the study was to evaluate influence of *H. pylori* eradication therapy on gut microbiota metabolic potential.

Stool samples from 102 *H. pylori*-positive patients before and immediately after eradication therapy (proton pump inhibitor, amoxicillin 1000 mg, clarithromycin 500 mg and bismuthate tripotassium dicitrate 240 mg bid for 14 days) and 29 samples 1 month after therapy from the same patients were collected. Stool samples total DNA was sequenced on SOLiD 5500xl-W. Reads were mapped to ChocoPhlAn using the HUMAnN2 algorithm for functional profiling. Relative abundances of metabolic pathways (MP) were calculated as "cpm" - a number of reads mapped to pathway divided by a total number of mapped reads,  $p < 0.05$  was considered as significant. MP were categorized by MetaCyc database.

**Results:** Serious alterations of the gut microbiota functional potential were observed due to *H. pylori* eradication therapy: significant differences were found in the relative abundance of 180 MP. Most of the changes were observed for biosynthesis pathways: immediately after the therapy 97 MP [biosynthesis of amino acids (6), carbohydrates (9), cell structures (4), cofactors, prosthetic groups, electron carriers (45), fatty acids and lipids (23), nucleosides and nucleotides (7), metabolic regulators (2), siderophores (1)] and 1 tRNA processing MP were more represented in the gut microbiota than initially. However, 8 biosynthesis MP [amino acids (2), cofactors, prosthetic groups and electron carriers (2), fatty acids and lipids (1), nucleosides and nucleotides (1)] became less represented compared to baseline. Changes in abundance of Degradation/Utilization/Assimilation pathways were observed immediately after the therapy, including increased representation of 43 MP [alcohols (2), aldehydes (1), amines and polyamines (4), amino acids (4), aromatic compounds (8), carboxylates (3), secondary metabolites (4), carbohydrates (8), inorganic nutrients (5), nucleosides and nucleotides (1), fatty acids and lipids (3)] while 4 pathways [degradation of pyrimidine nucleotides (1), carbohydrates (2) and formaldehyde assimilation (1)] became less represented after eradication than before therapy. Similar changes were noted for Generation of Precursor Metabolite and Energy processes: abundance of 6 MP decreased, however, abundance of 21 MP increased immediately after the therapy compared to initial level, including fermentation processes, acetyl-CoA biosynthesis, pentose phosphate pathway, TCA cycle, aerobic respiration, glycolysis.

By the end of the month after eradication therapy a tendency to return to the initial level was observed for most of functional potential changes. However, changes in abundance of 28 MP: Biosynthesis (22), Degradation/Utilization/Assimilation (4) and Generation of Precursor Metabolites and Energy (2) still persisted. Most of these pathways were more represented in the gut microbiota one month after the end of therapy than initially.

**Conclusion:** So *H. pylori* eradication therapy caused significant changes in the gut microbiota metabolic potential, some of which persisted even one month after the end of therapy. An increased abundance of most pathways could be associated with stress response of the gut microbiota on the background of antibacterial therapy.

**Disclosure:** Nothing to disclose

## P1836 THE ABUNDANCE OF SHORT-CHAIN FATTY ACIDS METABOLIC PATHWAYS IN THE HUMAN GUT MICROBIOTA AFTER *HELICOBACTER PYLORI* ERADICATION THERAPY

Safina D.D.<sup>1</sup>, Markelova M.<sup>1</sup>, Abdulkhakov S.R.<sup>1,2</sup>, Grigoryeva T.<sup>1</sup>, Boulygina E.<sup>1</sup>, Khusnutdinova D.<sup>1</sup>, Malanin S.<sup>1</sup>, Vasilyev I.<sup>1</sup>, Siniagina M.<sup>1</sup>, Abdulkhakov R.<sup>2</sup>

**Contact E-Mail Address:** diliarik@yandex.ru

**Introduction:** Butyrate is a major energy source for colonocytes and plays an important role in maintaining the stability of the gut microbiota, prevention of inflammation and gene expression regulation. Current data suggest a wide spectrum of positive effects of butyrate with a high potential for a therapeutic use. Antibacterial therapy is known to alter composition and functional potential of the gut microbiota.

**Aims & Methods:** The aim of the study was to assess the influence of *H.pylori* eradication therapy on the gut microbiota functional state with respect to short-chain fatty acids production.

Stool samples were collected from 102 *H.pylori*-positive patients before (the baseline) and immediately after eradication therapy (amoxicillin (1000 mg), clarithromycin (500 mg), proton pump inhibitor, bismuthate tripotassium dicitrate (240 mg) bid for 14 days), as well as 29 stool samples were collected one month after the end of treatment from the same patients. Total DNA extracted from stool samples was sequenced on SOLiD 5500xl-W platform (whole genome sequencing). For metabolic profiling reads were aligned to ChocoPhlAn database using the HUMAnN2 algorithm. Relative abundances of pathway were calculated as "cpm" - a number of reads mapped to pathway divided by a total number of mapped reads. Differences were assessed using Wilcoxon signed-rank test (p-value < 0.05 was considered statistically significant). Metabolic pathways were classified according to MetaCyc database.

**Results:** The pronounced functional changes of the gut microbiota, including metabolic pathways of fermentation to short-chain fatty acids were revealed immediately after the eradication therapy. Abundance of following pathways - fermentation to lactate (ANAEROFRUCAT-PWY: homolactic fermentation; P122-PWY: heterolactic fermentation), to acetate (P161-PWY: acetylene degradation), to propionate (PWY-7013: L-1,2-propanediol degradation) was increased comparing with baseline - 83.58±46.16 cpm vs. 61.87±33.04 cpm, 12.52±25.28 cpm vs. 4.24±9.02 cpm, 19.80±35.60 cpm vs. 7.99±10.58 cpm and 16.95±63.10 cpm vs. 2.88±8.09 cpm, respectively. However the abundance of metabolic pathways related to butyrate production - CENTFERM-PWY: pyruvate fermentation to butanoate and PWY-5676: acetyl-CoA fermentation to butanoate II - was decreased in the gut microbiota after therapy compared to initial level: 1.92±2.18 cpm vs. 3.12±3.62 cpm and 15.39±13.18 cpm vs. 17.88±9.72 cpm, respectively. Abundance of following metabolic pathways - PWY-7288 fatty acid β-oxidation, PWY66-391: fatty acid β-oxidation VI, where butyrate could be consumed as the initial agent of the reaction was increased after therapy comparing to baseline, 0.04±0.09 cpm vs. 0.03±0.17 cpm and 0.07±0.17 cpm vs. 0.05±0.25 cpm, respectively. Representation of PWY-6803: phosphatidylcholine acyl editing pathway, in which butyrate derivatives could be produced was increased immediately after the eradication treatment compared to initial level, 22.00±42.54 cpm vs. 6.45±16.12 cpm.

No significant changes were observed in the relative abundance of metabolic pathways involved in butyrate formation in the gut microbiota one month after eradication therapy compared to the baseline level that may be due to the compensatory possibilities of the gut microbiota.

**Conclusion:** So *H.pylori* eradication therapy leads to alteration of butyrate-producing metabolic pathways in the human gut microbiota, changes return to the initial level one month after the treatment.

**Disclosure:** Nothing to disclose

## P1837 VARIATION OF THE MUCOSA ASSOCIATED MICROBIOME ALONG THE HUMAN GASTROINTESTINAL TRACT IN HEALTH AND DISEASE

**Introduction:** Very little is known about the variation in the mucosa-associated microbiota (MAM) along the human gastrointestinal (GI) tract.

**Aims & Methods:** We aimed to determine the bacterial communities in different parts of the GI tract and compare patients without gastrointestinal disease with patients with Crohn's disease (CD) and Ulcerative colitis (UC). We recruited 72 patients undergoing upper GI endoscopy and colonoscopy for the assessment of a positive FGBT with normal results of the endoscopic investigations (other than small adenoma) and no symptoms reported utilising a standardised assessment of gastrointestinal symptoms (SAGIS). In addition, we recruited 44 patients with CD and 50 patients with UC. Utilising the Brisbane Aseptic Biopsy Device, we obtained biopsies from the proximal small intestine, terminal ileum, ascending colon and rectum without cross contamination from luminal contents or other regions of the GI tract. Biopsy samples were immediately placed under aseptic conditions into a sterile tube containing RNA later (Qiagen). Samples were allowed to incubate at room temperature for 30 minutes, then frozen and stored at -80°C. Total DNA was extracted from biopsies, and sample free reagent controls, using a repeated bead-beating based method. Samples were profiled by high-throughput amplicon sequencing with dual-index barcoding using the Illumina MiSeq platform, targeting the V6-V8 region of the gene encoding 16S ribosomal RNA. The libraries were sequenced on an Illumina MiSeq platform and the data were quality assessed, trimmed and filtered, then processed using the Quantitative Insights into Microbial Ecology version 2 (QIIME2) software. Microbiota and statistical analyses were performed in QIIME2 and R. Significant differences in Shannon and Chao1 alpha diversity metrics between sample types, and between disease states for each sample type, were calculated using Kruskal-Wallis and unpaired Wilcoxon rank sum tests. Differentially abundant taxa were identified with DESeq2 using a likelihood ratio test while correcting for age, BMI and gender.

**Results:** Across all patient groups, the three most abundant genera in the duodenum were *Streptococcus*, *Pseudomonas* and *Prevotella*. However, in the terminal ileum, right colon and rectum, *Faecalibacterium*, *Bacteroides*, and *Escherichia-Shigella* were the three most abundant bacterial taxa. There were significant differences in the Shannon and Chao1 diversity scores of the mucosa-associated microbiota (MAM) present in the duodenum and terminal ileum (P < 0.001-0.05) between UC and CD, and UC and controls, with greater diversity found for the control subjects. In the right colon and rectum, significantly lower Shannon diversities were observed in UC and CD vs controls (P < 0.05).

**Conclusion:** There are marked differences in the three most abundant bacteria in the upper and lower gut. Similarly, MAM from different parts of the human GI tract reveal distinct characteristics in the relation to the most prevalent bacterial taxa and the alpha diversity observed at these sites. Interestingly, both UC and CD patients have different MAM profiles in both proximal and distal sites of the GI, and these are different from those observed for healthy asymptomatic controls.

**Disclosure:** Nothing to disclose

## P1838 MULTIDONOR FMT CAPSULES INCREASES FECAL MICROBIOTA DIVERSITY IN PATIENTS WITH IBS FOR AT LEAST THREE MONTHS

Cold F.<sup>1,2,3</sup>, Browne P.D.<sup>4</sup>, Günther S.<sup>2</sup>, Halkjær S.L.<sup>3</sup>, Petersen A.M.<sup>3</sup>, Christensen A.H.<sup>2</sup>, Hansen L.H.<sup>1</sup>

**Contact E-Mail Address:** frederikcold422@hotmail.com

**Introduction:** Decreased microbial diversity of the fecal microbiota is recognized as a part of gut dysbiosis[1] and hence treatments increasing microbial diversity, such as fecal microbiota transplantation (FMT) have attracted much attention within recent years.

FMT has, in many studies, improved the fecal alpha-diversity which has also been correlated with improved clinical effects [2].

FMT treatment by capsules has emerged as a possible way to continuously transfer fecal material giving lower doses of fecal material, delivered on a daily basis.

**Aims & Methods:** The aim of our research was to investigate if, and potentially when, FMT delivered through capsules changes the fecal microbiota diversity in patients with Irritable Bowel Syndrome (IBS), and to investigate if the effects diminish over time.

To investigate this we analysed samples from a previously published placebo-controlled randomized clinical trial investigating the effects of 12 days of 25 daily multidonor FMT capsules treating 52 patients with IBS [3]. We tested fecal samples from baseline, and at 15 days, 1, 3 and 6 months following the commencement of treatment using 16S RNA sequencing. Wilcoxon signed-rank tests ( $p \leq 0.05$ ) were used to compare alpha-diversity levels at each time-point after baseline with the levels at baseline.

**Results:** From a median fecal alpha-diversity (Chao1 index) of 306.5 at baseline the median diversity increased at all the following timepoints. The increase was significant after 15 days (404.3,  $p=0.005$ ), 1 month (433.4,  $p=0.005$ ) and 3 months (421.3,  $p=0.0002$ ), but was no longer statistically significant after 6 months (379.1,  $p=0.08$ ). The placebo group did not significantly change their median fecal alpha-diversity at any timepoint. From a baseline level of 342.1 the median fecal alpha diversity was between 324.6 and 376.9 at the following timepoints.

The increases in fecal alpha-diversity was significant when compared to the changes in the placebo group after 15 days ( $p=0.03$ ) and 3 months ( $p=0.004$ ).

**Conclusion:** Twelve days of daily FMT treatment given by capsules significantly increases the fecal microbiological alpha-diversity of patients with IBS and this persists for at least three months.

However, the increased alpha-diversity was in general not associated with a beneficial clinical effect in the FMT group when compared to the placebo group. Future studies must assess if FMT might improve symptoms in some patients with IBS and in particular in patients with low fecal microbial diversity.

**Introduction:** Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder in which dysfunctions of the microbiota-gut-brain axis are increasingly recognized. In particular, alterations in gut microbiota or their metabolites, such as secondary biliary acids, have been suggested to contribute to ASD pathology. In order to study how dysbiosis could affect gut functions and enteric nervous system (ENS) homeostasis, we used fecal supernatant (FS) prepared from ASD patients and healthy controls (HC). Specifically, we studied the impact of FS on intestinal epithelial barrier functions and ENS phenotype.

**Aims & Methods:** Antibiotic-treated mice received enema of FS from ASD patients (n=16) and from healthy controls (n=10). Paracellular and transcellular gut permeability were measured *in vivo* and *ex vivo* in proximal colon. Gene and protein expression for glial (S100b, GFAP), neuronal (GAP43, synapsin1) and inflammatory molecules (IL-1 $\beta$ , TNF $\alpha$ ) were analyzed in proximal colon, brain and primary culture of ENS treated with FS from ASD patients or HC. Finally, concentrations of several bacterial metabolites (short chain fatty acids and biliary acids) were measured in FS by mass spectrometry. 16S metasequencing of the intestinal microbiota was performed for ASD patients and HC.

**Results:** No change of *in vivo* permeability was observed in mice treated with FS from ASD patients while *ex vivo* transcellular and paracellular permeability of proximal colon was decreased as compared to HC. FS from ASD patients induced a decrease of mRNA expression of TNF $\alpha$ , IL-1 $\beta$ , and an increase for S100 $\beta$  and GAP43 in the colon. This latter result was reproduced in primary cultures of ENS. In addition, the protein expression of the synaptic marker synapsin1 was decreased in the colon and showed a trend of reduction in the brain (amygdala) of mice treated with FS from ASD patients compared to controls. The concentration of the secondary bile acid deoxycholic acid was higher in the FS from ASD patients as compared to HC. Changes in bacterial proportion are observed in ASD patients as compared to HC, with a relative increase of Bacteroidetes and decrease of Firmicutes.

**Conclusion:** FS from ASD patients alter intestinal permeability and expression of inflammatory and ENS molecules. The factors in FS from ASD patients responsible for these changes remain to be identified.

This project was supported by "Fondation pour la Recherche Médicale".

**Introduction:** Fecal Microbiota transplantation (FMT) is a novel therapy, with proven efficacy against recurrent Clostridium difficile infection (CDI). For safe implementation and broader application of FMT, quality controlled stool banking is a must. Establishing a stool bank is a complex, time-consuming and expensive process, making it a real challenge in a country with lower Human Development Index (HDI)

**Aims & Methods:** We aimed to establish the first stool bank in an Eastern European country - Bulgaria. A multidisciplinary team of gastroenterologists, medical microbiologists, infectious diseases specialist and geneticists was set up. We used a questionnaire based on the First European FMT Consensus (1) in order to recruit possible stool donors. Microbiota analysis was performed on all selected donors.

**Results:** Between October 2018 and April 2019, 112 donor volunteers completed a questionnaire; 70 (62.5%) were excluded, mainly because age above 50, an unhealthy BMI and risk behavior. Forty-two (37.5%) donor candidates were invited for laboratory testing of blood and feces of which 12 (28.6%) passed this screening. Presence of *Helicobacter pylori* fecal antigen and Multi Drug Resistant Organisms were the most observed exclusion criteria. Of 12 donors, 4 (33%) failed at a following screening test, which is performed every three months. Finally, 8 (7.14%) active donors were enrolled.

**Conclusion:** Even though we found many healthy volunteers, only a low percentage (7.14%) of them are suitable to become feces donors. Establishing of a stool bank in a country with lower HDI is important for making FMT safer and more popular as a treatment method, finding further implementation and regulation of FMT and supporting physicians offering this treatment to their patients.

**Introduction:** An urgent problem of modern urology is the increase in the number and rejuvenation of the age of patients suffering from urolithiasis. It has been established that from 70 to 80% of stones excreted during urolithiasis are calcium oxalate, and the level of oxaluria depends in a certain way on the composition and functional activity of intestinal microbiota, in particular on the ability to degrade oxalates. Except for *Oxalabacter formigenes*, a number of normobiotic representatives are capable to metabolize oxalate salts (e.g. *Lactobacillus spp.*, *Bifidobacterium spp.*, *Eubacterium lentum*, *Bacillus spp.*, *Enterococcus faecalis*). The antibiotics decreased the quantity of oxalate-degrading bacteria (ODB) but there is no available data and approaches to evaluate the total oxalate-degrading activity (ODA) of fecal microbiota (without isolation of pure culture).

**Aims & Methods:** The aim of the present study was to develop approach for evaluation of total ODA of fecal microbiota and to assess the dynamics changes in the ODA of fecal microbiota after broad-spectrum antibiotic ceftriaxone treatment in rats. The object of the study was fecal microbiota of male Wistar rats (200-300 g, n = 6). Ceftriaxone (300 mg/kg, CJS "Darnitsa", Ukraine) was injected intramuscularly for 7 days. Faeces were collected before antibiotic treatment and on the 1<sup>st</sup>, 14<sup>th</sup> and 56<sup>th</sup> days after antibiotic withdrawal. The quantity of ODB was determined by culture method on a highly selective *Oxalate Medium* (g/L): K<sub>2</sub>HPO<sub>4</sub> - 0.25; KH<sub>2</sub>PO<sub>4</sub> - 0.25; (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> - 0.5; MgSO<sub>4</sub>·7H<sub>2</sub>O - 0.025; CH<sub>3</sub>COON - 0.82; yeast extract - 1.0; rezazurin - 0.001; Na<sub>2</sub>CO<sub>3</sub> - 4; L-cysteine-HCl - 0.5; *Trace element solution SL-10* - 1 ml with the following composition per L: HCl (25%; 7.7 M) - 10.00 ml, FeCl<sub>2</sub> x 4H<sub>2</sub>O - 1.50 g, ZnCl<sub>2</sub> - 70.00 mg, MnCl<sub>2</sub> x 4H<sub>2</sub>O - 100.00 mg, H<sub>3</sub>BO<sub>3</sub> - 6.00 mg, CoCl<sub>2</sub> x 6H<sub>2</sub>O - 190.00 mg, CuCl<sub>2</sub> x 2H<sub>2</sub>O - 2.00 mg, NiCl<sub>2</sub> x 6H<sub>2</sub>O - 24.00 mg, Na<sub>2</sub>MoO<sub>4</sub> x 2H<sub>2</sub>O - 36.00 mg; Ta Na<sub>2</sub>C<sub>2</sub>O<sub>4</sub> - 5 mg (cultivated anaerobically at 37°C for 48 hours). The redoximetric titration (with KMnO<sub>4</sub>) was adopted to evaluate the total ODA of faecal microbiota. The results were expressed in % degradation of oxalate for 0.01 g of feces.

**Results:** At the 1<sup>st</sup> day after ceftriaxone withdrawal, we observed increase a number of ODB from lg 8.02±0.25 CFU/g to lg 9.47±0.17 CFU/g (p< 0.05) and fecal microbiota ODA from 9.50±1.78 % to 11.67±2.99 %. At the 14th day there was a significant decrease a number of ODB by more than 2 orders of magnitude (from lg 8.02±0.25 CFU/g to lg 5.72±0.48 CFU/g, p< 0.05), that was accompanied diminish the fecal ODA - from 9.50±1.78 % to 6.3±1.46

%. By the 56th day, a number of ODB was almost unchanged vs. 14th day of experiment (lg 5.28±0.45 CFU/g, p< 0.05), but fecal ODA continued decrease (from 9.50±1.78 % to 4.67 ± 1.87%, p< 0.05).

**Conclusion:** 1) The redoximetric titration (with KMnO<sub>4</sub>) is the reliable method for evaluation of total ODA of the fecal microbiota without isolation of pure culture and might have clinical application. 2) Ceftriaxone treatment reduced the total oxalate-degrading activity of fecal microbiota independently on number of ODB.

**Disclosure:** Nothing to disclose

## P1842 THE DYNAMICS OF MUCOSA-ASSOCIATE BACTERIA IN IRRITABLE BOWEL DISEASE

Inoue J., Hayashi H., Oyama K., Ikegawa T., Tanaka S., Tanaka T., Kodama Y.

Kobe University Graduate School of Medicine, Gastroenterology, Kobe, Japan

**Contact E-Mail Address:** juninoue@med.kobe-u.ac.jp

**Introduction:** The gut microbiota between individuals varies greatly, while the composition of gut microbiota within individual slightly changes over time. Fecal samples can be easily collected and are often used to analyzing gut microbiota.

On the other hand, the composition of mucosal bacteria differs from that of luminal bacteria. Though mucosal bacteria are considered to be important in the pathophysiology of intestinal disease including irritable bowel disease (IBS), there are small numbers of study investigating the dynamic analysis of mucosa-associated bacteria because of the difficulty of collecting the sample comparing to fecal samples.

**Aims & Methods:** The purpose of this study is to analysis the dynamics of mucosa-associated bacteria over time in patient with IBS. The mucus samples including mucosal bacteria were collected from terminal ileum, cecum, transverse colon, sigmoid colon and rectum in same patient with IBS three times at the examination with lower endoscopy using cytology brush. After extracting DNA from mucus samples, 16S metagenome were performed by Miseq platform(Illumina). Sequence data were quality filtered and microbial composition, alpha and beta diversities were analyzed using QIIME open-source software.

**Results:** The microbial composition of mucosal samples collected by blush were comparable to that of mucosal samples collected by mucosal biopsy and microbial DNA amount in the mucus samples collected by blush were more than 1000 times larger than that of from biopsy samples. Though the microbial composition of mucosal bacteria were different from that of fecal samples, there were not big different change when comparing between each mucosal samples collected from terminal ileum, cecum, transverse colon, sigmoid colon and rectum.

Compared to luminal bacteria, the proportion of Sutterella, Enterobacteriaceae, Delftia and Pseudomonas were increased in the mucus samples on the other hands Phascolarctobacterium, Blautia, Lachnospiraceae, Parabacteroides were decreased. Interestingly PCoA analysis revealed that the microbial composition of mucosa-associate bacteria had slightly changed over time as with the fecal microbial composition.

**Conclusion:** In this study there are small dynamic changes of mucosa-associate bacteria as with luminal bacteria within the individuals in IBS patient over time and may constantly contribute to the pathophysiology of IBS.

**Disclosure:** Nothing to disclose

## P1843 PEOPLE'S MOTIVATION THROUGH SOCIAL NETWORKS COULD INCREASE PARTICIPATION IN COLORECTAL CANCER SCREENING CAMPAIGNS

**Contact E-Mail Address:** robert.benamouzig@aphp.fr

**Introduction:** Colorectal cancer (CRC) screening using fecal occult blood testing results in reduced CRC mortality. However participation rates in organized campaign remains low and rarely exceed 50% in most French departments. The Colorectal Cancer Screening Association in Seine-Saint-

Denis considered outreach via social networks to people aged 50-74 living in deprived target areas with a high proportion of NPAI (mail invitation campaign not distributed).

**Aims & Methods:** The purpose of this analysis was to describe the procedure and initial results of the pilot study.

67,000 people aged 50 to 74 years from six municipalities with low socio-economic background and a proportion of NPAI over 10% were considered. Accounting to the biannual frequency of departmental screening campaigns, the average participation rate in these area was only 25% in 2017 with a 19% exclusion rate due to medical reasons (previous colonoscopy, high risk patients...) and 11% NPAI. A pilot Facebook campaign ran for 2 months. Facebook presented the ads as defined by the scientific committee to the target population. The team operated using a simple web-based healthcare engagement platform designed to increase participation developed by Medorion©, Israel. No special computer skills are required and training is a simple 2-hour web seminar. The Facebook campaign does not require names, Emails or any predefined contact information. The rate of engagement can be adjusted to the capacity of the team as well as the project budget. In this campaign, 33,000 Facebook users living in this area were targeted. All data collected is stored outside of Facebook in a HIPAA and GDPR compliant platform according to European legislation.

**Results:** Over a two-month engagement period, 4317 people click on the CRC screening advertising and 298 people applied for a test kit. Overall, 84% of requests were made outside working hours (9 a.m-5 p.m) and 100% provided an email, postal address, and a phone number (100% mobile). Of these, 160 (53.7%) were eligible for CRC screening after verification on a dedicated regional eligibility site ([www.neonetidf.org](http://www.neonetidf.org)). Ineligible population included 38 people who resided outside Seine-Saint-Denis, 16 people who were outside the age range, 48 people that could not be verified because to inaccurate information provided, 30 people who had recent CRC screening, and 6 who had recent or ongoing colon disease. The average age of the 160 eligible people was 54 yrs and among them 64 (40%) carried out the screening test to date, higher than the 25% best effort so far. For the other 96 at 60 days after the Facebook campaign closure, a weekly email reminder is still sent to increase this participation.

**Conclusion:** Extrapolating to a possible year-long project, this method can easily reach a 3 to 5% increase in CRC screening within this target population, which has a history of non-compliance and have not been responsive to previous attempts. It is important to note that the results are based on modest pilot settings, small budget, no specific creative, and not backed by a state trusted entity promoting the screening, making these results even more significant.

**Contact E-Mail Address:** [stevewdixon@doctors.net.uk](mailto:stevewdixon@doctors.net.uk)

**Introduction:** Colorectal cancer (CRC) remains a major cause of cancer-related mortality worldwide. Recent reports from the United States<sup>[1,2]</sup>, Canada<sup>[3]</sup> & Australia<sup>[4]</sup> have suggested that the incidence of CRC in young adults is rising. Using a novel dataset from the English population we aimed to determine the temporal changes in CRC incidence trends by age group and cohort.

**Aims & Methods:** This was a retrospective, population-based cohort study of all patients aged 20 years and above diagnosed with CRC between 1974 and 2015 in England. Data were obtained from the National Cancer Registration and Analysis Service operated by Public Health England using ICD-9 and -10 codes for CRC. Mid-year population estimates were obtained from the Office for National Statistics and used to calculate age-specific incidence rates for ten age groups that were age-adjusted to the 2013 European Standard Population. Join-point regression analysis was performed to analyse the magnitude and direction of temporal changes in age-specific incidence rates. Age-period-cohort modelling was used to assess the independent effects of age, period and cohort on CRC incidence rates.

**Results:** Between 1974 and 2015 a total of 1,145,639 diagnosis of CRC were made (726887 colon, 418752 rectum). Since 1966 there has been a marked rise in the incidence rate ratio (IRR) for both colon and rectal cancer: compared with the reference year 1926, the IRR has doubled (1.92, 95% CI 1.08-3.43) for colon and tripled (3.07, 95% CI 1.79-5.26) for rectal cancer. Strikingly, since 2001 the incidence rate among 20-29 year olds has risen by 20.7% per year and by 12.7% per year among 30 - 39 year olds. CRC incidence initially rose following the introduction of the Bowel Cancer Screening Programme in 2006 but this has subsequently plateaued. The incidence rates of CRC among other age groups has remained largely unchanged.

**Conclusion:** This novel data from England mirrors the recently described trends in reported in other economically developed countries of rising incidence of CRC in young adults. Work is required to elucidate the underlying causes to allow public health measures required to slow or reverse the current trend which is likely to place further strain on already stretched healthcare resources in England.

Furthermore, understanding the mechanisms underpinning the trends described herein may allow risk stratification for screening tests in younger adults who would not otherwise qualify for testing. Any such expansion of screening practices is likely to have a significant impact on the cost and service provision requirement within the confines of the English National Health System.

**Introduction:** Colorectal cancer (CCR) is a leading cause of death worldwide. Since there is a strong correlation between mortality and the disease stage, focus on the preclinical phase to recognize and treat precursor lesions is the main priority. Organized screening programs for CCR are emerging in Europe to face the overall growing incidence.

**Aims & Methods:** The aim of this study was to evaluate the diagnostic performance of the program and to define potential adjustments to the strategy adopted.

Observational study from a pilot population-based screening program for CCR in a Portuguese district based on fecal immunochemical test (FIT) with a cut-off level of 100 ng/mL. Colonoscopy was the standard diagnostic follow-up test. Preliminary data were collected from January 2018 to March 2019 to analyze screening measures and quality indicators according with national advices adapted from the European Union guidelines. Advanced adenoma (AA) was defined as any adenoma with at least one of the following features: ≥10 mm in size, villous or tubulo-villous component, high grade dysplasia.

**Results:** The tested population consisted of 6636 individuals and the positivity rate was 4% (n=257). Of all those who tested positive, 55% (n=142) underwent colonoscopy. In total, 153 colonoscopies were performed, including 11 repeated for diagnostic/therapeutic purposes, with an overall adequate bowel preparation of 91%. The cecal intubation rate was 92%. The polyp and adenoma detection rates were 57% and 43%, respectively. The AA detection rate was 22% matching 51% of all detected adenomas with a true-positive rate of 24% and a false-positive rate of 32%. Neoplasia was diagnosed in 6 cases.

**Conclusion:** The AA detection rate was substantially high when compared with data published in literature alongside with an unexpected low positivity rate. These findings could justify lowering the FIT cut-off level, in order to increase the diagnostic yield, and carrying out actions to improve the colonoscopy participation rate.

**Contact E-Mail Address:** mariamdarweesh11@gmail.com

**Introduction:** Colorectal carcinoma (CRC) is one of the common malignancies with escalating incidence and mortality. Today, it is considered a double-faced disease; each face has a unique pathology, management, and prognosis. Immense efforts are applied to explore the behavior of CRC in both sides of the colon; therefore, in this study we focus on the metastatic pattern of CRC in right and left sides.

**Aims & Methods:** We identified 10714 patients who have been diagnosed with stage 4 CRC from 2010 to 2013 through Surveillance, Epidemiology and End Results (SEER) database. Metastatic pattern for liver, peritoneum, lung, bone and brain was analyzed.

**Results:** We found 6805 and 3909 patients had left and right CRC, respectively. Right CRC had higher incidence rate of liver and peritoneum metastases than left CRC (92.9 % vs. 89.7 % and 30% % vs. 27.3 % respectively,  $P=0.003$ ). While, on the other hand, left CRC had a higher incidence rate of lung metastases (31.5% vs. 25.6%) than right CRC. No statistical significance difference was found regarding pattern of bone or brain metastases between both colon sides. Males with right CRC were more susceptible to the five sites of metastases than females. Albeit males with left CRC were the least to develop peritoneum, lung and brain metastases compared to females. Concerning the survival rates, patients with tumors arising from left colon had better 1-year survival rates in comparison to those with tumors from right colon (64.7% and 49% respectively,  $p < 0.001$ ).

**Conclusion:** Right CRC patients are more vulnerable to liver and peritoneum metastases; however, those with left CRC have higher probability to develop lung metastases, furthermore, they have better survival rates.

**Disclosure:** Nothing to disclose

## P1848 ARE GI CANCERS BEING DIAGNOSED FROM OUTSIDE THE 'URGENT CANCER' REFERRAL PATHWAY?

Mehta A., Hong S., Sachdeva A., Patel R.N., Tariq Z., King J., Besherdas K.  
Royal Free London NHS Trust, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** rajan.patel@nhs.net

**Introduction:** The UK lags behind Europe in the diagnosis, treatment and survival rates of cancer. To improve on this and diagnose cancer early, patients with alarm symptoms from primary care are referred on a 'Two week wait' (2WW) urgent pathway. Previous data indicates that the majority of cancers diagnosed in the UK are from outside the 2WW pathway. However, demand for upper and lower GI endoscopy via the 2WW has risen dramatically above and beyond the steady increase in overall GI cancer incidence.

**Aims & Methods:** We aimed to study the diagnostic pathways via which GI cancers are diagnosed. We reviewed the common luminal upper and lower GI cancers diagnosed at endoscopy at a single centre between February 2017 and September 2018 via Unisoft GI Reporting Tool. Known malignancies and diagnoses made at other Trusts were excluded ( $n=72$ ). Retrospective analysis of 317 patients with 332 GI cancers was performed.

**Results:** 332 GI cancers (oesophagus 44 (13.9%), stomach 21 (6.6%), duodenum 6 (1.9%), colon 174 (54.9%), rectum 87 (27.4%)). Mean age 71.1 (range 24 - 97), Female 133 (42.0%). Median time to diagnosis (i.e. presentation to endoscopy) was 22 days (IQR 14 to 34).

Referral pathways included: 202 (63.7%) GP Target 2WW, 45 (14.2%) Inpatient, 30 (9.5%) Urgent 2WW from clinic/hospital discharge, 21 (6.6%) Abnormal imaging, 17 (5.4%) Routine clinic, 2 (0.6%) Surveillance.

Only 48 (15.1%) GI cancer patients went 'Straight To Test' (STT) whereas 198 (62.5%) were seen in clinic first. The mean time to diagnosis in those referred via the GP Target 2WW was 25.4 days (STT) versus 32.2 days (clinic review), ( $p=0.05$ ).

**Conclusion:** In this study, we conclude that two thirds of GI cancers were diagnosed following referral via the 2WW pathway but only one third of gastric cancers. Of the 2WW patients, two thirds had a clinic review prior to endoscopy which resulted in a 7 day delay in cancer diagnosis compared to STT patients. We conclude that more patients with cancer are diagnosed on the 2WW pathway than previously documented and triaging patients STT speeds up the diagnosis further by 7 days. We recommend that the majority of 2WW patients be triaged STT so that earlier diagnosis of cancer may result in improved survival and reduce the gap compared to our European counterparts.

**Contact E-Mail Address:** h.c.jodal@medisin.uio.no

**Introduction:** Patients who have had adenomas removed are believed to be at increased risk for colorectal cancer (CRC). Dependent on adenoma characteristics, these patients are recommended surveillance colonoscopy at regular intervals. Previously, we did not find increased risk for CRC among patients with previous adenoma 7.7 years after polypectomy (1). We have updated the results with more than 10 years follow-up, in accordance with the time horizon of current surveillance guidelines.

**Aims & Methods:** We identified all patients without a prior diagnosis of CRC who had adenomas removed in Norway from 1993 to 2007 through the Cancer Registry of Norway (1). Norwegian guidelines recommended colonoscopy surveillance after 10 years after removal of high-risk adenomas, and no surveillance after removal of low-risk adenomas. We calculated standardised incidence-based mortality ratios (SMRs) using age-, sex- and period-specific rates for the Norwegian population as comparison. High-risk adenomas were defined as multiple adenomas (two or more) and adenomas with either villous growth-pattern or high-grade dysplasia.

**Results:** We included 40,824 patients who had colorectal adenomas removed. During a median follow-up of 10.7 years (maximum 23.0 years), 1820 patients were diagnosed with and 520 died of CRC. Overall, adenoma patients had a similar risk of CRC death to the general population (SMR 0.98; 95 % confidence interval (CI) 0.90-1.07). Patients with high-risk adenomas had increased risk of CRC death (SMR 1.23; 95 % CI 1.09-1.39), while patients with low-risk adenomas had reduced risk (SMR 0.82; 95 % CI 0.72-0.92). The absolute risk of CRC death for patients with low-risk adenomas was 1.1 %, and 1.6 % for those with high-risk adenomas.

**Conclusion:** Patients with low-risk adenomas have a lower risk of CRC death than the general population and do not need surveillance. The risk for patients with high-risk adenomas is only marginally increased and surveillance should be discussed.

## P1850 SHOULD YOUNG PATIENTS WITH INCIDENTALLY DETECTED ADENOMAS FOLLOW CURRENT COLONOSCOPY SURVEILLANCE RECOMMENDATIONS? RISK OF METACHRONOUS NEOPLASIA AND REAL SURVEILLANCE PRACTICES

Chang H.E., Lee H.H., Choi Y.H., Kim S.-J., Cho Y.K., Park J.-M., Lee B.-I., Cho Y., Lee I.-S., Choi M.-G.  
*Catholic University of Korea Seoul St. Mary's Hospital, Department of Internal Medicine, Seoul, Korea (Republic of)*

**Contact E-Mail Address:** lia1999@naver.com

**Introduction:** The current guidelines for colonoscopy surveillance after screening and polypectomy are for patients aged 50 and older. It is not well known whether post-polypectomy surveillance recommendations are appropriate for young patients less than age 40 years with incidentally detected adenomas.

**Aims & Methods:** The aims of the study were to identify the occurrence of metachronous advanced neoplasia in young patients < 40 years and to investigate whether surveillance recommendations by endoscopists complied with the current national guidelines. We retrospectively analyzed the medical record obtained from the Catholic University of Korea Seoul St. Mary's Hospital and health screening center. Patients under the age of 40 with  $\geq 1$  adenoma removed on colonoscopy between January 2010 and December 2017 were eligible.

**Results:** Among a total of 8,168 subjects who underwent colonoscopy during the study period, 723 were eligible after excluding those with no neoplastic lesion (n=7,414), familial adenomatous polyposis (n=10), colorectal cancer (n=10), and neuroendocrine tumor (n=11). Of these 723 patients, 140 (19.4%) had high risk adenoma, which consisted of 3 or more adenomas (n=25), any adenoma larger than 10 mm (n=35), any tubulovillous or villous adenoma (n=7), any adenoma with high-grade dysplasia (n=52), and any serrated polyps larger than 10 mm (n=21). The high risk patients were younger (32 vs. 34 years,  $P = 0.015$ ), more female (42.9% vs. 31.7%,  $P = 0.016$ ) and had lower BMI (22.8 vs. 24.2,  $P = 0.001$ ) compared to the low risk patients. Surveillance colonoscopy was performed in 22.3% (130/583) of the low risk patients and 35.7% (50/140) of the high risk patients ( $P = 0.001$ ). Metachronous advanced neoplasia was identified in 1.5% (2/130) of the low risk patients and 12.0% (6/50) of the high risk patients ( $P = 0.002$ ). Furthermore, we could confirm the record of endoscopist surveillance recommendation in 142 patients. The compliance rates with the national guidelines were 25.0% for the low risk neoplasia and 55.0% for high risk neoplasia. Almost all noncompliant patients underwent follow up colonoscopy earlier than recommended.

**Conclusion:** Even in young patients less than age 40 years, a shorter interval of surveillance colonoscopy should be applied to the patients with high risk adenoma to detect the metachronous advanced neoplasia. Most noncompliant patients were observed to undergo surveillance colonoscopy earlier than recommended.

**Disclosure:** Nothing to disclose

## P1851 SHOULD COLORECTAL CANCER SCREENING IN PORTUGAL START AT AGE 45 YEARS-OLD?

**Contact E-Mail Address:** pedro\_currais@live.com.pt

**Introduction:** Colorectal cancer (CRC) is one of the most common cancers in Europe. Recently the American Cancer Society published a qualified recommendation advocating the start of CRC screening at 45 years, based on the increase in the incidence of CRC in individuals with <55 years (45-49 years: 31/100,000; 50-54 years: 58/100,000), in contrast to a reduction in individuals with >65 years. Mortality rate (MR) was stable in patients <55 years (45-49 years: 8/100,000; 50-54 years: 13/100,000) and decreased after 55 years.

**Aims & Methods:** We intended to evaluate if the changes in the CRC incidence/mortality observed in the USA also occur in Portugal and perform a cost-effectiveness analysis of CRC screening starting at 45 years of age. We evaluated the incidence of CRC by age group using data from the National Cancer Registry and MR according to the National Statistics Institute between 1993-2010 and 2003-2016, respectively. Cost-effectiveness analysis performed with a decision tree from a societal perspective comparing biennial faecal immunochemical test (FIT) or one single colonoscopy screening versus non-screening at the age of 45 years-old in Portugal. Efficacy was measured in quality-adjusted life years (QALY). For the base-case scenario, the incidence rate used for the age of 45-50 years-old was 30/100,000, the FIT cost was €3 with a 50% acceptance rate and the colonoscopy cost was €397 with a 38% acceptance rate. The threshold was set at €39,760/QALY and the primary outcome was the incremental cost-effectiveness ratio (ICER).

**Results:** In Portugal, between 1993 and 2010, there was an increase in CRC incidence of 17% (25/100,000 vs. 30/100,000), 35% (39/100,000 vs. 54/100,000) and 71% (52/100,000 vs. 97/100,000) in patients with 45-49 years, 50-54 years and 55-59 years, respectively. The MR of patients with 45-54 years remained stable between 2003 and 2016 (12/100,000) as a counterpoint to a moderate decrease in individuals with 55-64 (38/100,000 vs. 35/100,000) and a sharp reduction in 65-75 (93/100,000 vs. 75/100,000). Screening for CRC at the age of 45 was not cost-effective with the present incidence. FIT screening provided an ICER of €57,995/QALY while colonoscopy provided an ICER of €2,117,564/QALY. In one-way sensitivity analysis FIT screening would be cost-effective at the present cost and acceptance rates if the incidence rate rises above 38/100,000 (current rates for people aged  $\geq 50$  years-old); colonoscopy at this age was never cost-effective despite changes in costs and/or incidence rates.

**Conclusion:** In Portugal the incidence of CRC in patients aged 45-55 years has been increasing, with stable MR, contrary to the decrease in MR in the age groups covered by CRC screening programs. This scenario is similar to what has been described in the United States of America. However, CRC screening in Portugal, at the age of 45 years-old at present is not cost-effective and will only be cost-effective if the incidence rates rises to 38/100,000. The current CRC screening strategy, starting at the age of 50 years-old, by biennial FIT, is clearly cost-effective as the incidence rate is already 55/100,000.

**Introduction:** Worldly, Colorectal Cancer (CRC) is the third cancer more frequent in males and the second in women. Screening programmes have demonstrated the detection of CRC in early stages allowing a more effective treatment.

### Aims & Methods:

- To describe the findings and the differences in neoplastic findings between sexes in the asymptomatic participants.  
- Screening programme for CRC was introduced in our hospital in october 2014. We collected data until March 2019. Men and women between 50 and 69 years old were invited to undergo a Faecal Occult Blood Test (FOBT). Those who obtained a positive result were offered to perform a colonoscopy.

The following results have been calculated from the data base CRC Screening Programme of Junta de Castilla y León in Burgos.

**Results:** In total, 84559 subjects were invited to take part in the program. Of these, 32871 provided a faecal sample resulting in a 38.9% participation rate (52.2% females). FOBT was positive in 3228 individuals (9.8%), 58.1% of them were males; 2649 (82.1%) of them underwent a colonoscopy. Of those 2649, colonoscopies were negative or had non neoplastic findings in 422 (27.6%) males and 572 (51.1%) females. We detected low-risk adenomas (LRA) in 393 (25.7%) males and in 270 (24.1%) females,  $p < 0.01$ ; medium-risk adenoma (MRA) in 383 (25%) males and 177 (15.8%) females,  $p = 0.1$ ; and high-risk adenomas (HRA) in 186 (12.2%) males and 52 (4.6%) females,  $p = 0.0001$ . Adenoma detection rate (ADR) resulted in 55.2%. 194 invasive CRC were found (9.4% of males and 4.4% of females). The probability of being diagnosed of adenoma (RR 1.35, 95% IC 1.26 - 1.45;  $p < 0.0001$ ) and CRC (RR 2.16, 95% IC 1.59 - 2.94;  $p < 0.0001$ ) was higher in males.

**Conclusion:** Participation rate of the screening programme in our hospital is very low, remaining below 45%, established as the acceptable rate in European Guidelines. On the other hand, colonoscopy acceptance rate was 82.1%. However, there are an unknown percentage of people, who decide to perform FOBT and/or colonoscopies in private centres.

FOBT positivity rate was 9.8%, slightly higher than in the rest of Spain (6.8%).

ADR was 55.2%, more than 25% required by European quality guidelines. In more than half of participants, neoplastic adenomas were resected avoiding their progression to advanced neoplasia. CRC, LRA and HRA were more frequent in males with similar rates described in bibliography.

**Introduction:** Colorectal cancer (CRC) screening is important because survival mainly depends on the stage at diagnosis.

**Aims & Methods:** We aimed to analyze the impact of annual fecal immunochemical test-triggered colonoscopy (FIT-C) compared to screening colonoscopy (SCR-C) on the detection rates of low-risk adenomas (LRA), high-risk adenoma (HRA) and CRC among individuals with average CRC risk.

Two prospective population based CRC screening strategies, annual FIT screening vs. SCR-C were compared within a province of Austria. All asymptomatic individuals, who underwent FIT-C or SCR-C between 01/2003 and 12/2014, were included in this population-based screening study. We excluded individuals with a history of inflammatory bowel disease or hereditary CRC syndromes. The lesions were classified in three groups: CRC, HRA and LRA including tubular adenoma  $\leq 1$ cm.

**Results:** Fourteen thousand four hundred thirteen individuals (median age 62; 53% males) with FIT-C were compared to 10.083 individuals (median age 60; 52% males) with SCR-C.

The CRC detection rates were 1.26% (confidence interval (CI): 1.05; 1.48) in FIT-C compared to 0.54% (CI: 0.39; 0.68) SCR-C ( $p < 0.001$ ). The HRA detection rates were 14.22% (CI: 13.65; 14.79) in FIT-C compared to 6.84% (CI: 6.43; 7.25) in SCR-C ( $p < 0.001$ ). The LRA detection rates were 16.98% (CI: 16.25; 17.72) in FIT-C compared to 12.95% (CI: 12.3; 13.61) in SCR-C ( $p < 0.001$ ).

**Conclusion:** FIT-C presents an effective CRC-screening method in subjects with average CRC-risk as this population-based study demonstrated that FIT-C doubles detection rate of HRA and CRC in head-to-head comparison with SCR-C.

**Disclosure:** Nothing to disclose

## P1854 DIAGNOSTIC YIELD OF GERMLINE GENETIC TESTING IN NON-POLYPOSIS COLORECTAL CANCER IN YOUNG ADULTS

**Contact E-Mail Address:** caballol@clinic.cat

**Introduction:** Non-polyposis colorectal cancer (CRC) in young adults (aged  $\leq 50$  years) represents 10-15% of all CRC. Current clinical guidelines recommend performing tumour mismatch repair deficiency testing in all CRC patients (by immunohistochemistry (IHC) for MLH1, MSH2, MSH6 and PMS2), as a screening for Lynch syndrome (so-called universal strategy). When IHC reveals loss of protein expression, guidelines recommend performing germline genetic analyses to confirm Lynch syndrome<sup>1</sup>. However, recent studies in early-onset CRC cases suggest the existence of germline mutations in MMR or other genes in which IHC study may not be altered<sup>2</sup>.

**Aims & Methods:** To describe the diagnostic yield of performing universal germline genetic testing in patients with non-polyposis CRC aged 50 years or less in order to improve the identification of hereditary CRC syndromes.

A total of 253 patients, corresponding to all patients aged  $\leq 50$  years with non-polyposis CRC patients visited in the High-Risk CRC Clinic of Hospital Clínic de Barcelona between 2008 and 2018, were included. Until June 2016, 182 patients were included and studied by IHC.

If the study showed loss of protein expression or was inconclusive, mutations in MMR genes (*MLH1*, *MSH2*, *MSH6*, *PMS2*) were analysed by Sanger Sequencing and MLPA, while if IHC was normal *MUTYH* gene was evaluated (prevalent mutations in Caucasian population).

From July 2016 until the end of the study, 70 patients were included and performed multigene panel by Next Generation Sequencing, including *MLH1*, *MSH2*, *MSH6*, *PMS2*, *BRCA1*, *BRCA2* and *MUTYH*, regardless of the IHC result.

**Results:** IHC for MMR proteins was performed in 235 cases, showing loss of expression in 56 (23.8%) of which 35 (62%) patients were diagnosed of Lynch syndrome: 16 (46%) had mutation in *MLH1*, 13 (37%) in *MSH2*, 3 (8.5%) in *MSH6* and 3 (8.5%) in *PMS2*. Of the remaining 197 patients with normal IHC study ( $n = 179$ ) or without IHC study ( $n = 18$ ), in 7 (3.6%) a germline mutation was found: 4 biallelic mutations in *MUTYH* and 3 diagnoses of Lynch syndrome with normal IHC (2 mutations in *MSH6* and 1 in *MSH2*). Of the 42 patients with Lynch syndrome, 7 (16.7%) were diagnosed by a genetic study not directed by IHC.

**Conclusion:** Up to 17% of young patients with CRC carry germinal mutations in mismatch repair genes or *MUTYH* gene. In almost 20% of these patients, the mutation would not have been diagnosed with the standard strategy based on universal IHC. These results support the use of multigene panel testing in all patients with CRC  $\leq 50$  years.

**Introduction:** Autophagy is a key pathway involved in cellular homeostasis by orchestrating the degradation of cytoplasmic macromolecular constituents elicited by various stress stimuli (e.g. starvation). It has been suggested that proficient autophagy is involved in mounting an appropriate DNA damage response (DDR). The IBD risk gene ATG16L1 is a critical component of the autophagic machinery and absence of ATG16L1 has severe consequences for intestinal epithelial cell survival and function, however a potential role of the protein for DDR is unknown. We have previously shown that deficiency in the enzyme RNase H2b leads to impaired ribonucleotide excision repair and induces spontaneous DNA damage with subsequent p53-dependent suppression of stem cell proliferation. Absence of p53 and RNaseH2b in the intestinal epithelium leads to accumulation of somatic mutations and spontaneous intestinal carcinogenesis. The aim of our study was to test the role of Atg16l1 in coordinating DNA repair and epithelial cell fate decisions in this newly established DNA damage model.

**Aims & Methods:** Murine intestinal epithelial ModeK cells were gene silenced using siRNA (Atg16l1, Ctrl.) stimulated with the DNA-damaging agent Cytarabine A (AraC) and subjected to gene expression analyses, FACS cell death assays and immunoblot analyses. A conditional intestinal epithelial knockout of *Atg16l1*, *Rnaseh2b* and the combined DKO was established by crossing VillinCre mice with mice floxed for *Atg16l1*, *Rnaseh2b* both. Intestinal organoids of WT, *Atg16l1*<sup>ΔIEC</sup>, *Rnaseh2b*<sup>ΔIEC</sup> and *Rnaseh2b/Atg16l1*<sup>ΔIEC</sup> mice were derived by culturing small intestinal crypt cells in a collagen matrix and then used for immunoblot analyses, colony formation assays, RNA sequencing and transcriptome analysis. WT, *Atg16l1*<sup>ΔIEC</sup>, *Rnaseh2b*<sup>ΔIEC</sup> and *Rnaseh2b/Atg16l1*<sup>ΔIEC</sup> mice simultaneously delivered convenient *in-vivo* models for basal phenotyping, aging experiments and acute or chronic DSS-colitis models. *Post mortem* analyses included fluorescence or IHC stainings, western blot analyses and gene expression analyses.

**Results:** AraC stimulation led to profound induction of autophagy in IECs, which was dependent on Atg16l1. Vice versa knockdown of Atg16l1 led to increased AraC induced cell death, as shown by propidium iodide staining. *In-vivo* we observed that co-deletion of Atg16l1 in *Atg16l1/H2b*<sup>ΔIEC</sup> mice led to increased epithelial cell death and consecutive increase of histopathological inflammation. Likewise DSS induced colitis led to a strong manifestation of particular small intestinal inflammation, which was associated with increased cell death and DNA damage. Importantly, Atg16l1 deficiency completely impaired DNA damage induced suppression of stem cell proliferation, as small intestinal crypts in *Atg16l1/H2b*<sup>ΔIEC</sup> mice presented with increased numbers of Ki67 and BrdU+ cells, compared to *H2b*<sup>ΔIEC</sup> mice. *In-vitro* this finding was validated as intestinal organoids from *Atg16l1/H2b*<sup>ΔIEC</sup> mice showed significantly increased colony forming ability, compared to *H2b*<sup>ΔIEC</sup>. Mechanistically RNA sequencing reveals that Atg16l1 governs a distinct transcriptional programme involved with rescued epithelial proliferation.

**Conclusion:** We show that Atg16l1 is a critical component of physiological DDR and is involved in fate decisions of epithelial cells towards DNA damage-induced cell death. Importantly, we show that Atg16l1-deficiency impairs DNA damage-induced suppression of stem cell proliferation despite

ongoing epithelial cell death. Hence, Atg16l1 licenses an essential step of genome surveillance, which might point towards a novel role of the gene in intestinal carcinogenesis.

**Introduction:** Colorectal cancer (CRC) is the third most common type of cancer in the world, and its incidence continues to rise. SLC39A7 (ZIP7) is a zinc transporter that plays a key role in intestinal epithelial self-renewal. However, whether or not SLC39A7 is involved in human colorectal cancer remains unclear.

**Aims & Methods:** To assess the biological function of SLC39A7 in colorectal cancer, we constructed CRISPR/Cas9-based gene knockout. The SW620 and HCT116 cell lines were infected with the constructed virus, then cell proliferation, cell apoptosis and migration assays were detected to de the inhibition efficiency of the adenovirus on hepatoma cells. Immunohistochemical analysis was performed to determine SLC39A7 protein expression levels in the cancer tissues.

**Results:** Our results showed that the SLC39A7 protein expression levels in the CRC tissues were significantly higher than those in the adjacent normal mucosa, and was positively correlated with the lymph node metastasis. Knockout of SLC39A7 exhibited a significant decrease in cell viability and proliferation of colorectal cancer cells. It was also shown that knockout of SLC39A7 boosted apoptosis in colorectal cancer cells. Furthermore, down-regulation of SLC39A7 suppressed Nrf2 expression. In addition, migration assays further demonstrated that knockdown of Zn<sup>2+</sup> significantly reduced the migration and invasion ability in both SW620 and HCT116 cells.

**Conclusion:** In conclusion, our results suggest that SLC39A7 plays a crucial role in the proliferation and invasion of colorectal cancer cells, which provides evidence that SLC39A7 might be as a potential therapeutic target for colorectal cancer treatment.

## P1857 INCREASED RISK OF SESSILE SERRATED ADENOMAS ON INITIAL SCREENING COLONOSCOPY IN POST-BARIATRIC SURGERY PATIENTS

Fakhreddine A.<sup>1</sup>, Lee J.A.<sup>2</sup>, Gupta N.<sup>3</sup>, Magavi P.<sup>2</sup>, Takata M.<sup>4</sup>, Konijeti G.G.<sup>1</sup>

<sup>1</sup>Scripps Clinic, Division of Gastroenterology & Hepatology, La Jolla, United States, <sup>2</sup>Scripps Clinic, Internal Medicine, La Jolla, United States, <sup>3</sup>Kansas City University of Medicine and Biosciences, Kansas City, United States, <sup>4</sup>Scripps Clinic, Division of General/Bariatric Surgery, La Jolla, United States

**Contact E-Mail Address:** lee.joy@scrippshealth.org

**Introduction:** Bariatric surgery effectively induces weight loss in obese patients, decreasing obesity-related co-morbidities and overall cancer risk.<sup>1</sup> While a recent meta-analysis demonstrated a 27% decrease in CRC risk following bariatric surgery, a large cohort study showed an increase in the standardized incidence ratio of CRC with longer follow-up intervals after bariatric surgery.<sup>2,3</sup> By preferentially modulating epigenetic modifications versus de novo chromosomal mutations, the complex physiologic changes

following bariatric surgery may in fact drive CRC via the sessile serrated adenomas (SSA) pathway or conventional adenoma-carcinoma sequence, respectively.<sup>4,7</sup>

**Aims & Methods:** Our aim was to examine the risk of CRC precursors in post-bariatric surgery patients as compared to the general population. We conducted a single center retrospective case-control study using 2007-2019 data from the electronic medical record. Cases were defined as patients age 40 to 50 at time of bariatric surgery, with subsequent documented initial screening colonoscopy and pathology. Cases were excluded if they underwent a diagnostic colonoscopy or had a family history of CRC (1st-degree relative age < 60 years, or two 1st-degree relatives at any age). 88 patients met both inclusion and exclusion criteria. Cases were matched 1:1 by age  $\pm$  2 years and gender to controls with BMI  $\geq$  25 undergoing average-risk screening colonoscopy during the same time period. Chi-square and t-tests were performed to compare anatomic and histologic distribution of adenomas between groups.

**Results:** Among cases, bariatric procedures consisted of Roux-en-Y (51%), laparoscopic gastric band placement (28%), and vertical sleeve gastrectomy (20%). Mean BMI pre-surgery was 42 kg/m<sup>2</sup>, compared to 33 kg/m<sup>2</sup> at initial screening colonoscopy (Table 1). Average time from surgery to colonoscopy was 4.5 years (SD 2.5 years), with 45% undergoing colonoscopy  $\geq$  5 years post-surgery.

There was no significant difference in adenoma detection rate (ADR) between surgical and control groups (35% vs. 40%, p=0.34). SSA detection rate was significantly higher in post-surgery patients (9.1%) compared to controls (3.9%, p< 0.01). Of all detected adenomas, SSA proportion was significantly higher in surgical (15%) vs. control patients (8.2%, p=0.03). Rectal adenomas were more common in the surgical vs. control groups (12.3% vs 3.0%, p< 0.01), but otherwise we observed no difference in the proportion of adenomas by anatomic location or advanced adenomas. Neither group had high-grade dysplasia or CRC.

**Conclusion:** SSAs are more common among average-risk obese patients after bariatric surgery compared to non-surgical controls. By anatomic location, adenomas are more common in the rectum compared to non-surgical controls, but the overall distribution of adenomas was similar. Mucosal, metabolic, and microbiome-related changes associated with bariatric surgery may alter profile of CRC precursors. Further studies are needed to understand the risk of CRC following bariatric surgery.

	Bariatric Surgery (n=88)	Control (n=102)	P-value
Female	67 (76%)	70 (67%)	p=0.13
Mean Age at Colonoscopy	51.5 +/- 2.2	52.2 +/- 2.4	p=0.07
Mean BMI at Colonoscopy	33 +/- 6	31 +/- 6	p=0.07
Adenoma detection rate	35.2%	40.2%	p=0.34
Percent SSA	15.1%	8.2%	p=0.03
Percent Tubular Adenoma	84.9%	91.8%	p=0.03
SSA detection rate	9.1%	3.9%	p<0.01
Adenomatous polyps by location			
Percent adenomas right-sided	63.0%	62.0%	p=0.81
Percent adenomas left-sided	37.0%	38.4%	p=0.81
Percent adenomas rectal	12.3%	3.0%	p<0.01

**Introduction:** Although prevention and treatment of colorectal cancer (CRC) have improved during recent years due to screening colonoscopies, new chemotherapeutic and antibody approaches, CRC still ranks second in cancer mortality in 2018 worldwide. Therefore, research needs to focus on the prevention of neoplastic colonic lesions. Epidemiological studies showed that regular use of acetylsalicylic acid (ASA) is associated with a preventive effect on the development of CRC [1]. The mechanisms underlying this chemopreventive effect are still unclear, however ASA-mediated inhibition of cyclooxygenase (COX)-1 and COX-2, leading to suppression of prostaglandin biosynthesis, is the primary focus of interest. Recently, we detected significantly lower tissue eicosanoid levels of most COX derived metabolites in ASA treated individuals in healthy colonic mucosal tissue samples obtained during routine colonoscopy. Furthermore, we observed that LOX- and CYP-pathway product concentrations remained unaffected by ASA treatment [2]. Following the hypothesis that ASA could inhibit CRC development via lipid mediator modification, we now aim to investigate the effect of ASA chemoprevention on colon tumorigenesis.

**Aims & Methods:** Using liquid chromatography-tandem mass spectrometry (LC-MS/MS), we quantified a broad spectrum of omega-6 and omega-3 polyunsaturated fatty acid (PUFA)-derived lipid mediators in normal colonic mucosa and colon tumor tissue. The murine AOM/DSS-induced model of colitis-associated colorectal cancer (CAC) was employed to investigate lipid mediator changes in healthy versus neoplastic mucosa in ASA-naïve mice. We then analyzed the effect of ASA treatment on colon tumorigenesis and lipid mediator formation in mice. In order to assess the relevance of these findings in humans, lipid metabolite changes were also analyzed in colorectal adenoma and carcinoma tissues procured during routine colonoscopy examination.

**Results:** In murine colon tumors we confirmed increases of a variety of COX-metabolites such as PGE<sub>2</sub> and 11-HETE in tumor tissue as compared to normal mucosa and these increases were dampened by aspirin treatment in the murine AOM/DSS model. Aspirin led to a significant reduction of tumor incidence but not size in the AOM/DSS model. Furthermore, we detected strongly elevated levels of 5-LOX and 12-LOX pathway products in murine tumor tissues. A trend showing similar changes of lipid mediator profiles due to aspirin treatment were also found in human colorectal adenoma and carcinoma biopsy samples.

**Conclusion:** The data presented here provides insight into lipid metabolite profile changes in murine colonic tumorigenesis. Furthermore, these data confirm a chemopreventive anti-tumor effect of ASA treatment which is accompanied by specific changes particularly of COX-1 derived lipid mediators. Pointing towards the relevance of these animal data in humans, we were able to show similar lipid mediator changes in biopsies from patients with colon adenomas and colon carcinoma.

**Introduction:** Global DNA hypomethylation can be observed along aging of normal cells, and it is also related to genomic instability and the activation of proto-oncogenes during tumor development. S-adenosylmethionine (SAM) is a universal methyl donor molecule, used as a dietary supplement. SAM is involved in DNA methylation processes, thereby it may have a favorable effect on DNA remethylation, repair and remodeling.

**Aims & Methods:** Our aim was to analyze the effect of SAM treatment on global DNA methylation level, gene expression, DNA integrity and cell cycle of two different colorectal cancer cell lines (HT-29, SW480). HT-29 and SW480 cells were treated with SAM in different concentrations (0, 0.5, 1 mmol/l) for 48 hours. The global DNA methylation status was analyzed by immunohistochemistry and bisulfite pyrosequencing of long interspersed nuclear element-1 (LINE-1) retrotransposons. The gene expression changes were detected using Human Transcriptome Array 2.0 (HTA 2.0). Double-strand DNA break analysis was performed with γH2AX ELISA and immunostaining. Cell-free DNA level of the medium collected at the end of the treatments was quantified following DNA isolation. Flow cytometry measurements were assessed for cell cycle and apoptosis determination.

**Results:** DNA remethylation, elevated expression ( $p < 0.05$ ) of DNA-repair-related genes and decreased expression ( $p < 0.05$ ) of genes, that are involved in epithelial-mesenchymal transition were observed after SAM treatment. Increased phosphorylation of H2AX (74.9, 166.5, 200.6 pM) resulted by different SAM concentrations was also referred to the activation of reparative processes. Moreover, elevation of apoptotic cell number and cell-free DNA level (0.23, 0.26, 0.63 ng/ul) were also detected. Proportion of cells was decreased in both G0/G1 (48.4, 28.5, 20.4%) and G2/M (6.0, 10.7, 12.5%) phases by SAM; however, it was increased in S (45.7, 61.7, 67.0%) phase, where the double-strand DNA break checkpoint is located.

**Conclusion:** SAM can induce DNA methylation and activation of DNA repair processes, while inhibiting epithelial-mesenchymal transition. According to the results of our study, we suppose that DNA can be released from treated cells and apoptosis is also induced by initiating DNA repair. Tumor cells could be targeted by SAM through different pathways; therefore, it might be a potential agent in cancer treatment.

## P1860 β6-INTEGRIN ACCELERATES TUMOR GROWTH AND DECREASES T-CELL INFILTRATION IN A CECUM INJECTION MODEL OF COLON CANCER

Busenhardt P., Atrott K., Hering L., Katkeviciute E., Rogler G., Spalinger M., Scharl M.

University Hospital Zürich, University of Zürich, Department of Gastroenterology and Hepatology, Zürich, Switzerland

**Contact E-Mail Address:** philipp.busenhardt@usz.ch

**Introduction:** Integrins are receptors for extracellular matrix proteins and are involved in many critical cellular processes such as cell adhesion, migration, proliferation, differentiation and cell death. The β6-integrin subunit (ITGB6) is hardly ever detectable in normal epithelial tissues, whereas it is highly induced in epithelial cells during embryogenesis, wound repair as well as during tumorigenesis of many epithelial tumors such as colorectal cancer (CRC).

In CRC, patients with high ITGB6 expression in the tumor present with a more aggressive disease and reduced survival rates. ITGB6 is upregulated during epithelial-to-mesenchymal transition (EMT) and activates latent TGFβ that is present in the extracellular matrix. Since TGFβ has been shown to drive immune evasion in mouse colon tumors, TGFβ activation through ITGB6 might lead to a reduced immune response to the tumor,

explaining the reduced survival of patients with ITGB6 expressing tumors. In this study, we aimed at investigating the effect of ITGB6 overexpression on colon cancer growth *in vivo*.

**Aims & Methods:** To assess the effect of ITGB6 on tumor growth *in vivo*, we overexpressed ITGB6 in two mouse colon cancer cell lines, namely CT-26 and MC-38, derived from Balb/c (CT-26) or C57/BL6 mice (MC-38) using lentiviral vectors. Control cells were transduced with the empty control vector. These cell lines were injected into the cecum wall of Balb/c or C57/BL6 mice and the mice were sacrificed after 2-3 weeks. Tumors were cut out of the cecum and weighted to determine tumor mass. Cytokine and cytolytic enzyme expression in the tumor was measured by RT-qPCR. T-Cell infiltration was determined by immunohistochemical (IHC) stainings for CD3, CD4 and CD8.

**Results:** In both cell lines ITGB6 overexpression accelerated tumor growth *in vivo*, resulting in significantly larger tumors than in control cell tumors at day of sacrifice. RT-qPCR analysis of RNA isolated from the tumors showed decreased IFNγ, TNFα, Granzyme B and Perforin expression upon ITGB6 overexpression, indicating an effect on the tumor immune response. IHC staining of the tumors showed a significant decrease in the number of CD3, CD4 and CD8 positive T-cells in the ITGB6 overexpressing tumors. Ki67 expression was not altered by ITGB6 overexpression, demonstrating that the difference in tumor growth was not caused by enhanced cell proliferation. Therefore, the differences in tumor size are likely to be a consequence of an altered immune response and less tumor cell killing through cytotoxic CD8+ T-cells.

**Conclusion:** ITGB6 promotes tumor growth *in vivo* and reduces T-cell infiltration into the tumor. Because of its exclusive expression in epithelial tumors, the tumor growth promoting ITGB6 is an excellent drug target. Therefore, inhibiting ITGB6 alone or as part of a combination therapy might be a promising therapy approach for CRC patients.

## P1861 HYPOXIC TUMOR MICROENVIRONMENT REGULATES GRHL2 VIA REDUCING CELL ADHESION AND INCREASING EPITHELIAL-MESENCHYMAL-TRANSITION (EMT) TO PROMOTE COLON CANCER CELL INVASION AND MIGRATION

Zhou F.<sup>1</sup>, Zou X.<sup>2</sup>

<sup>1</sup>Nanjing Drum Tower Hospital Affiliated with Medical School of Nanjing University, Department of Gastroenterology, Nanjing, China, <sup>2</sup>Nanjing Drum Tower Hospital, Associate Dean, Nanjing, China

**Contact E-Mail Address:** zhoufan24@hotmail.com

**Introduction:** Grainyhead-like 2 (GRHL2) was reported to maintain the epidermal barrier by directly regulating expression of Cdh1 and Cldn4. Hypoxic microenvironment was important in promoting drug resistance of tumor stem cells. While colorectal cancer (CRC) originates from dysplasia in the epithelial stem cells and forms hypoxic microenvironment when expanding.

**Aims & Methods:** We aimed in this study to demonstrate the roles of GRHL2 in colorectal cancer in hypoxic environment. To create hypoxic microenvironment, cells were incubated in hypoxic incubator with 1% O<sub>2</sub> and 5% CO<sub>2</sub>. Then to investigate functional significance of GRHL2, human HCT116 cell lines with steady decreased GRHL2 expression was generated by lentiviral transfection, meanwhile, overexpressed GRHL2 expression was generated in SW620 cell lines by TrueORF cDNA transfection followed by monoclonal collection. CCK8, colony-formation and transwell assays were applied to evaluate the proliferation and metastasis of colon cancer cell lines. Real-time qPCR and western blotting were used to determine the expression level of EMT markers. Dual Luciferase Reporter Assay was used to examine transcription activity of given sequences *in vitro*. Chromatin Immunoprecipitation (ChIP) assay was applied to determine whether Hif-1α can functionally bind to promoter region of GRHL2 to inhibit its transcription. For *in vivo* study, cells were transplanted into wild-type mice through orthotopic or tail vein injection in order to test the function of GRHL2 in two major tumor-associated scenarios: primary tumor growth and remote metastasis.

**Results:** HCT116, HT29 and SW480 (all initiated from primary tumors) showed relatively higher GRHL2 expression, while SW620 (derived from metastasis lymph node) had a low GRHL2 level. All cell lines exhibited a decrease in GRHL2 expression under hypoxic environment (1% O<sub>2</sub>, 24h). Functional knockdown of GRHL2 in HCT116 demonstrated mesenchymal morphology, increased migration, but reduced colony formation ability.

While overexpressed GRHL2 in SW620 showed increased proliferation, but lower migration ability. Western Blot also indicated EMT in shGRHL2 HCT116 (lower E-cadherin and higher Vimentin expression). Also *in vivo*, lower GRHL2 expression led to reduced orthotopic implantations proliferation, but higher metastasis tendency. To understand the mechanism of down-regulation of GRHL2 in hypoxia, using Jaspar database, we predicted a Hif-1 $\alpha$  binding site within the promoter region of GRHL2 after excluding methylation in GRHL2 promoter. Luciferase results also showed decreased transcription activity of this region, possibly leading to down-regulation of GRHL2. Further CHIP assay validated that Hif-1 $\alpha$  can directly bind to the promoter region (-533~-523bp) of GRHL2.

**Conclusion:** Collectively, our findings identify that hypoxia promotes colon cancer metastasis via regulating GRHL2 expression, which may represent a rational therapeutic target in CRC.

Family Cancer Clinic, London, United Kingdom

**Contact E-Mail Address:** jamesalexander@doctors.org.uk

**Introduction:** Approximately one in twenty cases of colorectal cancer (CRC) are associated with germline mutations that confer higher susceptibility to the disease. Guidelines recommend that patients with ten or more adenomas be referred for genetic testing<sup>1</sup>, with evidence that suggests >9% of these patients with 10-19 adenomas have a highly penetrant CRC predisposition syndrome<sup>2</sup>.

**Aims & Methods:** The primary aim of this study was to quantify patients with ten or more adenomas in the West London (WL) and North Central London (NCL) Bowel Cancer Screening program (BCSP) centres. The secondary aim was to determine what proportion of these multiple adenoma patients were referred for genetic screening.

A retrospective cross-sectional study was performed of patients who underwent colonoscopy following a positive faecal occult blood test (FOBT) as part of the WL and NCL BCSPs between May 2007 & June 2018. All polyps were examined histologically and only confirmed adenomas were included. Clinicopathological data including age and gender was recorded from BCSP patient records. Referrals to regional clinical genetics services were ascertained. Statistical analysis was performed in Graphpad Prism.

**Results:** 11,337 patients underwent colonoscopy following positive FOBT and 5,650 (49.8%) had 1 or more adenomas. 107 patients (0.94%) had 10 or more adenomas. The proportion of patients with 10 or more adenomas was higher in NCL BCSP (1.1%) than in WL BCSP (0.7%) ( $p=0.02$ ;  $\chi^2$  test). 42 patients presented with 10 or more metachronous adenomas at the index colonoscopy or following an early follow up procedure; the remaining 65 patients undergoing excision of a total of 10 or more metachronous adenomas after subsequent surveillance colonoscopy. An accurate family history was not routinely collected in this population. Of the 107 patients with 10 or more adenomas, only 3 (2.8%) were referred to a clinical genetics service.

**Conclusion:** In two London BCSP centres, patients with ten or more metachronous adenomas are an uncommon finding. Despite guidelines advising genetic testing in this group, referral rates are low. A referral pathway and management strategies should be established to address this patient population.

**Introduction:** Participation rates for colorectal cancer (CRC) screening using faecal occult blood tests are suboptimal in many countries. There is therefore a need for the development of other test types that may improve screening uptake. The aim of this study was to evaluate the performance of a blood test for methylation-specific detection of circulating tumor DNA (ctDNA) in a study population with the full range of neoplastic and non-neoplastic pathologies encountered in the colon and rectum.

**Aims & Methods:** Study participants (n=1,621) had blood collected prior to colonoscopy or colonic surgery (median age, 64.2y (18-88yo), 56% males). Circulating cell-free DNA was extracted from plasma, bisulphite converted and assayed for the presence of methylated ctDNA using a multiplex, methylation-specific real-time PCR assay for detection of methylation in the genes *BCAT1*, *IKZF1* and *IRF4*. Detection of methylation for any of the three genes deemed a specimen positive for ctDNA. Adenomas were classified as High- (HRA), Medium- (MRA) or Low-Risk Adenoma (LRA) as previously described (1). CRC was staged according to AJCC 7<sup>th</sup> Edition. The ctDNA blood test performance estimates were calculated from true- and false-positive rates for cancer.

**Results:** The 3-gene methylation ctDNA blood test had an overall sensitivity for CRC of 73.9% (136/184, 95%CI: 67.1-79.1) with a better detection of later, 81.0%, (68/84; 71.3-87.9) versus earlier stage cancer, 67.3% (66/98; 57.6-75.8;  $p=0.0375$ ). The ctDNA test sensitivity for stage II, III and IV were 87.7% (50/57; 76.8-93.9), 78.4% (40/51; 60.8-89.5) and 84.8% (28/33; 69.1-93.3), respectively, and were not significantly different. However, the test had a reduced sensitivity for stage I (16/41, 39.0%; 25.7-54.3,  $p<0.0001$ ). To determine whether the apparent lower sensitivity for Stage I CRC was a biologically-determined issue, we examined the relationship between test positivity and tumor depth of invasion. Including only cases with no disseminated disease, a significant linear trend ( $p<0.0001$ ) was observed between assay positivity and T stage determined at surgery: T1NoMo, 25% (6/24, 12.0-44.9); T2NoMo, 58.8% (10/17, 36.0-78.4); T3NoMo, 85.7% (42/49, 73.3-92.9); T4NoMo, 100% (8/8, 67.6-100). Lesion location of cancer did not influence assay positivity rates (proximal, 38/50; distal, 89/117,  $p=0.9920$ ). The estimated specificity for cancer was 90.1% (81/820, 88.0-92.0), of which 82.7% (67/81) were methylation positive in a single gene only. Gender, smoking, family history and age were not significant predictors of test positivity. The sensitivity of the ctDNA blood test for adenoma detection was low (LRA, 9.3%, (26/280, 6.4-13.3); MRA 15.0% (27/180, 10.5-20.9); HRA, 16.6% (26/157, 11.6-23.2)), although a positive trend was observed with the HRA having the highest positivity rate of all the adenoma subtypes ( $p=0.0290$ ).

**Conclusion:** With a specificity of 90.1%, the 3-gene methylation ctDNA blood test had an overall sensitivity for CRC of 73.9% and was positive for 67.3% of early stage cancer (stage I and II). The overall cancer positivity rate appears to be a function of tumor invasiveness. Based on the data reported herein, it is justified to proceed to validation of this ctDNA assay in true screening populations.

## P1864 VOLATILE ORGANIC COMPOUNDS IN BREATH CAN SERVE AS NON-INVASIVE DIAGNOSTIC BIOMARKERS FOR THE DETECTION OF ADVANCED ADENOMAS AND COLORECTAL CANCER: PROOF-OF-PRINCIPLE STUDY

**Introduction:** Colorectal cancer (CRC) is the third most common cancer diagnosis in the Western world. Unfortunately, a non-invasive screening tool with the ability to accurately detect (pre-)malignant colon lesions is still lacking.

The aim of this study was to evaluate if exhaled volatile organic compounds (VOCs) can serve as non-invasive biomarkers for the detection of CRC and its precursor lesions using an electronic nose (e-nose).

**Aims & Methods:** This multicenter study was conducted in two hospitals in the Netherlands. All consecutive colonoscopy patients aged  $\geq 18$  years old, without inflammatory bowel disease or (previous) malignancy, were invited for breath testing. A random sample of two-thirds of the breath samples was used to train the artificial neural network to recognize disease-specific mixtures of VOCs. These training models for CRC and advanced adenomas (AAs) were then used to blindly predict the diagnosis of the remaining patients. Lastly, final disease-specific models were developed using all available data to further improve the discriminatory power of the algorithms.

**Results:** Breath samples of 511 patients were collected. Sixty-four patients were excluded due to an inadequate breath test ( $n=51$ ), incomplete colonoscopy ( $n=8$ ), or colitis ( $n=5$ ). Classification was based on the most advanced lesion detected. Seventy patients were diagnosed with CRC, 117 had  $\geq 1$  AA, and 128 patients had normal colonoscopy. The training model for CRC had a sensitivity and specificity of 83% and 60%, respectively, and predicted the blinded data with similar accuracy. The final disease-specific model for CRC had an AUC of 0.84, with a sensitivity of 95% and specificity of 64%. The final disease-specific model for AAs had an AUC of 0.73, with a sensitivity of 79% and specificity of 59%.

**Conclusion:** This study suggests that exhaled VOCs could potentially serve as non-invasive biomarkers for the detection of CRC and AA using e-nose technology. Future studies including more patients could further improve the discriminatory potential of VOCs for the detection of premalignant and malignant colorectal lesions.

**Disclosure:** The eNose company supplied the eNoses for free

## P1865 BLOOD COLLECTION AND CELL-FREE DNA ISOLATION METHODS INFLUENCE DNA METHYLATION LEVEL DETECTION IN COLORECTAL CANCER PATIENTS

**Introduction:** Cell-free DNA (cfDNA) level increases in several pathological processes including colorectal cancer (CRC). In addition, genetic (e.g. mutations) and epigenetic (e.g. DNA methylation) modifications of cfDNA molecules can be also observed; as DNA can originate from tumorous cells hence it carries cancer-specific DNA alterations. Identification of these quantitative and qualitative changes in peripheral blood - especially with the usage of automated methods - offers a promising tool for CRC screening or detection, however, differing results were reported in the case of several markers.

**Aims & Methods:** Our aim was to test different blood collection tubes, manual and automated cfDNA extraction methods in order to assess whether these factors influence the cfDNA yield and the methylation pattern of four previously described methylation markers in plasma samples of normal, adenoma and CRC patients.

Besides standard K3EDTA tubes ( $n=30$ ), Streck Cell-Free DNA BCT® ( $n=10$ ) and Roche Cell-Free DNA ( $n=30$ ) collection tubes were tested. In addition

to manual cfDNA isolation ( $n=121$ ), the MagNA Pure 96 (Roche) ( $n=30$ ) and InviGenius (STRATEC Biomedical AG) ( $n=69$ ) systems were used for automated cfDNA extraction from plasma specimens. After cfDNA quantification and bisulfite conversion steps, methylation pattern of *SFRP1*, *SFRP2*, *SDC2* and *PRIMA1* genes was determined using MethylLight PCR containing multiplex preamplification.

**Results:** Slightly higher cfDNA levels were noticed in case of both automated cfDNA extraction method compared to manual isolation. However, no significant difference was observed in the cfDNA amount after using different blood collection tubes. The methylation level of *SFRP1*, *SFRP2*, *SDC2* and *PRIMA1* showed continuous increase along normal - adenoma - carcinoma sequence after manual cfDNA preparation with methylation percentage values of 22%, 7%, 12% and 14% in CRC samples, respectively. Based on the methylation pattern of the 4 genes, CRC and AD specimens could be distinguished from normal controls with 91.5% and 89.2% sensitivity, and 97.3% and 86.5% specificity values. Interestingly, lower methylation frequencies and levels were observed in the case of all biomarkers using the automated instruments, however, methylation differences have been found between the clinical groups.

**Conclusion:** Automated isolation techniques may contribute to widespread, screening applications of methylation markers; however, further developments are needed in order to make the results comparable with manual extraction in respect to cfDNA yield and methylation analysis.

**Disclosure:** Nothing to disclose

## P1866 GLOBAL DNA HYPOMETHYLATION IN TISSUE AND LIQUID BIOPSY SAMPLES IN COLORECTAL CANCER PROGRESSION IS CAUSED BY DECREASED METHYL-DONORS

Szigeti K.A.<sup>1</sup>, Galamb O.<sup>1,2</sup>, Kalmár A.<sup>1,2</sup>, Valcz G.<sup>1,2</sup>, Zsigrai S.<sup>1</sup>, Bartak B.K.<sup>1</sup>, Nagy Z.B.<sup>1</sup>, Tulassay Z.<sup>1,2</sup>, Igaz P.<sup>1,2</sup>, Molnár B.<sup>1,2</sup>

**Introduction:** In cancerous diseases global DNA hypomethylation is characteristic, which can lead to genetic instability through the active mobile genetic elements. Alterations of DNA methyltransferase (DNMT) expression and level of methyl-donor molecules (folic acid (FA), S-adenosylmethionine (SAM)) can lead to aberrant global DNA hypomethylation.

**Aims & Methods:** Our aim was to examine global DNA methylation changes along aging and colorectal normal-adenoma-carcinoma sequence and in inflammatory bowel disease in tissue and liquid biopsy samples for diagnostic purposes. Moreover, we aimed to explore the reasons of global hypomethylation on gene expression level and methyl-donor molecule content.

Bisulfite treatment was performed on DNA isolated from 30 normal (N), 10 adenoma (Ad), 10 colorectal carcinoma (CRC), 10 colitis ulcerosa (UC) tissue samples and on 11 N, 10 Ad, 15 CRC, 12 UC plasma specimens. 30 N samples contained different age groups derived from under 20 to 70 years old healthy controls for examination of aging process. LINE-1 PCR product was generated and pyrosequenced. Whole genome expression level of 60 biopsy samples was evaluated by HTA 2.0 RNA microarraychip (Affymetrix). *In situ* tissue appearance of 5-methylcytosine, FA, SAM and expression of DNMTs were analysed by immunohistochemistry staining (IHC).

**Results:** According to LINE-1 bisulfite sequencing results, DNA methylation was 72.6 $\pm$ 1% in samples of healthy controls under 50 years old and 71.6 $\pm$ 1.8% in specimens of patients over 50 years old.

Significant DNA hypomethylation was found in CRC (62.9 $\pm$ 8.7%;  $p < 0.001$ ), Ad (66.7 $\pm$ 5.1%;  $p < 0.001$ ) tissue samples in comparison with N samples (72 $\pm$ 1.4%). Significant decrease of DNA methylation was observed in CRC (78.8 $\pm$ 1.7%;  $p < 0.02$ ), Ad (80.1 $\pm$ 1.7%;  $p < 0.02$ ) plasma samples compared to N specimens (82.2 $\pm$ 1.8%). Global DNA hypomethylation was not detected in UC samples.

Significantly elevated RNA expression of enzymes connected to nucleotide synthesis was observed in Ad and CRC samples compared to N ( $p < 0.05$ ), while no changes were detected in the RNA levels of DNA methylation-related proteins. RNA expression of enzymes in DNA repair was found up-regulated in Ad and CRC specimens. The intensity of 5-mC labelling of CRC and Ad samples was lower than in N tissue samples. Decreased FA and SAM levels were detected in CRC compared to N specimens and no expression changes of DNMT enzymes.

**Conclusion:** Significant decrease in DNA methylation level was found in tissue and liquid biopsy samples of colorectal normal-adenoma-carcinoma sequence, but not in UC specimens. Our results suggest that determination of global DNA hypomethylation could have prognostic and diagnostic value as well, and reduction of DNA methylation level could be linked to decreased FA and SAM availability and not to methylation related activity.

## P1867 THE ASSOCIATION OF TOLL-LIKE RECEPTOR (TLR) PATHWAY POLYMORPHISMS AND COLORECTAL CANCER RISK: A META-ANALYSIS

Lagrué D.<sup>1</sup>, Aggarwal N.<sup>2</sup>, Monahan K.J.<sup>3</sup>

<sup>1</sup>Imperial College School of Medicine, London, United Kingdom, <sup>2</sup>Imperial College London, Medicine, Westcliff on Sea, United Kingdom, <sup>3</sup>West Middlesex Hospital, Family Cancer Clinic, London, United Kingdom

**Contact E-Mail Address:** dl2813@ic.ac.uk

**Introduction:** Colorectal cancer (CRC) is the third commonest cancer worldwide. Approximately 35% of CRC risk is due to heritable factors but 5% attributed to associated with known syndromes. Single Nucleotide Polymorphisms (SNPs) are common, low penetrance gene variants that may contribute to the remaining heritable risk. The toll-like receptor (TLR) signalling pathway is a key mediator of inflammation and has unique roles in the gut due to the presence of commensal microbiota. It is also suggested to have a significant role in colorectal carcinogenesis. This systematic review and meta-analysis aims to investigate the association of polymorphisms in the TLR signalling pathway with CRC.

**Aims & Methods:** A systematic literature review of Pubmed, Ovid MEDLINE and HuGENet databases was conducted. Specific inclusion and exclusion criteria were used to select relevant papers. A per-allele, pooled odds ratio was used to assess the risk of each variant. Heterogeneity was investigated using Cochrane's Q test and I<sup>2</sup>. Publication bias was assessed through funnel plot asymmetry. Statistical analysis was conducted using the Metafor package in R.

**Results:** Sixty-seven SNPs were identified in published literature in 14 TLR pathway genes associated with CRC risk, of which 12 SNPs in five genes were eligible for meta-analysis. Two SNPs showed a significant association with CRC risk: TLR4 rs7873784 (Odds ratio = 1.356, p=0.011, 95% C.I. 1.07-1.71) and TLR4 rs5030728 (Odds ratio = 0.916, p=0.025, 95% C.I. 0.86-0.99). Funnel plots demonstrated no evidence of publication bias.

**Conclusion:** The TLR pathway is an potential target for CRC therapy and risk assessment. This study identifies two SNPs in the TLR4 gene associated with CRC risk. In order that conclusions might be made about the role of this pathway in colorectal carcinogenesis, adequately powered studies of greatly increased population size must be conducted.

## P1868 CELL-FREE DNA QUANTITY AND QUALITY ALTERATIONS IN DIFFERENT PHYSIOLOGICAL AND PATHOLOGICAL CONDITIONS

Bartak B.K.<sup>1</sup>, Szígeti K.A.<sup>1</sup>, Orbán-Márkus E.<sup>1</sup>, Kalmár A.<sup>1,2</sup>, Galamb O.<sup>1,2</sup>, Nagy Z.B.<sup>1</sup>, Zsigrai S.<sup>1</sup>, Tulassay Z.<sup>1,2</sup>, Igaz P.<sup>1,2</sup>, Molnár B.<sup>1,2</sup>

<sup>1</sup>Semmelweis University, 2nd Department of Internal Medicine, Budapest, Hungary, <sup>2</sup>Hungarian Academy of Sciences, Molecular Medicine Research Group, Budapest, Hungary

**Contact E-Mail Address:** bartak.barbara@gmail.com

**Introduction:** Elevation of cell-free DNA (cfDNA) level in peripheral blood was observed in certain physiological conditions, such as pregnancy, aging or high physical activity. Furthermore, altered cfDNA concentration can also be detected in some pathological processes, as autoimmune or inflammatory diseases, and different cancer types including colorectal cancer (CRC). However, to date, studies about quality changes of cfDNA molecules aimed to analysing the fragment profile and global methylation pattern of cfDNA are lacking.

**Aims & Methods:** Our aim was to define the quantity and quality changes of cfDNA, including concentration, fragment length and global DNA methylation level during high physical exercise, and in neoplastic and inflammatory colorectal diseases. Moreover, we aimed to monitor treatment response in metastatic CRC patients analysing the above-mentioned parameters during therapy.

Plasma fraction was separated from blood samples of 6 healthy athletes before, during and after physical training, and from healthy (n=16), adenoma (n=13), IBD (n=19), and CRC (n=16) patients. Moreover, plasma longitudinal assessment was performed in the case of 10 metastatic CRC patients treated with chemotherapy. After cfDNA isolation, it was quantified using Qubit 1.0 fluorimeter (Thermo Fisher Scientific), and fragment length distribution was examined with Bioanalyzer 2100 (Agilent). Global DNA methylation analysis was performed by bisulfite pyrosequencing of long interspersed nuclear element-1 (LINE-1) (Qiagen).

**Results:** Elevated cfDNA levels have been found in plasma of adenoma (72,1±37,5ng), IBD (78,0±50,9ng) and CRC (84,5±70,1ng) patients, compared to controls (36,2±11,3ng). Moreover, high increase of cfDNA amount was observed during physical exercise (198,5±90ng), in comparison with control phase (86,3±40,6ng), and then in restitution period significantly lower cfDNA level (155,6±119,3ng) was detected. CfDNA fragment length distribution showed different pattern in each sample group. Slightly decreasing tendency of global DNA methylation was noticed along normal-colorectal adenoma-carcinoma sequence. Interestingly, the amount and global methylation level alteration of cfDNA revealed negative correlation in CRC patients during therapy and progression.

**Conclusion:** Characteristic cfDNA level, fragment length and global DNA methylation level were identified in the different sample groups that might contribute to the diagnosis and therapy response analysis of colorectal disorders.

**Disclosure:** Nothing to disclose

## P1869 SEQUENTIAL USE OF FECAL IMMUNOCHEMICAL TEST FOR HEMOGLOBIN AND FECAL CALPROTECTIN IN COLORECTAL CANCER SCREENING

**Introduction:** Fecal immunochemical test for hemoglobin (FIT) is widely used in colorectal cancer (CRC) screening, in order to select screening participants more likely to have advanced adenoma (AA) or CRC. Fecal calprotectin (FC) or its subunits have been reported to show high sensitivity and negative predictive value for CRC. We developed an FC reagent adapted to sampling device designated for FIT, in order consecutively analyze FIT and FC from the same samples.

**Aims & Methods:** To better identify participants with CRC and AA in a screening program by combining FIT and FC in order to lower the need for colonoscopy.

We selected 801 out of 6,000 fecal samples collected with sampling devices for FIT, OC-Auto Sampling Bottle 3, in the SCREESCO study. They had all FIT > 10 ug/g and had been subjected to colonoscopy. The samples had been stored at -80 °C. We determined fecal hemoglobin and calprotectin concentrations, in the same sample consecutively by OC-SENSOR PLEDIA. Of 801 analyzed, 13 were not possible to analyze because of sample shortage. Sensitivity (Se), specificity (Sp), positive predictive value (PPV) and negative predictive value (NPV) of FC test were analysed at different FIT cut-offs.

**Results:** 54 participants had CRC (6.9%) and 152 had AA (19.3%) in the 788 subjects, the other had a normal colonoscopy or one adenoma < 5 mm.. In the participants with CRC the data for Se, Sp, PPV and NPV at FIT >15 ug/g FIT cut-off were 94.1%, 87.4%, 7.1%, 96.8%.. At FIT > 20 ug/g the values were 88.5%, 85.3%, 7.0%, 94.6%, and at FIT > 40ug/g 73.1%, 73.5%, 6.8%, 93.1%, on consecutive FC test.

For participants with AA, the same values at FIT > 15ug/g Hb were 83.1%, 89.0%, 18.3%, 73.1%, At FIT > 20 ug/g: 81.1%, 86.6%, 18.3%, 74.8% and at FIT > 40 ug/g, 64.9%, 75.6%, 17.1%, 74.4%, on consecutive FC test.

For the group CRC and AA, the values at FIT > 15ug/g were 85.4%, 88.6%, 23.5%, 71.0%, respectively, at FIT >20ug/g: 82.2%, 86.6%, 23.2%, 70.3% and at FIT > 40ug/g: 65.4%, 76.1%, 21.5%, 68.5%.

In cases with cut-off values of FIT between 10 and 20 µg/g, FC test following FIT had more than 90% of negative predictive value for CRC at cut-off values between 15 to 100 µg/g FC.

**Conclusion:** FC test following FIT positivity had more than 90 % of NPV with any cut-off values, and around 90% of sensitivity at 15 or 20 µg/g of FC cut-off. Our data suggest that FC test following FIT positivity have good sensitivity for CRC among average-risk population. For AA, the sequential FIT and FC test possibly has better performance than FIT alone with higher cut-off levels. Thus the combination of FIT and FC may be of use in reducing the number of colonoscopies needed in CRC screening.

**Disclosure:** The study was sponsored by Eiken Chemical.

## P1870 DIAGNOSTIC YIELD USING ARTIFICIAL INTELLIGENCE ASSISTED ENDOSCOPY FOR SESSILE SERRATED ADENOMA/ POLYP

**Introduction:** Sessile serrated adenoma/polyps (SSA/Ps) are known to be precursors of CRCs. Therefore, accurate endoscopic criteria to differentiate SSA/Ps from hyperplastic polyps (HPs) are needed. However endoscopic differentiation with endoscopists' eyes is considered difficult.

**Aims & Methods:** In this study, we evaluated the performance of the artificial intelligence (AI) combined with endocytoscopy in endoscopic identification of SSA/Ps. We developed the AI system based on the previously proposed model.

The AI system was combined with endocytoscopy (CF-H290ECI from Olympus Co.) which enables in vivo observation of cellular images at 500-fold magnification. The diagnostic algorithm of the AI consisted of the sequence of image acquisition, extraction of 312 visual features from nuclear images and contrast difference of the whole image, and classification into the two pathological groups (SSA/P and Non-neoplastic). We designed this retrospective study to assess the performance of the AI system for prediction of SSA/Ps by using 30 SSA/Ps (822 images) and 69 Non-neoplastic lesions (Total 1574 images) including 66 HPs (1524 images), 1 juvenile polyps (17 images) and 2 inflammatory polyps (33 images) resected between Jul. 2018 and Feb. 2019. Machine learning for the AI was performed by using 14222 images which were acquired and selected from Jan. 2016 to Jun. 2018. The main outcome measures were diagnostic sensitivity specificity, accuracy of the AI system in identifying SSA/P in the image-based analysis and the lesion-based analysis. In the lesion-based analysis, diagnosis of the target lesion was defined as SSA/P when the AI system shown at least one SSA/P output.

**Results:** The AI system automatically output the pathological prediction of 1667 images (SSA/P 510 images, HP 1157 images) out of total 2396 images immediately with high confidence (probability>=80%).

In the image-based analysis, the AI system showed sensitivity of 19.0% (97/510), specificity of 98.7% (1143/1157) and accuracy 74.4%(1240/1667). However, in the lesion-based analysis AI system showed sensitivity of 66.6% (20/30), specificity of 89.9% (62/69) and accuracy 82.8% (82/99).

**Conclusion:** This study revealed AI system diagnosed SSA/P with high specificity.

However further accumulation of endoscopic images for machine learning is required to make more robust model for diagnosing SSA/Ps.

**Introduction:** Colorectal cancer (CRC) is a common malignant tumor of the digestive tract and one of the leading causes of cancer death worldwide. The five-year survival rate of CRC drops from above 90% at stage I to less than 10% at stage IV. Therefore, colonoscopy is recommended as a screening method, but patient compliance can be low due to its invasiveness. Non-invasive biomarker tests have also been developed for years, but are limited in sensitivity and specificity, especially for early-stage CRC and pre-cancerous adenomas. We have established a highly accurate, next generation sequencing (NGS)-based, machine-learning guided screening assay (ColonES) detecting ctDNA methylation signatures in plasma.

**Aims & Methods:** In this study, we organized a multi-center prospective study to evaluate the clinical performance and utility of ColonES.

Blood samples were collected in EDTA tubes and centrifuged within 4 hrs to separate plasma. ColonES, an NGS based bisulfite sequencing assay covering approximately 2,181 genomic regions was employed to identify pre-cancerous lesion and CRC. Patient samples were separated into three groups based on colonoscopy results. The high risk group includes CRC, advanced adenoma (AA), and cases with more than three adenomas; the low risk group include healthy individuals or patients with non-malignant diseases; the indeterminate group include non-AA with a size under 1cm. Before this study, a separate cohort of 400 samples was used to train the classification model, and a cohort of 514 samples was used to validate the model. This study will enroll approximately 2000 patients covering a full spectrum of clinical conditions to evaluate the accuracy and reproducibility of the assay.

**Results:** The enrolled 2000 patients are divided equally between different categories. The first phase of the study, which is comprised of 259 patients, has been completed. Sensitivity and specificity of different categories were determined using this group of samples. The sensitivities of stage 0/I CRC, AA and multi-adenoma are 91.7%, 81.6% and 80.0%, respectively. Symptomatic patients free of neoplasm were divided into two groups: group with no findings in colonoscopy, and the group with pathologically benign condition(s) including inflammation, polypus, or ulcer. The specificities of these groups are 82.9% and 80.8%, respectively. Interestingly, 52.6% of non-AA patients were called positive, suggesting that cfDNA from these patients may contain cancer-specific methylation signals. In-depth analysis of the data revealed that the methylation scores, which are used to categorize the patients, are different in CRC patients of different stages and in CRC patients with different lesion sizes. In AA patients, methylation scores vary depending on sizes in tubular adenoma sub-category, but not in other AA sub-categories.

**Conclusion:** We demonstrated that cancer-specific methylation signatures can be used for CRC and AA detection in plasma samples with high sensitivity and specificity. This will provide a valuable tool for CRC and AA diagnosis and screening, especially in populations who cannot or are unwilling to undergo colonoscopy.

**Contact E-Mail Address:** choeyounghee29@gmail.com

**Introduction:** Organ transplantation has a higher risk for malignancies compared to general subjects.

**Aims & Methods:** The purpose of this study was to investigate the incidence of colorectal neoplasms in renal transplant recipients and to find risk factors for the development of advanced colonic neoplasias in renal transplant recipients.

Between 1992 and 2015, colorectal neoplasm screening was performed in renal transplant recipients with colonoscopic evaluation. The incidence of colorectal cancer was compared with that of the general population registered in the National Cancer Registration Statistics. To determine the risk factors for the development of advanced colonic neoplasia, we investigated demographics, body mass index, types of main immunosuppressive agents, and the interval of the first endoscopic evaluation from the transplantation.

**Results:** Among 1,828 renal transplant recipients, 748 patients underwent colonoscopic evaluation between 1992 and 2017. Colorectal neoplasms occurred in 191 patients (25.5%): non-advanced adenoma in 105 (14.0%), advanced adenoma in 70 (9.4%), cancer in 16 patients (2.1%). The incidence of colorectal cancer in 2016 Korean National Cancer Statistics was 0.06%, showing a higher incidence of colorectal cancer in renal transplant recipients. In multivariate analysis, age over 40 and more than five years interval between transplant and the first colonoscopy were independent risk factors for advanced colonic neoplasia. The risk of advanced neoplasia development in age over 40 was increased compared to under 40 (OR 8.7, 95% CI 2.01-34.33;  $P=.003$ ). The risk of advanced neoplasia was high if colonoscopy is performed more than 5 years after transplantation (OR 1.1, 95% CI 1.02-1.16;  $P=.016$ ).

Variables	Univariate analysis		Multivariate analysis	
	Odd ratio (95% CI)	p value	Odd ratio (95% CI)	p value
Age ( $\geq 40$ years)	8.7 (2.12-36.03)	0.003	8.3 (2.01-34.33)	0.003
Male sex	1.4 (0.88-2.27)	0.151	-	-
Obesity	1.5 (0.87-2.65)	0.139	-	-
DDKT/LDKT*	1.1 (0.94-1.20)	0.313	-	-
CyS/TAC**	1.4 (0.86-2.21)	0.182	-	-
Colonoscopy interval ( $\geq 5$ yrs)	1.1 (1.02-1.17)	0.008	1.1 (1.02-1.16)	0.016

\* DDKT: Deceased donor at kidney transplantation, LDKT: Living donor at kidney transplantation \*\* CyS: Cyclosporine, TAC: Tacrolimus

[Risk factors for Advanced colonic neoplasia after renal transplantation]

**Conclusion:** Renal transplant recipients had a higher incidence of colorectal neoplasms. Colon cancer screening should be recommended before 40 years in these patients.

**Introduction:** Exact endoscopic and morphological criteria of traditional serrated adenomas (TSAs) of the colon are still not indicated. We examined features of TSAs in patients of our population.

**Aims & Methods:** To characterize the endoscopic and histological features of traditional serrated adenomas and compare with nonserrated colorectal polyps.

Of the 500 epithelial lesions, removed via colonoscope in 265 patients, 14/500 (2.8%) TSAs with different degrees of dysplasia and focus of adenocarcinoma in 1/14 (7.1%) were histologically identified. The key endoscopic and pathological features of TSAs and immunohistochemical studies with CD44, Ki67, Msi-1 and 1-and 3 - claudins antibodies were evaluated.

**Results:** Polyps were located in the both parts of the colon, but most of them were located in the left colon (9/14; 64.3%), exactly in the rectum (7/14; 50%). Drew attention to their red color (13/14; 92.9%). The polyps size was 0.5-4.5 cm, while 2 (14.3%) polyps did not exceed 0.5 cm and 3 (21.6%) polyps were more than 2.5 cm. Macroscopically, 5/14 (35.7%) lesions were flat-elevated Type 0-IIa; 9/14 (64.3%) polyps were protruding Type 0-Is, 0-Isp, 0-I. Two (14.3%) polyps were covered with a mucus cap. Three (21.4%) flat-elevated TSAs had pit-pattern II and only one of them presented as dark-green colors on auto fluorescence imaging (AFI) colonoscopy that are similar to the normal surrounding mucosa. This polyps type difficult to differentiate from hyperplastic polyps (HP) and sessile serrated adenomas (SSA); 11/14 (78.6%) had pit-pattern IV and presented as magenta color tone on AFI colonoscopy. This endoscopic features are more typical for adenoma tubular-villous (ATV) and adenoma villous (AV). Immunohistochemically TSA is close to AT/ATV and fundamentally different from HP/SSA, despite the fact that in current classification they belong to the group of serrated lesions. Statistically significant differences are:

- similar distribution of CD44 (surface) of the AT, ATV and TSA;
- similar levels of Msi-1 cytoplasmic response in AT, ATV and TSA;
- similar levels of Claudine-1 and -3 expression in ATV and TSA.

**Conclusion:** Often TSA are located in the rectum and corresponds to red protruding type lesions with pit-pattern IV. The TSA diagnosis based on AFI based on changes in magenta color tone. These endoscopic features are the classical for nonserrated polyps with villous structure. The presence of characteristic ectopic crypts is almost impossible to distinguish from the branching of crypts in any ATV or AV, and there is no consensus on the number of ectopic crypts required for TSA verification. Given the low incidence of TSA, the similarity of endoscopic features and the absence of immunohistochemical differences between TSA and AT/ATV, the feasibility of TSA allocation in a separate classification group is debated and requires further study.

**Disclosure:** Nothing to disclose

**Introduction:** In contrast to the complication risk of endoscopic resection (ER) of adenomas, the intra-procedural and post-procedural complication risk of ER of T1 colorectal cancer (CRC) is scarcely reported in literature. One might hypothesize that ER of these early CRCs is associated with an increased complication risk, as these tumors grow into the submucosal layer and sometimes show incomplete lifting.

**Aims & Methods:** We aimed to identify the complication rate after primary ER of T1 CRCs and to identify risk factors associated with these complications. Medical records were reviewed of all patients diagnosed with T1 CRC between January 2000 and December 2014 within 15 hospitals in the Netherlands. Patients that underwent ER (with or without adjuvant surgery) were selected. Primary outcome was the occurrence of endoscopy related complications (i.e., bleeding, perforation, polypectomy electrocoagulation syndrome (PPES)) requiring re-colonoscopy, surgery, prolonged hospital stay, readmission, or other interventions such as antibiotic therapy or blood transfusion. Secondary outcome was the identification of independent risk factors associated with these complications. Additional information on treatment of complications, and intra-procedural hemoclip placement for prophylaxis was collected of all patients with complications and random controls (sub-cohort) from our total cohort in a 1:3 ratio. For the analysis of possible risk factors, the sub-cohort was used. Multivariate logistic regression was performed.

**Results:** From a retrospective cohort of 1879 T1 CRC patients, 1069 patients with ER of T1 CRC were selected. Endoscopic complications occurred in 59/1069 (5.5%) of patients, among which 37.3% of complications was classified as mild, 59.3% as moderate, and 3.4% as severe. These complications were delayed bleeding (N=40, 3.7%), perforation (N=13, 1.2%) and PPES (N=6, 0.6%). No fatal complications were observed. Independent predictors for complications were; age > 70 years (OR=2.111; 95% confidence interval (CI)=1.124-3.964), and tumor size >20mm (OR=2.224, 95% CI=1.054-4.694). Age > 70 years was also associated with an increased risk for delayed bleeding (OR=2.616; 95% CI=1.236-5.537).

**Conclusion:** In this large multicenter retrospective cohort study, complication rate of ER of T1 CRC (5.5%) was comparable with reported complication rates of ER of adenomas in current literature. These data supporting the relative safety of ER for T1 CRCs. More caution is warranted for ER of T1 CRC in patients older than 70 years, and large lesions (>20mm).

## P1876 LOW DOSE 5-AMINOSALICYLIC ACID (5-ASA) SUPPRESSES GROWTH OF HUMAN COLORECTAL ADENOMA DERIVED CELLS IN 3-DIMENSIONAL CULTURE: IMPLICATIONS FOR PREVENTION

Dixon S.<sup>1,2</sup>, Creed T.<sup>2</sup>, Williams A.C.<sup>1</sup>

<sup>1</sup>University of Bristol, Cell & Molecular Medicine, Bristol, United Kingdom,

<sup>2</sup>Bristol Royal Infirmary, Department of Gastroenterology, Bristol, United Kingdom

**Contact E-Mail Address:** stevedixon@doctors.net.uk

**Introduction:** 5-aminosalicylic acid (5-ASA) is a well-tolerated and inexpensive salicylate used in the treatment of ulcerative colitis and epidemiological data suggests that regular use reduces the risk of colitis-associated cancer[1]. Although aspirin (acetylsalicylic acid) has shown promise as a chemoprophylactic agent in patients with high colorectal polyp burden[2, 3] it is unknown if 5-ASA has the same benefit. Interestingly 5-ASA has been shown to suppress Wnt/b-catenin signalling, deregulation of which is a key event in the initiation of colorectal cancer (CRC) tumorigenesis. Here we demonstrate that 5-ASA can repress the stem potential of human adenoma cells in a 3D organoid culture system and suggest this drug has potential as a chemoprophylactic agent in patients with a high polyp burden.

**Aims & Methods:** The human colonic adenoma cell line PC/AA/C1 was seeded as a single-cell suspension into Matrigel® (Corning Life Sciences, USA) extracellular matrix and incubated with advanced DMEM/F12 (Sigma-Aldrich, UK) media supplemented with 0.1% bovine serum albumin (Sigma-Aldrich), 2mM glutamine (Gibco), 10mM HEPES (Sigma-Aldrich), penicillin & streptomycin (Life Technologies, UK), 1% N2 (Gibco, UK), 2% B27 (Gibco, UK), 0.2% N-acetylcysteine (Gibco, UK) and EGF (Peprotech, UK). 5-ASA (Sigma-Aldrich) was dissolved in this culture medium and pH balanced to 7.35 - 7.45.

Clinically achievable colonic luminal 5-ASA concentrations using oral preparations is 12 - 25mM[4]; we tested efficacy of lower doses in this 3D system. Serial images through the Matrigel hemispheres were acquired as a Z-stack using a DMI6000 widefield microscope (Leica, Germany) & LAS-X software (Leica) and analysed using a custom in-house Matlab programme to estimate spheroid number and size.

In parallel, cells were grown in T25 flasks (Corning, USA) and treated with 5-ASA before protein lysates were taken for SDS-PAGE and Western blotting for the stem cell marker and Wnt target leucine-rich G protein coupled receptor 5 (LGR5, Abcam, UK).

**Results:** Adenoma cells exposed to low doses of 5-ASA once seeded into Matrigel established fewer viable organoids than control cells: control mean 95 organoids (95% confidence intervals 49 - 141), 2mM 5-ASA mean 84 organoids (95% CI 36 - 131) & 5mM 5-ASA mean 30 organoids (95% CI 16 - 43; p < 0.005). After 21 days in culture, adenoma-derived organoids were significantly smaller than control: Control median 58800µm (inter-quartile range 4692 - 171560µm), 2mM median 1951µm (IQR 1207 - 3331µm), 5mM median 1540µm (IQR 1139 - 2304µm)). Cells exposed to 5mM 5-ASA at the time of seeding did not grow over 21 days of culture, but did form organoids if 5-ASA was removed from culture medium by day 11. Where 5-ASA treatment was delayed to day 7 of culture, 5-ASA slowed but did not abrogate growth. Western blots of cell lysates demonstrated downregulation of LGR5 at higher (but clinically achievable) doses but LGR5 expression returned to normal within 8 hours of removing 5-ASA from culture medium.

**Conclusion:** In these experiments we demonstrate that at low dose 5-ASA reduces the colony forming efficiency and growth of human colonic adenoma cells in 3-dimensional culture system, implying that 5-ASA suppresses stemness, further supported by observed downregulation of the putative cancer stem cell marker LGR5.

This data suggests that 5-ASA would be able to prevent formation and/or growth of adenomas in predisposed individuals. Clinical trials are required to establish if this affordable and well-tolerated drug could reduce polyp burden and cancer risk.

**Contact E-Mail Address:** charbelyazbeck@usek.edu.lb

**Introduction:** Colorectal cancer (CRC) is the third cancer in prevalence and in mortality worldwide. Inflammatory and genetic factors appear to play a role in the prognosis of CRC. A high neutrophil-to-lymphocyte ratio (NLR) is thought to be a predictor of poor prognosis in colorectal cancer. In addition, some authors consider that Transforming Growth Factor Beta Receptor (TGF $\beta$ R) polymorphism may have prognostic significance in colorectal cancer.

**Aims & Methods:** Our primary objective is to assess the prognostic impact of NLR and TGF $\beta$ R polymorphism, independently, on the 3-years and 5-years overall survival rates and on disease-free survival rates in colorectal cancer. Our secondary objective is to assess the prognostic impact of NLR, depending on the TGF $\beta$ R polymorphism, on the 3-years and 5-years overall survival rates and on disease-free survival rates in colorectal cancer.

This is a retrospective cross-sectional multivariate study conducted in two hospitals in Lebanon. A total of 91 patients diagnosed with colorectal adenocarcinoma prior to 2011, positive for either polymorphism TGF $\beta$ R\*6A/9A or TGF $\beta$ R\*9A/9A by genetic analysis DNA on blood samples and having a complete blood count at diagnosis prior to any treatment, were included in this study.

**Results:** The impact of NLR on the survival of CRC was statistically significant with a p-Value < 0.05: low NLR was associated with better 3-years and 5-years overall survival rates and with better disease-free survival rates compared to high NLR. The impact of TGF $\beta$ R polymorphism was not significant: TGF $\beta$ R\*9A/6A polymorphism was not associated with neither decreased overall survival rates nor decreased disease-free survival rates. To our knowledge, this is the first multivariate study to evaluate the impact of NLR and TGF $\beta$ R polymorphism at the same time.

**Conclusion:** NLR is a simple, non-invasive and unexpensive tool which can be easily used to classify patients and adapt disease management and follow up in order to optimize outcomes.

It would be interesting, in future studies, to evaluate the exact mechanism of the immunological response in CRC and the elaborate the role of cytokines of lymphocytes.

**Contact E-Mail Address:** rebecca.dru@ydh.nhs.uk

**Introduction:** Anaemia is common in patients with colorectal cancer and can be worsened by surgical blood loss. Preoperative optimisation aims to correct preoperative anaemia with comparably little attention given to the prevalence and consequences of postoperative anaemia.

**Aims & Methods:** The aim of this study was to investigate the frequency of postoperative anaemia and any associated short and long-term impacts of anaemia at discharge following laparoscopic colorectal cancer resection.

A dedicated, prospectively populated database of elective laparoscopic colorectal cancer procedures with curative intent within a fully implemented ERAS protocol was utilised. Patient demographics, tumour characteristics, and operative details were captured. The primary endpoint was anaemia at discharge. Anaemia was defined as haemoglobin (Hb) level of < 120g/L for women and < 135g/L for men. Secondary endpoints were anaemia at time of hospital admission, length of stay (LoS), postoperative complications, and overall survival. Median follow up was 61 months with overall survival calculated with the Kaplan-Meier log rank method stratifying for tumour stage. Data was analysed using the IBM SPSS® statistical tool.

**Results:** Complete data of 532 patients were included with median age of 72 years and BMI 26. 389 were male while 161(24.1%) were ASA III. 46.4% were anaemic preoperatively. Median operative time was 180min (inter-quartile range 150-250) with 100ml (0-200) median estimated blood loss. At discharge most patients were anaemic (76.6%, Hb 115 g/L (106-125), p< 0.001). 16.7% experienced postoperative complication(s) with a lower discharge Hb seen in this group (110g/L (105-120) vs. 116g/L (107-127), p=0.001). Anaemia at discharge was significantly associated with a longer stay (7 (5-11) vs. 6 (5-8), p=0.037) while preoperative anaemia was not (7 (5-10) vs. 7 (5-9), p=0.063). Admission and discharge anaemia were independently associated with worse overall survival (p=0.027 and p=0.018 respectively) and remained significant after adjusting for tumour stage.

**Conclusion:** Anaemia at time of discharge following elective laparoscopic colorectal cancer surgery is commonplace with associated negative impacts upon short-term outcomes and overall survival.

**Disclosure:** Nothing to disclose

### P1879 THE VERIFICATION OF THE VALIDITY OF AMBULATORY HOT SNARE EMR AND POLYPECTOMY FOR COLONIC NEOPLASIA

**Contact E-Mail Address:** kenrunaway@yahoo.co.jp

**Introduction:** Hot snare endoscopic mucosal resection (EMR) and polypectomy is an efficacious endoscopic therapy for colorectal neoplasia. Due to the complication such as delayed bleeding and perforation, these procedures generally need hospitalization. Ambulatory EMR and polypectomy are easier to manage and can be performed earlier compared to those with hospitalization. However, the curability and safety of ambulatory treatment is not clarified. Thus the aim of this study was to verify the validity of ambulatory hot snare EMR and polypectomy for colonic neoplasia.

**Aims & Methods:** From January 2007 to November 2018, 97 patients who underwent ambulatory hot snare EMR and polypectomy for colonic neoplasia (ambulatory group. male:female, 67:30; age, 64.3  $\pm$  12.5; 173 lesions), and 1184 patients who underwent those procedure for colonic neoplasia with hospitalization (hospitalization group. male:female, 813:371; age 66.2  $\pm$  10.8 ; 2752 lesions) in Chiba university hospital were included in this study. The curative resection rate, procedure-related complications were compared between the ambulatory group and hospitalization group retrospectively.

**Results:** Median tumor size (mm) was 7 (range 3-30) in the ambulatory group and 7 (range 2-50) in the hospitalization group. There was no significant difference. The breakdown of SSA/P / low grade intra-mucosal neoplasia/ high grade intra-mucosal dysplasia/ cancer was 10/ 105/ 57/ 1 and 109/ 1774/ 822/ 47 respectively. The curative resection rate was 82.1% in the ambulatory group and 75.5% in the hospitalization group (p=0.051 chi-square test). The number of the patients with the history of use of anticoagulants and/or antiplatelet drugs was 11 (11.3 %) and 226 (19.1%) respectively, and the difference was not significant.

Mean period of hospital stay in hospitalization group was 4.1  $\pm$  2.9 days. Perforation occurred in 0 (0%) patient and 2 (0.2%) patients respectively. Delayed bleeding occurred in 1 (1.0%) patient and 32 (2.7%) patients respectively, and the differences were not significant.

One patient with delayed bleeding in ambulatory group underwent endoscopic hemostasis without hospitalization 2 days after EMR.

**Conclusion:** Ambulatory hot snare EMR and polypectomy for colonic neoplasia can be performed safely with equivalent curability to those with hospitalization even if the patients had the history of use of anticoagulants and/or antiplatelet drugs.

**Introduction:** MRI and endoscopy are currently the main tools used to assess response and identify potential candidates for organ preserving treatments after chemoradiotherapy (CRT) for rectal cancer. For logistical reasons and when there is limited expertise in endoscopic imaging for restaging, MRI could play a role as a pre-selection tool to identify patients who would benefit from additional endoscopy to differentiate between potential complete responders who may be candidates for organ preservation and poor responders in whom surgery is unavoidable.

**Aims & Methods:** Aim of this study was to evaluate the performance of MRI (for readers with varying expertise levels) using a simplified structured report template in this specific setting.

Seven independent readers with varying expertise levels retrospectively evaluated 63 patients who routinely underwent a restaging MRI with Diffusion-Weighted Imaging (MRI-DWI). Using a simplified structured report template taking into account the morphologic response on T2W-MRI and the signal pattern on DWI, patients were categorized as:

- [1] good - potential complete responders (i.e., would benefit from endoscopy to identify complete responders),
- [2] intermediate responders - residual tumour most likely (i.e., endoscopy potentially useful to confirm residual tumour), and
- [3] poor responders - highly suspicious of tumour (i.e., endoscopy not required, surgery unavoidable).

The final response outcome of all patients was determined by histopathology in the operated patients or by long term follow-up (local recurrence free follow up of  $\geq 1$  year) in the patients with a sustained complete response undergoing watch-and-wait.

**Results:** The median number of patients categorized into the "poor responders" group by the 7 readers was 13(21%) (range 8-24). The vast majority of these patients had confirmed residual tumour at histopathology, with a low rate of "missed complete responders" varying from 0-4% for the different readers. The median number of patients categorized into the "intermediate responders" group was 31 (49%) (range 14-36). The rate of missed complete responders in this group ranged from 0-24% for the different readers. In the group categorized as the "good - potential complete responders" (median 18 (29%), range 14-26 per reader), the majority of patients (44-67%) were confirmed complete responders. When combining the MR poor-intermediate response group together, the risk of missing complete responders ranged from 3-12% for the 7 readers.

**Conclusion:** MRI using a simplified structured report template can aid in pre-selecting patients for immediate surgery, regardless of radiologists' experience level:

- When applying a stringent pre-selection (MR-poor responders only), the risk for missing complete responders is almost negligible (0-4%) and approximately 21% of patients can be safely referred for direct surgery.

- With a more conservative approach (including both MR-poor and -intermediate responders), around 71% of patients may be referred for direct surgery without endoscopic evaluation, at the cost of missing 3-12% of complete responders.

Using MRI in such a way, can thus facilitate a more selective use of endoscopy to identify the good responding patients and further select candidates for organ preservation.

**Contact E-Mail Address:** deborah\_costa@virgilio.it

**Introduction:** Although endoscopic submucosal dissection (ESD) of gastrointestinal (GI) neuroendocrine tumor (NETs) is an increasingly performed minimally invasive technique allowing complete en-bloc resection of mucosal and submucosal lesions, data on efficacy and safety outcome is limited. The aim of this study is to review three European centers experience of endoscopic treatment of superficial GI NET by ESD.

**Aims & Methods:** Clinical and technical data of patients treated by ESD from three tertiary European centers were prospectively collected from October 2014 to March 2019. Complete resection (R0) was defined as clear lateral and vertical margins.

**Results:** Thirty ESDs of NETs were performed in 28 patients (females 60.7%), median age of 61 years. Twenty-one NETs (70%) were removed from the stomach, 6 from the rectum (20%), 2 from the duodenum (6.6%) and 1 from the esophagus (3.3%). Seventeen out of 21 (80.9%) gastric NETs were associated with atrophic gastritis, 15 (88.2%) of which of autoimmune etiology. Moreover, 8 out of 21 patients (38.1%) with gastric NET had history of multiples NETs. Among them, 6 patients had been diagnosed with autoimmune atrophic gastritis (75%), 1 patient with helicobacter pylori related gastritis (12.5%) and 1 patient with gastritis of unknown origin (12.5%). En-bloc resection was achieved in all patients (100%). R0 resection rate was 80% (93.3% clear lateral and 80% clear vertical margins). Lymphovascular infiltration was diagnosed in three cases (10%).

Median ESD duration time, recorded in 21 procedures, was 60 min (range 20-240). One case of rectal and one case of duodenal NET removal, presented small perforations, treated conservatively by antibiotics and clip closure. The median specimen size was of 26 mm (range 12-65). Pathological examination showed 17 (56.6%) grade 1, 12 (40%) grade 2 and 1 (3.3%) grade 3 NETs. Sixty-nine percent of lesions were characterized as pT1 and 30.4% as pT2. Three patients were candidates for additional treatment: one had endoscopic mucosal resection for additional known lesions, one underwent surgery with oncological lymph node resection (finally pT2N1) and one refused systemic therapy. Follow up was performed in 21 patients. At the end of a median follow-up of 554 days, two cases of recurrence were identified: one was managed endoscopically, the second refused treatment.

**Conclusion:** Our series of ESD for selected GI NETs showed favorable results in term of efficacy and safety. However, further studies are needed to determine the role of ESD compared to other resection modalities.

**Disclosure:** Dr Despott and Dr Murino receive research/ education support from Aquilant Medical, Fujifilm, Olympus, Pentax Medical, Boston scientific and GI supply. All others authors have no conflicts of interest to disclosure.

## P1882 ENDOSCOPIC SUBMUCOSAL DISSECTION IN DYSPLASTIC LESIONS IN LONG-STANDING ULCERATIVE COLITIS: RESULTS OF A TERTIARY ENDOSCOPIC REFERRAL CENTER

**Introduction:** Endoscopic resection of superficial polypoid lesions in ulcerative colitis (UC) patients is appropriate if a complete resection can be achieved. However, endoscopic mucosal resection (EMR) is ineffective for large, nonpolypoid neoplasms (NPL) in UC, due to submucosal fibrosis and poor data are available on the efficacy of endoscopic submucosal dissection (ESD).

**Aims & Methods:** The aim of this study is to assess ESD feasibility and efficacy for large, NPL in UC patients in two tertiary endoscopic referral center. From April 2009 to October 2017 superficial NPL >20 mm within the colonic mucosa of ulcerative colitic patients, were retrospectively evaluated, in a tertiary Italian endoscopic referral center. Pre resection staging of NPLs was achieved by WLE+cromoendoscopy + NBI (Olympus Comp.) or I-scan System (Pentax Comp.). ESD was performed according to the standard technique, by using CO2 insufflation. Dual knife and Hook knife were used as ablation tools. A hyperosmotic solution (plasma expander + epinephrine + indigo carminio) was used to obtain the lifting of lesion. All endoscopic procedures were performed under conscious sedation (fentanyl + midazolam).

**Results:** Twenty-three patients (15M and 8F) were considered in the study; median age at time of resection was 62 (30-81). The colonic disease duration was 18 years (1-44) and 87% of the patients had extensive colitis (E3); 13% left side colitis (E2). Twelve of the 23 patients were under 5-aminosalicylic acid, 10 under biologics and 1 patient under azathioprine therapy. Mean lesion size was 38.6 ±22.1 (20-50) mm. En bloc resection was achieved in n=22 patients (95.6%), in 1 patient piecemeal was performed and there were no severe complications. All lesions removed were non polypoid with distinct margins, and no ulceration was observed. In all resected lesions low-grade dysplasia was diagnosed histopathologically. No patient was referred for colectomy.

**Conclusion:** In this study, ESD of large non polypoid lesions associated with UC seems to be feasible, safe and curative option. These data support the potential role of advanced endoscopic therapeutic technique for a management of dysplasia associated colitis in selected patients.

**Introduction:** Revised Bethesda Criteria (BC) are used to select patients with colorectal cancer (CRC) for Lynch Syndrome (LS) screening - **selective strategy**.

Given the low sensitivity of these criteria, screening for loss of expression of DNA repair proteins (DRP) / microsatellite instability (MSI) in all patients with CRC diagnosis, or in those < 70 years is currently recommended - **universal strategy**.

**Aims & Methods:** Our aim was to evaluate the benefits of applying the universal strategy in the identification of patients with LS.

Single-center cohort study. All patients < 70 years with an initial diagnosis of CRC discussed in a multidisciplinary appointment (07/2016 - 12/2017) and submitted to surgery were evaluated.

Clinical data, tumor features (including DRP expression), and genetic / epigenetic studies results were analysed (descriptive statistics).

**Results:** 105 patients were evaluated [57.1% males, mean age at diagnosis: 58.5 years (15-69)]. 7.7% of the tumours were mucinous or had signet ring cells. In 30% lymphocytic infiltrate was observed.

2.9% met the Amsterdam Criteria and 27.6% BC.

There was loss of DRP expression in 8.6% of tumours (7/9 MLH1 / PMS2; 1/9 MSH2 / MSH6; 1/9 MSH2). In the subgroup of patients with loss of DRP expression, one had a positive genetic diagnosis -LS (patient with MSH2 / MSH6 loss), 5 have ongoing studies (hipermethylation or genetic diagnosis), 2 died before being tested and one refused genetic diagnosis (patient with loss of MSH2). The patient with LS diagnosis fulfilled BC (age < 50 years). Of the remaining 8 patients, 3 did not fulfil BC and would not have been investigated by the selective strategy.

**Conclusion:** The preliminary results of our study demonstrate the importance of the universal strategy widespread implementation for screening of loss of DRP expression/ MSI in CRC.

**Contact E-Mail Address:** h.haak@nki.nl

**Introduction:** Patients with a regrowth in a wait-and-see-program are reported to have a higher risk for metastases. This is probably related to an inherent higher risk of incomplete responders, but it cannot be excluded that metastases can arise from the regrowth.

**Aims & Methods:** The aim of this study was to evaluate the risk of distant metastasis in wait-and-see patients with a clinical(near)complete response (cCR) after neoadjuvant chemoradiation (CRT) for rectal cancer, according to local regrowth and timing of inclusion.

Patients were included in a wait and see program between 2004 and 2019 when a three modality approach with digital rectal examination, endoscopy and MRI showed a (near) cCR. Patients were followed with frequent endoscopy and MRI every 3 months during the first year, and every 6 months thereafter. Oncological outcomes were assessed with Kaplan-Meier curves and a log rank test.

**Results:** We analyzed 313 patients with a median FU of 39 months (range 2-158) of which the majority (n=191) were prospectively analyzed. 52% (n=161) patients had an immediate cCR at restaging and 47% (n=147) patients had a near cCR during restaging with a cCR after reassessment of 3 months. 19% of the patients developed a local regrowth within 3 years (n=57, 49 luminal, 3 nodal, 5 both luminal and nodal). 9 patients with local regrowth developed distant metastasis (20%, 95%CI 62-90) within 3 years compared to 11 patients with distant metastasis without LR (5%, 95%CI:92-98) (p < 0.001). 7/9 patients developed a local regrowth first before detection of metastasis, 1 patient developed local regrowth and metastasis simultaneously and 1 patient developed metastasis 6 months prior to detection of local regrowth. Patients with a near CR and local regrowth tend to develop more metastasis compared to immediate complete responders who had a local regrowth. 3-year overall survival in patients with local regrowth was 93% (95%CI:80-98) vs. 97% (95%CI:94-99) in patients without local regrowth (p=0.25).

**Conclusion:** Rectal cancer patients selected for a wait-and-see-program who develop a regrowth have a higher risk of developing distant metastasis, especially in near CR. It is hypothesized that this is related to tumour biology but it remains unsure if metastasis arise from a regrowth. Overall survival outcomes in patients with and without regrowth did not differ significantly.

**Contact E-Mail Address:** m\_abu-arisha@rmc.gov.il

**Introduction:** Management of malignant colorectal polyps can be endoscopic or surgical and the best approach has yet to be defined since prospective data is lacking. Endoscopic mucosal resection (EMR) is the treatment of choice for large (>20 mm) lateral spreading colonic polyps (LSL) with high success rates, good safety profile and clinical and economic advantages compared with surgery. There is no data on the outcome and management of malignant LSL (M-LSL) following complete removal by piecemeal EMR.

**Aims & Methods:** We aimed to determine if salvage surgery for M-LSL following complete EMR resection is necessary. We analyzed data from a prospectively collected database of patients who underwent EMR at three hospitals in Israel. Patients with M-LSL were identified and their surgical and pathological data was reviewed for the presence of residual neoplastic tissue and complication. The primary end-point was the presence of residual localo-regional cancer.

**Results:** Over 34 months 313 LSL in 303 patients were removed by EMR. 249/313 (81.7%) were removed piecemeal. Complete endoscopic resection was achieved in 249/249 (100%) which endoscopically were not suspicious for containing deep submucosal invasive cancer. The final EMR pathology showed invasive cancer in 23/249 (9.2%).

After multidisciplinary meeting (MDT), 5 cases were not sent to surgery (curative resection or high operative risk). 18 cases were referred for surgery following MDT because EMR was considered non-curative (presence of LVI/tumor budding/submucosal invasion>1mm/poor tumor differentiation/absence of clear margins or a combination thereof). In all cases, 18/18 (100%) patients underwent laparoscopic oncological resection with no major complications. There was no evidence of residual cancer in the resected colons or lymph nodes in all patients.

**Conclusion:** Colonic LSL removed by piecemeal EMR, may not require surgery even when submucosal invasive cancer is present in the resected EMR specimen. Further research may define specific criteria for avoiding surgery.

**Disclosure:** Nothing to disclose

## P1886 THE IMPORTANCE OF INTRODUCING COLONOSCOPY SCREENING IN THE ADULT CYSTIC FIBROSIS PATIENTS: A SINGLE TERTIARY REFERRAL CENTRE ANALYSIS

Doherty J.<sup>1</sup>, Zulquernain S.<sup>1</sup>, Plant B.<sup>2</sup>

<sup>1</sup>Cork University Hospital, Department of Gastroenterology, Cork, Ireland, <sup>2</sup>Cork University Hospital, Cork Centre for Cystic Fibrosis, Cork, Ireland

**Contact E-Mail Address:** jaynedoherty@hotmail.com

**Introduction:** The risk of colorectal cancer (CRC) in patients with cystic fibrosis (PWCF) is 10times greater than the general population and 30times greater post-transplant. Due to this increased risk new screening guidelines were published in Gastroenterology by the CF Colorectal Cancer Screening Task Force in 2018.

**Aims & Methods:** Our aim was to benchmark current practise at our centre against current guidelines. Our endoscopy database was interrogated from 2012 to present to identify PWCF who received a previous colonoscopy.

**Results:**

**Group 1: PWCF non-transplant cohort;**

161 patients were included. 26 were >40years. 4 patients had a previous colonoscopy (total number colonoscopies = 4). No colonoscopies were done for screening, all as patients were symptomatic. One patient had a polyp at colonoscopy. Adenoma detection rate (ADR) was 25%.

21 patients >40 have no previous colonoscopy. Surveillance for CRC in this cohort has yet to be implemented with 0% compliance to date.

**Group 2: PWCF post solid-organ transplant;**

16 patients were included. 13 were >30 years. 11 patients had a previous colonoscopy (total number colonoscopies = 20).

Reasons for index colonoscopy: 5 screening, 3 symptomatic, 3 no indication on report.

10 colonoscopies in total were done for screening.

3 patients had polyps found at index colonoscopy (2 adenomas high grade dysplasia, 4 adenomas low grade dysplasia) and surveillance colonoscopies were arranged subsequently. ADR was 27.27%. Current practise in the post transplant cohort is close to new recommendations with 84% compliance, however only 45.45% of index colonoscopies were done initially for screening.

**Conclusion:** Current guidelines are only in existence just over 12months. Our analysis suggests there is an awareness of the need for CRC screening in the post-transplant cohort but there is need for improvement. In PWCF with no previous transplant screening has not been a priority and needs to be implemented. Currently we are implementing a screening programme in keeping with current guidelines.

**Contact E-Mail Address:** federico.iacopini@gmail.com

**Introduction:** Performance key measures of endoscopic resection and surgery referral are indefinite but heterogeneous operative skills can have a heavy impact on organized colorectal cancer screening programs.

**Aims & Methods:** Retrospective, observational 2-year study. Consecutive patients referred to surgery for colorectal neoplasms diagnosed in an organized screening program. Primary outcome: non-invasive neoplasm rates stratified on endoscopic staging (superficial vs. deep) and resection attempt. Invasive cancer was defined as cancer invading the submucosa (SM) or beyond on endoscopic and/or surgical specimens. Data were retrieved both from the county registry and cross-checked with data prospectively collected in endoscopy databases.

**Results:** A total of 468 patients were referred to surgery from 13 centers. Mean age was 64 (range 56-74); males 256 (58%); 213 (47%) from rural areas.

According to endoscopic morphology and approach before surgery, neoplasms were stratified in three groups: superficial underwent endoscopic resection (n.92, Sup-ER); superficial underwent biopsies (n.96, Sup-B); deep underwent biopsies (n.280, Deep-B). Sup-ER were significantly smaller (< 0.0001), more frequently pedunculated (< 0.0001) and in the left colon (< 0.0001) than Sup-B. Sup-ER underwent complete resection were significantly smaller (0.0059) and more frequently pedunculated (0.0433) than incomplete resections.

The non-invasive cancer rate was 11% for Sup-ER, 40% for Sub-B, and 9% for Deep-B. However, non-invasive cancer rate for mass ulcer-negative Deep-B (20%) was significantly higher than those in stricturing and ulcer-positive (3% and 5%, respectively: P=0.0002).

Centers showed significantly different rates of Sup-ER underwent complete resection (57% to 100%, P=0.0001), quite significantly different overall non-invasive rates (P=0.0549), and significantly different non-invasive rates in Sup-B (P=0.0187). Overall non-invasive cancer rates in the 13 centers ranged from 0% to 30% (P=0.0581), being < 10% and >20% in 5 (29%) centers, respectively.

Non-invasive cancer rate of sup-B was significantly different ranging from 0% (in 5 centers) to >60% in 3 centers.

**Conclusion:** The rate of noninvasive cancers referred to surgery in screening programs should be measured because rates can be high and center performances widely heterogeneous. Most of noninvasive cancer referred to surgery can be related to suboptimal resection skill or unavailability of advanced techniques that would guarantee an en bloc resection and

accurate histology. Corrective actions should consider: improvement in endoscopic characterization in all centers; expert 2<sup>nd</sup>-look in endoscopic referral centers in which hybrid EMR and/or ESD can be performed. Rate of noninvasive cancers referred to surgery should be a quality measure both for endoscopic and surgical screening centers.

**Contact E-Mail Address:** hebuterne.x@chu-nice.fr

**Introduction:** Malnutrition is frequent and negative in cancer patients. In particular, protein-energy malnutrition is associated with increased complications of chemotherapy.

**Aims & Methods:** This study aimed at assessing the benefits of an early and active individualized dietary counseling (DC) in patients receiving 1st-line chemotherapy for metastatic colorectal cancer (CRC). In a prospective multicentre study, non-malnourished patients were randomised to benefit (G1) or not (G2) from individualised DC by a dietician at treatment initiation and every 2 wk thereafter. ONS or EN/PN were prescribed based on guidelines. The primary endpoint was grade  $\geq 3$  toxicity over a 1-y follow-up. To show a 20% difference with a power of 80% and  $\alpha=0.05$ , 80 patients per group were needed. Statistics were performed with logistic regressions and Chi-2 tests.

**Results:** 173 patients were analysed in ITT: G1 (n=85, F/M:31/54, 64 $\pm$ 13 y); G2 (n=88, F/M:34/54; 63 $\pm$ 12 y). The number of metastatic sites, PS, BMI (25 $\pm$ 4 vs 26 $\pm$ 4), and treatment protocols were similar. A grade  $\geq 3$  toxicity was seen in 49.4% of G1 and 67.0% of G2 patients (RR=0.367; 95%CI: 0.186-0.722; p= 0.0037) with a median delay of 359 (182- ...) vs 169 d (118-252). 9.4% of G1 and 19.3% of G2 patients died (p=0.065). Energy and protein intake of G1 patients exceeded those of G2 patients by 222 $\pm$ 76 kcal/d and 11.4 $\pm$ 4.8 g/d (p=0.004). Weight variations favoured G1 (p=0.007): at M3, G1 patients had a stable weight and G2 patients had lost 1.2  $\pm$  0.6 kg. At M6, 14.8% of G1 and 30.8% of G2 patients (p=0.03) were malnourished. ONS were prescribed in 48.2% of G1 and 61.4% of G2 patients (p=0.08) and EN/PN in 7.1% of G1 and 14.8% of G2 patients (p=0.105).

**Conclusion:** An early and active DC reduces the risk of developing a grade  $\geq 3$  toxicity during the first-line chemotherapy of metastatic CRC. Even if further studies are needed in order to allow extrapolations, this work advocates a systematic dietary counselling in cancer patients receiving chemotherapy.

**Introduction:** The enteric nervous system (ENS) in dysmotility has been studied by classical light microscopy including immunohistochemistry. However, the procedure is rather time-consuming and only small components of the ENS in two dimensions can be analyzed. Novel x-ray imaging techniques, employed in this study, allow to obtain high-resolution three-dimensional scans of soft biological tissue over a longer segment with an overview of interganglionic neural connections, and different intraganglionic cell types, which would normally show no contrast with standard x-ray absorption microtomography.

**Aims & Methods:** The aim of the present study was to evaluate the ENS in a three-dimensional manner, to get a more complete architecture of the neural tissue in sickness and health. Full-thickness biopsies of ileum from a patient with Ehlers-Danlos syndrome and secondary severe gastrointestinal dysmotility and from a healthy resection border of proximal colon due to resection of the colonic carcinoma were embedded in paraffin and sectioned. Representative areas of the ENS with presence of myenteric ganglia and submucosal ganglia were identified in Hematoxylin & Eosin stained microscopic sections. By a 1-mm punch, a biopsy was extracted from the paraffin block and put into a plastic tube.

The samples were scanned, without any further preparation, in two different tomography instruments developed at the Institute for X-ray Physics of Georg-August-Universität, Göttingen [1]. The first instrument, a laboratory setup, allowed to image the whole 1-mm sample with a ~1mm effective voxel size during 8 hours with a microscope coupled sCMOS, enabling an identification of the neural tissue structure. Phase retrieval suitable for low coherence sources was performed using the Brannikov Aided Correction scheme, and cone beam tomographic reconstruction were implemented based on the ASTRA toolbox. Selected regions of interest were then scanned in the second instrument, a synchrotron-based instrument (GINI-X, P10, DESY, Hamburg), which allows to image regions of 320x320x320 mm<sup>3</sup> with an effective voxel size of 176 nm. At this resolution, individual cells inside the ganglia can be distinguished.

From the coarser-resolution tomographic scans, the neural tissue structure has been extracted with semi-automatic segmentation methods. Preliminary digital quantification of the volume of the neural tissue over total biopsy volume, were performed from the segmented volumes. A more-in-depth digital analysis, currently in progress, will allow to measure parameters such as the length and average diameter of the ganglia.

**Results:** The myenteric ganglia from the control were normal regarding both size and cellularity. Neurons and glia cells could be recognized. Between the ganglia, the nerve-bundles were thick and sharply demarcated. In contrast, the ganglia from the patient were smaller and the interganglionic nerves were uneven/irregular with alternating thin and "small nodular" regions. Preliminary digital quantification showed that the ratio of neural tissue volume over total biopsy volume in the patient (0.9%) was significantly diminished compared to the control (7.3%).

**Conclusion:** Three-dimensional nanotomography may be a useful tool and can give valuable information on the changes of the size and interganglionic neural connections of the ENS in dysmotility diseases which cannot be obtained/received by classical methods.

## P1890 THE SIGNIFICANCE OF ILEUS IN THE POST-KIDNEY TRANSPLANT SETTING: A HEALTHCARE UTILIZATION PERSPECTIVE

Kroner P.T.<sup>1</sup>, Kesler A.M.<sup>2</sup>, Corral J.E.<sup>3</sup>, Lukens F.<sup>3</sup>

**Introduction:** Ileus is a known early complication following kidney transplant (KTx). Approximately 16,000 KTx surgeries are performed each year in the US, thus it is imperative to study and find solutions to potential hospital complications post-transplant. There is limited data largely from case reports documenting the occurrence of ileus in KTx patients. Potential risk factors include post-operative setting, steroid withdrawal, or even peritoneal sclerosis in patients with a history of peritoneal dialysis (PD).

**Aims & Methods:** The aim of this study is to assess inpatient prevalence and outcomes of ileus in the same admission as the KTx occurred.

Case-control study using the NIS 2012-2016, the largest publicly available inpatient database in the US. The ICD9-10CM procedural codes for kidney transplant were used to identify all patients that underwent KTx during the same admission. None were excluded. Patients with associated ileus were identified using ICD9-10CM diagnostic codes. The primary outcome was determining the odds of ileus in post-KTx patients. Secondary outcomes were inpatient mortality, postoperative complications, measured by shock, ICU stay, resource utilization, length of hospital stay (LOS), total hospitalization charges and costs. Propensity score matching was used to create a matching population for gender, age and Charlson Comorbidity Index. Multivariate regression analyses were used to adjust for income in patients' zip code, hospital region, location, size and teaching status.

**Results:** A total of 89,065 KTx patients were identified, of which 16,880 were propensity score matched for the selected covariates. The mean patient age was 50 years, and 40% were female. On multivariate analysis, the odds of ileus in the KTx cohort was 3.90 ( $p < 0.01$ ) compared to patients who did not undergo KTx surgery. When patients that underwent KTx and developed ileus during the admission, they had greater adjusted odds of shock 6.22 ( $p < 0.01$ ), TPN 11.24 ( $p < 0.01$ ), AKI 1.97 ( $p < 0.01$ ), multi-organ failure 1.85 ( $p < 0.01$ ), post-op infection 17.7 ( $p < 0.01$ ), Deep Vein Thrombosis 2.3 ( $p = 0.02$ ), Pulmonary Embolism 2.79 ( $p = 0.02$ ), and bleeding 2.44 ( $p = 0.04$ ) compared to patients with no KTx. In addition, those who developed ileus had greater hospitals costs, charges, and length of stay (LOS) (Table 1).

Variable	aOR	95%CI	p-value
Ileus in patients with KTx	3.90	3.41-4.46	<0.01
Inpatient Mortality	2.94	0.67-12.83	0.15
ICU	1.60	0.68-3.73	0.27
TPN	11.24	2.43-52.10	<0.01
AKI	1.97	1.28-3.03	<0.01
Post-op infection	17.70	4.12-75.98	<0.01
DVT	2.30	1.12-4.75	0.02
PE	2.79	1.16-6.74	0.02
Post op Shock	2.96	0.69-12.68	0.14
Variable	Adjusted Means	95%CI	p-value
Additional Adjusted Costs	\$40,182	21216-59147	<0.01
Additional Adjusted Charges	\$129,933	52424-207441	<0.01
Additional Adjusted LOS (days)	13.1	5.1-21.1	<0.01

[Table 1 - Adjusted odds ratio and additional means to the evaluated variables in patients with kidney transplant surgery that develop ileus]

**Conclusion:** Patients undergoing kidney transplant are more likely to develop ileus than patients who did not have kidney transplant surgery, confirming known reports documenting ileus in the early post-operative period. This cohort of patients who developed ileus following transplant have greater odds of post-operative complications, as well as increased morbidity, resource utilization and economic burden. Future studies should focus on elucidating the etiology of ileus following kidney transplant, as well as associated factors, and creating strategies to address it.

**Contact E-Mail Address:** gaurav.nigam@nhs.net

**Introduction:** Despite advances in Ulcerative Colitis (UC) therapies, many patients suffer refractory symptoms in the absence of active inflammation. For this group, treatment remains challenging, with a paucity of therapeutic options. In this prospective, ongoing study, we aim to determine the prevalence and burden of functional colorectal disorders inpatients with quiescent UC using validated questionnaires.

**Aims & Methods:** In a cross-sectional study, consecutive patients with UC attending Inflammatory Bowel Disease (IBD) clinics were invited to participate. Patients completed a series of validated questionnaires; including Hospital Anxiety and Depression Scale (HADS), the Rome IV diagnostic questionnaire for functional gastrointestinal disorders (FGIDs), an IBD-QoL score and the IBD-control questionnaire. Participants were requested to return a Faecal Calprotectin (FCP) within 2 weeks of completing questionnaires. Quiescent UC was defined as IBD-control 8 score  $\geq 13$  and IBD-control-VAS  $\geq 85$ , and/or FCP levels  $\leq 250$  (where available, FCP data were used in preference to IBD-control to classify UC activity). Based on Rome IV diagnosis and UC disease activity (active or quiescent), patients were divided into groups and data compared using non-parametric tests.

**Results:** Overall, n=97 UC patients (n=50 males, mean age 48 (range 18-82)) participated. 41/97, (42%) UC patients met the Rome IV diagnostic criteria for  $\geq 1$  FGIDs (irritable bowel syndrome n=26, functional constipation n=6 and faecal incontinence (FI) n=22). Disease activity data (IBD-control and/or FCP) were available for all patients, and based on these 61/97, 63% had quiescent UC. Within the quiescent UC group, 25/61 (41%) met the Rome IV diagnostic criteria for  $\geq 1$  FGIDs (irritable bowel syndrome n=14, functional constipation n=3 and FI n=13). Within the active UC group, those with co-existing FGIDs, compared to those without FGIDs, had significantly worse median QoL scores ( $P=0.02$ ), higher HADS-depression ( $P=0.005$ ) and HADS-anxiety ( $P=0.05$ ). By contrast, in those with quiescent UC, those with an FGID did not have different median HADS scores (depression  $P=0.15$ , anxiety  $P=0.62$ ) or IBD-QoL scores ( $P=0.20$ ), compared to those without FGIDs.

**Conclusion:** This study is one of the first to use Rome IV criteria in UC and confirms that the prevalence of FGIDs is high. Patients with active disease and overlapping functional symptoms appear to have worse QoL and more psychological distress compared to those with quiescent disease. Clinicians should therefore be vigilant to this functional overlap and treat both functional and inflammatory driven symptoms.

Antonio Hospital Padova, Surgical Department, Padova, Italy

**Contact E-Mail Address:** zucchielena@gmail.com

**Introduction:** Transanal irrigation (TAI) is a safe technique designed to assist the evacuation of faeces from the bowel in a controlled manner by introducing water via the anus. This is a widely accepted alternative to

conventional management strategies and is intended to allow people with bowel dysfunction to flush out the distal colon as part of their bowel management strategy, promoting the rehabilitation of bowel function. This also enables the users to choose the time and place of evacuation and to develop a consistent bowel routine.

#### Aims & Methods:

**Aim:** To assess how TAI modifies Quality of Life (QoL) of patients with functional constipation (FC), fecal incontinence (FI) and low anterior resection syndrome (LARS).

**Methods:** Between 1/2016 and 12/2018 patients suffering from FC, FI or LARS were treated with TAI in 11 Italian centers. The primary endpoint was QoL, measured through VAS (all patients) and through validated questionnaires such as Pac-QoL (FC), FI-QoL (FI), Wexner score (FC, FI) and LARS score (LARS); secondary endpoint included patient's compliance analysing dropout rate.

**Results:** Results concern 195 patients (FI, N=14; FC, N=101; LARS, N=80). The Wexner score after 6 months dropped from  $13 \pm 5$  to  $1 \pm 2$  in FI patients ( $p < 0.001$ ) and, after 12 months, from  $16.6 \pm 6.5$  to  $11.2 \pm 3.1$  in FC ones ( $p < .001$ ). The VAS score increased significantly after 1 month ( $5.6 \pm 3.3$  vs.  $7.8 \pm 2.1$  for FI patients;  $3.8 \pm 2.7$  vs.  $6.8 \pm 1.9$  for FC patients and  $2.3 \pm 1.4$  vs.  $6.8 \pm 2.1$  for LARS patients,  $p < .001$  in all cases) and further improved over time. LARS patients experienced a drop in the LARS score from  $33.7 \pm 10.4$  to  $11.3 \pm 12.5$  ( $p < .001$ ) on the first month and at 24 months their LARS score was  $0.5 \pm 3.1$ . The average dropout rate at the last follow up was 20.4%.

**Conclusion:** Patients suffering from IF, FC or LARS were compliant to TAI and experienced significant QoL improvement.

<sup>4</sup>University of North Carolina at Chapel Hill, Centre for Functional GI and Motility Disorders, Chapel Hill, United States

**Contact E-Mail Address:** irina.midenfjord@gu.se

**Introduction:** Central sensitization (CS) has been proposed to be an important mechanism for symptom generation in functional gastrointestinal disorders (FGID). In this study, we explore the association between symptoms and CS in patients with FGID, and in volunteers with no or mild GI symptoms.

**Aims & Methods:** Patients with FGID according to Rome IV and volunteers completed questionnaires assessing central sensitization (CSI), sensory processing sensitivity (HSP), GI symptoms (GSR-IBS), psychological distress (HAD) and non-GI symptoms (PHQ-12). The validated cut-off of CSI ( $\geq 40$ ) distinguished between persons with and without reported CS.

**Results:** We included 77 FGID patients and 79 volunteers (median age 30 [26-39] vs. 25 [22-32] years ( $p < 0.001$ ); females 57 (74%) vs. 41 (52%) ( $p = 0.007$ )).

Thirty-three (43%) patients and one (1%) volunteer reported CS. Patients with CS were older (36 [27-47] years vs. 28 [24-33] years,  $p = 0.02$ ), had more severe overall GI symptoms (4.0 [3.8-4.5] vs. 3.7 [3.2-4.2],  $p = 0.03$ ) and non-GI symptoms (9 [8-10] vs. 6 [4-8],  $p < 0.001$ ) than patients without CS, but with no significant differences in psychological distress or sensory processing sensitivity. Linear trend analyses in all study subjects (divided into CS quintiles) demonstrated gradual increase of GI symptom severity with increasing severity of CS with large effect sizes (Table 1). Furthermore, moderate to strong correlations were seen between CS and GI symptoms (total:  $\rho = 0.68$ ; abdominal pain:  $\rho = 0.64$ ; bloating:  $\rho = 0.65$ ; constipation:  $\rho = 0.56$ ; diarrhoea:  $\rho = 0.58$ ; satiety:  $\rho = 0.55$ , all  $p < 0.001$ ).

GSR-IBS domain	p-value	Partial $\eta^2$
Total score	<0.001	0.44
Pain syndrome	<0.001	0.40
Bloating syndrome	<0.001	0.40
Constipation syndrome	<0.001	0.26
Diarrhoea syndrome	<0.001	0.29
Satiety syndrome	<0.001	0.27

[Table 1: Linear relationships between increasing level of central sensitization and gastrointestinal symptoms.]

**Conclusion:** Central sensitization is common in patients with functional gastrointestinal disorders, and clearly associated with GI symptom severity, indicating that it seems to be an important factor for GI symptom generation.

## P1894 FUNCTIONAL CONSTIPATION IN DIFFERENT PHENOTYPES OF ELDERLY PEOPLE. PREVALENCE OF CLINICAL SYMPTOMS, RISK FACTORS, PATHOPHYSIOLOGY AND IMPACT ON QUALITY OF LIFE

Mundet L.<sup>1</sup>, Arco S.<sup>1</sup>, Clavé P.<sup>2</sup>

<sup>1</sup>Consorci Sanitari del Maresme, Gastrointestinal Motility Lab., Mataró,

Spain, <sup>2</sup>Hospital de Mataró Consorci Sanitari del Maresme, Gastrointestinal Physiology Lab., Mataró, Spain

**Contact E-Mail Address:** lluismundetp@gmail.com

**Introduction:** Functional constipation (FC) is a prevalent disorder in elderly people. It impacts on healthcare and quality of life (QoL). The frail phenotype is associated to poor health outcomes including disability, hospitalization, and mortality.

**Aims & Methods:** To determine the prevalence, pathophysiology and symptoms of FC among older people, and its association with frailty.

This was an epidemiological study of individuals over 70 years of age, stratified into robust, pre-frail and frail (Fried criteria (2)), and recruited from the community, an acute hospital and a nursing-home. Variables collected were sociodemographic data, frailty, Rome III symptoms (1), Bristol scale for faecal consistency, dependence, cognitive status, and QoL. Anorectal manometry and CTT were performed on a second sample of 56 community-living patients with FC, and 25 hospitalized patients underwent a balloon expulsion test (BET).

**Results:** The study included 416 patients, 50.2% men, with a mean age of  $79.64 \pm 6.8$ . Prevalence of FC was 26.8% (32.4% women, 21.8% men;  $p = 0.019$ ). Excessive strain (89.3%) and hard stools (75.7%) were the most prevalent symptoms in FC, 20.4% showed  $< 3$  bowel movements/week. Patients with FC showed poorer results in QoL. Prevalence of FC was higher in the frail group (41.7%) than pre-frail (33.9%) or robust (24.2%) ( $p < 0.001$ ).

Obstructive defecation symptoms were very prevalent in frail and pre-frail (53.5% and 48.6%, respectively). In robust the most prevalent subtype was mixed.

Regarding pathophysiology, All robust patients showed dyssynergic defecation, and delayed CCT in 40%. Only 17.3% of the pre-frail had normal BET.

**Conclusion:** The prevalence of FC in older people, especially women, is very high, and is associated with frailty and poor QoL. Its pathophysiology is mainly associated with dyssynergic defecation and hard stools.

FC differs between gender, age and functional status. Management should be tailored to patient characteristics and underlying pathophysiology.

**Contact E-Mail Address:** jasper.pannemans@kuleuven.be

**Introduction:** Opioid induced constipation (OIC) is a prevalent condition amongst patients treated with opioids for chronic pain. Constipation and other side effects can be as prevalent as 40-90% resulting in non-compliance and quality of life reduction. The effects of opioids on colonic motor function and their reversal by opioid antagonists have been poorly studied. We therefore conducted a crossover trial to study effects of codeine and the peripheral  $\mu$ -opioid receptor antagonist naloxegol on colonic manometry patterns in healthy volunteers (HV).

**Aims & Methods:** On each of three study visits, participants underwent a colonoscopy (conscious sedation with midazolam 2-5mg IV) after half-standard PEG preparation for colonic manometry catheter (40-sensor high-resolution manometry catheter 2.5 cm spacing, Laborie, Mississauga, Canada) placement. Colonic motility was evaluated during 2 hours after a standardized bread meal (645 kcal). After waking up, HV received naloxegol (25mg)/placebo, placebo/codeine (60mg followed by 30mg one hour after the meal) or naloxegol/codeine by oral administration in a randomized, double-blind crossover fashion. Symptom registration for abdominal pain, discomfort, bloating, gas, desire to defecate and urge was performed every 15 minutes during the entire measurement on a visual analogue scale (VAS). A total symptom score was calculated for each symptom by adding the scores for the entire measurement. The data were analysed using mixed-models analysis in SAS with post-hoc analysis after correction for multiple testing.

**Results:** Ten HV [3 male, aged 26.5 (range 20 - 63) years] finalized all three study visits.

Data on motor pattern prevalence are presented in Table 1 [data are reported as median (interquartile range)]. (a)  $p < 0.01$  vs. placebo/codeine, (b)  $p < 0.05$  vs. placebo/codeine, (c)  $p < 0.05$  vs. naloxegol/placebo. Long antegrade propagating waves (PW) were significantly decreased in the codeine/placebo compared to codeine/naloxegol condition. No significant differences were found for short antegrade PW or short retrograde PW. The postprandial cyclic patterns were significantly altered by the treatment condition. First, the cyclic antegrade PW were lower in the placebo/codeine compared to the naloxegol/placebo and naloxegol/codeine treatment. Second, the cyclic retrograde were significantly more frequent in placebo/codeine compared to the two other treatment groups. Finally, significantly less cyclic simultaneous PW were present in the naloxegol/placebo vs. placebo/codeine condition.

The total score for abdominal discomfort was significantly less in the placebo/codeine condition compared to the naloxegol/codeine condition ( $p=0.046$ ). No significant differences were found for bloating, gas, desire to defecate, urge or abdominal pain.

	Naloxegol/Placebo	Placebo/Codeine	Naloxegol/Codeine	p-value main effect
Short antero- grade PW	3.0 (2.00-5.50)	2.5 (1.00-4.50)	4.0 (2.00-7.00)	0.307
Short retrogra- de PW	6.0 (2.75-15.00)	3.5 (2.00-4.00)	4.0 (3.25-7.75)	0.544
Long antero- grade PW	2.0 (0.75-7.00)	1.5 (0-3.00)	3.5 (2.00-12.00)a	0.005
Cyclic antero- grade PW	14.5 (7.25-21.75)b	7.0 (3.75-13.50)	15.0 (5.25-23.00)b	0.013
Cyclic retrogra- de PW	43.5 (20.75-65.00)b	78.0 (43.50-84.50)	37.5 (17.75-52.75)a,c	0.003
Cyclic simulta- neous PW	7.0 (2.25-16.25)a	17.5 (6.25-50)	10.0 (5.25-13.00)	0.006
Simultaneous PW	3.0 (0.75-6.50)	2.0 (0.75-3.25)	2.5 (2.00-7.25)	0.361

[Overview of colonic motor pattern prevalence in the postprandial period after codeine and naloxegol administration. (PW: Pressure wave)]

**Conclusion:** Codeine administration increased cyclic retrograde activity and decreased cyclic antegrade activity in the postprandial period and this effect was reversed by naloxegol. These observations enhance our understanding of the mechanism of OIC and its treatment with peripheral  $\mu$ -opioid receptor antagonists.

## P1896 PREDICTING SUCCESSFUL OUTCOMES OF ANORECTAL BIOFEEDBACK FOR CONSTIPATION: RESULTS OF EXTENSIVE PSYCHOLOGICAL EVALUATION BEFORE TREATMENT AND CORRELATIONS WITH TREATMENT OUTCOMES

Mazor Y.<sup>1,2</sup>, Beath A.P.<sup>3</sup>, Trieu R.<sup>1,2</sup>, Prott G.<sup>1</sup>, Sequeira C.<sup>1</sup>, Jones M.<sup>3</sup>, Kellow J.<sup>1,2</sup>, Malcolm A.<sup>1,2</sup>

<sup>1</sup>Royal North Shore Hospital, Department of Gastroenterology, Sydney, Australia, <sup>2</sup>The University of Sydney, Department of Medicine, Sydney, Australia, <sup>3</sup>Macquarie University, Department of Psychology, Sydney, Australia

**Contact E-Mail Address:** yoavmazor@gmail.com

**Introduction:** Anorectal biofeedback (BF) is a well-established treatment for patients with constipation and functional defaecation disorders, however demand greatly exceeds supply. There is some evidence that pre-treatment clinical or physiological factors may predict success of treatment<sup>1</sup>. As biofeedback is a form of behavioural therapy, we hypothesised that psychological traits could help predict response to BF in constipation.

**Aims & Methods:** To describe pre-BF treatment psychological traits of constipated patients and to evaluate these as predictors of favourable response to treatment.

77 consecutive constipated patients undergoing anorectal BF completed a pre-treatment computer-based questionnaire of multiple emotional state and cognitive psychology measures, in addition to baseline clinical and anorectal physiology testing. Patients underwent weekly BF visits over 6 weeks. The main outcome measure was physician-assessed response to BF (moderately-greatly improved), blinded to baseline psychological evaluation results. Secondary outcome measures included change in patient-rated visual analog scales of impact of bowel dysfunction on quality of life (VAS QOL), feeling of control (VAS control) and satisfaction with bowel motions (VAS satisfaction).

**Results:** 69 (90%) patients completed BF (mean age 51+-17 yrs, 62 female). Patients with paradoxical anal contraction on push were more likely to respond to BF (OR 5.3, 95% CI 1.2-24,  $p=0.3$ ), as well as patients with higher self-efficacy scores (OR 1.2, 95% CI 1.1-1.4,  $p=0.002$ ), higher treatment efficacy expectancy (OR 1.1, 95% CI 1.1-1.2,  $p=0.03$ ), higher internal health locus of control (OR 2.2, 95% CI 1.2-4.1,  $p=0.01$ ), and lower perceived stress sub-score of worries (OR 0.4, 95% CI 0.2-0.9,  $p=0.03$ ). On multivariate analysis incorporating all baseline physiology and psychological predictors, internal health locus of control was the only predictor of a favourable response to BF.

Psychological and cognitive measures also predicted all VAS secondary outcomes. For example, lower scores on perceived stress sub-scores of worries again predicted more improvement in VAS QOL (coef. -2.7, 95% CI -4.4 - (-1.1),  $p < 0.01$ ) and VAS control (coef. -2.7, 95% CI -4.4 - (-0.9)), while higher treatment efficacy expectancy predicted more improvement in VAS satisfaction (coef. +0.3, 95% CI 0.2-0.4,  $p < 0.001$ ) and VAS control (coef. +0.2, 95% CI 0.1-0.3,  $p=0.03$ ).

**Conclusion:** Success of anorectal biofeedback therapy for constipated patients is dependent on patients' psychological and coping strategies. Addressing potential psychological barriers prior to BF might optimise future patient outcomes

## P1897 VOLUMETRIC RECTAL SENSATION TESTING: IS IT CLINICALLY RELEVANT? RESULTS FROM A LARGE PATIENT COHORT

Mazor Y.<sup>1,2</sup>, Prott G.<sup>1</sup>, Trieu R.<sup>1,2</sup>, Jones M.<sup>3</sup>, Kellow J.<sup>1,2</sup>, Malcolm A.<sup>1,2</sup>

<sup>1</sup>Royal North Shore Hospital, Department of Gastroenterology, Sydney, Australia, <sup>2</sup>The University of Sydney, Department of Medicine, Sydney, Australia, <sup>3</sup>Macquarie University, Department of Psychology, Sydney, Australia

**Contact E-Mail Address:** yoavmazor@gmail.com

**Introduction:** Research based rectal sensory testing using a barostat and infinitely compliant balloon, has previously revealed correlations between disease states and both rectal hypo- and hyper- sensitivity<sup>1</sup>. Similar data for the volumetric only sensation testing methods employed in clinical practice (using a compliant balloon) are lacking, and differences between the commonly measured thresholds for first sensation, urge and maximal tolerated volume (MTV) are unknown.

**Aims & Methods:** Our aims were, therefore, to determine: (1) Does volumetric rectal balloon sensation testing correlate with disease states? (2) Which, if any, of the three sensory thresholds tested is most relevant for each disease state?

1251 patients (mean age 53+-18, 92% female) referred for volumetric rectal balloon sensation testing as part of anorectal manometry were included in the study. All patients completed the Rome and hospital anxiety and depression (HAD) questionnaires. Data regarding possible factors associated with alterations in rectal sensation were prospectively collected, including relevant surgical, medical and obstetric history. Univariate analysis of all factors was followed by multivariate analysis of positive variables, with sensation thresholds used as continuous outcome measures. Next, volumetric rectal sensitivity values were categorised into low, normal or high using data derived from 44 healthy female volunteers, and distribution of disease states across the categories was compared in a subgroup of female patients (n=1107).

**Results:** Presenting symptoms of constipation, older age and longer balloon expulsion time (BET) were associated with higher thresholds for all sensations (p< 0.05 for all comparisons). Presenting symptoms of faecal incontinence (FI) was associated with lower thresholds for all sensations (p< 0.001 for all comparisons). The presence of connective tissue disease was associated with lower urge to defecate and lower MTV, while previous pelvic radiation therapy and irritable bowel syndrome (IBS) were associated with lower values on MTV only (p< 0.05 for all).

Using normal values for reference in the female subgroup, older age was associated with hyposensitivity (higher than normal values) on first (OR 1.03, 95% CI 1.02-1.04), urge (OR 1.03, 95% CI 1.02-1.04), and MTV thresholds (OR 1.03, 95% CI 1.01-1.03, respectively) (p< 0.01 for all). Patients presenting with constipation were more likely to be hyposensitive on MTV (OR 2.6, 95% CI 1.8-3.7, p< 0.001), while FI were hypersensitive (lower than normal values) on urge (OR 0.3, 95% CI 0.2-0.5, p< 0.001). Hypersensitivity on first sensation was associated with inflammatory bowel disease (OR 0.3, 95% CI 0.1-0.9, p=0.03), and hypersensitivity on urge sensation with connective tissue disease (OR 0.4, 95% CI 0.2-0.9, p=0.04).

**Conclusion:** Volumetric sensory testing as commonly practiced is correlated with some disease states known to affect rectal sensation, and thus has clinical relevance. Several conditions, such as IBS, inflammatory bowel disease and connective tissue disease, were correlated with only two or even a single abnormal threshold, suggesting the three sensation thresholds may measure different pathophysiological pathways and should continue to be used in clinical practice.

**Introduction:** Manual abdominal massage has been shown to be effective in treating slow transit constipation even burdensome. To improve care efficacy, Bamk-001, a device for automatic abdominal massage, was newly developed.

**Aims & Methods:** The purpose of this study was to assess the effect of Bamk-001 on symptom profiles and the colonic transit time (CTT) in patients with chronic constipation.

Thirty seven patients with functional constipation diagnosed by Rome IV criteria were enrolled prospectively from December 2018 to February 2019. All of the patients received device assisted-automatic abdominal massage for 15minutes twice a day once in the morning before breakfast and once at night in 14days. CTT was done before and end of the study periods. Symptom profile including spontaneous bowel movements, straining, stool form, feeling of incomplete emptying, anorectal blockage, abdominal discomfort, overall defecation satisfaction, and device related adverse events were analyzed.

**Results:** Thirty seven patients were finally enrolled. Bamk-001 statistically significantly improved CTT from 54.0[33.6-75.6] hour to 28.8[18.0-52.8] (p=0.001). Both of left sided and rectosigmoid segmental CTT also significantly improved from 21.6[12.6-41.7] to 13.2[3.3-26.7] and from 15.0[6.9-26.7] to 3.6[0.0-13.2], respectively. Moreover, all of the patients' symptom profiles were alleviated after treating. No serious adverse events were reported.

**Conclusion:** Bamk-001, newly developed device for automatic abdominal massage, showed excellent care efficacies including improved CTTs and symptom profiles in patients with functional constipations. Device assisted-automatic abdominal massage, as an adjunct to management of constipation, offers an acceptable and potentially beneficial intervention to patients with chronic constipation.

**Introduction:** Computed tomography colonography (CTC) has been developed as a less invasive alternative method to colonoscopy for colorectal cancer screening. Some subjects who underwent CTC reported abdominal pain induced by carbon dioxide gas injection during examination. We speculated that pain perception during CTC might reflect visceral hypersensitivity related to irritable bowel syndrome (IBS).

**Aims & Methods:** A prospective study of consecutively registered patients who underwent CTC for colorectal cancer screening between April 2018 and March 2019 in a single medical center was conducted. IBS was diagnosed using the Rome IV criteria, and patients with IBS were classified into IBS subgroups according to the predominant stool pattern experienced by the patient. In addition, all subjects completed the IBS Severity Scale (IBS-SS) and IBS-QOL questionnaire. Pain perception during CTC

was quantified using the visual analog scale (VAS) at six time points during the CTC as follows: (1) before CTC, (2) immediately after carbon dioxide gas injection, (3) until the injection pressure reached a plateau (18 mmHg), (4) in the prone position after carbon dioxide gas injection, (5) in the supine position after carbon dioxide gas injection, and (6) after CTC. We also evaluated the association between the VAS and IBS-SS scores. In this study, we investigated whether pain perception induced by carbon dioxide gas injection during CTC is different between patients with IBS and healthy controls. Furthermore, we evaluated the correlation between the pain score during CTC and the severity of the IBS symptom or the quality of life of patients with IBS.

**Results:** One hundred twenty-three subjects who underwent CTC were enrolled in this study. Thirteen subjects were excluded because of incomplete questionnaires ( $n = 10$ ) or a diagnosis of colorectal cancer with CTC ( $n = 3$ ). Fifteen patients were diagnosed as having IBS on the basis of the Rome IV criteria for IBS. Patients with IBS were classified into the following groups: IBS with diarrhea (IBS-D,  $n = 1$ ), IBS with constipation (IBS-C,  $n = 3$ ), mixed IBS (IBS-M,  $n = 3$ ), and unspecified IBS (IBS-U,  $n = 8$ ).

No significant differences in background characteristics, including age, sex, alcohol consumption, and smoking habit, were found between the IBS and control groups. The volume of carbon dioxide gas injected during CTC did not show a significant difference between the two groups. The total colon length was not significantly different between the two groups. The VAS score of the IBS groups was significantly higher than that of the control group at two time points, (2) immediately after carbon dioxide gas injection ( $p < 0.01$ ) and (3) until the injection pressure reached a plateau (18 mmHg;  $p < 0.01$ ). The maximum VAS score during CTC was also significantly higher in the IBS groups than in the control group ( $p < 0.05$ ). Although the IBS-SS score was significantly higher in the IBS groups than in the control group, we found no significant correlation between the VAS and IBS-SS scores in the IBS groups. The IBS-QOL score also did not show any significant correlation with the VAS score.

**Conclusion:** Our study indicates that pain perception evaluated using the VAS during CT colonography might be a potential diagnostic method for IBS. Further study is necessary to clarify the association between pain perception induced by CT colonography and IBS severity.

**Contact E-Mail Address:** francescolapia9@gmail.com

**Introduction:** Diamine Oxidase (DAO) is the extracellular enzyme for histamine degradation pathway. It was recently reported that DAO is an accurate marker of intestinal mucosal integrity in intestinal diseases (Garcia Martin 2007) and after chemotherapy (Motoori 2017) and it was shown in rats that duodenal lipid infusion increases intestinal DAO activity (Ji 2013), suggesting its use to detect intestinal permeability alterations.

**Aims & Methods:** The aims of the study was the measurement of serum DAO levels in patients with IBS, IBD and HV to ascertain whether it could suggest intestinal barrier defects. We enrolled 31 IBS patients (12 F, mean age  $28 \pm 4$  yrs; 22 IBS-D and 9 IBS-C) and 21 HV (12 F, mean age  $27 \pm 5$  yrs). Moreover, as pathologic control group, 10 IBD patients in remission were also enrolled (4 F, mean age  $31 \pm 4$  yrs, 5 CD and 5 RCU). Serum samples were collected after an overnight fast and serum DAO was measured (DAO ELISA Listerfish, Italy). In all the subjects, intestinal permeability was detected with lactulose/mannitol test. Lactulose/mannitol % dose urinary recovery was determined after oral administration of 1g of mannitol and 5 g of lactulose.

**Results:** In HV, serum DAO was significantly higher than in IBS and IBD patients ( $9.5 \pm 1.7$ ,  $5.7 \pm 2.9$ , and  $4.1 \pm 1.8$  U ml, respectively,  $p < 0.01$ ). In IBS, the subgroup of patients with postprandial symptoms showed lower DAO levels than the subgroup without postprandial symptoms ( $2.3 \pm 1.0$  vs  $6.3 \pm 4.6$  U ml, respectively,  $p < 0.01$ ). In IBS patients, serum DAO was slightly correlated with %LMER ( $r = 0.41$ ). Serum DAO levels did not correlate with gender, age, severity of symptoms, duration of disease.

**Conclusion:** Serum DAO is reduced in both IBS and IBD patients, suggesting a role in the detection of intestinal permeability defects. Moreover, the reduced levels in IBS patients with postprandial symptoms may suggest a role of meal ingestion also in the pathophysiology of IBS symptoms.

**Introduction:** Patients with functional bowel disorders (FBD) are classified using the Rome criteria. However, this classification does not take account the intensity of symptoms and bloating.

**Aims & Methods:**

The purpose of this study is to evaluate whether the intensity of the cardinal signs of FBD (constipation, diarrhea, bloating, abdominal pain) could be used to identify homogeneous groups of patients regardless the Rome criteria.

In this observational study, 1729 consecutive ambulatory FBD patients (73% females) completed the Rome III questionnaire and 10-point Likert scales for the intensity of constipation, diarrhea, bloating and abdominal pain during the week preceding the consultation.

A Gaussian mixture model was used to aggregate patients according to the cardinal signs of FBD without prior information. A classification tree using the intensity of the cardinal signs of FBD was proposed. The comparison of these two classifications were analyzed using ANOVA and logistic regression.

**Results:** According to the Rome criteria, 707 patients (41%) were classified as having irritable bowel syndrome (IBS) (234 (14%) IBS-Constipation, 225 (13%) IBD-Diarrhea, 126 (7%) SII-Mixed, 122 (7%) IBS-Nonspecific), 374 (22%) functional constipation, 215 (12%) functional diarrhea, 101 (6%) bloating and 194 (11%) non-specific.

According to the intensity of cardinal signs of FBD, patients were divided into 8 clusters named according to their main symptomatology: "painful constipation" (285, 16%), "mild pain constipation" (236, 14%), "painful diarrhea" (166, 10%), "mild-pain diarrhea" (178, 10%), "mixed transit" (126, 7%), "bloating" (255, 15%), "abdominal pain" (89, 5%) and "non-specific" (394, 23%).

The study of the relationship between the Rome III classification and this new classification showed that IBS-Constipation is associated with "painful constipation" ( $P < 0.01$ ), SII-Diarrhea with "painful diarrhea" ( $P < 0.01$ ) and "mild pain diarrhea" ( $P < 0.01$ ), SII-Mixed with "mixed transit" ( $P < 0.01$ ), SII-nonspecific with "bloating" ( $P < 0.01$ ), functional constipation with "painful constipation" ( $P < 0.01$ ) and "mild pain constipation" ( $P < 0.01$ ), functional diarrhea with "mild pain diarrhea" ( $P < 0.01$ ) and "non-specific" ( $P < 0.01$ ), bloating with "bloating" ( $P < 0.01$ ) and nonspecific ( $P < 0.01$ ), non-specific FBD with "non-specific" ( $P < 0.01$ ) and functional abdominal pain with "bloating" ( $P < 0.01$ ) and "abdominal pain" ( $P < 0.01$ ).

**Conclusion:** This study conducted in a large FBD population shows that the symptomatic phenotype is partially associated with the Rome III criteria. This new classification can be used in addition with the Rome criteria to specify these criteria in clinical or therapeutic studies.

**Disclosure:** Nothing to disclose

## P1902 PROSPECTIVELY RECORDED GASTROINTESTINAL SYMPTOM LEVELS DISCRIMINATE GASTROINTESTINAL DISORDERS FROM HEALTH AND ARE SUPERIOR TO A VALIDATED WIDELY APPLIED SYMPTOM BURDEN MEASURE

**Contact E-Mail Address:** mike.jones@mq.edu.au

**Introduction:** Accurate measurement of gastrointestinal symptoms is essential for understanding the severity of disease. Traditionally, gastrointestinal symptoms have been recorded through patient recall of symptoms elicited through standardized instruments, such as the widely used gastrointestinal symptom rating scale<sup>1</sup> (GSRS). Recently our group has shown that symptoms as recalled differ substantially from those elicited prospectively through a diary<sup>2</sup>. Recall questionnaires also attempt to elicit average level of symptoms but generally make no attempt at capturing within-subject variation in symptom levels. Since it is known that functional gastrointestinal disorders (FGIDs) are relapsing and remitting disorders it would be clinically appropriate to also measure the variation in symptoms over time within patients.

**Aims & Methods:** This study set out to understand the relationship between gastrointestinal symptom burden as measured through the GSRS and as measured prospectively via a smart phone app using a method known as ecological momentary assessment<sup>3</sup> (EMA) in which individuals are asked symptom and other questions once per day over a 14-day period. We also sought to understand the incremental utility of EMA in differentiating gastrointestinal health from disorder versus the GSRS. EMA measures included current mood, gastrointestinal and non-gastrointestinal pain and interference in daily activities, all measured on a 7-point scale, where higher is better mood or worse symptoms. Average level of each measure was calculated across the week along with the within-person variance. Explained variance in GSRS was by calculated through multiple linear regression (Table 1) with bootstrapped statistical inference due to violation of the Normality assumption. Discrimination of GI disorder from health utilised unconditional logistic regression.

**Results:** 28 GI symptomatic and 27 asymptomatic individuals were recruited from the community. Symptomatic individuals reported higher average symptom scores and greater temporal variability in scores than asymptomatic individuals (Table 1). They also reported higher (better) average mood scores but did not differ in mood variability. The EMA-derived measures of average symptom and mood scores together with within-individual temporal variation in scores accounts for 64% of the variance in GSRS scores. The same EMA-derived measures provided good discrimination between GI symptomatic and asymptomatic groups with an AUC of 0.90. Adding GSRS score to the model increased the AUC to 0.92, indicating little incremental value over and above the EMA-derived measures. GSRS score alone yields an AUC of 0.84.

Measure	Symptomatic mean (SD)	Asymptomatic mean (SD)	Regression b (SE) p
GI pain mean	2.52 (1.30)	0.82 (1.35)	1.70 (0.37) <.001
GI pain SD	2.04 (0.83)	0.90 (0.95)	1.14 (0.23) <.001
GI pain interference mean	1.35 (1.15)	0.36 (0.61)	0.99 (0.25) <.001
GI pain interference SD	1.60 (0.82)	0.55 (0.72)	1.05 (0.20) <.001
Non-GI pain mean	2.56 (1.43)	0.90 (1.36)	1.66 (0.37) <.001
Non-GI pain SD	1.91 (0.78)	0.93 (1.10)	0.98 (0.25) <.001
Non-GI pain interference mean	1.39 (1.19)	0.47 (0.85)	0.93 (0.27) .001
Non-GI pain interference SD	1.56 (0.88)	0.66 (1.07)	0.90 (0.27) .001
Current mood mean	5.20 (1.14)	6.35 (1.59)	-1.16 (0.37) .002
Current mood SD	1.73 (0.68)	1.67 (0.88)	0.07 (0.21) 0.7
GSRS	3.30 (1.12)	1.90 (0.96)	1.39 (0.26) <.001

[Table 1. Discrimination of GI symptomatic from asymptomatic individuals]

**Conclusion:** EMA-derived measures of symptoms and mood provide superior discrimination of GI disorder from health compared with a widely used validated recall questionnaire, and add useful quantification of the variation that patients experience over time while avoiding potential recall bias. This makes EMA a useful tool worth considering in research and clinical practice.

## P1903 MAINTAINING WORK LIFE UNDER THREAT OF SYMPTOMS: A GROUNDED THEORY STUDY OF WORKING AND LIVING WITH IRRITABLE BOWEL SYNDROME

Frändemark A.<sup>1</sup>, Törnblom H.<sup>1,2</sup>, Simrén M.<sup>1,3</sup>, Jakobsson S.<sup>3,4</sup>

<sup>1</sup>Institute of Medicine, Sahlgrenska Academy, University of Gothenburg, Dept of Internal Medicine and Clinical Nutrition, Gothenburg, Sweden, <sup>2</sup>Sahlgrenska Academy Faculty of Medicine, Dept of Gastroenterology and Hepatology, Gothenburg, Sweden, <sup>3</sup>Centre for Person-Centered Care (GPCC), Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden, <sup>4</sup>Institute of Health and Care Sciences, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

**Contact E-Mail Address:** asa.frändemark@gu.se

**Introduction:** Irritable Bowel Syndrome (IBS) is a highly prevalent functional gastrointestinal disorder. Earlier studies have shown that IBS can affect work life, limiting ability to perform at work and leading to absenteeism. However, there are few studies focusing on work experiences based on patients' narratives. Further, factors that influence performance have not yet been fully explored.

**Aims & Methods:** The aim of this study was to construct a theory for how persons with IBS maintain their work life. A qualitative study was conducted using constructivist grounded theory. Semi-structured interviews with 15 women and 8 men with IBS were conducted. The participants were recruited at an outpatient clinic specialized in functional gastrointestinal disorders and were between 26 and 64 years of age. Of the participants, 5 had mild IBS, 10 had moderate IBS and 8 had severe IBS. Fourteen worked full-time, 6 worked part-time and 3 were currently on sick leave. In accordance with grounded theory, the data collection and analysis were conducted simultaneously. The interviews were transcribed verbatim and coded line-by-line, incident-by-incident and thereafter focused coding was done. From the data and codes, categories were generated. Finally, a core category was constructed.

**Results:** A core category, *balancing work life and living with IBS*, was developed and interpreted as being constituted of four categories illustrating the process of maintaining work life while constantly *being under threat of symptoms*. Persons with IBS coped with being under threat of symptoms by *restricting impact* of IBS on work by using strategies and upholding daily routines; *being ahead* by exerting control over work life; and *reconciling* IBS with work life, which was understood as a successful outcome from being ahead and restricting impact, but also influenced by the individual's outlook on life. These were ongoing processes that took place both during and outside of work hours, and that served to limit the influence of IBS on work by symptoms being milder, perceived as less frequent, or not as bothersome. *Adjusting* to other people in work life interfered with the strategies of being ahead, restricting impact and reconciling, that aimed to limit influence of IBS on work, leaving persons with IBS more susceptible to symptoms.

**Conclusion:** This study deepens the understanding of the work situation of persons with IBS, and the impact of IBS on work. Health care professionals can use the results of this study in the patient meeting when discussing IBS in regard to work ability and sick leave. The results imply that although balancing work life with living with IBS can be a struggle, there are ways for persons with IBS to reduce impact on work on several different levels.

**Disclosure:** Nothing to disclose

## P1905 DETERMINATION OF SYMPTOM SEVERITY, QUALITY OF LIFE, AND WORK PRODUCTIVITY IN PRIMARY CARE IBS PATIENTS

Van den Houte K.<sup>1</sup>, Carbone F.<sup>2</sup>, Tack J.<sup>3</sup>

<sup>1</sup>KULeuven, TARGID, Leuven, Belgium, <sup>2</sup>University of Leuven, Gastroenterology, Leuven, Belgium, <sup>3</sup>University of Leuven, University Hospital Gasthuisberg, Gastroenterology, Leuven, Belgium

**Contact E-Mail Address:** karen.vandenhoute@kuleuven.be

**Introduction:** Irritable bowel syndrome (IBS) is highly prevalent in primary care, although characteristics of patients diagnosed with IBS by general practitioners, still remain to be studied. Therefore, the objective of this study was to evaluate IBS symptom severity, quality of life, and work productivity in IBS patients diagnosed by general practitioners.

**Aims & Methods:** IBS patients, included by 62 general practitioners, completed questionnaires evaluating demographics, stool types, Rome IV criteria, IBS symptom severity (IBS-SSS), quality of life (IBS-QoL), anxiety (GAD), depression (PHQ9), somatization (PHQ15), and work productivity and activity impairment (WPAI). Patients were subdivided into severity categories based on their IBS-SSS scores: normal < 75, mild 75-175, moderate 175-300, severe ≥300.

**Results:** 299 primary care IBS patients (75% females, mean age 42±0.9 years, mean BMI 24±0.3) were included and characterized by the following stool types: constipation (22%), diarrhea (26%), mixed stool type (40%), and normal (11%). Normal, mild, moderate, and severe IBS-SSS were represented in 3, 17, 40, and 40% of all patients respectively. Patients with severe IBS-SSS differed significantly from the other IBS-SSS subgroups in QoL, GAD, PHQ9, PHQ15, and WPAI with all p-values lower than 0.05. Symptom severity scores were positively correlated with IBS-QoL (R=0.55), GAD (R=0.35), PHQ9 (R=0.38), PHQ15 (R=0.60), and WPAI (R=0.46).

The Rome IV criteria were fulfilled by 70 percent of all patients (Rome+). Rome+ patients were characterized by a significantly higher IBS-SSS score (290±6 vs. 194±10, p<0.0001), IBS-QoL (35±1.2 vs. 23±1.5, p<0.0001), GAD (7±0.4 vs. 5±0.4, p=0.0002), PHQ9 (7±0.3 vs. 5±0.5, p=0.005), and PHQ15 (13±0.3 vs. 10±0.5, p<0.0001) compared to Rome-. In addition, the work productivity was more affected in the Rome+ group (3.1±0.2) compared to Rome- (1.7±0.3, p=0.0004).

**Conclusion:** In IBS patients, diagnosed by general practitioners, more than two thirds fulfill the Rome IV criteria. Symptom severity, quality of life, anxiety, depression, somatization, and work productivity were significantly different between the Rome + and Rome - group and the group with severe IBS-SSS compared to normal, mild, and moderate IBS-SSS.

## P1906 USEFULNESS OF DIRECT CLIPPING OF THE BLEEDING SOURCE OF COLONIC DIVERTICULAR HEMORRHAGE

Kishino T.

Nara City Hospital, Center for Digestive and Liver Disease, Nara, Japan

**Contact E-Mail Address:** t-kishino@nara-jadecom.jp

**Introduction:** The current standard treatment for diverticular hemorrhage is endoscopic hemostasis by clipping, endoscopic band ligation (EBL), or injection therapy. EBL has been used more frequently than clipping because the early recurrent bleeding rate after EBL is lower than that after clipping. However, adverse events, such as diverticulitis and perforation, after EBL have been reported, albeit rarely. On the other hand, the endo-clip approach offers the theoretical advantage of causing less injury to adjacent tissues. However, the efficacy of endoclips for diverticular hemorrhage is unclear.

**Aims & Methods:** To retrospectively evaluate the safety and efficacy of endoclips versus EBL for the treatment of colonic diverticular hemorrhage.

**Study population:** At Nara City Hospital, 93 patients with colonic diverticular hemorrhage with stigmata of recent hemorrhage (SRH) were treated using endoclips or EBL between January 2013 and December 2018. SRH was defined as a densely adherent clot despite vigorous irrigation, a non-bleeding visible vessel, or active hemorrhage visualized on colonoscopy.

**Colonoscopic examinations:** All patients received standard supportive medical care for lower gastrointestinal bleeding, including hemodynamic monitoring and fluid resuscitation. Packed red blood cells were transfused to correct severe anemia if necessary. Bowel preparation with polyethylene glycol or glycerin enema was performed before colonoscopic examinations. All patients underwent colonoscopy using water-jet scopes with

a tip hood (PCF-Q260AZI or GIF-Q260 J: Olympus Optical Company Ltd, Tokyo, Japan), and a water-jet system was used for vigorous irrigation. To improve endoscopic visualization of colonic diverticula, we observed the colonic diverticulum under full water immersion (Digestive Endoscopy 2018; 30: 121-122) since 2016.

**Endoscopic hemostasis with endoclips:** We classified the patients treated by endoclips into the direct clipping group and indirect clipping group. Endoclips were placed directly onto the vessel if technically feasible (direct clipping group). When direct placement of endoclips onto the vessel was not possible, the diverticulum was closed in a zipper fashion (indirect clipping group).

**Endoscopic hemostasis with endoscopic band ligation:** At our institution, we introduced EBL for colonic diverticular hemorrhage in February 2016. After the site of bleeding had been marked with endoclips, the colonoscope was removed and subsequently reinserted after attachment of a band-ligator device. The diverticulum was pulled via suction into the cup of the endoscopic ligator, and the elastic O-ring was released.

**Evaluation items:** Rate of early rebleeding within 30 days after initial treatment, and complications were retrospectively evaluated.

**Results:** Of the 93 patients, 34, 28, and 31 were in the direct clipping group, indirect clipping group, and EBL group, respectively. The rate of early rebleeding in the direct clipping, indirect clipping, and EBL groups was 5.9% (2/34), 35.7% (10/28), and 6.5% (2/31), respectively (p=0.001: direct clipping group vs indirect clipping group, p=1: direct clipping group vs EBL group, Chi-squared test). No complications occurred in all groups. All early rebleeding cases in the direct clipping group stopped with EBL.

**Conclusion:** Direct clip placement is acceptable as the first treatment choice for colonic diverticular hemorrhage. When direct placement of endoclips is not possible, EBL should be performed instead of indirect clipping.

**Disclosure:** Nothing to disclose

## P1907 RISING PREVALENCE OF COLONIC DIVERTICULOSIS IN A MULTI-ETHNIC ASIAN COUNTRY

**Introduction:** Singapore is a multi-ethnic country that has undergone rapid development over the last few decades, with increasing influence of western culture, and also faces a rapidly aging population. However, recent data on the prevalence of colonic diverticulosis is lacking.

**Aims & Methods:** This study aims to evaluate the prevalence of colonic diverticulosis in Singapore and determine its risk factors and association with common gastrointestinal symptoms. We also aim to evaluate any racial differences amongst the three main races in Singapore - the Chinese, Malays and Indians.

We retrospectively reviewed data obtained from the endoscopy database for colonoscopies performed between 2006 to 2016 in National University Hospital Singapore. Colonoscopies were included if they had at least one of the following indications: screening, diarrhea, abdominal pain and constipation. Patients below the age of 21, or with a history of colorectal cancer, colonic surgery, inflammatory bowel disease and Lynch syndrome were excluded. Patients with incomplete or repeated colonoscopies done during the study period were also excluded.

**Results:** We reviewed 55,679 colonoscopies from 2006 to 2016. After excluding 35,284 colonoscopies, a total of 20,395 were included. The overall prevalence of diverticulosis was 19.6%, and its prevalence has progressively increased from 2006 to 2016 (14.9% vs 23.9%, adjusted trend<0.001). Patients with diverticulosis were older and had higher BMI. Diverticulosis was significantly more prevalent in Chinese compared to Malay and Indian races (20.5% vs 18.9% vs 15.5%, p<0.05), and in males compared to females (21.5% vs 17.6%, p<0.05). There was no significant trend difference in terms of age, ethnicity and gender distribution of colonic diverticulosis patients recruited from 2006 to 2016. Right-sided diverticulosis was more common than left-sided or pan-diverticulosis (16.2% vs 8.3% vs 4.8%, p<0.05). Multivariate regression analysis revealed age (odds ratio [OR],

1.054; 95% confidence interval [CI], 1.048-1.059), BMI (OR, 1.049; 95% CI, 1.035-1.063), male gender (OR, 1.269; 95% CI, 1.135-1.419), Chinese ethnicity (OR, 1.307; 95% CI, 1.080-1.582), alcohol consumption (OR, 1.227; 95% CI, 1.012-1.487), presence of adenoma (OR, 1.168; 95% CI, 1.032-1.322) and abdominal pain symptom (OR, 1.218; 95% CI, 1.055-1.408) as independent risk factors for colonic diverticulosis. Constipation was negatively associated with diverticulosis (OR, 0.698; 95% CI, 0.573-0.852).

Variable	Odds Ratio (OR)	95% Confidence Interval (CI)	P-value
Age	1.054	1.048-1.059	<0.001
BMI	1.049	1.035-1.063	<0.001
Male Gender	1.269	1.135-1.419	<0.001
Ethnicity (Chinese)	1.307	1.080-1.582	0.006
Alcohol consumption	1.227	1.012-1.487	0.037
Presence of adenoma	1.168	1.032-1.322	0.014
Diarrhea symptom	1.096	0.899-1.336	0.366
Constipation symptom	0.698	0.573-0.852	<0.001
Abdominal pain symptom	1.218	1.055-1.408	0.007

[Multivariate logistic regression for association between colonic diverticulosis and risk factors]

**Conclusion:** The overall prevalence of colonic diverticulosis in Singapore was 19.6% with a significant increase of 9.0% from 2006 to 2016. There were no significant differences in age, gender and ethnicity distribution of patients with diverticulosis over the years suggesting that there may be other risk factors that contribute to the increasing prevalence of diverticulosis. The most common form of diverticulosis in our Singaporean cohort remained predominantly right-sided. Age, male gender, Chinese ethnicity, elevated BMI, alcohol consumption, colonic adenoma and abdominal pain symptom are associated with diverticulosis.

**Introduction:** Diverticulosis of the colon is the most frequent anatomical alteration detected during colonoscopy. The endoscopic classification called “DICA” (Diverticular Inflammation and Complication Assessment)

has been recently developed in order to have an objective endoscopic description of the colon harbouring diverticula. Retrospective study found a significant relationship between severity of DICA score and clinical and demographic characteristics of people having diverticulosis/diverticular disease.

**Aims & Methods:** Aim of this multicentre, international, prospective study was to assess the predictive value of this classification in term of acute diverticulitis and surgery occurrence on a 1-year observational follow-up period.

2215 prospective patients at the first diagnosis of diverticular disease were enrolled after exclusion of radiological signs of acute diverticulitis; inflammatory bowel diseases; ischemic colitis; prior colonic resection; patients with severe liver failure (Child-Pugh C) or severe kidney failure; pregnant women; patients who are currently using or who have received any laxative agents or mesalazine or probiotics or antibiotics < 2 weeks prior to the enrollment; inability to comply with study protocol and to give informed consensus to the procedure; patients with or history of cancer, of any origin, within 5 years before enrollment; history of alcohol, drug, or chemical abuse. All patients were classified according to DICA classification.

**Results:** 1377 (62.15%) patients were classified as DICA 1, 599 (27.04%) as DICA 2, and 239 (10.80%) as DICA 3.

The risk of acute diverticulitis occurrence/recurrence, as well as the risk of surgery, were significantly linked to the severity of DICA score at entry. Overall, acute diverticulitis occurred in 79 (3.6%) patients: it occurred in 17 (1.38%) DICA 1, 30 (5.11%) DICA 2 and 30 (12.82%) DICA 3 patients respectively ( $p < 0.0001$ ).

Overall, surgery occurred in 29 (1.3%) patients: it occurred in 2 (0.14%) DICA1, 11 (1.87%) DICA 2 and 16 (6.83%) DICA 3 patients respectively ( $p < 0.0001$ ).

**Conclusion:** The 1-year results of this prospective study seems to confirm that DICA endoscopic classification has a significant prognostic role on the risk of acute diverticulitis occurrence/recurrence and on the risk of surgery in people having colonic diverticulosis detected at colonoscopy.

**Disclosure:** Nothing to disclose

## P1909 COLORECTAL CANCER IN DIVERTICULOSIS PATIENTS: LOCATION AND DIAGNOSIS RATE AS COMPARED TO A MATCHED CONTROL GROUP

**Introduction:** Diverticulosis is considered one of the most common and burdensome GI disorders. Several observations hold that certain epidemiological and etiological characteristics are shared between colonic diverticulosis and colorectal cancer (CRC), suggesting a possible association between these two conditions. This connection is of paramount clinical relevance, as several reports demonstrated that patients with diverticular disease have a higher risk of harboring CRC as well as adenomas. However, data are still controversial and inconclusive, as other recent studies failed to confirm this association. Unraveling the dilemma appears to be clinically relevant, as tailored screening or surveillance intervals for CRC and polyp follow up could be of benefit in patients with diverticular disease.

**Aims & Methods:** The present study aims to compare the CRC detection rate and location as well as polyp detection rate between patients with diverticular disease and a matched group. In this retrospective single center study, patients diagnosed with diverticulosis on colonoscopy over a 10-year period were included. Each diverticulosis patient was matched with 1 control by age, gender, setting (inpatient/outpatient) and procedure's indication. CRC and polyp detection rates were recorded and compared between the groups before and after adjustment for bowel preparation quality and exam completion (cecal intubation).

**Results:** A cohort of 13680 patients (6840 patients with diverticulosis and 6840 matched controls) were included. Diverticulosis was located mainly to the sigmoid and left colon (88.5%). The CRC diagnosis rate was lower in the diverticulosis group (2% vs. 4.5%, odds ratio=0.472,  $p < 0.001$  and 95%CI=0.382-0.584). Moreover, location of CRC was unrelated to diverticulosis location, as more CRCs in the diverticulosis group were located

proximal to the splenic flexure as compared to control group (42.5% vs 29.5% respectively;  $P=0.03$ ). Diverticulosis, however, was associated with increased polyp detection rate compared to controls (30.5% vs. 25.5%; odds ratio=1.2,  $P < 0.001$  and 95%CI=1.11-1.299). These trends were kept also after multivariate analysis.

**Conclusion:** Diverticulosis was not linked with increased risk for CRC, nor was its location correlated with CRC location.

**Disclosure:** Nothing to disclose

## P1910 CLINICAL FEATURES AND DRUG USE ASSOCIATED TO DIVERTICULAR DISEASE COMPLICATIONS: RESULTS FROM THE REMAD REGISTRY

**Introduction:** A variety of drugs have been suggested to act as potential risk factors or protective against complications in diverticular disease (DD).

**Aims & Methods:** Aim of this study was to assess the role of clinical features and drug use potentially predisposing to [non-steroidal anti-inflammatory drugs (NSAIDs), antiplatelets, anticoagulants] or protective against [statins] the development of complications such as acute diverticulitis (AD) or diverticular bleeding (DB) in a cohort of patients with DD.

The REMAD Registry (Diverticular Disease Registry) is an ongoing 5-year prospective, observational, cohort study, involving 47 centres (Trials.gov: NCT03325829).

For the purpose of this analysis, patients were categorized in: a) patients without history of DD complications; b) patient with past AD (without diverticular bleeding); c) patients with past DB.

Demographic, clinical features and use of drugs assumed before the DD diagnosis [frequent use of NSAIDs (at least once a week: aspirin, NSAIDs, COX-2 inhibitors), antiplatelets (aspirin, ticlopidine, clopidogrel), anticoagulants (heparin, warfarin, factor X and thrombin inhibitors), and statins] were collected in order to identify factors associated with DD complications.

**Results:** Out of 1217 patients (45.7% female; 75.4% age  $\geq 60$  yrs; 15.9% BMI  $\geq 30$  kg/m<sup>2</sup>; 14.4% Charlson index  $\geq 3$ ; 21% family history for DD), 998 (82%) had no history of DD complications, 194 (15.9%) had a past episode of AD and 25 (2.1%) had a past DB.

Compared to patients with no history of DD complications, age  $\geq 60$  yrs was inversely (OR=0.48; 95%CI:0.34-0.67) whereas first degree family history for DD was positively (OR=1.68; 95%CI:1.17-2.41) associated to patients with past AD. On the other hand, age  $\geq 60$  yrs (OR=4.30; 95%CI:1.16-15.94) and Charlson index  $\geq 3$  (OR=2.58; 95%CI:1.07-6.23) were associated to history of past DB.

Regarding drugs potentially predisposing to DD complications, no significant differences were found regarding assumption of frequent NSAIDs and chronic antiplatelets in mono or dual therapy [5.3%, 2.6%, 8.3% (NSAIDs:  $P > 0.05$ ) and 8.7%, 15.8%, 29.2% (antiplatelets:  $P > 0.05$ ) in patients without DD complications, past AD and past DB, respectively]. By considering only ticlopidine assumption, it was significantly associated with past history of AD (3.2%) compared with patient without DD complications (0.9%) (OR 4.0; 95%CI:1.25-12.85).

Anticoagulants were more frequently taken in patients with past DB (12.5%) compared to patients with past AD (2.1%) ( $P=0.035$ ); particularly warfarin use, was associated to patients with past DB (12.5%) compared to both patients without history of DD complications (2.4%; OR 4.86; 95%CI:1.32-17.87) and patients with past AD (1%; OR 9.53; 95%CI: 1.1-79.10). Regarding drugs potentially protective against DD complications, no significant differences were found regarding use of statins (15.2%, 13.5%, 20.8% in patients without DD complication, past AD and past DB respectively;  $P > 0.05$ ).

**Conclusion:** This Registry study showed that some distinctive clinical features distinguish patients with two different kinds of DD complications: younger age and first degree family history for DD were associated to AD

whereas older age and higher Charlson index were associated to DB. Regarding drugs, since ticlopidine use was associated with past AD whereas use of anticoagulants (particularly warfarin) was associated with past DB, clinicians should pay particular attention at complications in using drugs in DD patients.

**Disclosure:** Nothing to disclose

## P1911 DEVELOPMENT AND VALIDATION OF DICS (DIVERTICULAR CLINICAL SCORE) FOR SYMPTOMATIC UNCOMPLICATED DIVERTICULAR DISEASE IN A PROSPECTIVE PATIENTS COHORT

Lahat A.<sup>1,2</sup>, Ben-Horin S.<sup>3</sup>

**Introduction:** Following an attack of acute diverticulitis (AD) many patients suffer from persistent symptoms and impaired quality of life. These patients are diagnosed as suffering from symptomatic uncomplicated diverticular disease (SUDD). Few treatment strategies exist in order to improve patients' symptoms. However, there is no validated clinical score for standardized patients' assessment.

**Aims & Methods:** Our aim was to develop and validate a simplified easy to use diverticular clinical score. Data from long term prospective study of 261 patients AD was reviewed. Patients' most relevant clinical symptoms were recorded and processed. A simplified questionnaire based on these clinical symptoms and relevant validated questionnaires for pain assessment (VAS) and inflammatory bowel disease activity (IBD control) was designed. Validation was performed using a pilot study focus group containing 20 patients suffering from SUDD after a documented attack of (AD). Personal interview with all patients was conducted using structured cognitive interview questions. Thereafter, a validation cohort consists of 48 patients suffering from SUDD post AD attack was established. Questionnaire's results were compared to physicians' global assessment for disease severity obtained during the visit and to inflammatory markers. questionnaire consists of 9 basic questions, assessing frequency, duration and severity of the abdominal pain, additional symptoms, missed plans activities, mood disturbances and desire for treatment.

**Results:** A total of 52 questionnaires were filled by 48 patients. Correlation between single questions and total score to disease severity and inflammatory markers is shown in table 1. Correlation matrix demonstrates a very strong correlation between the total score of the questionnaire and the elevation of inflammatory markers ( $p = 0.84$ ).

Cronbach's alpha for measuring internal consistency was 0.91. The area under a ROC curve examining the overall ability of the test to discriminate between patients with/without active disease produced AUC = 0.989.

	Abdominal pain-frequency	Abdominal pain-duration	Abdominal pain-severity	Additional symptoms	Missed activities	Total score	Disease activity	Inflammatory markers
Abdominal pain-frequency	1	0.77	0.93	0.74	0.88	0.94	0.9	0.85
Abdominal pain-duration	0.77	1	0.82	0.56	0.68	0.8	0.74	0.7
Abdominal pain-severity	0.93	0.82	1	0.7	0.85	0.95	0.9	0.86
Additional symptoms	0.74	0.56	0.7	1	0.67	0.82	0.57	0.53
Missed activities	0.88	0.68	0.85	0.67	1	0.85	0.92	0.88
Total score	0.94	0.8	0.95	0.82	0.85	1	0.86	0.84
Disease activity	0.9	0.74	0.9	0.57	0.92	0.86	1	0.96
Inflammatory markers	0.85	0.7	0.86	0.53	0.88	0.84	0.96	1

[Correlation between single questions and total score to disease severity and inflammatory markers]

**Conclusion:** Patients suffering from SUDD post AD express a wide range of symptoms. Following further research the new DICS questionnaire may help in monitoring those symptoms, facilitate patients' stratification and support therapeutic decisions.

**Disclosure:** Nothing to disclose

## P1912 THE PROGNOSTIC VALUE OF A NEW ENDOSCOPIC CLASSIFICATION FOR DIVERTICULAR DISEASE: DICA (DIVERTICULAR INFLAMMATION AND COMPLICATION ASSESSMENT)

**Introduction:** Colonic Diverticulosis is one of the most common anatomic alterations found in the clinical practice. This condition has 60% incidence in the population over 60 years old. About 20% of patients with this condition will develop Diverticular Disease, and 5% of them will evolve into Diverticulitis. Recently the first endoscopic classification of Diverticular Disease, useful for the clinical management of those patients, has been proposed: DICA.

**Aims & Methods:** The aim of the study is to analyze the distribution of the severity according to DICA score amongst patients with diagnosis of colonic Diverticulosis in relation to age, gender, the occurrence-recurrence of diverticulitis, other associated complications, and the necessity of surgical procedures, as well as the duration and the economic cost of the hospitalization. We analysed and classified 5635 cases identified at colonoscopy according to the DICA score, in the period between January 2012 and April 2018. Hospital discharge forms for all patients with hospital admissions for diverticular disease or its complications during the same time interval were retrieved.

**Results:** 69.9% of patients had a DICA score of 1, while 21% and 9.1% of patients have a DICA 2 or DICA 3 score, respectively. Aging increased the frequency and severity of diverticular disease (mean ages for each DICA score being 65.8 years, 67.0 years, and 69.6 years for DICA 1, 2, and 3, respectively). Higher severity scores were found in female patients (DICA1=44.6%, DICA2=50.8%, DICA3=57.8%). The occurrence of overall complications was 5.4%, being 3.5%, 7.7% and 14.2% for DICA scores 1, 2, and 3, respectively. Diverticular disease was not complicated diverticular disease (DICA1=1%, DICA2=1.8%, DICA3=3.5%); not complicated diverticulitis (DICA1=2.1%, DICA2=4.7%, DICA3=6.4%); bleeding in diverticulitis (DICA1=0.4%, DICA2=1.2%, DICA3=4.5%); diverticular perforation (DICA1=0.0%, DICA2=0.1%, DICA3=0.4%). The complications that needed a surgical procedure were for DICA1 about 0.2%, for DICA2 0.8% and for DICA3 2.5%. As well, the average of the occupant days in the hospital and the cost, respectively, was for DICA1, 8.5 days and 2300 Euro, for DICA2, 9.5 days and 3080 Euro, for DICA 3, 13 days and 4090 Euro.

**Conclusion:** In conclusion, the majority of the patients with Diverticular Disease belonged to the severity score DICA1 and the patients classified with DICA3 were mainly female and older than 69 years old. The study confirmed the prognostic value of the endoscopic classification DICA since the occurrence of complication resulted in a statistically significant relation with the score DICA3. DICA classification was able to discriminate, based on endoscopic records, the patients that could develop complications for Diverticular Disease.

**Disclosure:** Nothing to disclose

## P1913 EVALUATION OF RISK FACTORS FOR COLONIC DIVERTICULOSIS IN EASTERN AND CENTRAL EUROPEAN POPULATION

**Contact E-Mail Address:** j.kupcinskis@yahoo.com

**Introduction:** Colonic diverticulosis (CD) is a frequent condition of the large intestine and an important cause of hospital admissions in Western and industrialized nations [1, 2, 3]. Several factors have been associated with increased risk of CD and its related complications including advanced age, obesity, physical inactivity, and a low-fiber diet [4-8]. Nevertheless, reported data are conflicting and high-powered comprehensive analysis on different dietary and lifestyle factors linked with CD is lacking [1, 4]. Therefore, we set out to investigate the association between potential risk factors and the prevalence of CD using inclusive data from a colonoscopy-based cross-sectional study in eastern and central European population.

**Aims & Methods:** Study cohort was conducted at two tertiary referral centers in Germany and Lithuania (the Saarland University Medical Center in Homburg and the University Hospital of Kaunas). The local Ethics Committee and National Data Protection Committee approved the study. Adult participants underwent routine colonoscopy and completed a detailed questionnaire on diet, bowel habits and various lifestyle aspects. We considered multiple risk factors for diverticulosis including diet (portion size, amount of meals per day, amount of fluids, amount of fish and red meat per week etc.), frequency of bowel movements, various symptoms of constipation, tobacco use, alcohol use, nonsteroidal anti-inflammatory drug (NSAID) use, education, obesity and gender. Link between risk factors and CD was assessed using logistic regression and standard hypothesis testing methods where pertinent.

**Results:** The study included 1333 patients, 634 (47.6%) males with a mean age of 61.89 years and 698 females with a mean age of 62.95 years. CD was diagnosed in 858 (64.4%) of patients. Univariate analysis revealed that age (OR 1.073, 95% CI, 1.062-1.085,  $p < 0.05$ ) and obesity (OR 1.529, 95% CI, 1.155-2.025,  $p = 0.003$ ) were associated with colonic diverticulosis in accordance with prior findings. Our analysis also revealed new risk factors related with CD including frequency of bowel movements (OR 0.131, 95% CI, 0.040-0.426,  $p = 0.001$ ) and rectal tenesmus (OR 1.922, 95% CI, 1.19-3.104,  $p = 0.008$ ). We used a multivariate analysis to re-affirm obtained results. Univariate analysis also showed a significant association between CD and education ( $p = 0.004$ ), working night shifts ( $p < 0.05$ ), amount of meals per day ( $p = 0.006$ ) and previous abdominal surgery ( $p = 0.028$ ); however, these associations were not significant in the multivariate logistic regression. Likewise, we did not find a significant association between CD and gender, NSAID use, alcohol and tobacco use, various symptoms of constipation, education and different dietary aspects.

**Conclusion:** Our analysis using large population cohort establish older age, obesity, frequency of bowel movements and rectal tenesmus as the main risk factors associated with CD.

**Introduction:** Several evidences suggest that diet has a critical role in the pathophysiology of diverticular disease (DD). However, no data are available regarding nutritional status of patients with DD and diverticulosis.

**Aims & Methods:** The aim of this study was to investigate the nutritional characteristics of patients with DD and diverticulosis.

Diverticular Disease Registry (REMAD) is an ongoing 5-years prospective, observational, multicentre, cohort study, involving 47 Centers (Trials.gov:NCT03325829). Patients were categorized according to the following criteria: i) Diverticulosis: presence of diverticula in the absence of abdominal symptoms; ii) Symptomatic uncomplicated diverticular disease (SUDD): recurrent abdominal symptoms as abdominal pain and/or changes in bowel habit, attributed to diverticula in the absence of overt inflammation; iii) Previous diverticulitis (PD): patients who experienced at least 1 episode of diverticulitis in the past.

At the baseline, 1217 [45.7% female, age 66±10 y] patients were enrolled. 705 (58%), 300 (24.7%) and 212 (17.3%) patients fulfilled criteria for diverticulosis, SUDD and PD, respectively.

All patients who were asked to fill in a food frequency questionnaire to assess energy and nutritional intake. In order to compare results, 100 healthy subjects (HS) were asked fill in food frequency questionnaire. WinFood software was used for the estimation of nutrient and caloric intake.

**Results:** 332 patients with diverticulosis, 147 with SUDD and 83 with PD accepted to fill in self-administered nutritional questionnaire. In order to reduce age-related differences, 205 patients with diverticulosis, 100 patients with SUDD, 73 with PD and 82 HS were included in the analysis (62.6±8.1, 62.5±8.9, 62.2±9.5 and 62.1±7.5 years, respectively;  $p = 0.965$ ).

Patients with PD and SUDD showed a lower calorie intake compared to patients with diverticulosis and HS (1416±405 and 1582±519 vs 1642±554 and 1778±439 kCal;  $p < 0.001$ ).

Consumption of fat was lower in PD group compared to diverticulosis, SUDD and HS groups (53±18 vs. 60±23, 63±27 and 75±22 g/die;  $p < 0.001$ ), whereas protein consumption was lower in PD group only compared to diverticulosis group (71±22 vs. 83±27 g/die;  $p = 0.007$ ). No differences were observed in terms of carbohydrate consumption among the four groups. Compared to diverticulosis, SUDD and HS groups, patients with PD reported a lower intake of total fiber (18±7, 18±7 and 20±6 vs. 15±6 g/die;  $p < 0.001$ ), soluble fibers (4.4±1.7, 4.5±1.9 and 4.9±1.7 vs. 3.7±1.6 g/die;  $p < 0.001$ ) and insoluble fibers (12±5 12±5 14±4 vs. 10±4 g/die;  $p < 0.001$ ). Lastly, patients with PD also reported a reduced intake of Vitamin A, Vitamin C, Vitamin D, Vitamin E and Polyphenols (data not shown).

**Conclusion:** Our data showed that patients with diverticular disease, in particular patients with PD, have a modified intake of calories, fiber and some macronutrients compared to other groups included HS. Moreover, these patients also showed nutritional deficiencies of molecules with anti-oxidant effects, predisposing to recurrence of diverticulitis. If these changes are the consequence of diet modifications after acute diverticulitis needs to be clarified. These data rise attention on dietary interventions in the management of DD.

<sup>2</sup>Tampere University Hospital Dept. of Pediatrics, Tampere, Finland

**Contact E-Mail Address:** marleena.repo@finnet.fi

**Introduction:** During the past few decades, prevalence of pediatric inflammatory bowel diseases (IBD) has increased and diagnostic methods improved. However, data on the frequency and significance of upper gastrointestinal tract (UGT) findings remain limited.

**Aims & Methods:** Comprehensive medical data of 2395 consecutive children who had undergone gastrointestinal endoscopy with systematic biopsy sampling were collected. Next, IBD patients (n=129) were divided to those with and without histological UGT findings in esophagoduodenoscopy for comparisons of the disease features and treatment response. Control group comprised corresponding children who did not receive any diagnosis in endoscopic and other investigations (n=178).

**Results:** UGT findings were more common in IBD patients than in controls (70% vs 32%,  $p < 0.001$ ). Of IBD patients, 19% had findings in esophagus, 63% in ventricle and 11% in duodenum, while corresponding figures for controls were 18%, 17% and 5%. Fifty-five percent of IBD patients had ulcerative colitis (UC), 34% Crohn's disease (CD) and 11% IBD unclassified (IBD-U). The findings were more common in CD (84%) than in UC (62%) and IBD-U (64%) ( $p=0.038$ ). Four CD patients had UGT granulomas, while the other histological findings did not affect to the IBD diagnostics. IBD patients with and without UGT findings did not differ in gender or age distribution, family history, or laboratory results other than albumin at diagnosis (Table 1). The groups were also comparable in the distribution of colonic involvement and clinical presentation at diagnosis, but children with UGT findings showed more often primary treatment response (83% vs. 64%,  $p=0.024$ ).

	UGT findings N=90		No UGT findings N=39		P value
	N	%	N	%	
Girls	41	45.6	14	35.9	0.308
IBD in relatives	13	14.4	8	20.5	0.391
Positive calprotectin (1)	55	90.2	24	88.9	0.856
	N:o of data	Median (Q1, Q3)	N:o of data	Median (Q1, Q3)	
Age, years	90	13 (11, 14)	39	12 (8, 14)	0.150
ESR, mm	85	18 (12, 34)	37	20 (9, 34)	0.956
Albumin, g/l	56	36 (31, 40)	27	39 (36, 41)	0.020

(1) Data available for 61 patients with and 27 patients without UGT findings.

[Table 1. Baseline characteristics and diagnoses of 129 IBD children with and without upper gastrointestinal tract (UGT) findings.]

**Conclusion:** UGT findings are common in pediatric IBD, especially in CD patients and in ventricle and, in some cases, may affect the diagnosis. However, they do not seem to associate with more severe disease presentation or poorer initial treatment response.

**Disclosure:** Nothing to disclose

**Introduction:** Crohn's disease (CD) is a chronic disease often originating in childhood and requiring daily attention. We aimed to assess the health literacy (HL), quality of life (QoL) and related outcomes in CD patients prospectively followed in the Belgian Crohn's disease registry (BELCRO), compared to young type 1 diabetes mellitus (DM) patients.

**Aims & Methods:** Demographics, clinical data (including Crohn's Disease Activity Index (CDAI) for CD) and validated HL and QoL questionnaires (HLS-EU-Q16, EQ-5D-5L and WPAI) were obtained from young adult CD and DM patients diagnosed in childhood and followed in the BELCRO or Diabetes Clinic UZ Brussel. HL was scored as inadequate (0-8), problematic (9-12) or sufficient (13-16). QoL was dichotomized into 'problems' (EQ-5D levels 2 to 5) or 'no problems' (level 1). Work productivity and activity impairment (WPAI) were scored as percentages. Univariate non-parametric (Mann-Whitney U and chi-squared test) and correlation (Spearman) analyses were performed.

**Results:** In total, 46 CD (median (IQR) age 25 (24-27) years, 63% male) and 50 DM (age 20 (19-22) years, 50% male) patients were included. Median CDAI-score in CD patients was 67 (30-138). Median HL was the same in CD and DM patients (both 14 (11-15),  $p=0.81$ ) with similar proportions of inadequate, problematic and sufficient HL (all  $p>0.05$ ) in CD vs. DM patients. Median QoL was similar in CD and DM patients (both 75 (65-80),  $p=0.47$ ) with similar proportions of problems with mobility, self-care, usual activities and anxiety/depression but a significance for higher pain/discomfort in CD vs. DM patients (53 vs. 32%,  $p=0.04$ ). Median work (10 (0-30) vs. 20 (10-40)%,  $p=0.45$ ) and activity impairment (20 (0-40) vs. 20 (10-40)%,  $p=0.95$ ) was similar in CD and DM. HL correlated positively with QoL in CD and DM (both  $r=0.6$ ,  $p<0.01$ ) and negatively with work impairment in CD ( $r=-0.4$ ,  $p=0.02$ ) but not DM patients. Work impairment for CD correlated with the CDAI ( $r=0.5$ ,  $p=0.01$ ) and number of hospitalizations and surgeries in the last 3 years ( $r=0.4$ ,  $p=0.03$ ). CD patients with recent hospitalization and surgery (22%) had a trend for higher CDAI (107 (58-252) vs. 41 (20-114),  $p=0.07$ ) with lower HL (11.5 (10-12) vs. 14 (11-16),  $p=0.06$ ) and QoL (68 (60-75) vs. 80 (70-85),  $p=0.02$ ) compared to those without.

**Conclusion:** In the studied populations, HL is sufficient in the majority of cases. Despite a comparable QoL and WPAI to DM patients, young CD patients with recent hospitalizations and surgeries have lower QoL and HL than those without. Interventions and programs aimed at improving HL and QoL in children and adolescents with CD should be installed to increase health-related outcomes in early adult life.

**Disclosure:** This study was supported by a grant from MSD to BESPUGHAN.

## P1917 LATENT TUBERCULOSIS TESTING IN PAEDIATRIC PATIENTS WITH INFLAMMATORY BOWEL DISEASE TREATED WITH ANTI-TUMOUR NECROSIS FACTOR AGENTS: DO WE NEED NEW TESTING RECOMMENDATIONS?

Henriques A., Mourão F., Monteiro J., Espinheira M.C., Pinto Pais I., Fernandes R., Campos L., Trindade E., Amil Dias J.  
Unidade de Gastroenterologia Pediátrica, Centro Hospitalar e Universitário de S. João, Porto, Porto, Portugal

**Contact E-Mail Address:** andremartinshenriques@gmail.com

**Introduction:** Anti-tumour necrosis factor (anti-TNF) agents are one of the therapeutic cornerstones in inflammatory bowel disease (IBD). These agents increase the risk of reactivation of latent infections. Latent tuberculosis (LT) testing is recommended prior to anti-TNF therapy in paediatric patients with IBD. In the European Union, Portugal is one of the countries with the highest prevalence of tuberculosis, and the country's northern region has the third highest national notification rate registered in 2017: 20,6 cases per 100.000 inhabitants. Our department is Portugal's northern region paediatric gastroenterology reference centre.

**Aims & Methods:** We performed a retrospective and descriptive analysis of paediatric patients with IBD eligible for anti-TNF therapy followed at our department during the last 2 years. This study aimed to evaluate the prevalence of LT and active tuberculosis in this group of patients.

**Results:** Clinical data from 273 paediatric patients with IBD was analysed. 120 of these patients were eligible for anti-TNF therapy (77,5% Crohn's disease, 21,7% Ulcerative Colitis, 0,8% IBD unclassified). The median age was 13 years. LT prevalence was 7,3% (n=9): positive Tuberculin skin test (TST) in 5 cases and positive Interferon-gamma release arrays (IGRA) in 4. In 2 cases initial IGRA testing was negative. A single patient had contact with a case of active tuberculosis. All patients diagnosed with LT were treated with isoniazid. Follow up after treatment of LT varied between 28 and 1496 days. We had no cases of complications or development of active tuberculosis.

**Conclusion:** Testing for LT prior to anti-TNF therapy is mandatory. Repeating this testing process while under anti-TNF therapy is dependent on a case-by-case analysis. Even in the absence of contact with active tuberculosis it's important to test and treat LT. We believe that further studies are needed to formulate new recommendations for LT testing / testing repetition.

**Contact E-Mail Address:** laura\_palomino\_perez@hotmail.es

**Introduction:** Graft-versus-host disease (GVHD) is a life-threatening multisystemic complication of allogeneic hematopoietic cell transplantation.

**Aims & Methods:** The aim of this retrospective study was to describe the features of the hematopoietic stem cell transplanted (HSCT) patients diagnosed with Gastrointestinal (GI) GVHD. Paediatric patients (< 18y of age) that had received an HSCT from January 2014 to November 2018 were included. Diagnosis, epidemiological and clinical data were compared between patients who developed GVHD and the rest of patients with HSCT.

**Results:** A total of 177 patients received HSCT and 28 (14.2%) of them developed GVHD, 50% were women. At the moment of the HSCT, the average age was 8.85 years old (±5.9 y) and GVHD was diagnosed at the age of 9.4 y (±5.8 y). The type of HSCT and the underlying conditions for which HSCT was indicated in patients who developed GVHD (n=28), versus those who did not develop GVHD (n=149) are shown in Table 1.

The most common symptoms of GI GVHD were vomiting in 21 patients (75%), diarrhoea and anorexia in 19 (67.9%) respectively, abdominal and pain in 18 (64.3%), weight loss in 16 (57.1%) and hepatomegaly in 8 (28.6%).

A total of 19 (67.9%) presented cutaneous GVHD demonstrated by biopsy, 9 (32.1%) bronchiolitis obliterans and 14 (50%) had clinical criteria of hepatic GVHD. The diagnosis of GI GVHD was made by upper endoscopy in 11

(39.3%), lower endoscopy in 9 (32.1%) and both of them in 8 (28.6%). No side effects of the endoscopy were notified.

The types of GVHD were classic acute GVHD in 14 (50%), acute and persistent or recurrent GVHD in 3 (10.7%), classic chronic GVHD in 4 (14.3%), and overlap (both acute and chronic GVHD were present) in 7 (25%).

Most of the patients received several treatments, including methylprednisolone in 26 (92.8%), budesonide in 7 (25%), beclomethasone in 2 (7%), photopheresis in 19 (67.9%), etanercept in 17 (60.7%), calcineurin inhibitors in 13 (46.4%), ruxolitinib in 7 (25%), mycophenolate mofetil, antithymocyte globulin and mesenchymal stem cells infusion and immunoglobulin in 3 patients (10.7%) respectively, and sirolimus in 1 (3.6%). These treatments were totally effective in 15 patients (53.6%), partially effective in 8 (28.6%) and non-effective or refractory in 5 (17.9%).

		Transplanted patients who developed GVHD (n=28)	Transplanted patients who did not develop GVHD (n=149)	P
Type of HSCT	Haploidentical allogeneic	11 (39,3%)	59 (39,6%)	0,8625
	HLA-matched allogeneic related	5 (17,9%)	27 (18,1%)	0,8231
	HLA-mismatched related	0	2 (1,3%)	1
	HLA-matched allogeneic non-related	10 (35,7%)	13 (8,7%)	0,0003

	Other	0	62 (41,6%)	0,0001*

[Table 1]

**Conclusion:** The treatments for GI GVHD are not always effective. A higher percentage of patients who received an HLA-identical unrelated allogeneic HSCT and who had ALL in the group that developed GVHD when compared to those who did not develop GVHD was observed (differences statistically significant), suggesting a possible association with these factors. Most patients with GI GVHD also presented cutaneous GVHD.

**Introduction:** The human gut microbiome consists of trillions of microbiota and the majority of these microbiota reside in the gut. Many previous researches have received considerable attention to the association between gut metagenome and chronic diseases, such as obesity, inflammatory bowel disease, and other diseases. The roles of gut microbiota in human health not only in influencing the normal processes, but also associating with the occurrence and development of disease. With the increasing number of Chinese travelers around the world, there is undoubtedly drastic change of their diet as well as living environment, which would profoundly affect the gut microbial communities of these Chinese travelers. In general, when a person to a new environment, his/her may be feel inadaptability and the body has discomfort with a few symptoms, such as dizzy, flummed and emesis, and the time of inadaptability vary from person to person. We human are known to be inadaptable for the changing environments and foods. However, the mechanisms behind the inadaptability phenomenon remain unclear. Researches have already revealed that for short-term travelers, our gut microbial communities have been profoundly affected by the changing environments, and they have also asserted powerful feedbacks for our adaptation. Yet for mid- or long-term stays, the effect of changing environments on gut microbial communities as well as their feedback remain elusive.

**Aims & Methods:** In this study, we have followed a Chinese medical team's expedition from China to Trinidad and Tobago, stay in half a year, and come back again. During the whole monitoring duration of more than 9 months, we have collected 184 feces samples from Chinese medical team, 28 feces samples from native of Trinidad and Tobago and 5 food and water samples from Trinidad and Tobago, as well as 57 feces samples from native of Beijing, China. To characterize the taxonomic profile of the gut microbiome, the V4 hypervariable region of the bacterial 16S rRNA gene were amplified using the universal bacterial/archaeal primers 515F (5'-GTG-CAGCMGCCGCGTAA-3') and 806R (5'-GGACTACHVGGGTWTCTAAT-3'). To characterize gut microbiome functional potential, 61 faecal samples were selected and performed shotgun metagenome sequencing, mainly including the faecal samples of MT3, MT6, and MT10 people.

**Results:** The number of OTUs and PD\_whole\_tree varied from 511 to 6,695 and from 42.21 to 330.42, respectively. Whilst, the Shannon index and Simpson index ranged from 1.51 to 7.06 and 0.58 to 0.98, respectively. These differences revealed that the most significant changes of the gut microbiota occur directly after the shift of diet and locations. The mantel test between composition data (taxonomical composition and functional composition) and diet information showed that the changes of the gut microbiota community was strongly associated with diet, especially dairy products, pickled food, salty snack and sodas.

**Conclusion:** Based on which taxonomical structure profiling and association studies have been conducted, we have found that (i) the most significant changes of the gut microbiota occur directly after the shift of diet and locations; (ii) the stable states of the gut microbiota were diet dependent, while those states were related more with hosts than with enterotype; (iii) there were obvious differences in gut microbiota between Chinese groups with short stay and those with long stay in Trinidad and Tobago; (iv) there were obvious differences in gut microbiota between Chinese (with short and long stay in Trinidad and Tobago) and those natives.

**Disclosure:** On behalf of all the authors, there is no conflict of the interest

### P1920 SCREENING FOR *H. PYLORI* AND CLARITHROMYCIN RESISTANCE BY PCR FROM GASTRIC BIOPSIES: COMPARATIVE STUDY OF 2 KITS, AMPLIDIAG *H. PYLORI*+CLARIR (MOBIDIAG) AND RIDAGEN *HELICOBACTER PYLORI* (R-BIOPHARM)

**Introduction:** Because of the increasing rate of clarithromycin-resistant *Helicobacter pylori* strains in France, the HAS French guidelines recommend antimicrobial susceptibility testing before starting the first-line eradication treatment. We evaluated the feasibility of this new approach in our hospital by studying 2 qualitative PCR kits: Amplidiag *H. pylori*+clarir kit (MOBIDIAG) targeting the 23S rRNA gene and SNPs in 2142 and 2143 positions, mostly involved in clarithromycin resistance, and RIDAGEN *Helicobacter pylori* kit (r-biopharm) targeting 16S rRNA and 23S rRNA genes.

**Aims & Methods:** Patients with indication for endoscopy with gastric biopsies were included in this study. Two antral and 2 corpus biopsies were analysed by PCR, and 2 additional biopsies were used for histological analysis. The 4 biopsies dedicated for PCR, were pooled, extracted on an iPrep extractor, and DNA amplifications were performed on a Rotorgene thermocycler.

**Results:** Among the 50 screened patients, 37 were *H. pylori* negative with both PCR kits (35 were confirmed negative and 1 was found positive by histology, 1 had no histological analysis), 13 were *H. pylori* positive with both PCR kits without detection of clarithromycin resistance (12 were confirmed positive and 1 was found negative by histological analysis).

**Conclusion:** Preliminary results of this study prove the feasibility of *H. pylori* and clarithromycin resistance screening by PCR from gastric biopsies, and show a good correlation between the 2 kits and histology results. They are both easy to use and give rapid results (1h45 for MOBIDIAG kit and 70 min for RIDAGEN kit). Samples can be tested in triplicate with the MOBIDIAG kit. We are currently working to complete these results with additional samples, to evaluate the PCR performances for clarithromycin resistance detection.

### P1921 SELECTIVE MICROBIOTA TRANSPLANTATION INDUCES RADIATION ENTERITIS IMPROVEMENT: A PILOT STUDY

Ding X., Li Q., Li P., Zhang T., Xiang L., Zhang F.

Second Affiliated Hospital of Nanjing Medical University, Medical Center for Digestive Disease, Nanjing, China

**Contact E-Mail Address:** xding@njmu.edu.cn

**Introduction:** The intestinal microbiota is implicated in the pathogenesis of radiation-induced bowel toxicity. Microbiota transplantation might be a therapeutic option for radiation enteritis.

**Aims & Methods:** This study aimed to assess the efficacy and safety of selective microbiota transplantation (SMT) through mid-gut in patients with radiation enteritis through a prospective cohort study. Eighteen patients with a median age of 56 (IQR, 49.8-63.5) years, were included after informed consent and institutional ethics approval according to registered trial (NCT03516461). The prepared 200ml selective microbiota suspension (mixed species of cultured bacteria) was infused daily into the distal duodenum through the nasojejunal transendoscopic enteral tubing (TET) tube for 3 days. Clinical and endoscopic data were collected during the follow-up. Endoscopic evaluations were assessed using the Vienna Rectoscopy Score (VRS). Fecal metatranscriptomes and metagenomes analysis were performed to assess associated microbial changes. The urinary metabolic profiles of those patients were generated using nuclear magnetic resonance (NMR) spectroscopy.

**Results:** 66.7 (12/18), 66.7% (12/18), 61.1% (11/18) and 44.4% (8/18) patients responded to SMT [≥1 grade reduction in Radiation Therapy Oncology Group (RTOG) European Organization for Research and Treatment of Cancer (EORTC) Radiation Toxicity Scales] at week 1, 2, 3 and 4 weeks, respectively. The stool frequency per day reduced from 5.9 ± 0.7 (mean ± SE) to 3.4 ± 0.6 four weeks after SMT (p < 0.001). The improvements in

quality of life was demonstrated by a decreased European Organization for Research and Treatment of Cancer Quality of Life Module for Proctitis-21 items questionnaire (EORTC QLQ PRT21) score from  $56.8 \pm 2.0$  to  $47.8 \pm 3.1$  four weeks after SMT ( $p = 0.001$ ). Patients with VRS  $\leq 2$  at baseline achieved significantly more response than those with VRS  $\geq 3$  [100 % (5/5) vs. 23.1% (3/13),  $p = 0.007$ ]. SMT was associated with a significantly higher response rate in patients with EORTC QLQ PRT21 score  $\leq 63$  at baseline than those  $> 63$  [61.5% (8/13) vs. 0.0 % (0/5),  $P = 0.029$ ]. Microbiota analysis showed that SMT altered the composition greatly. SMT induced significant alterations in urinary metabolic profiles. No serious adverse event related to SMT occurred during treatment and follow-up.

**Conclusion:** SMT induces clinical and endoscopic improvement in radiation enteritis and is associated with distinct microbial and metabolic changes that relate to outcome. SMT is a promising novel therapeutic option for radiation enteritis.

**Contact E-Mail Address:** hannahhannhann@yahoo.com.tw

**Introduction:** Second-look endoscopy would be scheduled, if rebleeding is suspected after primary endoscopic hemostasis of upper gastrointestinal (UGI) bleeding. However, the routine second-look endoscopy is a high-cost intervention and could even increase unnecessary risk. Thus, we aimed to develop a novel continuous UGI monitoring system to improve the tracking of UGI bleeding.

**Aims & Methods:** The UGI monitoring system consisted of a tiny and thin tube camera, a wearable host device, and a mobile display device. The tube camera was connected to the host device and then inserted into stomach via nasal tunnel. The host device was set to acquire images every minute and sent the images to the mobile device, in which an image analysis application was installed for rebleeding detection.

Patients with Rockall scores  $\geq 3$  were eligible for this study. They were put on the UGI monitoring system by the trained medical staff. The monitoring period was  $\leq 3$  days because most of rebleeding occurred within 3 days. The comfort level was scaled from 0 to 5 by the patients.

**Results:** Eight patients who had UGI bleeding and received primary endoscopy hemostasis were included in this study (age  $41 \pm 83$ , 6 males, Rockall score 3-9) and the trial is still ongoing. From the images, how the contents inside the stomach changed over time was observed. Coffee-ground, blood clots, red blood, and food contents were photographed. Up to date, the included patient had not rebleeding during the system monitoring. However, this system could confirm no active bleeding in stomach 1-4 days earlier than observation of melena. Moreover, the comfort level of using the UGI monitoring system was less than 2 in average.

**Conclusion:** This UGI monitoring system could confirm no active gastric bleeding earlier. It is potential to evaluate various scenarios in the UGI tract with an endurable comfort level.

**Introduction:** Endoscopic submucosal dissection (ESD) has become the standard treatment for early gastric cancer in Japan. Hemorrhage is often encountered after ESD, and endoscopic hemostasis is required in some cases. Some institutions do not perform upper gastrointestinal endoscopy after ESD (hereinafter referred to as 2nd look), and some authors have reported that 2nd look on the day after ESD is unnecessary. In our department, however, exposed blood vessels and blood clots without active bleeding in the post-dissection ulcer floor have been recognized in addition to active bleeding after resection. In addition to active bleeding, we consider that exposed and/or observable vessel findings and clots on the ulcer floor after resection are important risk factors for hemorrhage. Here, we report comparison and examination of the frequency of active bleeding and "ulcer after resection with a risk of bleeding" on the day after ESD in relation to their risk factors. We also discuss the necessity of 2nd look after ESD.

**Aims & Methods:** In this paper, 2nd look refers to upper gastrointestinal endoscopy examination on the day after ESD. We examined 447 cases with 2nd look retrospectively in patients treated with ESD in our department during the period from August 2008 to March 2018. Active bleeding was examined in 447 cases. After excluding 51 cases with active bleeding, the occurrence of ulcers after resection with a risk of bleeding was examined in 396 cases. Patient background and pathological findings were checked on electronic medical records, and images and endoscopic findings were checked using a device for recording images of endoscopic findings (Solemio ENDO; Olympus, Tokyo, Japan).

**Results:** Active bleeding was seen in 51 cases (11.4%). Site of lesion, resected specimen size, and history with/without antithrombotic drug administration were found to be factors that significantly determined the occurrence of active bleeding. In cases with upper body lesions, hazard ratio (HR) was 0.259 ( $P = 0.0256$ ) with a low risk of bleeding. For specimens resected by ESD exceeding 30 mm in size, HR was 2.736 ( $P = 0.0019$ ) indicating a higher risk of bleeding. This suggested that larger specimens are associated with higher risk of bleeding. Patients with a history of antithrombotic drug administration showed an increased risk of active bleeding (HR = 1.957,  $P = 0.0477$ ). We found 88 cases (22.2%) of "post-dissection ulcer floor with a risk of bleeding." HR was 0.318 ( $P = 0.0074$ ) for upper body lesions. Thus the frequency of "post-dissection ulcer floor with a risk of bleeding" was low. Conversely, HR was 1.868 ( $P = 0.0120$ ) for lesions in the antrum with a higher risk of bleeding. HR for specimen length  $> 30$  mm was 1.982 ( $P = 0.0060$ ), and the frequency of "post-resection ulcer with a risk of bleeding" was high.

**Conclusion:** The results of this study indicated that the frequencies of active bleeding after ESD and "ulcer with a risk of bleeding" were higher than expected. In addition, their risk factors were elucidated. We believe that 2nd look is necessary to safely discharge patients.

**Contact E-Mail Address:** julio.iglesias.garcia@sergas.es

**Introduction:** Pharmacological therapy with thalidomide or somatostatin analogues is indicated in patients with intestinal angiodysplasias, who did not respond to standard endoscopic treatment with argon-plasma coagulation. Previous studies support the efficacy of these therapies, but this has not been proven in real clinical practice.

**Aims & Methods:** The aim of this study was to evaluate the effectiveness of thalidomide and/or octreotide-LAR in patients with intestinal angiodysplasias not responding to standard endoscopic therapy in the daily clinical practice.

**Methods:** A retrospective, single-center, cohort study was designed. Patients diagnosed with intestinal angiodysplasias between 2012 and 2018 at the University Hospital of Santiago de Compostela, Spain, who were treated with thalidomide and/or octreotide-LAR were included. Hemoglobin levels, transfusion needs (red blood cells units per month), intravenous iron, and bleeding episodes were analyzed. Results are shown in percentages, mean and standard deviation, and analyzed by Student-t or U-Mann Whitney test.

**Results:** 31 patients were included (19 males, median age 77.3 years). 25% of the patients suffered from liver cirrhosis, 32% had chronic renal injury, 13% ischemic heart disease, and 25% aortic stenosis. Three patients were initially treated with thalidomide 100mg/24h, and 28 with octreotide-LAR 20mg/month. Eight patients, who did not respond to octreotide-LAR switched to thalidomide. Compared with baseline before treatment, hemoglobin levels increased with octreotide-LAR (0.98, 95%CI 0-1.97, p=0.05). However, needs per month of packed red blood cells (0.29, 95%CI -0.60-1.19, p>0.05), intravenous iron (-0.01, 95%CI -0.49-0.47, p>0.05) and bleeding episodes (-0.03, 95%CI -0.16-0.10, p>0.05) did not decrease.

No significant benefit was either observed after thalidomide therapy (needs of packed red blood cells per month 1.47, 95%CI -1.77-4.72, p>0.05; hemoglobin levels 0.59, 95%CI -0.64-1.82, p>0.05 and bleeding episodes per month 0.05, 95%CI -0.29-0.18, p>0.05). There were two mild adverse reactions in patients with octreotide-Lar and four with Thalidomide.

**Conclusion:** Effectiveness of pharmacological treatment with octreotide analogues or thalidomide of intestinal angiodysplasias refractory to endoscopic therapy in clinical practice is questionable. These results have to be confirmed in larger multicenter studies.

**Disclosure:** Nothing to disclose

## P1925 ATP-DEPENDENT POTASSIUM CHANNELS, SOLUBLE GUANYLYL CYCLASE AND ENDOGENOUS PROSTAGLANDINS IN CARBON MONOXIDE-MEDIATED PREVENTION AGAINST OXIDATIVE ISCHEMIA/REPERFUSION-INDUCED GASTRIC DAMAGE

**Contact E-Mail Address:** m.magierowski@uj.edu.pl

**Introduction:** Carbon monoxide (CO), produced endogenously or released from tricarbonyldichlororuthenium (II) dimer (CORM-2) was shown to protect gastric mucosa against injury caused by NSAIDs or stress. However, the role of this gaseous transmitter in prevention of oxidative ischemia/

reperfusion (I/R)-induced gastric damage has not been extensively elucidated. Therefore, we determined the effect of pretreatment with CORM-2 on gastric lesions formation induced by 30 min of I followed by 3 h of R.

**Aims & Methods:** Thirty minutes before I/R, male Wistar rats were pretreated i.g. with vehicle, CORM-2 (1-10 mg/kg) or ZnPP (10 mg/kg) as an inhibitor of endogenous CO-producing heme oxygenase (HO) administered alone or combined with ODQ (10 mg/kg i.p.), inhibitor of soluble guanylyl cyclase (sGC), indomethacin (5 mg/kg), non-selective inhibitor of cyclooxygenases (COXs), L-NNA (15 mg/kg), inhibitor of nitric oxide (NO) synthase or glibenclamide (10 mg/kg), ATP-dependent potassium channels (K-ATP) blocker. Gastric lesions area, mucus production and gastric blood flow (GBF) were assessed by planimetry, AB/PAS staining and laser flowmetry, respectively. Gastric mucosal mRNA and/or protein expression for HO-1, HO-2 and Nrf-2, but also COX-1, COX-2, iNOS, TNF- $\alpha$ , IL-1 $\beta$ , K-ATP subunits Sur2 and Kir6.1 and sGC subunits  $\alpha$ -1 and  $\beta$ -1 were determined by real-time PCR and/or Western blot or IHC. 8-hydroxydeoxyguanosine (OHG) level in gastric mucosa as a molecular marker of oxidative DNA damage and PGE2 concentration were determined by ELISA. CO content in gastric mucosa was determined by gas chromatography. Serum concentration of 11 pro- and anti-inflammatory cytokines and TGF $\beta$ 1-3 was determined by Luminex platform.

**Results:** Pretreatment with CORM-2 (5 mg/kg) but not ZnPP increased CO content in gastric mucosa, decreased I/R-induced gastric damage, increased GBF, decreased OHG, increased PGE2 content and mRNA expression of COX-2, iNOS, TNF- $\alpha$ , IL-1 $\beta$  mRNA as compared with vehicle-control. CORM-2 maintained physiological mucus production. Glibenclamide and L-NNA but not indomethacin or ODQ reversed gastroprotective effects of CORM-2. Exposure to I/R decreased gastric mucosal mRNA expression for Sur2 and Kir6.1 previously decreased by exposure to I/R. CORM-2 decreased blood concentration of 11 cytokines and TGF $\beta$ 3 elevated by I/R.

**Conclusion:** We conclude that CO released from CORM-2 prevented gastric mucosa against oxidative I/R-induced damage by the maintenance of gastric microcirculation only in part dependently on sGC activity. These gastroprotective and hyperemic effects of CO against I/R-injury involve biosynthesis of endogenous NO but not co-activity of COXs. However, CO maintained physiological level of protective PGE2 under I/R conditions. Since increased bioavailability of CO did not modulated mRNA expression for K-ATP subunits and pharmacological blockade of these channels reversed protective and hyperemic effect of CORM-2 we conclude that this molecule acts via K-ATP activity. CO attenuated I/R-induced inflammatory response and DNA oxidation in gastric mucosa and on systemic level confirming its strong anti-inflammatory and anti-oxidative properties. [Funding source: National Science Centre, Poland (UMO-2016/23/N/NZ4/01890)].

**Introduction:** Variceal hemorrhage is a life-threatening emergency and a major cause of death. Currently, the use of Sengstaken-blakemore (SB) tube is recommended as a temporary measure in uncontrolled variceal bleeding when endoscopic therapy fails or is not possible. Even though it is recommended, there are no recent studies about the outcomes of its use.

**Aims & Methods:** The aim of this study was to evaluate the safety and efficacy of SB tube placement, as well as the rebleeding rate and associated mortality. We also sought to identify associated predictors of hemostasis and mortality.

It was done a retrospective analysis of all the patients treated with SB tube for uncontrolled variceal hemorrhage at a single tertiary care hospital between 01/01/2007 and 31/12/2018.

**Results:** Over a twelve-year period, 34 patients underwent SB tube placement, 26 males, average age of 56 ( $\pm 13.5$ ) years old, 88% (30/34) had portal hypertension due to cirrhosis with an average Child-Pugh score of 10.6 ( $\pm 2.1$ ) and average MELD-Na score of 20.9 ( $\pm 7.6$ ). 86% of these patients had alcohol-related cirrhosis and 50% had active alcohol consumption.

At the time of the insertion of the SB tube, all the patients were medicated with a vasoactive drug and 94% (32/34) had active hemorrhage. Successful initial hemostasis was achieved in 62% (21/34) of the cases, despite rebleeding in 43% (9/21). The SB tube use was associated with complications in 32% of the cases, 8% of them was severe. The overall mortality rate within 30 days was 70% and within 1 year was 84%.

Univariate analysis indicated as potential predictors of mortality at 1 year the octreotide use (vs terlipressina;  $p = 0,02$ ), hepatocellular carcinoma ( $p=0,006$ ), and active alcohol consumption ( $p=0,04$ ). Multivariate analysis did not point out any predictor of hemostasis or mortality.

**Conclusion:** SB tube seems to be a beneficial option as a rescue therapy for uncontrolled variceal bleeding but it is associated with a high rate of complications and bleeding recurrence.

**Disclosure:** Nothing to disclose

**Introduction:** Mallory-Weiss syndrome (MWS) is characterized by superficial non-perforated mucosal laceration, commonly at gastroesophageal junction, and is estimated to be the cause of 8% to 15% of upper gastrointestinal bleeding of non-varicose origin<sup>1,2</sup>. The mechanism behind the injury is the sudden and repeated increase in intra-abdominal pressure caused by nausea, vomiting, hiccups, tension, coughing, abdominal or thoracic trauma<sup>2</sup>. Laceration originates at the gastroesophageal junction and may extend proximally into the esophagus or distally into the stomach<sup>1</sup>. The main predisposing factor is alcoholism, present in 30% to 70% of cases<sup>2,3</sup>. The severity of bleeding appears to be greater in the presence of portal hypertension and esophageal varices. Other related causes include bulimia nervosa, hyperemesis gravidarum and gastroesophageal reflux disease<sup>1</sup>. In most cases, it has a self-limiting course and does not require emergency endoscopy or surgical intervention.

**Aims & Methods:** Characterize the epidemiological profile of the patient in a university hospital that presents gastrointestinal bleeding due to MWS, from September 2017 to January 2019. A retrospective study was carried out with data collection of medical records and the protocol implanted in 772 patients of the Digestive Hemorrhage Service. In September 2017, this hospital became a unique reference for acute cases of gastrointestinal bleeding in Curitiba-PR and metropolitan region. Descriptive and statistical analysis of the prevalences according to age, sex, need for transfusion, death, symptomatology of entry, smoking, alcoholism, medications, comorbidities, clinical-surgical management, endoscopic diagnosis, endoscopic treatment was made.

**Results:** Of the 772 patients evaluated, 15 (1.9%) presented endoscopic reports confirming MWS, composing the sample. The most prevalent gender was male (13 patients) and the most affected age group was between 61-70 years (26.7%). The median age was 52 years (SD16.5). One man died (6.7%), non-related to MWS. Transfusion of red blood cells was necessary in 4 patients (26.7%), all male. The most present entry symptom was hematemesis with 14 cases (93.3%) and the most common association was hematemesis and melena with 4 cases (26.7%). The mean hemoglobin level at admission was 11.7 g / dL (5.1 - 16.4). Of the 15 patients, 10 were alcoholics, all men, for 27 years on average. As for smoking, 5 people smoked and 2 were ex-smokers, accounting for 46.7% of the sample. Cirrhosis was observed in only one individual, having the alcoholism as the etiology. The continuous medication more associated with bleeding was the use of anti-inflammatory drugs with 2 cases (13.3%). The most prevalent diagnosed etiology os MWS was alcoholism, corresponding to 8 cases (53.3%), followed by unidentified causes in 3 patients (20%), acute

gastroenterocolitis and gastroesophageal reflux disease, each with 2 cases (13.3%). At the endoscopy exam, in addition to MWS, 3 patients presented with enanthematous gastritis, one with erosive gastritis, one with esophageal varices and another with healing gastric ulcer.

**Conclusion:** The results set the profile of patients with MWS as men, alcoholics, presenting with hematemesis associated or not with melena and median age of 52 years. It is important to recognize this entity in cases of upper gastrointestinal bleeding, especially of non-varicose origin in alcoholic patients.

## P1928 ACUTE UPPER GASTROINTESTINAL BLEEDING - ADHERENT CLOTS, ADHERENCE TO GUIDELINES

Patel R.N.<sup>1</sup>, Ikidde S.<sup>2</sup>, Oza C.<sup>2</sup>

<sup>1</sup>Royal Free London NHS Trust, Gastroenterology, London, United Kingdom,

<sup>2</sup>Broomfield Hospital, Essex, United Kingdom

**Contact E-Mail Address:** rajan.patel@nhs.net

**Introduction:** Acute upper gastrointestinal haemorrhage secondary to peptic ulcer disease carries a significant mortality risk. The management of peptic ulcers with adherent clots (Forrest IIB) remains uncertain. ESGE recommends consideration of endoscopic clot removal. We aim to describe the demographics and outcomes of patients with adherent clots at a district general hospital.

**Aims & Methods:** Data for patients admitted to our Trust and diagnosed with a peptic ulcer over the last 3 years was obtained from the coding department using ICD-10 codes (K25.0, K25.2, K26.0, K26.2, K27.0 and K27.2). 89 patients that had undergone inpatient endoscopy were identified.

**Results:** 89 patients; female 28 (31.5%), mean age 72.9 (23 - 96). 17 (19.1%) patients were taking anticoagulants/antiplatelets (8 warfarin, 4 DOACs, 5 clopidogrel / ticagrelor). Mean length of stay 12.7 days. 6 (6.7%) patients had rebleeds, 2 (2.2%) patients underwent surgery and 6 (6.7%) patients died.

29 (32.6%) patients had adherent clots found at endoscopy.

Of 29 patients with adherent clots; 3 (10.3%) had documented endoscopic removal; 14 (48.3%) had documented not removal and 12 (41.4%) had no documentation of adherent clot management. 13 of the 14 adherent clots (93%) that were not removed were located in D1. 8 (27.6%) patients with an adherent clot received monotherapy.

	Adherent Clot (n=29)	No adherent clot (n=60)	*p value
Indication (Haematemesis & Melena), n (%)	15 (51.7)	10 (16.7)	0.0006
Size (cm), mean (range)	1.5 (0.5 - 5)	1.1 (0.5 - 3)	0.009
Transfused, n (%)	26 (89.7)	42 (70.0)	0.04

[Table 1. Adherent Clot versus No Adherent Clot - Demographics and ulcer outcomes]

**Conclusion:** Patients with adherent clots presented with more severe symptoms, had larger ulcers and required more transfusions. Only 10% of adherent clots had documentation of endoscopic removal and almost half of adherent clots were not removed. Clearer documentation is required for future practice. Ambiguous guidelines could be contributing to variability in practice and suboptimal management.

**Disclosure:** Nothing to disclose

**Introduction:** With increasing advances and complexity of endoscopic therapy, there is an increased risk of post procedure bleeding. Hemospray (Cook Medical, North Carolina, USA) is a novel haemostatic powder for GI bleeding. The aim of this study is to look at outcomes in patients with upper Gastrointestinal bleeds (UGIBs) following endoscopic therapy treated with hemospray in 14 centres worldwide.

**Aims & Methods:** Data was prospectively collected on the use of hemospray from specialist centres (Jan'16-September'18). Hemospray was used during emergency endoscopy for UGIBs post endoscopic therapy at the discretion of the endoscopist as a monotherapy, dual-therapy with standard haemostatic techniques or rescue therapy once standard methods have failed. Haemostasis was defined as the cessation of bleeding within 5 minutes of the application of hemospray. Rebleeding was defined as a sustained drop in Hb (>2g/l), haematemesis or melaena with haemodynamic instability after the index endoscopy.

**Results:** 59 patients had UGIBs post endoscopic therapy (41 male, 18 female, 34/59 (58%) post Endoscopic mucosal resection (EMR), 5/59 (9%) post ESD, 5/59 (9%) post biliary sphincterotomy). The median Blatchford score at baseline was 4 (IQR, 0-8). The average Rockall score was 6 (IQR, 5-7).

Haemostasis following the application of hemospray was achieved in 60/60 (100%) of patients. 14/59 (24%) patients had monotherapy with hemospray, 32/59 (54%) had combination therapy and 13/59 (22%) had rescue therapy. 2/46 (4%) had a rebleed post hemospray, one was following oesophageal EMR and the other post duodenal EMR. There were no patients' deaths within 30 days.

**Conclusion:** Hemospray is effective in achieving immediate haemostasis following endoscopic therapy, with a low rebleed rate and no 30-day mortality.

**Disclosure:** Nothing to disclose

## P1930 VERY EARLY ENDOSCOPY IN UPPER GASTROINTESTINAL BLEEDING

**Introduction:** Acute upper gastrointestinal bleeding is a common condition in the emergency unit and has significant associated morbidity and mortality. Worldwide the most common causes of UGIB are nonvariceal, from peptic ulcers, Mallory Weiss syndrome, angiodysplasia or malignancy of the upper GI tract. ESGE guideline recommends performing early endoscopy (< 24 hours) after hemodynamic resuscitation. Very early endoscopy (< 12 hours) is recommended in patients with high risk clinical features like persistent hypotension and tachycardia after volume resuscitation.

**Aims & Methods:** The aim of the study was to evaluate the causes of UGIB, assess the time for early endoscopy and the hemostatic techniques used. We performed a retrospective study between 1st September 2018 to 31st December 2018 and included 182 patients who were admitted in our department with upper gastrointestinal bleeding. We divided them into variceal bleeding (69 patients) and nonvariceal bleeding (113 patients).

**Results:** The mean age in the variceal bleeding lot was 55 years old, the youngest being 28 years old and the oldest 79 years old. 8 patients had bleeding from gastric varices GOV I and in one case was used injection of Glubran and in the other 7 patients band ligation. 61 patients had haemorrhage from esophageal varices and band ligation was performed.

The average time passed from presentation until the performance of the therapeutic endoscopy in patients with variceal bleeding was 3 hours and 55 minutes and the hospitalization period was around 3 days. From 69 patients with variceal bleeding 7 died, but they were having important comorbidities related mainly to advanced cirrhosis (hepatic cirrhosis Child B or C and hepatocarcinoma).

In the non variceal lot, the average age was 59 years old, the youngest being 18 years old and the oldest patient being 90 years old. The most common causes were gastric ulcer (30 cases) or duodenal ulcer (35 cases), followed by 16 patients with Mallory Weiss lesions, 7 with Dieulafoy lesions and 6 with bleeding from gastric angiodysplasia. Rare causes of UGIB were haemorrhage from Vater ampullary cancer, gastric polyps and hemotoxic pancreatitis. The therapeutic tools used in UGIB from ulcers were injection of epinephrine 1:10.000 in saline, followed by a second hemostatic procedure, like electrocoagulation using GoldProbe and application of endoscopic hemoclips.

In patients with bleeding from Dieulafoy lesions and gastric angiodysplasia we used diluted epinephrine injection followed by electrocoagulation with GoldProbe and in Mallory Weiss lesions we frequently used dilute adrenaline injection and hemoclips.

The time passed from presentation until we performed the therapeutic endoscopy in the nonvariceal group was on average 5 hours, and the duration of hospitalization was on average 4 days. We had 8 deaths, 5 with duodenal ulcer and 3 with Dieulafoy lesion, related to cardiovascular comorbidities and anticoagulation drugs.

**Conclusion:** Very early endoscopic approachment seems to lower the mortality rate and the duration of hospitalization, especially in patients with active bleeding or important comorbidities. From our experience, a good patient orientated rapid hemodynamic equilibration and early endoscopy seems to be the best management for the UGIB.

**Disclosure:** I have nothing to disclose.

## P1931 RISK FACTORS FOR EARLY MORTALITY IN VARICEAL BLEEDING

Barbulescu A., Ratiu I.M., Sporea I., Danila M., Popescu A., Lupusoru R., Miutescu B.P., Ghiuchici A.M., Sirli R.L.D.  
*'Victor Babes' University of Medicine and Pharmacy, Gastroenterology and Hepatology, Timisoara, Romania*

**Introduction:** Acute haemorrhage from ruptured esophageal varices is most probably the most serious consequence of uncontrolled portal hypertension in cirrhotic patients, with a significant mortality. Overall survival is improving, due to new therapeutic approaches and improved medical care. However, early mortality after an episode of acute variceal bleeding remains high.

**Aims & Methods:** The aim of this study was to evaluate the risk factors affecting 5-day mortality rate after acute variceal bleeding in unselected cirrhotic patients.

537 cirrhotic patients admitted in our department with variceal bleeding were evaluated, 351 men and 186 women, with a mean age of 58.8 years, during a 7 years period. We divided the group of patients into three groups: group A, who died due to severe variceal bleeding (n=32), group B, the survivors (n=452), and group C, patients who died from other complications (n=53).

We tried to identify prognostic factors for massive, uncontrollable variceal hemorrhage by comparing patients' characteristics among the three groups.

**Results:** Total in hospital mortality rate was 15.8% (n=85), with a death rate of 5.9% (n=32) due to severe bleeding, while 9.8% of patients died from other complications.

There were no significant differences regarding the proportion of grade 3 EV and grade 2 EV in group A vs. group B vs. group C, nor regarding the mean age. The proportion of class Child Pugh class C in group A was significantly higher than in group B, but similar to group C. The MELD score was significantly higher in group A than in group B, but similar to group C. Severe thrombocytopenia (< 50.000/mm<sup>3</sup>) and haemorrhagic shock at admission were significantly more frequent in group A than in group B, but similar to group C.

Characteristics	Group A (32p) vs. Group B (452p)	Group A (32p) vs. Group C (53p)
EV grade 3	11/32 vs. 195/452 p= NS	11/32 vs. 22/53 p= NS
EV grade 2	20/32 vs. 257/452 p= NS	20/32 vs. 31/53 p= NS
Age	58 y/o vs. 59 y/o p= NS	58 y/o vs. 59 y/o p= NS
Child Pugh Class C	22/32 vs. 151/452 p=0.0006	22/32 vs. 31/53 p= NS
Meld score	24.5 vs. 17.4 p= 0.0005	24.5 vs. 24.8 p= NS
Severe thrombocytopenia	10/32 vs. 76/452 p< 0.0001	10/32 vs. 11/52 p= NS
Haemorrhagic shock	24/32 vs. 12/452 p< 0.0001	24/32 vs. 13/53 p= NS

[Table]

**Conclusion:** Liver failure, severe thrombocytopenia and haemorrhagic shock at admission were the risk factors we identified for in hospital 5-day mortality rate due to variceal bleeding.

**Disclosure:** Nothing to disclose

## P1932 EVALUATION OF OUR IN-PATIENT ENDOSCOPY WORKLOAD AND MEETING NATIONAL STANDARDS FOR THE MANAGEMENT OF UPPER GASTROINTESTINAL BLEEDING IN A UNIVERSITY HOSPITAL

Samani S.<sup>1</sup>, Lee H.L.<sup>1</sup>, Wurm P.<sup>1</sup>, Ramiah R.D.<sup>2</sup>

<sup>1</sup>University Hospitals of Leicester NHS Trust, Gastroenterology, Leicester, United Kingdom, <sup>2</sup>University Hospitals Leicester, Dept. of Gastroenterology, Leicester, United Kingdom

**Contact E-Mail Address:** eddysamani@gmail.com

**Introduction:** The 2015 United Kingdom (UK) National Confidential Enquiry into Patient Outcome and Death (NCEPOD) report, 'Time to get control' and National Institute for Health and Care Excellence (NICE) clinical guideline (CG141), England highlighted the need for endoscopy within 24 hours for patients presenting with suspected acute upper gastrointestinal bleeding

(AUGIB). However, endoscopy demand has increased in recent years. We set out to evaluate our in-patient endoscopy procedure mix, workload, assess the timeliness of endoscopy and intervention rates for patients with AUGIB following a revised service arrangement. The updated service offers gastroenterology in-reach ward rounds on the acute medical units and once daily dedicated emergency inpatient endoscopy list at the University Hospitals of Leicester, UK NHS Trust which serves a catchment population of 1.1 million.

**Aims & Methods:** Patients referred for inpatient endoscopy from 1<sup>st</sup> of January to 31<sup>st</sup> of December 2017 were retrospectively identified via our online Integrated Clinical Environment (ICE) referral system, inpatient endoscopy procedure books and consultant's call out time sheets. ICE referrals and endoscopy database records were reviewed and cross referenced. Basic demographics, indications, number and type of endoscopic procedures including intervention rates for AUGIB were analysed. Time to endoscopy was defined as time of ICE referral to time of completion of endoscopy report. Simple regression analysis and Chi-Square test were used for statistical analysis.

**Results:** The total number of in-patient endoscopic procedure performed was 2033 with a mean number of 169 (1400 OGDs, 585 flexible-sigmoidoscopies, and 48 colonoscopies). 745 OGDs were performed for suspected AUGIB with a mean number of 61 procedures per month. Median and mean time to endoscopy was 5.2 hours (Interquartile Range [IQR] 3-21.9h) and 13.1 hours respectively. 84% of OGDs for AUGIB were performed within 24 hours. Overall intervention rate was 27.2%. The intervention rate was lower for procedures done outside of 24 hours compared to procedures done within 24 hours (17.6% versus 29.2% p = 0.010). 81.9% of ICE referrals were logged during in hours (9:00 to 17:00) and 18.1% were logged out of hours (17:00 to 08:00). We did not find an association between the timing of referral with timing of endoscopy (p = 0.912).

**Conclusion:** Despite proactive emergency working arrangements, a large proportion of endoscopies for patients with AUGIB were performed outside the time frames set by NICE guidelines and the NCEPOD report. Overall intervention rate was high but lower in procedures performed outside of 24 hours suggesting a degree of triage in utilizing the in-patient endoscopy list. To meet the 24 hour standard, an all-day rolling emergency endoscopy list maybe needed, a luxury few UK NHS Trusts can afford at times of severe constraints on endoscopy services.

**Disclosure:** Nothing to disclose

## P1933 WITHDRAWN

## P1934 ENDOSCOPIC MANAGEMENT OF UPPER GASTROINTESTINAL BLEEDING AS PART OF A MULTIDISCIPLINARY TEAM IN AN EMERGENCY TERTIARY CARE HOSPITAL: A SINGLE-CENTER COHORT STUDY

Rinja E., Diaconu I.-G., Sandru V., Nedelcu I.C., Plotogea O.M., Hortopan A., Oprita R., Chioncel C., Pestroiu Calescu D., Ilie M., Constantinescu G.

*Bucharest Clinical Emergency Hospital, Gastroenterology, Bucharest, Romania*

**Contact E-Mail Address:** ecatarina.rinja@gmail.com

**Introduction:** Upper gastrointestinal bleeding (UGIB) represents the main endoscopic emergency worldwide and despite the development of new therapeutic methods its treatment can still be very challenging.

**Aims & Methods:** The aim of this paper is to assess the patients with UGIB, both variceal and non-variceal who underwent early endoscopic treatment (< 12 hours) in a tertiary care emergency hospital. This is a retrospective analysis that enrolled patients with UGIB from January 2015 to December 2018, hospitalized in the Bucharest Clinical Emergency Hospital in Romania. Both the variceal and non-variceal bleeding were evaluated in terms of the type of lesion and the follow-up of the endoscopic treatment: re-bleeding, admission in Intensive Care Unit (ICU), surgical treatment and death.

**Results:** The study included a total of 1677 patients, which were separated into two groups, non-variceal bleeding (1066 patients) and variceal bleeding (611 patients). In the non-variceal bleeding group, 32.74% had gastric ulcer, 30.86% had duodenal ulcer, 10.22% had Mallory-Weiss lesions, 7.61% of patients were bleeding from vascular lesions (angiodysplasias and Dieulafoy lesions), 6.56% from tumours (oesophageal, gastric and

duodenal tumours), 3.29% from esophageal ulcers, 3.19% had endoscopic retrograde cholangio-pancreatography (ERCP) post-sphincterotomy bleeding, 3.18% had acute hemorrhagic gastroduodenitis, while smaller percentages had acute necrotizing oesophagus (1.03%), post-gastric polypectomy bleeding (0.94%) and arterial fistulas or aneurysms (0.38%). Only 85.55% required endoscopic treatment and all patients received proton pump inhibitors drugs. Rebleeding was assessed in 48 patients (5.26%), mostly from gastric ulcers (24 patients), duodenal ulcers (14 patients) and ERCP post-sphincterotomy (3 patients). ICU admission was needed in 7.42% of total cases. A mortality rate of 12.29% (131 patients deceased) was recorded, mostly because of major comorbidities. Emergency surgery was needed in 22.92% of the patients with rebleeding, of which 27.27% of patients had good outcome and 72.73% of patients had deceased. In the variceal bleeding group, from the total of 611 patients receiving endoscopic treatment in our unit, 529 had esophageal varices (EV), 49 had gastroesophageal varices type 1 (GOV1), 20 had gastroesophageal varices type 2 (GOV2) and 13 had isolated gastric varices (IGV). All the patients received adequate endoscopic treatment as well as medical treatment (vasoactive drugs such as terlipressin). The rebleeding rate was of 2.12% and was evaluated considering each type of varices: 8 patients with EV, 3 patients with IGV, 1 patient with GOV1 and 1 patient with GOV2. Sengstaken-Blakemore tube was necessary in 9 patients (1.47%) and admission in the ICU was required in 5% of the patients. We assessed the outcome of these patients: 94.44% had a positive outcome and were discharged and 5.56% deceased.

**Conclusion:** Our experience as an emergency tertiary care center with UGIB emphasizes the importance of early endoscopic approach as a safe and effective procedure with a high success rate, reducing the need for surgery. However, the mortality rate in both variceal and non-variceal bleeding remains high, therefore a multidisciplinary management (endoscopists, surgeons and anesthesiologists) is still considered the best approach for these patients.

**Introduction:** There is frequent and growing use of medications that prevent abnormal blood clotting, including anticoagulants and antiplatelets<sup>1</sup>. However, their therapeutic benefits must be balanced against the risks<sup>2</sup>. The reported incidence of hemorrhagic complications in patients treated with anticoagulated drugs ranges from 12 to 40%<sup>3</sup>. The commonest site of significant bleeding is the gastrointestinal tract.

**Aims & Methods:** The aim of this study was to assess the clinical and demographic characteristics of anticoagulated patients hospitalized with gastrointestinal bleeding in a university hospital. A retrospective study was carried out with data collection of medical records and the protocol implanted in 772 patients of the Digestive Hemorrhage Service. From September 2017 to January 2019, 39 patients with gastrointestinal bleeding (GIB) were hospitalized while on oral anticoagulants. The patients were categorized according to age, sex, need for transfusion, death, symptomatology of entry, alcoholism, medications, comorbidities, endoscopic diagnosis, endoscopic treatment. The clinical outcome of these patients was compared with those of 591 patients hospitalized in the same time with GIB who were not taking anticoagulation or antiplatelets.

**Results:** 39 patients used oral anticoagulants (5%). The most prevalent gender was the female (51%). The mean age was 74 years (19-91). Eleven patients died (28.3%), mostly men (9). Transfusion of red blood cells was necessary in 27 patients (69.2%) and the higher international normalized ratio (INR) didn't increase the number of blood bags or the mortality. The most common entry symptoms were hematemesis with 24 cases (61.5%) and melena (53.8%). The mean hemoglobin level at admission was 8.8 g / dL (4.1-17.2). Warfarin was the mostly used anticoagulant (50%). Of the

39 patients, 10 were alcoholics (25.6%), all men. Cirrhosis was observed in only one individual, having the alcoholism as its etiology. The most frequent comorbidity was systemic arterial hypertension (64%). At endoscopic examination, 21 presented mucosal lesions (53.8%), 9 with peptic ulcers (23%), 2 with duodenal ulcers, 1 with esophageal ulcer, 2 with gastric varices and one sclerotherapy was needed. We found no significant difference between the death rate between anticoagulated (28.3%) and non-anticoagulated patients (20.3%; p=0.22).

**Conclusion:** Acute gastrointestinal bleeding is a severe complication in patients receiving long-term oral anticoagulant therapy, with high mortality. These patients usually bleed from mucosal disease, a non-varicose cause. However, in this study, there was no statistically significant difference between the death rate between anticoagulated and non-anticoagulated.

**Contact E-Mail Address:** braghini.marina@gmail.com

**Introduction:** Upper gastrointestinal bleeding (UGIB), defined as bleeding from lesions in the digestive tract proximal to the Treitz ligament is a medical emergency with high mortality rates<sup>1</sup>. Of the cases of UGIB, 10% to 30% have varicose origin, and these varicose veins are present in 50% of cirrhotic patients<sup>2</sup>. Volemic reposition is used as the initial management of UGIB and should be more carefully chosen in patients with varicose UGIB, as they have a persistente state of hypervolemic circulation, with splanchnic vasodilation and low effective arterial volume, tending to arterial hypotension. Formal platelet transfusion indications are bone marrow failure or secondary hemorrhagic manifestations treatment<sup>3</sup>.

There is no consensus, however, some authors indicate that values above 50,000 platelets/mm<sup>3</sup> are safe for performing invasive procedures<sup>3</sup>, and at least 20,000 platelets/mm<sup>3</sup> for performing non-invasive procedures. Transfusion, therefore, is only indicated below 50,000 platelets/mm<sup>3</sup> in invasive procedures and below 20,000 platelets/mm<sup>3</sup> in non-invasive procedures. There is no indication of prophylactic transfusion in cases other than these.

**Aims & Methods:** To characterize the need for platelet transfusion in the cirrhotic patient with gastrointestinal bleeding treated in a university hospital from September 2017 to January 2019. This is a retrospective study with data gathering from the 772 patients of the Digestive Hemorrhage Department of the Hospital Universitário Evangélico Mackenzie, Curitiba, Brazil. In September 2017, this hospital became a unique reference for acute cases of gastrointestinal bleeding in Curitiba. Descriptive and statistical analysis was made of the prevalences according to age, sex, need for transfusion, death, symptomatology of entry, smoking, alcoholism, comorbidities, clinical-surgical management, endoscopic diagnosis, endoscopic treatment.

**Results:** Of the 772 patients, 12 presented with cirrhosis and were subject to platelet transfusion (1.5%), composing the sample 10 men (83.3%) and 2 women (16.7%). At admission, the average platelet count of these patients was 98,000/mm<sup>3</sup> (15,000-285,000). Only one patient had platelets below 20,000/mm<sup>3</sup> (8.3%) and other 3 patients had platelets equal to or below 50,000/mm<sup>3</sup> (33.3%). Therefore, there were 8 platelets transfusions without indication (66.6%). The median age was 51.5 years (SD = 8.8). 4

patients died (33.3%). The mean hemoglobin level at admission was 7.4 g/dL (3.7-9.7). Red blood cell transfusion was required in 11 patients (91.6%). The most present entry symptom was hematemesis with 11 cases (91.6%) and the most common association was hematemesis and melena with 7 cases (58.3%). Of the 12 patients, 9 were alcoholics (75%), all of them cirrhotic. At endoscopic examination, the most prevalent cause of UGIB was esophageal varices, corresponding to 10 cases (83.3%), of which 3 needed elastic ligation, followed by portal hypertensive gastropathy with 4 patients (33.3%).

**Conclusion:** The profile of the cirrhotic patient with gastrointestinal bleeding and platelet transfusion need is of men with a mean age of 51.5 years, alcoholics, presenting with hematemesis. The Department, facing so many platelet transfusions without indication, decided to better educate residents and attending physicians, as well as to restrict transfusion to extreme thrombocytopenia (less than 15,000 platelets/mm<sup>3</sup>) and to wait for the improvement of platelet metrics with drugs, to perform procedures, invasive or not.

**Introduction:** Dyspepsia is common in the community, causing a substantial impact on quality of life for sufferers as well as financial implications for society. The initial management of dyspepsia in primary care is a classical medical decision-making problem, with a number of competing strategies for the physician to consider. However, there is equipoise between some of these, and current guidelines do not agree on which approach should be used first-line.

**Aims & Methods:** Our aim was to conduct a network meta-analysis to compare the effectiveness of first-line strategies for the management of patients with uninvestigated dyspepsia.

MEDLINE, EMBASE, EMBASE Classic, the Cochrane central register of controlled trials, and clinicaltrials.gov were searched through March 2019 to identify randomised controlled trials (RCTs) assessing effectiveness of five management strategies (prompt endoscopy, "test and treat", "test and scope", empirical acid suppression, or symptom-based management) for uninvestigated dyspepsia. Trials reporting a dichotomous assessment of symptom status at final point of follow-up (≥12 months) were included. Data were pooled using a random effects model. Effectiveness was reported as a pooled relative risk of remaining symptomatic at final follow-up, with 95% confidence intervals (CIs) to summarise effectiveness of each comparison tested, and ranked according to P-score. We also analysed likelihood of patients in each treatment arm requiring endoscopy, dissatisfaction with management, and rates of upper gastrointestinal cancer.

**Results:** We identified 15 eligible RCTs, containing 6162 patients. Of the five strategies, "test and treat" was ranked first, using both an intention-to-treat and per protocol analysis (P-score 0.79 for both) (Figure), but none of the strategies were significantly less effective than "test and treat", or more effective than each other, on direct or indirect comparison. Prompt endoscopy ranked second, but performed similarly (P-score 0.71 and 0.69 on intention-to-treat and per protocol analysis).

Patients assigned to "test and treat" were significantly less likely to require subsequent endoscopy (P-score 0.98), compared with all other strategies on indirect comparison. Dissatisfaction rates were significantly lower

among patients randomised to prompt endoscopy, compared with "test and treat" and empirical acid suppression on indirect comparison. Only 20 upper gastrointestinal cancers (0.4%) were detected in 11 RCTs reporting this endpoint, containing 5028 patients. Detection rates were broadly similar between treatment arms.

**Conclusion:** In a network meta-analysis of RCTs, "test and treat" and prompt endoscopy performed similarly in terms of effect on symptoms at last point of follow-up, but "test and treat" was ranked first, and led to significantly fewer endoscopies than all other approaches. This suggests, of the five management strategies we studied, "test and treat" is the likely to be the most cost-effective.

**Introduction:** The epidemiology including the prevalence and risk factors of dyspepsia varies in different population. Moreover, functional dyspepsia (FD), though is commoner than organic in hospital studies, community data, particularly from rural areas, are lacking in Asia due to difficulty in performing endoscopy in the community. Hence, we performed a rural community study in Bangladesh with the following aims:

- (1) to study the prevalence of uninvestigated dyspepsia (UD), FD and structured dyspepsia (SD) in the community,
- (2) to evaluate the frequency of *H. pylori* in FD and peptic ulcer (PU),
- (3) to study its virulence-associated genes (CagA, vacA and specifically the vacA allelic variants) among patients with FD as compared to PU, and
- (4) to determine the risk factors for dyspepsia.

**Aims & Methods:** This prospective cross-sectional house-to-house survey was undertaken by trained field interviewers among adult population (>18-y) in three villages (Charcharia, Churain of Dhaka district and Kharrar of Munshiganj district of Bangladesh) using enhanced Asian Rome III questionnaire and General Health Questionnaire-28 translated and validated in Bengali language. Dyspepsia, functional heartburn (FH) and IBS were defined by Rome III criteria.

Dyspeptic subjects were offered an upper gastrointestinal endoscopy including tests for *H. pylori* (rapid urease test, histology and multiplex polymerase chain reaction, PCR; infection was diagnosed if PCR or two other tests were positive) and its genotyping by PCR for CagA, vacA and specifically the vacA allelic variants. SD was diagnosed in presence of duodenitis or erosions, PU and erosive esophagitis.

**Results:** 3351/3559 subjects responded [(94.15%), mean age 40.41±16.05 y, female, 1924 (57.4%)]. 547 (16.3%) had UD [female 346 (18%) vs male 201 (14%); p=0.002]. 201 (6%), 88 (2.6 %) and 258 (7.7%) had postprandial distress syndrome (PDS), epigastric pain syndrome (EPS) and PDS-EPS overlap, respectively.

On multivariate analysis increasing age, female gender, being married, lower education of less than class V, lower family income, use of non-steroidal anti-inflammatory drugs, history of acute gastroenteritis in last year and presence of psychological distress were found as risk factors for UD. Of 346 (63.25%) agreeing to endoscopy; 232 (67.05%) and 114 (32.95%) had FD and SD [PU 99 (28.61%); EE, 13 (3.76%) and both peptic ulcer and EE, 4 (1.16%)] respectively. Of 232 FD subjects, 35 (15%), 73 (31%) and 124 (54%) had EPS only, PDS only and EPS-PDS overlap, respectively. *H. pylori* was positive among 266/342 (78%) dyspeptics [FD, 173/230 (75.2%) vs SD, 92/114 (82.1%) (p=0.169)]. *H. pylori* infected patients with PU had higher frequency of Cag A and vac A genotype s1m1 positivity than those with FD (p< 0.05). Of the 547 UD subjects, 203 (37%) had FH, 110 (20%) had IBS and 52 (9.5 %) had both FH and IBS.

**Conclusion:** 16%, 11% and 5% rural adult population of Bangladesh had UD, FD and PU, respectively. About half of the patients with dyspepsia had PDS-EPS overlap and 20% had overlap with IBS. About third of the subjects with UD had SD, mostly PU. Patients with PU had more virulent *H. pylori* compared to those with FD.

**Introduction:** Functional dyspepsia (FD) is a disorder of the brain-gut axis characterised by symptoms of abdominal discomfort. Mindfulness-based therapies use meditation and relaxation to achieve a state of consciousness, mindfulness, during which one consciously attends to his or her moment-to-moment experience. Its efficacy for FD treatment is uncertain.

**Aims & Methods:** To determine the effectiveness of group mindfulness based intervention in improving the symptoms and quality of life in patients with functional dyspepsia. We performed an assessor-blinded randomised treatment-as-usual waitlist controlled trial. Patients who fulfilled Rome-3 FD were prospectively recruited from a tertiary care gastroenterology unit in Singapore and randomised to undergo Mindfulness Based Cognitive Therapy (MBCT) or Treatment-as-Usual (TAU). Subjects in the MBCT arm underwent weekly 2-hour-long standardised MBCT sessions for 8 weeks and 1 half-day retreat conducted by 2 accredited psychologists. Outcomes were assessed using Short Form Nepean Dyspepsia Index (NDI-SF) and the EuroQOL VAS scale which were administered pre and post treatment by assessors blinded to the treatment assignment. The Primary outcome was change in NDI-SF and EuroQoL at end of treatment compared to baseline. Ethics Board review was obtained.

**Results:** Fifty three patients were referred and 27 (59.9%) patients were recruited over 3 months. Amongst those who did not agree to recruitment, 10 were not fluent in English, 10 cited time constraints and unsuitability of the MBCT schedules, and 6 had no cited reasons. 21 of 27 patients (78%) completed the intervention. Of those who withdrew, 5 found difficulty in attending the intervention schedule due to time commitments, 1 had difficulty in following with the intervention instructions, 1 lost interest, and 2 were unable to complete "homework" due to time constraints. There was significant difference in change of NDI-SF at end of treatment compared to baseline between MBCT and TAU (mean change: -11.33 (7.53) Vs -2.0 (9.16),  $p < 0.01$ ) (see table) indicating that participants in the MBCT arm experienced a greater symptom improvement as compared to those in the TAU arm. There was no significant difference in change of EuroQOL VAS scale between baseline and post-treatment assessment between groups.

		Mean Baseline (SD)	Mean End of MBCT (SD)	Mean change baseline to end (SD)	Mean difference between MBCT and TAU (SD)	p
NDI-SF	MBCT	28.14 (9.54)	16.81 (4.75)	-11.33 (7.53)	6.19 (8.38)	<0.01
	TAU	25.00 (8.72)	23.00 (9.58)	-2.0 (9.16)		
EuroQoL-VAS	MBCT	57.79 (21.43)	61.45 (15.34)	3.66 (18.64)	1.8 (18.45)	0.53
	TAU	62.69 (16.91)	63.25 (19.50)	0.56 (18.25)		

[Table of Results]

**Conclusion:** FD patients who underwent MBCT experienced a greater improvement in their symptoms compared to those in the TAU arm. Language proficiency and time constraints were the major barriers to attendance of MBCT. Modifications to the intervention to address these limitations and careful patient selection should be considered in future studies.

### P1940 DYSPESIA E-LEARNING: NOVEL TOOL FOR DYSPESIA MANAGEMENT

de Jong J., Lantinga M.A., Drenth J.P.H.

Radboud University Medical Center, Department of Gastroenterology and Hepatology, Nijmegen, Netherlands

**Contact E-Mail Address:** judith.dejong@radboudumc.nl

**Introduction:** Digital educational tools hold several advantages over non-digital information. Patient engagement in self-management is an important application of digital tools. Dyspepsia is a condition primarily managed by lifestyle intervention, making patient engagement and educational motivation essential. Adoption of an educational tool depends on its development process and information transfer methods. We provide a detailed description of a successful dyspepsia e-learning development process.

**Aims & Methods:** We assessed users' needs by focus groups and interviews, followed by scientific validation of information against a systematic literature review. Subsequently, we developed the content based on most important themes, provided by the focus group participants and current literature. All content was organized into chapters and we supplemented information with text, videos, and 3D visualizations. The e-learning was pilot-tested and adjusted accordingly.

**Results:** We performed a focus group both with dyspeptic patients (n = 5) and general practitioners (n = 5). Main themes revealed were 1) Reassurance; 2) Pathophysiology of dyspepsia; 3) Prevalence, symptoms and prognosis of dyspepsia; 4) Lifestyle interventions; 5) Availability and value of therapy and diagnostics; 6) Psychosocial factors in dyspepsia, and 7) Peers' experiences. We wrote short text blocks providing information per item and added videos of a gastroenterologist, dietician and patient, explaining gastric function, dietary interventions and patient experiences. We created 3D visualizations of dyspepsia prevalence, upper gastrointestinal endoscopy procedure, gastric anatomy, function and mucosal damage, and pharmacological mechanisms of acid-reducing drugs.

**Conclusion:** The dyspepsia e-learning is a novel multi-media educational tool to assist patients and physicians in management of dyspepsia. This tool may be deployed to stimulate patient engagement and improve health outcomes. The presented protocol can be used to guide development of future e-learning for dyspepsia, or similar conditions.

**Introduction:** Upper gastro-intestinal (GI) endoscopy is frequently performed in dyspeptic patients. Diagnostic yield is low and clinical implications are limited. Therefore, dyspeptic patients are exposed to an avoidable invasive procedure. Symptom comprehension and lifestyle modifications potentially reduce patients' need for upper GI endoscopy.

**Aims & Methods:** Our aim was to study whether education of dyspeptic patients by e-learning reduces upper GI endoscopies in patients referred for direct-access upper GI endoscopy. We performed a multi-center, randomized, controlled trial in dyspeptic patients aged 18-70 years, referred for direct-access upper GI endoscopy. We excluded patients with alarming features or family history of upper GI malignancy. We recruited patients from four district hospitals in the Netherlands and randomly assigned (1:1 ratio) patients to receive either e-learning education (intervention) or endoscopy (control). Primary outcome was the difference in proportion of cancelled upper GI endoscopies at 12 weeks. Secondary outcomes included

symptom type and severity (PAGI-SYM), dyspepsia-related quality of life (SF-NDI) and health anxiety (SHAI). NCT03205319.

**Results:** We randomized a total of 119 patients (median age 48 yrs [IQR:37-56], male 40%, Western European ethnicity 90%, use of acid-suppressive drugs 74%, previous upper GI endoscopy 24%). There were no baseline differences between study groups (intervention n=62; control n=57) with respect to symptom type/severity, quality of life and health anxiety. At 12 weeks, 61% of patients in the intervention group had cancelled endoscopy, vs. 14% of controls (RR 0.44 [95% CI 0.31-0.62],  $p < 0.001$ ). No GI malignancy was detected.

**Conclusion:** E-learning education of dyspeptic patients effectively and safely reduces 47% of upper GI endoscopies. Education by e-learning may be broadly implemented in clinical practice to improve efficient use of upper GI endoscopies.

**Disclosure:** Nothing to disclose

## P1942 PHARMACOLOGICAL PROFILE OF NALDEMEDINE, A PERIPHERAL ACTING $\mu$ -OPIOID RECEPTOR ANTAGONIST-COMPARISON WITH NALOXONE AND NALOXEGOL

**Introduction:** Opioid-induced constipation (OIC), a common side effect of opioids, is due to the activation by opioids of the  $\mu$ -opioid receptors in the enteric nervous system<sup>1</sup>. Peripherally acting  $\mu$ -opioid receptor antagonists (PAMORAs) can reverse OIC by blocking the peripheral action of opioids in the gastrointestinal tract without affecting centrally mediated analgesia<sup>2</sup>. Naldemedine<sup>3</sup> is a PAMORA indicated for OIC in adult patients with chronic non-cancer pain in the US, in patients with chronic non-cancer pain and cancer in Japan and in adult patients who have previously been treated with a laxative in EU.

**Aims & Methods:** This study evaluated the in vitro and in vivo pharmacological profiles of naldemedine compared with those of naloxone and naloxegol.

In vitro binding affinity, antagonistic activity, Schild plot analysis of antagonism, and binding kinetics were evaluated for naldemedine, naloxegol, and naloxone. In vivo effects of each opioid antagonist on rat small intestinal transit (SIT) as well as withdrawal symptoms in morphine-dependent rats were also evaluated.

		Naldemedine	Naloxone	Naloxegol
Binding affinities/ Antagonist activities	$\mu$ (nM)	0.34/ 0.50	1.52/ 4.05	5.04/ 38.35
	$\delta$ (nM)	0.43/ 0.27	56.90/ 41.74	99.16/ 145.93
	$\kappa$ (nM)	0.94/ 0.44	2.63/ 18.43	40.78/ 38.51
Schild analysis of antagonism	Schild slope	1.42	0.88	0.93
Binding kinetics to human $\mu$ -opioid receptor	Kon (nM <sup>-1</sup> min <sup>-1</sup> )	0.041	0.350	0.056
	Koff (min <sup>-1</sup> )	0.023	0.290	0.390
	T1/2 (min)	30.78	2.44	1.78

[Summary of in vitro pharmacological profile of naldemedine compared with naloxone and naloxegol in human opioid receptors]

**Results:** In vitro, the antagonist activity of naldemedine at human  $\mu$ ,  $\delta$  or  $\kappa$  opioid receptors were 0.50, 0.27 or 0.44 nM, respectively. These values are more potent compared with those of other compounds. The Schild plot analysis indicated that naldemedine antagonized the effect of opioid agonist in a non-competitive manner while other compounds antagonized in a competitive manner. In receptor binding kinetics analysis, naldemedine showed slower  $K_{on}$  and  $K_{off}$  profile than other compounds. In vivo, naldemedine dose-dependently ameliorated the morphine-induced SIT inhibition. This effect was not dependent on the dose of morphine between 1 and 3 mg/kg. On the contrary, the dose-response curve of naloxegol was significantly shifted between the doses of morphine. This difference in inhibition pattern of naldemedine and naloxegol could be attributed to type

of antagonism. In morphine-dependent rats, naldemedine caused peripheral and central withdrawal symptoms at doses higher than 0.3 and 3 mg/kg, respectively, while the ED<sub>50</sub> for preventive effect of constipation was 0.03 mg/kg. Naldemedine showed slower onset and lower severity of diarrhea, which is a peripheral withdrawal symptom, than other compounds at each ED<sub>50</sub> in the SIT model. These differences could be attributed to binding kinetics.

**Conclusion:** Naldemedine acted differently with the  $\mu$ -opioid receptor when compared with naloxegol and naloxone as demonstrated by slower kinetics and acting as a non-competitive antagonist. These results may explain the clinical profile observed in the clinical trials with naldemedine.

## P1943 EFFECT OF NALDEMEDINE ON FREQUENCY OF SPONTANEOUS BOWEL MOVEMENTS AND ASSOCIATED SYMPTOMS

Wild J.<sup>1</sup>, Hale M.<sup>2</sup>, Yamada T.<sup>3</sup>, Ferreira J.C.A.<sup>3</sup>

<sup>1</sup>Upstate Clinical Research Associates, Williamsville, United States, <sup>2</sup>Gold Coast Research LLC, Plantation, United States, <sup>3</sup>Shionogi Inc, Florham Park, United States

**Contact E-Mail Address:** jwild@roadrunner.com

**Introduction:** Opioid-induced constipation (OIC) is a well-known side effect of opioid therapy. NAL is a peripherally-acting  $\mu$ -opioid receptor antagonist approved for the treatment of OIC in patients with chronic non-cancer pain.

**Aims & Methods:** To assess the effect of naldemedine (NAL) 0.2 mg once daily vs placebo (PBO) on the frequency of bowel movements (BMs), specifically the frequency of spontaneous BMs (SBMs), complete spontaneous BMs (CSBMs), SBMs without straining, and SBMs with a Bristol Stool Scale (BSS) score of 3 or 4 based on pooled results from the COMPOSE-1 and COMPOSE-2 studies during 12 weeks of treatment.

Two randomized, double-blind PBO controlled 12-week studies (NCT01965158 and NCT01993940), assessed the effect over time of NAL 0.2 mg once daily vs PBO in the frequency of SBMs, CSBMs, defined as SBMs with a perception of complete evacuation, SBMs without straining, and SBMs with a BSS score of 3 or 4 in adult (age 18-80 years) subjects with chronic non-cancer pain and OIC. Subjects were required to not be on laxatives at screening or to agree to discontinue laxatives upon signing informed consent. The mean changes in the frequency per week from baseline to each week was compared between NAL and PBO, with a mixed-effects model repeated measures with opioid dose strata and study as a covariate and treatment group, time, time-by-treatment group interaction as fixed effects. Safety was assessed based on the incidence of adverse events (AEs).

**Results:** In the two studies pooled, 1095 subjects were randomized 1:1 to NAL (N=549) or PBO (N=546) for 12 weeks. In all four endpoints, NAL was associated with a significantly ( $P \leq 0.0001$ ) greater improvement from baseline at each week relative to PBO, starting at Week 1 and up to Week 12. The overall incidence of AEs was generally similar between groups. Treatment with NAL was associated with a greater incidence of gastrointestinal AEs (abdominal pain, diarrhea, nausea) compared with PBO.

**Conclusion:** Treatment with NAL over 12 weeks compared with placebo improved the frequency of bowel movements as well as the signs and symptoms of OIC frequently reported with bowel movements including perception of incomplete evacuation, need for straining, and hard stools. NAL was generally well tolerated.

**Disclosure:** James Wild received a one-time stipend from Shionogi for performing a review of the clinical study report. **P1944 SAFETY AND EFFICACY OF NALDEMEDINE FOR THE TREATMENT OF OPIOID-INDUCED CONSTIPATION IN PATIENTS WITH CHRONIC NON-CANCER PAIN RECEIVING OPIOID THERAPY: A SUBGROUP ANALYSIS OF PATIENTS ≥65 YEARS OF AGE**

**Wild J.**<sup>1</sup>, Webster L.<sup>2</sup>, Yamada T.<sup>3</sup>, Hale M.<sup>4</sup>

**Contact E-Mail Address:** jwild@roadrunner.com  
**Introduction:** Chronic non-cancer pain (CNC) is commonly managed with opioid analgesics, yet opioid-induced constipation (OIC), one of the most common side effects, is under-recognized and undertreated in elderly patients. Naldemedine (NAL), an oral peripherally acting  $\mu$ -opioid receptor antagonist, is indicated for treatment of OIC in adult patients with CNC in the US and in patients with CNC and cancer in Japan.  
**Aims & Methods:** To evaluate the safety and efficacy of NAL for up to 12 weeks in a subgroup of elderly patients from an integrated analysis across 3 global phase 3 trials.  
 Results up to 12 weeks from 3 double-blind, randomized, placebo (PBO)-controlled trials were integrated. Patients aged 18-80 years (y) with CNC treated with opioids for  $\geq 3$  months and OIC received oral NAL 0.2 mg or PBO once daily. Patients aged  $\geq 65$  y were included in this subgroup analysis. Safety assessments from the 3 studies up to 12 weeks (safety population) included overall incidence of treatment-emergent adverse events (TEAEs), TEAEs in Gastrointestinal (GI) Disorders System Organ Class (SOC), and TEAEs of opioid withdrawal (OW) or possible OW. Efficacy was based on the primary endpoint from the two 12-week studies (intent-to-treat population), ie, proportion of responders. A responder was defined as having  $\geq 3$  spontaneous bowel movements (SBMs)/week and  $\geq 1$  SBM/week increase from baseline (BL) for  $\geq 9$  of 12 weeks and  $\geq 3$  of the last 4 weeks.  
**Results:** At BL, 14.8% (344/2328) of patients in the safety population were  $\geq 65$  y. The incidence of TEAEs in the NAL vs PBO groups was 45.9% vs 51.6% ( $\geq 65$  y) and 47.1% vs 45.6% (overall), and the incidence of GI disorder SOC TEAEs in the NAL vs PBO groups was 20.2% vs 16.1% ( $\geq 65$  y) and 21.8% vs 13.8% (overall), respectively. The incidence of TEAEs of OW in the NAL vs PBO groups was 1.1% vs 0% ( $\geq 65$  y) and 1.0% vs 0.6% (overall), and the incidence of TEAEs of possible OW was 1.1% vs 0.6% ( $\geq 65$  y) and 1.6% vs 0.5% (overall), respectively. The proportion of responders was higher in the NAL vs PBO groups for patients  $\geq 65$  y (51.8% vs 37.6%; difference [95% confidence interval]: 12.6 [-2.3, 27.5]) and overall (50.1% vs 34.1%; 16.0% [10.2, 21.8]), respectively.  
**Conclusion:** This integrated analysis across 3 phase 3 clinical trials up to 12 weeks confirmed that OIC treatment with NAL 0.2 mg was generally well tolerated and effective in patients aged  $\geq 65$  y with CNC. The incidence of OW and possible OW was low and similar between NAL and PBO. Safety and efficacy results were consistent with the overall population.

**P1945 SAFETY OF NALDEMEDINE FOR THE TREATMENT OF OPIOID-INDUCED CONSTIPATION IN SUBJECTS WITH CHRONIC NON-CANCER PAIN RECEIVING OPIOID THERAPY: RESULTS OF THREE GLOBAL PHASE 3 CLINICAL TRIALS**

**Webster L.**<sup>1</sup>, Magazine H.I.<sup>2</sup>, Yamada T.<sup>2</sup>  
<sup>1</sup>PRA Health Sciences, Salt Lake City, United States, <sup>2</sup>Shionogi Inc, Florham Park, United States

**Contact E-Mail Address:** lrwebstermd@gmail.com  
**Introduction:** Opioid-induced constipation (OIC) is a common side effect of opioids in the treatment of chronic non-cancer pain (CNC). Effective treatment of OIC can be impacted by how particular treatments are tolerated. Naldemedine (NAL), an oral, peripherally acting  $\mu$ -opioid receptor antagonist, is approved for the treatment of OIC in adult patients with CNC in the US.  
**Aims & Methods:** To evaluate the safety and tolerability of NAL from integrated analysis across three global phase 3 trials up to 12 weeks. Results from three phase 3, double-blind, randomized, placebo (PBO)-controlled trials were integrated to evaluate the safety and tolerability of NAL up to 12 weeks. Subjects 18 to 80 years old, with CNC and OIC, taking opioids for  $\geq 3$  months, received either NAL 0.2 mg (N=1163) or PBO (N=1165) taken orally once daily with or without food. Tolerability and adverse events, including potential opioid withdrawal (OW) were analyzed.  
**Results:** The majority of subjects completed the trial (NAL, 88.7%, PBO, 88.4%) and the proportion that discontinued was similar across treatment groups. The duration of treatment was similar across treatment groups with a mean exposure of 76.6 and 77.2 days in the NAL and PBO groups respectively, approaching the maximal possible exposure of 84 days for the 12-weeks of study. Adverse Drug Reactions were reported more frequently in the NAL group compared with PBO across the studies and in the pooled population (NAL, 20.1%, PBO, 13.6%, 95% CI of difference: 3.4, 9.5). The assessment of summary measures of Treatment Emergent Adverse Events (TEAEs) demonstrated that the overall incidence was similar between groups in all studies and associated primarily with the gastrointestinal system. TEAEs reported for  $\geq 1\%$  of subjects in at least one treatment group and at a higher incidence in the NAL group compared to PBO are shown in Table 1. TEAEs with  $\geq 1\%$  difference between the NAL and PBO groups were limited to abdominal pain, diarrhea, and nausea. In general, TEAEs were mild to moderate in severity and short in duration. The majority of reports of diarrhea occurred early in the study, reports of abdominal pain occurred early and only once, and nausea generally occurred early but with reports throughout the study. The incidence of OW was low in the NAL and PBO groups (NAL, 1.0%, PBO, 0.6%).  
**Conclusion:** An integrated analysis across three Phase 3 trials demonstrated that treatment of OIC with NAL in subjects with CNC was well tolerated with the majority of TEAEs occurring early, of short duration, mild to moderate in nature and generally limited to the gastrointestinal system. Furthermore, the incidence of OW was low and similar between NAL and PBO.

Treatment Emergent Adverse Events	Naldemedine 0.2 mg (%)	Placebo (%)
Diarrhea	7.7	2.4
Abdominal Pain	6.4	1.9
Nausea	5.3	3.3
Abdominal Pain - Upper	2.7	1.5
Back Pain	2.7	2.2
Headache	2.2	2.1
Vomiting	2.3	1.4
Nasopharyngitis	1.8	1.6
Abdominal Distension	1.7	1.6
Hyperhidrosis	1.5	0.7
Arthralgia	1.5	1.2
Viral Gastroenteritis	1.4	0.6
Influenza	1.1	0.9
Drug Withdrawal Syndrome	1.0	0.6
Bronchitis	1.0	0.9

## P1946 CLINICAL, IMAGING AND PHYSIOLOGICAL CHARACTERISTICS OF CHRONIC INTESTINAL PSEUDO-OBSTRUCTION IN SYSTEMIC SCLEROSIS, AMYLOIDOSIS AND PARANEOPLASTIC SYNDROMES: A TERTIARY CARE CENTER EXPERIENCE

Pamathy R.<sup>1</sup>, Breen-Lyles M.<sup>1</sup>, Sundt W.<sup>1</sup>, Makol A.<sup>2</sup>, Grover M.<sup>1</sup>  
<sup>1</sup>Mayo Clinic, Division of Gastroenterology and Hepatology, Rochester, United States, <sup>2</sup>Mayo Clinic, Division of Rheumatology, Rochester, United States

**Contact E-Mail Address:** grover.madhusudan@mayo.edu

**Introduction:** Chronic intestinal pseudo-obstruction (CIPO) is a rare disabling disorder characterized by a severe impairment of intestinal motility, mimicking mechanical obstruction in the absence of an obstructing luminal lesion.

**Aims & Methods:** To describe the clinical correlates, imaging findings, and physiological studies (scintigraphic transit and manometry) in pseudo-obstruction associated with systemic sclerosis (SSc), amyloidosis and paraneoplastic syndromes evaluated at a single large tertiary referral center. A retrospective cohort of patients with intestinal pseudo-obstruction associated with SSc, amyloidosis or paraneoplastic syndromes treated at our institution between Jan 1, 2008-Aug 1, 2018 was assembled. Subjects with an alternative luminal or systemic etiology for bowel dilatation were excluded. Demographics, clinical characteristics, autoimmune serologies, imaging, physiological testing and biopsy results were abstracted from electronic medical records using a standardized data abstraction form.

**Results:** We identified 100 cases of pseudo-obstruction {mean age 58 y, 54% female, 86% Caucasian}; 55 associated with SSc, 27 with amyloidosis and 18 with paraneoplastic syndromes. The clinical features, radiological and physiological study findings were as listed in the table below. Female preponderance was seen in SSc, in comparison to male dominance in the other two groups. The most common symptom was abdominal bloating in all 3 groups. Vomiting and weight loss were more common in SSc compared to the other two groups. Diarrhea was less common in paraneoplastic syndromes compared to the other two groups. Only small bowel dilatation was seen in 70%, 32% & 44% of patients in SSc, amyloidosis and paraneoplastic, respectively. Only large bowel dilatation was seen in 44% & 44% of patients in amyloidosis and paraneoplastic, respectively. Remaining had both small and large bowel dilations. 5/8 were myopathic in SSc group and 3/5 were neuropathic in paraneoplastic group on gastroduodenal manometry.

**Conclusion:** Small bowel is more commonly involved than large bowel both on imaging and transit studies in SSc patients, whereas both small and large bowel showed equal involvement in the other 2 groups. Myopathic involvement was more common in SSc, whereas neuropathic involvement was more common in paraneoplastic syndromes.

## P1947 MANOMETRY DATA OF THE LOWER ESOPHAGEAL SPHINCTER LINEARLY CORRELATE WITH CLINICAL SEVERITY IN TYPE I AND II ACHALASIA

Bancila L.<sup>1</sup>, Dimitriu A.<sup>2</sup>, Iacob R.<sup>3</sup>, Gheorghe C.<sup>1</sup>  
<sup>1</sup>Fundeni Clinical Institute, Gastroenterology and Hepatology, Bucharest, Romania, <sup>2</sup>Fundeni Clinical Institute, Gastroenterology - Endoscopy, Bucharest, Romania, <sup>3</sup>Fundeni Clinical Institute, Bucharest, Romania

**Contact E-Mail Address:** ibancila@yahoo.com

**Introduction:** Achalasia is a very heterogeneous disease, with no obvious correlation between symptom duration, symptom severity, radiology and manometric data. The aim of our study was to investigate possible correlations between symptom severity (Eckardt score) and manometric data.

**Aims & Methods:** We analysed a cohort of 61 consecutive patients with achalasia, diagnosed according to the Chicago classification v 3.0; 41 patients had achalasia type II, 17 had type I and only 3 patients had achalasia type III. Due to the low number of type III achalasia patients we included in the analysis only patients with type I and II. The patients were divided according to the Eckardt score in two groups, with a score ≤ 6 and with a score > 6 (representing clinically severe achalasia). The manometric data of the two groups were compared using Mann-Whitney U-test and student t-test and multivariate analysis. A  $p < 0.05$  was considered significant.

**Results:** All the manometric variables of the esophagogastric junction [LES resting (LESP) and residual (LESRP) pressure and integrated relaxation pressure (IRP)] showed differences between the two groups, in the sense of higher values corresponding to the Eckardt score > 6 ( $p = 0.029$  for LESP,  $p = 0.0009$  for LESRP,  $p = 0.003$  for IRP). The univariate analysis showed linear correlations between IRP ( $r^2 = 0.17$ ;  $p = 0.004$ ), LESRP ( $r^2 = 0.26$ ;  $p = 0.0004$ ), LESP ( $r^2 = 0.08$ ;  $p = 0.048$ ) and the Eckardt score. The multivariate analysis of the correlations between the Eckardt score and the manometric variables at the level of the LES was done by multiple regression and found that LES resting pressure is not an independent predictor for the severity of the Eckardt score (regression coefficient -0.03,  $p = 0.08$ ), while IRP (regression coefficient 0.04;  $p = 0.0004$ ) and LESRP (regression coefficient 0.09;  $p = 0.002$ ) are independent predictors of the Eckardt score. The distal contractility integral showed no significant differences between the two groups ( $p = 0.97$ ).

**Conclusion:** Our results have shown that in type I and II achalasia there is a linear correlation between the degree of incompleteness of LES relaxation and the clinical severity measured by the Eckardt score. These results validate the Eckardt score as a sensitive tool in determining the severity of achalasia before treatment and underline that the main determinant of symptoms in achalasia is the absence of relaxation of the LES, with a superior pathophysiological importance compared to that of aperistalsis.

**Contact E-Mail Address:** drprapul@gmail.com

**Introduction:** Jackhammer esophagus (JE) is a major disorder of esophageal motility, characterized by hypercontractile peristalsis, diagnosed by high resolution manometry (HRM) showing  $\geq 20\%$  swallows with increased contractile vigor (distal contractile integral (DCI)  $> 8000$  mmHg/s/cm). We hypothesize that the hypercontractile peristalsis in JE could be a compensatory mechanism for impaired EGJ relaxation, which even when integrated relaxation pressure (IRP) is normal ( $< 15$  mmHg) may be expressed by a delayed onset of relaxation.

**Aims & Methods:** Our aim was to assess and compare time to onset of EGJ relaxation in JE patients with normal IRP, "control" patients (presenting for evaluation of esophageal symptoms) with normal HRM, and asymptomatic healthy volunteers.

We evaluated time to onset of EGJ relaxation in 44 patients (24 with JE, 20 with normal HRM) who presented to our motility lab for evaluation of esophageal symptoms, and in 21 asymptomatic healthy volunteers who underwent HRM. Demographic characteristics and validated esophageal questionnaires (GERDQ, BEDQ, Eckardt) were collected for all subjects. HRM was performed with a solid-state catheter with 36 pressure sensors; ten 5-ml liquid swallows administered, Chicago Classification version 3.0 used to diagnose JE and normal esophageal motility. Time to onset of EGJ relaxation after swallow initiation was measured in seconds, from the time of upper esophageal sphincter opening to EGJ opening. EGJ opening was determined at an isobaric contour of 23 mmHg, based on analysis in the healthy volunteers showing persistent EGJ effacement at this value in 100% of the volunteers. Median times to onset of relaxation for the study groups were compared by Wilcoxon rank sum test.

**Results:** Demographics and questionnaire scores are shown in Table 1; patients were older and had higher scores compared to healthy volunteers. HRM metrics were different among the study groups with the exception of DL (Table 1). Median times to onset of relaxation after swallow initiation are shown in figure 1. There was no significant difference in median time to onset of relaxation for healthy volunteers compared to patient controls with normal HRM (0.20 s versus 0.90 s,  $p = 0.149$ ). Median time to onset of relaxation was significantly longer in JE patients compared to healthy volunteers and patient controls (3.30s vs 0.20 s vs 0.90 s,  $p=0.001$ ).

	Healthy Volunteers	Control patients with normal HRM	Jackhammer Esophagus	p
Age	35 (28 - 41)	55 (40 - 67)	64.5 (59.5 - 71)	0.001
BMI	24.34 (23.01 - 28.08)	25.40 (21.75 - 29.17)	27.26 (24.36 - 29.57)	0.543
BEDQ	0 (0 - 0)	0 (0 - 4)	8 (0.5 - 17)	0.001
GERDQ	0 (0 - 0)	7.50 (1.50 - 15.50)	10 (4 - 18.5)	0.001
Eckardt	0 (0 - 0)	2.5 (1 - 3.5)	2 (2 - 3.5)	0.001
IRP	8 (3.30 - 13.30)	4.95 (4.95 - 6.95)	9.10 (5.85 - 13.70)	0.044
DCI	1081 (568 - 1676)	1635 (1409 - 2128)	8635 (7143 - 11370)	0.001
DL	6.50 (5.60 - 7.30)	6.35 (5.75 - 7)	6.35 (5.80 - 7.65)	0.779
EGJ	22.4 (14.5 - 27.9)	23 (21.75 - 29.15)	36.95 (29.05 - 52.10)	0.001
Seconds	0.20 (0 - 3.30)	0.90 (0.30 - 2.50)	3.30 (2.80 - 5.30)	0.001

[Table 1]

**Conclusion:** Patients with Jackhammer esophagus and normal EGJ relaxation by IRP have significantly delayed onset of EGJ relaxation compared to healthy subjects and control patients with normal HRM. These findings suggest that hypercontractile peristalsis in these JE patients could be a compensatory mechanism to overcome outflow obstruction manifested as delayed EGJ relaxation. Therefore, if our findings are confirmed, therapies to address impaired EGJ relaxation could be considered for these patients.

**Contact E-Mail Address:** wangkun5555@sina.com

**Introduction:** The diagnosis of EGJ outlet obstruction (EGJO) is mainly based the high 4 second integrated relaxation pressure (IRP4s) with peristaltic contraction during wet swallows. In some situations, the IRP4s was hard to get because patients couldn't well accomplish the wet swallows. EGJ contractile index (EGJCI) is a newly defined metric to reflect the function of EGJ in resting state.

**Aims & Methods:** The aims of this study were to analyze the values of EGJCI in the diagnosis of EGJO.

One hundred and seven EGJO patients and 103 non-EGJO subjects were enrolled in this study. All subjects completed the CRF questionnaire, blood tests, gastroendoscopy and HRM. The values of EGJCI were compared between the two groups. The correlations between EGJCI, LES rest pressure and IRP4s were analyzed respectively and furtherly the AUC value of EGJCI in diagnosing EGJO was analyzed by ROC curve.

**Results:** There was significant difference of the EGJCI values between the EGJO group and the non-EGJO subjects ( $34.85 \pm 2.95$  vs.  $14.42 \pm 1.38$ ,  $P < 0.001$ ). Among these 210 subjects, significant positive correlation between EGJCI and IRP4s was found ( $r=0.574$ ,  $P < 0.001$ ) while no significant correlation was found between IRP4s and LES rest pressure ( $r=0.107$ ,  $p=0.085$ ). Further analysis showed the AUC of EGJCI was 0.778. And the cutoff value of EGJCI was 14.02 to differentiate the EGJO and non EGJO with sensitivity of 0.804 and specificity of 0.66.

**Conclusion:** EGJCI is an effective metric to represent the EGJ function of both resting state and the swallowing state. When the cutoff was 14.02, EGJCI can help to differentiate the EGJO patients from non-EGJO subjects with a high sensitivity.

**Contact E-Mail Address:** nanna.sutter@gmail.com

**Introduction:** Gold standard for diagnosis of gastroparesis is gastric emptying scintigraphy. Unfortunately, the association between symptoms and results of scintigraphy is poor. The Motilis 3D-Transit system allows minimally invasive and completely ambulatory description of transit patterns throughout the whole gastrointestinal tract.

**Aims & Methods:** The aim was to establish normative data for gastric emptying time and contractility patterns assessed with the 3D-Transit system and determine if gastric emptying time and contractility patterns were affected by age, BMI, gender or the content of the test meal.

3D transit recordings from 130 healthy were reanalysed using newly developed software.

**Results:** The median gastric emptying time was 2.7 hours (range 0.1–21). In 90% the capsule passed the pylorus within the fasting period of 6 hours after ingestion. The median contraction frequency in the stomach was 3.1 contractions pr. Minute (range 2.6–3.9). The frequency was highest in women and increased with age ( $p < 0.05$ ). The median amplitudes were 35° (range 4–85) based on rotation of the capsule and 11 mm (range 6–31) based on capsule position. The amplitude based on rotation higher in women and decreased with increasing BMI ( $p < 0.05$ ). The amplitude was higher in women, increased with the total amount of calories in the test meal and decreased with increasing BMI and age ( $p < 0.05$ ). We did not find any systematical day-to-day variation ( $p > 0.05$ ). Inter-rater variability was minimal.

**Conclusion:** The 3D-Transit is a safe, minimally invasive, radiation free and ambulatory system for assessment of GE. We have established normative data on gastric emptying and motility. In future studies with 3D-transit, gender, age, BMI should be matched and the test meal should also be standardized.

**Disclosure:** Schlageter V is co-owner of Motilis Medica SA and has been technical partner in terms of improving and creating new system software but had no influence on the study itself. Other authors have no competing interests.

## P1951 FREE DRINKING AND SOLID SWALLOWS PERFORMED DURING HIGH-RESOLUTION MANOMETRY HELP BETTER DEFINE THE CLINICAL RELEVANCE OF ESOPHAGOGASTRIC JUNCTION OUTFLOW OBSTRUCTION

**Introduction:** Esophagogastric junction outflow obstruction (EGJO) is a high-resolution manometry (HRM) derived diagnosis with unclear clinical implications; some require invasive therapy similar to achalasia, while others are of little significance. We hypothesized that adjunctive testing during HRM (free drinking and solids) would help determine EGJO that is relevant and warrants therapy.

**Aims & Methods:** Between July 2015 and December 2018, all those with EGJO on HRM at a tertiary center in London were assessed. HRM was performed with ten 5 mL water swallows followed routinely by a rapid drink challenge (RDC; 200 mL water drunk freely) and then solid swallows (either five 1 cm<sup>3</sup> buttered bread or 200 g rice). EGJO was defined as raised integrated relaxation pressure (IRP) during 5 mL swallows (median IRP >15 mmHg), RDC (IRP >8 mmHg) and/or solid swallows (IRP >25 mmHg in at least 2 swallows) with preserved peristalsis.<sup>1</sup> EGJO was divided into Functional or Secondary (anatomic/mucosal disorder). Eckardt symptom score, stasis on barium swallow, presence of peristaltic dysfunction and therapeutic outcome were assessed.

**Results:** From a total of 1705 HRM studies performed, 78 subjects (4.6%) were identified as having EGJO (median age 55y; 29 males). Dysphagia was the primary symptom in 54 (69%). Hiatus hernia >2 cm was present in 30 (38%). Fifty-four (70%) had functional EGJO, of whom 19 were opioid users. 17 had Secondary etiologies; post-fundoplication (N=7), crural diaphragm impingement within a hernia (N=3), stricture (N=3) and eosinophilic esophagitis (N=4). Secondary EGJO had a significantly lower mean IRP during single water swallows compared to functional EGJO (12.1 vs 18.2 mmHg,  $P < 0.01$ ).

In 26 patients (31%), raised IRP was evident only with RDC or solids and not with 5 mL water; this occurred in a larger proportion of Secondary compared to Functional EGJO subjects (65% vs. 25% respectively;  $P = 0.003$ ). 7 received endoscopic therapy with significant improvement in

median Eckardt score (6 pre and 2 post-therapy;  $P = 0.02$ ). On the other hand, 13 (17%) with raised IRP during 5 mL water swallows had normal IRP with RDC/solids, 11 of whom had no concomitant peristaltic abnormalities or holdup of barium at the EGJ and did not require any form of therapy. Fifty-two subjects (69%) had normal esophageal body motility, while 24 (31%) exhibited hypertensive, fragmented or ineffective patterns with any swallow modality. Of the 55 who had subsequent barium studies, patients with peristaltic abnormalities exhibited holdup of contrast significantly more often than those with normal peristalsis (42% vs. 16% respectively;  $P = 0.02$ ).

19 (35%) of Functional EGJO patients had endoscopic therapy (7 botulinum toxin, 13 pneumatic dilatation and 1 per-oral endoscopic myotomy) leading to a reduction in mean Eckardt score from 5.9 to 1.0 at a minimum of 3 months post-therapy ( $P < 0.0001$ ). Of the Secondary EGJO subjects, 5 (29%) received endoscopic therapy: 2 balloon or Savary-Gilliard dilatation (mucosal stricture) and 3 pneumatic dilatation (tight fundoplication). This led to a reduction in mean Eckardt score from 6.2 to 3.0 at a minimum of 3 months post-therapy ( $P = 0.03$ ).

**Conclusion:** The addition of adjunctive testing to the HRM protocol (RDC/solids) increases the likelihood of identifying clinically relevant EGJO, by increasing both sensitivity and specificity of its diagnosis. These findings, along with abnormalities in esophageal motor pattern during RDC and solid swallows as a further discriminating factor may assist in better determining who might benefit from therapy.

**Introduction:** Gastroparesis (GP) is a chronic debilitating condition. Current pylorus-targeted procedures are either invasive or have questionable efficacy. Gastric per-oral pyloromyotomy (G-POEM) has been proposed as a minimally invasive intervention for refractory GP.

**Aims & Methods:** We performed a systematic review and pooled analysis to evaluate the efficacy and safety of G-POEM for GP.

Electronic databases (Medline, Scopus, EMBASE) were searched up to January 2019. Only studies including patients who underwent G-POEM for GP were eligible. The primary outcome of interest was the technical success rate. Secondary outcomes included the mean procedural time, the rate of clinical success and the rate of adverse events, namely intra- and post-procedural bleeding, perforations and strictures. The pre- and post-procedural Gastroparesis Cardinal Symptom Index (GCSI) scores and results of Gastric Emptying Scintigraphy (GES), if provided, were also assessed. Procedural, clinical and safety outcomes were assessed by pooling data by means of a random- or fixed-effect models according to the degree of heterogeneity to obtain a proportion with a 95% confidence interval (CI).

**Results:** Ten studies were eligible for inclusion (292 patients), only 2 of which were prospective. Seven studies were performed in the United States, 2 in France and 1 in China. All studies but 2 were single-center experiences. Endoscopic pyloromyotomy was technically successful in all patients. Significant symptomatic improvement was achieved after 83.9% of the procedures (mean follow up period 7.8±5.5 months). Six studies reported the pre- and post- procedural Gastroparesis Cardinal Symptom

Index score: the mean pre-procedural GCSI score was  $3.3 \pm 0.6$  and dropped to  $1.61 \pm 0.61$  after G-POEM ( $p < 0.001$ ). When comparing the mean values of pre- and post-procedural scintigraphic evaluation, there was a significant decrease in the residual percentage at both 2 and 4 hours:  $74.9 \pm 5.2$  % vs  $52.5 \pm 10.8$  % ( $p < 0.001$ ) and  $44.1 \pm 13.0$  % vs  $20.6 \pm 9.5$  % ( $p < 0.001$ ), respectively. The overall adverse event rate was 6.8%. Immediate and post-procedural bleeding occurred in 1.9% ( $I^2 = 27.8\%$ ) and 2.6% ( $I^2 = 0\%$ ) of procedures, respectively. Gastric ulcers were reported in 5 cases, with a pooled rate of 2.3% ( $I^2 = 0\%$ ). Moreover, perforations were reported in 3 cases and a peritoneal abscess occurred in 1 case. Late events such as pyloric strictures were reported after 1% ( $I^2 = 0\%$ ) of cases.

**Conclusion:** In the short-term, G-POEM appears to be a promising technique in terms of safety and efficacy outcomes. While comparison to other pylorus-directed interventions in large controlled trials is awaited, G-POEM should be considered as a therapeutic option when dealing with refractory gastroparesis.

**Introduction:** There is literature suggesting an association between oesophageal motility disorders and eosinophilic oesophagitis (EoE) with a few cases reporting patients with co-existing oesophageal achalasia and EoE.<sup>1,2</sup>

**Aims & Methods:** The aim of this study was to undertake a histological evaluation for the presence of eosinophils in oesophageal biopsies (mucosal and muscle) in patients with achalasia who underwent POEM to determine if any association of eosinophilic oesophagitis and achalasia existed in our cohort.

All patients undergoing POEM for achalasia from 2013 onwards were included, with data extracted from the hospital electronic patient record. Patients had routine pre-treatment assessment with high resolution manometry, barium swallow and Eckardt score. Results of oesophageal biopsies (mucosal and oesophageal) that were taken were recorded.

Histology samples were processed by our local histopathology department. Samples were routinely fixed in formalin and embedded in paraffin wax before sectioning onto glass slides for review.

**Results:** 105 patients underwent POEM at our institution from November 2013 onwards (45F; mean age  $51 \pm 14$  yrs). Mean duration of disease was  $4.9 \pm 4.5$  yrs and the most common sub-type of achalasia according to Chicago Classification was Type II (71 patients). The mean Eckardt score pre-POEM was  $8 \pm 2$  points.

44 (42%) patients underwent oesophageal biopsies (39 mucosal, 5 muscle) in our cohort. 21 patients underwent oesophageal biopsies prior to undergoing POEM, 5 had oesophageal biopsies taken during POEM and 18 underwent oesophageal biopsies post POEM (during their Day 1 post POEM oesophagogastrroduodenoscopy).

31 patients had both lower and mid oesophageal biopsies, 6 only had lower oesophageal biopsies and 2 only mid oesophageal biopsies. The 5 that had muscle biopsies taken had their sample taken from mid oesophagus. No patient had oesophageal biopsies that contained eosinophils. 20 samples were reported as normal, 19 biopsies chronic inflammation, 2 biopsies with diathermy effect and therefore not interpretable, 1 fibrosis and 2 with other diagnoses (leukoplakia and candidiasis).

**Conclusion:** In our cohort no oesophageal biopsies reported eosinophils. Most biopsies either had evidence of chronic inflammation or no abnormality. Our study could not identify a link between eosinophilic oesophagitis and achalasia. The main finding of chronic inflammation is in keeping with stasis related inflammation that occurs in achalasia. Our finding could challenge the need to do routine oesophageal biopsies in work up endoscopy for achalasia patients who already have a confirmed diagnosis with high resolution manometry. This could have significant cost and time saving benefits. Further research is required to determine the utility of oesophageal muscle biopsies, a novel resource uncovered by submucosal endoscopy.

### P1954 SYMPTOM PROFILE OF NON-CARDIAC CHEST PAIN DEPENDS ON PATHOPHYSIOLOGY OF ESOPHAGEAL DISEASES

Kuribayashi S.<sup>1</sup>, Hosaka H.<sup>1</sup>, Shimoyama Y.<sup>1</sup>, Kawamura O.<sup>2</sup>, Kusano M.<sup>3</sup>, Uraoka T.<sup>2</sup>

<sup>1</sup>Gunma University Hospital, Gastroenterology and Hepatology, Maebashi, Japan, <sup>2</sup>Gunma University Graduate School of Medicine, Gastroenterology and Hepatology, Maebashi, Japan, <sup>3</sup>Gunma University Hospital, Maebashi, Japan

**Contact E-Mail Address:** shikokuri@yahoo.co.jp

**Introduction:** Non-cardiac chest pain (NCCP) is one of major symptoms in patients with esophageal motility disorders (EMDs) or gastroesophageal reflux disease (GERD), but, the symptom profile of NCCP in different diseases is not fully understood.

**Aims & Methods:** A total of 91 consecutive patients (57 females, mean age: 54 years) with NCCP who underwent esophageal manometry using high resolution manometry (HRM) between March 2009 and February 2018 at Gunma University Hospital were enrolled. Most of the patients (92%) had dysphagia as well as NCCP. NCCP was assessed by a questionnaire concerning location, time and duration of NCCP. Esophagogastrroduodenoscopy (EGD) was performed in all patients. When reflux esophagitis was seen on EGD or when a proton pump inhibitor (PPI) was effective, patients were diagnosed as GERD. When eosinophil infiltration ( $\geq 15$ /HPF) in the esophageal mucosa was seen, patients were diagnosed as eosinophilic esophagitis (EoE) regardless of presence of EMDs or GERD. Esophageal motility was assessed retrospectively according to the Chicago classification v3.0. Major EMDs were divided into five groups based on HRM findings: Achalasia type I or II, achalasia type III, esophago-gastric junction outflow obstruction (EGJOO), spastic esophageal motility disorders (SMDs) and absent contractility (AC). When major EMDs were found, it was considered that NCCP was caused by EMDs. When a PPI was not effective and there was no abnormal finding on both EGD and HRM, a 24-hour esophageal pH-impedance monitoring was performed. When abnormal esophageal acid exposure or positive symptom association were found, patients were diagnosed as GERD. When neither of those was present, patients were diagnosed as functional chest pain (FCP).

**Results:** There were 33 achalasia (type I or II), 8 achalasia (type III), 8 EGJOO, 7 SMDs, 3 AC, 7 EoE, 22 GERD and 3 FCP. Fifty seven (63%), 45 (49%), 32 (35%) and 27 (30%) patients had pain in the lower part, middle part, back or upper part of the chest, respectively. The location of pain was not significantly different among patient groups. The time of pain was significantly different among groups ( $p < 0.05$ ).

	Within 1 minute	1-5 minutes	5-10 minutes	10-30 minutes	More than 30 minutes
Type I or II achalasia	27%	18%	21%	9%	24%
Type III achalasia	0%	50%	25%	13%	13%
Esophago-gastric junction outflow obstruction	13%	50%	13%	13%	13%
Spastic esophageal motility disorders	29%	29%	29%	14%	14%
Absent contractility	0%	33%	0%	33%	33%
Eosinophilic esophagitis	14%	14%	14%	29%	29%
Gastroesophageal reflux disease	27%	9%	9%	0%	55%
Functional chest pain	33%	0%	33%	0%	33%

[Duration of chest pain among groups]

Most patients had pain between meals or during or after meals. Some patients with achalasia or EoE had pain in the wake-up period; patients with EGJOO or SMDs did not have pain in the wake-up period. Patients with type I or II achalasia tended to have pain during nighttime as well as during post prandial periods. The duration of pain was also significantly different among groups ( $p < 0.05$ , Table). It was shorter in patients with type III achalasia, EGJOO or SMDs, while, it was longer in patients with GERD. **Conclusion:** The symptom profile of NCCP was different among patient groups. The NCCP profile may represent pathophysiology of diseases. **Disclosure:** Nothing to disclose

## P1955 INCREASED OESOPHAGEAL SYMPTOMS AND MANOMETRIC ABNORMAL PATTERNS IN OPIOIDS USERS: EXPERIENCE OF A LARGE TERTIARY REFERRAL CENTRE

Nikaki K., Woodland P., Gabieta-Sonmez S., Yazaki E., Sifrim D. *Barts and the London School of Medicine and Dentistry, Queen Mary University of London, Wingate Institute of Neurogastroenterology, London, United Kingdom*

**Contact E-Mail Address:** k.nikaki@qmul.ac.uk

**Introduction:** Opioid induced oesophageal dysfunction is increasingly recognized. The inability to discontinue opioids poses a challenge in the management of these patients. Opioids mainly affect organization of peristalsis and relaxation of the lower oesophageal sphincter. The relationship between type of opioids intake, symptoms and manometric pattern is still unclear.

**Aims & Methods:** To record the prevalence of major and minor oesophageal disorders in patients using opioids and compare this to non-users. We identified 155 patients on opioids registered on our HRM database between October 2013 and March 2019. Type of opioids, symptoms and manometric features were reviewed and compared between opioids users and non-users ( $n = 6465$ ). Patients with an incomplete test, studied following fundoplication or with a known major motility disorder were excluded. **Results:** The prevalence of opioid use in our patient population was 2.3%. Opioids used included Tramadol ( $n = 50$ ), Codeine ( $n = 45$ ), Morphine Sulphate ( $n = 12$ ), Co-dydramol ( $n = 9$ ), Fentanyl ( $n = 7$ ), Oxycodone ( $n = 6$ ) and Combination therapy ( $n = 26$ ). The commonest reason for opioid use was a musculoskeletal disorder (55%). The main complaint was dysphagia in 21%, chest pain in 10%, heartburn and regurgitation in 35%, cough in 8% and other (abdominal pain, vomiting, belching, globus) in 26%. Another 42.5% reported dysphagia as secondary symptom. Compared to non-users of opioids, dysphagia was the main complaint in 13.5% and chest pain in 4.8%, whilst another 21% reported dysphagia as secondary symptom. There was a significant difference in the prevalence of all major and minor manometric abnormalities between opioid users and non-users ( $p < 0.0001$ ). The incidence of GOJ obstruction was 11.6% vs 1.6% respectively, Jackhammer oesophagus and Distal Oesophageal Spasm 4.5% vs 1.2%, Achalasia type 3 1.9% vs 0.18%, Absent peristalsis 1.3% vs 0.09%, Nutcracker oesophagus 3.9% vs 0.17%, IEM 29.6% vs 10%. Amongst opioid users whose main complaint was dysphagia or chest pain, Achalasia type 3 was present in 6% and GOJ obstruction in 19%. Although numbers are relatively small, more potent opiates (Fentanyl, Oxycodone) and combinations of opiates appeared associated with a greater risk of major motility disorders.

**Conclusion:** The prevalence of symptoms and oesophageal dysmotility was higher in opioids users. This highlights the awareness physicians and physiologists should have about an increasing problem in our patient group.

**Disclosure:** Nothing to disclose

## P1956 PATHOPHYSIOLOGY OF SWALLOWING DYSFUNCTION AND DOPAMINERGIC EFFECTS IN PARKINSON'S DISEASE

Nascimento W.<sup>1</sup>, Arreola V.<sup>2</sup>, Sanz P.<sup>3</sup>, Necati E.<sup>4</sup>, Bolivar-Prados M.<sup>2</sup>, Clavé P.<sup>2,5</sup>

<sup>1</sup>Gastrointestinal Physiology Laboratory, Mataró, Spain, <sup>2</sup>Gastrointestinal Physiology Laboratory, Mataró, Spain, <sup>3</sup>Mataró Hospital, Neurology Unit, Mataró, Spain, <sup>4</sup>Faculty of Health Sciences, Department of Physiotherapy and Rehabilitation, Mersin, Turkey, <sup>5</sup>CiBER de Enfermedades Hepáticas y Digestivas (CIBERehd), Barcelona, Spain

**Contact E-Mail Address:** pere.clave@ciberehd.org

**Introduction:** The pathophysiology of OD and the effect of dopaminergic medication on swallowing dysfunction are not fully understood in Parkinson's disease.

**Aims & Methods:** Our aim was to describe the pathophysiology of impaired safety of swallow in Parkinson's disease (PD) and to assess whether the OFF/ ON state related to dopaminergic medication affects swallow function.

We studied 50 patients with PD and 12 healthy volunteers (HV). Videofluoroscopic (VFS) signs and kinematics of swallow response were assessed. In 40 patients with PD, all tests were performed in OFF (12 hours without any medication) and ON (1 hour after usual dopaminergic medication) state.

**Results:** Mean age of PD patients was  $70.46 \pm 10.03$  yr (24 women), mean time of disease  $5.094 \pm 3.86$  yr, the Hoehn-Yahr stage  $2.32 \pm 0.81$  and mean dose of dopamine  $567.10 \pm 302.35$  mg. Mean age of HV was  $40.20 \pm 2.50$  yr (six women). PD Patients had high prevalence of impaired safety of swallow (36% of penetrations in PD, higher PAS mean  $2.16 \pm (1.35)$ , delayed laryngeal vestibule closure time (LVC,  $293.33 \pm 90.07$  ms) when compared to HV ( $164.00 \pm 39.78$  ms), both unaffected by dopaminergic treatment ( $305.00 \pm 105.90$  ms). A cutoff level of delayed LVC  $\geq 380.00$  ms predicts unsafe swallow with sensitivity=0.67; specificity=0.79 and AUC of 0.80. There was no significant difference in swallow between OFF and ON states for VFS signs of efficacy and safety, or kinematics of swallow response. In both situations patients presented similar high prevalence of oral residue (OFF: 92.50%; ON: 90.00%), piecemeal swallow (OFF: 75.00%; ON: 80.00%) and pharyngeal residue (OFF: 85.00%; ON: 85.00%).

**Conclusion:** Swallowing function appears to be severely impaired in the initial stages of PD and do not improve by dopaminergic treatment. Patients with PD require new strategies for active treatment of the severe swallowing dysfunction they suffer from the initial stages of the disease.

**Disclosure:** Nothing to disclose

## P1957 COMPARISON OF SAFETY OF TREATMENT OPTIONS FOR END-STAGE ACHALASIA OR SIGMOID ESOPHAGUS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Gopalakrishnan Ravikumar N.P.<sup>1</sup>, Ravindran A.<sup>1</sup>, Thota P.<sup>2</sup>, Raja S.<sup>3</sup>, Sanaka M.<sup>3</sup>

<sup>1</sup>University at Buffalo, Internal Medicine, Buffalo, United States, <sup>2</sup>Cleveland Clinic Foundation Digestive Disease Institute, Gastroenterology, Cleveland, United States, <sup>3</sup>Cleveland Clinic Foundation Digestive Disease Institute, Cleveland, United States

**Contact E-Mail Address:** ravikumar.naveen1@gmail.com

**Introduction:** End-stage achalasia is characterized by massive esophageal dilatation with loss of the esophageal straight axis giving rise to a sigmoid appearance. Several effective treatment options are available for early achalasia. However, these interventions might be technically difficult and associated with higher complication rates in the management of end-stage achalasia.

**Aims & Methods:** We aimed to compare the relative safety of various treatment modalities used in patients with end-stage achalasia and sigmoid esophagus through a systematic review and meta-analysis. The meta-analysis was performed using the Preferred Reporting Items for Systematic Reviews for Meta-analyses (PRISMA) guidelines. We searched PubMed, Embase, Cochrane library, Medline, Google Scholar, and Science Citation Index to identify relevant studies between January 2012 and January 2018. Keywords used were "sigmoid esophagus", "end stage achalasia", "achalasia", "Laparoscopic Heller myotomy (LHM)", "esophagectomy", "esophageal resection", "peroral endoscopic myotomy (POEM)" and "advanced achalasia". Statistical analysis was performed using Review Manager Version 5.3 (RevMan) software.

**Results:** Using the predefined search strategy, 33 studies were included in the meta-analysis. A total of 1987 patients were included of which 1497 underwent esophagectomy, 386 had LHM and 104 had POEM. Based on the meta-analysis, POEM was found to be most effective treatment option in terms of major complications [OR = 0.51, 95% confidence interval (CI) = 0.28 to 0.89], length of hospital stay [standardized mean difference (SMD) = -1.1, 95% CI = -1.18 to -0.07] and operative time [SMD = -1.82, 95% CI = -2.76 to -0.11] (table 1). P score ranking result showed that POEM was ranked top in major complications, hospital stay and operative time (P score = 0.907, 0.996, 0.991, respectively)(table 2).

Treatments	Major Complications	Hospital Stay	Operative time
Esophagectomy	0.438	0.428	0.456
LHM	0.176	0.478	0.526
POEM	0.907	0.996	0.991

[P score rankings]

**Conclusion:** Our results show that POEM is safer and is associated with shorter length of hospital stay compared to esophagectomy and LHM in treating sigmoid esophagus or end-stage achalasia. We believe this is the first meta-analysis to compare the safety of treatment options in end-stage achalasia with sigmoid esophagus. Further studies are needed to assess the efficacy of these interventions in this patient population.

**Disclosure:** Nothing to disclose

## P1958 OUTCOME OF PER ORAL ENDOSCOPIC MYOTOMY FOR TREATMENT OF ACHALASIA - NORWEGIAN SINGLE CENTER EXPERIENCE WITH MEDIAN FOLLOWING-UP OF 24 MONTHS

Pham K.D.-C.<sup>1,2</sup>, Havre R.F.<sup>3</sup>, Gilja O.H.<sup>4</sup>, Hatlebakk J.G.<sup>5</sup>

<sup>1</sup>Haukeland University Hospital, Medicine, Bergen, Norway, <sup>2</sup>University of Bergen, Clinical Medicine, K1, Bergen, Norway, <sup>3</sup>Haukeland University Hospital, Department of Medicine and University of Bergen, Department of Clinical Medicine, Bergen, Norway, <sup>4</sup>University of Bergen, Medical Dept. A, Bergen, Norway, <sup>5</sup>Haukeland University Hospital Dept. of Medicine, Bergen, Norway

**Contact E-Mail Address:** phamkdc@gmail.com

**Introduction:** Long term effects of Per Oral Endoscopic Myotomy (POEM) are still unknown. The aim of this study was to investigate and report the feasibility, safety, efficacy and complications of POEM from the introductory phase in a tertiary referral center in Norway.

**Aims & Methods:** Collected prospective data from the first 68 patients with achalasia who underwent POEM at Haukeland University Hospital from February 2014 until December 2017 were analyzed. The patients were followed up for 12 months with respect to acute and delayed complications, and efficiency of the treatment. The diagnosis was based on findings on high resolution manometry (HRM) and timed barium swallow X-ray (TBS). We repeated HRM, TBS, in addition to impedance and 24-hours pH measurement 12 months after POEM. Reflux was regarded as pathological if the acid exposure (pH< 4) time was more than 6%. Eckardt score was used for symptom evaluation before, and at 6, 12 and up to 56 months after POEM.

**Results:** 41 males and 27 females with symptomatic achalasia and Eckardt score ≥6 were included. The mean age was 44.6y. Based on HRM, 15 patients had achalasia type I, 34 type II and 19 with type III. 36 patients (53%) were naïve to other treatment, while 11 (16%) had been previously treated with botulinum toxin injection, 14 (22%) with pneumatic balloon dilatation, and 10 (15%) with Heller's myotomy. The average resting pressure over lower esophageal sphincter (LES) was median 25 mmHg (0-72) prior to POEM, and 6.5 mmHg (0-23.1) after. Dysphagia improved in all patients on follow up. The Eckardt score was significantly reduced from median 7 (4-12) before POEM to 1 (0-9) at 12 months after POEM (p < 0.0001). The median myotomy length was 11 cm (4-20). 43 patients (63%) patients had posterior myotomy, while 25 (27%) anterior. The procedure time was mean 130 min, and admission time was mean 3 days. We did not experience any serious complications but observed capnoperitoneum and capnothorax in 10 patients (15%). 3 patients (4%) required peritoneal decompression during POEM (Grade 2 complication). At 12 months, 86.8% had Eckardt score ≤3, and 75.5% Eckardt score ≤2. 24 -hours pH monitoring was recorded on 55 patients (80%). 12 months post-POEM pathological reflux was measured in 45%, but only 37% reported reflux symptoms, 22% needed proton pump inhibitors (PPI) daily while 9% needed PPI occasionally.

**Conclusion:** Results with 12-56 months following-up from our cohort of consecutive patients show that POEM is safe and relieves symptoms of achalasia significantly, but the risk of reflux is higher than what is previously reported in the literature. Further studies are needed to confirm the findings in a long-term follow-up.

**Contact E-Mail Address:** jafari.jafari@gstt.nhs.uk

**Introduction:** It is known that Small Intestinal Bacterial Overgrowth (SIBO) is linked with gut hypomotility as well as long term use of acid suppressants. However, due to difficulties for investigating small intestinal motility, identifying the underlying cause for SIBO in patients remains mainly unknown and speculative.

**Aims & Methods:** The aim of this study is to investigate the relation of oesophageal motility findings with SIBO, as an indicator of gut hypomotility. Methodology

Patients referred to Guy's Hospital London for upper GI investigation who completed oesophageal high resolution manometry, lactulose test to rule out SIBO and also 24hr impedance-pH reflux monitoring from June 2017 to Dec. 2018. Diagnoses were made based on: Chicago classification for oesophageal motility disorders v3 [1], the North American consensus guideline for Hydrogen and Methane breath testing 2017 [2], and the Lyon consensus on reflux monitoring 2017 [3].

Statistical analysis was made using Graphpad Prism tool to obtain ROC analysis, two tailed Fisher's exact test and demographic analysis. P value < 0.05 was considered significant.

**Results:** 71 patients completed both HRM and SIBO testing (F:M= 46:25, median age 49, 25-70 years old). 25/71 patients were diagnosed with SIBO out of whom 17 (68%) had also ineffective oesophageal motility, 6 (24%) normal oesophageal motility and 2 (8%) oesophagogastric outflow obstruction.

57 patients completed both 24hr impedance-pH reflux monitoring and SIBO test. 20/57 diagnosed with SIBO of whom, pathological gastro-oesophageal reflux was confirmed in 5 (20%). ROC curve analysis revealed that detection of distal contractile integral (DCI) < 450mmHg.cm.s has a sensitivity of 63.64% and specificity of 52% in predicting SIBO (95% CI: 47%-77%).

There was statistically significant different number of patients with SIBO diagnosed with IOM as opposed to having normal motility (P < 0.004). However majority of the SIBO patients were not suffering from GORD (GORD vs having no GORD: P < 0.008). Lower oesophageal sphincter basal pressure and DCI were not significantly different between patients with and without SIBO.

Gender had a slight impact on presence of SIBO (female with SIBO 39%, male with SIBO 24%). Highest prevalence of SIBO was detected in patients in their 50s (50%) but there was a dramatic reduction beyond the age 60 (18%).

**Conclusion:** SIBO is significantly associated with poor oesophageal body motility. This can be due to underlying poor small intestinal motility in a group of patients with IOM. A further study with larger sample size and concomitant investigation of small intestinal as well as oesophageal motility testing is required to further confirm these findings before use of oesophageal motility as a surrogate to determine small intestinal motility.

**Contact E-Mail Address:** jukka.ronkainen@fimnet.fi

**Introduction:** Functional dyspepsia (FD) is a common condition in the population. It is associated with duodenal eosinophilia<sup>1</sup> and it has been shown that anxiety at baseline is associated with new-onset functional dyspepsia in long term.<sup>2</sup> Innate immunity response is linked with gut-brain/brain-gut regulation and psychological distress.<sup>3</sup>

**Aims & Methods:** Our aim was to investigate whether FD (Rome III) is associated with new-onset anxiety and/or depression and if this can be predicted by duodenal inflammation in a population based 10-year follow-up study.

Participants of the study (n=3000) were randomly selected from the national Swedish population register and surveyed in 1998 by a validated abdominal symptom questionnaire (ASQ) and hospital anxiety and depression scale (HADS). 1000 individuals were randomly selected to complete an esophagogastroduodenoscopy in 1999-2001. All eligible from the latter cohort (n=887, response rate 79%) were invited to a follow-up in 2010 with the ASQ and HADS. In a case-control study of 213 subjects (FD vs. healthy controls), histology from the oesophagus, stomach and the duodenum was evaluated at baseline (the pre-specified cut off being the mean, 23 eosinophils in duodenal bulb (D1) and 24 eosinophils in second part of the duodenum (D2)). The cut off for gastric eosinophilia was also the mean, 11 eosinophils in all three locations: cardia, corpus and antrum. The possible association of FD and duodenal eosinophilia to incident anxiety was analysed. Data were analyzed by Fisher's exact test and logistic regression. **Results:** FD was reported by 89 subjects (42%), duodenal eosinophilia in D1 was found in 78 subjects (37%) and in 84 subjects in D2 (39%) at baseline. Incident anxiety was found in 12 subjects (6%) and depression only in 2 subjects (1%). None of the study subjects had oesophageal eosinophilia. Duodenal eosinophilia was not associated with gastric eosinophilia (OR=0.18, 95 CI 0.02-1.70, P=0.135).

Incident anxiety was associated with baseline functional dyspepsia (10/83 vs. 2/116, p=0.004), especially postprandial distress syndrome (10/65 vs. 2/134, p< 0.001) but not with epigastric pain syndrome (1/27 vs. 11/172, p=1.0). Incident anxiety was also associated with duodenal eosinophilia in D1 at baseline (9/75 vs. 3/124, p=0.011, OR=5.2, 95% CI 1.31-20.4, adjusting for age, gender and FD).

**Conclusion:** Incident anxiety is significantly associated with baseline FD and duodenal eosinophilia is associated with a 5-fold increased risk of anxiety in a 10-year follow-up supporting the concept that mucosal immune system can regulate the bidirectional gut-brain communication.

**Contact E-Mail Address:** drorhansezgin@gmail.com

**Introduction:** There are no population-based studies determine the prevalence of gastrointestinal symptoms and associated diseases, in Turkey. It is necessary to know the prevalence of the diseases in the community for health professionals and their providers, in order to establish forward-looking targets and to use the resources correctly. Therefore, this study was designed to determine the frequency of the most common gastrointestinal system (GIS) symptoms, and diseases in a community-based sample.

**Aims & Methods:** The study is a cross-sectional cohort study. The "Cappadocia cohort" consisting of Avanos and Gülşehir districts of Nevşehir is shown to represent exactly the Turkey, in terms of population distribution. Therefore, it was found appropriate for the sample. The study was conducted between October 2017 and July 2018. Volunteers over 18 years of age were included in the study. The "Gastrointestinal Symptom Questionnaire" consisting of 16 questions for the upper GIS and 18 questions for the lower GIS was applied by the contracted research company by phone or face to face. It was accepted that the symptom was present if the symptom severity was  $\geq 2$  on a 6 scale, and gastrointestinal disease was accepted if the symptoms were present in at least 3 areas. The questionnaire was questioned for the last month. Body mass indexes were calculated.

**Results:** A GI symptom questionnaire was performed in 3369 (81.7%) of total 5042 people, who met the study criteria and accepted to participate, and 2797 people (67.8%) were evaluated for height and weight. The 39% of the participants were male, 61% were female and the median age was 52 years. The median BMI was 29.6 kg/m<sup>2</sup> and 35% of the participants were overweight and 45% were obese. The rate of smokers was 24%, and the rate of alcohol drinkers was 5.2%. The use of aspirin and NSAIDs was 52%, PPI use was 25.5%, and the rate of H2RA use was 6.2%. The 70.5% of the population had at least one GIS symptom. The most common symptoms of upper GIS were bloating, burning and pain, and the most common symptoms of lower GIS were abnormal defecation, gurgling and swelling. The presence of upper GIS disease associated with symptom severity was 32.7%, the presence of lower GI disease was 12.9%, and the presence of both were 9.9%. The frequency was significantly higher in women (p < 0.001). The presence of symptoms and the presence of upper GIS disease were directly proportional to BMI. There was a significant decrease in upper gastrointestinal symptoms and upper GIS disease frequency with age.

**Conclusion:** This community-based cross-sectional cohort study, evaluating the gastrointestinal symptoms and the burden of disease, which was held in Turkey for the first time, has revealed that gastrointestinal symptoms were 70% among the community. The study showed that 1/3 of the population had upper GIS disease, 1/10 had lower GIS disease, and this frequency increased significantly in women. There was a linear relationship between weight gain and symptoms and presence of upper GI disease. It has been found that the prevalence of gastroenterological diseases is high and they are serious in terms of public health in Turkey.

**Contact E-Mail Address:** michele.russo@studenti.unipr.it

**Introduction:** Gastroesophageal reflux disease (GERD) is claimed to be a multifactorial disease involving both environmental and dietary factors [1] [2], but the scientific literature on this topic is lacking.

**Aims & Methods:** Aim of the study is to assess the impact of such factors in the outcome of GERD in a population of patients in a secondary care setting.

We enrolled 208 GERD patients in a private gastroenterological ward in North-East Italy; we selected GERD patients with problems at work (harassment, mobbing, interpersonal conflict, bullying, low motivation and job satisfaction, discrimination, etc.) or who did night work or smokers (10 to 20 cigarettes per day) or heavy coffee drinkers (3 or more daily). Patients were singled out in 4 groups according to the factors involved in their clinical history: group A in which problems at work played an important role, group B that experienced discomfort due to night shifts; group C with the smokers and group D composed of heavy coffee drinkers. The observation time was divided into 2 periods marked by 3 symptom evaluations carried out with the Visual Analogue Scale (VAS) (ranged from 0 to 10 with increasing gravity of pain) and with a Symptomatic Score (SS) that considered only heartburn and regurgitation (the score ranged from 0 to 6 with the single symptom score ranging from 0 to 3 with increasing gravity); the first period lasted 6 months, in which all patients performed therapy with antacids or PPI only when needed; symptoms were assessed at baseline and at the end of 6 months; in the second period, which lasted 6 months, patients were made to change their habits, changing profession, being diverted to daily shifts, quit smoking and stop drinking coffee. The clinical outcome of GERD has been evaluated through VAS and Symptomatic Score modifications.

**Results:** We selected 208 pts (M: 108, mean age 48 years, range 19-73 years) divided into 4 groups according with the study design: group A: 43 pts (M: 19, mean age 46 years, range 19-52) that have changed their occupation during the follow-up; group B: 37 pts (M: 28, mean age 41 years, range 24-54) that changed shift; group C: 61 pts (M: 27, mean age 52 years, range 25-73) that quit smoking and group D: 67 pts (M: 34, mean age 54 years, range 23-71) that stopped drinking coffee. Table 1 summarizes the results (expressed as mean value (m.v.)) before and after the critical environmental event.

**Conclusion:** The study seems to confirm the importance of environmental factors on GERD outcome, focusing on the crucial role of break through life events like shift and carrier changes; dietary and voluptuous factors such as drinking coffee and smoking seem to be less important in improving these patients' quality of life.

	To (Baseline)	T1 (Environmental event)	T2 (After 6 months)
Group A VAS m.v.	5	6	2
Group A SS m.v.	5	5	1
Group B VAS m.v.	5	6	1
Group B SS m.v.	4	5	1
Group C VAS m.v.	5	6	5
Group C SS m.v.	4	5	6
Group D VAS m.v.	6	5	5
Group D SS m.v.	5	4	5

## P1963 BOTULINUM TOXIN PROVIDES SYMPTOMATIC RELIEF FOR PATIENTS WITH TYPE 3 SPHINCTER OF ODDI DYSFUNCTION

Evans J., Gordon H., Ainley C.

Royal London Hospital, Gastroenterology, London, United Kingdom

**Contact E-Mail Address:** jonathan.evans2@bartshealth.nhs.uk

**Introduction:** Type 3 Sphincter of Oddi dysfunction, or biliary visceral hypersensitivity, causes considerable morbidity. However in the wake of the EPISOD study, which refuted the role of sphincterotomy, there is lack of clarity regarding whether any endoscopic intervention is beneficial. We therefore performed a retrospective single centre study of papillary injection of botulinum toxin for management of Type 3 Sphincter of Oddi dysfunction.

**Aims & Methods:** Electronic endoscopy records were searched from 2015-2018 for cases of botulinum toxin injection for Type 3 Sphincter of Oddi dysfunction. All had received injections of 100 units of botulinum toxin into the papilla, during duodenoscopy. Electronic patient records were retrospectively reviewed for symptomatic response, duration of response, further procedures and adverse events.

**Results:** 19 patients were identified. All underwent at least one procedure, with 11 undergoing repeat procedures. Following first procedure, (63.2% N=12/19) reported complete resolution of symptoms and (15.7%, N=3/19) reported a partial response. Median duration of response was 4 months (IQR 4-4.5). Following repeat procedures, (36.4%, N= 4/11) reported total response, and (18.2%, N=2/11) reported partial response. There were no serious adverse events identified.

**Conclusion:** 78.9% patients reported symptomatic improvement following first injection with botulinum toxin. 54.6% reported improvement after a follow up procedure. Papillary botulinum toxin injection may be a useful and relatively safe treatment option for Type 3 Sphincter of Oddi dysfunction, however placebo controlled trials are required to further evaluate benefit, especially regarding repeat procedures.

## P1964 HOW LONG SHALL WE MAKE MYOTOMY FOR GASTRIC SIDE TO PREVENT REFLAX ESOPHAGITIS AFTER POEM?

Takahashi A., Oyama T.

Saku Central Hospital Advanced Care Center, Endoscopy, Nagano, Japan

**Contact E-Mail Address:** aurevoireurope@yahoo.co.jp

**Introduction:** According to guideline of Peroral endoscopic myotomy (POEM), the endpoint of the myotomy is recommended from 1 to 2cm into the gastric side. GERD after POEM is one of adverse event, because fundoplication is not performed in POEM as compared with Heller-Dor operation. Previous papers have reported that GERD occurs 13 to 60% after POEM.

**Aims & Methods:** The aim of this study is to evaluate the effect of short length myotomy for gastric side.

Forty-two cases of Achalasia or non-achalasia esophageal motility disorders treated by POEM from December 2012 to December 2017 were enrolled in this study.

The length of myotomy was decided by esophagography and/or high resolution manometry (HRM). 1cm myotomy was performed for gastric side. When balloon dilatation (BD) and/or re POEM were performed, it was defined as recurrence.

Gender (Male / Female) was 24 and 18, respectively. Median age was 55 (19-92) years old. Previous treatment is as follows; BD: 10, medication: 10, medication plus BD: 2, BD plus operation: 1. Type of disease is as follow; Achalasia: 31 (Type I: 9, Type II: 12, unknown type: 10 because of without HRM), DES: 5, Jackhammer esophagus: 1, others: 5. Median duration of symptoms was 48 (1-480) months. Median follow up periods was 19 (1-72) months.

**Results:**

1. Median procedure time was 58 (28-131) mins.
2. Median length of myotomy was 7 (4-19) cm.
3. Complication: a. Four cases (9.5%) had the mucosal laceration. Three cases were treated by endo clip and/or PGA sheet, and one case was treated by laparoscopic drainage. b. There was no severe bleeding.
4. Median Eckardt score (ES) of pre-POEM and post-POEM were 5 (1-11) and 0 (0-4), respectively. Clinical success rate (ES≤2 or reduced more than 4 points) was 95% (40/42).

5. EGD was performed 1 year after POEM. Nine cases (24%) had GERD-A, and 5 cases (14%) had GERD-B.  
 6. Only two cases (5%) had heart burn. Both cases had GERD-B.  
 7. Three cases (7%) had recurrence. BD was performed, and 2 cases were improved. However, BD for 1 case was not effective, and re-POEM was performed.  
 8. Peristalsis was partially recovered in 19% of the patients after POEM. Median length of myotomy for these cases was 6(4-10) cm.  
**Conclusion:** Clinical success rate of short gastric myotomy was fare, and GERD was lower as compared with previous reports. Therefore, short gastric myotomy is acceptable.

## P1965 INSUFFICIENT ROME CRITERIA TO DIAGNOSE PURE FUNCTIONAL ABDOMINAL PAIN AND EPIGASTRIC PAIN SYNDROME: THE NEED OF RULING OUT CHRONIC ABDOMINAL WALL PAIN

Song K.-H.<sup>1</sup>, Huh K.-C.<sup>2</sup>, Kim S.M.<sup>1</sup>, Koo H.S.<sup>1</sup>, Lee T.H.<sup>1</sup>, Choi Y.W.<sup>1</sup>, Kang Y.W.<sup>1</sup>, Ryu K.<sup>1</sup>, Rim C.B.<sup>1</sup>

<sup>1</sup>Konyang University Hospital, Gastroenterology & Hepatology, Deajon, Korea (Republic of), <sup>2</sup>Konyang University Hospital, Gastroenterology, Daejeon, Korea (Republic of)

**Contact E-Mail Address:** postit2@daum.net

**Introduction:** There is firm evidence that chronic abdominal wall pain (CAWP) is one of the major cause of chronic abdominal pain. CAWP has been easily ignored and the physician may misdiagnose CAWP as functional abdominal pain syndrome (FAPS) or even as epigastric pain syndrome (EPS). We investigated whether there is a difference between clinical response for local anesthetic injection or a somatic nerve block (a major therapeutic option for CAWP) in CAWP alone and in CAWP-FAPS overlap.

**Aims & Methods:** From January 2012 to April 2017, patients complaining of abdominal pain were undergone relevant studies. CAWP with negative screening exams were enrolled. Greenbaum's criteria were adopted to diagnose CAWP while FAPS was diagnosed according to the Rome III criteria. For eligible patients, Rome IV criteria of EPS were surveyed also if they were Rome III-based EPS. CAWP alone group and CAWP-FAPS overlap group were treated by tap block. Baseline and post-treatment pain score were recorded by 10-Likert scale. The 0.1% lidocaine mixture was used for the local anesthetic injection. After the local treatment, the responsiveness was assessed and 1 or 2 sessions of additional injection were performed if it is warranted. Clinical responsiveness was defined by over 50% degree reduction in symptom score.

**Results:** A total of 595 Patients complained with chronic abdominal pain were underwent EGD, colonoscopy, blood exam and imaging study (US or CT scan). Among them, 49 participants without obvious abnormal result to explain the pain were enrolled (11 of overlap, 38 of CAWP only). Mean age was 49.5±11.2 and female were predominant by 1.45 fold. The most frequently affected area was epigastrium followed by right iliac in both groups. Kaplan-Meiser analysis of unresponsiveness after the local treatment revealed no significant difference between the two groups (p= 0.781). The responsiveness at 3 months after the treatment also was not significantly different. When we diagnosed with Rome III criteria, EPS-CAWP overlap was less common (p= 0.035, McNemar test).

**Conclusion:** Clinical responsiveness to the local anesthetic injection was not different between CAWP-FAPS overlap and CAWP alone. Rome III criteria of EPS is more suitable to discriminate EPS from CAWP than Rome IV criteria.

**Disclosure:** Nothing to disclose

## P1966 ANALYSIS OF POST-POEM REFLUX PREDICTORS AND PPI CONSUMPTION

Estremera-Arevalo F.<sup>1,2</sup>, Albéniz-Arbizu E.<sup>2,3</sup>, Ezquer S.<sup>4</sup>, Areste I.<sup>1</sup>, Zúñiga Ripa A.<sup>1</sup>, Rullan Iriarte M.<sup>5</sup>, Iglesias R.<sup>1</sup>, Macias E.<sup>1</sup>, Vila J.J.<sup>6</sup>  
<sup>1</sup>Complejo Hospitalario de Navarra, Gastroenterology, Pamplona, Spain, <sup>2</sup>Fundacion Miguel Servet, Pamplona, Spain, <sup>3</sup>Complejo Hospitalario de Navarra, Servicio Aparato Digestivo, Pamplona, Spain, <sup>4</sup>Complejo Hospitalario de Navarra, Nursing, Pamplona, Spain, <sup>5</sup>Complejo Hospitalario de Navarra, Gastroenterology, Sarriren, Spain, <sup>6</sup>Complejo Hospitalario de Navarra, Endoscopy Unit. Gastroenterology, Pamplona, Spain

**Contact E-Mail Address:** festremera15@gmail.com

**Introduction:** Post-POEM reflux (reflux) appears in 16-68% of the patients and it is the main burden after POEM. There is scarce evidence of factors predicting reflux.

**Aims & Methods:** 22 patients with complete pre and post-POEM procedure work up - upper endoscopy, high-resolution manometry (MMS<sup>®</sup>, 22 channels water perfused), barium swallow, 24 h pH testing - were selected from our POEM prospective cohort (June 2016-april 2019, n=52). OGJ-Cl as by Nicodeme. Symptoms: Eckardt and GERDQ score. Reflux diagnosis: Lyon consensus criteria. Parametric data expressed as mean, ±SD, t-test for mean comparison. Non-parametric data expressed as median (IQR), Mann-Whitney test for median comparison. Pearson test was used for correlation analysis. Significant variables p < 0.05, possibly associated variables p < 0.2.

**Results:** POEM was successful in all patients except one, who needed a second POEM procedure due to a mistaken manometric diagnosis. Reflux was found in 11/22 (50%) patients. Age was significantly associated with reflux, with older patients within this group. Post-POEM body mass index (BMI) was also higher in patients with reflux. Gender, time from symptoms onset, previous BMI, BMI increment, previous treatments, anaesthetic risk and antiplatelet agents intake were not different between groups. Basal (pre-POEM) reflux symptoms were lower in patients with reflux, however, no differences were noticed after POEM with a GERDQ median of 1 in patients with reflux and 3 in non-reflux patients. Only one patient with reflux scored more than 3 in GERD-Q. No differences were shown in tunnel length nor oesophageal/gastric myotomy. Reflux incidence was unaffected by learning curve since it was equal in the first eleven procedures compared to the second half. Basal mean lower oesophageal sphincter pressure (LOSP) was lower in the reflux group, as well as the basal OGJ-Cl and the basal 4sIRP. Manometric diagnosis, post-POEM LOSP, decrease of LOSP, post-POEM 4sIRP, decrease of 4sIRP, post-POEM OGJ-Cl and decrease of OGJ-Cl were similar between groups. Post-POEM 5 min barium column, but not basal nor decrease of barium column, was lower in reflux patients. See table 1. The most significant correlations were found for age (p 0.065) and post-POEM BMI (p 0.078) with distal oesophageal acid exposure time. Endoscopic studies revealed grade A oesophagitis in 2 patients and grade C in 1 patient. All patients controlled reflux symptoms with a single PPI dose. 4 patients consumed PPI because of antiplatelet agent treatment. Overall, there were fewer patients on PPI after POEM procedure - 14/22 vs 18/22. 7 non-reflux and 1 reflux patients ceased PPI consumption.

**Conclusion:** PostPOEM procedure reflux is common. Older age and a low basal GERD-Q score are associated with reflux appearance. There are no significantly associated variables in the work-up test, observing lower basal LOSP, 4s-IRP pressures and shorter post-POEM barium column in the reflux group. Reflux burden is debatable, since globally there were less reflux related symptoms after the procedure and the PPI consumption decreased. All patients controlled their symptoms with a single dose of PPI.

**Contact E-Mail Address:** sylvls@mail.ru

**Introduction:** In gastroesophageal reflux disease (GERD) the refluxate provokes active esophageal mucosa inflammation with moderate immune cells infiltration, which includes macrophages (M), obtaining M1 or M2 phenotype. Considering the modern concept of immune response development, changes of M phenotype strongly correlate with Th1/Th2 systemic immune response. So, M of different phenotypes can greatly influence esophageal mucosa inflammation and affect GERD clinical variants.

**Aims & Methods:** Analysis of M polarization and phenotypic plasticity in patients with different clinical variants of GERD. Patients with non-erosive reflux disease (NERD; n=26; 41.2±3.6 y.o.), erosive reflux disease (ERD; n=25; 41.9±3.1 y.o.), and Barrett's esophagus (BE; n=19; 43.7±4.2 y.o.) were included in the study. M phenotype and polarization was assessed by in vitro model included adding refluxates of patients (n=70) with different pH (4.6-8.1) to peritoneal M of C57/BL6 mice (n=70) culturing in standard conditions for 36 hours. M polarization analysis included secretory function assessment (Th1/Th2 cytokines in culture medium, Antigenix, USA), receptor characteristics - typical M1/M2 CD markers (CD80 / CD206, respectively) performed by flow cytometry (FC500, Beckman Coulter). Phenotypic plasticity was measured as changes of CD expression (CD80/CD206) and cytokine production (IL-12p70/IL-10) during 36 hours of M reprogramming in the presence of 0%, 10%, 40% standard FBS. Changes in 0% FBS vs 10% FBS reflected plasticity towards M1 phenotype, in 40% FBS vs 10% FBS - to M2 phenotype. Mean pH values of refluxates were assessed for all patients' groups.

**Results:** Analysis of M polarization in different variants of GERD by cytokine production and CD markers expression revealed the prevalence of Th1 and Th1/Th2 bivalent cytokines and M1 markers expression in all groups with variable changes of indices probably due to various mean pH values of the refluxates (6.53±0.41 in ERD, 5.52±0.24 in BE, 5.44±0.32 in NERD). Analysis of macrophage plasticity showed the ability of macrophages to change their phenotype both towards M1 and M2 in all groups, but max changes were observed in production of IL-10 in 40% FBS in all groups (increased as compared to 10% FBS standard conditions in 3.77 in NERD group, 3.8 - in BE and 3.4 - in ERD). The level of CD markers expression also changed in various FBS concentrations, but the changes were significant only for CD206 in 40% FBS in all groups. The data were comparable between the groups: CD206 expression increased in 1.6 in NERD, in 1.5 in BE, in 1.6 ERD.

**Conclusion:** Analysis of macrophage polarization in different variants of GERD showed that secretion and receptor profile of the cells is typical for M1 phenotype with some variations of different cytokines production and CD markers expression that may be due to the type and pH value of the refluxate influencing macrophages. Macrophages in all GERD variants can change their phenotype according to the micro-environment. Phenotypic plasticity of the cells was confirmed by changing the cytokine production and CD markers expression. The highest phenotypic plasticity was shown

towards M2 phenotype for macrophages in all groups. These data can indicate the possibility to influence macrophage-mediated immune response in different clinical variants of GERD.

**Contact E-Mail Address:** shikokuri@yahoo.co.jp

**Introduction:** Patients with gastroesophageal reflux disease (GERD) often have nocturnal symptoms. However, pathophysiology of nocturnal symptoms is not fully understood.

**Aims & Methods:** A total 25 subjects were enrolled (11 females, median age 58 year-old). Subjects were divided into five controls, six reflux esophagitis (RE) patients without nocturnal reflux symptoms and 14 RE patients with nocturnal reflux symptoms. We evaluated esophageal motility, and gastroesophageal reflux (GER) and esophago-pharyngeal reflux (EPR) events with a high-resolution impedance manometry system using a Unisensor catheter. The system has 36 pressure sensors and 16 impedance measurement sites. Pharyngeal and esophageal pH sensors were located 1.5 cm above the proximal border of the upper esophageal sphincter (UES) and 5 cm above the proximal border of the lower esophageal sphincter (LES) to detect EPR and GER events. Sleep stages were assessed using polysomnogram. These measurements were concurrently recorded for about 6-hours post-prandially in the supine position during sleep. Subjects, who took proton pump inhibitors (PPIs), were made to stop taking PPIs at least one week prior to the study. Subjects had a standard meal (1000 kcal) before recording. The presence of RE was evaluated by esophagogastroduodenoscopy and the severity of nocturnal symptoms was assessed by nocturnal gastro-esophageal reflux disease symptom severity and impact questionnaire (N-GSSIQ) in all subjects. The number of transient LES relaxation (TLESR), GER, EPR events and the length of proximal extent of liquid refluxate from the proximal border of the LES in each liquid or mixed GER event were evaluated. Data is shown as median (25%, 75%).

**Results:** Most GER events were associated with TLESR events and they occurred during awakening or just after arousals. There was no acid EPR event. The incidences of TLESR, TLESR with liquid or mixed GER, TLESR with acid GER and TLESR with UES relaxation were not different among three groups (Table). The length of the proximal extent of liquid refluxate in RE patients with nocturnal symptoms was significantly longer than other groups (p< 0.05).

	Controls	RE patients without nocturnal reflux symptoms	RE patients with nocturnal reflux symptoms
Number of subjects	5	6	14
Number of TLESR events	11 (6, 20)	19 (14, 25)	12 (9, 18)
Number of TLESR events with liquid or mixed GER events	8 (4, 14)	14 (6, 18)	11 (8, 18)
Number of TLESR events with acid GER	0 (0, 6)	2 (0, 6)	5 (0, 8)
Number of TLESR events with UES relaxation	1 (1, 4)	3 (0, 6)	0 (0, 1)
Length of proximal extent of liquid refluxate	5 (4, 11)	5 (3, 13)	8 (5, 14)*

[Number of events among groups]

**Conclusion:** Nocturnal reflux symptoms are related to the proximal extent of liquid refluxate during nighttime. Acid EPR event is not common during nighttime.

**Disclosure:** Nothing to disclose

## P1969 THE ROLE OF ESOPHAGEAL EPITHELIAL INTEGRITY ON PROTON PUMP INHIBITOR RESPONSE IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE

**Introduction:** 20-30% of patients with gastroesophageal reflux disease (GERD) do not adequately respond to proton pump inhibitors (PPI). It is not known whether esophageal epithelial integrity is one of the determinant of the response.

**Aims & Methods:** We evaluated the relationship between PPI response rate and esophageal epithelial integrity in GERD patients.

24 healthy controls (HC) 16 functional heartburn, 11 reflux hypersensitivity, 35 true non-erosive reflux (NERD), 48 erosive GERD A-B (ERD AB) and 12 erosive GERD C-D (ERD CD) in total 146 subjects were included. GERD and QoL questionnaires, high-resolution esophageal manometry, off-PPI intra-esophageal 24-h impedance-pH monitoring, upper gastrointestinal endoscopy with distal esophageal biopsies performed in all patients. Esophageal epithelial resistance (TEER) and tissue permeability via fluorescein diffusion within 2 hours were measured by mini-Ussing chamber system. Patients were analysed according to phenotypes and PPI responses; >80% very good, 50-79% good, < 50% no response.

**Results:** TEER of all GERD patients were significantly lower than the healthy controls. TEER of all GERD groups were decreased compared to HC however only ERD groups were significant. The tissue permeability of all phenotypes and functional heartburn was significantly higher than controls. According to PPI response, TEER was significantly lower and tissue permeability was significantly higher than the controls. Tissue permeability in >80% responder group was significantly lower compared to "good" and "no response" groups. While TEER results of "17-34" age group were higher but insignificant than older patients (>55 yo) (p=0.072), tissue permeability was significantly lower. In addition, the tissue permeability of patients ≤50 yo healthy controls was significantly lower than older healthy controls.

	TEER (ohm)	Permeability (pmols)
Healthy controls	166.8 ± 46.2	36.9 ± 13.5
PPI response ≥80%	147.0 ± 39.1**	45.9 ± 23.8*
PPI response 50-79%	136.0 ± 37.6**	57.6 ± 33.1* ^^
No response <50%	138.9 ± 51.8**	60.1 ± 38.9** ^
ERD (all)	129.3 ± 33.3*	51.7 ± 30.7 **
ERD A/B	133.7 ± 34.1* ¥¥	46.9 ± 28.1***
ERD C/D	112.1 ± 37.1* ¥	60.1 ± 38.9**
NERD	151.4 ± 48.0	57.5 ± 32.9**
Reflux hypersensitivity	153.6 ± 46.5	65.4 ± 34.1**
Functional heartburn	159.5 ± 55.1	54.5 ± 34.1***
All patients	141.8 ± 39.4**	55.0 ± 32.8*
GERD patients 17-34 yo	150.1 ± 39.4	50.4 ± 25.0
GERD patients >55 yo	133.0 ± 51.6	67.5 ± 43.2

\* p≤ 0.001 vs HC, \*\* p<0.01 vs HC, \*\*\* p<0.05 vs HC ¥ p≤ 0.01 vs NERD, ¥¥ p<0.05 vs NERD ^ p≤ 0.01 vs Very good PPI response, ^^ p≤ 0.05 vs Very good PPI response ∞ p<0.05 vs >55 aged

[Trans epithelial resistance and permeability results of the groups]

**Conclusion:** Tissue resistance was lower and tissue permeability higher in all GERD patients compared to healthy controls implicates that tissue integrity decreases in GERD. Although the PPI response criteria in the literature have been determined in "50% and above" range; this rate is not adequate at the clinical level. We found that a higher and clinically more significant level which is >80% range was significantly related with a better epithelial integrity. This finding implicates that lower ion (H<sup>+</sup>) permeability might be related with higher PPI response. The tissue permeability of older healthy controls was higher than younger subjects implicates the importance of aging by itself.

**Disclosure:** Nothing to disclose

## P1970 THE THICKNESS OF THE CRURAL DIAPHRAGM IS THINNER IN HELICOBACTER PYLORI INFECTED GERD PATIENTS

Souza M.<sup>1</sup>, Andrade M.<sup>2</sup>, Coutinho T.<sup>2</sup>, Nobre M.<sup>3</sup>, Franco L.<sup>4</sup>, Souza M.<sup>2</sup>, Santos A.<sup>5</sup>

Contact E-Mail Address: mans@ufc.br

**Introduction:** The crural diaphragm is an essential component of the esophagogastric junction (EGJ). Inspiratory EGJ pressure is lower in GERD and patients fail to increase EGJ pressure during graded increase in inspiratory resistance. Also, some reflux esophagitis patients may have a weaker and thinner crural diaphragm. Inflammation is an important factor of muscle dysfunction. One of the most common causes of human inflammation is the infection by *Helicobacter pylori*, which has a complex relationship with GERD.

**Aims & Methods:** The aim of this study is to measure the thickness of the crural diaphragm in GERD patients and analyze its relation to symptoms, gastric inflammation, and the infection with *H. Pylori*. Thirty patients (18 females, age 46.7 yr, weight 71.5 kg, in average) with GERD (distal esophageal acid exposure > 4.2%) were studied after approval by the local ethical committee (HUWC-Ceará Federal University, Fortaleza, Brazil). The right crus of the diaphragm (RC) is easily identified with an endoscopic ultrasound (EUS) probe positioned in the EGJ region during expiration (12 MHz, radial probe, Fujinon, Japan). The RC images were stored for posterior blinded measurement of its orthogonal section, in mm. GERD patients were categorized according to the RC thickness (cutoff=4mm, lower limit of our laboratory 95%CI). During the endoscopic procedure, biopsies of the antrum and gastric corpus (five different sites) were taken for blinded, four-points (0-3), histologic analysis for each of the following items: inflammation, inflammatory activity (neutrophil infiltration), metaplasia, atrophy, and *H. pylori* infection. The total score of each histologic item were summed up for statistical analysis. The maximal inspiratory oral pressure (maxIP, in cmH<sub>2</sub>O) was measured with a digital manometer during maximal isometric inhalation in sitting position with nostrils closed, as marker of inspiratory muscles strength. The volunteers also completed two GERD questionnaires: RSI for atypical and RDQ for typical symptoms. Data were analyzed with Student t or Mann-Whitney Tests. Results are presented in mean ± SEM or median (minimum-maximum).

**Results:** Age and weight did not differ between patients with normal (n=23) or abnormal (n=7) RC thickness. Symptoms total scores did not differ significantly between the two groups: RDQ (9 (2-30) vs 20 (2-25), p=0.10) and RSI (13 (1-42) vs 21 (6-38), p=0.17). However, the epigastric burning sensation (RDQ item) and the respiratory difficulty (RSI item) were higher in the group with a thinner RC (0 (0-5) vs 3 (0-5), p=0.03; 0 (0-5) vs 5 (0-5), p=0.023; respectively). Inflammation, inflammatory activity, and *H. pylori* infection scores were significantly higher in the patients with a thinner RC (5 (1-8) vs 5 (5-6), p=0.042; 0 (0-9) vs 5 (0-10), p=0.003; 0 (0-13) vs 8 (0-15), p=0.008; respectively). Atrophy and metaplasia did not differ between the groups. The positivity of the rapid urease test was also higher in the patients with abnormal RC thickness (p=0.008). Acid exposure in the distal esophagus did not differ between the two groups of GERD patients. The maxIP were less negative in the patients with abnormal RC thickness (-75.5±7.5 cmH<sub>2</sub>O vs -56.1±3.9 cmH<sub>2</sub>O).

**Conclusion:** In GERD patients, the thickness of the RC and the strength of inspiratory muscles were associated with gastric inflammation due to the infection with *H. Pylori*. The esophageal acid exposure and the typical symptoms of the two groups of GERD patients did not differ. These results brings about new evidence that may help interpret the complex relationship between *H. Pylori* infection and GERD.

**Contact E-Mail Address:** salvatore.tolone@unicampania.it

**Introduction:** A normal function and morphology of the esophagogastric junction (EGJ) is essential in preventing gastroesophageal reflux disease (GERD). Crural diaphragm (CD) is responsible for a part of the antireflux barrier. High-resolution manometry (HRM) provides information on axial separation between lower esophageal sphincter (LES) and CD and can evaluate the EGJ antireflux barrier using the EGJ contractile integral (EGJ-CI). However, comprehensive data about the correlation between presence of LES-CD separation, EGJ-CI and GERD features determined at impedance-pH monitoring (MII-pH) are scarce.

**Aims & Methods:** To verify if a increasing distance of LES-CD separation and a decreasing EGJ-CI could better correlate with a positive MII-pH testing, with symptoms and the presence of esophagitis.

Consecutive patients with predominant typical GERD symptoms (heartburn and/or regurgitation) and a recent upper endoscopy were enrolled. Esophagitis was defined according to Los Angeles classification. The presence of further symptoms and PPIs response were recorded. All patients underwent HRM to assess the EGJ morphology, the EGJ-CI and 10 single water swallows to evaluate peristalsis and EGJ function, according to the Chicago Classification (CC) 3.0. EGJ Type I was further divided into Type I-CO, a complete overlap of LES and CD, and Type I-MS, a minimal separation, with LES located from the upper border of CD (in correspondence of pressure inversion point, 0.0 cm) to 1 cm above. Also, intra-hernia pressure and contractile integral of CD (CD-CI, when distinguishable from LES) were recorded.

The patients then underwent impedance-pH testing off-therapy. We recorded the esophageal acid exposure time (AET), number of total reflux episodes, mean nocturnal baseline impedance (MNBI), post-reflux swallow-induced peristaltic wave index (PSPW + if < 53%) and symptom association analysis using symptom association probability (SAP + if ≥ 95%) and symptom index (SI + if ≥ 50%).

McNemar test and Anova test were performed among groups determined according to LES-CD separation.

	EGJ Type I-CO (n=72)	EGJ Type I-MS (n=54)	EGJ Type II (n=42)	EGJ Type III (n=35)	P Value
Patients with GERD (%)	33.3	70.3	76.1	94.2	0.001* (n.s. type I-MS vs Type II)
Total number of reflux (mean ± S.D.)	29±15	48± 29	49±21	79±28	0.001* (n.s. type I-MS vs Type II)
AET % (mean ± S.D.)	2.7±0.8	4.8±2.2	11±12	17±13	0.001*
PSPW% (mean ± S.D.)	68± 25	45± 32	50± 37	28± 13	0.001* (n.s. type I-MS vs Type II)
MNBI (mean ± S.D.)	3211±895	1811±676	1796±943	1279±1285	0.001* (n.s. type I-MS vs Type II)
Patients with positive symptom association (%)	26	55	70.2	86.6	0.001*
EGJ-CI	21±8	15±11	15±14	5±10	0.001* (n.s. type I-MS vs Type II)

[Table 1]

**Results:** We enrolled 203 [96M/107F; mean age 46] consecutive patients and identified 72 (35.4%) patients with EGJ Type I-CO, 54 (26.6%) Type I-MS, 42 (20.7%) Type II and 35 (17.2%) Type III. Patients with Type III EGJ had lower EGJ-CI, decreased mean DCI, a higher median number of reflux episodes, a greater mean AET, a lower MNBI and PSPW and had more frequently a positive symptoms association compared to patients with Type II and Type I-CO/MS (Table 1). Type I-MS had a higher number of reflux episodes (48 vs. 29, p < 0.03), a greater mean AET (4.8 vs. 2.7, p < 0.05) and a greater positive symptom association (55% vs. 26%, p < 0.02) compared to Type I-CO. At Anova, PPI response was significantly linked to EGJ Type III, whereas dysphagia was linked to higher intra-hernia pressure and CD-CI values.

**Conclusion:** With increasing separation between LES and CD, patients had a gradually and significantly increase of reflux episodes and esophageal acid exposure. Even a minimal separation can be responsible for GERD development and supports the role of CD in preventing reflux.

**Disclosure:** Nothing to disclose

**Contact E-Mail Address:** icetea0414@gmail.com

**Introduction:** Erosive esophagitis is defined as esophageal mucosal breaks proven by endoscopy because of gastroesophageal reflux exposure. Through Genome-Wide Association Studies (GWAS), we aimed to identify genetic factors associated with erosive esophagitis, especially gender differences.

**Aims & Methods:** The GWAS was conducted with 4,242 healthy participants who underwent upper endoscopies for health check-ups; 3,620 subjects comprised the discovery set and 622 subjects comprised the replication set. Erosive esophagitis was diagnosed by endoscopy and assessed for severity. After the quality control and imputation, we used the multivariable linear regression and SNPs with  $p < 5.0 \times 10^{-8}$  were considered significant genome-wide.

**Results:** We detected six genome wide significant SNPs associated with erosive esophagitis in male subjects; rs518309 ( $p = 2.12 \times 10^{-8}$ ), rs654455 ( $p = 2.12 \times 10^{-8}$ ), rs562589 ( $p = 2.504 \times 10^{-8}$ ), rs594589 ( $p = 2.786 \times 10^{-8}$ ), rs513126 ( $p = 2.93 \times 10^{-8}$ ), and rs4445064 ( $p = 5.864 \times 10^{-8}$ ). All the SNPs were replicated in the replicated set ( $p < 0.05$ ). We could predict the severity of erosive esophagitis based on genetic risk score established by these SNPs. These SNPs were located in topologically associated domain of glutamate ionotropic receptor kainite type subunit 2 (GRIK2) gene on chromosome 6q16.3.

**Conclusion:** This is the first GWAS to identify SNPs associated erosive esophagitis diagnosed by endoscopy. We found six genome wide significant SNPs associated with erosive esophagitis and these variation could help predict its severity.

 University Hospital and Faculty of Medicine Masaryk's University, Department of Internal Medicine and Gastroenterology, Brno, Czech Republic

**Contact E-Mail Address:** dolina.jiri@fnbrno.cz

**Introduction:** Proton pump inhibitor (PPI) therapy is usually associated with serum gastrin elevation. Prolonged use of PPI may promote a development of fundic gland polyps (FGPs). Concerns have been raised about the course of chronic gastrin elevation and relations to FGPs grow. Published studies regarding long term PPI use exceed 5 years interval rarely.

**Aims & Methods:** The aim of this study was to analyze the time evolution of gastrin elevation during long term PPI therapy of gastroesophageal reflux disease and consequences in FGPs development.

This prospective observational study included patients with gastroesophageal reflux disease (GERD) on long term PPI therapy. Patients followed 8 years and longer were selected for analysis. The level of serum gastrin during follow up was compared to dose of PPI, sex, H. pylori and presence of FGPs on endoscopy.

**Results:** The data from 109 patients (51 males) were available. Mean follow up was 10.9 years. Median serum gastrin level gently fluctuates about upper limit of gastrin (115 ng/l) during the period, without any significant progression in time. Mean gastrin was non-significantly higher in females than males (160 vs 109 (p 0.5)). In 55 patients FGPs were found on gastroscopy.

The mean serum gastrin in patients with and without FGPs was not different (131 vs 140 ng/l (p=0.82)). Lower than standard, standard and higher PPI doses were related to different gastrin elevation (mean 65 vs 125 vs 192 ng/l). Neither neuroendocrine tumor nor gastric cancer was recorded in the study cohort.

**Conclusion:** Gastrin elevation is mild without any significant progression in time during more than 10 years of PPI therapy of GERD. Although chronic PPI use is associated with development of fundic gland polyps, this was not related to serum gastrin level. The correlation between serum gastrin and PPI dose was observed.

**Introduction:** A potassium-competitive acid blocker (P-CAB), DWP14012, is under development for the treatment of acid-related esophageal-gastric disease. This study aimed to compare the pharmacokinetics (PK), pharmacodynamics (PD) and safety of DWP14012 among different ethnic groups.

**Aims & Methods:** A randomized, double-blind, placebo-controlled, single-and multiple-dose study was conducted in Korean, Caucasian and Japanese healthy subjects. Ten subjects in each dose group randomly received DWP14012 or placebo in a ratio of 8:2. Each subject was orally received DWP14012 (40 mg, 60 mg or 80 mg in Korean; 40 mg or 80 mg in Caucasian; 20 mg, 40 mg or 80 mg in Japanese) or placebo once-daily for 7 consecutive days. Serial blood samples were collected for PK evaluation. For PD evaluation, a 24-hour intra-gastric pH monitoring was performed at baseline (a day prior to first dose), after a single dose and steady-state after multiple doses. Safety profiles were assessed throughout the study. A general linear model was developed to compare PK and PD parameters. Geometric mean ratios (GMRs) and its 90% confidence intervals (CIs) of PK parameters for Caucasian and Japanese over Korean were calculated and the mean differences and its 90% CIs of PD parameters between each ethnic group was also calculated.

**Results:** After multiple treatment of 40 mg of DWP14012, the plasma concentration of DWP14012 and the gastric acid suppression was similar among the ethnic groups. The GMR (90% CI) of area under the curve within a dosing interval at steady-state ( $AUC_{0-24}$ ) for Caucasian and Japanese to Korean were 1.08 (0.76-1.53) and 1.07 (0.76-1.52), respectively. The mean percentages of time pH above 4.0 for DWP14012 in Korean, Caucasian and Japanese were 64.3%, 62.8% and 70.3%, respectively, and the mean difference of PD parameter for Caucasian and Japanese compared to Korean were not statistically significant (both  $P > 0.05$ ).

After multiple treatment of 80 mg of DWP14012, the GMR (90% CI) of  $AUC_{0-24}$  for Caucasian and Japanese were 0.70 (0.49-0.99) and 0.73 (0.52-1.04), respectively. However, the gastric acid suppression was similar between each ethnic group (both  $P > 0.05$ ); The mean percentages of time pH above 4.0 for DWP14012 in Korean, Caucasian and Japanese were 94.8%, 90.6% and 90.6%, respectively.

The increased gastric acid suppression according to dose of DWP14012 and clear exposure-response relationship were observed in all ethnic groups. There were no serious adverse events and no clinically significant changes in tolerability parameters in all dose groups in every ethnicity.

**Conclusion:** After 7-day multiple administration of DWP14012 40 and 80 mg, the gastric acid suppression and the exposure-response relationship were similar among Korean, Caucasian and Japanese. These results suggested that the gastric acid suppression of DWP14012 may not be sensitive to ethnic factors.

**Introduction:** Although symptomatic gastroesophageal reflux disease (GERD) is a chronic clinical condition treated with initial and maintenance therapies, there has been no established consensus for a long-term maintenance therapy. Several studies have reported the efficacy of vonoprazan (VPZ), a novel potassium-competitive acid blocker, as an initial therapy for GERD; however, an optimal maintenance therapy with VPZ remains to be evaluated.

**Aims & Methods:** The aim of this study was to evaluate the efficacy of an on-demand therapy with VPZ as a maintenance therapy for mild symptomatic GERD. A retrospective observational study of case data from patients with upper gastrointestinal endoscopy-proven symptomatic GERD (defined as modified Los Angeles [LA] classification grades A or B, and more than 8 points on the Frequency Scale for the symptoms of GERD [FSSG]) was conducted. We included patients who achieved symptomatic remission, which was defined as an FSSG score  $\leq 8$  points, after receiving an initial therapy with 20 mg VPZ for 8 weeks. These patients were then treated with on-demand therapy by taking 20 mg VPZ only when reflux symptoms occurred (on-demand group), or with continuous therapy with 10 mg VPZ (continuous group) as maintenance therapy. Clinical symptoms were retrospectively compared between the two groups using the FSSG questionnaire at the start of the maintenance therapy, and after 4, 8, 12, 24, 48, and 52 weeks. An endoscopic evaluation using the modified LA classification system was also performed at 12 weeks in both the groups. Furthermore, health related quality of life (HRQOL) was assessed using reflux esophagitis specific HRQOL questionnaires at 52 weeks.

**Results:** Forty-eight patients (22 men, 26 women; mean age, 72.5 years [range, 32-88 years]; on-demand group, 31 patients; continuous group, 17 patients) completed the study. FSSG scores, modified LA classification grades at diagnosis of GERD, and FSSG scores at the start of the maintenance therapy were similar in both the groups ( $12.0 \pm 3.5$  vs.  $12.8 \pm 3.5$ ,  $P = 0.20$ , grade A; 61.3% vs. 47.1%,  $P = 0.34$ ;  $3.3 \pm 2.3$  vs.  $2.8 \pm 2.2$ ,  $P = 0.20$ ; respectively). There was no significant difference in the persistence rate of maintenance therapy at week 52 between the groups (85.9% vs. 88.2%,  $P = 0.68$ ). Two patients (6.5%) dropped out because of worsening of symptoms, and 3 patients (9.7%) changed regimen to continuous therapy on their own volition at remission state in the on-demand group. Moreover, two patients (11.8%) dropped out because of worsening of symptoms in the continuous group. The average number of VPZ tablets taken per week during the 28-52 weeks tended to be lower than that during the 0-28 weeks in the on-demand group ( $1.6 \text{ tablets} \pm 0.15$  vs.  $1.3 \text{ tablets} \pm 0.2$ ,  $P = 0.13$ ). Although FSSG scores after 4, 8, 24, 48, and 52 weeks were significantly higher in the on-demand group than in the continuous group, there was no significant difference in the endoscopic severity, evaluated by the modified LA classification system, after 12 weeks between the two groups (grade M; 75.0% in the on-demand group vs. 93.8% in the continuous group,  $P = 0.12$ ), and no patients experienced symptomatic recurrence at 52 weeks in the on-demand group. Furthermore, there was no significant difference in HRQOL assessed by reflux esophagitis HRQOL questionnaires at 52 weeks between the two groups.

**Conclusion:** On-demand therapy with 20 mg VPZ was an effective alternative maintenance therapy for mild GERD that was comparable to half-dose continuous therapy with a sufficient persistence rate, symptom control rate, and HRQOL.

**Introduction:** As a treatment for gastroesophageal reflux disease (GERD), proton pump inhibitors (PPIs) are the mainstay of medical therapy. However, up to 40% of patients are reported to have persistent GERD symptoms despite PPI therapy. Several endoscopic procedures have been attempted but no procedure has been widely accepted as the standard endoscopic treatment for GERD. We developed Anti-reflux mucosal ablation (ARMA) as a minimally invasive treatment.

**Aims & Methods:** The aim of this study is to clarify the efficacy and safety of ARMA. The indication of ARMA is PPI refractory GERD patient without prominent sliding hernia. The purpose of ARMA is to narrow the space of hiatus hernia by performing ablation to the mucosa at the gastric cardia. Step 1: marking of scheduled ablation area on the mucosa. Mucosal ablation is scheduled along the gastric cardia in butterfly shape to avoid stenosis. Markings on the mucosa were placed using Triangle Tip Knife J connected to the electrocautery generator (VIO300D ERBE) in soft coagulation mode, 50 W, effect1.

Step 2: Saline with indigo carmine dye was injected into submucosa along the markings using 25-Gauge needle. Correct submucosal saline injection was confirmed by lifting of the mucosal surface.

Step 3: Near circumferential (butterfly shape) mucosal ablation was made using Triangle Tip Knife J in spray coagulation mode, 50W, effect2.

The efficacy of ARMA was evaluated using the objective findings (flap valve grade: I/II/III/IV as point 0/1/2/3, 24-hour multi-channel intraluminal impedance-pH monitoring) and subjective findings (Frequent Scale for the Symptoms of GERD:FSSG, and GERD-HRQL).

**Results:** A total of 12 patients with median age of 54.5 (29-75), Female 5: Male 7, with PPI-refractory GERD were enrolled in this study between May 2018 and March 2019. The procedure time was 40.3 (20-69) minutes without any immediate complications. GERD-HRQL score improved significantly from median of 30.5 to 12 ( $p=0.0005$ ), and the FSSG was significantly improved from median of 25 to 10.5 ( $p=0.0078$ ) both at 2-month follow-up. The Hill's flap valve grade score significantly improved from 1.91 to 0.5 ( $p<0.001$ ). The DeMeester composite score improved from 33.5 to 2.8 ( $p=0.0547$ ) and percent time clearance pH improved from 9 to 0.5 ( $p=0.0781$ ) after ARMA. ARMA was successful in all cases and mild stenosis was observed in one patient which was managed by balloon dilatation, and no bleeding nor perforation were observed.

**Conclusion:** This case series suggests that endoscopic anti-reflux mucosal ablation (ARMA) may represent an effective anti-reflux procedure safely, with the added advantage of simplicity, low cost, less invasive, and leaving no artificial prostheses in situ. Larger studies with long-term follow up are warranted to confirm this result.

**Introduction:** Esophageal intraluminal baseline impedance (BI) is determined by the conductivity of esophageal wall and is considered a surrogate marker of mucosal integrity, which impairment is associated to the development of gastro-esophageal reflux disease (GERD). Indeed, patients with GERD exhibit decreased distal BI as compared to healthy controls and this finding has been correlated with abnormal distal esophageal acid exposure time (AET). Current research is being focused on novel compounds able to protect the esophageal mucosa and restore its integrity. Recently, a new medical device based on a combination of hyaluronic acid, chondroitin-sulphate and aluminum hydroxide, in a single melt in mouth tablet (GERDOFF®, Sofar) has been marketed

**Aims & Methods:** We aimed to investigate whether GERDOFF® was able to modify the esophageal mucosal integrity in patients with GERD. This was a prospective, single center, randomized, controlled study (EC approval 4203/AO/17). Within 1-5 days from the upper endoscopy carried out off-therapy, 32 patients with typical reflux symptoms and evidence of erosive esophagitis greater than Los Angeles (LA) grade B, completed the Reflux Disease Questionnaire (RDQ) to assess severity and frequency of GERD symptoms, the GERD health-related quality of life (GERD-HRQL) and underwent high-resolution impedance manometry (HRIM) followed by a 10 minutes impedance-pH recording. Thereafter, they were randomized in a 1:1 ratio to receive GERDOFF®, 6 tablets per day, to be administered after each daily meal, at mid-morning and mid-afternoon and at bedtime (Group A), or an oral antacid or alginate on as needed basis for 14±2 days (Group B). Thereafter, patients repeated the questionnaires, filled in a VAS scale to measure the palatability of GERDOFF® and underwent a 24-hour impedance-pH monitoring. Tracings were blindly and manually reviewed and BI was measured at distal (at 3cm), mid (at 9cm) and proximal (at 15cm) esophagus off-therapy (10 minutes recording) and after 14±2 days of treatment. Secondary study parameters were: symptoms relief after 14±2 days of treatment, palatability, safety and tolerability of GERDOFF®.

**Results:** Two patients did not complete the study and were excluded. So far, data from 30 patients [18M/12F; mean age 54 (27-72) years; mean BMI 26 (18-34)] were further analyzed. Seventeen patients had Grade B, 4 grade C, 2 grade D esophagitis and 7 had short-segment Barrett Esophagus. Demographic, clinical and conventional impedance-pH features did not differ between Group A and Group B ( $p=ns$ ). Also BI at distal, mid and proximal esophagus was similar ( $p=ns$ ) between the two groups (1553Ω vs. 1284Ω, 1639Ω vs. 1769Ω, 2140Ω vs. 2303Ω, respectively). In contrast, after treatment BI at distal, mid and proximal esophagus was different ( $p<0.05$ ) between the two groups (2093Ω vs. 1247Ω, 2337Ω vs. 1751Ω, 2785Ω vs. 2212Ω, respectively). Twelve out of 15 (80%) patients treated with GERDOFF® showed a significant increase of BI after treatment, whereas only 2/15 (14%) had a similar effect ( $p<0.0007$ ). The palatability, safety and palatability of GERDOFF® were good.

**Conclusion:** Our data showed that in patients with proven GERD, GERDOFF® treatment for two weeks is able to restore the esophageal mucosal integrity in the majority of the patients, at both distal and proximal esophagus. These data provide a clear rationale for GERDOFF® use in the management of GERD.

**Introduction:** Proton pump inhibitors represents the current mainstay of gastroesophageal reflux disease (GERD) treatment. However, there is increasing evidence of their failure (i.e. 20-40% of the cases) and adverse events. Thus, current research is being focused on novel compounds able to protect the esophageal mucosa and reduce the damaging effect of the refluxate. Recently, a new medical device based on a combination of hyaluronic acid, chondroitin-sulphate and aluminum hydroxide, in a single melt in mouth tablet (GERDOFF®, Sofar) has been marketed.

**Aims & Methods:** We aimed to investigate whether GERDOFF® was able to modify the esophageal mucosal integrity in patients with GERD. This was a prospective, single center, randomized, controlled study (EC approval 4203/AO/17). Secondary study parameters were: symptoms relief after 14±2 days of treatment, palatability, safety and tolerability of GERDOFF®. Within 1-5 days from the upper endoscopy carried out off-therapy, 32 patients with typical reflux symptoms and evidence of erosive esophagitis greater than Los Angeles (LA) grade B, completed the Reflux Disease Questionnaire (RDQ) to assess severity and frequency of GERD symptoms, the GERD health-related quality of life (GERD-HRQL) and underwent high-resolution impedance manometry (HRIM) followed by a 10 minutes impedance-pH recording. Thereafter, they were randomized in a 1:1 ratio to receive GERDOFF®, 6 tablets per day, to be administered after each daily meal, at mid-morning and mid-afternoon and at bedtime (Group A), or an oral antacid or alginate on as needed basis for 14±2 days (Group B). Thereafter, patients repeated the questionnaires, filled in a VAS scale to measure the palatability of GERDOFF® and underwent a 24-hour impedance-pH monitoring. Tracings were blindly and manually reviewed and BI was measured at distal (at 3cm), mid (at 9cm) and proximal (at 15cm) esophagus off-therapy (10 minutes recording) and after 14±2 days of treatment.

**Results:** Two patients did not complete the study and were excluded. So far, data from 30 patients [18M/12F; mean age 54 (27-72) years; mean BMI 26 (18-34)] were further analyzed. Demographic, clinical and conventional impedance-pH features did not differ between Group A and Group B. In particular, mean RDQ [28.6 (15-45) vs. 27.6 (4-42),  $p=0.7800$ ] and mean GERD-HRQL [20.2 (3-35) vs. 22.2 (4-35),  $p=0.864$ ] were similar at baseline. In contrast, after treatment mean RDQ [28.6 (15-45) vs. 16.9 (1-36),  $p=0.0054$ ] and mean GERD-HRQL [20.2 (3-35) vs. 12.3 (2-24),  $p<0.0030$ ] decreased compared to baseline only in the GERDOFF® group, whereas no variation was observed in the control group [27.6 (4-42) vs. 31.5 (5-70) and 22.2 (4-35) vs. 22.9 (0-33),  $p=0.1767$  and  $p=0.6451$ , respectively]. The palatability [6.6 (2-10)], safety and tolerability of GERDOFF® were good.

**Conclusion:** Our data showed that in patients with proven GERD, GERDOFF® treatment for two weeks is able to improve GERD-related symptoms and quality of life. Larger studies are necessary to confirm these preliminary clinical data.

**Disclosure:** Edoardo Savarino serve as consultant for SOFAR

**Contact E-Mail Address:** takusan.yamasan@gmail.com

**Introduction:** The situation surrounding upper gastrointestinal tract diseases is about to change completely due to the decrease in *H. pylori* infection rate and the spread of eradication in Japan. In the future, it is expected that the use of gastric acid secretion inhibitors will continue to increase due to the further increase of gastroesophageal reflux disease (GERD). On the other hand, the negative effect and verification of safety associated with more potent acid suppression and long-term acid suppression have not been sufficiently obtained. Potassium Competitive Acid Blocker (P-CAB) is the most potent acid secretion suppressant among similar acid secretion inhibitors (PPIs and H<sub>2</sub> blockers), the use of P-CAB has been increasing rapidly in Japan and some countries. But, the negative effect of P-CAB (for example progression to neuroendocrine tumors (NET) have been remain unknown, so it is necessary to pay attention to the unknown side effects of P-CAB.

**Aims & Methods:** We aimed to find out an index for avoiding the risk of developing neuroendocrine tumor (NET) under the long time use of gastric acid secretion inhibitors. We think hypergastrinemia as one of the side effects of acid secretion inhibitors is the most important factor of NET induction. In addition, the appearance of ECL cells hyperplasia and degeneration of parietal cells are important precursors of NET, and the presence of ECL micronest may be considered as a preneoplastic status of NET onset. We examined the serum gastrin levels (normal range  $\leq 200$  pg / ml) and gastric biopsy specimens in 55 cases using gastric acid secretion inhibitors for GERD from April 2017 to March 2019. We compared the serum gastrin levels and the presence of parietal cell degeneration and ECL cell hyperplasia on each drug. We examined whether it could be an important index for avoiding the risk of developing NET.

**Results:** All 55 cases were divided into 20 cases in the P-CAB group and 35 cases in the PPI group, we compared the serum gastrin levels in fasting conditions. In the P-CAB group the serum gastrin levels were significantly higher (160~35,000 median 2,600) than in the PPI group (40~2,000 median 280) ( $p<0.01$ ). Furthermore, in 26 cases (10 cases in the P-CAB group and 16 cases in the PPI group) where stomach biopsy specimens were present, 90% (9/10) of the P-CAB group and 50% (8/16) of PPI group showed the presence of parietal cell degeneration and ECL cell hyperplasia. In addition, the results of comparing the degree of parietal cell degeneration and ECL cell hyperplasia showed severe changes in P-CAB group 67% (6/9) rather than PPI group 25% (2/8). Two cases of short-term use of P-CAB (6 months) were included, it was suggested that histological changes due to short-term use of P-CAB occurred in the gastric gland. In summary, significant hypergastrinemia associated with strong inhibition of gastric acid secretion was revealed, and histologically, parietal cell degeneration and ECL cell hyperplasia had been occurred at high rates. Furthermore, it became clear that more pronounced changes appeared due to the stronger suppression of acid secretion. We believe that long-term potent inhibition of acid secretion may increase the risk of developing NET.

**Conclusion:** More potent gastric acid secretion suppression resulted in marked hypergastrinemia, hyperplasia of ECL cells and degeneration of parietal cells. Therefore, when continuing strong suppression of gastric acid secretion, it is recommended that serum gastrin levels and histologic evaluation be performed to reduce the risk of developing NET.

**Introduction:** Antireflux surgery is an option for patients with symptoms of gastroesophageal reflux disease (GORD) who have an unsatisfactory response to proton pump inhibitor (PPI) therapy or seek an alternative to lifelong medication. However, long-term PPI therapy is associated with an altered gut microbiota.<sup>1,2</sup> Candidates for antireflux surgery are not routinely screened for dysbiosis of the gut microbiota. We performed a hydrogen and methane breath test (HMBT) in patients under consideration for antireflux surgery with a history of PPI use.

**Aims & Methods:** 138 patients on long-term PPIs (>6 months) and referred for antireflux surgery performed a lactulose HMBT. A positive result for small intestinal bacterial overgrowth (SIBO) and/or excessive methane production was indicative of dysbiosis (determined by a rise in hydrogen  $\geq 10$  ppm above baseline within 60 minutes after ingestion of substrate and determined by methane levels  $\geq 10$  ppm at any interval, respectively). Patients who underwent a complete 24-hour ambulatory pH study and HMBT were analysed for association with GORD (determined by a distal acid exposure time of  $>4\%$ ) and reflux symptom association (determined by a symptom index of  $\geq 50\%$  and symptom association probability of  $\geq 95\%$ ) statistically using Pearson Chi-Square test.

**Results:** In total 59.4% of subjects (82/138) had gut dysbiosis (25.3% were positive for SIBO, 19.6% were positive for excessive methane production and 14.5% had concomitant SIBO and excessive methane). 63 patients provided a complete 24-hour pH study and HMBT. The presence of dysbiosis was not associated with an abnormal AET ( $p=0.05$ ) but was associated with a positive reflux-symptom association ( $p=0.001$ ). Belching and regurgitation were the most frequently reported symptoms associated with reflux episodes.

**Conclusion:** A large proportion of patients considering antireflux surgery as a management strategy present with altered gut microbiota as determined by HMBT. Those patients with dysbiosis are more likely to have a positive association between reflux episodes and symptoms. Breath testing may be a useful adjunctive test in the pre/post-operative assessment of antireflux surgery. Although, further prospective study is required to determine the impact of altered gut microbiota on clinical outcomes following antireflux surgery.

## P1982 RISK FACTORS FOR EROSION TOOTH WEAR IN PATIENTS WITH GASTROESOPHAGEAL REFLUX DISEASE (GORD) SYMPTOMS: A PROSPECTIVE CROSS-SECTIONAL CASE CONTROL STUDY

Alharthi R.<sup>1,2</sup>, Moazzez R.<sup>1</sup>, Bartlett D.<sup>1</sup>, Jafari J.<sup>3</sup>

<sup>1</sup>King's College London, Centre of Oral, Clinical & Translational Sciences, London, United Kingdom, <sup>2</sup>Pirincess Noura bnt Abdulrahman University, Riyadh, Saudi Arabia, <sup>3</sup>Guy's and St Thomas Hospital, London, United Kingdom

**Contact E-Mail Address:** rasha.alharthi@kcl.ac.uk

**Introduction:** The most common oral manifestations of patients with GORD symptoms is erosive tooth wear (ETW). It is not clear why a group of patients with GORD symptoms develop ETW whereas others don't. The aim of this study is to assess the risk factors associated with developing ETW in patients with GORD symptoms, and to identify the predictive factors for ETW.

**Aims & Methods:** Consecutive patients referred for assessment of GORD to the Oesophageal Laboratory at Guy's Hospital were recruited (REC Ref 18/NE/0099). After consenting, validated self-reported Reflux Symptom Questionnaire 7-day recall (RESQ-7) was used to assess the frequency and intensity of GORD symptoms. Patients underwent 24hr impedance-pH reflux monitoring; acid exposure times, Symptoms index (SI) and symptoms association probability (SAP) were reported.

A clinical assessment of ETW was done using Basic Erosive Tooth Wear Examination (BEWE) protocol; a validated index in which the mouth is divided into 6 areas each scored from 0 to 3 (0= no ETW, 1= initial loss of surface texture, 2= loss of hard tissue  $< 50\%$  of surface area and 3= loss of hard tissue  $\geq 50\%$  of surface area). Those with a cumulative score of  $\geq 12$  and at least 1 oral area scoring 3 were included in the ETW group (ETW) and the rest were included in the NETW group (No ETW).

Data were analysed using STATA software, mean (SD), t-test analysis and ROC curve analysis were applied.  $P < 0.05$  was considered significant.

**Results:** 121 patients were recruited: ETW (n=64), NETW (n=57). Patients reported a range of 9 symptoms more commonly: heartburn, chest pain, regurgitation, cough, hoarseness, acid taste, throat burning, belching and epigastric pain. (mean $\pm$ SD) of intensity and frequency of individual symptoms of heartburn, hoarseness and coughing were significantly higher in ETW group:

Heartburn intensity (ETW:  $12.7 \pm 0.9$  vs NETW:  $9.7 \pm 0.9$ ;  $P = 0.03$ ), frequency (ETW:  $14.3 \pm 1.0$  vs NETW:  $10.3 \pm 1.0$ ;  $P = 0.007$ ). Hoarseness intensity (ETW:  $2.25 \pm 0.2$  vs NETW:  $1.32 \pm 0.2$ ;  $P = 0.004$ ), frequency (ETW:  $2.8 \pm 0.2$  vs NETW:  $1.5 \pm 0.2$ ;  $P = 0.0004$ ). Coughing intensity (ETW:  $3.0 \pm 0.2$  vs NETW:  $1.6 \pm 0.2$ ;  $P = 0.004$ , frequency (ETW:  $3.5 \pm 0.2$  vs NETW:  $1.98 \pm 0.2$ ;  $P = 0.0001$ ).

ROC curve analysis, considering all symptoms on RESQ-7, showed that patients with total frequency of  $>25$  (54.01% were correctly classified with a specificity of 30.88% and sensitivity of 76.8%) and/or total intensity of  $>36$  (61.36% were correctly classified with a specificity of 81.5% and sensitivity of 41.8%) are more likely to develop ETW amongst GORD patients.

119/121 patients completed impedance-pH testing, total acid exposure time was significantly higher in ETW ( $1.48 \pm 0.06$ ) patients vs NETW ( $1.28 \pm 0.06$ );  $P = 0.02$ . However, there was no significant difference between the two groups when upright and/or supine acid exposure time was considered individually.

**Conclusion:** This study demonstrates that there are three predictive values of developing ETW in GORD patients:

- 1) Heartburn, hoarseness and coughing as opposed to other reflux symptoms. Hoarseness and cough may indicate progression of reflux to proximal oesophagus and oral cavity.
- 2) Abnormal total acid exposure time, regardless of the body position or diurnal changes, on reflux monitoring.
- 3) Total frequency  $>25$  and/or intensity  $>36$  of all symptoms on RESQ-7; although not yielding in high accuracy.

**Introduction:** Barrett's Oesophagus (BE) is associated with increased risk of oesophageal cancer (EAC). The optimal management of low-grade dysplasia (LGD) arising in BE remains controversial. We performed a retrospective study from a tertiary referral centre for BE neoplasia, to estimate time to progression in patients with confirmed LGD compared to down-staged LGD.

**Aims & Methods:** We carried out retrospective analysis of tertiary BE LGD referrals in a single tertiary centre (July '06-October '18). Patients underwent high definition white light endoscopy with chromoendoscopy with targeted and Seattle protocol biopsies following referral. All biopsies were reviewed by at least two expert pathologists. We carried out analysis in ablation naïve patients with at least one follow-up endoscopy post index procedure. The primary end point was time to progression to high grade dysplasia (HGD)/EAC.

**Results:** 141 LGD patients were included. 13 were diagnosed during surveillance at our centre. 128 were tertiary referrals. 43/128 (34%) were upstaged at index endoscopy after referral to HGD/intramucosal adenocarcinoma

(IMC). 12 were upstaged to IMC, all had endoscopic mucosal resections at index.

44/128(34%) were down-staged, 28/128(34%) to non-dysplastic Barrett's oesophagus (NDBO), 15/128(12%) to indefinite for dysplasia (IND), one had no BE on index endoscopy. In the NDBO/IND group, 34 had no ablations and at least one follow-up endoscopy during surveillance at our centre, 5/34(15%) progressed to HGD/IMC over a median time of 36 months (IQR,13-42).

41/128(32%) of all referrals had confirmed LGD at index endoscopy. There was 54/141(38%) confirmed "true" LGD including patients diagnosed under our surveillance programme. In this cohort 34 had no ablations and at least one follow-up endoscopy during follow-up surveillance. 10/34(32%) progressed to HGD/IMC over a median time of 10 months (IQR,4-16). The remainder of this cohort had a median follow up of 27 months (IQR,14-45), and average number of 2 follow-up endoscopies with biopsies.

	'True' LGD (n=34)	IND (n=13) (Downstaged cohort)	NDBO (n=21) (Downstaged cohort)
Mean age, years	66	71	69
Male sex	30/34 (88%)	12/13 (92%)	16/21 (76%)
Median progression time to HGD/IMC (months)	10 (IQR, 4-16)	19 (IQR, 11-28)	42 (IQR, 28-72)
Median months of follow-up	17 (IQR, 6-39)	31 (IQR, 15-46)	17 (IQR, 6-31)

[Analysis of ablation treatment naïve patients]

**Conclusion:** Our data shows the variability in the diagnosis of LGD from referring centres, with 32% of referrals with confirmed LGD. The cumulative incidence of progression to HGD/IMC and time to progression varied across subgroups. Confirmed LGD had a shorter progression time compared to the down-staged group (NDBO/IND). It is important to differentiate these subgroups so that decisions on surveillance/endothrapy can be more personalised and resources utilised more wisely.

**Introduction:** Barrett's oesophagus (BE) is the main risk factor for oesophageal adenocarcinoma (OAC). The presence of dysplasia significantly increases the risk of BE malignant progression, hence, endoscopic treatment such as radiofrequency ablation (RFA) is recommended in those cases. After RFA, random 4-quadrant biopsies at the gastro-oesophageal junction (GOJ) are taken to detect residual disease. It is debatable whether intestinal metaplasia (IM) at the GOJ is a reliable marker of residual disease since it is subjective and patchy in nature. We have previously shown that methylation panel is accurate in identifying IM within the oesophageal tissue<sup>1</sup>.

**Aims & Methods:** In this single-centre, retrospective study we aimed to investigate whether a methylation panel in GOJ biopsies could be used to stratify patients after RFA. We analysed paraffin-embedded 4-quadrant BE and GOJ biopsies from adult patients with BE who underwent RFA, achieved remission, and had at least 2 follow-up endoscopies with biopsies taken at the GOJ. Biopsy sets from each treatment time-point (pre-RFA, 1st and 2nd follow-up) were included. The extent of IM was classified using a dedicated 4-tier histological score (IM-Score) and immunochemistry score using trefoil factor-3 staining (TFF3-score). The IM-Score was based on number of glands with goblet cells (1, 2-5 or >5 glands) and number of biopsies with IM (0=no IM, 1=focal, 2=moderate

and 3=extensive) and a total score of 0-1 was regarded as 'focal IM' and 2-3 as 'diffuse IM'. TFF-3 was scored as positive in the presence of intense cytoplasmic staining. Promoter methylation at 3 genes (ZNF345, TFP12, ZNF569) was assessed by MethyLight and a mean value was generated (Meth-Score). Methylation levels were compared using one-way ANOVA and Wilcoxon test, where appropriate. The accuracy of methylation panel in predicting diffuse IM after RFA treatment was assessed by calculating the area under the receiver operating characteristic curve (AUC). The correlation between Meth-score and IM-Score / TFF3 was assessed using Spearman's method.

**Results:** We included 45 patients, who achieved endoscopic remission after RFA. The pre-RFA grades included: non-dysplastic BE (NDBE; 24.4%), low-grade dysplasia (LGD; 31.1%), and high-grade dysplasia/intramucosal carcinoma (HGD/IMC; 44.4%). Overall, the methylation levels correlated with the degree of dysplasia, with a Meth-Score of 40.5%, 63.0% and 80.6% in NDBE, LGD, HGD/IMC, respectively (P<0.001). One-hundred-and-five GOJ biopsy sets (post-RFA) were analysed, of which 87 (82.9%) had focal IM, and 18 (17.1%) had wide-spread IM, with corresponding mean methylation levels of 2.4% and 35.5%, respectively (P=.018). The accuracy of methylation panel in predicting wide-spread IM at the GOJ was high (AUC 91.6%, 95%CI 87.0%-96.2%). Within the GOJ biopsy sets we found a significant correlation between methylation levels and amount of IM, measured both with IM-Score (rho=66.0%, P<0.001) and TFF3 positivity (rho=75.6%, P<0.001).

**Conclusion:** The methylation panel can differentiate grades of dysplasia in Barrett's and significantly correlates with the extent of IM at the GOJ. We propose the Meth-Score as an objective measure of residual and recurrent disease following RFA.

**Introduction:** Barrett's Oesophagus (BE) is associated with an increased risk of oesophageal cancer (EAC). The optimal management of patient's with low-grade dysplasia (LGD) arising in BE remains controversial. In the past 3 years there is a shift toward offering endoscopic eradication therapy to avoid cancer progression. We performed a retrospective study from a tertiary referral centre for BE neoplasia, our aim was to look at risk factors for progression of 'true' low grade dysplasia (LGD confirmed at endoscopy by two expert Barrett's histopathologists).

**Aims & Methods:** We carried out a retrospective analysis of all confirmed LGD BE in a single tertiary centre (July 2006-October 2018) and assessed risk factors which may affect rates of progression. Extent was defined as unifocal (One endoscopic level of LGD) or multifocal (>1 endoscopic level of LGD in BE segment). All patients underwent high definition white light endoscopy with chromoendoscopy with targeted and Seattle protocol biopsies following referral. All biopsies were reviewed by at least two expert pathologists. The primary end point was time to progression to high grade dysplasia (HGD)/EAC.

**Results:** A total of 54 patients had confirmed low grade dysplasia following index endoscopy, 34 patients (30m, 4f) were ablation treatment naïve and had at least one follow-up endoscopy. The average age of this cohort was 66. Patients had an average of 2 (IQR,1-3) follow-up endoscopies with biopsies following index endoscopy at our centre. Their median follow-up time was 22 months (IQR,8-39).

16/34 (47%) patients had multifocal low-grade dysplasia. 8(50%) of these patients progressed to HGD/EAC over a median time of 14 months (IQR,6-19). 2/18 (11%) patients with unifocal low grade dysplasia progressed to HGD/EAC over a median time of 2 months (IQR, 2-3). There was significant difference in numbers that progressed between both groups (P < 0.05).

6/34 (18%) patients had nodularity in Barrett's at baseline. 4/6 (67%) of these patients progressed to HGD/EAC over a median time of 8 months (IQR, 3-14). Most of these patients (75%) had an endoscopic mucosal resection for staging. 6/28 (21%) patients with no nodularity progressed to HGD/EAC over a median time of 11 months (IQR, 5-21). There was a significant difference in the numbers that progressed between the two cohorts ( $P < 0.005$ ).

5/34 (15%) patients had a short segment of Barrett's (< 3cm). 1/5 (20%) of these patients progressed to EAC after one month. 9/29 (31%) patients with a long segment of BE ( $\geq 3$ cm) progressed to HGD/EAC over a median follow up time of 13 months (IQR, 4-17).

	Unifocal LGD	Multifocal LGD	Short BE segment	Long BE segment	Nodularity	No nodularity	Male	Female
Number progressed to HGD/EAC (%)	2/18 (11%)	8/16 (50%)	1/5 (20%)	9/29 (31%)	4/6 (67%)	6/28 (21%)	9/30 (30%)	1/4 (25%)
P-value	$P < 0.05$		$P = 0.6$		$P < 0.05$		$P = 0.8$	

[Analysis of radio frequency ablation naive patients]

**Conclusion:** LGD in BE can be difficult to accurately diagnose pathologically and therefore management can often be variable. Robust prognostic markers are needed to differentiate those patients that need surveillance or endotherapy. Multifocal LGD and nodularity were associated with a significant risk of progression to HGD/EAC. The presence of a longer segment of BE was associated with a higher progression risk.

There is an argument that the treatment of LGD with endotherapy should be individualised given the possible risks associated. Identifying key risk factors of progression will tailor treatment in a specific, higher risk cohort.

## P1986 COLUMNAR EPITHELIUM MORPHOLOGY AFTER ESOPHAGECTOMY: CLINICAL INSIGHT INTO THE DEVELOPMENT OF BARRETT'S ESOPHAGUS

Iizuka T.<sup>1</sup>, Ohkura Y.<sup>2</sup>, Ueno M.<sup>2</sup>

<sup>1</sup>Toranomon Hospital, Gastroenterology, Tokyo, Japan, <sup>2</sup>Toranomon Hospital, Gastrointestinal Surgery, Tokyo, Japan

**Contact E-Mail Address:** t-iizuka@toranomon.gr.jp

**Introduction:** The mechanism of development of Barrett's esophagus (BE) has been investigated in animal experiments; however, clinical studies are rare. Acid reflux is considered to play a major role in the development of BE, but there is little evidence to prove this. Given that changes in columnar epithelium due to acid reflux are used as a surrogate marker of BE, we investigated the link between the development of BE and acid reflux.

**Aims & Methods:** This retrospective study involved 158 patients who underwent esophagectomy in a single institution between 2004 and 2018. Patients without detailed data such as operative method, patients without an intact stomach, and patients without endoscopic follow-up were excluded. Patients were divided into two groups. The first group comprised 106 patients who had undergone esophagectomy and gastric pull-up reconstruction (St), while the second group comprised 52 patients who had undergone esophagectomy and ileocolic interposition (Ic). The incidence of BE, the interval between surgery and the development of BE, and the severity of BE and reflux esophagitis were analyzed. BE was defined as an endoscopic columnar epithelium extending to the oral side from the site of anastomosis. Scheduled endoscopic examination was performed as follow-up once or twice a year.

**Results:** Clinical characteristics were as follows: mean age 64.7 years in St, 61.3 years in Ic ( $p=0.017$ ); male patients 95 (90%) and 43 (83%), respectively ( $p=0.31$ ); mean follow-up period 67.6 and 51.3 months, respectively ( $p=0.013$ ); and mean number of endoscopic examinations 8.8 and 7.7, respectively ( $p=0.17$ ). Occurrence of BE was seen in 47 cases (44.3%) and 1 case (1.9%), respectively ( $p < 0.01$ ). Reflux was observed in 68 cases and 1 case, respectively ( $p < 0.01$ ). The median interval to development of BE was 524 (168-3002) days. The mean length of BE was 11.7 mm. Univariate and multiple logistic analysis revealed that the method of reconstructive surgery (odds ratio 22.6) and reflux (odds ratio 4.91) were independent risk factors. There was no incidence of Barrett's adenocarcinoma during follow-up.

**Conclusion:** The development of BE is closely linked to reflux, including gastric acid reflux, and is rarely observed in ileocolic interposition.

**Disclosure:** Nothing to disclose

## P1987 DIAGNOSTIC YIELD OF SEATTLE PROTOCOL AND TARGETED BIOPSY - COMPARATIVE STUDY IN BARRETT'S ESOPHAGUS SURVEILLANCE

Silva J.C., Fernandes C., Pinho R., Proença L., Silva A.P., Sousa M., Gomes A.C., Afeto E., Carvalho J.

Centro Hospitalar Vila Nova de Gaia/Espinho, Gastroenterology, Vila Nova de Gaia, Portugal

**Contact E-Mail Address:** catarina.rib.gomes@gmail.com

**Introduction:** Endoscopic surveillance in Barrett's Esophagus (BE) is recommended according to the Seattle protocol (SP) with random 4-quadrant biopsy specimens obtained every 1-2 cm to detect dysplasia, complemented with targeted biopsies (TB) of suspicious lesions.

Narrow-Band Imaging (NBI) has the potential to increase diagnostic accuracy, although it is not routinely recommended. The main limitations of SP are sampling error and costs associated with histology.

**Aims & Methods:** The main aim was compare diagnostic yield (DY), defined by dysplasia in the histology, of SP with TB alone.

Cross-sectional study, which consecutively included patients undergoing BE surveillance between 2015 and 2018. Exams were executed with high resolution scopes under white light (WL) or NBI according to endoscopist's preference and experience. Surveillance of BE was made according to SP in all patients. TB were performed if suspected focal lesions were identified.

**Results:** A total of 127 surveillance exams referring to 94 patients were included. Mean age was  $60 \pm 15$  years and most patients were male (74.5%). WL evaluation was complemented with NBI in 40.2% ( $n=51$ ). Random biopsies were performed in 112 (88.2%) and targeted biopsies in 15 (11.8%). DY of SP was very low (2.7%,  $n=3$ ) and dysplasia was confirmed in a subsequent examination in only 1 case (0.9%). TB demonstrated a significantly higher DY (40%;  $n=6$ ) ( $p < 0.001$ ). Considering only patients in whom WL evaluation was complemented with NBI, SP maintained a significantly lower DY (SP-2.6%, TB-41.70%,  $p=0.002$ ). There was a significant association between TB surveillance and dysplasia identification in histology, both in WL ( $p < 0.001$ ) and NBI assessment ( $p = 0.002$ ).

**Conclusion:** Targeted biopsies had a significantly higher diagnostic yield, either under WL or with NBI, compared to Seattle Protocol.

**Disclosure:** Nothing to disclose

## P1988 BARRETT'S OESOPHAGUS SURVEILLANCE AT A LARGE UNIVERSITY HOSPITAL IN THE UNITED KINGDOM

Mak J.K.C., Nar R., Boulton R., Butt M.A.

Queen Elizabeth Hospital Birmingham, University Hospitals Birmingham NHS Foundation Trust, Department of Gastroenterology, Birmingham, United Kingdom

**Contact E-Mail Address:** ralph.boulton@uhb.nhs.uk

**Introduction:** Barrett's oesophagus represents the most important risk factor for the development of oesophageal cancer. According to NICE, surveillance should be considered for Barrett's diagnosed endoscopically and on biopsy<sup>1</sup>. British Society of Gastroenterology (BSG) guidelines recommend Barrett's surveillance to be performed at specific prescribed intervals dependent upon the length and histology<sup>2</sup>. Additionally, the BSG has proposed the use of a Minimum Endoscopic Dataset (MED) for reporting endoscopic findings<sup>3</sup>.

**Aims & Methods:** The main aims of this service improvement project were to:

1. Evaluate whether Barrett's surveillance is being conducted within recommended levels of tolerance at our hospital.
2. Assess the standard of our endoscopy reporting in comparison to the BSG MED.

A total of 137 Barrett's cases diagnosed endoscopically at Queen Elizabeth Hospital Birmingham (QEHB) between 2015 and 2018 were identified. The QEHB serves as the primary teaching hospital for the University of Birmingham and is one of the largest single-site NHS hospitals in the UK. Patients found to have Barrett's with dysplasia were excluded from surveillance. In addition, patients who were subsequently diagnosed with

oesophageal cancer (as identified from the Somerset Cancer Registry) were excluded. Adherence of the endoscopy report findings to the criteria outlined in the BSG MED was assessed including documentation of the Prague endoscopic classification and concordance with Seattle protocols for biopsy.

**Results:** Of the 137 Barrett's cases, 50 (36%) were excluded from the surveillance programme. As shown in Table 1, these included 23 patients with dysplasia and a single patient with subsequent oesophageal cancer diagnosed on biopsy. 57 of the remaining 87 patients (66%) were identified to be overdue for surveillance. Of these 57 cases, 11 (19%) had the Prague classification documented, while 2 (4%) had biopsies taken.

Total no. of Barrett's cases:	137	Proportion of cases
No. excluded:	50/137	36%
-Dysplasia	23/50	46%
-Subsequent diagnosis of oesophageal cancer	1/50	2%
-Previous diagnosis of oesophageal cancer (i.e. under cancer surveillance)	2/50	4%
-Endoscopy report unavailable	11/50	22%
-Other (e.g. failed endoscopy or inconclusive Barrett's)	13/50	26%
No. eligible for surveillance:	87/137	64%
No. with surveillance overdue:	57/87	66%
-Prague classification	11/57	19%
-Biopsies	2/57	4%

[Table 1: Breakdown of Barrett's cases diagnosed at QEHB in 2015-18]

It is clear that a significant proportion of Barrett's patients at our hospital are overdue their surveillance endoscopy outside of tolerance. Furthermore, most of them have neither been properly reported nor sampled according to BSG standards at their last endoscopy. The latest National Oesophago-cancer Gastric Audit reported a decreased number of Barrett's patients diagnosed with dysplasia in 2012-17 in the West Midlands (in contrast to the rest of the UK)<sup>3</sup>. Our results suggest that poor Barrett's surveillance at our hospital in recent years could have at least partially contributed to this decline.

**Conclusion:** An unacceptable number of Barrett's patients at our hospital are overdue their surveillance as per BSG guidelines. Efforts to implement a co-ordinated surveillance programme and improve our standard of endoscopy reporting are now underway. Barrett's patients identified to have surveillance overdue have been entered into a prospective database for prioritised follow-up in order to bring our Barrett's surveillance service back to tolerance.

## P1989 NARROW BAND IMAGING IN SCREENING OF BARRETT'S ESOPHAGUS IN GASTROESOPHAGEAL REFLUX DISEASE PATIENTS

ElSheaita A.<sup>1</sup>, Nouh H.<sup>2</sup>, Elbially M.<sup>1</sup>, Shamseya M.M.<sup>1</sup>, Shawky Ahmed S.<sup>3</sup>, Madkour M.A.<sup>1</sup>, Shamseya A.<sup>4</sup>, Khalil H.<sup>4</sup>

<sup>1</sup>Medical Research Institute, Alexandria University, Experimental and Clinical Internal Medicine, Alexandria, Egypt, <sup>2</sup>Alexandria Faculty of Medicine, Internal Medicine, Alexandria, Egypt, <sup>3</sup>Medical Research Institute, Alexandria University, Pathology, Alexandria, Egypt, <sup>4</sup>Alexandria Faculty of Medicine, Alexandria, Egypt

**Contact E-Mail Address:** mougazi@hotmail.com

**Introduction:** Seattle protocol described as targeted and random four-quadrant biopsies every 2 cm has long been considered as the gold standard of screening and surveillance of Barrett's esophagus (BE) to minimize sampling error (1), however its difficulty limits its applicability in practice specially as a screening tool for BE among specific populations. With the rising need to do selective screening in gastroesophageal reflux disease (GERD) patients with certain risk factors other protocols as Narrow band imaging (NBI) guided biopsy need to be investigated.

**Aims & Methods:** To validate the utility of NBI guided biopsy as a screening protocol for BE among certain GERD patients compared to Seattle protocol. Endoscopy and biopsy taking was done in 2 different sessions 2 weeks apart to allow mucosa to heal for 100 patients in Alexandria, Egypt. In the first session Seattle protocol was applied and in the second session NBI guided biopsy was done. Patients had at least one of the following: Chronic Gastroesophageal reflux disease (more than 5 years), frequent Gastroesophageal reflux disease (more than once weekly), two or more of the following risk factors for Barrett's esophagus: Old age >50 years, central obesity (waist circumference >102 cm in males and >88 cm in females), current or past history of smoking and family history of BE or esophageal adenocarcinoma (EAC) and family history of BE or EAC (2). All patients with known Barrett's esophagus were excluded. Suspicious lesions were defined as follows: in Seattle protocol mucosal irregularities (e.g. nodules/ulcers) (3), in NBI suspicious lesions were defined as per Barrett International NBI Group (BING) classification as any lesion with irregular/absent mucosal pattern and/or any lesion with irregular vascular pattern (focally or diffusely distributed vessels not following normal architecture of the mucosa) (4).

**Results:** Considering the overall worst diagnosis by histopathology as the true diagnosis, Of the 100 consecutive GERD patients, 17 patients had Barrett's esophagus either by one of the two techniques or by both, 35.3% by both methods, 41.2% by narrow band imaging alone and 23.5% by Seattle protocol alone ( $p < 0.001$ ,  $\kappa = 0.461$ ). Sensitivity, specificity, negative predictive value and positive predictive value for Seattle protocol were 58.8%, 100%, 92.2%, 100% vs 76.5%, 100%, 95.4%, 100% respectively for narrow band imaging. A mean of 7.73 samples/patient were taken in Seattle protocol vs 3.42 samples in narrow band imaging ( $p < 0.001$ ). A mean of 8.63 minutes was consumed in Seattle protocol vs 2.65 minutes in narrow band imaging ( $p < 0.001$ ). No statistically significant difference in the detection rate of dysplasia between the two techniques was found.

**Conclusion:** Though this study has some limitations due to the relatively small number of patients beside the lack of magnifying NBI which led to some difficulty in detection of abnormal vascular pattern, this study indicates that NBI guided biopsy might be a valid alternative to Seattle protocol and further multicentric larger studies are needed.

## P1990 AN AUTOMATED, QUANTITATIVE MULTIPLEX IMMUNOFLUORESCENCE ASSAY ACCURATELY RISK STRATIFIES BARRETT'S ESOPHAGUS PATIENTS WITH A COMMUNITY-BASED DIAGNOSIS OF LOW-GRADE DYSPLASIA AT A RATE COMPARABLE TO EXPERT PATHOLOGISTS

Frei N.<sup>1</sup>, Konté K.<sup>1</sup>, Bossart E.A.<sup>2</sup>, Zhang Y.<sup>2</sup>, Critchley-Thorne R.J.<sup>2</sup>, Pouw R.E.<sup>1</sup>, Bergman J.J.<sup>1</sup>

**Introduction:** Low-grade dysplasia (LGD) in Barrett's esophagus (BE), is the strongest predictor of malignant progression, yet an accurate histological diagnosis of LGD is challenging. The majority of community-based LGD diagnoses are down-staged to non-dysplastic (ND)BE when reviewed by an expert pathologist, whereas patients in whom the diagnosis of LGD is confirmed have a 10% annual risk of progression to high-grade dysplasia (HGD) or cancer (Ca), justifying the consideration of prophylactic endoscopic ablation. Although guidelines recommend expert pathologist review of all LGD cases, expert review is poorly defined, prone to observer

variation, and not widely available. Recent studies suggest that an automated, quantitative multiplex immunofluorescence assay may identify NDBE patients with an increased risk of malignant progression. We investigated if this assay also allows objective risk stratification for cases with a community-based diagnosis of LGD at a rate comparable to expert pathologists.

**Aims & Methods:** A blinded nested case-control cohort was derived from the screening cohort of the SURF-study, a randomized controlled trial of SURveillance vs. RadioFrequency ablation for BE patients with LGD. 60 patients with a community-based diagnosis of LGD of whom 30 progressed to HGD/EAC (progressors) and 30 patients who did not progress (non-progressors) were matched for age, sex and maximal BE length. All random biopsy levels of the baseline endoscopy and subsequent endoscopies were independently reviewed by 3 expert pathologists with an international reputation. All levels of the baseline endoscopy were additionally tested by a multiplex biomarker assay (TissueCypher Barrett's Esophagus Assay, Cernostics). The assay integrates quantitative biomarker and morphology scores extracted from whole slide images of multiplex immunofluorescence-labeled standard formalin-fixed paraffin-embedded biopsies to classify patients as low-risk (LR), intermediate-risk (IR) and high-risk for progression to HGD/EAC within 5 years. A histological revision diagnosis of NDBE was considered as low- (LR), while indefinite for dysplasia (IND) and LGD were considered as high-risk (HR) for progression.

**Results:** 60 BE patients (52 male), mean age 63±9 years, were studied. Clinical characteristics were similar between progressors and non-progressors. Median time between baseline endoscopy and progression was 2.5 years (1.3-5.4). Accuracy, sensitivity and specificity of the biomarker assay vs. the 3 expert pathologists were 73% vs 72-77%, 66% vs 77-80% and 80% vs 63-77%, respectively. 20/26 (78%) patients classified as IR/HR by the biomarker panel and 69-77% classified as HR (IND/LGD) by the 3 expert pathologists progressed to HGD/EAC.

**Conclusion:** A quantitative multiplex immunofluorescence assay risk stratified BE patients with a community-based diagnosis of LGD with an accuracy comparable to three renowned expert pathologists. The assay allows for automated, objective risk stratification which may be a practical and effective solution to the lack of standardization of expert pathology review of LGD as advocated by all guidelines.

**Introduction:** The incidence of esophageal adenocarcinoma (EAC) has been increasing over the past decades. Current consensus states that all visible lesions in the context of Barrett's Esophagus (BE) should be endoscopically resected due to the high likelihood of containing significant pathology. Conversely, extensive resection aiming for metaplasia eradication should not be preferred over ablation strategies given the higher risk of subsequent stricturing. Current methods of mucosal resection include the cap-assisted technique and more recently multi-band mucosectomy (MBM). Since its first description, several prospective and retrospective series have been published, but data on efficacy and safety of MBM has yet to be systematically reviewed.

**Aims & Methods:** We performed a systematic review with pooled-analysis to evaluate the efficacy and safety of MBM in patients with BE. Electronic databases (Medline, Scopus, EMBASE) were searched up to March 2019. Studies including patients with BE who underwent MBM were eligible. The primary outcome was the rate of adverse events such as intra- and

post-procedural bleeding, perforation and stricture. Of note, we developed subgroup meta-analytic models selecting a priori variables which could affect the outcomes, such as the indication for performing MBM (focal lesion resection vs metaplasia eradication). Secondary outcomes were focused on MBM performed for resecting visible lesions. The rates of complete resections and R0 resections were assessed. The endoscopic resection was considered macroscopically complete if the visible lesion was entirely removed. The absence of neoplastic invasion at deep and lateral margins of the resected specimens was considered as an R0 resection for lesions resected in an en-bloc fashion. In cases of piecemeal resections, R0 at the deep margin of all resected specimens derived from a single lesion was required. Primary and secondary outcomes were assessed by pooling data by means of a random- or fixed-effect model according to the degree of heterogeneity to obtain a proportion with a 95% confidence interval (CI).

**Results:** Thirteen studies were eligible for inclusion, providing data on 1334 procedures performed in 986 patients; 839 out of 1334 procedures were performed in order to resect focal lesions on BE. Ten studies were performed in Europe and 3 in North America. All studies but 3 had a retrospective design. According to data reported by 6 studies, there was a mean number of 4.2±1.6 specimens per procedure. Considering the histological findings, 52.2% of the lesions were adenocarcinomas and 31.3% were HGD. The overall adverse event rate was 5.3% (I<sup>2</sup>:83.4%). Immediate and post-procedural bleeding occurred in 0.2% (I<sup>2</sup>:0%) and 0.7% (I<sup>2</sup>:0%) of procedures, respectively. Moreover, perforations and strictures were reported in 0.3% (I<sup>2</sup>:0%) and 3.9% (I<sup>2</sup>: 80.4%) of procedures, respectively.

The sensitivity analysis focused on focal lesion resection (8 studies, 584 procedures) reported an overall adverse event rate of 5.5% (I<sup>2</sup>:0%), with rates of bleeding, perforation and stricture of 1.6%, 1.0% and 3.3%, respectively. Focal lesions were resected at a complete rate of 97.6% (I<sup>2</sup>:49.9%) with an R0 resection rate of 94.1% (I<sup>2</sup>:81.7%).

**Conclusion:** Our results confirm MBM as a safe and effective technique to treat visible lesions in patients with Barrett's esophagus. Further studies with longer follow-up periods are still necessary to provide definitive reassurance in terms of long term efficacy.

**Contact E-Mail Address:** w.januszewicz@gmail.com

**Introduction:** Barrett's esophagus (BE) is a well-established precursor condition to esophageal adenocarcinoma and the presence of dysplasia is the main risk factor for malignant progression. The BE with indefinite for dysplasia (BE-IND) diagnosis is used when the significance of epithelial abnormalities is uncertain due to inflammation or technical artifact. The natural behaviour of BE-IND is poorly understood.

**Aims & Methods:** In this retrospective, single-center study we aimed to characterize the risk of prevalent and incident neoplasia in patients with BE-IND. We reviewed the BE research database to identify patients diagnosed with BE-IND. We excluded patients under 18 years old, with a follow-up of less than 1 year, with a previous diagnosis of definitive dysplasia, and previous endoscopic therapy. Times and rates of progression to neoplasia were calculated and categorized as prevalent neoplasia when the progression occurred within 1 year of follow-up (FU), and incident neoplasia, for progression after >1 year FU. A multivariable regression model adjusted for age, sex, length of BE segment, the extent of IND (focal vs multifocal) and baseline IND diagnosis was used to identify risk factors for both prevalent and incident neoplasia.

**Results:** In total, 345 patients with  $\geq 1$  diagnosis of BE-IND were identified between 1999 and 2018, of which 147 (42.6%) were excluded, and the remaining 198 (57.4%) were analyzed. Hundred-fifty-one patients (76.3%) showed regression to a non-dysplastic epithelium at the first follow-up biopsies and 19 patients (9.6%) had prevalent dysplasia of any grade including 17 low-grade dysplasia (LGD) and two cases of advanced neoplasia (1.0%): 1 high-grade dysplasia (HGD) and 1 intramucosal cancer (IMC). Twenty-eight patients (14.1%) had incident dysplasia progressing to LGD (21), HGD (5), and IMC (2) after a median FU of 32.8 months (range 12.3 - 124.5), yielding an incidence rate of dysplasia (any grade) and advanced neoplasia (HGD/IMC) of 3.9 and 1.3 cases per 100 patient-years, respectively. The length of BE segment was associated with the increased risk of prevalent dysplasia (odds ratio 1.14; 95%CI 1.00-1.30,  $P=0.046$ ), however not incident dysplasia, for which none of the analyzed risk factors were found predictive.

**Conclusion:** Patients with BE-IND, especially with a long segment of BE, should be closely monitored as nearly 10% harbor prevalent dysplasia. A significant proportion of patients with BE-IND will progress to more advanced stages and molecular biomarkers are required for stratification, as clinical criteria to predict patients at high-risk for progression are lacking.

**Introduction:** While esophagectomy is the standard treatment for submucosal (T1b) esophageal adenocarcinoma (EAC) and squamous cell cancer (SCC), many elderly patients -the age group that esophageal cancer tends to affect- are not candidates for surgery.

Endoscopic submucosal dissection (ESD) is a minimally invasive procedure that allows for en-bloc resection of early esophageal cancer and allows for precise histopathologic staging of the tumor. ESD could be curative in submucosal cancer without lymph node metastasis, and it allows for precise histopathologic staging.

**Aims & Methods:** We aimed to evaluate the long-term outcomes of ESD in patients with EUS-staged T1b esophageal cancer.

A retrospective multicenter study was performed at three academic hospitals in the U.S. Patients who underwent ESD with a pre-procedural or post-procedural histopathologic diagnosis of T1b No Mo EAC or SCC were included in the study. Data was collected on demographics, tumor and procedure characteristics, procedure pathology, and follow-up. Local recurrence was confirmed by endoscopic findings and pathological analysis. Metastasis was confirmed by cross-sectional imaging. The main outcome was a composite of rate of metastasis and local recurrence. Follow-up time was defined as months from initial procedure to recurrence or last follow-up visit if recurrence-free. A time-to-event analysis was performed to evaluate recurrence. A Cox proportional hazard ratio regression analysis was performed to identify predictors of recurrence.

**Results:** Thirty-seven patients underwent ESD (mean age 70 years +/-9; 25 males; median tumor size 25 mm). Based on available comorbidity data, 42% patients were not fit for surgery, as determined by an age-adjusted Charlson Comorbidity Index  $> 6$ . En bloc and R0 rates were 73% and 52%, respectively. Twenty tumors (54%) were found to be HGD or T1a on post-ESD specimen analysis, while one was staged as T2. Immediately after ESD, 4 patients were referred for surgery, 2 underwent chemoradiation therapy, and 4 radiation alone. Patients were followed for a median of 9 months, and the calculated 12- and 48-month recurrence rate was 13% and 30%, respectively. Not achieving en bloc resection was identified as a predictor for recurrence.

**Conclusion:** This multicenter trial showed that ESD for T1b esophageal cancer can be acceptable for patients who deemed not surgical candidates. However, close follow up is necessary. ESD can also serve as a staging procedure, as our data confirms inaccurate EUS-staging of T1b cancer, with 54% of tumors being down-staged to T1a, as has been previously reported.

**Contact E-Mail Address:** c.helsper@gmail.com

**Introduction:** In gatekeeper healthcare systems, an efficient diagnostic process in primary care is pivotal for reducing cancer related disease burden.

**Aims & Methods:** This study aims to explore reasons for long time to referral for upper gastrointestinal (GI) cancer patients in Dutch primary care.

A retrospective cohort study, using anonymized free text primary care records of 6 routine primary care databases in the Netherlands. Patients diagnosed with oesophageal- or gastric cancer (2010-2015), who symptomatically presented in primary care, were included. Based on manual free text exploration, time from presentation to referral in primary care was determined. Duration was calculated per characteristic (median, IQR). We performed uni- and multivariable log-binomial regression analyses to find associations of patient- and presentation characteristics with relatively "long duration" ( $\geq 75$ th percentile value). Routes to referral of patients with relatively "longest durations" ( $\geq 90$ th percentile value) were explored using thematic free text analyses.

**Results:** 174 symptomatic oesophageal cancer patients and 138 symptomatic gastric cancer patients were included. Longer median durations and/or univariable association with  $\geq P75$  were found for;

- (1) patients without alarm symptoms (both types),
- (2) female sex, higher socio-economic status score (SES) and psychiatric comorbidity (oesophageal cancer),
- (3) youngest age category (gastric cancer). In multivariable analysis, presentation without alarm symptoms showed a statistically significant association with "long duration" ( $\geq P75$ ) for both cancer types. For oesophageal cancer, high SES was associated with long duration. Thematic exploration of routes to diagnosis for patients with "longest durations" ( $\geq P90$ ) showed one dominating theme: "an initial low clinical suspicion of cancer", and only few preventable factors for long duration.

**Conclusion:** The main reason for long time to referral of oesophageal and gastric cancer patients is an initial low cancer suspicion. Absence of alarm symptoms is the main contributor to this lower suspicion and therefore, the longer times to referral.

Only few preventable factors for delayed referral could be identified. These findings reflect a well-functioning gatekeeper system, with most to be gained from improving upper GI cancer recognition among those with non-alarm symptoms.

### P1995 A PROSPECTIVE STUDY OF SM2 CARCINOMA DIAGNOSIS USING THE EXTENT OF TYPE B2 VESSELS IN THE JAPAN ESOPHAGEAL SOCIETY CLASSIFICATION

Takeuchi M., Azumi M., Kohisa J.

Nagaoka Red Cross Hospital, Department of Gastroenterology, Nagaoka, Japan

**Contact E-Mail Address:** yasuzuka2000@yahoo.co.jp

**Introduction:** Although the Japan Esophageal Society (JES) classification for superficial squamous cell carcinoma has been simplified and is now widely used, the low diagnostic accuracy of invasion depth on the basis of type B2 vessels is a topic of concern. Based on the fact that in pSM2 carcinoma type B2 vessels appear at a similarly high rate to type B3 vessels, and the larger the area they cover, the higher the possibility of invasion,

we have previously reported that the extent of type B2 vessels in cases of pSM2 carcinoma is significantly larger than that in cases of pMM/pSM1 carcinoma, and that the appropriate cut-off value is 7 mm.

**Aims & Methods:** In the present study, we carried out a prospective study of the accuracy of the diagnosis of invasion depth based on the extent of these type B2 vessels. We examined 99 lesions in 78 patients who underwent endoscopic submucosal dissection in our department between April 2016 and September 2018. The patients were 71 men and 7 women of median age 70 years (range 50-89 years). The main macroscopic tumor type was IIa in 12 cases, IIb in 35, IIc in 47, Is in 4, and III in 1; the main tumor location was the cervical esophagus (Ce) in 4 cases, the upper thoracic esophagus (Ut) in 9, the middle thoracic esophagus (Mt) in 57, the lower thoracic esophagus (Lt) in 27, and the abdominal esophagus (Ae) in 2; the circumferential ratio was  $< 1/2$  the circumference of the esophagus in 61 cases,  $< 2/3$  of the circumference in 13,  $\geq 2/3$  of the circumference in 21, and circumferential in 4; and the mean tumor diameter was 20 mm (range 3-100 mm). The region of interest containing the highest concentration of atypical vessels was marked with two points, the invasion depth at this point was diagnosed, and the diagnostic accuracy was investigated. For type B2 vessels in particular, both ends of the largest region were marked, and the distance between these marks was then measured by using biopsy forceps. The largest diameter was also measured under stereoscopic microscopy. In this study, type B2 vessels were defined as irregularly branched vessels corresponding to type 4 vessels in the Arima classification.

**Results:** The vessels in the region of interest were type B1 in 75 lesions, type B2 in 21, and type B3 in 3. Of the 75 lesions with type B1 vessels, the tumor had invaded to EP or LPM in 69 cases, MM in 4, and SM2 in 2, and the diagnostic accuracy was 92% (69/75). All 3 lesions with type B3 vessels had invaded the submucosa to a depth of  $\geq 200$  mm (SM2), and the diagnostic accuracy was 100% (3/3). Both these results were similar to those of previous studies. However, of the 21 lesions with type B2 vessels, 14 had invaded either the MM or the submucosa to a depth of  $< 200$  mm (SM1) and 7 were SM2, and following the conventional procedure the diagnostic accuracy was only 66.7% (14/21). However, when the extent of the vessels was taken into account, 15 lesions had type B2 vessels with an extent of  $< 7$  mm. The invasion depth for these 15 lesions was MM/SM1 in 14 and SM2 in 1, and the diagnostic accuracy was 93% (14/15). The invasion depth of all 6 lesions with type B2 vessels with an extent of  $\geq 7$  mm was SM2, and the diagnostic accuracy was 100% (6/6). Taking the extent of type B2 vessels into account significantly improved diagnostic accuracy from 68% to 95% ( $p < 0.01$ ).

**Conclusion:** Although our prospective study involved only a small number of cases, it suggested that the extent of type B2 vessels may be useful for the diagnosis of invasion depth. The designation of irregularly branched vessels as type B2 may also be an important assessment criterion.

**Introduction:** Obesity was known to be the risk factor of the incidence of Barrett's esophagus (BE) and Barrett's esophageal adenocarcinoma (BEA). Especially excessive visceral fat have recently reported to promote some cancers, including BEA, development and progression because of metabolic disruption. It elaborates cytokines, adipokines and growth factors, resulting in systemic inflammation which could be carcinogenesis. To our best knowledge, there is no report to mention to the differences of relationship between abdominal fat distribution and progression of BEA based on the length of BE.

**Aims & Methods:** This study aimed to clarify the impact of abdominal fat distribution on progression of BE to adenocarcinoma in long-segment BE (LSBE) and short-segment BE (SSBE).

**Study 1:** We retrospectively reviewed the 124 patients with pathologically defined superficial BEA who underwent endoscopic resection, including 4 endoscopic mucosal resection (EMR) and 85 endoscopic submucosal dissection (ESD), or surgical operation (35 esophagectomy) in our institution between January 2004 and December 2018. 124 BEA cases included 34 LSBE (length  $\geq 3$  cm) cases and 90 SSBE (length  $\geq 1$  and  $< 3$  cm) cases. Using computed tomography volumetry, we measured areas of visceral (VFA) and subcutaneous (SFA) fat at the level of the umbilicus, and calculated the VFA/SFA ratio in each patient, defining high-VFA/SFA ratio ( $\geq 1.0$ ) and low-VFA/SFA ratio ( $< 1.0$ ). We also measured body mass index (BMI) and waist circumference (WC). VFA/SFA ratio, BMI and WC in the patients were compared and analyzed between BEA with LSBE group and BEA with SSBE group.

**Study2:** We divided 62 patients who had LSBE into two groups based on prognosis of BEA; BEA with LSBE (34 patients) and non-BEA with LSBE group (18 patients). Above-mentioned parameters were compared and analyzed between these two groups.

**Results:** Study1: High VS ratio were seen in 22 (64.7%) patients among BEA with LSBE group and 34 (37.8%) patients among BEA with SSBE group, which is statistically significant ( $p = 0.0072$ ). However, difference of BMI or WC were not significant between BEA with LSBE group and BEA with SSBE group as follow; median BMI (range) 24.2 (13.1-31.8) kg/m<sup>2</sup> vs. 23.2 (16.2-36.9) kg/m<sup>2</sup>, WC (range) 85.8 (59.8-122.6) cm vs. 86.0 (62.4-151.4) cm. Study2: In non-BEA with LSBE group, BMI (range) and WC (range) were 23.7kg/m<sup>2</sup> (18.8-26.8) kg/m<sup>2</sup> and 86.1 (77.0-104.9) cm. These were not significant either, compared to BEA with LSBE group. High VS ratio were seen in 6 (33.3%) patients among non-BEA with LSBE group. This result was statistically significant compared to BEA with LSBE group (0.038).

**Conclusion:** High VFA/SFA ratio was significantly associated with progression of long-segment Barrett's esophagus to esophageal adenocarcinoma.

## P1997 OUTCOME OF ENDOSCOPIC SUBMUCOSAL DISSECTION FOR SUPERFICIAL PHARYNGEAL SQUAMOUS CELL CARCINOMA - ESPECIALLY FOR THE SCC LOCATED ANTERIOR SIDE OF EPIGLOTTIS

Oyama T.<sup>1</sup>, Takahashi A.<sup>2</sup>

<sup>1</sup>Saku Central Hospital Advanced Care Center, Endoscopy, Nagano, Japan,

<sup>2</sup>Saku Central Hospital Advanced Care Center, Gastroenterology, Nagano, Japan

**Contact E-Mail Address:** oyama@coral.ocn.ne.jp

**Introduction:** ESD for pharyngeal SCC (PSCC) is difficult, because of narrow space and poor maneuverability. Especially, ESD for PSCC located in the anterior side of epiglottis is extremely difficult. Because, the intubated tube elevates the epiglottis, and working space of anterior side of epiglottis will become narrow.

**Aims & Methods:** The aim of this study is to clarify the usefulness of ESD for pharyngeal SCC, especially located in the anterior side of epiglottis. 119 pharyngeal SCC in 91 patients treated by ESD from Apr. 2006 to Mar. 2019 in Saku Central Hospital Advanced Care Center were enrolled to this retrospective study.

Male/Female was 90/1. Mean age was 68.5 (40-92). Mean size of tumor and specimen were 20.0 (1 - 51) and 29.1 (8 - 90) mm, respectively.

Location: pyriform sinus, middle pharynx epiglottis, and were 55, 58 and 6.

All ESD was performed by a hook knife under intubated general anesthesia.

ESD for the SCC located in anterior side of epiglottis: An intubated tube elevated epiglottis, and the approach to anterior side of epiglottis becomes impossible. Therefore, a temporary tracheotomy was performed before ESD. Clip with line was used to get enough traction. Autocut mode was used for dissection to prevent burning effect to the cartilage of epiglottis. Surveillance: 1 - 2 endoscopy, CT scan and neck US were performed as surveillance after ESD.

**Results:**

1. En bloc resection rate was 100%. R0 resection (En bloc + lateral margin negative) rate was 96.6% (115/119)

2. Complication: Delayed bleeding rate was 1.1% (1/91). Re-intubation was needed for the hemostasis. Dysphasia was shown in 3.3% (3/91). Two patients had mild dysphagia and improved in two weeks. The remaining one patient had severe dysphagia. The patient had a big SCC, 50mm in size, and the SCC extend from light piriform sinus to ary-epiglottic fold.

3. Invasion depth: Epithelial (EP) and subepithelial (SEP) SCC were 57% (68/119) and 43% (51/119), respectively.

4. The rate of lymph-duct involvement of EP and SEP were 0% and 5.7% (5/119), respectively.

5. The rate of venous involvement of EP and SEP were 0% and 2.9% (1/35), respectively. The only patient who had venous involvement was 92 years old, and followed up without an additional therapy.

6. Local recurrent rate was 0 %.

7. LNM rate of EP and SEP was 0% and 4.7% (2/43 cases), respectively. A cervical LNM was diagnosed 6 months after ESD. Lymph node dissection and CRT was performed for the patient. The patient died of other disease without recurrence of pharyngeal SCC. The other patient also had a cervical LNM and treated by LND + CRT. The patient is alive without recurrence for 10 years.

8. Prognosis and distant metastasis  
One patient died of lung metastasis. The patient had SEP SCC with lymph duct involvement.

9. ESD for SCC in anterior side of epiglottis  
A temporary tracheotomy was performed before ESD. Clip with line was used to get enough traction for all cases. All of six cases were completed successfully without any complications.

**Conclusion:** ESD is a safe and useful treatment for superficial pharyngeal SCC, even if SCC located in anterior side of epiglottis. We have to observe carefully to detect such superficial pharyngeal SCC when we insert endoscope.

**Introduction:** Achalasia of the esophagus is a benign disease caused by dyskinesia of an esophageal motor disorder characterized by insufficient relaxation of the lower esophageal sphincter and the absence of progressive peristalsis. Achalasia is presumed to be a premalignant lesion and esophageal carcinoma is the most serious late complication clinically. Chronic inflammation by retained food may induce carcinogenesis of the esophageal squamous epithelium. Carcinoma may develop progressively from hyperplastic and dysplastic changes of esophageal achalasia. However, the detailed mechanism of carcinogenesis in achalasia patients has not been clarified yet.

**Aims & Methods:** We analyzed 21 cases of achalasia-associated carcinoma of the esophagus clinically, and examined pathological and morphological characteristics of carcinogenesis in achalasia, surgically or endoscopically resected, using endoscopic, histological and immunohistochemical procedures. The invasive parts of each carcinoma, in situ carcinoma, dysplasia as well as hyperplasia were examined for histological mapping, and with immunohistochemical expression for p53 protein.

**Results:** The patients ranged in age from 43 to 76 years, with a mean age of 60 years. The mean interval between the diagnosis of achalasia and carcinoma was 21.7 years. Nine of the 21 cases were superficial cancers, and the other 12 cases were advanced cancers invading the adventitia. Radiographically, 10 of the 21 cases were sigmoid type, the other 11 cases were straight (flask) type. Six cases were grade III, the other 15 cases were grade II, and none was grade I. Surgical treatment for achalasia was 12 cases, balloon dilatable bouginage was 6 cases, and 3 cases were no treatment. Endoscopically, 8 cases of carcinomas were protruding type, and the

others were superficial depressed type and ulcerative type. Twelve cases were composed of squamous cell carcinoma and the other one was basaloid-squamous carcinoma. Histological mapping of the resected specimens demonstrated marked hyperplastic changes of stratified squamous epithelium and multiple foci of dysplastic changes. The squamous cell carcinomas showed well to moderately differentiated type with low-grade atypia, closely associated with dysplastic foci. Immunohistochemical over-expression of p53 was detected in the invasive parts of the carcinoma, in situ carcinoma, and dysplasia, and was not detected in the hyperplastic epithelium.

**Conclusion:** Chronic inflammatory irritation by retained food in achalasia may induce chronic hyperplastic esophagitis and eventually malignant transformation of esophageal epithelial cells, associated with dysplasia-carcinoma sequence. Achalasia seems to be a risk factor for developing squamous cell carcinoma of the esophagus, even if after surgically treated. Careful long-term follow-up to detect and treat early stage cancer for patients with achalasia by endoscopic screening is recommended.

**Introduction:** Esophagectomy is a standard treatment for patients with 'high-risk' early esophageal cancer (EEC) despite a growing evidence that endoscopic treatment could be a safe alternative even for these patients.

**Aims & Methods:** The aims were 1. to prospectively assess results of endoscopic vs. surgical treatment in consecutive patients with 'high-risk' EEC and 2. to determine lymph node (LN) metastases and micrometastases (including risk factors) in those who underwent surgery. Firstly, patients with EEC underwent endoscopic resection (ER) or submucosal dissection (ESD). Those patients with 'high-risk' EEC without contraindications were referred to surgery, the remaining patients continued in endoscopic treatment, if necessary. 'High-risk' cancer was defined as any cancer with sm invasion or mucosal cancer with at least one of the following: poor differentiation (G3/G4), invasion to blood (A+) or lymphatic vessels (L+) and high tumor cell dissociation (TCD3). The patients have been followed up for a median of 32.5 months (range 1-171). LNs were processed as a sentinel LN, thus it was completely cut into 2-3 mm thick slices and embedded into paraffin blocks. Serial levels were stained for hematoxylin-eosin to evaluate metastases and for immunohistochemistry to evaluate micrometastases and isolated tumor cells.

**Results:** A total of 67 patients was included, 18 (26.9%) had T1a cancer with 'high-risk' features and 49 (73.1%) had T1b cancer with sm invasion; 48 had adenocarcinoma (EAC), 18 had squamous carcinoma (SCC) and 1 had mixed adenoneuroendocrine carcinoma (MANEC); 27 patients (40.3%) were referred to surgery and 40 (59.7%) continued in endoscopic treatment.

**Endoscopy:** Complete local remission (CLR) was achieved in 35/40 patients (87.5%). Four patients without CLR continued endoscopic therapy with a palliative intent and one patient died due to other comorbidity. Tumor generalization occurred in 2 patients (1 EAC and 1 SCC, both with sm3 invasion, G3, TCD3, A+ and L+) and local relapse occurred in 1 patient (EAC, sm1, G3, TCD3). All of the remaining patients with CLR (n=32; 21 EAC, 10 SCC, 1 MANEC) have not experienced either local relapse or generalization. Tumor-free survival was 28.5 months (range 1-131).

**Surgery:** Among 27 patients who were referred for esophagectomy, one patient had generalization revealed during the operation. The remaining 26 patients underwent esophagectomy; local residua of malignancy were present in 5/26 patients (19.2%, expected residua as these patients did not achieved CLR). A total of 532 LNs were evaluated, LN metastases were

detected in 1 (16 LNs) (EAC: G3-4, sm3, TCD3, A+, L+) and micrometastases in another 2 patients (EAC: sm3, G3, TCD 2, A+, L+; SCC: sm2, G2, TCD1, A+). Surgery related mortality was 3,9% (1/26, the cause of death was anastomotic dehiscence).

**Conclusion:** Endoscopic treatment provided long-term remission (or cure) in considerable number of patients with high risk EAC and it may represent a valid alternative to surgery. The risk of LNs metastases/micrometastases was low. The risk of metastatic progression increased with rising amount of risk features (Prob > |t| 0.0366). None of the patients with sm1 invasion or well-differentiated tumor (G1) have experienced generalization, thus advanced sm invasion (sm2, sm3) and poor differentiation may be crucial factors.

**Introduction:** Endoscopic ultrasound (EUS) and EUS-guided fine-needle aspiration (FNA) are potential tools for detection of residual disease after neoadjuvant chemoradiotherapy (nCRT) in patients with esophageal cancer. This is the first prospective study that investigated the yield of EUS and FNA for detection of malignant lymph nodes (LNs) 10-12 weeks after nCRT.

**Aims & Methods:** EUS was performed 10-12 weeks after nCRT. <sup>18</sup>F-FDG PET-CT was used to guide targeting of suspicious LNs. If suspicious LN were identified with radial EUS, a linear EUS was performed with concurrent FNA-sampling. Endoscopic nodal staging was compared to histopathological examination of the resection specimen (ypN). Primary outcome was the proportion of correctly identified patients with malignant LNs (ypN+).

**Results:** 101 consecutive patients were included. Seventy-nine patients had ypN- residual disease, of whom 62 were classified correctly by EUS (specificity 78%). Twenty-two patients had ypN+ residual disease of whom 11 were identified by EUS (sensitivity 50%). Six of these patients had ≥1 LN not fulfilling the EUS-criteria for malignant LNs (round, hypo-echogenic, >5mm). Malignant LNs in falsely negative patients were predominantly located at the distal LN stations. Specificity and sensitivity of FNA were 100% (10/10) and 75% (3/4), respectively.

	ypN-	ypN+	Total
yuN-	62	11	73
yuN+	17	11	28
Total	79	22	101

[Positive and negative findings by EUS (yuN) and histopathological examination of the resection specimen (ypN).]

**Conclusion:** EUS detected 50% of ypN+ patients 10-12 weeks after nCRT. Remarkably, in 55% (6/11) of these patients ≥1 suspect LNs did not meet EUS-criteria for malignant LNs. To optimize sensitivity and minimize the risk of missing residual disease after nCRT, FNA of local LNs should be performed even in cases of low suspicion.

**Introduction:** Endoscopic submucosal dissection (ESD) is a well-established treatment for early-stage malignant lesions of the stomach, esophagus, and colorectum with no risk of lymphatic metastasis. ESD requires precise and complicated maneuvers. But the esophageal wall is thinner than the stomach and moves with respiration and heartbeat, swallowing, peristalsis in a narrow space. It causes difficult maneuverability of devices.

Therefore, intraoperative management of the patient's general condition is very important during esophageal ESD. In Japan, ESD is usually performed under conscious sedation in the endoscopy room.

However, it is difficult to control patient movement completely because of insufficient effect of sedation, and it has a risk of aspiration pneumonia. Any patient movement during the procedure can result in complications such as perforation and hemorrhage. Therefore, we perform ESD under general anesthesia with mechanical ventilation.

**Aims & Methods:** The aim of this presentation is to evaluate the effect and safety of Esophageal ESD under general anesthesia.

In the past 10 years from January 2008 to December 2017, 371 lesions (277 patients) had undergone ESD under general anesthesia for diseases of the esophagus. We retrospectively investigated the efficacy and safety of esophageal ESD under general anesthesia.

**Results:** The male: female ratio was 244:33 (88.1%:11.9%) and the patients' average age was 68.1 ± 8.5 years (42-89 years). The diameter of the resected specimen was 43.0 ± 18.3 mm (8-115 mm) and average circumference rate of resected specimen was three-fifth (one-fifth to whole circumference). The *en bloc* resection rate was 89.0%. The average operating time was 113.8 ± 62.3 min (25-340 min), and the average anesthesia time was 146.4 ± 67.6 min (50-370 min). The location of the lesion was cervical in 20 lesions, upper esophagus in 53 lesions, middle esophagus in 169 lesions, lower esophagus in 97 lesions, esophagogastric junction in 32 lesions. The pathological findings was squamous cell carcinoma in 280 lesions and adenocarcinoma in 20 lesions, neoplasia in 56 lesions, others in 11 lesions. The invasion depth of carcinoma was M in 266 lesions, SM in 34 lesions. Average postoperative hospital stay was 7.7 days (2-64). Average years of experience as a doctor was 13 years (6-21). About one-third of the patients were performed ESD by a non-expert doctor (6-8 years of experience as a doctor). With regard to complications, intraoperative perforation occurred in 3 (1.1%) patients, delayed perforation occurred in 1 (0.4%), delayed bleeding occurred in 4 (1.4%). These complications were occurred in patient performed ESD by expert doctor (over 11 years of experience as a doctor), because of difficulty factor to perform ESD (location, size, severe comorbidities, etc).

**Conclusion:** For ordered management of accidental events during esophageal ESD, general anesthesia might be a crucial option for a better clinical outcome even when administered by non-experienced operators.

**Disclosure:** Nothing to disclose

## P2002 A NOVEL MAGNIFIED ENDOSCOPIC FINDING FOR THE DIFFERENTIAL DIAGNOSIS BETWEEN INFLAMMATION AND SUPERFICIAL ESOPHAGEAL SQUAMOUS CELL CARCINOMA

Takahashi A., Oyama T.

Saku Central Hospital Advanced Care Center, Endoscopy, Nagano, Japan

**Contact E-Mail Address:** aurevoireurope@yahoo.co.jp

**Introduction:** Magnified endoscopic findings were subclassified into type B1, B2 and B3 in Japanese esophageal society (JES) classification to diagnose invasion depth of esophageal superficial squamous cell carcinoma (ESCC). Type B2 is defined as irregular vessels without a loop-like formation, and it diagnoses as T1aMM/T1bSM1 SCC.

Sometimes T1aESCC has erosion / inflammation, and NBI magnified endoscopy revealed non loop irregular vessels. If it is judged as JES type B2,

the lesion was overdiagnosed as T1aMM/T1bSM1. Therefore, we have to investigate the differential diagnosis between SCC and erosion, when non loop irregular vessels were observed.

**Aims & Methods:** The aim of this study is to investigate the characteristics of type B2 vessels.

Four hundred ninety-nine ESCC in 298 patients were treated by ESD from January 2011 to May 2018. Precise comparison between magnified endoscopic findings and histology is necessary to measure the target vessels correctly. We selected consecutive 53 ESCC in 51 patients which had type B2, and precious comparison was possible.

The distance between top of IPCL and surface, the density and minor axis of type B2 using CD34 staining were investigated.

Based on endoscopic findings, we subclassified B2 into B2 pure and B2 inflammation (B2 i.) B2 pure was defined as non-loop irregular vessels. B2 i was defined as thin vessels with high density.

B2 pure was 44 lesions, and B2 i was 9 lesions. Macroscopic type; 0-IIa, 0-IIb, 0-IIc and 0-III were 10, 2, 31, 1 and 0, 0, 9, 0 respectively. Location; Ce, Ut, Mt, Lt and Ae were 6, 4, 26, 6, 2 and 0, 0, 7, 2, 0, respectively. Mean tumor size was 37mm and 39mm, respectively. There was no significant difference in background between B2 pure and B2 i.

#### Results:

1. Histological findings of B2 area: All of the pathological diagnosis in 44 lesions which showed B2 pure were SCC. Pathological diagnosis of 9 lesions which showed B2 i were SCC in 2, and erosion or inflammation in 7 lesions.

2. How deep can we observe by NBI magnified endoscopy? The distance between top of IPCL and surface was measured in 66 points of non-neoplastic squamous epithelium randomly. The mean distance was 88 (31-174)  $\mu$ m. Therefore, we concluded that we can observe at least 100  $\mu$ m under the surface.

3. Microvessels which exist 100  $\mu$ m under the surface in B2 i (n=6) and B2 pure (n=16) were investigated.

a. Density was calculated using CD34 staining. The mean density was 3.35/mm in B2 pure and 8.22 /mm in B2 i, respectively (p=0.001).

b. Minor axis of vessels was measured using CD34 staining. The mean minor axis of vessels was 12.3  $\mu$ m and 6.65  $\mu$ m, respectively. (p=0.0028). B2 i has thin vessels with high density, and B2 pure has thick vessels with low density.

**Conclusion:** B2i is an important parameter to show erosion in superficial ESCC. B2 should be subclassified into B2 pure and B2 i to prevent over-diagnosis.

**Disclosure:** Nothing to disclose

## P2003 TUMOR SIZE INCREASES THE RISK FOR LYMPH NODE METASTASES IN T1B ESOPHAGEAL ADENOCARCINOMA

Sadaps M.<sup>1</sup>, Mehta N.<sup>2</sup>, Jang S.<sup>2</sup>, Vargo J.<sup>2</sup>, McNamara M.<sup>1</sup>, Sohal D.<sup>1</sup>, Raja S.<sup>3</sup>, Khorana A.<sup>1</sup>, Bhatt A.<sup>2</sup>, Murthy S.<sup>3</sup>

**Contact E-Mail Address:** sadapsm@ccf.org

**Introduction:** The decision to give adjuvant therapy after endoscopic resection of T1b esophageal adenocarcinoma (EAC) who are not surgical candidates is largely based on a lesion's risk of lymph node metastasis (LNM). However, risk factors for LNM in esophageal T1b EAC are still not clearly defined.

**Aims & Methods:** The aim of this study is to evaluate risk factors for LNM in T1b EAC patients who underwent esophagectomy or endoscopic resection with  $\geq$  5 years of follow-up post-procedurally. This was a single center, retrospective analysis carried out at a large tertiary referral center. Our pathology database assisted in identifying patients who underwent esophagectomy or ER with  $\geq$  5 years follow-up, with histologically proven T1b EAC between 2010 and 2017.

Patients were excluded from the study if they (a) received chemoradiation prior to esophagectomy (b) received chemoradiation before or after ER (c) had any other primary cancer treated within the preceding 5 years. LNM was considered positive if there was histologically or radiologically confirmed metastasis (a) in esophagectomy specimens or (b) within 5 years of follow up post ER. All pathologic specimens were reviewed by an expert gastrointestinal pathologist for T1b accuracy and depth of submucosal invasion.

**Results:** A total of 40 patients [median age 69y (IQR 61.5-76); 87% males] formed the study cohort of which 36 patients (90%) underwent esophagectomy and 4 patients who were not surgical candidates (10%) underwent endoscopic resection. Of the total, seven (17.5%) patients developed LNM per study criteria (Table 1). Tumor size was significantly (p-value 0.019) associated with the risk of LNM. Applying a non-parametric ROC curve, 3 cm is the optimal threshold at which the size of the tumor is positively associated with metastasis. No other risk factors including lymphovascular invasion, differentiation on pathology, macroscopic appearance, infiltration growth pattern, or tumor distance from the gastroesophageal junction were significant risk factors for LNM.

**Conclusion:** In T1b esophageal adenocarcinoma, tumor size greater than 3 cm appears to be the variable with the most potential as a risk factor for metastasis at five years following surgical or endoscopic resection. Adjuvant therapy should be considered in patients with tumor size greater than 3 cm.

**Disclosure:** Nothing to disclose

## P2004 MICA HAS A PROTECTIVE EFFECT TO NON-STEROIDAL ANTI-INFLAMMATORY DRUGS ENTEROPATHY VIA REGULATING LONG NON-CODING RNA-NCRPUR AND PAR2

Wang Y., Ye F., Zhang S.

The First Affiliated Hospital, Zhejiang Chinese Medical University, Hangzhou, China

**Contact E-Mail Address:** zhangshuotcm@126.com

**Introduction:** NSAIDs (non-steroid anti-inflammatory drugs) have a wide range of clinical applications. Studies have shown that the incidence of small intestine injury in patients with long-term NSAIDs is about 70%. Currently, the prevention and treatment methods are limited, thus it is of great significance to elucidate its pathogenesis for the safe clinical application of NSAIDs.

**Aims & Methods:** Caco-2 cells were cultured and divided into the following six groups:

Group A: blank control group;

Group B: diclofenac sodium treatment group;

Group C: Control RNAa group;

Group D: ncRuPAR over expression group;

Group E: diclofenac sodium+mica containing serum group; and

Group F: diclofenac sodium treatment+PAR-2 (proteinase-activated receptor-2) blocker FSLRY-NH<sub>2</sub> group.

Transwell detected the intestinal epithelial cell permeability, western-blot detected the expression of PAR-2, Occludin and Claudin-1, and qRT-PCR detected the expression of ncRuPAR and PAR-2 mRNA.

**Results:** After diclofenac sodium treatment, intestinal epithelial cell permeability increased (143.02 $\pm$ 1.70 vs 100 $\pm$ 4.43, P< 0.05), the expression of Occludin (0.29 $\pm$ 0.02 vs 0.45 $\pm$ 0.01, P< 0.05) and Claudin-1 (0.20 $\pm$ 0.01 vs 0.31 $\pm$ 0.01, P< 0.05) decreased. The expression of ncRuPAR mRNA (7.01 $\pm$ 1.17 vs 1.17 $\pm$ 0.81, P< 0.05) and PAR-2 mRNA (5.52 $\pm$ 0.92 vs 1.03 $\pm$ 0.29, P< 0.05) also increased. Mica medicated serum and PAR-2 blocker FSLRY-NH<sub>2</sub> inhibited the increase of intestinal epithelial cell permeability induced by diclofenac sodium (108.18 $\pm$ 1.96 ; 111.29 $\pm$ 4.23, P< 0.05), as well as its effect on the expression of ncRuPAR mRNA (3.40 $\pm$ 1.89; 4.18 $\pm$ 0.35, P< 0.05), PAR-2 mRNA (2.73 $\pm$ 0.39; 3.60 $\pm$ 0.69, P< 0.05), Occludin (0.38 $\pm$ 0.02; 0.35 $\pm$ 0.01, P< 0.05) and Claudin-1 (0.25 $\pm$ 0.01; 0.24 $\pm$ 0.02, P< 0.05). After ncRuPAR over expression, intestinal epithelial cell permeability increased (147.93 $\pm$ 1.96, P< 0.05), the expression of PAR-2 mRNA (24.71 $\pm$ 4.17, P< 0.05) and ncRuPAR mRNA (4686.48 $\pm$ 1191.9, P< 0.05) increased, while the expression of occludin (0.35 $\pm$ 0.02, P< 0.05) and claudin-1 (0.18 $\pm$ 0.01, P< 0.05) decreased.

**Conclusion:** Small intestinal epithelial cell permeability increased and mucosal mechanical barrier function is impaired in NSAIDs enteropathy. ncRuPAR affect the mechanical barrier function of intestinal mucosa by regulating the expression of PAR-2, and mica may play a preventive role by affecting the expression of ncRuPAR.

**Disclosure:** Nothing to disclose

## P2005 IMPLEMENTATION OF PROTON PUMP INHIBITOR DEPRESCRIPTION PROTOCOL AT HOSPITAL DISCHARGE: THE DE-PIB PROJECT

<sup>2</sup>Instituto de Investigación Sanitaria (IIS) Aragón, Zaragoza, Spain, <sup>3</sup>Unidad de Investigación Traslacional. Hospital Universitario Miguel Servet, Instituto Aragonés de Ciencias de la Salud (IACS), CIBEROBN, Instituto de Salud Carlos III, Madrid, Spain

**Contact E-Mail Address:** paulagarciamacara@gmail.com

**Introduction:** Proton pump inhibitors (PPIs) are among the most prescribed drugs. Despite a safe profile, their prolonged use has been associated with some complications such as enteric infections and fractures. It is hence recommended to adjust their prescription according to the existing guidelines of scientific societies.

**Aims & Methods: Objectives:** To evaluate the applicability of a deprescription algorithm in hospitalized patients with chronic consumption of PPIs, and to determine the number of patients who maintain deprescription after 4, 12 and 24 weeks, as well as the factors associated with the lack of compliance with the deprescription algorithm.

**Methodology:** prospective study with consecutive inclusion of patients who were under PPI treatment for at least 8 weeks and had been admitted to the Gastroenterology Department (GED) of the University Hospital Miguel Servet (Zaragoza, Spain). PPI prescription was classified as adequate or inadequate according to the criteria of the Spanish Association of Gastroenterology. Those with inadequate prescription who agreed to participate in the study completed the Spanish version of the Gastrointestinal Short Form Questionnaire (GSF-Q). Exclusion criteria were: GSF  $\geq 13$ , occasional use of PPI ( $\leq 2$  times / week), severe comorbidity (ASA IV or higher), advanced cognitive impairment, pregnancy, and hospital stay less than 24 hours. Patients without exclusion criteria were included in the deprescription protocol based on the recommendations of the Canadian Primary Care Society, with follow-up at 4, 12 and 24 weeks to assess the reappearance of symptoms, necessity to reintroduce PPIs and why. The protocol was approved by the Ethics Committee.

**Results:** Between September 2018 and April 2019, 1173 patients were admitted more than 24 hours to the GED, of whom 513 (43.73%) consumed PPIs chronically. 142 met some other exclusion criteria. 371 patients were included, 54% males, with mean age 74.4 (SD 12.5) years. The prescription was considered adequate in 284 patients (76.55%), being over 60 year old individuals taking antiaggregant drugs the most frequent group (76.05%). The prescription was inadequate in 87 patients (23.45%), the majority because of polypharmacy (52%). 12 patients refused to participate in the deprescription protocol. 35 patients stopped PPI treatment immediately while 26 gradually reduced the treatment, 7 switch to on-demand treatment and 7 decreased dosed indefinitely. Sex was not a risk factor for inadequate prescription ( $p = 0.251$ ), while age  $> 75$  years was indeed associated with inadequate prescription ( $p = 0.025$ ). Follow-up information, which was available at 4 weeks for 64 patients, showed that 53 individuals (82.81%) complied with the deprescription protocol while 11 subjects had reintroduced PPIs again at the previous dose (7 without justified cause). At 12 weeks, 32 out of 45 patients (71.1%) with follow-up information complied with the deprescription protocol. No patient presented serious adverse effects attributable to deprescription.

**Conclusion:** Inadequate indication of PPI is very common in patients admitted to a Gastroenterology ward. The application of algorithm of deprescription is a safe and effective strategy to reduce the inadequate consumption of PPIs in the medium term.

**Disclosure:** Nothing to disclose

## P2006 PROTON PUMP INHIBITORS: IMPLEMENTATION OF A DE-PRESCRIBING STRATEGY

**Contact E-Mail Address:** campilloarregui@gmail.com

**Introduction:** Proton pump inhibitors (PPI) are the most consumed drugs in Spain. Prescribing a PPI without indication contributes to polypharmacy and drug interactions.

**Aims & Methods:** Our objective was to develop a strategy in order to optimize the use of PPI in a northern region of Spain (616,758 inhabitants). Methods: A so-called "PPI optimization strategy" was implemented including the following activities:

- 1) A multidisciplinary group (gastroenterologists, general practitioners (GPs) and primary care pharmacists (PCP)) was established to design the strategy;
- 2) Evidence on PPIs and gastroprotection was assessed;
- 3) Criteria for selection of candidates for intervention was agreed (patients with PPI prescribed for more than 12 months without authorized indication);
- 4) Pharmacists presented the program and gave a training session to GPs and nurses.
- 5) Patient-oriented support materials were provided to doctors (explanatory leaflets for candidates and general public too);
- 6) Candidates for intervention were retrieved through an in-house developed software called Observa (Observatory of medication safety), that interacts with all clinical records in our province;
- 7) A message was sent through this tool to GPs whose patients met the inclusion criteria asking to withdraw the drug in November'17 for patients  $> 65$  years. In June'18 a message was sent for patients  $< 65$  years meeting the inclusion criteria and a second message to those patients  $> 65$  years for whom there had not been an answer after the first invitation;
- 8) A mass media campaign supporting the strategy was launched that included press release for local newspapers.
- 9) PPIs withdrawal was monitored and evaluated.

**Results:** A total of 15,794 patients were candidates for the intervention; 9,325  $> 65$  years and 6,469 patients  $< 65$  years. A 53% (n: 8,293) of deprescription invitations were answered; 40% were accepted, 11% rejected and 2% non-valid.

Among patients  $> 65$  years, who were invited twice to withdraw PPIs, 62% of deprescription invitations were answered (n: 5,735) and 47% of all the proposals were accepted, 76% of those answered. (n: 4,631). In patients younger than 65 years, who got a single invitation, there were a 40% of answers (n:2,558) and a 30% of proposals were accepted (n:1,912), 74% of those that had been answered.

The strategy was started in the end of 2017. During 2018 the amount of defined daily dose (DDD) for PPIs in our region descended a 13% compared to 2017.

**Conclusion:** There is a high use of PPI in general population, quite often without meeting any medical criteria for it. The use of web tools such as Observa can contribute to the optimization of pharmacotherapy and avoids PPI overuse. A 75% of the evaluated proposals of de-prescribing were accepted, which has had an impact on the consume of PPIs in our region.

## P2007 CLINICOPATHOLOGICAL AND IMMUNOHISTOCHEMICAL STUDY OF THE MECHANISM OF SPORADIC FUNDIC GLAND POLYP PROLIFERATION AND ENLARGEMENT IN LONG-TERM PPI-USERS

Matsumura M., Tsuji N., Yoshida S., Tomooka M., Umehara Y., Kudo M.  
Kindai University Faculty of Medicine Gastroenterology and Hepatology,

**Contact E-Mail Address:** mariko.tarte@gmail.com

**Introduction:** An association between sporadic fundic gland polyps (SFGP) and long-term PPI use has previously been suggested, and SFGP with dysplasia-carcinoma in rare cases has recently been reported.

**Aims & Methods:** To investigate the relationship between SFGP and PPI, we enrolled 86 SFGP patients (32 PPI-users of more than 6 months and 54 non-users) and compared clinical and endoscopic characteristics and histological findings including parietal cell protrusion (PCP), number and size of microcysts, parietal cell nuclear density, and MIB1 and  $\beta$ -catenin immunohistochemistry of biopsy specimens.

**Results:** All patients were *H. pylori*-negative, with no or slight gastric atrophy. The proportion of patients with cobble stone-like appearance in background mucosa and with more than 20 polyps were significantly higher among PPI-users (66% of users vs. 6% of non-users and 63% of users vs. 19% of non-users, respectively). The maximum diameter of the polyps was significantly larger in PPI-users than non-users (5.3 mm vs. 3.6 mm, respectively). Histologically, the number of microcysts and ratio of patients with PCP was significantly greater in PPI-users than non-users (8.4 vs. 4.9 and 53% vs. 13%, respectively). There was no difference in the maximum diameter of microcysts, parietal cell nuclear density, or MIB1-index between the two groups. At no point was nuclear accumulation of  $\beta$ -catenin observed.

**Conclusion:** Our results suggest that an increased number of microcysts drives the enlargement and proliferation of SFGP in long-term PPI-users. The proliferative activity of the neck zone and  $\beta$ -catenin immunohistochemistry did not differ between users and non-users. There was no parietal cell hyperplasia; however, parietal cell hypertrophy was found in PPI-associated SFGP.

**Introduction:** Endoscopic submucosal dissection (ESD) can be curative in early gastric cancer (EGC), particularly in lesions with favourable histology. (1) ESD provides an *en bloc* specimen, enabling accurate staging, and has significantly lower morbidity and mortality compared to gastrectomy. (2) It is the recommended treatment for EGC in multiple international guidelines and is widely performed in Asia where gastric cancer has high prevalence. (3-5) ESD is not commonly performed in Western countries. (6) One proposed reason is that a lower proportion of gastric cancer present at early stage than in high prevalence regions. To assess the potential need for ESD, the incidence of EGC must be established.

**Aims & Methods:** This study aims to evaluate the proportion of gastric cancer that met histological criteria for EGC, and proportion of EGC that were suitable for and treated by endoscopic resection in a Western population.

This is a retrospective analysis of all gastric cancers reported to Victorian Cancer Registry, a mandatory reporting process of new cancer diagnoses in the state of Victoria (26% of the population). (6) All EGCs (T1a and T1b lesions) diagnosed between January 2011 to December 2016 were identified from histological reports. Demographic, tumour characteristics and treatment data were collected. Japanese and European ESD guidelines (3,5) were applied to assess the number of potential ESD candidates.

**Results:** 1779 gastric cancers were reported. 237 (13.3%) were EGCs, with mean annual incidence of 47 cases. 33 endoscopic and 149 surgical resection specimens were available. On application of ESD resection criteria, 132 (72.5%) met extended and 84 (46.2%) met standard criteria. Of these, 26 (19.7%) were treated endoscopically and 106 (80.3%) by surgery. Tumour location, depth and involvement of pathologic margins was significantly

different between treatment strategies (Table 1). Endoscopic resections were performed using snare-based technique and ESD in 93.4% and 6.6%, respectively.

		Surgical, n = 149	Endoscopic, n = 33	P value
Age at diagnosis (median, range)		68.7 (25.5 - 92.9)	70.9 (50.9 - 87.8)	0.168
Male (n, %)		105 (70.5)	23 (69.7)	0.690
Location of tumour (n, %)	Antrum/Incisura	60 (40.3)	3 (9.09)	<0.005
	Lesser curvature	6 (4.0)	4 (12.1)	<0.005
	Greater curvature	27 (18.1)	2 (6.06)	NS
	Fundus	5 (3.4)	1 (3.03)	NS
	GOJ/cardia	42 (28.2)	16 (48.5)	<0.005
Depth of tumour (n, %)	Tis	3 (2.0)	4 (12.1)	NS
	T1a	55 (36.9)	20 (60.6)	NS
	T1b	91 (61.1)	9 (27.3)	<0.005
Differentiation (n, %)	Well/Moderate	64 (43.0)	15 (45.4)	0.205
	Poor	37 (24.8)	3 (9.09)	0.145
	Not reported	48 (32.2)	15 (45.5)	0.305
Diameter (mm, median, range)		21.2 (0.2 - 65)	17.6 (6 - 90)	0.179
Lymphovascular invasion (n, %)		24/146 (16.4)*	4/31 (12.9)*	0.346
Perineural invasion (n, %)		4/134 (3.0)*	0/24 (0)*	0.015
Pathologic margins clear (n, %)		143 (96)	23/30 (76.7)*	<0.005

\*not reported in all cases. NS; not significant

[Table 1. Comparison of early gastric cancers treated with surgical versus endoscopic resection]

**Conclusion:** In this State Cancer Registry study, 237 EGCs were diagnosed over a 5-year period, representing 13.3% of gastric cancers. Within limitations of retrospective analysis, most EGCs fulfilled criteria for ESD. Advanced resection techniques should be considered part of the management algorithm for EGC, ideally after discussion at a multidisciplinary meeting involving an Interventional Endoscopist. To increase the utilisation of ESD, patients should be referred to centres with expertise in lesion assessment and advanced endoscopic resection, and systems implemented to improve training, accreditation and access to ESD.

Contact E-Mail Address: spaceplag@gmail.com

**Introduction:** Endoscopic surveillance after total gastrectomy for gastric cancer is routinely performed for detecting tumor recurrence or adverse effects of surgery.<sup>1</sup> But, there were only a few reports for clinical benefits of endoscopic surveillance.<sup>2-5</sup>

**Aims & Methods:** We investigated the necessity for endoscopic surveillance after total gastrectomy for gastric cancer. We reviewed the medical records of 385 patients who underwent total gastrectomy for gastric cancer between January 2011 and December 2011 in single tertiary hospital. Finally, we enrolled 143 early gastric cancer (EGC) patients and 175 advanced gastric cancer (AGC) patients who received surveillance programs after total gastrectomy including endoscopy and abdominopelvic computed tomography with contrast (APCT).

**Results:** Median follow-up period of APCT was 58.4 months and endoscopy was 55.5 months. We performed an R0 resection in 313 of 318 patients. Tumor recurrence was confirmed in 59 patients (19%), all of which were confirmed by APCT. Of 59 patients, four patients were EGC and 55 patients were AGC patients. The sites of recurrences were as follows: peritoneum in twenty-five, distant metastasis in twenty-one, loco-regional recurrence in six, and mixed recurrence in seven. Endoscopically confirmed recurrences were in five patients. Only one patient was confirmed recurrence by endoscopy earlier than APCT. This patient was performed R1 resection with the involvement of proximal margin. The postoperative benign stricture was confirmed by endoscopy in 2 patients (1%) without symptom and endoscopically passage disturbance. Other postoperative adverse effects including surgical stump or anastomosis site leakage, jejunal intussusception, and mechanical ileus were confirmed by APCT in 7 patients (2%).

**Conclusion:** Endoscopic surveillance after total gastrectomy with R0 resection for gastric cancer is a limited role for detecting tumor recurrence or adverse effects of surgery. Abdominopelvic computed tomography with contrast is maybe sufficient for surveillance modality after total gastrectomy with R0 resection for gastric cancer.

**Introduction:** It is well known that eradication of *Helicobacter pylori* (*H. pylori*) reduces the risk of gastric cancer (GC) development. In contrast, *H. pylori* eradication does not prevent gastric cancer development in all

individuals. There would be some risk factors in the background gastric mucosa after eradication of *H. pylori*. However, it is still unclear that histological features of the background gastric mucosa would be a predictable marker for the development of GC after eradication of *H. pylori*. Thus, we investigated risk factors of early GC development after eradication of *H. pylori* based on the histological characteristics of gastric mucosa.

**Aims & Methods:** 61 patients who underwent endoscopic submucosal dissection of GC after successful *H. pylori* eradication (defined as group A), and 122 patients without developing gastric neoplasm over 3 years after successful *H. pylori* eradication for control group, (defined as group B) were analyzed. Moreover, we used propensity score-matching analysis to adjust significant differences in the baseline clinical characteristics of patients. Before and after propensity score-matching, we compared the score in the histological evaluation of these enrolled patients between group A and group B. Three biopsy specimens were obtained from the greater curvature of the antrum, the lesser curvature of the corpus, and the greater curvature of the corpus.

Gastric mucosa samples were evaluated according to the updated Sydney system.

**Results:** Comparison of clinical characteristics between two groups revealed that males, elderly patients were significantly higher, and years after successful eradication were longer, although not significantly, in group A.

Updated Sydney system scores of group A were significantly higher than group B at all site except for intestinal metaplasia (IM) in the greater curvature of the corpus. However, there may be some bias, because of the difference depending on gender, age, and years after successful eradication. Therefore, we matched to reduce the influence of confounding these factors. After propensity score-matching, 54 patients with gastric cancer and 54 patients without gastric cancer were included in each group. Inflammation (mononuclear cells infiltration) in background gastric mucosa of Group A were significantly higher than the scores for the matched group B with the greater curvature of the antrum ( $0.78 \pm 0.57$  vs  $0.28 \pm 0.45$ ,  $p < 0.01$ ), the lesser curvature of the corpus ( $0.89 \pm 0.42$  vs  $0.64 \pm 0.59$ ,  $p < 0.01$ ) and greater curvature of the corpus ( $0.59 \pm 0.60$  vs  $0.35 \pm 0.48$ ,  $p = 0.03$ ). Other significant differences were observed in atrophy of the greater curvature of the antrum ( $1.13 \pm 0.87$  vs  $0.64 \pm 0.77$ ,  $p < 0.01$ ), the lesser curvature of the corpus ( $1.61 \pm 1.01$  vs  $0.92 \pm 1.01$ ,  $p < 0.01$ ), and in IM of the greater curvature of the antrum ( $0.78 \pm 0.82$  vs  $0.46 \pm 0.77$ ,  $p = 0.02$ ), the lesser curvature of the corpus ( $1.57 \pm 1.19$  vs  $0.85 \pm 0.98$ ,  $p < 0.01$ ).

**Conclusion:** Continuous high level of inflammation in the background gastric mucosa would be a risk factor of gastric cancer onset after *H. pylori* eradication.

<sup>3</sup>Nippon Medical School Hospital, Gastroenterology, Tokyo, Japan

Contact E-Mail Address: nobue@nms.ac.jp

**Introduction:** The number of the cases who take warfarin or direct oral anticoagulant (DOAC) is increasing because they have cardiovascular diseases. Japanese guidelines for gastroenterological endoscopy have recommended continuation of warfarin and temporary withdrawal of DOAC on the day of endoscopic submucosal dissection (ESD). However, anticoagulants were temporarily withdrawn until the guidelines were revised in 2017. In Japan, DOAC has been used since 2011, however, the effect on endoscopic treatment is not clear. In this study, we evaluated the effect of warfarin and DOAC.

**Aims & Methods:** 417 patients with gastric neoplasms underwent ESD at the Nippon Medical School from January 2012 to February 2018. We excluded 32 patients who underwent injection of triamcinolone into ulcer after ESD, 27 patients who took NSAIDs, and 9 patients who had been on dialysis. Among them, 96 cases were taking antithrombotic drugs. 21 patients taking anticoagulant drugs were divided into two groups; warfarin group (13 patients; male 10) and DOAC group (8 patients; male 8). The

types of DOAC were dabigatran, apixaban, edoxaban or rovaroxaban. We compared retrospectively the post-bleeding rate, blood data, and complications between two groups.

**Results:** The post-bleeding rate were no differences between warfarin group (15.3%; 2/13) and DOAC group (12.5%; 1/8). No perforation occurred in both groups. The warfarin group had a slight longer ESD procedure time than the DOAC group. There were no differences in the rate of increase on the next day after ESD with platelet counts, PT (%) and APTT, but D-dimer was significantly increased in the warfarin group (61.0% vs 15.4%;  $p = 0.04$ ). There were no complications such as thromboembolism in both groups.

**Conclusion:** Although there was no thromboembolism, withdrawing warfarin made anticoagulant action unstable and may be risk of thromboembolism.

**Disclosure:** Nothing to disclose

## P2012 ENDOSCOPIC ULTRASOUND IN THE DIAGNOSIS AND FOLLOW-UP OF GASTRIC SUBEPITHELIAL LESIONS: RESULTS FROM A REGIONAL CENTRE

Haddock R.<sup>1</sup>, Tham J.<sup>2</sup>, Paterson S.<sup>3</sup>, Stanley A.J.<sup>2</sup>

<sup>1</sup>NHS Greater Glasgow and Clyde, Gastroenterology, Glasgow, United Kingdom, <sup>2</sup>Glasgow Royal Infirmary GI Unit, Department of Gastroenterology, Glasgow, United Kingdom, <sup>3</sup>NHS Forth Valley, Gastroenterology, Larbert, United Kingdom

**Contact E-Mail Address:** rosiehaddock1@doctors.org.uk

**Introduction:** Gastric subepithelial lesions (SEL) found on conventional endoscopy or CT have a broad differential including malignant disease. Endoscopic ultrasound (EUS) +/- fine needle aspiration (FNA) has become an important modality in assessing SELs and guiding management. The optimum assessment and follow-up strategy for smaller lesions remains unclear. Our aim was to assess outcomes of patients undergoing EUS for gastric SELs in our regional centre. Secondary aims included assessing the use of EUS FNA, surveillance strategy and outcomes by lesion size (<10, 10-20 and >20mm).

**Aims & Methods:** We undertook a retrospective analysis of our prospectively collated regional EUS database, to identify patients who underwent EUS for SELs. Electronic patient records were analysed to obtain relevant data including imaging, cytopathology and follow-up. Patients with SELs out-with the stomach and patients undergoing EUS for investigation of known (or strongly suspected) malignancy were excluded.

**Results:** Between 1/1/14 and 31/12/17, 70 patients were referred for EUS due to the identification of an SEL on endoscopy (97%) or CT scan (3%). Mean age was 60 years with 44% (n=31) male. 56% (n=38) patients also underwent endoscopic biopsy together with EUS. All patients were followed up for a minimum of 12 months. Mean lesion size on EUS was 24.8mm. 15.7% (n=11), 42.9% (n=30) and 40% (n=28) of lesions were < 10mm, 10-20mm and >20mm respectively. One patient had mucosal thickening only, and one patient had incidental lung adenocarcinoma diagnosed at EUS. Table 1 shows the EUS diagnosis according to size of lesion.

31.4% (n=22) patients underwent FNA of lesion, (0%, 4.2% and 27.1% patients for lesion size < 10mm 10-20mm and >20mm respectively). 4.2% (n=3) patients had biopsies within biopsies and 5.7% (n=4) patients were not sampled due to patient factors.

68% (n=15) of EUS-FNAs were diagnostic. 62.5% (n=10) FNAs were diagnostic of GIST, with 12.5% (n=2) leiomyoma, and one each adenocarcinoma, lymphoma, and lipoma.

All patients with lesions < 20mm (n=42) were alive and well with at least one-year follow-up, or had died of unrelated causes. 19 underwent repeat EUS or surveillance CT/endoscopy, 19 had no planned follow up due to lesions being deemed low risk or patient choice, one had a resection and two died of other causes. Of the 27 patients with lesions >20mm, 11 underwent resection/received Imatinib and 11 underwent EUS/CT/endoscopy surveillance due to patient co-morbidities or lesion being deemed low risk on EUS, with static size of lesion. Three lesions >20mm were cysts requiring no follow-up, two received other chemotherapy/surgery and one died of unrelated causes.

**Conclusion:** EUS is a useful tool in the assessment, diagnosis and follow-up of small SELs. Management of lesions < 2cm remains controversial, however in our series, patients with SEL within this size range had no clinical sequelae and no EUS findings of concern during follow-up of at least one-year.

EUS imaging diagnosis (n)	Size of lesion <10mm	Size of lesion 10-20mm	Size of lesion >20mm	Total
Probable GIST	1	6	14	21
Benign lesion	5	15	1	21
Indeterminate	0	0	4	4
Pancreatic rest	1	5	0	6
Lipoma	1	3	1	5
Suspicion of malignancy	0	0	5	5
Cyst	0	0	3	3
Normal	1	0	0	1
Polyp	1	2	0	3

**Introduction:** Endoscopic submucosal dissection (ESD) for superficial non-ampullary duodenal epithelial tumor (SNADET) is often caused high rate of delayed complications. We reported that ESD using a scissor-type knife was efficient for gastrointestinal tumors and ESD with prophylactic laparoscopic closure is one of the minimally invasive treatments for SNADET. In contrast, there have been some reports with regard to the usefulness of the over-the-scope clip (OTSC) for prevention of delayed complications after endoscopic treatment.

**Aims & Methods:** The consecutive patients with SNADET who underwent ESD at the hospital of Kyoto Prefectural University of Medicine were retrospectively enrolled between January 2009 and April 2019. The inclusion criteria were SNADETs larger than 10mm without submucosal invasion with a low risk for lymph node metastasis clinically. We had mainly performed ESD using a needle-type knife (Flush Knife) between January 2009 and September 2017, or using a scissor-type (Clutch Cutter) between October 2017 and April 2019. The mucosal defect was prophylactically closed using conventional clips, laparoscopic hand-saw suturing, or OTSC.

The primary endpoint was to evaluate the rate of en block resection, intra-operative complications (perforation and bleeding) between Flush Knife cases and Clutch Cutter cases. The secondary end point was to evaluate the rate of delayed complications among three closing methods. All patients provided written informed consent.

This study was approved by the ethical committee of Kyoto Prefectural University of Medicine.

**Results:** A total of 77 lesions in 75 patients (male/female 54/23 and median age 67 years) were resected by ESD. There were 37 and 40 cases resected using the Flush Knife and the Clutch Cutter, respectively. Moreover, there were 14, 13, and 50 cases using conventional clip, laparoscopic hand-sewn suturing, and OTSC for prophylactic closure of the mucosal defect after ESD, respectively. Histopathological diagnosis (adenoma/ T1a cancer/ T1b cancer) in Flush Knife and Clutch Cutter cases revealed 2/33/2 and 1/34/5, respectively. In Flush Knife and Clutch Cutter cases, the rate of R0 resection was 83.8% and 97.5%, respectively, with no significant difference. Median resection time in Clutch Cutter cases was significantly shorter than that in Flush Knife cases (40 min and 54 min, respectively,  $P < 0.01$ ). The rates of complete closure were 78.6%, 92.3%, and 98.0% for the conventional clip, the laparoscopic closure, and OTSC, respectively, with no significant difference ( $P = 0.13$ ).

However, the closing time for OTSC was significantly shorter than that of the conventional clip and the laparoscopic closure ( $P < 0.01$ ). Adverse events such as delayed perforation and delayed perforation was 15.4%,

7.7%, and 2.3%, and 0%, 0%, and 2.3% for the conventional clip, the laparoscopic closure, and OTSC, respectively, with no significant difference ( $P=0.56$  and  $P=1$ ).

**Conclusion:** ESD using Clutch Cutter with OTSC closure is safe and feasible for the less invasive treatment of SNADET.

**Introduction:** In Japan, the guidelines for gastric cancer treatment specify several criteria for curative resection of endoscopic submucosal dissection (ESD), and additional surgery after endoscopic ESD is recommended for all patients who did not meet the curative criteria for gastric cancer. The submucosal deep invasion (SM-d; depth of submucosal invasion  $\geq 500\mu\text{m}$ ) is one of the risk factors for the predicted lymph node metastasis, and is used in the new curative criteria "eCura system" in the Japanese Gastric Cancer Treatment guidelines 2018 (ver.5). However, the data about the long-term outcomes of the preceding ESD for the patients with pathological SM-d (pSM-d) gastric cancer is insufficient. In this study, we analyzed the influence of preceding ESD on the prognosis of patients with pSM-d gastric cancer after additional surgery using propensity score-matching.

**Aims & Methods:** We retrospectively assessed 316 consecutive patients with 319 pSM-d gastric cancers who underwent ESD prior to additional surgery or surgery alone between February 2002 and February 2017 at the Hiroshima University Hospital. Of the patients after ESD, patients who did not meet curative criteria of the guidelines were advised to undergo additional surgery. Of the 316 patients, 63 patients were treated by ESD alone because of various reasons (refusal to surgery, comorbidity and/or advanced age), and they were excluded. Finally, 248 patients with pSM-d gastric cancer who underwent ESD prior to additional surgery (Group A:  $n=101$ ) or surgical resection alone (Group B:  $n=147$ ) were included in this study. Propensity score-matching was used to control for potential confounders. After matching the propensity scores, we analyzed pathological characteristics between the 2 groups and the prognoses of patients with  $\geq 60$  month follow-up period was analyzed.

**Results:** The baseline characteristics before propensity score matching were following: There were significantly more male in Group A than Group B, and the patients in Group A were significantly older than the patients in Group B. A higher proportion of patients in group B had tumors located in the middle third of the stomach. Likewise, depressed type tumors and undifferentiated type tumors in Group B were significantly more than tumors in Group A, the mean tumor diameter in Group B were significantly larger than that in Group B and the mean depth of submucosal invasion in Group B was significantly deeper than in Group A. The en bloc resection rates in Group A were 91% (93/102) and the rates of vertical margin positive were 23% (23/102). Perforation occurred in 5% (5/102) and all cases could be improved by conservative treatment. Local recurrence had not occurred but metastasis to lymph nodes or other organs occurred in 2% (2/102) in Group A and 3% (4/147) in Group B. Propensity scores were calculated using a logistic regression model, and the variables included in the model were age, sex, tumor size, and gross type in Group A. After propensity score-matching, 80 patients in group A and 80 patients in group B were picked up. There were no significant differences in 5-year overall survival rates (87.5% vs. 91.2%) and 5-year disease-specific survival rates (96.3% vs. 96.4%) after treatment of pSM-d gastric cancer between 2 groups.

**Conclusion:** Preceding ESD for patients with pSM-d gastric cancer did not affect their clinical outcomes adversely after additional surgery.

## **P2015 GERMLINE MUTATIONS IN TWO FAMILIAL EARLY-ONSET GASTRIC CANCER FAMILIES**

Zhou F.

Nanjing Drum Tower Hospital affiliated with Medical School of Nanjing University, Department of Gastroenterology, Nanjing, China

**Contact E-Mail Address:** zhoufan24@hotmail.com

**Introduction:** Gastric cancer (GC) is highly heterogeneous and most cases are sporadic. While only 10% cases showed family aggregation overall, the frequency of hereditary GC can rise up to 25% in early-onset GC patients. At present, the only known cause of hereditary diffuse gastric cancer is *CDH1* germline mutation in the Caucasian population. Recent studies using next-generation sequencing have identified several recurrent somatic genes mutated in sporadic GC. However, germline mutations of familial gastric cancer (FGC) have not been thoroughly investigated in Chinese patients.

**Aims & Methods:** We searched our previously published cohorts of 152 young GC patients and identified two FGC families. In each family, two patients were re-admitted to our hospital. Patients' demographics, clinical results, detailed family history, and endoscopic-pathological findings were gathered and analyzed. Patients' peripheral blood was collected to extract DNA for whole-genome sequencing. The sequencing data were aligned with the reference genome sequence, filtered out synonymous alterations, and compared with previously published results in the literature and the TCGA data of the United States National Institute of Health.

**Results:** In four patients (two male patients and two female probands, average age: 50.2 years), three had poorly differentiated adenocarcinoma with mixed mucinous and signet ring carcinoma components; the other was moderately differentiated adenocarcinoma in the cardia. Tumor stages ranged from pI to pIIA. All 4 patients were well at the last follow up. Whole-genome sequencing demonstrated 8 shared non-synonymous SNPs and Indels among all four patients, 4 unique variations shared in the first family and 7 in the second family. Go analysis showed that the genes for cytoskeleton, actin binding, myosin complex, keratin filament, cytoskeletal protein binding and intercellular non-membrane-bounded organelle terms were significantly associated with FGC. Two germline genes, 1) Leukocyte immunoglobulin-like receptor subfamily A member 4 (*LILRA4*) with a missense mutation (NM\_012276.4:c.953-2A>G), 2) Myomesin-2 (*MYOM2*) with a missense mutation (NM\_003970.3:c.3695A>G), were validated by PCR Sanger Sequencing. No *CDH1* mutation or p53 alterations were found in any 4 Chinese patients.

**Conclusion:** These findings showed that 2 germline genes, *LILRA4* and *MYOM2*, may act as tumor suppressor genes and might be used as a diagnostic marker for FGC. Further validation of these two genes mutations in FGC is obligatory and on-going.

**Contact E-Mail Address:** jiyouon.y@gmail.com

**Introduction:** Duodenal adenocarcinoma is the second leading cause of cancer in familial adenomatous polyposis (FAP). Spigelman stage (SS) of duodenal polyposis predicts cancer risk. Advanced SS requires consideration of duodenal resection. Post-duodenectomy data indicate polyps occur in the post-anastomotic jejunum, distal to the flow of bile, but limited data exists regarding their significance. Our study aims to evaluate the prevalence, natural history, and severity of polyposis of the jejunum after duodenectomy in patients with FAP.

**Aims & Methods:** We identified consecutive FAP patients following duodenal resection, including Whipple procedure, pancreas-sparing duodenectomy (PSD), or segmental duodenectomy, at Cleveland Clinic between 08/1978 and 01/2018 from the David G. Jagelman Inherited Colon Cancer Registries. Patients without endoscopic follow up data were excluded. Medical records were used to determine demographics, time to diagnosis of jejunal polyps, length of post-operative endoscopic follow up, and maximal SS of jejunal polyposis (neo-Spigelman stage). The Spigelman and neo-Spigelman stage (0-IV) was calculated according to cumulative points (1,2,3) for each category within the following characteristic: largest polyp size (1-4 mm, 5-10 mm, > 10 mm), polyp number (1-4, 5-20, > 20), histology (tubular adenoma, tubulovillous adenoma, villous adenoma), degree of dysplasia (1 for low grade, 3 for high grade). Stage I is 1-4 points, II is 5-6 points, III is 7-8 points and IV is 9-12 points.

**Results:** 64 patients were identified; mean age 61.7 ±12.3 years, 53% male, 83% white. 28% underwent Whipple, 61% PSD, and 11% segmental duodenectomy. Advanced polyposis (81%, SS III-IV) was the most common indication for surgery. Post-operatively 38/64 (59%) developed jejunal polyposis (Table 1), with median time to diagnosis of 55 months and follow up time of 127 months. On most recent endoscopy, neo-Spigelman stage was I in 29%, II in 50%, III in 18.4%, and IV in 2.6%. No cases of high-grade dysplasia or carcinoma were noted during surveillance. 48% of jejunal polyps were treated with endoscopic resection or ablation. One patient with neo-Spigelman stage III jejunal polyposis had Whipple procedure 21 years after initial PSD for progressive polyposis of the jejunum, with surgical specimen demonstrating high grade dysplasia.

Number of patients (%)		
Time to diagnosis, median months [Q1, Q3]		55 [22, 84]
Duration of post-operative endoscopic follow up, median months [Q1, Q3]		127 [78, 175]
Neo-Spigelman stage	Stage I	11 (29)
	Stage II	19 (50)
	Stage III	7 (18.4)
	Stage IV	1 (2.6)
Carcinoma/ HGD on surveillance biopsy		0
Management of jejunal polyposis	Surveillance	18 (47.4)
	Endoscopic resection/ ablation	19 (50)
	Surgical resection	1 (2.6)

Q1 first quartile; Q3 third quartile; HGD high grade dysplasia

[Table 1. Jejunal polyposis detected on post-operative surveillance (N=38)]

**Conclusion:** In spite of surgical management of duodenal polyposis, jejunal polyposis occurs in the majority of patients after surgical duodenectomy and is advanced in 1 in 5 patients. Further studies are required to evaluate the significance and risk of polyposis of the jejunum in FAP patients. In the meantime, continued endoscopic surveillance is indicated.

**Disclosure:** Nothing to disclose

## P2017 THE PREVALENCE AND SIGNIFICANCE OF DUODENAL BULB POLYPOSIS AFTER DUODENECTOMY IN PATIENTS WITH FAMILIAL ADENOMATOUS POLYPOSIS

**Contact E-Mail Address:** jiyeon.y@gmail.com

**Introduction:** Consideration of prophylactic duodenal surgery is recommended in patients with Familial Adenomatous Polyposis (FAP) and Spigelman stage IV duodenal polyposis to prevent cancer. Pylorus-sparing approaches of pancreatoduodenectomy (PD) and pancreas-sparing duodenectomy (PSD) are often performed over a complete Whipple procedure. Pylorus-sparing techniques, with the benefit of reduced rates of gastric

dumping syndrome, create a duodeno-jejunal anastomosis at the apex of the duodenal bulb, which remains at risk of recurrent adenoma. Our study aims to evaluate the prevalence and severity of polyposis of the duodenal bulb after pylorus-sparing duodenectomy.

**Aims & Methods:** We identified consecutive FAP patients following duodenal resection (PD, PSD, or segmental duodenectomy) at Cleveland Clinic, between 05/1992 and 01/2018 from the David G. Jagelman Inherited Colon Cancer Registries. Those who had a pylorus-sparing procedure with a remnant duodenal bulb on post-operative anatomy were included in the study. Those without endoscopic follow up data after surgery were excluded. Medical records data was used to determine time to occurrence, maximal size, histology, and dysplasia of duodenal bulb polyps in patients after duodenal resection.

**Results:** 55 FAP patients had a pylorus-sparing duodenal resection and were included in the study (20% PD, 69% PSD, 11% segmental duodenectomy). Mean age was 61.5 ±12.6 years, 56% were male, and 82% were white. 6/55 (11%) patients with duodenal bulb polyposis were identified (Table 1). All patients were post-PSD. Median time to polyp occurrence in the duodenal bulb was 43 months [IQR 19-62]. All 6 patients developed large polyps > 20 mm. 1 of 6 had tubulovillous adenoma, the remainder tubular adenoma on biopsy. Endoscopic resection with submucosal injection was attempted on 5 of 6 cases, and complete resection was achieved in one case. The remaining 4 lesions demonstrated no lift on submucosal injection. In one case, initial endoscopic resection was successful, but recurrent adenoma at the site of resection after 12 months was not amenable to resection due to fibrosis. There were no cases of carcinoma or surgical resection for duodenal bulb polyps.

Patient	Time to polyp detection (months)	No. of post operative EGDs	Maximal size (mm)	Maximal histology	Success of endoscopic therapy
1	19	16	60	TA	No
2	43	4	20	TA	Yes
3	56	2	40	TA	No
4	62	12	50	TA	No
5	14	7	25	TVA	No
6	105	9	35	TA	Not attempted

[Table 1: Bulb polyp characteristics (N=6)]

**Conclusion:** A minority of patients develop polyps in the duodenal bulb after pylorus-sparing duodenectomy. They are difficult to manage endoscopically due to failure of endoscopic resection with frequent non-lifting with submucosal injection. This could be secondary to the proximity to the surgical anastomosis, prevalence of Brunner's glands in the proximal duodenum, and previous attempted removal. Optimal approaches to prevent duodenal bulb polyps after pylorus-sparing duodenectomy are needed.

**Contact E-Mail Address:** kimbj@cau.ac.kr

**Introduction:** Vonoprazan, a novel potassium-competitive acid blocking agent, has been used in the management of endoscopic submucosal dissection (ESD)-induced artificial ulcers. This study aimed to perform a systematic review and meta-analysis for the comparison of the effects of vonoprazan and proton pump inhibitors (PPI) in treating ESD-induced artificial ulcers and preventing delayed bleeding in randomized controlled trial and cohort studies.

**Aims & Methods:** We searched OVID-MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), Google Scholar, and clinical trial registries in April 2018 to identify all studies that assess and compare the effects of vonoprazan and PPI in treating ESD-induced artificial ulcers and

preventing delayed bleeding. Primary outcome of ulcer healing rate and secondary outcomes of shrinkage rate, ulcer size, and delayed bleeding were studied.

**Results:** A total of 1265 patients from 12 studies was included in the final analysis. Healing rate at 4 weeks post-ESD was significantly higher in the vonoprazan group than in the PPI group (RR 1.20 (1.03-1.40)). However, healing rate at 8 weeks post-ESD was significantly higher in the PPI group than in the vonoprazan group (RR 0.68 (0.48-0.97)).

There was no evidence of significant difference between groups in shrinkage rate at 4 weeks post-ESD, shrinkage rate at 8 weeks post-ESD, delayed bleeding, ulcer size at 0 weeks post-ESD, and ulcer size at 8 weeks post-ESD.

**Conclusion:** There was no substantial difference in ulcer healing and post-ESD bleeding between vonoprazan and PPIs. However, vonoprazan more rapidly and effectively treated artificial ulcers after ESD than did PPIs.

**Contact E-Mail Address:** david.tai@nhs.net

**Introduction:** The United Kingdom BSG and AUGIS quality standards in upper gastrointestinal endoscopy recommend taking biopsies for histological examination to diagnose inflammatory, pre- or malignant lesions which may or may not be visible to the naked eye [Beg, Gut 2018]. This may increase the duration and cost of the procedure and potentially reduce the focus on mucosal inspection. This study aimed to investigate the diagnostic value (changes in diagnosis and contribution to management) added by histology and its cost.

**Aims & Methods:** Patients under going consecutive diagnostic gastroscopies performed by four fellows were recruited. Incomplete, surveillance or therapeutic procedures, procedures for dysphagia and those arranged in order to obtain histology (eg. positive coeliac serology) were excluded. Biopsies were performed according to BSG quality standards [Beg, Gut 2018]. The utility of biopsies (changes in diagnosis and contribution to management) were examined from endoscopic and histological findings.

**Results:** Of 509 patients examined, 314 were included. Gastroscopies was performed for dyspepsia (66%), anaemia (26%), weight loss (16%), diarrhoea (2%) and vomiting (1%). Biopsies occurred in 86% of patients with an mean of 1.5 samples per patient biopsied. Biopsy sampling provided additional pathological information not evident at endoscopy in 28% of cases. However, if benign pathologies are excluded (mostly chemical or Helicobacter gastritis or duodenitis), this falls to 6.7% (n=18: dysplasia n=3, adenocarcinoma n=1, gastric intestinal metaplasia (GIM) n=7, villous atrophy (VA) n=2, Barretts n=5). In total, management change occurred in 19% consequent on histological findings, but this falls to 12% (n=34: adenocarcinoma n=2, dysplasia n=3, GIM, n=10, Barretts n=15, VA n=3, peptic stricture n=1) where Helicobacter pylori (which can be detected by other non-invasive methods) eradication is excluded.

Fifty seven focal lesions were biopsied where dysplasia or cancer was diagnosed in 7% (1/14 oesophageal, 2/35 gastric and 1/8 duodenal). Barretts (58% vs 0% p=0.02), GIM (81% vs 18% p=0.05) and VA (20% vs 1% p=0.02) were found more commonly in abnormal compared to normal mucosa. The overall cost of tissue sampling approximates to £17,100 (£82 per person). Routine biopsies of patients with only normal mucosa costed over £3,500.

**Conclusion:** Although 86% undergoing gastroscopy have biopsies taken, contributing to aetiopathological understanding in 28%, only a small mi-

nority (6.7%) have pre-malignant or malignant pathologies and result in a change in management in only 12%. Non-targeted biopsies are of limited value and costly when sampled from normal mucosa.

## P2021 ROUTINE EXAMINATION OF STOMACH AND DUODENUM IN PATIENTS ATTENDING FOR BARRETT'S SURVEILLANCE- IS IT REALLY INDICATED?

Shaikh F.K.<sup>1</sup>, Mundre P.<sup>2</sup>

<sup>1</sup>Bradford Teaching Hospitals NHS Trust, Gastroenterology, Bradford, United Kingdom, <sup>2</sup>Bradford Teaching Hospitals NHS Trust, Leeds, United Kingdom

**Contact E-Mail Address:** pradeepmundre@gmail.com

**Introduction:** Patients undergoing OGD for Barrett's surveillance have examination upto D2 before detailed examination of Barrett's mucosa and Seattle protocol biopsies. This may lead to less time dedicated to examine Barrett's segment potentially leading to reduction in the yield of dysplasia. Most patients undergo such procedures with throat spray or sedation, hence potentially reducing the compliance of patients towards the end of procedure when examination of Barrett's segment is performed in routine practice.

**Aims & Methods:** Our aim is to find out what percentage of surveillance OGDs incidentally pick up significant pathologies in stomach and duodenum (cancer, pyloric stenosis, polyp with dysplasia, benign ulcer and varix) compared with their index procedures; whether we could potentially avoid examination of stomach and duodenum during surveillance procedures and focus this time on longer inspection of Barrett's segment

We retrospectively analysed all OGD reports retrieved from hospital's Endoscopy reporting tool for patients who underwent OGD within last 10 years (January 2009- December 2018) for Barrett's surveillance. Data was extracted electronically using the endoscopy audit tool on the reporting system. We analysed all these OGDs for presence of significant pathologies in stomach and duodenum that were found incidentally. Procedures with Barrett's oesophagus as index diagnosis or OGD earlier than the proposed surveillance interval for other indications were excluded. Reports of all procedures with a diagnosis of Barrett's oesophagus over a period of one year (2018) were individually validated manually to confirm accuracy of the electronic data set and to get a gross estimate of surveillance procedures over 10 years.

**Results:** Yearly procedure count was 155 patients undergoing Barrett's surveillance OGD which approximates to about 1550 procedures over 10 years. The median age was 68 years. Average surveillance interval was 3.45±1.12 years. There were no cases of gastric or duodenal cancer, however 1 patient had incidental follicular lymphoma (0.06%), single case of gastric adenoma with focal HGD (0.06%) and 2 patients with duodenal adenoma (0.1%) were found over 10 years. Incidental benign ulcers (gastric and duodenal) were found in 4% (n=61) and gastric varices in 5 patients (0.3%, all with known chronic liver disease).

**Conclusion:** Our study demonstrates that incidental findings of significant pathology during surveillance OGD for Barrett's oesophagus is very rare. Hence in patients undergoing Barrett's surveillance, a focussed examination of oesophagus and gastro-oesophageal junction rather than examination of stomach and duodenum may be more appropriate with an aim to increase pick up rates of dysplasia. Previous studies have demonstrated that longer inspection time is associated with increase in detection rate of high grade dysplasia and cancer (1).

A shortcoming in our study is the retrospective nature of data. We also noted a longer surveillance interval than what we expected. This could be explained by surveillance procedures performed outside our local authority, but this would not have influenced our results other than the overall numbers. We do not have any data regarding separate time intervals for the completion of OGD and examination of Barrett's segment. We would recommend detailed prospective data collection for these aspects. Multi-centre data may further validate the above results.

**Introduction:** Recent guidelines on quality in endoscopy recommend a regular assessment of patient experience. Nevertheless, there is a paucity of data in this research area. Most studies did not question the experience from the patient perspective. The aim of this study was to develop a satisfaction questionnaire in order to identify the main elements affecting patient experience and satisfaction during an upper-endoscopy.

**Aims & Methods:** Based on literature review and information collected from exploratory interviews with patients, before and after the examination, a satisfaction questionnaire was created. This questionnaire includes an interactive part with 11 variables about patient experience classified by importance by the patients. This questionnaire was administered by the same interviewer to outpatients undergoing upper-endoscopy after discharge from Saint-Pierre Hospital, Brussels, Belgium from the 14th of march to the 4th of april 2019. An informed consent validated by local ethics committee was presented before each interview. The statistical analyses were performed with IBM SPSS.

**Results:** Out of the 54 consecutive interviewed patients, 52 fully responded (35 women). 46.1% of the sample was aged between 26 and 45 years old. The mean of the global satisfaction was 8.82 out of 10 with a standard deviation of 0.989. Perceived « Kindness of the care team », « Professionalism of the care team » and « Explanation of the results right after the examination » were considered as the 3 most important factors influencing the global satisfaction of the patient, by respectively 84.6%, 57.7% and 50% of the sample. On the other hand, « Fasting the day of the exam », « Waiting time before the exam » and « Pain » were considered as the 3 least important factors influencing the global satisfaction of the patient, by respectively 57.7 %, 57.7% and 36.5%. There is a statistically significant difference in rank between both the 11 variables ( $p < 0.001$ ), and the 3 most important factors ( $p = 0.001$ ). There is a significant difference between « Kindness of the care team » and « Professionalism of the care team » ( $p = 0.006$ ).

**Conclusion:** Patient satisfaction is a key quality indicator of upper-endoscopy. It is necessary to draw attention on how patients feel before and after an endoscopy procedure and not only focus on the exam itself. Our interesting results show that kindness and communication stand out as the most important factors of patient satisfaction during upper-endoscopy. Larger studies should confirm these results in order to design a validated questionnaire.

**Introduction:** Histopathological changes in gastric mucosa during *Helicobacter pylori* (HP) infection can be associated with HP fitness adaptation through genetic events leading to reduced virulence as precancerous lesions develop.

**Aims & Methods:** In this study we dissected the heterogeneity of the HP genotypes in patients (pts) at higher gastric cancer (GC) risk to understand if they exploit an increased genetic stability and consequent virulence. 14 Autoimmune Gastritis (AG), 25 First Degree Relatives of GC pts (FDR), 39 GC and 13 Dyspeptic pts without familiarity (D) were investigated. Gastric biopsies were grown in HP selective medium; HP was identified by standard methods. As representation of HP strain heterogeneity, 10-12 colonies-forming-unit (CFU)/pt were isolated and analyzed by PCR. A total of 915 CFU were examined. Three CagPAI loci (*cagA*, *cagE*, *virB11*) were studied as proxy marker of CagPAI plasticity. *VacA* s, i and m regions, *homB/A* alleles were also evaluated as markers of additional virulence. A stable CagPAI was defined by simultaneous presence of *virB11*, *cagE*, *cagA* genes in  $\geq 9$  isolated CFU/pt. Increased virulence was determined with  $\geq 9$ CFU with *vacA* s*i1mx* aptotype (vs. s*i2m2* or *vacA* deletion) or  $\geq 9$ CFU with *homB* gene. Histological grading of gastritis was made by Sydney system. OR and 95% confidence intervals (C.I.) were calculated.

**Results:** FDR status was associated with significant higher atrophy (OR=6.3, 95%C.I.:1.2-31.9) and neutrophil infiltration (activity) (OR=7.2, 95%C.I.:1.2-44.7) than D, while metaplasia and mononuclear cell infiltration were comparable. Moreover, FDR showed a reduced risk to host mixed infections (OR=2.7, 95%C.I.:0.03-0.81). Additionally, FDR exhibited a higher frequency of subtypes carrying the CagPAI-*vacA* s*i1mx*-*homB* positive profile (OR=2.7, 95%C.I.:1.7-4.4). Conversely, AG patients presented a lower frequency of subtypes carrying a stable CagPAI and *vacA* s*i1mx*.

**Conclusion:** These results underline H. pylori different plasticity in the gastric niche of populations at risk of GC, suggesting a different host-bacterium interaction capacity that might affect the outcome of the infection.

**Disclosure:** Nothing to disclose

## P2024 *HELICOBACTER PYLORI* CAGA PROMOTES GASTRIC CANCER TUMORIGENESIS VIA THE P-ERK/AUF1/GKN1 PATHWAY

Yanlei G.<sup>1</sup>, Shigang D.<sup>2</sup>

<sup>1</sup>Peking University Third Hospital, Gastroenterology, Beijing, China, <sup>2</sup>Peking University Third Hospital, Beijing, China

**Contact E-Mail Address:** guoyanleidr@163.com

**Introduction:** *Helicobacter pylori* (HP) was the carcinogen of gastric cancer, especially the *cagA*-positive HP. *Gastrokine1*(GKN1), an important tumor suppressor, is downregulated in HP infected gastric mucosa. However, the underlying mechanism that HP *cagA* promotes carcinogenesis by influencing the anti-tumor gene GKN1 was not clearly elucidated.

**Aims & Methods:** We investigated whether GKN1 was downregulated during HP infection in vivo and in vitro by real-time PCR, western blot and immunohistochemistry. The AUF1 gene was knocked down in GES-1 and BGC-823 cells, we measured GKN1 expression by real-time PCR and western blot to find their inner relationship.

In addition, we conducted RNA-Protein Pull-Down and RNA-immunoprecipitation to judge whether AUF1 can bind GKN1. By measuring turnover and luciferase activity, we explored the GKN1mRNA stability while AUF1 was knockdown. During HP infection, we measured AUF1, GKN1 and p-ERK expression. We also observed the cell proliferation, migration, cell cycle

when AUF1 was knockdown. Furthermore, we conducted the cagA knock-out HP and measured the expression of AUF1, GKN1 and p-ERK.

**Results:** we suggested that GKN1 was downregulated during HP infection. In addition, GKN1 expression was negatively correlated with AUF1. RNA-Protein Pull-Down and RNA-immunoprecipitation experiment proved AUF1 can bind with GKN1mRNA. Further investigation revealed that AUF1 can influence the GKN1mRNA stability to regulate its expression. Moreover, We observed AUF1 was induced during HP infection and biological function studies demonstrated that AUF1 can promote cell proliferation ,migration and accelerated G1/S phase transition. What's more, HP cagA can activate the p-ERK/AUF1/GKN1 pathway and the expression of AUF1 and GKN1 can be rescued by p-ERK inhibitor.

**Conclusion:** These data showed that HP cagA may promote gastric cancer tumorigenesis via the p-ERK/AUF1/GKN1 pathway. The AUF1/GKN1 axis might serve as a prognostic biomarker as well as a novel potential target in the treatment of gastric cancer.

**Disclosure:** Nothing to disclose

## P2025 OPTIMUM SECOND-LINE REGIMENS FOR *HELICOBACTER PYLORI* ERADICATION: INTERIM RESULTS OF AN ON-GOING COCHRANE SYSTEMATIC REVIEW

**Introduction:** *H. pylori* infection represents a significant healthcare burden, and first-line eradication treatment often fails, mainly due to antibiotic resistance.

**Aims & Methods:** To evaluate the effects of second-line treatments on *H. pylori* (Hp) eradication through systematic review of randomised controlled trials (RCTs).

We searched electronic databases and other sources up to January 2019. Selection criteria: RCTs comparing the efficacy of at least two different second-line Hp treatments. The previous failed first-line regimen should have contained at least two antibiotics. We excluded studies assessing a second-line therapy based on bacterial antibiotic susceptibility or resistance or the use of any type of adjuvant in any of the treatments. We determined the effects on Hp eradication rates based on intention-to-treat analysis. We attempted to combine results by meta-analysing risk differences (RD). We stratified results by first-line therapy used. Meta-analysis was conducted with at least two studies based on the Mantel-Haenszel method. We planned to explore sources of heterogeneity by subgroup analysis. We assessed risk of bias of the included studies with the Cochrane risk-of-bias tool for RCTs.

**Results:** Up to now, the review has included 41 RCTs. In total, we have evaluated 39 comparisons of second-line different antibiotic combinations, which are stratified by five different first-line therapy failures. *Effects on Hp eradication rates:* The table below summarises the meta-analyses performed for the 9 second-line therapy comparisons after failure of a first-line standard triple therapy. Two comparisons improved eradication rates. Triple therapy with amoxicillin and metronidazole was more effective than triple with amoxicillin and levofloxacin (2 studies, *P*=0%; High risk of bias). Also, standard bismuth quadruple therapy during 14 days was more effective as compared to 7 days (3 studies, *P*=53%; High risk of bias).

Experimental arm	Control arm	RD [95%CI]	Nº of studies <sup>1</sup>
PPI + A + M	PPI + A	0.01 [-0.23, 0.22]	3
PPI + A + M	PPI + A + L	0.21 [0.09, 0.33]*	2
PPI + A + Ma	PPI + A + Mb	0.03 [-0.08, 0.14]	3
E + A + Mox	E + M + Tc + TDB	0.03 [-0.16, 0.09]	3
O + Bs + A + M	O + A + Tc + Bs	0.12 [-0.01, 0.24]	2
PPI + M + Tc + Bs (14 days)	PPI + M + Tc + Bs (7 days)	0.16 [0.07, 0.26]*	3
PPI + L + Azit	PPI + M + Tc + Bs	-0.08 [-0.40, 0.24]	2
PPI + L + T	PPI + M + Tc + Bs	0.04 [-0.36, 0.45]	2
PPI + A + L	PPI + M + Tc + Bs	0.04 [-0.27, 0.36]	3

1- Number of studies included in each comparison; RD-risk difference; CI-confidence interval; PPI-proton pump inhibitor; A-amoxicillin; Azit- azithromycin; Bs-bismuth salts; C-clarithromycin; E-esomeprazole; L-levofloxacin; Mox-moxifloxacin; M-metronidazole; Ma-metronidazole 750mg; Mb-metronidazole 500mg; O-omeprazole; T-tinidazole; Tc-tetracycline; TDB-tripotassium dicitrate bismuthate; \* significance level *p*≤0.05

[Meta-analyses for the 9 second-line therapy comparisons after failure of a first-line standard triple therapy]

**Conclusion:** There is an amalgam of anti-*H. pylori* second-line treatments used in the clinical setting. After a first-line standard triple therapy (PPI, clarithromycin and amoxicillin) failure, triple therapy with a PPI, amoxicillin and metronidazole showed higher eradication rates than the combination of a PPI, amoxicillin and levofloxacin. Standard quadruple therapy during 14 days, as compared to 7 days, showed better results. However, these are preliminary results and need to be read cautiously due to the limited number of studies included for each comparison and their high risk of bias.

**Introduction:** *Helicobacter pylori* (Hp) eradication is challenging, especially in high clarithromycin (Cla)-resistant areas where the classical triple therapy has to be abandoned.

**Aims & Methods:** Evaluation of real-life data for Hp eradication in patients who applied Maastricht V treatment guidelines in a high Cla-resistant area. Consecutive patients evaluated prospectively for Hp eradication after receiving 1<sup>st</sup>, 2<sup>nd</sup> or 3<sup>rd</sup> line treatments according to Maastricht V guidelines during a period of 31 months (08/2016-03/2019). Cla-resistance was 30% in our population by means of culture and/or PCR. Hp eradication was evaluated with <sup>13</sup>C urea breath test (UBT) at least 4 weeks after treatment. Medications offered for 1<sup>st</sup> line treatment were: Esomeprazole (Eso) 40mg, Amoxicillin (Amo) 1gr, Metronidazole (Metro) 500mg and Cla 500mg all bid in different quadruple combinations or a commercial combination of Bismuth subcitrate potassium, Metro, Tetracycline hydrochloride (BMT) 3 pills qid administered with Eso 40mg bid. For 2<sup>nd</sup> line they received either Eso and Amo bid plus Levofloxacin 500mg (Levo) qd (Eso/Amo/Levo) or Eso/BMT for 10 days and for 3<sup>rd</sup> line: only Eso/BMT for 10 days. Results 371 out of 387 patients received treatment according to Maastricht V guidelines, mean age 55.8±14.8 years, 46% males. Overall Hp eradication after the 3 lines of treatment was achieved in 306 patients with an intention to treat (ITT) and per protocol (PP) analysis success rates of 82.5% (95% C.I. 78.6-86.4) and 89.7% (86.5-93.0) respectively. For 1<sup>st</sup> line treatment 252 received Eso/Amo/Cla/Metro bid for 10 days (CONCO10), 27 received Eso/Amo bid for 7days and then Eso/Cla/Metro bid for another 7 days (SEQ14), 44 received Eso/Amo bid for 7days and then Eso/Amo/Cla/Metro bid for another 7 days (HYBRID14) and 6 received Eso/BMT for 10 days. For 2nd line treatment 34 patients received Eso/Amo/Levo for 10 days and 2 Eso/BMT for 10 days while for 3<sup>rd</sup> line treatment all 6 received Eso/BMT for 10 days.

**Results:** Overall 1<sup>st</sup> line eradication rates for 329 patients were 82.7 (95% C.I. 78.6 - 86.8) in ITT and 90.1 (95% C.I. 86.7-93.4) in PP analysis. Details are depicted in the table.

	CONCO10 (252)	SEQ14 (27)	HYBRID14 (44)	ESO/BMT(6)
ITT%(95%C.I.)	84.5(80.1-89.0)	88.9 (77.0 -100)	65.9(51.9-79.9)	100
PP%(95% C.I.)	90.0 (86.5-94.0)	88.9 (77.0 -100)	87.9(76.7 - 99)	100

#### [1st Line Treatment]

For second line 26 eradicated with Eso/Amo/Levo [ITT = 76.5% (95% C.I. 62.2-90.7) and PP = 83.9% (95% C.I. 70.9-96.8)] and all 2 (100%) with Eso/BMT while in the 3<sup>rd</sup> line 6 out of 6 eradicated Hp (100%) with Eso/BMT. Univariate analysis revealed that younger age (OR=3.4) and alcohol consumption (OR=2.12) were associated with non-compliance regarding reevaluation with UBT. 19.6 % of patients reported side effects (16 % dysgeusia, 12% nausea, 8% soft or frequent bowel movements, 1% rash). No patient discontinued treatment due to side effects.

#### Conclusion:

- 1) Real life Hp eradication rates are satisfactory in high clarithromycin resistant areas when Maastricht V guidelines are applied
- 2) The most frequently used 1<sup>st</sup> line treatment regimen is ten day concomitant with a high eradication rate
- 3) Bismuth subcitrate combination had a success rate of 100% in all 3 lines of treatment when administered, although limited by low availability in many countries.

**Introduction:** The resistance of Helicobacter pylori to antibiotics has increased the need for new first line treatment. The aim of this study was to assess and compare the efficacy and safety of concomitant treatment with sequential therapy and dual therapy with high dose esomeprazole and amoxicillin.

**Aims & Methods:** This prospective randomized study was performed during July 2016 to September 2018. Consecutive naïve helicobacter pylori infected patients were included. Patients included were randomized and divided into 3 groups using a high dose PPI based on esomeprazole 40mg twice daily:

\*BT group: dual therapy= PPI + amoxicillin 1g 3\*/d for 14 days

\*SQ group: sequential therapy= PPI + amoxicillin 1g twice daily for 5 days followed by PPI + clarithromycin 500mg and metronidazole 500mg twice daily for 5 days.

\*CT group: concomitant therapy= PPI + amoxicillin 1g + clarithromycin 500mg + metronidazole 500mg twice daily for 10 days.

At the end of the treatment, compliance to therapy and reported side effect were evaluated. At least 6 weeks after the end of the treatment a C13 urea breath test (UBT) was performed to assess H. pylori eradication rate.

**Results:** A total of 393 patients agreed to participate in the study. The Mean age of patients was 43.9 +/- 15 years (16-90 years). Sex ratio was= 1. Groups BT, SQ and CT included respectively 130, 132 and 131 patients. They were comparable in terms of age, sex, clinical and endoscopic presentation. The eradication rate in intention to treat (ITT) was 63.1%, 86. 4% and 90.8% respectively in the BT, SQ and CT groups (P = 0.0001).

The corresponding rate of eradication by protocol was 67. 7%, 88.5% and 95.3% (P = 0.00016). No significant results were seen in the eradication rate between CT and SQ both in PP analysis and in ITT analysis (P= 0.09). The prevalence of the side effects following the concomitant treatment was

38. 2% significantly higher (P = 0.001) than BT group (13. 80%) and SQ group (22%). Therapeutic compliance was 94%, 98.5% and 95. 4% respectively in patients receiving the BT, SQ and CT protocol (P= 0.16).

**Conclusion:** This study demonstrated that concomitant therapy led to a non-statistically significant over sequential therapy, with higher side effects.

**Disclosure:** Nothing to disclose

**Introduction:** Antimicrobial resistance may reduce response to Helicobacter pylori (HP) eradication therapy. Recently, a prospective multicenter clinical study revealed high rates of clarithromycin (21%) and/or chinolone (13%) resistant Helicobacter pylori (HP) species in a large treatment-naïve Austrian patient population.

**Aims & Methods:** The aim of this subsequent study was to assess the clinical impact of this antimicrobial resistance on the actual HP-eradication treatment success of study subjects. Follow-up data of patients participating in the afore mentioned prospective clinical trial were analyzed regarding HP-eradication treatment regimen, treatment success rates and subsequent HP-eradication therapies. Of note, results of antimicrobial resistance testing (as assessed by real-time PCR in the previous study) were not yet available when subjects underwent individual HP-eradication therapy.

**Results:** Four study centers provided their follow-up data on a total of 116 HP-positive patients. 108/116 pts. (93%) received HP-eradication treatment: sequential therapy, 58/108 (54%); clarithromycin triple therapy, 26/108 (24%); levofloxacin sequential therapy, 20/108 (19%). Treatment response was tested in 54/108 pts. (50%) by histology, stool antigen or urea breath test. Among these 54 patients, 20 subjects (37%) had been identified to have clarithromycin (15/54, 28%) and/or quinolone (6/54, 11%) resistant HP species. Nevertheless, eradication was successful in 50/54 pts. (93%) including 10 patients with proven antimicrobial resistance against antibiotic compounds used for eradication. Those 4/54 pts. (7%) who failed initial HP-eradication (most likely due to proven clarithromycin resistance) underwent another treatment course of the same eradication regimen and cleared HP upon final investigation.

**Conclusion:** This follow-up study revealed high success rates of standard HP-eradication therapy despite proven antimicrobial resistance against antibiotic compounds used for eradication. Although reporting a small number of subjects, these results warrant further investigation regarding selection of compounds and treatment duration for HP-eradication therapy in the future.

**P2029 FOURTEEN DAY SEQUENTIAL THERAPY CONTAINING RABEPRAZOLE VERSUS 10 AND 14 DAY CONCOMITANT THERAPY IN THE FIRST LINE TREATMENT OF HELICOBACTER PYLORI INFECTION: AN OPEN LABEL, SINGLE CENTER, RANDOMIZED CLINICAL TRIAL**

Boutallaka H., Seddik H., Berrag S., Mrabti S., Sair A., Elkoti I., Berraida R., Loubaris K., Sentissi S., Benkirane A.  
*Military Instruction Hospital Mohammed V, Gastroenterology II, Rabat, Morocco*

**Contact E-Mail Address:** hanaeboutallaka@gmail.com

**Introduction:** Helicobacter Pylori infection remains currently a common infection worldwide.

The decline in the efficacy of traditional triple therapies has generated since 2010 new combinations of antibiotics. The last guidelines of Maastricht V recommend concomitant quadritherapy or bismuth quadritherapy to reach an eradication rate of at least 90%. These values remain higher than those obtained with standard sequential therapy, but with a higher cost and more adverse effects.

**Aims & Methods:** We aimed to compare a modified sequential therapy to 10 and 14 day quadritherapies currently recommended in terms of efficacy, incidence of adverse effects and cost.

We conducted an open-label prospective study at gastroenterology II department in Military teaching hospital of Rabat from January 2016 to March 2019 and randomized patients with confirmed Helicobacter pylori infection to 3 groups (1:1:1): The first group received quadruple therapy of twice-daily (bid) Omeprazole 20mg, Amoxicillin 1g, Clarithromycin 500mg and Metronidazole 500mg for 10days (QT-10), the second group received a 14 day quadruple therapy following the same regimen (QT-14), and the third received an optimized sequential therapy consisting on a bid Rabeprazole 20 mg plus amoxicillin 1g for 7 days, followed by bid Rabeprazole 20 mg, clarithromycin 500 mg and metronidazole 500mg for the next 7days (OST-14). Adverse events (AEs) were recorded throughout the study, and the H.pylori eradication rate was determined 6 weeks after treatment using the 13C urea breath test.

**Results:** There was no significant difference in relation to demographic, clinical, endoscopic and histologic findings between the three groups.

In intention to treat analysis (ITT), eradication rate was 87%, 92,3% and 95,8% respectively in QT-10, QT-14 and OST-14 groups, with no significant difference between the groups. In the per protocol analysis, and compared to QT-10, QT-14 and OST-14 showed a significant higher eradication rate with 91,2%, 95% and 96,8% respectively ( $p=0,03$ ). The overall incidence of AEs was also significantly lower in the OST-14 group, compared to QT-10 and QT-14 groups (21,2%, 37,2% and 41,6% respectively,  $p=0,02$ ).

**Conclusion:** Optimizing standard sequential therapy in terms of duration and using a second-generation Proton Pump Inhibitor is a safe and effective alternative that allows an eradication rate comparable to those currently recommended by the Maastricht V guidelines, while causing fewer adverse effects and allowing a gain in term of cost. Further studies are needed to substantiate these findings.

**P2030 PREVALENCE OF HELICOBACTER PYLORI INFECTION IN PATIENTS WITH FUNCTIONAL DYSPEPSIA AND EFFECTS OF ERADICATION ON SYMPTOMS - URBAN INDIAN SCENARIO**

Shah R., Banka N.H., Patel T., Udawat P., Dhir V.  
*S L Raheja Hospital, Gastroenterology, Mumbai, India*

**Contact E-Mail Address:** rahulshah@hotmail.com

**Introduction:** Functional dyspepsia (FD) is classically defined as continuous or frequently recurring epigastric pain or discomfort centred in upper abdomen for which no organic cause can be determined. The last Consensus of an International panel of clinical investigators on gastroduodenal functional disorders (Rome III) recommended Helicobacter Pylori (HP) eradication in all infected patients with non ulcer dyspepsia diagnosed at upper endoscopy, also suggesting non-invasive testing followed by HP eradication (test and treat) in those patients with no alarm features, although many infected patients with FD may not gain symptomatic benefit.

**Aims & Methods:** Effect of eradication of HP on symptoms of functional dyspepsia is uncertain, and the data in Asian scenario are scanty. The study aimed to see HP positivity rate in patients of functional dyspepsia and primarily the effect of its eradication on symptoms. All patients who

were diagnosed with functional dyspepsia of more than 3 months duration were enrolled into this study. Patients of functional dyspepsia were tested for HP infection by the urease breath test by Heliprobe analyser, Sweden. These patients had no alarm symptoms, red flags to warrant an endoscopy. Symptoms were documented on our standard Performa and symptoms on a seven-point Likert scale, ranging from extremely improved compared with the baseline period to extremely aggravated compared with the baseline period. HP positive patients were treated with standard triple therapy for 15 days with amoxicillin, ornidazole and clarithromycin.

**Results:** HP positivity rate in functional dyspepsia was 274/994 (27.5%). Repeat UBT was performed between 12-14 weeks (off PPI for 2 weeks) 19 patients were lost to follow up in the treatment arm and 86 patients in the HP negative arm at 6 months. At 12 weeks, the eradication rate for HP in triple therapy was 201/255 (78.8%). The patients who were H pylori negative were treated with standard dose PPI and prokinetic (domperidone). On intention-to-treat analysis, the symptom resolution at 24 weeks in the HP positive group and negative group was (187/255) [73.3%] and 136/634 [21.4%] respectively ( $X=209.380$ ;  $p\text{ value} < 0.001$ ). Symptom resolution/ improvement was defined as a 3 point reduction in the Likert scale.

**Conclusion:** 187/255 (73.3%) patients who had helicobacter pylori eradication had resolution of symptoms vs. the population of HP negative patients 136/634 (21.4%) at 6 months ( $p\text{ value} < 0.001$ ). Complete resolution of symptoms occurred in 38/187 (20.3%) of the HP treated patients. Of the various upper GI symptom clusters epigastric pain resolved the most and bloating the least on Likert scale. There is a high HP positivity rate in patients of a presumed diagnosis of functional dyspepsia. The eradication of H pylori seems to resolve the symptoms (albeit partially) of functional dyspepsia. The number needed to treat/harm is 2.

**Introduction:** The use of an optimal second-line regimen to eradicate *Helicobacter pylori* (*H. pylori*) infection refractory to the previous treatment prescribed is crucial in order to save antibiotics for future infections, specially considering the relevance of antibiotic resistance growth worldwide.

**Aims & Methods:** The aim was to evaluate the efficacy of the second-line treatments more frequently prescribed in a Spanish cohort arising from routine clinical practice. We conducted an observational, prospective, multicenter study, carried out in 48 Spanish hospitals as part of the 'Pan-European Registry on *H. pylori* management'. The project was provided by AEG-REDCap. Patients were included from February 2013 to January 2018 by Spanish gastroenterologists. A multivariate analysis was performed considering the most efficacious therapies. The sex of the patient, type of PPI (first vs. second-generation), type of PPI dose (simple vs. double), treatment duration (10 vs. 14 days), compliance and penicillin allergy, were considered for evaluation.

**Results:** 1,868 patients received a second-line eradication therapy in our cohort: 67% of them were women, 6% had penicillin allergy and their median age was 50±14 years. 90% of the patients had previously received a therapy containing clarithromycin. The therapies most frequently prescribed were (all of them including a proton pump inhibitor, PPI): triple therapy comprising levofloxacin and amoxicillin (T-LA, 43%), quadruple therapy adding bismuth to the triple therapy mentioned (Q-BLA, 22%), three-in-one single capsule bismuth containing metronidazole, bismuth and tetracycline (Q-SINGLE, 15%), triple therapy combining moxifloxacin and amoxicillin (T-MXA, 5%), and the non-bismuth quadruple concomitant therapy (Q-NBCT, 5%). 10% of the remaining patients received other minority therapies. Efficacy of these therapies was analyzed on a modified ITT (mITT) and PP basis. Results are shown in Table 1, depending on treatment duration. Good compliance was associated with higher efficacy in Q-BLA and T-LA therapies ( $p < 0.05$ ). The longer treatment duration (14 days) was also associated with higher efficacy in T-LA therapy ( $p < 0.001$ ).

	Duration (days)	mITT efficacy		PP efficacy	
		N included	mITT (95% C.I.)	N included	PP (95% C.I.)
T-LA	10	593	70% (66-74%)	564	73% (69-76%)
	14	193	86% (80-90%)	180	92% (87-95%)
Q-BLA	14	408	86% (82-89%)	375	91% (87-93%)
Q-SINGLE	10	263	82% (77-87%)	232	92% (88-95%)
T-MXA	14	69	86% (75-93%)	66	89% (79-96%)
Q-NBCT	10	39	77% (61-89%)	37	78% (62-90%)
	14	46	80% (66-91%)	45	82% (68-92%)

[Table 1: Efficacy obtained in mITT and PP basis with the five more common treatments used as second-line regimens.]

**Conclusion:** The best efficacy results (closer to 90%) as second-line therapies were obtained using quadruple therapy combining levofloxacin and bismuth, and triple therapies with amoxicillin and a quinolone (levofloxacin/moxifloxacin), all of them prescribed for 14 days.

**Introduction:** The impact of consensus, prescription choices and efficacy trends on clinical practice over time has not been studied in depth.

**Aims & Methods:** International multicenter prospective non-interventional registry starting in 2013 aimed to evaluate the decisions and outcomes of *H. pylori* management by European gastroenterologists. All infected adult

patients were systematically registered at AEG-REDCap e-CRF. *Variables included:* Patient's demographics, previous eradication attempts, prescribed treatment, adverse events, and outcomes. Intention-to-treat analyses were performed. Data monitoring was performed to ensure the quality of the data.

**Results:** So far 25,256 patients from 27 European countries have been included, 19,754 (77%) were naïve empirical prescriptions. Although, overall, the most common prescribed treatments in the 2013-18 period were triple therapies, a shift in antibiotic regimens was identified. Triple therapies decreased from over 50% of prescription in 2013/14 to less than 25% in 2017/18 while Pylera® has increased from 0-1% (2014/2015) to 25% (2018). Full description of most common treatments is shown in Table 1. Regarding the efficacy of each treatment no trend has been identified (data now shown), however there has been a 5% overall improve in first-line efficacy (Table 1).

**Conclusion:** European gastroenterological practice is constantly adapting to the newest published evidence and recommendations, and although this shift is delayed and slow, it improves clinical practice outcomes.

Treatment	2013	2014	2015	2016	2017	2018

**Introduction:** The best approach for *Helicobacter pylori* management remains unclear. Audit processes are essential to ensure that clinical practice is aligned with best standards of care.

**Aims & Methods:** International multicenter prospective non-interventional registry starting in 2013 aimed to evaluate the decisions and outcomes of *H. pylori* management by European gastroenterologists. All infected adult patients were systematically registered at AEG-REDCap e-CRF. **Variables included:** Patient's demographics, previous eradication attempts, prescribed treatment, adverse events, and outcomes. Intention-to-treat and per-protocol analyses were performed. Data monitoring was performed to ensure the quality of the data.

**Results:** So far, 21,487 first-line prescriptions from 27 European countries have been evaluated. Average age was 49 years, 60% women, and 18% had peptic ulcer. Pre-treatment resistance rates were: 24% to clarithromycin, 34% metronidazole, and 14% both. Drug prescription and efficacy is shown in the table. Triple therapy with amoxicillin and clarithromycin was the most commonly prescribed (45%), achieving, overall, < 80% eradication rate. Over 90% eradication was obtained only with 10-day bismuth quadruple therapies or 14-day concomitant treatment. Longer treatment duration, higher acid inhibition and compliance were associated with higher eradication rates in the multivariate analysis.

**Conclusion:** Triple therapies account for the majority of prescriptions, however, only quadruple therapies lasting at least ten days are able to achieve over 90% eradication rates.

Treatment	N	% Use	ITT	mITT	PP
PPI + C+A	8,374	39%	68.4%	84.2%	84.7%
PPI + C+A+M	4,156	19%	86.1%	90.0%	90.5%
PPI + C+A+B	1,525	7.1%	78.6%	92.8%	93.1%
PPI + M+Tc+B s.c.	1,520	7.1%	82.9%	94.7%	95.3%
PPI + C+A+T seq	1,166	5.5%	76.9%	91.3%	91.9%
PPI + C+M	1,043	4.9%	70.0%	81.1%	81.5%
PPI + C+A+M seq	608	2.8%	74.8%	81.0%	83.2%
PPI + A+M	560	2.6%	65.8%	85.4%	85.5%
PPI + A+L	404	1.9%	76.6%	81.4%	81.8%
PPI + M+Tc+B	188	1.3%	77.6%	93.1%	93.7%
PPI + C+A+T	172	0.9%	83.6%	94.9%	96.1%

ITT - intention to treat, PP - per-protocol, 95%CI - 95% confidence interval, PPI - proton pump inhibitor, Seq - sequential, C - clarithromycin, M - metronidazole, T - tinidazole, A - amoxicillin, L - levofloxacin, B - bismuth, Tc - tetracycline, s.c. - single capsule

[Overall first-line eradication rate per by treatment]

## P2034 WITHDRAWN

## P2035 APPLICATION OF SCREENING AND SCORING SYSTEM FOR THE ANALYSIS OF A NEW TYPE OF GASTRIC CANCER

Jinyong H.<sup>1</sup>, Ali R.W.<sup>1</sup>, Xiaojun H.<sup>1</sup>, Shanshan M.<sup>2</sup>, Kai X.<sup>2</sup>, Manan A.<sup>3</sup>, Akram M.A.<sup>3</sup>, Ahmad I.<sup>4</sup>, Yaoping Z.<sup>2</sup>, Haiyan W.<sup>2</sup>

<sup>1</sup>Lanzhou University Second Hospital, Internal Medicine/Gastroenterology, Lanzhou, China, <sup>2</sup>Lanzhou University Second Hospital, Lanzhou, China, <sup>3</sup>Lanzhou University, School of Life Science, Lanzhou, China, <sup>4</sup>Fudan University, School of Medicine, Shanghai, China

**Contact E-Mail Address:** rjwqrli@yahoo.com

**Introduction:** Approximately 500,000 deaths from gastric cancer reports in china annually. In addition, almost 680,000 new cases - half of which globally - attributed to the low rate of early screening and detection. High-risk groups over the age of 40 get screening for gastric cancer every year. Risk factors include having previously gastric illnesses suffering, immediate family member with gastric cancer, or antibodies for the *Helicobacter pylori* (Hp) bacteria. In China, almost 90 percent of the patients when detected for gastric cancer are already in the progressive stage.

**Aims & Methods:** To explore the screening and scoring system of a new type of gastric cancer and its application in gastric cancer screening for comprehensive analysis.

The 451 screened patients at gastric cancer risk from April 2018 to October 2018 were selected. According to the survey, serum pepsinogen (PGI, PGII, PGI/PGII) and gastrin 17 (G17) were determined by enzyme-linked immunosorbent assay. *Helicobacter pylori* positive rate was tested by a 13C urea breath test. According to the "China Early Gastric Cancer Screening Process Expert (of Shanghai) Consensus, 2017" scoring standard, the patients were

divided into three groups, i.e. low-risk groups (n=306), intermediate risk group (n=130) and high-risk group (n=15). All patients underwent gastroscopy, biopsy and pathological diagnosis for suspicious lesions under endoscopy.

**Results:** In the low-risk group, we detected 11 cases of low-grade intra-epithelial neoplasia (detection rate was 3.6%). In case of the intermediate-risk group, one was differentiated with adenocarcinoma (progressive phase), four were high-grade tumors (detection rate 3.1%) and 23 were found low-grade tumors (detection rate 17.7%). While in the high-risk group, there were two high-grade tumors (detection rate 13.3%) and nine low-grade tumors (detection rate 60%). Among them, the infection rate of *Helicobacter pylori* for the low-risk group, intermediate-risk group and high-risk group found was 33%, 51%, and 60%, respectively that showed an upward trend.

Groups	Total Cases	Hp		Hp Infection Rate	Main Pathology			
		Positive	Negative		Advanced Cancer	High Level Intra-epithelial Neoplasia	Low Level Intra-epithelial Neoplasia	Atrophic Gastritis
low-risk group	306	204	102	0.333333	/	/	11	227
Intermediate-risk group	130	64	66	0.507692	1	4	23	80
High-risk group	15	6	9	0.6	/	2	9	4

[Statistical Results: ]

**Conclusion:** According to our study, the high-risk groups of new gastric cancer screening and scoring system can effectively improve the detection rate of early gastric cancer. Furthermore, it will be helpful to secure a large number of therapeutic assets/resources in gastric cancer screening.

**Introduction:** Early detection and adequate surveillance of gastric precancerous lesions (GPL) may prevent the development of gastric cancer (GC) and reduce GC-related mortality. However, some patients with GPL are lost for follow up. The aims of this prospective study were:

- 1) to evaluate the feasibility and efficacy of a "phone-call" strategy to rescue the patients lost for follow-up, and
- 2) to assess the evolution of GPL in these patients.

**Aims & Methods:** Among all the patients diagnosed with GPL (atrophic gastritis, AG, intestinal metaplasia, IM, low grade dysplasia, LGD) in our center between January 2000 and December 2015, we identified those who according to the European MAPS guidelines [1] should undergo a surveillance endoscopy, who were under the age of 80, and who had no severe comorbidities. They were all contacted by phone (three calls) by a medical doctor, and invited to undergo a surveillance endoscopy. In those who accepted, the upper endoscopy was performed during which 5 random gastric biopsies (2 from the antrum, 1 from the angulus, and 2 from the corpus) were obtained for histological analysis performed by an expert pathologist with the evaluation of the presence of GPL and their severity. The results were compared to those of the initial endoscopy.

**Results:** Among the 535 patients with a GPL, 134 fulfilled the inclusion criteria and were contacted by telephone. Among them, 62 could not be joined, 16 were followed in another center, 8 agreed to participate but never came, 8 refused endoscopy, and 3 had endoscopy but without biopsies. Thus fi-

nally, 36 patients (27%) were included in the analysis. There were 22 males (61%), the mean age was 57 years at index endoscopy and 63 years at inclusion, and the mean duration of follow up was 65 months. At index endoscopy, 3 patients had AG, 27 IM, and 6 LGD. Nine patients (25%) were *H. pylori* positive and in all of them the bacterium was successfully eradicated. During the follow up, 7 patients (19%) showed a progression of GPL [1 from AG to IM, 4 from antrum- or corpus-limited IM to pangastric IM, 1 from IM to LGD, and 1 from extensive IM to GC which could be treated curatively (pT2pN0)]. Eleven patients (31%) showed regression of GPL (1 from AG to normal mucosa, 6 from IM to normal mucosa, 1 from pangastric- to corpus limited-IM, 3 from LGD to IM), and 18 patients (50%) showed stability of the lesions.

**Conclusion:** This study shows that:

- 1) despite several phone calls, a follow-up endoscopy could only be performed in a quarter of patients who had indication for control endoscopy according to the current guidelines, and
- 2) most of the patients showed stability of the GPL, but one patient progressed to GC and thanks to this strategy, he could be diagnosed on time and successfully treated.

**Introduction:** Although *Helicobacter pylori* (HP) eradication therapy (antibiotic therapy) has been established as the first line therapy for gastric mucosa-associated lymphoid tissue (MALT) lymphoma regardless of their HP infection status, therapeutic strategy for superficial gastric MALT lymphoma in patients not responding to antibiotic therapy (non-responders) has been an important issue to be solved. Watch & wait strategy has been assumed to be a choice after antibiotic therapy, however, the malignant potential of the disease remains uncertain.

**Aims & Methods:** We analyzed the long-term outcome of watch & wait strategy for non-responders. During the period between January 1995 and January 2017, 119 patients received antibiotic therapy as the first-line therapy for superficial gastric MALT lymphoma. Among them, we selected 45 patients who met the inclusion criteria;

- a) the first-line therapy of antibiotic therapy could not lead complete response of the disease,
- b) watch & wait strategy was subsequently applied for at least a year in case no disease progression,
- c) the disease confined to either mucosal layer or submucosal layer under endoscopic ultrasonography.

Clinical data were collected by reviewing electrical medical records, and long-term outcome of superficial gastric MALT lymphoma occurring in HP-negative patients (HP-negative disease) was analyzed by comparing the outcome occurring in HP-positive patients (HP-positive disease).

Overall survival rate (OSR) and progression free survival rate (PFSR) were calculated by the Kaplan-Meier method and the values were compared using the log-rank test. We also compared clinicopathological features between HP-negative and HP-positive diseases.

**Results:** The study subjects comprised 25 HP-negative disease and 20 HP-positive disease, and the mean follow-up period was 56 months [range; 9-224 months]. OSR of the study subjects at 5 and 10 years after HP eradication were 100% and 92%, and PFSR at 5 years was 53%. PFSR was significantly higher in HP-negative disease than in HP-positive disease (PFSR at 5 years; 73% vs 27%, p=0.0026). Age ≤ 60 years (16/25 vs 5/20), the disease confined to the mucosal layer (20/25 vs 8/20), and superficially spreading

type in morphology (22/25, 11/20) were significantly more frequent in HP-negative disease than in HP-positive disease. Eleven patients (55%) in HP-positive disease and 4 patients (16%) in HP-negative disease experienced disease progression. Interestingly, the progression pattern was obviously different between HP-positive disease and HP-negative disease (enlargement of gastric lesion/extra-gastric lesion, 10/1 vs 0/4,  $p=0.0027$ )

**Conclusion:** Careful follow-up by EGD seems appropriate to monitor disease progression of superficial gastric MALT lymphoma in non-responders. In HP-negative patients with MALT lymphoma, watch & wait strategy can be reasonable after antibiotic therapy, however, careful follow-up using systemic imaging modalities should be necessary.

**Contact E-Mail Address:** jamalsara24@gmail.com

**Introduction:** *Helicobacter pylori* (Hp) is a pathogenic bacterium that contributes to an inflammatory reaction of the gastric mucosa. The extent and severity of gastric mucosal inflammation, as well as the occurrence of pre-neoplastic lesions (atrophy and intestinal metaplasia), depend on a number of factors that are related to the bacterium, host, and environmental factors.

**Aims & Methods:** The aim of this work is to study the gastric lesions associated with Hp infection, and to determine the relationship between bacterial density and the appearance of gastric histological lesions.

We performed a single-centric prospective study from March 2014 and March 2019. We included 406 patients who benefited from high endoscopy and who had Hp infection documented on a histological study of gastric biopsies.

**Results:** The average age of patients was 43.9 years (range, 15 to 87 years). The sex ratio (H / F) was 1.23. Chronic smoking was found in 17.9% of cases. The frequency of antritis and moderate to severe chronic funditis was 78.5% and 40.5% respectively. Moderate to severe activity was noted in 48.5% at the antrum in 21% at the fundus. The incidence of gastric atrophy and intestinal metaplasia was 12.7% and 7.2%, respectively. The density of HP was higher in the antrum than in the fundus (67.2% vs. 26.8% respectively). In univariate analysis, only antral and fundic gastritis activity was significantly associated with bacterial density (OR: 4.3, 95% CI (2.7 - 6.8)  $p < 0.001$ , OR: 5.9, 95% CI (3.5 - 9.9)  $p < 0.001$  respectively).

**Conclusion:** In our study the density of *Helicobacter pylori* significantly influences the activity of gastritis. We found no correlation between bacterial density and gastric pre-neoplastic lesions. Other studies with large case series including other factors, including the genetic profile of *Helicobacter pylori*, are needed.

## P2039 IS IT WORTH TO SCREEN THE PATIENTS FOR PRENEOPLASTIC GASTRIC LESIONS AND HELICOBACTER PYLORI?

Bataga S.M.<sup>1</sup>, Macarie M.<sup>2</sup>, Negovan A.<sup>2</sup>

<sup>1</sup>Clinical Emergency County Hospital, First Clinic of Gastroenterology, Targu Mures, Romania, <sup>2</sup>University of Medicine and Pharmacy, Targu-Mures, Romania

**Contact E-Mail Address:** simonabataga@yahoo.com

**Introduction:** In spite of declining incidence in the last years, gastric cancer (GC) is still the fifth most common cancer in the world, however, GC is the third worldwide cause of mortality from malignant diseases.

The prevention of GC includes the primary prevention: eradication of *Helicobacter pylori* (HP) and secondary prevention: the detection, surveillance and/or treatment of the preneoplastic lesions.

As it is known, the first step in carcinogenesis initiation process is the colonization of the gastric mucosa with HP. Identifying and surveillance in patients with these gastric preneoplastic lesions leads to early diagnosis of gastric cancer with more treatment options and an improvement in survival rate.

**Aims & Methods:** The purpose of this study was to determinate the incidence of gastric preneoplastic lesions from several points of view: gender, age, histopathology type, and the presence of the HP and to evaluate the best time for screening.

Upper digestive endoscopy has been performed in 12541 patients with dyspeptic syndrome in First Gastroenterology Clinic from Targu Mures, from 2014-2018. Patients with hemorrhage were excluded from the study. In all the patients gastric biopsies and histopatological exam were made, OLGA classification was used.

**Results:** In 2131 patients (52.9% males and 47.1% females) were found gastric changes. Histopathologically, 32.7% of the patients had atrophic gastritis, 43.1% intestinal metaplasia (23.7% complete metaplasia and 19.4% incomplete metaplasia) and 0.7% dysplasia. Active gastritis/pangastritis with HP was identified in 59.3% of the patients. In 4.8% of cases there were revealed polyps (hyperplastic, adenomatous) and were removed. The incidences of preneoplastic lesions reported to the total numbers of patients were: 5.55% atrophic gastritis, 7.30% intestinal metaplasia and 0.11% dysplasia.

The premalignant lesions were present mostly in the patients between 60 and 70 years. There was no statistically significant difference between males and females ( $P>0.05$ ) regarding the incidence of preneoplastic lesions.

**Conclusion:** HP was identified in more than half of the patients, so HP has still a high incidence in Romania. After the age of 60 is worth to screen the patients by endoscopy or to perform non-invasive tests like pepsinogen. Women are as much exposed as man to premalignant gastric lesions after 60 years

## P2040 A SPECIALTY PHARMACY COHORT STUDY EVALUATING THE EFFECTIVENESS OF TEDUGLUTIDE IN SUBGROUPS OF SHORT BOWEL SYNDROME PATIENTS RECEIVING PARENTERAL SUPPORT DEFINED BY BOWEL ANATOMY

Chen K.<sup>1</sup>, Yang H.<sup>2</sup>, Zhao J.<sup>2</sup>, Briggs A.<sup>2</sup>

<sup>1</sup>Shire Human Genetic Therapies, Inc., a Member of the Takeda Group of Companies, Cambridge, United States, <sup>2</sup>Analysis Group, Inc., Boston, United States

**Contact E-Mail Address:** kristina.chen@takeda.com

**Introduction:** This specialty pharmacy cohort study assessed the effectiveness of teduglutide in reducing parenteral support (PS) in patients with short bowel syndrome-associated intestinal failure (SBS-IF) across anatomy subgroups.

**Aims & Methods:** Adult patients with SBS-IF who received PS and teduglutide (2013Q1-2017Q2) from Option Care, a specialty pharmacy in the United States, were classified into anatomy subgroups as defined in Jeppesen et al. 2018: 1) stoma group (defined as 0% colon remaining, stoma, and no colon-in-continuity), 2)  $\geq 50\%$  colon remaining group (defined as  $\geq 50\%$  colon remaining, no stoma, and colon-in-continuity), 3)  $>0-<50\%$  colon remaining group. Response ( $\geq 20\%$  reduction in weekly PS volume) and weaned off (weekly PS volume of 0) rates during follow-up and time to first response/weaned off were summarised.

**Results:** The 23 patients in the study included 10 in the stoma group (mean $\pm$ SD age, 57.2 $\pm$ 9.0 years) and 13 in the  $\geq 50\%$  colon remaining group (54.2 $\pm$ 16.2 years). No patients had colon remaining between 0% and 50%. Crohn's disease was the most common reason for bowel resection in patients with stoma (70.0%) and patients with  $\geq 50\%$  colon remaining (36.4%). Before teduglutide initiation, mean duration of SBS was 11.4 $\pm$ 10.6 and 12.2 $\pm$ 12.6 years, duration of PS was 4.4 $\pm$ 2.5 and 9.5 $\pm$ 10.7 years, and PS volume was 12.4 $\pm$ 6.3 and 11.5 $\pm$ 5.5 L/week in patients with stoma and  $\geq 50\%$  colon remaining, respectively. After teduglutide initiation, among 10 patients with stoma (mean follow-up duration 24.2 $\pm$ 18.1 months), 7

(70.0%) achieved response and 5 (50.0%) weaned off PS; mean time to first response and weaning off was 9.8±11.5 and 17.7±14.7 months, respectively. Among 13 patients with ≥50% colon remaining (mean follow-up duration, 32.0±14.8 months), 10 (76.9%) achieved response and 6 (46.2%) weaned off PS; mean time to first response and weaning off was 2.7±2.6 and 10.2±14.2 months, respectively.

**Conclusion:** Teduglutide reduced weekly PS volume and patients with SBS-IF achieved weaning off across anatomy subgroups. The response rate to teduglutide is consistent with findings from prior clinical trials but time to response and PS-wean off differ, which may reflect differences in SBS-IF management between clinical trials and real world use, and care with or without the expertise of a Center of Excellence multidisciplinary team. Further research is warranted to confirm current findings.

## P2041 PREDICTIVE POTENTIAL OF BIOMARKERS OF INTESTINAL BARRIER FUNCTION FOR THERAPEUTIC MANAGEMENT WITH TEDUGLUTIDE IN PATIENTS WITH SHORT BOWEL SYNDROME

Büttner J.<sup>1</sup>, Maasberg S.<sup>1,2</sup>, Bochow B.<sup>1</sup>, Naranjo S.<sup>1</sup>, Werich M.<sup>1</sup>, Pape U.-F.<sup>1,2</sup>

**Contact E-Mail Address:** ul.pape@asklepios.com

**Introduction:** Teduglutide, an analog of glucagon-like peptide 2, improves intestinal rehabilitation in chronic intestinal failure frequently caused by short bowel syndrome (SBS). However, the mechanisms in the intestinal barrier related to regulation of intestinal permeability (IP) during adaptive response or therapy are not well understood. We analyzed whether measurement of IP or gene expression analysis from mucosal biopsies of selected candidate genes likely associated with IP are useful biomarkers to describe the regulation mechanisms in the intestinal barrier in patients with SBS with or without teduglutide therapy.

**Aims & Methods:** IP was assessed using a sugar drink test containing lactulose and mannitol and urinary recovery rate was used to determine lactulose/mannitol ratio. Gene expression analyses of mucosal biopsies was performed using qRT-PCR Quantitec Primer Assays for tight junction genes and epithelial markers.

**Results:** SBS patients (n=29) showed increased Lac/Man ratio compared to healthy controls (HC, n=34), (p=0.0001). Mannitol recovery was decreased in SBS (Mean HC 13.8% vs. SBS 5.4%, p= 0.0001), whereas lactulose recovery was similar to HC (mean HC 0.21% vs. SBS 0.36% p= 0.2). qRT-PCR analyses showed significant differences in gene expression between SBS patients (n=30) and HC (n=7) for YBX3 p=0.048, CRB3 p=0.009, CDK4 p=0.048, CASK p=0.03, and SI p=0.02.

For 12 patients, gene expression data were analyzed before and after up to 12 month of teduglutide treatment. Significant differences in gene expression were received for CASK p=0.01 and SI p=0.028. Further, analysis of citrullin levels in this cohort showed increased citrullin levels in patients with teduglutide therapy (p=0.012).

**Conclusion:** The analysis of IP gave first insights into changes of intestinal sugar absorption but has not yet been established in SBS patients. Further paired and controlled studies are required to evaluate the specific influence of both altered bowel anatomy and/or changes in barrier function. Furthermore, altered specific gene expression was shown for both, tight junction formation and genes involved in nutrient transport and should be further analyzed.

**Disclosure:** Nothing to disclose

## P2042 GOTHENBURG INTESTINAL TRANSPLANT ENDOSCOPY SCORE: A PROSPECTIVE, SINGLE CENTER EVALUATION

Varkey J.<sup>1,2</sup>, Herlenius G.<sup>3</sup>, Pischel A.<sup>1</sup>, Yamamoto S.<sup>1</sup>, Oltean M.<sup>3</sup>

<sup>1</sup>Sahlgrenska Universitetssjukhuset, Division of Gastroenterology, Department of Internal Medicine, Göteborg, Sweden, <sup>2</sup>Cambridge University Hospitals NHS Foundation Trust, Cambridge Intestinal Failure and Transplant, Cambridge, United Kingdom, <sup>3</sup>Sahlgrenska University Hospital, Transplantation Institute, Göteborg, Sweden

**Contact E-Mail Address:** jonas.varkey@nhs.net

**Introduction:** The results of intestinal transplantation have drastically improved during the last decade. However, the major factor that influences the survival is the presence of acute rejection. In the absence of timely treatment rejection may rapidly evolve towards mucosal loss, which is associated with a poor outcome.

Microscopic examination of the endoscopic biopsies forms the basis of acute cellular rejection monitoring today. Nevertheless, the findings during endoscopy in acute cellular rejection (ACR) are well-known, but a grading system for its severity is lacking. Gothenburg Intestinal Transplant Endoscopy Score (GITES) is a novel, five-stage endoscopic score constructed by us aiming to describe and categorize the endoscopic findings after intestinal transplantation<sup>1</sup>. In theory, this system could result in a more objective evaluation of the visual findings and subsequently a faster diagnosis of rejection

**Aims & Methods:** We prospectively graded the endoscopic findings with GITES in 13 adult patients (3 isolated intestinal grafts, 10 multivisceral grafts) at one single center using white light high definition endoscopy systems. The scoring was performed by the endoscopist at the time of endoscopy and later we correlated the results with histology. Our aim with this study was to establish the usefulness of GITES in diagnosing acute cellular rejection.

**Results:** Eighty-five ileoscopies were performed between January 2015 to feb 2019. In 52 (61%) cases the endoscopic findings were normal. Twenty-three (69%) out of the 33 abnormal endoscopies revealed mild alterations represented by mild/moderate edema, erythema or blunted villi (GITES 1 and 2). Acute rejection was found in biopsies from 11 (14%) endoscopy sessions (4 mild & 7 moderate/severe) and in three specimens the biopsies revealed CMV enteritis. GITES above 1 (erythema, edematous villi) had 91% sensitivity and 94% specificity for ACR whereas positive (PPV) and negative predictive values (NPVs) were 78% and 98%, respectively. During moderate and severe ACR, GITES revealed an 87% sensitivity and 94% specificity whereas positive (PPV) and negative predictive values (NPVs) were 78% and 98% respectively

**Conclusion:** This study suggest that evaluation of the endoscopic findings with GITES results in a satisfactory identification and stratification of rejection. A prospective, multicentre evaluation is needed.

**Contact E-Mail Address:** yokamoto@intmed2.med.kyushu-u.ac.jp

**Introduction:** We previously demonstrated an exacerbating effect of proton pump inhibitors (PPI) on small bowel injuries by nonsteroidal anti-

inflammatory drugs (NSAID) in the randomized, double-blind, placebo-controlled trial [1]. However, when considering the prevention of upper GI damage by NSAIDs, simultaneous medication of NSAID and PPI is reasonable. Thus, preventive measures for small bowel injuries by NSAID and PPI need to be determined.

**Aims & Methods:** We aimed to ascertain the influence of *Lactobacillus salivarius* WB21 on small bowel injuries using capsule endoscopy (CE) in subjects who take both NSAID and PPI.

Sixty healthy subjects were randomly assigned into two groups; one given celecoxib (200 mg, twice daily), rabeprazole (20 mg, once daily) and placebo for 2 weeks (placebo group, n=30), and the other given celecoxib, rabeprazole and *Lactobacillus salivarius* WB21 ( $7.0 \times 10^8$  CFU, twice daily) for 2 weeks (WB21 group, n=30). The subjects completed questionnaires about GI symptoms, and laboratory tests and CE before and after 2 weeks' medication. We then compared the incidence and the numbers of small bowel mucosal lesions determined by second CE between WB21 and placebo groups. We also compared positive rates of GI symptoms and anemia between the two groups. In the present study, patients in whom small bowel mucosal lesions were identified by initial CE were omitted in the data analysis.

**Results:** Fifty-seven patients (27 subjects in the WB21 group and 30 subjects in the placebo group) underwent the full analysis. The incidence rate of small bowel ulcers was significantly lower in the WB21 group than the placebo group (14.8% vs. 40.0% respectively;  $P=0.043$ ). In addition, the mean number of ulcers was significantly smaller in the WB21 group than the placebo group (0.7 vs. 1.1 respectively;  $P=0.049$ ). However, the incidence rates and the mean number of small bowel erosion did not differ between the two groups. GI symptom score by Gastrointestinal Symptom Rating Scale did not differ between the two groups, and no subject developed anemia after the medication.

**Conclusion:** *Lactobacillus salivarius* WB21 seems to exert preventive effect on small bowel mucosal injuries in subjects taking NSAID and PPI simultaneously.

**Introduction:** Teduglutide (TED) is a medical treatment for functional rehabilitation of short bowel syndrome (SBS) in patients with chronic intestinal failure (cIF). Its application and effectivity is routinely monitored by a structured home care service program within a multicentric approach in Germany.

**Aims & Methods:** From these prospectively documented data, a retrospective data base was generated in order to study treatment characteristics and outcome parameters in a clinical routine setting of TED-treated cIF-patients. An interim analysis for TED treatment characteristics up to one year is presented. Statistical analyses were performed with SPSS by using Friedman-Test with subsequent Bonferroni-adjusted post-hoc analyses and Spearman's Rank-Order Correlation.

**Results:** So far, 44 patients (f:26 / m:18, median age 53 years) were included in this interim analysis. Causes of SBS included vascular (n=13) and inflammatory diseases (n=16), ileus (n=6), injury (n=5) and others (n=4). Median time on parenteral support (PS) before TED was 31 (range 3 - 301) months. At TED start, 64% of patients (28/44) received individually compounded parenteral nutrition (PN), 18% (8/44) received standard-

ized PN; the remaining patients received either no parenteral support although medically indicated (n=3), solely intravenous fluid support (n=3) or support details were unknown (n=2). PS was administered by patients themselves (n=17), by relatives (n=3), by nurses (n=13) or others/unknown (n=3/5). TED treatment resulted in a significant reduction in PN calories and volume requirements as well as reduced infusion days per week and shortened infusion times (see Table 1).

	i.v.-Volume per week [L]	i.v.-Energy per week [kcal]	PN-Infusion time per serving [h]	PN days per week
Baseline	12.8 (±7.5)	7,119 (±4,475)	10.6 (±3.8)	5.0 (±2.4)
Week 12 ± 1	11.3 (±7.1)	6,315 (±4,454)	10.3 (±4.0)	4.4 (±2.3)*
Week 24 ± 3	10.4 (±6.8) **	5,425 (±4,517) **	9.5 (±4.9)	3.8 (±2.6)***
Week 49 ± 6	9.6 (±7.3) **	5,254 (±4,719) **	7.9 (±5.5) **	3.6 (±2.8)***

[Parenteral support characteristics on teduglutide treatment. n=34;  $p<0.05$ , \*\*  $p<0.01$ , \*\*\*  $p<0.001$  vs. baseline; PN = parenteral nutrition; Mean (SD)]

The reduction of infusion time was positively correlated with the reduction of PN volume ( $p<0.001$ ;  $r=0.63$ ) and calories ( $p=0.001$ ;  $r=0.58$ ) after one year of TED treatment. After one year, 29 of 39 patients (74%) were considered responders to TED treatment (with a minimum of 20% i.v.-volume reduction).

**Conclusion:** In this multicentric real-world analysis of PS-dependent SBS/cIF-patients, TED shows effectivity in improving intestinal absorptive function as indicated by significantly reduced weekly i.v.-volume and calorie requirements. In addition, the findings demonstrate a reduction of effective infusion days and times, which both importantly affect patients' well-being. These data indicate the effectivity of TED treatment in a national routine treatment setting in concordance with clinical trial data and guideline recommendations.

## P2045 BONE MARROW MESENCHYMAL STEM CELL CONDITIONED MEDIUM WITH INFLAMMATORY ACTIVATION FOR REPAIR OF RADIATION-INDUCED IEC-6 CELL INJURY

Chen H.<sup>1,2</sup>, Luo Y.<sup>1</sup>, Sha W.<sup>1,3</sup>

**Contact E-Mail Address:** 464695938@qq.com

**Introduction:** Conditioned medium from mesenchymal stem cells (MSC-CM) may represent a promising alternative to MSCs transplantation. Our previous study has demonstrated that MSC-CM with inflammatory activation improves the structural and functional restoration of the small intestine after radiation-induced intestinal injury, improve the survival status of rats with acute radiation injury, but its potential cellular mechanism has not been further explored.

**Aims & Methods:** To observe the effect of MSC-CM with inflammatory activation on the proliferation and apoptosis of intestinal epithelial cells (IEC-6) after radiation injury and to investigate the cellular mechanism of pre-activated MSC-CM in repairing the small intestinal mucosa. : IEC-6 cells were divided into four groups: control group, radiation injury group, normal MSC-CM (MSC-CMIEC-6(NOR)) group and inflammatory pre-activated MSC-CM (MSC-CMIEC-6(IR)) group. IEC-6 cells in the latter three groups were exposed to 10 Gy X-ray irradiation and cultured in DMEM-F12 medium, MSC-CMIEC-6(IR) and MSC-CMIEC-6(NOR) respectively. Cells in the control group were only cultured in DMEM-12 medium. Cultured cells were collected at 3 days after radiation to observe the proliferation of IEC-6 cells by using proliferating cell nuclear antigen immunofluorescence staining, and to observe the apoptosis by using TUNEL apoptosis staining and western blot assay.

**Results:** Compared with the radiation injury group, in the MSC-CMIEC-6(IR) group, the number of cells positive for proliferating cell nuclear antigen increased significantly ( $P<0.05$ ), the number of TUNEL positive cells decreased significantly ( $P<0.05$ ), and the expression of Caspases-3 decreased significantly ( $P<0.05$ ). However, there was no significant difference between the MSC-CMIEC-6(NOR) group and radiation injury group ( $P>0.05$ ).

**Conclusion:** Taken together, MSC-CMIEC-6(IR), but not non-activated MSC-CM, significantly promotes the proliferation and reduces apoptosis of intestinal epithelial cells after radiation injury and therefore repair the injured intestinal tissue.

**Disclosure:** Nothing to disclose

## **P2046** GINSENOSE Rg1 ENHANCES THE PARACRINE EFFECTS OF BM-MSCS ON RADIATION INDUCED INTESTINAL INJURY

<sup>1</sup>Guangdong Provincial People's Hospital, Gastroenterology, Guangzhou, China, <sup>2</sup>Guangdong general hospital, Guangdong general hospital, GuangZhou, China, <sup>3</sup>Guangdong General Hospital Dept. of Gastroenterology, Gastroenterology, Guangzhou, China

**Contact E-Mail Address:** 464695938@qq.com

**Introduction:** Radiation induced intestinal injury(RIIL) is commonly seen in patients with intra-abdominal and/or pelvic malignancy. However, there are still no effective strategies in treating this life-threatening disease. Stem cell therapy using pleiotropic mesenchymal stromal cell(MSCs) seems to be one of the most promising therapies for treating the adverse effects related to the radiotherapy. However, the amounts of active molecules secreted by MSCs under normal condition are too low to reach the effective therapeutic concentrations, and thus couldn't exert its beneficial effect on tissue reparation. Ginsenoside Rg1 is available to promote proliferation and differentiation of stem cells and plays an important role in tissue repair. Therefore, it's becoming an ideal stimulatory factor for stem cells to enhance the therapeutic effect of MSCs[18, 19]. There were few studies reporting that Rg1 could increase the concentrations of VEGF, G-CSF around the damaging tissue, raising the idea of its potential on regulating paracrine[18, 20, 21]. Therefore, we used Rg1 to stimulate MSC and explored whether the paracrine effect was improved and if there's any therapeutic benefits on RIIL.

**Aims & Methods:** We used Rg1 to stimulate MSC and explored whether the paracrine effect was improved and if there's any therapeutic benefits on RIIL. For all the vivo experiments, 2 ml DMEM-F12 or concentrated conditioned medium with different concentrations of Rg1, Rg1 with or without neutralizing antibodies were injected intraperitoneally.

**Results:** Systemic infusion of Rg1-MSC-CM, but not MSC-CM, significantly improved intestinal damage and survival of RIIL rats. We found that the level of VEGF and IL-6 were significantly higher in Rg1-MSC-CM than MSC-CM. Further antibody neutralizing investigations confirmed that VEGF and IL-6 were two most key factors in Rg1-MSC-CM-mediated tissue repair. We explored the mechanism and enhancing effects of Rg1 on MSC paracrine. It has been found that PI3K/Akt signaling pathway is essential in epithelial survival and neoangiogenesis<sup>[24]</sup>. What's more, the activation of PI3K-AKT pathway can enhance the expression of VEGF and IL-6<sup>[25]</sup>. Some investigators found that Rg1 could activate the PI3K-AKT pathway by binding to glucocorticoid receptor<sup>[20, 27]</sup>. As expected, through examining the related molecules involved in this pathway, we found that the concentration of phosphorylated-AKT, IKK increased significantly with the utilization of Rg1. In addition, nuclear translocation was enhanced by activating NF-κB. On the contrary, after using the corresponding inhibitor of NF-κB(BAY11-7082), the increased expression of IL-6 and VEGF and even the therapeutic effect of Rg1-MSC-CM were canceled out. This suggested that the PI3K-AKT/NF-κB pathway was critical in the Rg1-mediated paracrine enhancement of MSC. Further investigation on CHIP studies showed that there were several binding sites for NF-κB on the gene promoter of VEGF and IL-6, which further confirmed the hypothesis that Rg1 could activate NF-κB via the PI3K-AKT pathway, increase the expression of VEGF and IL-6 secreted by MSC and thus play a role in RIIL.

**Conclusion:** The present study showed that Rg1 could enhance the paracrine effect of MSC for VEGF and IL-6, which helped to promote tissue repair in RIIL. This indicated that Rg1 could be served as a promoter in stem cell therapy for treating RIIL.

## **P2047** IN ADULT COELIAC DISEASE HISTOLOGICAL RECOVERY AND PERSISTENT VILLOUS ATROPHY SEEM SIMILAR AFTER 1 AND 2-3 YEARS OF ADEQUATE GLUTEN-FREE DIET

Galli G.<sup>1</sup>, Conti L.<sup>1</sup>, Lahner E.<sup>1</sup>, Cazzato M.<sup>1</sup>, Esposito G.<sup>1</sup>, Magi L.<sup>1</sup>, Pillozzi E.<sup>2</sup>, Annibale B.<sup>1</sup>

<sup>1</sup>Sant'Andrea Hospital, Sapienza University of Rome, Department of Medical-Surgical Sciences and Translational Medicine, Rome, Italy, <sup>2</sup>Sant'Andrea Hospital, Sapienza University of Rome, Pathology Unit, Department of Clinical and Molecular Medicine, Rome, Italy

**Contact E-Mail Address:** lau88.conti@gmail.com

**Introduction:** In adult coeliac disease (CD) the gold standard to assess duodenal mucosal recovery after gluten-free diet (GFD) should be histological control through duodenal biopsies taken by esophagogastroduodenoscopy. Timing and effective need of this follow-up is nowadays debated. Only a limited percentage of CD patients achieve complete histological recovery after 1 year of adequate GFD<sup>1</sup>. Refractory CD is defined as persistent villous atrophy associated to malabsorptive signs or symptoms despite adequate GFD for more than 12 months, but data on the timing and occurrence after GFD are scarce and conflicting<sup>2,3</sup>

**Aims & Methods:** The study's first aim was to verify if longer histological control is able to obtain higher percentage of complete histological recovery. Second aim was to determine number of patients with refractory coeliac disease at 1 and 2-3 years of follow-up.

Longitudinal cohort study of 168 CD adult patients (F=72%; median age=38, range 18-71 years) followed from 2009 to 2018, who randomly underwent endoscopic/histological control after adequate GFD (Biagi-questionnaire score 3-4) at 1 year (Group 1 n=113 patients; mean follow-up 13±1.6 months) or 2-3 years (Group 2 n= 55 patients; mean follow-up 27.2±4.8 months). Anthropometric, clinical, serological data and duodenal histology (at baseline and follow-up) were compared between Group 1 and Group 2. Total histological recovery was defined as absence of villous atrophy and < 30/100 intraepithelial lymphocytes, partial histological recovery as improvement of at least one grade of the Marsh classification while no histological recovery as the total absence of improvement compared to the baseline histology at CD diagnosis. Refractory coeliac disease was defined as persistence of villous atrophy associated to gastrointestinal symptoms and biochemical alterations, when excluded other causes of villous atrophy.

**Results:** Total and partial histological recovery were similar in Group 1 and Group 2 (Total recovery: 61.9% vs 54.5%, respectively; p=0.40; partial recovery 36.3% vs 38.2%, respectively; p=0.86). No histological recovery was slightly more frequent in Group 2 although statistical significance was not reached (1.8% in Group 1 vs 7.3% in Group 2; p=0.09). Features at baseline and at follow-up (gender, median age, GI symptoms, CD specific antibodies and Marsh 3C) were similar between groups. Villous atrophy persisted in 27 (23.9%) Group 1 patients and in 14 (25.5%) Group 2 patients (p=0.84). In 1 (0.9%) Group 1 patient and 1 (1.8%) Group 2 patient (p=0.59) with persisting villous atrophy, presence of severe gastrointestinal symptoms, antibodies positivity and/or biochemical alterations were associated, thus displaying a clinical picture of refractory CD. Between patients with no histological recovery, 2 (100%) patients in Group 1 and 3 patients (75%) in Group 2 reported improvement or resolution of their diagnosis symptoms.

**Conclusion:** Total, partial and no histological recovery similarly occurs after 1 and 2-3 years of adequate GFD. Villous atrophy persists in about one forth of patients in both Groups. Features of refractory celiac disease are infrequent (1.2% of the total population) and occur in similar proportions after 1 or 2-3 years of adequate GFD. Thus, in adult CD patients histological recovery and occurrence of refractory CD after adequate GFD seem not to be time-dependent, and the first histological follow-up after 2-3 years of adequate GFD seems to be safe.

**Contact E-Mail Address:** knut.lundin@medisin.uio.no  
**Introduction:** The objective of the study is to describe celiac disease (CeD) outcomes and monitoring patterns in patients with CeD in the United Kingdom (UK), USA, and Norway.  
**Aims & Methods:** A retrospective medical chart review study was performed at three gastroenterology centres. Data from medical charts of patients with biopsy-confirmed CeD, who were diagnosed between 2008 and 2012 and who had at least one follow-up before December 31, 2017, were collected. Patients were classified into four groups at diagnosis and follow up: 1: no symptoms & normal duodenal histology; 2: no symptoms & abnormal duodenal histology; 3: symptoms & normal duodenal histology; and 4: symptoms & abnormal duodenal histology. Any biopsy results other than normal or increased intraepithelial lymphocytes were considered abnormal. Symptoms included in this classification were diarrhoea, abdominal pain/distention, poor appetite, weight loss, tiredness/lethargy, brain fog, malabsorption and bloating.  
**Results:** To date, 200 eligible patients were included (100 in Norway, 100 in the USA). Data collection is currently ongoing at the UK site. Patients were 72.5% female with a median age at diagnosis of 35 years (IQR: 23-48), and a median follow-up of 26.5 months (IQR: 12-51.5). Overall, 52% presented with diarrhoea, 49% had abdominal pain, 38.5% had nutritional deficiencies, 32% experienced bloating and 11.5% presented with anaemia. At diagnosis, 17.5% and 82.5% were in class 2 and 4 respectively. All patients were advised to commence a gluten free diet (GFD) after diagnosis, and 4 patients discontinued the GFD during follow-up. Adherence to the GFD was not assessed. Ninety-three (46.5%) patients reported symptoms following acute gluten exposure while attempting to follow a GFD. After esophagogastroduodenoscopy (55%), bone densitometry was the next most frequent (33.5%) procedure performed during follow-up, where 45% of US patients received this procedure compared to 22% of Norwegian patients. One hundred and eight (54%) patients underwent at least one follow-up duodenal biopsy, which comprised 26% and 82% of US and Norwegian patients respectively. Of these 108 patients, 4% of US patients and 25% of Norwegian patients had ≥ 2 follow-up biopsies after diagnosis. However, the US site had a greater number of follow-up visits and longer follow-up duration compared to the Norway centre. During follow-up, 68% had persistent CeD-related gastrointestinal symptoms, 40.5% had nutritional deficiencies, and 26.5% had tiredness/lethargy indicated in their charts. Of the patients with a follow-up biopsy, the median follow-up time from diagnosis to last biopsy result within the study period was 25.5 months (IQR: 12-45), and 38 patients (36%) had persistent villous atrophy at this time regardless of symptoms (Table 1). Patients with persistent atrophy were significantly older at diagnosis (43 vs. 35 years old, p<0.01).

Baseline disease class	N <sup>†</sup>	During follow-up, n (%)			
		Class 1	Class 2	Class 3	Class 4
Class 2 (n=35)	18	9 (50%)	2 (11.1%)	4 (22.2%)	3 (16.7%)
Class 4 (n=165)	88	34 (38.6%)	14 (15.9%)	21 (23.9%)	19 (21.6%)

Class 1: No symptoms & normal duodenal histology; Class 2: No symptoms & abnormal duodenal histology; Class 3: Symptoms & normal duodenal histology; Class 4: Symptoms & abnormal duodenal histology. <sup>†</sup>Considered only the last symptoms and biopsy results available during the follow-up period. 17 subjects in class 2 and 75 subjects in class 4 at baseline did not have any available biopsy results during the follow-up period. <sup>‡</sup>2 subjects with follow-up biopsy results as „other“ were excluded from this analysis.

[Changes in celiac disease class from baseline through follow-up (N=108)\*]  
**Conclusion:** Follow-up biopsy is not universally conducted even at large referral centres. Initial findings suggest a large proportion of patients continue to have abnormal duodenal histology and/or ongoing symptoms after diagnosis despite GFD. Further, the majority of patients continue to experience gastrointestinal symptoms after diagnosis.

**Contact E-Mail Address:** song.wang@takeda.com  
**Introduction:** Strict adherence to a gluten-free diet (GFD) is the sole treatment option for patients with celiac disease (CeD). Many patients still experience symptoms and develop complications of the disease, as well as bear additional burden due to maintaining the GFD (1-6).  
**Aims & Methods:** The objective of the study is to assess the burden of CeD and treatment experiences through a multi-country patient survey. A cross-sectional survey was developed, in collaboration with patient advocates, clinicians, outcomes researchers and patients with CeD. Survey questions included socio-demographic and clinical characteristics, symptoms, and patient-reported outcome (PRO) measures, e.g., the Celiac Symptom Index (CSI), Celiac Dietary Adherence Test (CDAT), and Work Productivity and Activity Impairment Questionnaire (WPAI). CeD severity was self-reported as mild, moderate, severe, or very severe. Adult participants were eligible if they had self-reported biopsy-confirmed CeD (or serology with family history of CeD) and on a GFD for ≥6 months. Participants are being recruited through patient advocacy groups and patient panels in the US, UK, Spain, and Germany.  
**Results:** To date, 101 UK and 100 US patients have completed the survey. The UK sample's mean age was 35.5 years, with 73% female and 84% White-British. The US sample's mean age was 37.2 years, with 60% female and 78% White/Caucasian-American. Most patients were diagnosed by biopsy (80% of UK, 80% of US). Seventy three percent of US patients and 85.2% of UK patients self-reported their CeD severity as "moderate", "severe" or "very severe".

		UK (N=101)	US (N=100)
Method of Diagnosis:	Biopsy via endoscopy	40%	19.8%
	Blood tests for serology/antibodies related to CD	20%	19.8%
	Biopsy and blood tests	40%	60.4%
Self reported CeD severity:	Mild	14.9%	27%
	Moderate	30.7%	30%
	Severe	30.7%	31%
	Very Severe	23.8%	12%
CSI means score (SD)		41.9 (11.4)	41.7 (11.8)
CDAT mean score (SD)		16.0 (4.1)	15.6 (4.7)
WPAI mean score (SD):	Impairment at Work	35% (25.1%)	39.9% (27.8%)
	Work Productivity Loss	41.3% (29.4%)	47.4% (30.9%)
	Overall Activity Impairment	36.6% (25.4%)	44% (26.4%)

[US and UK Demographics and PRO scores]  
The majority of patients (72.2% of UK, 75% of US) reported having CeD-related symptoms more than once a month, with 63% of UK patients and 57% of US patients reporting at least one episode of symptomatic suspected gluten exposure within the last month. 19.8% of UK patients and 23% of US patients experienced CeD-related symptoms at daily basis, and more patients (37.6% of UK, 30% of US) reported having a couple of symp-

toms at weekly basis. The most frequently reported symptoms experienced in the past month for both US and UK patients included abdominal pain, tiredness, flatulence, diarrhoea, and bloating, with the most bothersome being tiredness, abdominal pain and concentration issues.

Table 1 illustrates that only 18 (17.8%) UK and 31 US patients (31%) were considered to have excellent/very good adherence (CDAT < 13). Mean WPAI scores indicated relatively high work productivity and activity impairment reported in both US and UK patients' prior week. The US general population estimates for average percent lost productivity at work was 14%, (absenteeism=4%, presenteeism=10%)<sup>7</sup>.

**Conclusion:** In this preliminary analysis of an on-going patient survey, the large majority of adult patients with CeD in the US and UK have significant burden of disease including frequent symptoms, challenges with GFD adherence, and diminished work productivity.

**Contact E-Mail Address:** liisa.viitasalo@tuni.fi

**Introduction:** Relatives of celiac disease (CD) patients are at higher risk of developing the disease due to genetic predisposition and possible environmental factors. We have previously reported increased seropositivity to *Saccharomyces cerevisiae* (anti-*Saccharomyces cerevisiae* antibodies, ASCA), *Pseudomonas fluorescens* (anti-I2 antibodies) and *Bacteroides Cacciae* (anti-OmpW antibodies) in CD.

**Aims & Methods:** We hypothesized that also relatives of CD patients could show hyperreactivity to these three microbial markers. Frequency of seropositivity and concentrations of ASCA IgA and IgG, IgA-class anti-I2 and anti-OmpW antibodies were compared between 463 first-degree relatives of CD patients, 58 untreated and 55 treated CD patients and 80 non-CD controls. In addition, CD-associated HLA haplotypes and tissue transglutaminase (tTGab) and endomysium (EmA) antibodies were determined.

**Results:** Altogether 49 relatives of CD patients were positive for tTGab and/or EmA and were analyzed as a separate group. Among the 414 CD autoantibody negative relatives, one or more of the three microbial markers was positive in 73%, in 97% of untreated and in 87% of treated CD patients and 44% of non-CD controls. The relatives also had higher median ASCA IgA (8.90 vs 4.50 U/ml,  $p < 0.001$ ), ASCA IgG (8.37 vs 5.75 U/ml,  $p < 0.001$ ) and

anti-I2 antibody (absorbance 0.71 vs 0.32,  $p < 0.001$ ) concentrations than the controls. The percentage of seropositivity (86%) and concentrations of microbial markers were somewhat higher in the autoantibody positive group (median ASCA IgA 11.1 U/ml, ASCA IgG 12.8 U/ml, median absorbance for anti-I2 antibodies 0.93 and for anti-OmpW antibodies 1.00). In this subgroup, also anti-OmpW antibody concentrations were higher than in the control group. There was a weak positive correlation between tTGab and ASCA IgA ( $r = 0.31$ ,  $p < 0.001$ ). Seropositivity of relatives was not significantly associated with HLA genotypes (DQ2.5, DQ8, DQ2.2, DQ2+DQ8 or DQ2 and DQ8 negative).

**Conclusion:** Relatives of CD patients demonstrated higher frequency of seropositivity and increased concentrations of ASCA, anti-I2 and anti-OmpW antibodies compared with non-CD controls. These findings were not associated with HLA DQ2 or DQ8, suggesting the role of environmental factors and other genetic variants.

**Disclosure:** Nothing to disclose

## P2051 FACTORS ASSOCIATED WITH NON ADHERENCE TO GLUTEN FREE DIET IN ADULT CELIAC PATIENTS IN ISRAEL

Zelnik Yovel D.<sup>1</sup>, Shirin H.<sup>2</sup>, Broide E.<sup>2</sup>

<sup>1</sup>Shamir (Assaf Harofeh) Medical Center, Department of Internal Medicine 'C', Zerifin, Israel, <sup>2</sup>Shamir (Assaf Harofeh) Medical Center, The Kamila Gonczarowski Institute of Gastroenterology and Liver Diseases, Zerifin, Israel

**Contact E-Mail Address:** danazelnik@gmail.com

**Introduction:** The cornerstone of the recommended treatment for celiac disease (CD) is a lifelong strict gluten-free diet (GFD). We aimed to identify prospectively the demographic, clinical, social and psychological profile associated with non adherence to a GFD in adult CD patients in Israel

**Aims & Methods:** An anonymous online questionnaire has been sent via the Israeli Celiac association and through social networks. Only CD patients  $\geq 18$  years old were included. Socio-demographic, laboratory and clinical data as well as anxiety and depression score were reported. Adherence to GFD was assessed by Biagi questionnaire.

**Results:** 301 patients completed the questionnaire, mean age of  $37.5 \pm 14.9$  years, 79.2% female. The most common presenting symptoms were: anemia (59.7%), abdominal pain (50.8%) and diarrhea (42.8%). According to the Biagi score, 82% of patients were found to be high adherent to GFD (Biagi 3-4) and 18% were low adherent (Biagi 0-2). Univariate analysis revealed that: age of patient, age at diagnosis, duration of disease, education, income level, origin, smoking, gastroenterological follow up and membership in a supporting group, were all significantly associated with adherence to GFD. However in multivariate analysis, only age at diagnosis and smoking were significantly associated with adherence to GFD (HR 1.083, 0.287, respectively).

**Conclusion:** Understanding risk factors for non adherence in celiac disease is an important issue. Intervention strategies in young adult celiac patients as well as in smokers might improve adherence and reduce future complications with better quality of life.

**Disclosure:** Has been accepted to present as well in the international celiac disease symposium ICDS 2019 in Paris.

## P2052 HEMORHEOLOGICAL ALTERATIONS IN CELIAC DISEASE AND INFLAMMATORY BOWEL DISEASE

**Contact E-Mail Address:** szakig2@gmail.com

**Introduction:** Hemorheological changes predispose to the development of arterial thrombotic events; however, limited information is available on the status of these changes in celiac disease (CeD) and inflammatory bowel disease (IBD).

**Aims & Methods:** In this study, we aimed to describe the hemorheological profile of CeD and IBD patients to investigate whether any alterations contribute to elevated cardiovascular risk. This is a case-control study involving newly diagnosed and followed CeD and IBD patients with non-CeD, non-IBD subjects. In addition to routine laboratory parameters, hemorheological parameters i.e. erythrocyte deformability and aggregation (with LORCA), viscosity of whole blood and plasma (with Brookfield viscometer) were measured from venous blood. We calculated mean±standard deviation (for continuous variables) and frequencies (for categorical variables) and used two-sample t-test and linear correlation in the statistical analysis. Registration number: ISRCTN49677481.

**Results:** Study participants included 52 CeD, 41 IBD (73% with Crohn's disease) and 54 control patients. There was no difference in age and gender distribution between CeD and control patients, nor in hematocrit (41.2±3.5% vs. 41.4±3.6%, respectively; p=0.717), viscosity of plasma (1.24±0.16 mPa·s vs. 1.27±0.14 mPa·s, respectively; p=0.253), viscosity of whole blood (4.07±0.43 mPa·s vs. 4.13±0.46 mPa·s, respectively; p=0.534) and erythrocyte aggregation. In contrast, erythrocyte deformability was impaired at three different levels of shear. Patients with IBD were younger than controls (36±14 years vs. 44±17 years, respectively; p=0.013) with male dominance (46.3% vs. 62.9%, respectively; p=0.029), there was no difference in hematocrit (40.3±3.9% vs. 41.4±3.6%, respectively; p=0.159), viscosity of plasma (1.31±0.17 mPa·s vs. 1.27±0.14 mPa·s, respectively; p=0.234), viscosity of whole blood (4.14±0.49 mPa·s vs. 4.13±0.46 mPa·s, respectively; p=0.896) and erythrocyte aggregation between groups. In contrast, aggregation index and  $\gamma$  were higher (p=0.008), while  $t_{1/2}$  was lower in IBD patients (p=0.024). In Crohn's disease, viscosity of plasma positively correlated with disease activity ( $\rho=+0.579$ , p=0.001).

**Conclusion:** An impaired erythrocyte deformability in CeD, an increased aggregability in IBD, and an activity-dependent increase in viscosity of the plasma in Crohn's disease may predispose to thrombus formation.

**Disclosure:** Nothing to disclose

## P2053 EFFECT OF BIFIDOBACTERIUM INFANTIS NSL SUPER STRAIN IN HIGHLY SYMPTOMATIC CELIAC DISEASE PATIENTS ON LONG-TERM GLUTEN-FREE DIET. A PILOT STUDY

**Contact E-Mail Address:** esmecuol@intramed.net

**Introduction:** A strict gluten-free diet (GFD) is currently the only recommended treatment for celiac disease (CeD). Despite apparent compliance with the diet, 30-50% of treated patients have gastrointestinal (GI) symptoms. A recent DBPC trial showed that oral administration of *Bifidobacterium infantis* NSL super strain (*B. infantis* NSL-SS) alleviated symptoms in newly diagnosed CeD patients consuming gluten, and that this effect could be attributed to the modulation of innate immunity.

**Aims & Methods:**

**Aim:** We explore the effect of a three-week course of *B. infantis* NSL-SS on persistent symptoms in patients with CeD following a long-term GFD.

**Methods:** We conducted a prospective, randomized, cross-over, double-blind, placebo-controlled trial. Adult patients were enrolled if they were on a GFD for at least two years and were symptomatic at screening according to the GI symptom rate score (GSRS) (>3 points in the mean global score or >2 for any individual syndromes). Patients voluntarily consuming gluten, with complications, other treatments that might have affected results, or limitations for following protocol or collecting stool or urine samples were excluded. After a one-week run-in period, patients were randomized to receive *B. infantis* NSL-SS (Natren LIFE START 2 Natren Inc. CA.) (2 capsules 3 t.i.d.; 2 x 10 CFU/capsule) or placebo for 3 weeks. After a 2-week wash-out period, patients switched treatment for the next 3 weeks. Outcome was assessed based on changes ( $\Delta$ ) in the celiac symptoms index (CSI) for each treatment. Stool and urine samples were also collected at the end of each period for detection of gluten immunogenic peptide (GIP) excretion.

**Results:** Eighteen patients were enrolled; 2 were excluded due to intentional transgressions and 4 due to inconsistency in symptoms questionnaire reports. In the per protocol analysis (n=12), there were no significant changes in the CSI total score and subscales comparing probiotics vs. placebo. However, there was a significant improvement of specific CeD symptoms in *B. infantis* treatment compared to placebo (median  $\Delta$  [range]: 5.0 points [0 to 9] vs. 2.5 [-7 to 4], respectively; p<0.03; Mann-Whitney) when this analysis was restricted to patients with total CSI scores above the median. There was a significant placebo effect in general health subscale (p<0.04). Globally, we observed a non-significant carryover effect when probiotics was the first treatment. GIP excretion in stools and urine was similar in both treatments. No side effects were detected in either intervention.

**Conclusion:** This exploratory study suggests that *B. infantis* NSL-SS may improve specific CeD symptoms in a subgroup of GFD treated patients with higher symptomatic

**Introduction:** Patients with celiac disease (CeD) treated with a gluten-free diet (GFD) are often exposed to gluten contamination. However, the frequency of such transgressions in a real life scenario is unclear.

**Aims & Methods:** **Aim:** To explore the pattern of fecal and urinary excretion of gluten immunogenic peptide (GIP) during a 4-week period in CeD patients on long-term GFD.

**Methods:** This prospective study enrolled consecutive series of adult CeD patients on a GFD for more than two years. At baseline, patients completed a celiac symptom index (CSI) questionnaire to determine presence of symptoms. Patients collected stool and urine samples for 4 weeks. The collection protocol was designed to ensure coverage of gluten excretion during week-days and week-ends.

Thus, the last stool on Fridays, and two urine samples during Sunday morning and evening, were collected. Urine samples were pooled in one single week-end assay. An ELISA test for stool (iVYLISA GIP-S, Biomedal S.L. Spain) and point-of-care tests (GlutenDetect; Biomedal S.L., Spain) for urine were used for GIP detection.

**Results:** We enrolled 23 patients who were on a GFD for a median time of 7 yrs. The median number of transgressions for the overall population was 3/4w. (IQR: 1-5). GIP excretion in week-end (urine samples) was positive in 21/23 patients (91.3%), while GIP in stools collected during week-days was detected in 11/23 patients (47.8%) (Fisher's Exact test:  $p < 0.004$ ). While 41/92 (44.6%) GIP determinations in urine were positive, GIP was detected in 24/92 (26.0%) of stools (Chi square test:  $p < 0.02$ ). Frequency of GIP excretion for each of the 4 weeks, progressively increased as the study progressed (1 vs. 4 week GIP excretion in either stool and/or urine:  $p < 0.05$ ).

No differences were observed comparing symptomatic (CSI scores  $> 35$  points) vs. asymptomatic patients. A significant correlation was observed between frequency of transgressions and baseline serology ( $\rho$  vs. IgA tTG  $p < 0.04$ ; vs. IgA DGP  $p < 0.0009$ ).

**Conclusion:** The study shows evidence of a high frequency of dietary indiscretions in CeD patients on long term treatment with GFD, independently of the presence of symptoms. Ingestion of gluten was notably more frequent during week-end than during week-days. We show evidence of a relaxation of dietary control along the 4-week study.

**Introduction:** UK guidelines recommend that patients with suspected coeliac disease should have endoscopy and biopsy within 6 weeks of referral. This helps to avoid adult patients abstaining from gluten products prior to establishing a histological diagnosis. Our unit traditionally receives written referrals from primary care for a specialist review prior to gastroscopy and biopsy. This resulted in diagnostic delays leading to non-compliance with the national 6-week target. Therefore, we have introduced a new direct access gastroscopy service for primary care physicians to bypass the first specialist consultation with the aim of streamlining the process, thus improving patient experience and meeting the national target.

**Aims & Methods:** We retrospectively reviewed cases of newly elevated TTGs from primary and secondary care between 2014 and 2018 (n=108). Of these, 52 patients were referred for specialist review for probable coeliac disease. 43 of these were referred from primary care physicians (the other 9 were excluded as they were internal hospital referrals) however 1 of the direct access referrals refused endoscopy. We then compared the performance of the new direct access gastroscopy service to the traditional referral route, using an unpaired t-test to compare time to endoscopy.

**Results:** Patients referred via the traditional pathway (n=21) took a mean time of 94.4 days (95% C.I. 46.58 to 142.22) to undergo a gastroscopy and biopsy. Conversely, patients referred on the direct access gastroscopy pathway (n=21) took a mean of 39.7 days (95% C.I. 16.63 to 62.77), which was significantly quicker than the traditional pathway ( $p = 0.04$ ). 17 patients (81%) seen on the direct access pathway and 16 patients (76.1%) on the indirect access pathway demonstrated a positive histology.

**Conclusion:** The direct access gastroscopy pathway enabled the unit to meet national standards and improve the patient experience by instigating earlier introduction of gluten free diet.

**Introduction:** Celiac disease (CD) is autoimmune, genetic pathology of digestive system, that characterized by primary or secondary dysbiosis.

**Aims & Methods:**

**Aim:** To investigate of fecal microbiota composition and to identify candidate biomarkers of CD by serum metabolomics analysis.

**Methods:** Fresh fecal samples were collected from 43 CD patients on a gluten-free diet and 42 healthy controls (HC). The quantitative real-time polymerase chain reaction (qRT-PCR) was used for fecal microbiota assessment. Serum metabolomic assays were conducted using the GC-MS.

**Results:** CD patients had lower butyrate-producing *Faecalibacterium prausnitzii* and *Bifidobacterium* spp. counts than HC. Taxonomic dysbiosis in CD was characterized by a higher *Bacteroides fragilis*/*Faecalibacterium prausnitzii* ratio compared to HC. Serum of CD patients showed significant increases in stearic acid, 2-hydroxyisovaleric acid (2-HIVA), succinate, fumarate and benzoate compared to HC. The ratio of arachidonic acid (AA) to eicosadienoic acid (EDA) (C20:4n-6/C20:2n-6) was increased in CD. Oral butyrate plus inulin (as supplement for 28 days) significantly enhanced fecal butyrate-producing bacteria (evaluated as BCoAT gene content), reduced elevated baseline *B. fragilis*/*F. prausnitzii* ratio and lowered serum levels of pro-inflammatory succinate and 2-HIVA in CD patients.

**Conclusion:** An increased *B. fragilis*/*F. prausnitzii* ratio can serve as available biomarker for intestinal proinflammatory dysbiosis in CD. Low counts of butyrate-producing *F. prausnitzii* suggest the desirability of co-treatment with oral butyrate or butyrate-enhancing agents (probiotics, prebiotics, metabiotics) in CD. Treatment that increases colonic bifidobacteria (e.g., some *Bifidobacterium* probiotics or inulin-type prebiotics) can be considered in CD. Significant changes in serum levels of microbial and endogenous metabolites, reflecting some metabolic pathways disturbances (glycolysis, TCA cycle, fatty acid metabolism, ketone body metabolism, phenylalanine, tyrosine and tryptophan metabolism, microbial metabolism) are observed in CD. Some metabolites (e.g., a microbial metabolite 2-HIVA), as well as a new metabolomic index (AA/EDA ratio), reflecting the balance between pro-inflammatory and anti-inflammatory components of the omega-6 fatty acid pool, may be considered as candidate biomarkers of chronic intestinal inflammation and metabolic dysbiosis in CD.

**Disclosure:** No Conflict of Interest

## P2057 CLINICOPATHOLOGICAL FEATURES OF THE MUCIN PHENOTYPES IN SPORADIC NON-AMPULLARY DUODENAL SUBMUCOSAL INVASIVE CARCINOMA

**Introduction:** We previously revealed the clinicopathological difference of non-ampullary duodenal neoplasia between the oral and anal side of the papilla of Vater. However, the reason of the difference by tumor location is not clarified. There are some reports about the differences of mucin phenotype of non-ampullary duodenal epithelial neoplasia depending on tumor location. However, previous studies have targeted only superficial tumors, like adenoma and mucosal carcinoma.

**Aims & Methods:** We tried to reveal the clinicopathological features and the significance of mucin phenotype in carcinoma with submucosal invasion. We retrospectively collected all the case of non-ampullary duodenal carcinoma (NADC) which invaded into submucosal layer at 4 institutions in Japan between January 2003 and December 2018. Moreover, we investigated consecutive mucosal NADCs in Okayama University Hospital as a control group during the same period. The mucin expression of MUC5AC, MUC6, MUC2, CDX2, and CD10 and the proliferative activity of Ki-67 were evaluated in both submucosal and mucosal carcinomas by immunohistochemistry. Tumors were classified into gastric, gastric and intestinal mixed, and intestinal phenotype according to combination of mucin expression. We measured the distribution of tumor cells stained for Ki-67 to assess the proliferative activities of tumor cells.

**Results:** There were 11 submucosal carcinomas at 4 institution, and 12 mucosal carcinomas in Okayama University Hospital. Among the patients with submucosal carcinoma, 8, 1, and 2 received radical resection with lymphadenectomy, partial resection without lymphadenectomy, and endoscopic resection, respectively. There were no significant differences in sex, age, tumor size, macroscopic type, or histological type between the submucosal and mucosal groups.

However, all the submucosal carcinomas were located on the oral side of the papilla of Vater (oral-Vater), and the proportion of NADCs on oral-Vater was significantly higher in submucosal carcinoma than mucosal carcinoma (100% vs. 58.3%,  $P = 0.0016$ ). These lesions were classified gastric type ( $n=8$ ) and mixed type ( $n=3$ ), and no lesions were intestinal type. The proportion of gastric and mixed type was significantly higher in submucosal carcinoma than in mucosal carcinoma (100% vs. 41.7%,  $P = 0.0024$ ). The distribution of Ki-67 expression showed that the diffusely stained pattern was more frequently seen in submucosal carcinoma than mucosal carcinoma (66.7% vs. 9.1%,  $P = 0.0047$ ).

	Submucosal (n=11)	Mucosal (n=12)	P-value
Tumor location (oral-Vater/anal-Vater) (%)	11/0 (100/0)	7/5 (58.3/41.7)	0.016
Mucin phenotype (gastric+mixed/intestinal) (%)	11/0 (100/0)	5/7 (41.7/58.3)	0.0024
Ki-67 (superficial type/diffuse type) (%)	1/10 (9.1/90.9)	8/4 (66.7/33.3)	0.0047

[Table. Comparison of clinicopathological features between submucosal and mucosal carcinomas]

**Conclusion:** Our data clarified the differences in the clinicopathological features such as tumor location, mucin phenotype, and proliferation behavior of tumor between submucosal and mucosal carcinoma. That might suggest there is different origin and pathway in the carcinogenesis of submucosal invasive carcinoma from mucosal carcinoma.

**Introduction:** Duodenal and ampullary adenomas have the potential for malignant transformation to carcinomas by an adenoma-to-carcinoma sequence as seen elsewhere in the gastrointestinal tract. Endoscopic resection of these lesions is increasingly being used in place of invasive surgery. However, endoscopic resection in the duodenum can be challenging due to its anatomy and may be associated with a higher risk of complications. This study aims to evaluate the safety and efficacy of endoscopic resection of such lesions.

**Aims & Methods:** All patients with ampullary and large non-ampullary (>10mm) duodenal polyps who underwent endoscopic resection in a tertiary referral centre were included in the study. A retrospective analysis on data including demographics, size, histology, location, method of resection and complications was performed.

**Results:** A total of 122 patients underwent endoscopic resection of duodenal polyps. Out of these 37 underwent ampullectomy and 85 underwent resection for non-ampullary duodenal polyps >10mm.

**Ampullary Adenomas**

There were a total of 37 patients who underwent ampullectomy (median age 66 years [IQR 50-83]). 27 (73%) had a submucosal injection, whereas pancreato-duodenal stent was placed in 26 (73%) of the patients. 7 (20%) patients had adjunct tissue ablation (APC). 62% of the lesions were pure ampullary, whereas 38% polyps involved the duodenum.

The mean polyp size was 21.6mm [IQR5-80]. 75.7% (28/37) of the polyps were removed in a single session with an en-bloc resection rate of 43.2%.

**.Non Ampullary Duodenal Adenomas**

A total of 85 patients with polyps >10mm referred for endoscopic therapy (median age 64 years, [IQR] 27-87 years, 52% male). 58 (70%) underwent endoscopic mucosal resection (EMR) and 27 (30%) had knife assisted resection (KAR). The histology revealed 63 (77%) low grade dysplasia, 14 (14%) high grade dysplasia, 2(3%) carcinoids, 1(1%) Brunner gland hyperplasia and 5 (5%) hyperplastic polyps. The majority of the lesions were found in D2 (70.82%). 8/85 patients (10%) had a diagnosis of familial adenomatous polyposis syndrome.

The mean polyp size was 25.3 mm [IQR 10-80]. 93.5% (80/85) of the polyps were removed in a single session with an en-bloc resection rate of 40%. Table 1 shows the complication and recurrence rates stratified by lesion size (< 30mm vs >30mm) for both ampullary as well as non ampullary lesions.

	Non ampullary duodenal adenomas		Ampullary adenomas	
Lesion size	< 30 mm	> 30 mm	< 30 mm	> 30mm
Number	53	32	28	9
Delayed Bleeding	2 (4%)	5 (16%)	1 (4%)	1 (11%)
Perforation	1 (2%)	1 (3%)	0 (0%)	0 (0%)
Pancreatitis	0 (0%)	0 (0%)	0 (0%)	1 (11%)
Recurrence	1 (2%)	5 (16%)	4 (14%)	3 (33%)

[Table 1]

The bleed rate was significantly higher in larger lesions. All complications in this series were managed endoscopically. The mean follow up period was 38 months for non ampullary duodenal adenomas and 16 months for ampullary adenomas. Recurrence rate was higher in the larger lesions in both sub groups and a majority of the recurrences (70%) were treated endoscopically.

**Conclusion:** Endoscopic resection of duodenal lesions is a safe and effective technique for complete removal of these polyps. Lesion assessment is crucial in patient selection for endoscopic removal as noted by the absence

of cancers in this cohort. The risk of complications, particularly bleeding is significantly higher in lesions greater than 3cm in size. Similarly, recurrence rates are also higher in this group. Nevertheless, we demonstrated that all complications and most recurrences were successfully managed endoscopically.

**Introduction:** Upper gastrointestinal bleeding (UGIB) is one of the major manifestations of gastrointestinal stromal tumor (GIST) of gastrointestinal tract. Several studies have reported that GIST bleeding is associated with poor prognosis. However, only few reports have reported the prognosis of duodenal GIST and its hemostasis modalities for tumor bleeding.

**Aims & Methods:** To identify clinical outcome of duodenal GIST bleeding, we analyzed risk factors and prognosis of hemorrhagic duodenal GIST evaluating hemostasis methods. Total 179 patients histopathologically diagnosed with primary duodenal GIST between January 1998 and December 2017 were enrolled to this study and medical records were reviewed, retrospectively.

**Results:** Of 179 total patients, 49 (27.4%) patients showed UGIB. Endoscopic intervention and transarterial embolization were performed for initial hemostasis in 17 and 1 patients, respectively and other 31 were treated conservatively. In endoscopic treatment group, re-bleeding was found in 6 cases (35.3%) and all of the patients finally received surgery. Over a median of 48 months of follow-up, 7 patients in the bleeding group and 20 patients in the non-bleeding group died; the 5-year survival rate was 83.3% in the bleeding group and 85.7% in the non-bleeding group ( $P = 0.431$ ). Multivariate analysis showed that significant risk factors for duodenal GIST bleeding was P53 positivity (hazard ratio [HR] = 2.601,  $P = 0.019$ ) and risk factors for overall survival were old age (HR = 1.070,  $P = 0.004$ ), large maximal diameter (HR = 1.197,  $P = 0.002$ ), and mitotic count > 5/HPF (HR 5.029,  $P = 0.002$ ). A tumor diameter of 5 cm was cut-off value in predicting overall survival with a sensitivity of 81.0 % and specificity of 65.3%.

	Total (n=179)	Bleeding group (n=49)	Non-bleeding group (n=130)	P value
Age (median, IQR)	55 (44-64)	55 (44-63)	55 (44-64)	0.792
Sex (male/female)	91/88	34/15	57/73	0.003
Size of tumor, cm	4.0 (3.0-6.0)	4.0 (3.0-6.0)	4.0 (3.0-6.0)	0.938
Mitotic count	2.0 (1.0-4.3)	3.0 (1.0-5.0)	2.0 (1.0-4.0)	0.112
Antithrombotic drugs	14 (7.8%)	4 (8.2%)	10 (7.7%)	1.000
Recurrence	27/163 (15.1%)	7/47 (14.9%)	20/116 (17.2%)	0.196
Recurrence free survival, months	40 (19-76)	49 (19-88)	39 (19-69)	0.226
Death	27 (15.1%)	7 (14.3%)	20 (15.4%)	1.000
Median survival, months	48 (21-77)	49 (23-99)	43 (20-75)	0.196

[Table. Clinicopathologic characteristics.]

**Conclusion:** Surgical removal of duodenal GIST should be considered when tumor bleeding is detected because re-bleeding rate is somewhat high after endoscopic hemostasis. And, in duodenal GIST patients with old age, large tumor diameter, and mitotic count > 5/HPF, managements should be performed carefully due to the poor prognosis.

## P2060 AN EVALUATION OF THE RISKS AND BENEFITS OF BIOPSY OF THE PAPILLA IN PATIENTS WITH FAMILIAL ADENOMATOUS POLYPOSIS (FAP)

Mehta N.<sup>1</sup>, Yoon J.<sup>2</sup>, Shah R.<sup>2</sup>, O'Malley M.<sup>1</sup>, Laguardia L.<sup>1</sup>, Mankaney G.<sup>1</sup>, Bhatt A.<sup>1</sup>, Burke C.<sup>1</sup>

<sup>2</sup>Cleveland Clinic, Internal Medicine, Cleveland, United States

**Contact E-Mail Address:** mehtan5@ccf.org

**Introduction:** Nearly all patients with FAP will develop duodenal adenomas. Ampullary and duodenal cancer are the leading cause of death in patients with FAP after colectomy. The risk of duodenal cancer can be predicted by the Spigelman stage of duodenal polyposis. International and national guidelines recommend upper endoscopic surveillance with forward and side viewing scopes to evaluate the duodenum and visualize the papilla for patients with FAP at a frequency according to the Spigelman stage. There is no consensus whether the papilla should be routinely biopsied or included in the Spigelman staging system of duodenal polyposis. Some endoscopists refrain from biopsy of the papilla due to a theoretical risk of pancreatitis. No data is available to support the risk of pancreatitis related to biopsy of the papilla.

**Aims & Methods:** We aim to identify the rate of pancreatitis after biopsy of the papilla in FAP patients and the effect of biopsy on Spigelman stage. This is a retrospective cohort study identifying consecutive FAP patients at the Cleveland Clinic, between 05/1992 and 01/2018 from the David G. Jagelman Inherited Colon Cancer Registries. All FAP patients who have undergone at least one endoscopy with biopsy of the duodenal papilla were included. Patients with previous history of ampullary carcinoma or in whom pathology results were not available were excluded. Medical records were used to determine demographics, endoscopic history, risk factors for pancreatitis, and Spigelman staging with and without biopsy. Post-procedural pancreatitis was defined as two out of three of:

- typical symptoms of pancreatitis
- lipase three times the upper limit of normal or
- presence of radiography consistent with pancreatitis within 7 days of esophagogastroduodenoscopy (EGD).

**Results:** 77 FAP patients (51.9% male) were identified with a total of 120 individual upper endoscopies (range: 1-6 biopsies per patient) resulting in biopsy of the duodenal papilla. 1.6% (2/120) developed pancreatitis after ampullary biopsy. Normal papilla was biopsied in 49/120 EGDs. No patients with endoscopically normal appearing papilla developed pancreatitis. 71 abnormal duodenal papilla were biopsied with 2 episodes of pancreatitis post-biopsy. Both episodes of acute pancreatitis occurred in the same patient. Biopsy of the normal papilla changed Spigelman stage in 3 patients:

- stage 1 to 2
- stage 2 to 3
- stage 3 to 4.

In the patient who was up-staged from Spigelman III to IV due to normal papilla biopsy underwent pancreas-sparing duodenectomy.

**Conclusion:** No FAP patients with biopsies of endoscopically normal papilla developed pancreatitis. Biopsy of normal duodenal papilla in FAP does have the potential to change management by increasing Spigelman stage. It should be further studied if multiple biopsies of the papilla affect this risk-benefit ratio.

**Introduction:** Bariatric surgery predisposes patients to development of cholelithiasis and therefore the need of a subsequent cholecystectomy; however, the incidence of cholecystectomy after bariatric surgery is debated.

**Aims & Methods:** Medical records of 601 patients hospitalized for bariatric surgery between January 1, 2010 and July 1, 2018 were reviewed. Our aim was to evaluate the incidence of cholecystectomy following different types of common bariatric procedures.

All patients who developed cholelithiasis and a subsequent cholecystectomy were included. Cholelithiasis was diagnosed by clinical criteria and characteristic ultrasound findings. We used the Israeli community medical data system "Ofek" in order to find patients' missing data. Twenty-one patients were excluded because of missing data.

Categorical variables were summarized with frequencies and percentages. Continuous variables were summarized using sample size, Mean, Standard deviation, Median, Minimum, Maximum and 95% C.I. Correlations between categorical variables and Incidence of cholelithiasis after surgery were tested for significance using the Chi-Square test. Correlations between Continuous variables and incidence of cholelithiasis after surgery were tested for significance using the independent T-Test.

**Results:** We evaluated retrospectively 580 patients with an average follow-up of 12 months (range 6-24 months). Mean age was 48±19 years (78% females). Twenty-nine patients (5%) underwent laparoscopic cholecystectomy (LC) before the bariatric surgery and 58 patients (10%) performed concomitant LC with the bariatric procedure due to symptomatic gallstone disease (including stones, sludge and polyps). There were 203 laparoscopic sleeve gastrectomy (SG) (35%), 175 laparoscopic gastric band (LAGB) (30%), 55 Roux-en-Y gastric bypass (RYGB) (9.5%) and 147 (25%) mini gastric bypass (MGB) procedures during the study period. At the follow-up period 36 patients (6.2%) developed symptomatic cholelithiasis while the most common clinical presentation was biliary colic.

Statistically, there was a significant difference between the type of the bariatric operation and the incidence of cholelithiasis after the operation. The incidence of symptomatic gallstones formation in patients who underwent RYGB was 14.5 %. This was significantly higher comparing to 4.4% following SG, 4.1% following LAGB and 7.5% following MGB (p=0.04). We did not find any predictive risk factors including smoking, BMI at surgery, change in BMI, comorbidities such as diabetes, hyperlipidemia, hypertension and COPD for gallstone formation or a subsequent cholecystectomy. Interestingly, previous bariatric surgery was a risk factor for gallstone formation and cholecystectomy [15.8% (13/82 patients) in those with previous bariatric surgery compared to 4.6% (23/492 patients) among those without previous bariatric operation (P< 0.001)].

**Conclusion:** Our data demonstrate that patients with previous bariatric surgery or patients planned for RYGB are at high risk to develop post-operative symptomatic gallbladder disease. Concomitant cholecystectomy during the bariatric procedure should be considered in those asymptomatic patients with cholelithiasis.

**Disclosure:** Nothing to disclose

### P2062 POSSIBLE IMPACT OF VAGOTOMY ON POSTOPERATIVE WEIGHT LOSS AFTER SELECTED BARIATRIC SURGERY PROCEDURES. IMPORTANCE OF THE MODULATION OF THE SECRETION OF GASTROINTESTINAL HORMONES BASED ON ANIMAL EXPERIMENTAL MODELS

**Introduction:** Obesity is one of the major health problems in the developed countries and bariatric surgery procedures are effective in the treatment of this disorder. Nevertheless, all present bariatric surgery procedures, with the exception of intra-gastric balloon insertion, have significant impact on the innervation of the vagus nerve. Many experimental studies have shown, that signals from the vagus nerve play an important role in the gastrointestinal hormones regulation and transmission of information between enteric nervous system and brain centers responsible for food intake regulation.

**Aims & Methods:** Therefore, we aimed to determine the effect of vagal innervation on the regulation of food intake and secretion of enterohormones in the pathophysiology of simple obesity as well as the change of these parameters after selected bariatric surgery procedures.

Male Wistar rats were fed with a high-caloric diet for 8 weeks to induce obesity (DIO). Next, sleeve gastrectomy (LSG), truncal vagotomy with pyloroplasty (VAG) and intra-gastric balloon insertion were performed alone (BAL) or in combination with truncal vagotomy (VAG + BAL). Animals weight was monitored weekly. After 12 weeks, rats were sacrificed and gastrointestinal biopsies and serum samples from portal vein were collected. Glucagon-like peptide-1 (GLP-1), gastric inhibitory polypeptide (GIP), peptide YY (PYY), ghrelin, glucagon, insulin, leptin and pancreatic polypeptide (PP) concentration was measured using Luminox platform or ELISA.

**Results:** In rats with VAG, LSG, and BAL+VAG significant weight loss was observed during 4 and 12 weeks after surgery. However, in animals with BAL temporal reduction of weight observed after 4 weeks was reversed after 12 weeks. VAG alone decreased serum content of ghrelin, GIP, PYY and PP but did not affect glucagon, leptin or GLP-1 as compared with intact DIO. BAL increased GLP-1, GIP, decreased ghrelin but did not affect serum concentration of other enterohormones. LSG decreased content of ghrelin, PYY and PP. BAL combined with VAG decreased GLP-1, GIP, PYY, PP as compared with BAL alone.

**Conclusion:** We assume that the effect of VAG on weight loss was mediated by the modulation of particular enterohormones release. We conclude that VAG increased the effectiveness of BAL implementation maintaining its weight loss effect 12 weeks after surgery via modulation of PYY and PP concentration possibly affecting food intake in these animals. [Funding source: National Science Centre, Poland (UMO-2016/23/N/NZ4/03252)].

**Introduction:** Obesity is a global epidemic and is associated with greater morbidity and mortality. Surgically induced weight loss has become the best treatment for morbidly obese patients. Obesity has been shown to be an important risk factor for several gastrointestinal diseases. Many of these conditions can be clinically relevant and have a significant impact on

patients undergoing bariatric surgery. The indication Esophagogastroduodenoscopy (EGD) prior to bariatric surgery is controversial in particular in asymptomatic patients. ASMBs and ASGE recommends preoperative endoscopy in patients with symptoms and individualized H. Pylori screening however, most studies recommend its implementation in all patients. A lack of correlation between patient symptoms and endoscopic findings has been documented by many authors. However, considering the relatively weak clinical relevance of the majority of lesions discovered on routine EGDS and the cost and invasiveness of the procedure, several authors have instead advocated a non-endoscopic approach for asymptomatic patient. Furthermore, many surgeons consider reflux esophagitis or Barrett's oesophagus a contraindication to Laparoscopic Sleeve Gastrectomy (LSG)

**Aim:** The purpose of this study was to compare the prevalence of abnormal relevant findings and HP status in preoperative EGD before bariatric surgery in asymptomatic and symptomatic patients undergoing bariatric surgery.

**Methods:** Data was collected from a prospective database of a consecutive series of 212 obese patients undergoing bariatric surgery. The patients were divided into two groups according to gastrointestinal symptoms. *Group 1:* Upper gastrointestinal symptoms *Group 2:* asymptomatic. The endoscopic findings were classified by clinical relevance in: Not relevant findings (did not change the surgical approach) or Relevant findings (change surgical approach or postpone surgery). Moreover, Helicobacter Pylori (HP) assessment by histology was performed in all the patients. Gastric biopsies were performed in elective patients according to the endoscopic findings

**Results:** In the *Group 1* (symptomatic, 72 patients) 20% of the patients had a normal endoscopy and 37 % of the patients had relevant findings (mainly hiatus hernia, reflux esophagitis) that changed the surgical approach, 10 % of the patients had another major finding (gastric adenoma, Barrett's oesophagus, celiac disease). 62% were HP positive. 10% had intestinal metaplasia. In the *Group 2* (asymptomatic, 140 patients) 25 % of the patients had a normal endoscopy and 32 % of the patients had relevant findings (mainly hiatus hernia, reflux esophagitis). 12 % of the patients had another relevant finding (gastric adenoma, ulcers and Barrett's esophagus, celiac disease). 12% had intestinal metaplasia. 68% were HP positive.

**Conclusion:** Preoperative EGD in asymptomatic and symptomatic patients undergoing bariatric surgery revealed significant pathology in many patients that alter the medical and surgical management. Similar rates of relevant findings were found in asymptomatic and symptomatic patients. Our results support routine EGD in asymptomatic patients undergoing bariatric surgery

**Introduction:** Population-based studies have identified regional variations in individual compositions of the fecal microbiota, limiting the relevance of disease-associated signatures from currently available cross-sectional cohorts. KORA is a regionally confined and prospectively followed population study with a focus on cardiometabolic health. In an interval of 5-years, microbiota profiling was performed on consecutive stool samples using high-throughput sequencing

**Aims & Methods:** Bacterial profiling of two sampling time points ( $t_1=1,976$  and  $t_2=701$  samples) was performed by amplicon sequencing of the V3/V4 and V1/V2 regions of 16S rRNA genes. Data were adjusted to control over confounding variables such as metformin intake, physical activity, vitamin D, PPI, age and gender. To assess shifts in the microbiota linked to metabolic conditions, individuals were stratified based on body mass index (BMI), impaired glucose tolerance (HOMA, fasting glucose and OGTT) to discriminate between healthy, prediabetic and Type-2 diabetes (T2D) conditions.

**Results:** We obtained a total of 13,352 (V3-V4) and 14,379 (V1-V2) high-quality sequences per sample representing  $370\pm 76$  OTUs and  $255\pm 55$  OTUs, respectively, with a Shannon diversity of  $4.71\pm 0.37$  and  $3.99\pm 0.37$ . Permutational multivariate analysis identified 46 subject-related variables that significantly explained nearly one third of the variations in gut microbiota profiles. Besides triglyceride concentration in blood and body weight, rural versus urban habitats strongly influenced compositional profiles (explaining 0.9% variations). Unsupervised clustering identified three distinct microbiota profiles characterized by significant differences in richness and in the relative abundance of dominant bacterial genera, including *Prevotella* (C1), *Bacteroides* (C2) and *Ruminococcus* (C3). Richness was highest in C1 ( $423\pm 65$  OTUs) associated with a significantly reduced prevalence of obese ( $p=0.004$ ) and T2D individuals ( $p=0.015$ ). Lowest diversity and richness was observed in C3 ( $333\pm 72$  OTUs). Richness and Shannon diversity was significantly reduced in obese individuals (BMI > 30).

Interestingly, microbiota profiles of T2D compared to metabolically healthy individuals revealed significantly reduced richness and Shannon diversity in populations with a BMI > 30. *Paired analysis of 701 prospective samples are in the process aiming to validate microbial risk profiles for the development of T2D.*

**Conclusion:** The microbial ecosystem in the human gut is characterized by a large variation influenced by environmental factors associated with geographic regions, lifestyle, and health conditions. BMI is an important variable to stratify the microbiota profiles of T2D. The prospective fecal microbiota analysis in KORA will allow the identification of microbial profiles that can be predictive of T2D development.

<sup>4</sup>Universidade Federal de Minas Gerais, Surgery, Belo Horizonte, Brazil

**Contact E-Mail Address:** brunosander@hotmail.com

**Introduction:** Intra-gastric Balloon (IGB) has gained popularity recently, however, studies addressing long-term weight loss with IGB are scarce in the current literature. Although different studies cite the importance of the multidisciplinary team in the control and prevention of weight regimen, there are still no studies that quantify the benefits of this follow-up.

Thus, the objective of this study was to evaluate the long-term weight regimen, in a cohort of patients who underwent IGB, among those who did or did not follow the treatment with the multidisciplinary team.

**Aims & Methods:** Obese patients treated with intra-gastric balloon (IGB) for a six-month period who underwent balloon removal at least two years before the collection of data, were invited to participate in the study. Patients were stratified based on length of follow-up after IGB removal on the date of interview (2, 3, and 4 years), and relevant factors to weight control as well as behavioral habits were analyzed (A survey was conducted to evaluate the frequency and adherence of the behaviors stipulated by the psychologist and nutritionist, as well as the rhythm of physical activity, in all years of follow-up), and compared by using a logistic multivariate analysis.

**Results:** A total of 224 patients were included in the study. The mean weight regain was  $4.66\pm 4.91$  kg,  $8.66\pm 6.96$  kg, and  $9.99\pm 8.44$  kg at follow-up on 2, 3 and 4 years, respectively. Multivariate logistic analysis determined risk factors for weight regain according to time span after IGB removal. After 2 years of balloon removal, the significant risk factor was lack of follow-up with a psychologist during treatment; increasing the chance of weight regain 1.13 times compared with those subjects that received psychological follow up (ODDS for 2 years: 1.13;  $p=0.02$ ; IC95%: 0.55-1.89). An independent and significant risk factor for weight regain after 3 years of IGB removal was the lack of follow-up with a nutritionist after the use of IGB. Chance of weight regain was 3.36 times higher in this group than in individuals who did the nutritional follow-up (ODDS for 3 years: 3.36;  $p<0.01$ ; IC95%: 1.42-7.94). After 4 years of IGB removal, sedentary behavior was an independent and significant risk factor, increasing the chance of weight regain 3.86 times compared with physically active behavior (ODDS for 4 years: 3.86;  $p=0.03$ ; IC95%: 1.13-12.67).

**Conclusion:** Weight regain occurs commonly after intragastric balloon removal in up to two-thirds of patients. Lack of psychological and nutritional follow up during and after treatment, as well as sedentary behavior are important risk factors for weight regain.

**Contact E-Mail Address:** brunosander@hotmail.com

**Introduction:** The intragastric balloon (IGB) has been used for more than 20 years in Brazil as an endoscopic method for assisting weight loss, and some intercurrents were observed during more than 10,000 procedures performed. One of these intercurrents is the presence of fungi in the IGB, increasing the friability of the silicone and inducing the premature rupture of the IGB, as well as gas hyperinflation.

**Aims & Methods:** To evaluate the effectiveness of the use of antifungal (Nystatin), diluted in intragastric balloon filling saline solution, in order to prevent the appearance of fungi in silicon, 120 patients (76.7% women) who underwent adjustable intragastric balloon Spatz3 throughout the year 2017.

Patients were divided into two groups by randomized clinical trial: 60 patients had 50 nystatin milliliters (100,000 IU / ML) mixed with saline solution with Methylen Blue in the IGB filling and the other 60 patients had their IGB filled with saline solution and Methylene Blue. Only the nursing team knew which patients had received antifungals in the filling of the balloon (double-blind study).

The initial volume of IGB filling in all patients was 700ml.

Initial BMI started at 27 kg/m<sup>2</sup> and IGB maximum period implant was 12 months.

When the IGB was removed, the Endoscopist described whether there was fungal colonization on the silicone surface and, when there was, divided the colonization on the silicone surface in 4 stages: less than 10% (insignificant), between 10% and 25% (light), between 20 and 50% (moderate) and more than 50% (accentuated). When there was insignificant colonization (up to 10%) it was described as normal in the database.

**Results:** 19 patients (15.84%) were excluded from the final analysis: 2 (1.66%) due to early removal, 15 (12.5%) did volume adjustment during the IGB and 2 (1.66%) balloon spontaneous deflation or leakage.

Among the 101 patients analyzed, 54 had antifungal in the IGB and 47 only saline and methylene blue.

In the group with antifungal the incidence of fungal colonization was 9.25% (n = 5).

In these 5 IGBs with fungal colonization, 4 (80%) presented light colonization (between 10% and 25% of the surface) and 1 (20%) with moderate colonization (between 25% and 50% of the surface).

In the group without the use of antifungal the incidence of fungal colonization was 19.15% (n = 9). In these 9 IGBs with fungal colonization, 4 (44.5%) presented light colonization (between 10% and 25% of the surface), 3 (33.3%) with moderate colonization (between 25% and 50% of the surface) and 2 (22.2%) with accentuated colonization (more than 50% of the surface).

There was no significant difference in outcomes between men and women and mean age was 30.49 years.

The mean weight loss was -20.64kg (+/- 16.8kg).

**Conclusion:** The use of mixed nystatin to the saline solution in the IGB filling reduced the fungal colonization in the silicone coating by half, demonstrating that this practice has a positive effect with low cost and significant difference in fungal prevention.

However, even associated with IGB friability, fungal colonization does not prove to be of such importance since balloon spontaneous deflation or leakage corresponded to only 1.66% of the total initial sample and the 14 patients who presented fungi in the IGB (13.86 %) did not present any clinical symptoms.

**Introduction:** Recently it has been shown that Vitamin D has a role in immunomodulation processes. Namely it promotes differentiation of lymphocytes as well as different interleukins such as IL-10, and it may have an effect on production of interferon  $\gamma$ .

**Aims & Methods:** We aimed to assess Vitamin D levels in inflammatory bowel disease (IBD) patients as well as healthy individuals, and to examine is there a correlation of Vitamin D levels with disease activity. Complete medical records of all patients with histologically diagnosed IBD were evaluated. As a control group we analyzed medical records of age and sex matched healthy volunteers, who had done their annual health check up. A case-control study was performed among 45 newly diagnosed IBD patients and the same number age, sex matched healthy controls. All patients underwent a total colonoscopy with ileoscopy. Complete blood count was obtained in addition to inflammatory markers (CRP, erythrocyte sedimentation rate-ESR) and serum levels of 25-hydroxyVitamin D. Mayo score, UCEIS and CDAI respectively were calculated for each patient.

**Results:** Vitamin D deficiency was noted in 60% of patients with IBD and 32% healthy individuals. Serum levels of Vitamin D were significantly lower ( $P < 0.05$ ) in IBD patients than controls. There were no significant differences in values of Vitamin D in relation to age or gender ( $P > 0.05$ ), although the average values were lower in women. Additionally we have not found statistically significant differences in levels of Vitamin D in patients with UC compared to CD. Moreover serum levels of Vitamin D negatively correlated with CRP and ESR ( $P < 0.05$ ). Additionally lower levels of Vitamin D negatively correlated with CDAI, UCEIS and Mayo score ( $P < 0.05$ ).

**Conclusion:** Our results suggest that IBD patients may have micronutrient deficiency more common than assumed. Additionally patients with active disease have significantly lower levels of Vitamin D, so there is a need for adequate supplementation.

**Introduction:** Intravenous (IV) iron is commonly used to treat iron deficiency in patients with severe symptomatic anaemia or intolerance to oral iron supplements [1]. Ferric carboxymaltose (FCM) is a high dose IV iron known to cause a drop in serum phosphate level that often leads to hypophosphatemia [2]. Hypophosphataemia following FCM administration has been reported to be up to 75%, but its clinical significance remains unknown [3].

**Aims & Methods:** The purpose of this study was to investigate the proportion of patients developing hypophosphataemia following FCM administration and the potential clinical sequel in a tertiary university hospital. The medical records of inpatients that received an FCM infusion between Apr-2016 and Dec-2017 were retrospectively examined. Data on basic demographics, haematinics, phosphate and related biochemistry, were collected at baseline and five follow-up time points.

**Results:** A total of 321 patients received FCM during the audit period; 61.4% were females. Mean weight  $\pm$  SD at baseline was  $66.7 \pm 20.3$  kg, age  $54.3 \pm 23.8$  years, haemoglobin  $92.2 \pm 0.8$  g/L, ferritin  $163.1 \pm 288.5$   $\mu$ g/L, transferrin saturation  $13.2 \pm 13.5\%$ . 25% of patients had inflammatory bowel disease (IBD). Mean iron dose per administration was  $902.8 \pm 177.4$  mg, and 19/321 (5.9%) of patients experienced a hypersensitivity reaction, of which 3/321 (0.9%) requiring IV steroids. Mean baseline phosphate was  $1.1 \pm 0.3$  mmol/L and dropped to  $0.97 \pm 0.3$  following FCM administration. 94/216 (43.5%) of patients with available records had a phosphate level of  $< 0.8$  mmol/L, 63/216 (29.2%)  $< 0.65$  mmol/L and 6/216 (2.8%)  $< 0.33$  mmol/L at any time point up to 90 days post-infusion. The temporal trend of phosphate reduction is shown in Table 1.

Patients that had a phosphate of $<0.65$ mmol/L at any point hypophosphataemia (n=63)	% of patients with phosphate of $<0.8$ mmol/L	% of patients with phosphate of $<0.65$ mmol/L
0-7 days post FCM infusion (n with available data = 51)	42/51 (82.4%)	37/51 (72.6%)
8-14 days post FCM infusion (n with available data = 38)	25/38 (65.7%)	19/38 (50%)
15-29 days post FCM infusion (n with available data = 35)	23/35 (65.7%)	16/35 (45.7%)
30-60 days post FCM infusion (n with available data = 35)	27/35 (77.1%)	22/35 (62.8%)
>60 days post FCM infusion (n with available data = 11)	6/11 (54.5%)	5/11 (45.5%)

### [Temporal trend of hypophosphatemia]

Of those developing hypophosphataemia, 11/94 (11.7%) received oral phosphate and 45/94 (47.9%) IV phosphate. Mean alkaline phosphatase increased from 113.3 IU/L at baseline to 130.0 IU/L at 0-7 days and 146.7 IU/L at 8-14 days post iron infusion ( $p < 0.05$ ).

**Conclusion:** In the population examined, a high proportion of patients developed hypophosphataemia following FCM administration. In almost half of the cases that developed hypophosphataemia treatment with Oral/IV phosphate was necessary. A high proportion of those developing hypophosphataemia had a low phosphate up to 90 days post iron infusion. Our data suggest that FCM-induced hypophosphataemia is persistent and has important clinical consequences.

## P2070 A EUROPEAN E-DELPHI SURVEY: EXPERT CONSENSUS ON MANAGEMENT OF IRON DEFICIENCY ANAEMIA IN PATIENTS WITH GASTROINTESTINAL BLEEDING

Schieffe I.<sup>1</sup>, Aksan A.<sup>2,3</sup>, Wehkamp J.<sup>4</sup>, Teich N.<sup>5</sup>, Keshav S.<sup>6</sup>, Stein J.<sup>2,3,7</sup>, For the Delphi Study Group

<sup>1</sup>Klinik für Gastroenterologie, Hepatologie, Diabetologie und Endokrinologie, Leipzig, Germany, <sup>2</sup>Interdisciplinary Crohn Colitis Centre Rhein-Main, Frankfurt am Main, Germany, <sup>3</sup>Goethe University, Institute of Pharmaceutical Chemistry, Frankfurt am Main, Germany, <sup>4</sup>Medizinische Universitätsklinik, Innere Medizin I, Tübingen, Germany, <sup>5</sup>Gastroenterologische Gemeinschaftspraxis, Leipzig, Germany, <sup>6</sup>Oxford University Hospital, Nuffield Department of Medicine, Oxford, United Kingdom, <sup>7</sup>DGD Clinics Sachsenhausen, Teaching Hospital of the Goethe University, Gastroenterology and Clinical Nutrition, Frankfurt/Main, Germany

**Contact E-Mail Address:** ayscak@gmail.com

**Introduction:** Gastrointestinal bleeding (GIB) is a common complication of many gastrointestinal conditions with a high mortality rate (5-11%), and one of the most common causes of iron deficiency anaemia (IDA) (1, 2). While IDA is known to occur in different gastrointestinal disorders, recording and characterising GIB-related IDA (GIB-IDA) in heterogeneous GI conditions is challenging. Therefore, data are scarce and guidelines for diagnosis and management are lacking.

**Aims & Methods:** This study aimed to use Delphi methodology to obtain an expert consensus on the optimal management of GIB-IDA. An e-Delphi Survey was conducted among 26 European experts in gastroenterology and IDA. Potential participants were chosen based on publications, established clinical expertise and seniority in the workplace, and asked to complete a narrative questionnaire about their clinical practice and opinion on GIB-IDA management. Questionnaires were qualitatively analysed to identify unique propositions for optimal management of GIB-IDA, which were used to formulate a Delphi Questionnaire with 13 different categories including 126 core statements. Here, we present data from the 5 main categories (with 54 statements): 1) Iron treatment for iron deficiency and IDA; 2) Oral iron (reasons to use); 3) Oral iron (reasons not to use); 4) Intravenous (IV) iron (reasons to use); 5) IV iron (reasons not to use). Consensus was defined as at least 75% agreement on the proposition.

**Results:** Consensus was reached in support of 17 of the 54 statements proposed. The 5 statements with the strongest (>91%) consensus were: 1) In mild anaemia, oral iron may suffice; 2) Clinical findings which suggest the use of IV iron as part of the treatment of IDA include a history of malabsorption states associated with poor absorption of oral iron, such as coeliac disease; 3) First line IV iron treatment should be considered when adverse effects of oral iron occur; 4) The price of IV iron formulations is mostly the reason to use oral iron first line to treat anaemia due to GI bleeding; and 5) A consensus on methods for administration of available IV iron products is needed to reduce inappropriate blood transfusion.

**Conclusion:** Our study suggests that current use of iron therapy by experts in the field is driven by clinical and cost-orientated considerations, rather than by clinical assessment and therapeutic targets or treatment thresholds. Although experts recognise the importance and effectiveness of IV iron products, consensus is lacking regarding the use of IV iron as first-line therapy in patients with GIB-IDA, although studies show that it may be faster and more cost-effective than oral iron.<sup>1,2</sup> New guidance is therefore needed concerning the optimal therapy of GIB-IDA, including recommendations on the use of IV iron formulations.

**Introduction:** Maintaining health requires a homeostatic equilibrium between the microbial community and the intestinal epithelium that serves as the regulatory interface with the host. Nutritional stressors such as malnutrition, starvation or caloric restriction disturb this equilibrium and thus provoke changes in the function of the intestinal microbiota and intestinal mucosa.

**Aims & Methods:** We aimed to elucidate the mechanisms underlying the complex tripartite interplay between microbiota, the intestinal epithelium and the environment (nutritional stressors). We therefore developed experimental protein energy malnutrition (PEM) models to investigate the effects of adult, postnatal and prenatal PEM on the microbiota and host physiology, in particular inflammatory susceptibility.

**Results:** We found that PEM induced drastic modifications of the host's gastrointestinal tract but also systemic immunity and metabolism. A single episode of PEM extensively changed the overall microbiota composition enriching for Gammaproteobacteria and Bacteroidaceae while depleting for Actinobacteria and Verrucomicrobia along with the functional metagenomic repertoire. The intestinal epithelial transcriptome was also largely reprogrammed in response to PEM. PEM-induced changes in the microbiota and epithelial transcriptome partially remained upon switching to control diet, indicating a "memory effect". Most important, the long lasting PEM-induced microbiome and transcriptome changes also altered the inflammatory susceptibility in an experimental colitis model *in vivo*. On-going experiments aim at determining whether PEM phenotypes are transmissible, for example from the mother to offspring or solely through the altered microbiome.

**Conclusion:** Our data identified alterations in the microbiome and epithelial transcriptome as potential molecular mechanisms underlying the long lasting physiologic consequences of PEM, thus paving the way to develop probiotic therapeutic interventions for malnutrition.

## P2072 DELIVERING PARENTERAL NUTRITION - REAL WORLD CHALLENGES

Rayner D., Harkess S., McFarland D., Lee S., Dhar A.

Darlington Memorial & Bishop Auckland Hospitals, Gastroenterology, Co. Durham, United Kingdom

**Contact E-Mail Address:** daniellarayner@nhs.uk

**Introduction:** Parenteral nutrition (PN) is widely used to intravenously deliver nutrition to patients with non-functioning or inaccessible gut. The National Confidential Enquiry into Patient Outcome and Death (NCEPOD) report in 2010, "A Mixed Bag" found good practice regarding PN in only 19% of cases. It recommended an urgent need to deliver high quality nutrition to all patients in hospital.

**Aims & Methods:** This audit was designed to evaluate our Parenteral Nutrition Service against NCEPOD review. The primary aim was to establish whether the key recommendations of the NCEPOD report are being adhered to: documentation of indication and its appropriateness, consideration of enteral options, clinical and biochemical monitoring during PN, duration of PN and any complications. All adult inpatients who received PN at Darlington Memorial Hospital and University Hospital of North Durham between June- August 2018 were identified from 2 electronic databases viz. referrals to dietetics and electronic prescribing software.

Data collection was done from case notes, inpatient electronic prescription charts and pathology results. Baseline demographics, documented indication for PN, anticipated and actual duration of PN, reason for discontinuing PN and associated complications were recorded and analysed using Excel®.

**Results:** 49 in-patients were identified over the 3month period, an annualised PN workload of approx. 200 pts/yr. Mean age was 69.2y (46-93), mean weight prior to commencing PN 75.3kg (41.1-114.8kg). 22/49 pts were surgical, 1/49 medical and 16/49 on intensive care. 25/49 pts had a clearly documented indication (ITU 5/16, medicine 10/11, surgery 10/22) but only 1 patient had a documented anticipated duration for PN. Mean duration was 10 days (1-32) and mean length of inpatient stay was 21 days (4-53). Only 7/49 pts were reviewed by a Nutritional MDT team, although all pts were regularly reviewed by Dietitians.

Reasons for discontinuing PN: oral feeding resumed in 28 pts, death/end of life care commenced in 10 pts, NG/NJ/PEG feeding commenced in 6 pts, patient refusal in 2 pts and 3 pts transferred to a tertiary service.

Complications: Abnormal LFTs in 3 pts, abnormal electrolytes in 33 pts and 1 midline associated thrombophlebitis. 16/49 pts had daily testing of serum biochemistry. 30 day all-cause mortality from commencing PN was 18% (9/49).

**Conclusion:** Our study shows the need for a quality improvement program for PN including documentation of indications and goals of PN treatment. Patients commencing PN should be reviewed by a Nutrition MDT to improve initial assessment and monitoring. A decreased compliance with daily serum biochemistry correlates with an increased incidence of electrolyte abnormality.

**Introduction:** The Percutaneous Endoscopic Gastrostomy (PEG) is an option for long-term enteric feeding, specially in patients with neurologic conditions that affect swallowing or with oropharyngeal malignancies.

**Aims & Methods:** With this study, we intend to determine how the PEG affect health-related quality of life (HRQoL) and the nutritional status (NS) in patients who were submitted to the procedure. Prospective and unicentric study, designed to assessment HRQoL and NS in patients who received PEG between November 2018 and February 2019 as well as the impact of the procedure in these variables. The HRQoL was assessed with the portuguese version of EQ-5D questionnaire and the NS with *Mini Nutritional Assessment* (MNA), that were performed to the patient or his/her caregiver (in case of response incapacity of the patient), at the time of PEG perform and 2-3 months after that.

**Results:** A total of 21 patients were included, 52% of male gender, with a mean age of 71±18 years. The nasogastric tube was the main form of feeding (76%), with a median time of use of 5 months (IQR 2-12). In 31% of cases, the body mass index (BMI) was lower than normal (mean BMI of 20±4 kg/m<sup>2</sup>). According to MNA, 60% of patients were undernourished and 33% with risk of that; among these two groups, an early age was associated to undernourished (p=0.024). In 43% of cases, the health status was considered worse when compared with 12 months before the PEG perform. Nine patients were contacted after received the PEG, in a mean time of 3±1 months; 10% of cases were death, due to causes not related to the procedure. It was verified an improvement in NS with a paired increase of the mean value of MNA after PEG placement (p=0.027). In EQ-5D, it was verified an improvement in capacity of perform daily routine activities (p=0.046). Moreover, a subjective improvement in terms of physical, psychological and emotional welfare was reported (100%, 86% and 71%, respectively).

**Conclusion:** PEG placement was associated to an improvement in NS and also to one factor in terms of HRQoL. The subjective assessment, in terms of welfare, was overall positive.

**Disclosure:** Nothing to disclose

## P2074 SIMPLE BEDSIDE PREDICTORS OF PERCUTANEOUS GASTROSTOMY TUBE INSERTION FOR SHORT-TERM MORTALITY

Khoury T.<sup>1</sup>, Kadah A.<sup>2</sup>, Mahamid M.<sup>3</sup>, Mari A.<sup>4</sup>, Salman A.<sup>5</sup>, Sbeit W.<sup>2</sup>

**Contact E-Mail Address:** tawfik.khoury.83@gmail.com

**Introduction:** Percutaneous endoscopic gastrostomy (PEG) tube insertion has become the most common method for oral enteral nutrition and is mainly reserved for patients who are unable to maintain long-term adequate oral feeding for at least 2-3 weeks and for malnourished patients who are unable to satisfy the body energy requirements. The American Gastroenterological Association recommend PEG insertion in patients who are expected to survive for more than 1 month after the procedure.

**Aims & Methods:** We aimed to explore simple easily available clinical and laboratory predictors for short-term survival (within 1- month) after PEG insertion. We performed a single center retrospective study of all patients 18 years old or older who underwent primary PEG insertion for various clinical indication at Galilee Medical Center from January 1<sup>st</sup> 2014 to December 30<sup>th</sup> 2018. Primary comparison was performed between patients who survived more than 1 month after PEG insertion (long-term survival) to patients who died within 1 month of the procedure (short-term mortality).

**Results:** A total of 272 patients who underwent primary PEG insertion. Sixty-four patients (23.5%) died within one month after PEG insertion (group A), compared to 208 patients (76.5%) survived more than 1 month (group B). The mean age in group A was 77.3 ± 14 years as compared to 70.4 ± 17 years in group B. Thirty-two patients (11.8%) were males in group A, compared to 103 patients (37.8%) in group B. The most common two indications for primary PEG insertion in groups A and B were dementia (43.7% vs. 34.6%) and stroke (40.6% vs. 35.6%), respectively.

In univariate regression analysis, only serum albumin and hemoglobin levels were positively correlated with long-term survival following PEG insertion (more than 1-month) (OR 2.973, 95% CI 1.641-5.387, P=0.0003, OR 1.294, 95% CI 1.101-1.520, P=0.0018), respectively. On the other hand, several predictors identified showed negative correlation with long-term survival. Older age (OR 0.971, 95% CI 0.952-0.991, P=0.005), ischemic heart disease (OR 0.494, 95% CI 0.273-0.893, P=0.0197), higher creatinine level (OR 0.438, 95% CI 0.249-0.772, P=0.0043), elevated CRP level (OR 0.992, 95% CI 0.988-0.996, P< 0.0001) and CRP to albumin ratio (OR 0.9, 95% CI 0.970 - 0.989, P< 0.0001). On multivariate logistic analysis, older age (OR 0.9, 95% CI 0.952-0.996, P=0.019), higher creatinine level (OR 0.63, 95% CI 0.379-1.046, P=0.074), and elevated albumin to CRP ratio (OR 0.9, 95% CI 0.974-0.994, P=0.002) correlated with short-term mortality after PEG insertion, while hemoglobin level remained positively correlated with long-term survival (OR 1.18 95% CI 0.995-1.401, P=0.05), with ROC of 0.7274.

**Conclusion:** We have showed that simple clinical and laboratory bedside parameters including old age, higher creatinine level and elevated CRP to albumin ratio could be useful aid in avoiding gratuitous PEG insertion in these patients population with high risk for short-term mortality.

**Disclosure:** Nothing to disclose

## Paediatric: Upper GI III

## P2075 VARIANTS OF THE CHRONIC HP-ASSOCIATED INFLAMMATORY PATHOLOGY OF THE STOMACH AND DUODENUM IN CHILDREN

Eugeniy S., I.S.Akkuratova, E.M.Spivak, R.M.Levit, Yaroslavl State Medical University, Paediatric, Yaroslavl, Russian Federation

**Contact E-Mail Address:** spivak58@mail.ru

**Introduction:** The detailed location of the process in chronic inflammatory pathology of the stomach and duodenum it is important, because different variants of location have their own etiopathogenetic mechanisms and prognosis.

**Aims & Methods:** To give clinical, endoscopic and morphological characteristics of various variants of chronic inflammatory pathology of the stomach and duodenum in children.

**Patients and methods.** 112 children aged 6 - 17 with chronic inflammatory pathology of the stomach and duodenum were examined.

**Results:** Chronic inflammatory disorders of the stomach and duodenum in children presents 4 variants: isolated duodenitis, duodenogastric, antrum gastritis and pangastritis. In isolated duodenitis in children (17.9 %), morphologically, moderate or severe inflammation in the duodenum mucosa in the intact body and the antral region of the stomach is determined. Duodenogastric (19.6 %) characterizes by the appearance of a slight superficial inflammation in the antrum. In antrum-gastritis (10.7 %), it has a moderate or severe degree, and in some patients can be combined with an initial process in the body of the stomach.

Pangastritis (51.8 %) is characterized by the presence of moderate or severe common inflammation often hyperplastic with follicular or erosive bulbitis. Colonization of the gastric mucosa Hp has differences, depending on the topical version. In the body of the stomach, it is absent or insignificant in patients with the first three options, in pangastritis. Hp is determined in the body in all cases, and in a third of patients (34.4 %) a moderate or severe degree of colonization Of Hp of the body of the stomach is recorded. In antrum-gastritis and pangastritis 83.2 % of children found highly pathogenic strains of Hp. A common feature of all topic variants is the presence of chronic duodenitis. Insulated gastritis without involving in process of the mucosa of the duodenum in children is not detected. There are no significant differences in clinical manifestations of certain topical variants of chronic inflammatory pathology of the stomach and duodenum in children.

**Conclusion:** Chronic inflammatory disorders of the stomach and duodenum in children is heterogeneous and includes 4 variants: isolated duodenitis, duodenogastric, antrum gastritis and pangastritis. In the absence of differences in clinical manifestations, each variant is characterized by features of pathomorphology of the mucosa of the stomach and duodenum, as well as colonization of Hp.

**Contact E-Mail Address:** haimsh@asaf.health.gov.il

**Introduction:** Helicobacter pylori (*H. pylori*) infection in children is often acquired in the first five years of life and differs from that in adults. The ELISA stool antigen test is considered convenient for use in children due to lack of a more convenient method. The performance of the Urease breath test (UBT) was reported to be with a sensitivity of only 76.2%, due to antibiotic and PPI consumption.

**Aims & Methods:** Our aim was to investigate the safety and efficacy of the Exalenz Bioscience 13C-Urea Breath Test using the BreathID® Hp systems compared to the stool antigen test in the pediatric population.

Fifty three (53) children were enrolled to perform the 13C-Urea Breath Test via both the BreathID® Hp Point-of Care (POC) System and the BreathID® Hp Lab System means of breath collection. Results of both breath collection methods were compared with stool antigen testing

**Results:** BreathID® Hp POC System sensitivity was 93.3% [95% CI (68.05%; 99.83%)] and specificity was 100% [95% CI (86.77%; 100.00%)] compared to stool antigen. The overall agreement in detection of H.pylori using the BreathID® Hp POC System breath test compared to the stool antigen test was 97.56% [95% CI (87.14%; 99.94%)]. BreathID® Hp Lab System sensitivity was 93.3% [95% CI (68.05%; 99.83%)] and specificity was 100% [95% CI (87.23%; 100.00%)] compared to stool antigen. The overall agree-

ment in detection of *H. pylori* using the BreathID® Hp Lab System breath test compared to the stool antigen test was 97.62% [95% CI (87.43%; 99.94%)]. One minor possibly related adverse event was recorded

**Conclusion:** The 13C-Urea Breath Test is an accurate, safe, easy to perform, non-invasive method, which aids in confirming the presence or eradication of *H. pylori* infection. Both breath sample collection methods –the BreathID® Hp POC System and the BreathID® Hp Lab System– are safe and efficacious diagnostic tests in children, without serious adverse events (SAE). The substrate dose used in children is safe.

**Contact E-Mail Address:** petra.riznik@gmail.com

**Introduction:** Coeliac disease (CD) is one of the most common systemic immune-mediated disorders. Undiagnosed and untreated CD can seriously affect nutritional status and growth of affected children.

**Aims & Methods:** The aim of our study was to assess the influence of diagnostic delays on growth in newly diagnosed children with CD in the Central European (CE) region.

We conducted an anonymised multi-centre web-based survey that was filled out by paediatric gastroenterologists from five CE countries, providing us with data from medical records of CD patients aged < 19 years with CD diagnosis in 2016. Z-scores for weight and height of children with CD at the time of diagnosis were calculated, based on the WHO reference, and related to diagnostic delays measured as the time interval from the symptom onset to confirmation of the diagnosis. Statistical analysis was performed using IBM SPSS Statistics 22.0 for Windows.

**Results:** Data from 393 symptomatic children (65% female) diagnosed at a median age of 7 years (range 7m-18.5y) from Croatia, Hungary, Germany, Italy and Slovenia were included. The median delay from onset of symptoms to confirmation of the diagnosis was 6m (range 0m-10y). At the time of CD diagnosis, median z-score for weight was -0.44 (min -4.59; max 3.53) and for height -0.07 (min -4.60; max 7.29). No differences were found between girls and boys. Twenty-six of the included children (6.6%) had diagnostic delays longer than 3 years (Table 1). They had lower weight and shorter stature compared to those with the delays of less than one year (z-score for weight: -0.93 and -0.39 respectively,  $p < 0.05$ ; z-score for height: -0.50 and -0.04 respectively; NS). There was a weak negative correlation between diagnostic delays and z-scores for weight ( $r = -0.105$ ) and height ( $r = -0.115$ ) (both  $p < 0.05$ ).

DIAGNOSTIC DELAY	Number of patients (%)	Weight z-score (median)	Height z-score (median)
0-12 months	288 (73.3%)	-0.39	-0.04
13-24 months	58 (14.8%)	-0.45	-0.27
25-36 months	21 (5.3%)	-0.78	-0.29
>36 months	26 (6.6%)	-0.93*	-0.50

\*significant difference vs. 0-12m delays ( $p < 0.05$ )

[The influence of diagnostic delays on weight and height of children with coeliac disease.]

**Conclusion:** Children with CD had slightly lower body mass at the time of diagnosis but similar height compared to healthy children. Longer diagnostic delays lead to progressively lower body mass and, to a lesser de-

gree, also to shorter stature. Efforts are needed to prevent long diagnostic delays and resulting complications, which may permanently affect child development as well as final height and health in adulthood.

**Introduction:** Family members of patients with coeliac disease (CeD) have 10-40% risk of CeD during lifetime and most affected subjects develop the disease between the age of 2-6 years according to prospective cohort studies. In this study we investigated whether 9 and 12 years old children have new seroconversion and whether gluten consumption habits influence the prevalence.

**Aims & Methods:** First-degree family members (FDR) presenting for screening were prospectively enrolled and followed by measuring serum transglutaminase 2-specific (TGA) and endomysial (EMA) antibodies at age 3 and 6 years. Children currently aged 9 and 12 years were called for new blood drawings. The investigated cohorts included 134 children from the PREVENTCD study (www.preventcd.com) with randomised early gluten introduction at age 4 or 6 months, a wild cohort (n=302) born in the same years but starting gluten as wished by parents, and other FDR persons with multiple screenings. CeD diagnosis was confirmed by histology showing Marsh III lesions. Results were compared with prevalence data of cross-sectional FDR screening performed first time at the specified age time-points. HLA-DQ testing was performed if a genetic sample was available.

**Results:** Altogether 1007 FDR children at risk had an evaluation by TGA testing at age 9 (n=506) or 12 (n=501), or both. No cases occurred in children who were negative for both HLA-DQ2 and DQ8 alleles and gluten introduction time did not influence prevalence. From the children who were still negative at age 3, 10.2% (19/185) developed CeD by age 6, and from those still negative at age 6, 12.0% (3/25) developed CeD by age 9, but no new cases occurred between 9 and 12 years of age. Higher proportions of positives were found at 9 years of age (66/362, 18.2%) or 12 years of age (51/326, 15.6%,  $p < 0.01$ ), if screening has not been implemented before these timepoints or the index patient was diagnosed only at that time.

**Conclusion:** Periodic screening of children at risk should be continued until the age of 9 years.

**Introduction:** Past studies reported differences in disease expression, epidemiology, coexisting diseases, complications, and association with obesity, between pediatric and adult patients with celiac disease (CD). The purpose of this study was to compare demographic, clinical and social data as well as adherence status between pediatric and adults celiac disease patients.

**Aims & Methods:** An anonymous online questionnaire has been sent via the Israeli Celiac association and through social networks. Socio-demographic and clinical data were reported. Adherence to GFD was assessed by Biagi questionnaire.

**Results:** 445 patients were included in the study, mean age  $25.7 \pm 17.5$  years, 71.9% female. Patients were divided into 6 different age groups- under 6 years old (134 patients), 6-12 (79 patients), 12-18 (41 patients), 18-30 (81 patients), 30-45 (79 patients) and 45 + years old (23 patients). Abdominal pain, diarrhea, distended abdomen, anemia, TSH abnormalities and short stature had different prevalence among the different age groups. We found significant differences in - Gender (more females in the adult group- 78% vs 63%,  $P < 0.001$ ) as well as in ethnicity (more Ashkenazy Jew in the adult group, 62% vs 45%,  $P < 0.001$ ). The pediatric group had more frequent gastroenterology and dietitian follow up ( $p < 0.001$  in both). Pediatric patients reported to be more frequent a part of a supporting group compared to adults ( $p = 0.002$ ). Finally, pediatric patients were found to be more compliant to GFD compared to adults ( $p < 0.001$ ).

**Conclusion:** there are differences in the clinical profile of celiac disease between children and adults. Pediatric celiac patients are more adherent to GFD. Different management approach should be considered in the different age groups.

**Disclosure:** Has been accepted to present as well in the international celiac disease symposium ICDS 2019 in Paris.

## **P2080 DOES SHORT SEGMENT COELIAC DISEASE CONFINED TO THE DUODENAL BULB HAVE A UNIQUE CLINICAL, SEROLOGICAL OR HISTOLOGICAL PROFILE?**

Broide E.<sup>1</sup>, Paz H.<sup>2</sup>, Shalem T.<sup>3</sup>, Zelnik Yovel D.<sup>4</sup>, Shirin H.<sup>1</sup>

**Contact E-Mail Address:** danazelnik@gmail.com

**Introduction:** Coeliac disease (CD) is a common autoimmune enteropathy with increased prevalence worldwide. The diagnosis is based on positive serological tests with proved histological findings in the duodenum. Due to possible patchy villous atrophy pattern, the histological features may be presented only at the duodenal bulb in about 11% of CD patients. So far, any possible association between isolated CD of the duodenal bulb and unique profile of such patients has not been fully explored.

We aimed in this study to investigate whether short segment coeliac disease (SSCD) confined only to the duodenal bulb in pediatric patients has a unique demographic, clinical, laboratory or histological profile at the time of diagnosis compared to more extensive CD.

**Aims & Methods:** We conducted a retrospective study which included all children, aged 1-18 years who underwent upper endoscopy with duodenal biopsies for a suspicious CD at the Pediatric Gastroenterology Unit in "Assaf Harofeh" Medical Center, Israel. Endoscopies were done between January 2013 and August 2018. The diagnosis of CD was made in accordance with the ESPGHAN criteria. Demographic, clinical data (celiac-associated symptoms), family history of CD and laboratory results (hemoglobin, ferritin, and coeliac serology) at diagnosis as well as histological data were recorded. Histological severity was assessed by MARSH classification.

**Results:** Out of 160 suspected CD patients, 22 and 19 children were excluded due to lack of serology or a diagnosis of potential CD respectively. Twenty two out of the remaining 113 children had disease confined only to the duodenal bulb-SSCD (19%). The only difference between SSCD to more extensive CD was that children diagnosed with SSCD had lower serum level of anti-TTG antibodies at presentation ( $p < 0.01$ ).

No significant differences between the two groups were documented in the demographic, clinical and histological features.

**Conclusion:** SSCD is more common than previously reported in the literature. Despite lower serology titer the histological severity is similar. More prospective studies are needed to illuminate this issue.
